phased.ADPCACanceller System object

Package: phased

Adaptive DPCA (ADPCA) pulse canceller

Description

The `ADPCACanceller` object implements an adaptive displaced phase center array pulse canceller for a uniform linear array (ULA).

To compute the output signal of the space time pulse canceller:

1. Define and set up your ADPCA pulse canceller. See "Construction" on page 1-2.
2. Call step to execute the ADPCA algorithm according to the properties of `phased.ADPCACanceller`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object™, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.ADPCACanceller` creates an adaptive displaced phase center array (ADPCA) canceller System object, `H`. This object performs two-pulse ADPCA processing on the input data.

`H = phased.ADPCACanceller(Name,Value)` creates an ADPCA object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`). See "Properties" on page 1-3 for the list of available property names.

Properties

`SensorArray`

Uniform linear array

Uniform linear array, specified as a phased.ULA System object.

Default: phased.ULA with default property values

`PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

Default: Speed of light

`OperatingFrequency`

System operating frequency

Specify the operating frequency of the system in hertz as a positive scalar. The default value corresponds to 300 MHz.

Default: `3e8`

`PRF`

Pulse repetition frequency

Specify the pulse repetition frequency (PRF) of the received signal in hertz as a scalar.

Default: `1`

`DirectionSource`

Source of receiving mainlobe direction

Specify whether the targeting direction for the STAP processor comes from the `Direction` property of this object or from an input argument in step. Values of this property are:

`'Property'`	The `Direction` property of this object specifies the targeting direction.
`'Input port'`	An input argument in each invocation of `step` specifies the targeting direction.

Default: `'Property'`

`Direction`

Receiving mainlobe direction (degrees)

Specify the receiving mainlobe direction of the receiving sensor array as a column vector of length 2. The direction is specified in the format of `[AzimuthAngle; ElevationAngle]` (in degrees). Azimuth angle should be between –180 and 180. Elevation angle should be between –90 and 90. This property applies when you set the `DirectionSource` property to `'Property'`.

Default: `[0; 0]`

`NumPhaseShifterBits`

Number of phase shifter quantization bits

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

Default: `0`

`DopplerSource`

Source of targeting Doppler

Specify whether the targeting Doppler for the STAP processor comes from the `Doppler` property of this object or from an input argument in step. Values of this property are:

`'Property'`	The `Doppler` property of this object specifies the Doppler.
`'Input port'`	An input argument in each invocation of `step` specifies the Doppler.

Default: `'Property'`

`Doppler`

Targeting Doppler frequency (Hz)

Specify the targeting Doppler of the STAP processor as a scalar. This property applies when you set the `DopplerSource` property to `'Property'`.

Default: `0`

`WeightsOutputPort`

Output processing weights

To obtain the weights used in the STAP processor, set this property to `true` and use the corresponding output argument when invoking step. If you do not want to obtain the weights, set this property to `false`.

Default: `false`

`PreDopplerOutput`

Output pre-Doppler result

Set this property to `true` to output the processing result before applying the Doppler filtering. Set this property to `false` to output the processing result after the Doppler filtering.

Default: `false`

`NumGuardCells`

Number of guarding cells

Specify the number of guard cells used in the training as an even integer. This property specifies the total number of cells on both sides of the cell under test.

Default: `2`, indicating that there is one guard cell at both the front and back of the cell under test

`NumTrainingCells`

Number of training cells

Specify the number of training cells used in the training as an even integer. Whenever possible, the training cells are equally divided before and after the cell under test.

Default: 2, indicating that there is one training cell at both the front and back of the cell under test

Methods

step — Perform ADPCA processing on input data

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Process radar data cube using ADPCA processor.

Process a radar data cube using an ADPCA processor. Weights are calculated for the 71st cell of the data cube. Set the look direction to (0,0) degrees and the Doppler shift to 12.980 kHz.

Load radar data file and compute weights

```
load STAPExampleData;
Hs = phased.ADPCACanceller('SensorArray',STAPEx_HArray,...
    'PRF',STAPEx_PRF,...
    'PropagationSpeed',STAPEx_PropagationSpeed,...
    'OperatingFrequency',STAPEx_OperatingFrequency,...
    'NumTrainingCells',100,...
    'WeightsOutputPort',true,...
    'DirectionSource','Input port',...
    'DopplerSource','Input port');
[y,w] = step(Hs,STAPEx_ReceivePulse,71,[0; 0],12.980e3);
```

Create AnglerDoppler System object and plot response

```
sAngeDop = phased.AngleDopplerResponse(...
    'SensorArray',Hs.SensorArray,...
    'OperatingFrequency',Hs.OperatingFrequency,...
    'PRF',Hs.PRF,...
    'PropagationSpeed',Hs.PropagationSpeed);
plotResponse(sAngeDop,w)
```

Introduced in R2012a

step

System object: phased.ADPCACanceller
Package: phased

Perform ADPCA processing on input data

Syntax

```
Y = step(H,X,CUTIDX)
Y = step(H,X,CUTIDX,ANG)
Y = step(___,DOP)
[Y,W] = step(___)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X,CUTIDX)` applies the ADPCA pulse cancellation algorithm to the input data `X`. The algorithm calculates the processing weights according to the range cell specified by `CUTIDX`. This syntax is available when the `DirectionSource` property is `'Property'` and the `DopplerSource` property is `'Property'`. The receiving mainlobe direction is the `Direction` property value. The output `Y` contains the result of pulse cancellation either before or after Doppler filtering, depending on the `PreDopplerOutput` property value.

`Y = step(H,X,CUTIDX,ANG)` uses `ANG` as the receiving mainlobe direction. This syntax is available when the `DirectionSource` property is `'Input port'` and the `DopplerSource` property is `'Property'`.

`Y = step(___,DOP)` uses `DOP` as the targeting Doppler frequency. This syntax is available when the `DopplerSource` property is `'Input port'`.

`[Y,W] = step( ___ )` returns the additional output, `W`, as the processing weights. This syntax is available when the `WeightsOutputPort` property is `true`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`H`

Pulse canceller object.

`X`

Input data. `X` must be a 3-dimensional M-by-N-by-P numeric array whose dimensions are (range, channels, pulses).

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

`CUTIDX`

Range cell.

`ANG`

Receiving mainlobe direction. `ANG` must be a 2-by-1 vector in the form `[AzimuthAngle; ElevationAngle]`, in degrees. The azimuth angle must be between –180 and 180. The elevation angle must be between –90 and 90.

Default: `Direction` property of `H`

`DOP`

Targeting Doppler frequency in hertz. `DOP` must be a scalar.

Default: `Doppler` property of `H`

Output Arguments

Y

Result of applying pulse cancelling to the input data. The meaning and dimensions of Y depend on the PreDopplerOutput property of H:

- If PreDopplerOutput is true, Y contains the pre-Doppler data. Y is an M-by-(P–1) matrix. Each column in Y represents the result obtained by cancelling the two successive pulses.
- If PreDopplerOutput is false, Y contains the result of applying an FFT-based Doppler filter to the pre-Doppler data. The targeting Doppler is the Doppler property value. Y is a column vector of length M.

W

Processing weights the pulse canceller used to obtain the pre-Doppler data. The dimensions of W depend on the PreDopplerOutput property of H:

- If PreDopplerOutput is true, W is a 2N-by-(P-1) matrix. The columns in W correspond to successive pulses in X.
- If PreDopplerOutput is false, W is a column vector of length (N*P).

Examples

Plot Response of ADPCA Processor with Quantized Weights

Process a radar data cube using an ADPCA processor. Weights are calculated for the 71st cell of the data cube. Load the data cube from STAPExampleData.mat. Quantize the weights to 4 bits. Set the look direction to (0,0) degrees and the Doppler shift to 12.980 kHz.

```
load STAPExampleData;
sADPCA = phased.ADPCACanceller('SensorArray',STAPEx_HArray,...
    'PRF',STAPEx_PRF,...
    'PropagationSpeed',STAPEx_PropagationSpeed,...
    'OperatingFrequency',STAPEx_OperatingFrequency,...
    'NumTrainingCells',100,...
    'WeightsOutputPort',true,...
    'DirectionSource','Input port',...
    'DopplerSource','Input port',...
```

```
    'NumPhaseShifterBits',4);
[y,w] = step(sADPCA,STAPEx_ReceivePulse,71,[0; 0],12.980e3);
sAngDop = phased.AngleDopplerResponse(...
    'SensorArray',sADPCA.SensorArray,...
    'OperatingFrequency',sADPCA.OperatingFrequency,...
    'PRF',sADPCA.PRF,...
    'PropagationSpeed',sADPCA.PropagationSpeed);
plotResponse(sAngDop,w);
```

phased.AngleDopplerResponse System object

Package: phased

Angle-Doppler response

Description

The `AngleDopplerResponse` object calculates the angle-Doppler response of input data.

To compute the angle-Doppler response:

1. Define and set up your angle-Doppler response calculator. See "Construction" on page 1-14.
2. Call step to compute the angle-Doppler response of the input signal according to the properties of `phased.AngleDopplerResponse`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.AngleDopplerResponse` creates an angle-Doppler response System object, `H`. This object calculates the angle-Doppler response of the input data.

`H = phased.AngleDopplerResponse(Name,Value)` creates angle-Doppler object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`SensorArray`

Sensor array

Sensor array specified as an array System object belonging to the `phased` package. A sensor array can contain subarrays.

Default: phased.ULA with default property values

`PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

Default: Speed of light

`OperatingFrequency`

System operating frequency

Specify the operating frequency of the system in hertz as a positive scalar. The default value corresponds to 300 MHz.

Default: `3e8`

`PRF`

Pulse repetition frequency

Specify the pulse repetition frequency (PRF) in hertz of the input signal as a positive scalar.

Default: `1`

`ElevationAngleSource`

Source of elevation angle

Specify whether the elevation angle comes from the `ElevationAngle` property of this object or from an input argument in step. Values of this property are:

`'Property'`	The `ElevationAngle` property of this object specifies the elevation angle.

`'Input port'`	An input argument in each invocation of `step` specifies the elevation angle.

Default: `'Property'`

`ElevationAngle`

Elevation angle

Specify the elevation angle in degrees used to calculate the angle-Doppler response as a scalar. The angle must be between –90 and 90. This property applies when you set the `ElevationAngleSource` property to `'Property'`.

Default: `0`

`NumAngleSamples`

Number of samples in angular domain

Specify the number of samples in the angular domain used to calculate the angle-Doppler response as a positive integer. This value must be greater than 2.

Default: `256`

`NumDopplerSamples`

Number of samples in Doppler domain

Specify the number of samples in the Doppler domain used to calculate the angle-Doppler response as a positive integer. This value must be greater than 2.

Default: `256`

Methods

plotResponse	Plot angle-Doppler response
step	Calculate angle-Doppler response

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Calculate Angle-Doppler Response

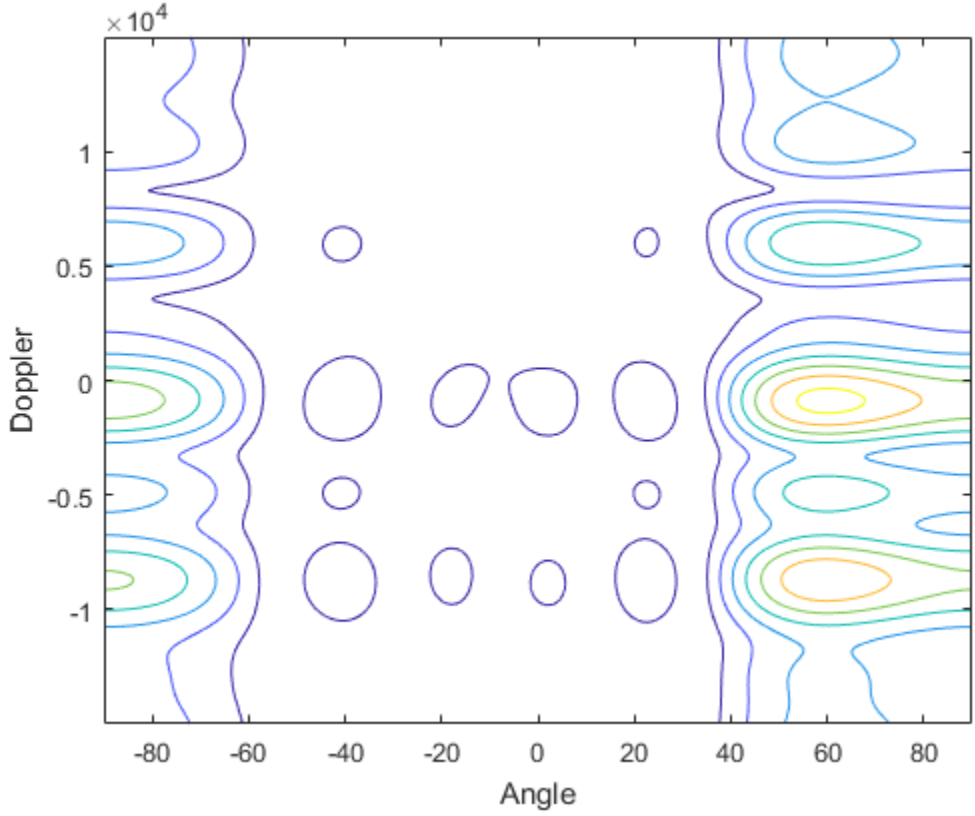
Calculate the angle-Doppler response of the 190th cell of a collected data cube.

Load data cube and construct a `phased.AngleDopplerResponse` System object™.

```
load STAPExampleData;
x = shiftdim(STAPEx_ReceivePulse(190,:,:));
response = phased.AngleDopplerResponse(...
    'SensorArray',STAPEx_HArray,...
    'OperatingFrequency',STAPEx_OperatingFrequency,...
    'PropagationSpeed',STAPEx_PropagationSpeed,...
    'PRF',STAPEx_PRF);
```

Plot angle-Doppler response.

```
[resp,ang_grid,dop_grid] = response(x);
contour(ang_grid,dop_grid,abs(resp))
xlabel('Angle')
ylabel('Doppler')
```



Algorithms

`phased.AngleDopplerResponse` generates the response using a conventional beamformer and an FFT-based Doppler filter. For further details, see [1].

plotResponse

System object: phased.AngleDopplerResponse
Package: phased

Plot angle-Doppler response

Syntax

```
plotResponse(H,X)
plotResponse(H,X,ELANG)
plotResponse( ___ ,Name,Value)
hPlot = plotResponse( ___ )
```

Description

`plotResponse(H,X)` plots the angle-Doppler response of the data in `X` in decibels. This syntax is available when the `ElevationAngleSource` property is `'Property'`.

`plotResponse(H,X,ELANG)` plots the angle-Doppler response calculated using the specified elevation angle `ELANG`. This syntax is available when the `ElevationAngleSource` property is `'Input port'`.

`plotResponse( ___ ,Name,Value)` plots the angle-Doppler response with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = plotResponse( ___ )` returns the handle of the image in the figure window, using any of the input arguments in the previous syntaxes.

Input Arguments

`H`

Angle-Doppler response object.

`X`

Input data.

`ELANG`

Elevation angle in degrees.

Default: Value of `Elevation` property of `H`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'NormalizeDoppler'`

Set this value to `true` to normalize the Doppler frequency. Set this value to `false` to plot the angle-Doppler response without normalizing the Doppler frequency.

Default: `false`

`'Unit'`

The unit of the plot. Valid values are `'db'`, `'mag'`, and `'pow'`.

Default: `'db'`

Examples

Plot Angle-Doppler Response

Plot the angle-Doppler response of the 190th cell of a collected data cube.

```
load STAPExampleData;
x = shiftdim(STAPEx_ReceivePulse(190,:,:));
hadresp = phased.AngleDopplerResponse(...
    'SensorArray',STAPEx_HArray,...
    'OperatingFrequency',STAPEx_OperatingFrequency,...
    'PropagationSpeed',STAPEx_PropagationSpeed,...
    'PRF',STAPEx_PRF);
plotResponse(hadresp,x,'NormalizeDoppler',true);
```

`phitheta2azel` | `uv2azel`

step

System object: phased.AngleDopplerResponse
Package: phased

Calculate angle-Doppler response

Syntax

```
[RESP,ANG_GRID,DOP_GRID] = step(H,X)
[RESP,ANG_GRID,DOP_GRID] = step(H,X,ELANG)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[RESP,ANG_GRID,DOP_GRID] = step(H,X)` calculates the angle-Doppler response of the data `X`. `RESP` is the complex angle-Doppler response. `ANG_GRID` and `DOP_GRID` provide the angle samples and Doppler samples, respectively, at which the angle-Doppler response is evaluated. This syntax is available when the `ElevationAngleSource` property is `'Property'`.

`[RESP,ANG_GRID,DOP_GRID] = step(H,X,ELANG)` calculates the angle-Doppler response using the specified elevation angle `ELANG`. This syntax is available when the `ElevationAngleSource` property is `'Input port'`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

H

Angle-Doppler response object.

X

Input data as a matrix or column vector.

If X is a matrix, the number of rows in the matrix must equal the number of elements of the array specified in the SensorArray property of H.

If X is a vector, the number of rows must be an integer multiple of the number of elements of the array specified in the SensorArray property of H. In addition, the multiple must be at least 2.

ELANG

Elevation angle in degrees.

Default: Value of Elevation property of H

Output Arguments

RESP

Complex angle-Doppler response of X. RESP is a P-by-Q matrix. P is determined by the NumDopplerSamples property of H and Q is determined by the NumAngleSamples property.

ANG_GRID

Angle samples at which the angle-Doppler response is evaluated. ANG_GRID is a column vector of length Q.

DOP_GRID

Doppler samples at which the angle-Doppler response is evaluated. DOP_GRID is a column vector of length P.

Examples

Calculate Angle-Doppler Response

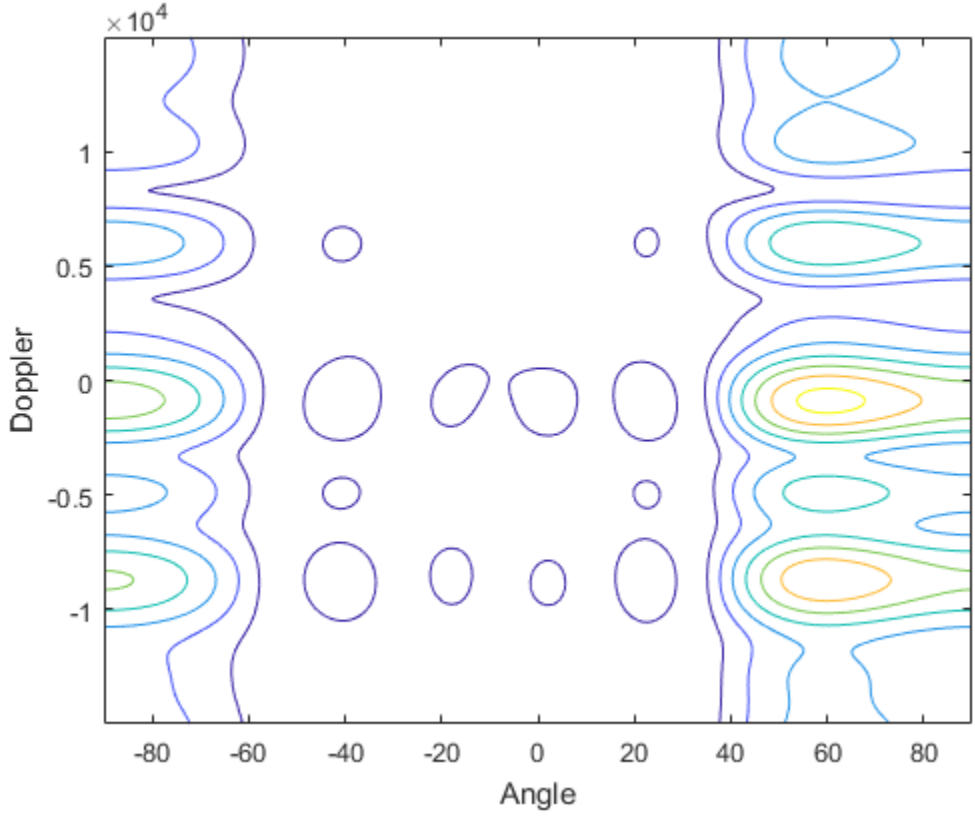
Calculate the angle-Doppler response of the 190th cell of a collected data cube.

Load data cube and construct a `phased.AngleDopplerResponse` System object™.

```
load STAPExampleData;
x = shiftdim(STAPEx_ReceivePulse(190,:,:));
response = phased.AngleDopplerResponse(...
    'SensorArray',STAPEx_HArray,...
    'OperatingFrequency',STAPEx_OperatingFrequency,...
    'PropagationSpeed',STAPEx_PropagationSpeed,...
    'PRF',STAPEx_PRF);
```

Plot angle-Doppler response.

```
[resp,ang_grid,dop_grid] = response(x);
contour(ang_grid,dop_grid,abs(resp))
xlabel('Angle')
ylabel('Doppler')
```



Algorithms

`phased.AngleDopplerResponse` generates the response using a conventional beamformer and an FFT-based Doppler filter. For further details, see [1].

phased.ArrayGain System object

Package: phased

Sensor array gain

Description

The `ArrayGain` object calculates the array gain for a sensor array. The array gain is defined as the signal to noise ratio (SNR) improvement between the array output and the individual channel input, assuming the noise is spatially white. It is related to the array response but is not the same.

To compute the SNR gain of the antenna for specified directions:

1. Define and set up your array gain calculator. See "Construction" on page 1-28.
2. Call step to estimate the gain according to the properties of `phased.ArrayGain`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.ArrayGain` creates an array gain System object, `H`. This object calculates the array gain of a 2-element uniform linear array for specified directions.

`H = phased.ArrayGain(Name,Value)` creates and array-gain object, `H`, with the specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`SensorArray`

Sensor array

Sensor array specified as an array System object belonging to the `phased` package. A sensor array can contain subarrays.

Default: phased.ULA with default property values

`PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

Default: Speed of light

`WeightsInputPort`

Add input to specify weights

To specify weights, set this property to `true` and use the corresponding input argument when you invoke step. If you do not want to specify weights, set this property to `false`.

Default: `false`

Methods

step	Calculate array gain of sensor array

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Array Gain of 4-Element ULA

Calculate the array gain for a 4-element uniform linear array (ULA) in the direction 30° azimuth and 20° elevation. The array operating frequency is 300 MHz.

```
fc = 300e6;
array = phased.ULA(4);
gain = phased.ArrayGain('SensorArray',array);
g = gain(fc,[30;20])
```

```
g =

   -17.1783
```

Definitions

Array Gain

The *array gain* is defined as the signal to noise ratio (SNR) improvement between the array output and the individual channel input, assuming the noise is spatially white. You can express the array gain as follows:

$$\frac{SNR_{\text{out}}}{SNR_{\text{in}}} = \frac{\left(\frac{w^H v s v^H w}{w^H N w}\right)}{\left(\frac{s}{N}\right)} = \frac{w^H v v^H w}{w^H w}$$

In this equation:

- w is the vector of weights applied on the sensor array. When you use `phased.ArrayGain`, you can optionally specify weights by setting the `WeightsInputPort` property to `true` and specifying the `W` argument in the `step` method syntax.
- v is the steering vector representing the array response toward a given direction. When you call the `step` method, the `ANG` argument specifies the direction.

- s is the input signal power.
- N is the noise power.
- H denotes the complex conjugate transpose.

For example, if a rectangular taper is used in the array, the array gain is the square of the array response normalized by the number of elements in the array.

step

System object: phased.ArrayGain
Package: phased

Calculate array gain of sensor array

Syntax

```
G = step(H,FREQ,ANG)
G = step(H,FREQ,ANG,WEIGHTS)
G = step(H,FREQ,ANG,STEERANGLE)
G = step(H,FREQ,ANG,WEIGHTS,STEERANGLE)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`G = step(H,FREQ,ANG)` returns the array gain `G` of the array for the operating frequencies specified in `FREQ` and directions specified in `ANG`.

`G = step(H,FREQ,ANG,WEIGHTS)` applies weights `WEIGHTS` on the sensor array. This syntax is available when you set the `WeightsInputPort` property to `true`.

`G = step(H,FREQ,ANG,STEERANGLE)` uses `STEERANGLE` as the subarray steering angle. This syntax is available when you configure `H` so that `H.Sensor` is an array that contains subarrays, and `H.Sensor.SubarraySteering` is either `'Phase'` or `'Time'`.

`G = step(H,FREQ,ANG,WEIGHTS,STEERANGLE)` combines all input arguments. This syntax is available when you configure `H` so that `H.WeightsInputPort` is `true`, `H.Sensor` is an array that contains subarrays, and `H.Sensor.SubarraySteering` is either `'Phase'` or `'Time'`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`H`

Array gain object.

`FREQ`

Operating frequencies of array in hertz. `FREQ` is a row vector of length L. Typical values are within the range specified by a property of the sensor element. The element is `H.SensorArray.Element`, `H.SensorArray.Array.Element`, or `H.SensorArray.Subarray.Element`, depending on the type of array. The frequency range property is named `FrequencyRange` or `FrequencyVector`, depending on the type of element in the array. The element has zero response at frequencies outside that range.

`ANG`

Directions in degrees. `ANG` can be either a 2-by-M matrix or a row vector of length M.

If `ANG` is a 2-by-M matrix, each column of the matrix specifies the direction in the form [azimuth; elevation]. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

If `ANG` is a row vector of length M, each element specifies a direction's azimuth angle. In this case, the corresponding elevation angle is assumed to be 0.

`WEIGHTS`

Weights on the sensor array. `WEIGHTS` can be either an N-by-L matrix or a column vector of length N. N is the number of subarrays if `H.SensorArray` contains subarrays, or the number of elements otherwise. L is the number of frequencies specified in `FREQ`.

If `WEIGHTS` is a matrix, each column of the matrix represents the weights at the corresponding frequency in `FREQ`.

If WEIGHTS is a vector, the weights apply at all frequencies in FREQ.

STEERANGLE

Subarray steering angle in degrees. STEERANGLE can be a length-2 column vector or a scalar.

If STEERANGLE is a length-2 vector, it has the form [azimuth; elevation]. The azimuth angle must be between –180 and 180 degrees, and the elevation angle must be between –90 and 90 degrees.

If STEERANGLE is a scalar, it represents the azimuth angle. In this case, the elevation angle is assumed to be 0.

Output Arguments

G

Gain of sensor array, in decibels. G is an M-by-L matrix. G contains the gain at the M angles specified in ANG and the L frequencies specified in FREQ.

Examples

Array Gain of 6-Element ULA

Construct a uniform linear array (ULA) having six elements and operating at 1 GHz. The array elements are spaced at one-half the operating wavelength. Find the array gain in dB in the direction 45° azimuth and 10° elevation.

Create the phased.ArrayGain System object™.

```
fc = 1e9;
lambda = physconst('LightSpeed')/fc;
array = phased.ULA('NumElements',6,'ElementSpacing',lambda/2);
gain = phased.ArrayGain('SensorArray',array);
```

Determine array gain at the specified operating frequency and angle.

```
arraygain = gain(fc,[45;10])

arraygain =
```

```
-17.9275
```

Definitions

Array Gain

The *array gain* is defined as the signal to noise ratio (SNR) improvement between the array output and the individual channel input, assuming the noise is spatially white. You can express the array gain as follows:

$$\frac{SNR_{\text{out}}}{SNR_{\text{in}}} = \frac{\left(\frac{w^H vsv^H w}{w^H Nw}\right)}{\left(\frac{s}{N}\right)} = \frac{w^H vv^H w}{w^H w}$$

In this equation:

- w is the vector of weights applied on the sensor array. When you use `phased.ArrayGain`, you can optionally specify weights by setting the `WeightsInputPort` property to `true` and specifying the `W` argument in the `step` method syntax.
- v is the steering vector representing the array response toward a given direction. When you call the `step` method, the `ANG` argument specifies the direction.
- s is the input signal power.
- N is the noise power.
- H denotes the complex conjugate transpose.

For example, if a rectangular taper is used in the array, the array gain is the square of the array response normalized by the number of elements in the array.

phased.ArrayResponse System object

Package: phased

Sensor array response

Description

The `ArrayResponse` object calculates the complex-valued response of a sensor array.

To compute the response of the array for specified directions:

1. Define and set up your array response calculator. See "Construction" on page 1-36.
2. Call step to estimate the response according to the properties of `phased.ArrayResponse`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.ArrayResponse` creates an array response System object, `H`. This object calculates the response of a sensor array for the specified directions. By default, a 2-element uniform linear array (ULA) is used.

`H = phased.ArrayResponse(Name,Value)` creates object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`SensorArray`

Handle to sensor array used to calculate response

Specify the sensor array as a handle. The sensor array must be an array object in the `phased` package. The array can contain subarrays.

Default: phased.ULA with default property values

`PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

Default: Speed of light

`WeightsInputPort`

Add input to specify weights

To specify weights, set this property to `true` and use the corresponding input argument when you invoke step. If you do not want to specify weights, set this property to `false`.

Default: `false`

`EnablePolarization`

Enable polarization simulation

Set this property to `true` to let the array response simulate polarization. Set this property to `false` to ignore polarization. This property applies only when the array specified in the `SensorArray` property is capable of simulating polarization.

Default: `false`

Methods

step	Calculate array response of sensor array

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Plot Array Response

Calculate array response for a 4-element uniform linear array (ULA) in the direction of 30 degrees azimuth and 20 degrees elevation. Assume the array's operating frequency is 300 MHz.

Construct ULA and ArrayResponse System objects

```
fc = 300e6;
c = physconst('LightSpeed');
array = phased.ULA(4);
response = phased.ArrayResponse('SensorArray',array);
resp = response(fc,[30;20])
```

```
resp =

    0.2768
```

Plot the array response in dB

Plot the normalized power in db as an azimuth cut at 0 degrees elevation.

```
pattern(array,fc,[-180:180],0,'PropagationSpeed',c,'CoordinateSystem','rectangular','Ty
```

step

System object: phased.ArrayResponse
Package: phased

Calculate array response of sensor array

Syntax

```
RESP = step(H,FREQ,ANG)
RESP = step(H,FREQ,ANG,WEIGHTS)
RESP = step(H,FREQ,ANG,STEERANGLE)
RESP = step(H,FREQ,ANG,WEIGHTS,STEERANGLE)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`RESP = step(H,FREQ,ANG)` returns the array response `RESP` at operating frequencies specified in `FREQ` and directions specified in `ANG`.

`RESP = step(H,FREQ,ANG,WEIGHTS)` applies weights `WEIGHTS` on the sensor array. This syntax is available when you set the `WeightsInputPort` property to `true`.

`RESP = step(H,FREQ,ANG,STEERANGLE)` uses `STEERANGLE` as the subarray steering angle. This syntax is available when you configure `H` so that `H.Sensor` is an array that contains subarrays, and `H.Sensor.SubarraySteering` is either `'Phase'` or `'Time'`.

`RESP = step(H,FREQ,ANG,WEIGHTS,STEERANGLE)` combines all input arguments. This syntax is available when you configure `H` so that `H.WeightsInputPort` is `true`, `H.Sensor` is an array that contains subarrays, and `H.Sensor.SubarraySteering` is either `'Phase'` or `'Time'`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`H`

Array response object.

`FREQ`

Operating frequencies of array in hertz. `FREQ` is a row vector of length L. Typical values are within the range specified by a property of the sensor element. The element is `H.SensorArray.Element`, `H.SensorArray.Array.Element`, or `H.SensorArray.Subarray.Element`, depending on the type of array. The frequency range property is named `FrequencyRange` or `FrequencyVector`, depending on the type of element in the array. The element has zero response at frequencies outside that range. The element has zero response at frequencies outside that range.

`ANG`

Directions in degrees. `ANG` can be either a 2-by-M matrix or a row vector of length M.

If `ANG` is a 2-by-M matrix, each column of the matrix specifies the direction in the form [azimuth; elevation]. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

If `ANG` is a row vector of length M, each element specifies a direction's azimuth angle. In this case, the corresponding elevation angle is assumed to be 0.

`WEIGHTS`

Weights on the sensor array. `WEIGHTS` can be either an N-by-L matrix or a column vector of length N. N is the number of subarrays if `H.SensorArray` contains subarrays, or the number of elements otherwise. L is the number of frequencies specified in `FREQ`.

If `WEIGHTS` is a matrix, each column of the matrix represents the weights at the corresponding frequency in `FREQ`.

If WEIGHTS is a vector, the weights apply at all frequencies in FREQ.

STEERANGLE

Subarray steering angle in degrees. STEERANGLE can be a length-2 column vector or a scalar.

If STEERANGLE is a length-2 vector, it has the form [azimuth; elevation]. The azimuth angle must be between –180 and 180 degrees, and the elevation angle must be between –90 and 90 degrees.

If STEERANGLE is a scalar, it represents the azimuth angle. In this case, the elevation angle is assumed to be 0.

Output Arguments

RESP

Voltage response of the sensor array. The response depends on whether the EnablePolarization property is set to `true` or `false`.

- If the EnablePolarization property is set to `false`, the voltage response, RESP, has the dimensions *M*-by-*L*. *M* represents the number of angles specified in the input argument ANG while *L* represents the number of frequencies specified in FREQ.
- If the EnablePolarization property is set to `true`, the voltage response, RESP, is a MATLAB® `struct` containing two fields, RESP.H and RESP.V. The RESP.H field represents the array's horizontal polarization response, while RESP.V represents the array's vertical polarization response. Each field has the dimensions *M*-by-*L*. *M* represents the number of angles specified in the input argument, ANG, while *L* represents the number of frequencies specified in FREQ.

Examples

Array Response of ULA

Find the response of a 6-element uniform linear array operating at 1 GHz. The array elements are spaced one-half wavelength apart. The incident signal direction is 45° azimuth and 10° elevation. Obtain the response at this direction.

```
fc = 1e9;
lambda = physconst('LightSpeed')/fc;
```

Create the ULA array.

```
array = phased.ULA('NumElements',6,'ElementSpacing',lambda/2);
```

Create the array response System object™.

```
response = phased.ArrayResponse('SensorArray',array);
resp = response(fc,[45;10]);
```

phased.BackscatterRadarTarget System object

Package: phased

Backscatter radar target

Description

The `phased.BackscatterRadarTarget` System object models the *backscattering* of a signal from a target. Backscattering is a special case of radar target scattering when the incident and reflected angles are the same. This type of scattering applies to monostatic radar configurations. The radar cross-section determines the backscattering response of a target to an incoming signal. This System object lets you specify an angle-dependent radar cross-section model that covers a range of incident angles.

The `phased.BackscatterRadarTarget` System object creates a backscattered signal for polarized and nonpolarized signals. While electromagnetic radar signals are polarized, you can often ignore polarization in your simulation and process the signals as scalar signals. To ignore polarization, specify the `EnablePolarization` property as `false`. To employ polarization, specify the `EnablePolarization` property as `true`.

For nonpolarized signals, you specify the radar cross section as an array of radar cross-section (RCS) values at discrete azimuth and elevation points. The System object interpolates values for incident angles between array points. For polarized signals, you specify the *radar scattering matrix* using three arrays defined at discrete azimuth and elevation points. These three arrays correspond to the *HH*, *HV*, and *VV* polarization components. The *VH* component is computed from the conjugate symmetry of the *HV* component.

For both nonpolarized and polarized signal cases, you can employ one of four Swerling models to generate random fluctuations in the RCS or radar scattering matrix. Choose the model using the `Model` property. Then, use the `SeedSource` and `Seed` properties to control the fluctuations.

`EnablePolarization`	Use these properties
`false`	`RCSPattern`
`true`	`ShhPattern`, `SvvPattern`, and `ShvPattern`

To model a backscattered radar signal:

1. Define and set up your radar target. You can set `phased.BackscatterRadarTarget` System object properties at construction time or leave them to their default values. See "Construction" on page 1-46. Some properties that you set at construction time can be changed later. These properties are *tunable*.
2. To compute the reflected signal, call the `step` method of `phased.BackscatterRadarTarget`. The output of the method depends on the properties of the `phased.BackscatterRadarTarget` System object. You can change tunable properties at any time.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`target = phased.BackscatterRadarTarget` creates a backscatter radar target System object, `target`.

`target = phased.BackscatterRadarTarget(Name,Value)` creates a backscatter radar target System object, `target`, with each specified property `Name` set to the specified `Value`. You can specify additional name and value pair arguments in any order as (`Name1,Value1,...,NameN,ValueN`).

Properties

`EnablePolarization` — Enable polarized signals

`false` (default) | `true`

Option to enable processing of polarized signals, specified as `false` or `true`. Set this property to `true` to allow the target to simulate the reflection of polarized radiation. Set this property to `false` to ignore polarization.

Example: `true`

Data Types: `logical`

`AzimuthAngles` — Azimuth angles

`[-180:180]` (default) | 1-by-*P* real-valued row vector | *P*-by-1 real-valued column vector

Azimuth angles used to define the angular coordinates of each column of the matrices specified by the `RCSPattern`, `ShhPattern`, `ShvPattern`, or `SvvPattern` properties. Specify the azimuth angles as a length *P* vector. *P* must be greater than two. Angle units are in degrees.

Example: `[-45:0.1:45]`

Data Types: `double`

`ElevationAngles` — Elevation angles

`[-90:90]` (default) | 1-by-*Q* real-valued row vector | *Q*-by-1 real-valued column vector

Elevation angles used to define the angular coordinates of each row of the matrices specified by the `RCSPattern`, `ShhPattern`, `ShvPattern`, or `SvvPattern` properties. Specify the elevation angles as a length *Q* vector. *Q* must be greater than two. Angle units are in degrees.

Example: `[-30:0.1:30]`

Data Types: `double`

`RCSPattern` — Radar cross-section pattern

`ones(181,361)` (default) | *Q*-by-*P* complex-valued matrix | *Q*-by-*P*-by-*M* complex-valued array | 1-by-*P* complex-valued vector | *M*-by-*P* complex-valued matrix

Radar cross-section (RCS) pattern, specified as a *Q*-by-*P* complex-valued matrix or a *Q*-by-*P*-by-*M* complex-valued array. *Q* is the length of the vector in the `ElevationAngles` property. *P* is the length of the vector in the `AzimuthAngles` property. *M* is the number of target patterns. The number of patterns corresponds to the number of signals passed into the step method. You can, however, use a single pattern to model multiple signals reflecting from a single target. Pattern units are square-meters.

You can also specify the pattern as a function only of azimuth for a single elevation. In this case, specify the pattern as either a 1-by-*P* vector or an *M*-by-*P* matrix. Each row is a separate pattern.

This property applies when the `EnablePolarization` property is `false`.

Example: `[1,1;1i,1i]`

Data Types: `double`
Complex Number Support: Yes

`ShhPattern` — Radar-scattering matrix *HH* polarization component

`ones(181,361)` (default) | *Q*-by-*P* complex-valued matrix | *Q*-by-*P*-by-*M* complex-valued array | 1-by-*P* complex-valued vector | *M*-by-*P* complex-valued matrix

Radar scattering matrix *HH* polarization component, specified as a *Q*-by-*P* complex-valued matrix or a *Q*-by-*P*-by-*M* complex-valued array. *Q* is the length of the vector in the `ElevationAngles` property. *P* is the length of the vector in the `AzimuthAngles` property. *M* is the number of target patterns. The number of patterns corresponds to the number of signals passed into the step method. You can, however, use a single pattern to model multiple signals reflecting from a single target. Scattering matrix units are meters.

You can also specify the pattern as a function only of azimuth for a single elevation. Then, specify the pattern as either a 1-by-*P* vector or an *M*-by-*P* matrix. Each row is a separate pattern.

This property applies when the `EnablePolarization` property is `true`.

Example: `[1,1;1i,1i]`

Data Types: `double`
Complex Number Support: Yes

`SvvPattern` — Radar scattering matrix *VV* polarization component

`ones(181,361)` (default) | *Q*-by-*P* complex-valued matrix | *Q*-by-*P*-by-*M* complex-valued array | 1-by-*P* complex-valued vector | *M*-by-*P* complex-valued matrix

Radar scattering matrix *VV* polarization component, specified as a *Q*-by-*P* complex-valued matrix or a *Q*-by-*P*-by-*M* complex-valued array. *Q* is the length of the vector in the `ElevationAngles` property. *P* is the length of the vector in the `AzimuthAngles` property. *M* is the number of target patterns. The number of patterns corresponds to the number of signals passed into the step method. You can, however, use a single pattern to model multiple signals reflecting from a single target. Scattering matrix units are meters.

You can also specify the pattern as a function only of azimuth for a single elevation. In this case, specify the pattern as either a 1-by-*P* vector or an *M*-by-*P* matrix. Each row is a separate pattern.

This property applies when the `EnablePolarization` property is `true`.

Example: `[1,1;1i,1i]`

Data Types: `double`
Complex Number Support: Yes

`ShvPattern` — Radar scattering matrix *HV* polarization component

`ones(181,361)` (default) | *Q*-by-*P* complex-valued matrix | *Q*-by-*P*-by-*M* complex-valued array | 1-by-*P* complex-valued vector | *M*-by-*P* complex-valued matrix

Radar scattering matrix *HV* polarization component, specified as a *Q*-by-*P* complex-valued matrix or a *Q*-by-*P*-by-*M* complex-valued array. *Q* is the length of the vector in the `ElevationAngles` property. *P* is the length of the vector in the `AzimuthAngles` property. *M* is the number of target patterns. The number of patterns corresponds to the number of signals passed into the step method. You can, however, use a single pattern to model multiple signals reflecting from a single target. Scattering matrix units are meters.

You can also specify the pattern as a function only of azimuth for a single elevation. In this case, specify the pattern as either a 1-by-*P* vector or an *M*-by-*P* matrix. Each row is a separate pattern.

This property applies when the `EnablePolarization` property is `true`.

Example: `[1,1;1i,1i]`

Data Types: `double`
Complex Number Support: Yes

`Model` — Target fluctuation model

`'Nonfluctuating'` (default) | `'Swerling1'` | `'Swerling2'` | `'Swerling3'` | `'Swerling4'`

Target fluctuation model, specified as `'Nonfluctuating'`, `'Swerling1'`, `'Swerling2'`, `'Swerling3'`, or `'Swerling4'`. If you set this property to a value other than `'Nonfluctuating'`, use the `update` input argument when calling phased.BackscatterRadarTarget.step.

Example: `'Swerling3'`

Data Types: `char`

`PropagationSpeed` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. Units are in m/s. The default value of the speed of light is the value returned by `physconst('LightSpeed')`.

Example: `3e8`

Data Types: `double`

`OperatingFrequency` — Signal carrier frequency

`300e6` (default) | positive real-valued scalar

Signal carrier frequency, specified as a positive real-valued scalar. Units are in Hz.

Example: `1e9`

Data Types: `double`

`SeedSource` — Seed source of random number generator for RCS fluctuation model

`'Auto'` (default) | `'Property'`

Seed source of random number generator for RCS fluctuation model, specified as `'Auto'` or `'Property'`. When you set this property to `'Auto'`, the System object generates random numbers using the default MATLAB random number generator. When you set this property to `'Property'`, you specify the random number generator seed using the `Seed` property. This property applies when you set the `Model` property to `'Swerling1'`, `'Swerling2'`, `'Swerling3'`, or `'Swerling4'`. When you use this object with Parallel Computing Toolbox™ software, you set this property to `'Auto'`.

Example: `'Property'`

Data Types: `char`

`Seed` — Random number generator seed

`0` (default) | nonnegative integer less than 2^{32}

Random number generator seed, specified as a nonnegative integer less than 2^{32}. This property applies when the `SeedSource` property is set to `'Property'`.

Example: `32301`

Data Types: `double`

Methods

reset	Reset states of System object

step	Backscatter incoming signal

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

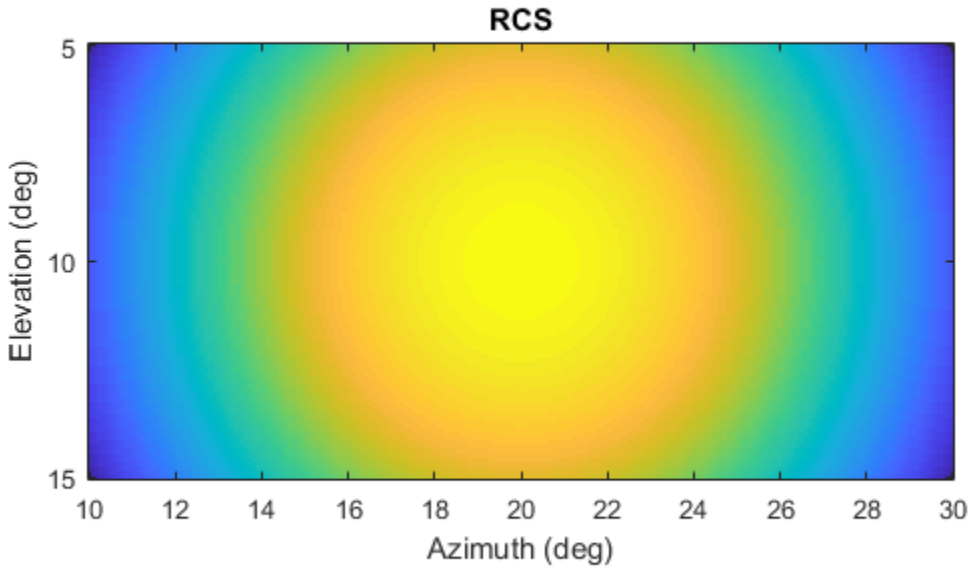
Backscatter Nonpolarized Signal

Calculate the reflected radar signal from a nonfluctuating point target with a peak RCS of 10.0 m^2. Use a simplified expression of an RCS pattern of a target for illustrative purposes. Real RCS patterns are more complicated. The RCS pattern covers a range of angles from 10°–30° in azimuth and 5°–15° in elevation. The RCS peaks at 20° azimuth and 10° elevation. Assume that the radar operating frequency is 1 GHz and that the signal is a sinusoid at 1 MHz.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

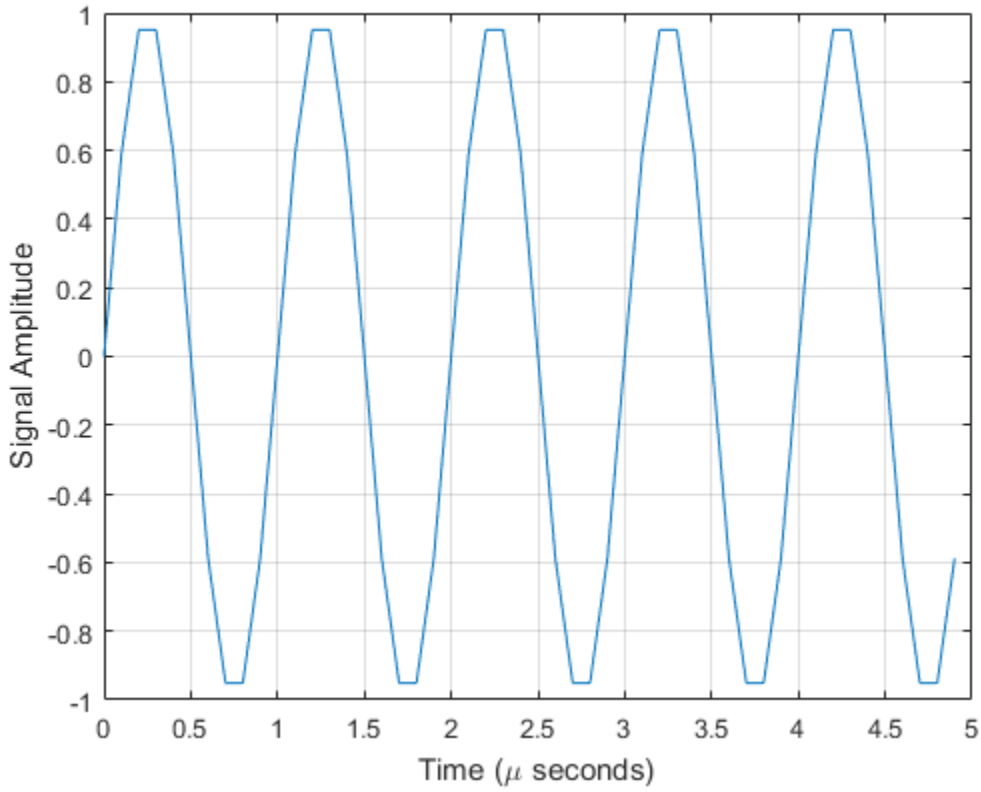
Create and plot the RCS pattern.

```
azmax = 20.0;
elmax = 10.0;
azpatangs = [10.0:0.1:30.0];
elpatangs = [5.0:0.1:15.0];
rcspattern = 10.0*cosd(4*(elpatangs - elmax))'*cosd(4*(azpatangs - azmax));
imagesc(azpatangs,elpatangs,rcspattern)
axis image
axis tight
title('RCS')
xlabel('Azimuth (deg)')
ylabel('Elevation (deg)')
```



Generate and plot 50 samples of the radar signal.

```
foper = 1.0e9;
freq = 1.0e6;
fs = 10*freq;
nsamp = 50;
t = [0:(nsamp-1)]'/fs;
sig = sin(2*pi*freq*t);
plot(t*1e6,sig)
xlabel('Time (\mu seconds)')
ylabel('Signal Amplitude')
grid
```



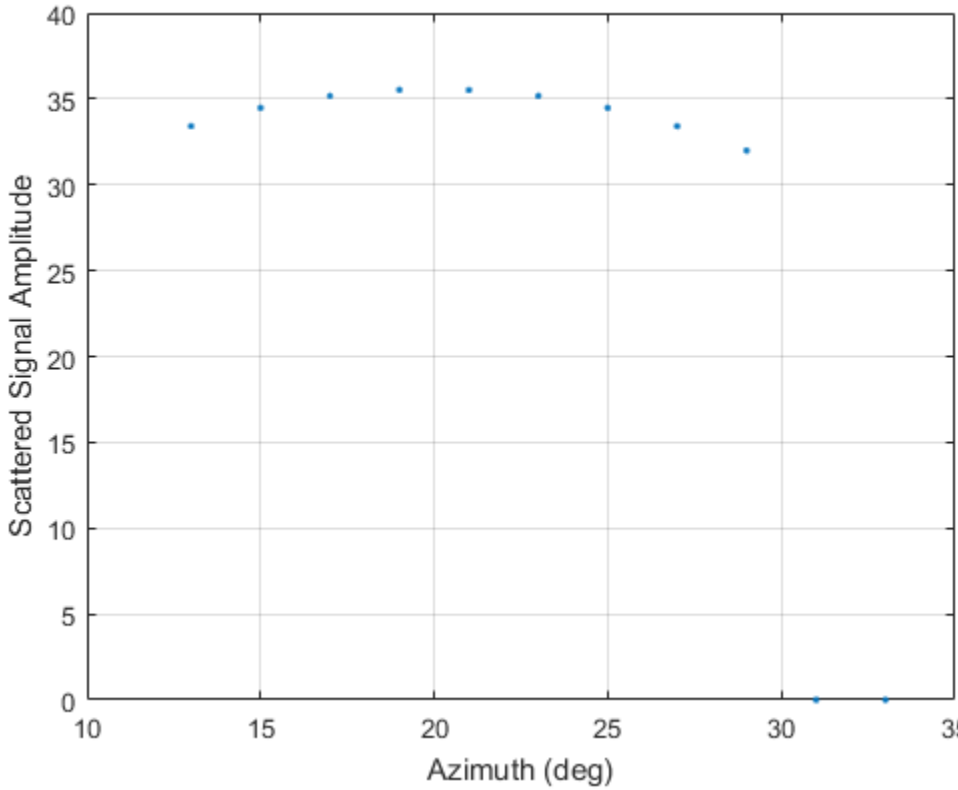
Create the `phased.BackscatterRadarTarget` System object™.

```
target = phased.BackscatterRadarTarget('Model','Nonfluctuating',...
    'AzimuthAngles',azpatangs,'ElevationAngles',elpatangs,...
    'RCSPattern',rcspattern,'OperatingFrequency',foper);
```

For a sequence of incident angles at constant elevation angle, find and plot the scattered signal amplitude.

```
az0 = 13.0;
el = 10.0;
naz = 20;
az = az0 + [0:2:20];
naz = length(az);
```

```
ss = zeros(1,naz);
for k = 1:naz
    y = target(sig,[az(k);el]);
    ss(k) = max(abs(y));
end
plot(az,ss,'.')
xlabel('Azimuth (deg)')
ylabel('Scattered Signal Amplitude')
grid
```



Backscatter Polarized Signal

Calculate the polarized radar signal scattered from a Swerling1 fluctuating point target. Assume the target axis is rotated from the global coordinate system. Use simple

expressions for the scattering patterns for illustration. Real scattering patterns are more complicated. For polarized signals, you need to specify the *HH*, *HV*, and *VV* components of the scattering matrix for a range of incident angles. In this example, the patterns cover the range 10°–30° in azimuth and 5°–15° in elevation. Angles are with respect to the target local coordinate system. Assume that the radar operating frequency is 1 GHz and that the signal is a sinusoid with a frequency of 1 MHz. The incident angle is 13.0° azimuth and 14.0° elevation with respect to the target orientation.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Create and plot the scattering matrix patterns.

```
azmax = 20.0;
elmax = 10.0;
azpatangs = [10.0:0.1:35.0];
elpatangs = [5.0:0.1:15.0];
shhpat = cosd(4*(elpatangs - elmax))'*cosd(4*(azpatangs - azmax));

- "Modeling Target Radar Cross Section"
- "Designing a Basic Monostatic Pulse Radar"

Definitions

Backscattered Radiation

For a narrowband nonpolarized signal, the reflected signal, Y, is

$$Y = \sqrt{G} \cdot X,$$

where:

- X is the incoming signal.
- G is the target gain factor, a dimensionless quantity given by

$$G = \frac{4\pi\sigma}{\lambda^2}.$$

  - σ is the mean radar cross-section (RCS) of the target.
  - λ is the wavelength of the incoming signal.

The incident signal on the target is scaled by the square root of the gain factor.

For narrowband polarized waves, the single scalar signal, X, is replaced by a vector signal, (E_H, E_V), with horizontal and vertical components. The scattering matrix, S, replaces the scalar cross-section, σ. Through the scattering matrix, the incident horizontal and vertical polarized signals are converted into the reflected horizontal and vertical polarized signals.

$$\begin{bmatrix} E_H^{(scat)} \\ E_V^{(scat)} \end{bmatrix} = \sqrt{\frac{4\pi}{\lambda^2}} \begin{bmatrix} S_{HH} & S_{VH} \\ S_{HV} & S_{VV} \end{bmatrix} \begin{bmatrix} E_H^{(inc)} \\ E_V^{(inc)} \end{bmatrix} = \sqrt{\frac{4\pi}{\lambda^2}} [S] \begin{bmatrix} E_H^{(inc)} \\ E_V^{(inc)} \end{bmatrix}$$

For further details, see [1] or [2].

Introduced in R2016a

reset

System object: phased.BackscatterRadarTarget
Package: phased

Reset states of System object

Syntax

```
reset(sBSTgt)
```

Description

`reset(sBSTgt)` resets the internal state of the `phased.BackscatterRadarTarget` object, `sBSTgt`. This method resets the random number generator state if `SeedSource` is a property of this System object and has the value `'Property'`.

Input Arguments

`sBSTgt` — Backscatter radar target

System object

Backscatter radar target, specified as a System object.

Example: `phased.BackscatterRadarTarget`

Introduced in R2016a

step

System object: phased.BackscatterRadarTarget
Package: phased

Backscatter incoming signal

Syntax

```
refl_sig = step(target,sig,ang)
refl_sig = step(target,sig,ang,update)

refl_sig = step(target,sig,ang,laxes)
refl_sig = step(target,sig,ang,laxes,update)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`refl_sig = step(target,sig,ang)` returns the reflected signal, `refl_sig`, of an incident nonpolarized signal, `sig`, arriving at the target from the angle, `ang`. This syntax applies when you set the `EnablePolarization` property to `false` and the `Model` property to `'Nonfluctuating'`. In this case, the values specified in the `RCSPattern` property are used to compute the RCS values for the incident and reflected directions, `ang`.

`refl_sig = step(target,sig,ang,update)` uses `update` to control whether to update the RCS values. This syntax applies when you set the `EnablePolarization` property to `false` and the `Model` property to one of the fluctuating RCS models: `'Swerling1'`, `'Swerling2'`, `'Swerling3'`, or `'Swerling4'`. If `update` is `true`, a new RCS value is generated. If `update` is `false`, the previous RCS value is used.

`refl_sig = step(target,sig,ang,laxes)` returns the reflected signal, `refl_sig`, of an incident polarized signal, `sig`. The matrix, `laxes`, specifies the local target

coordinate system. This syntax applies when you set `EnablePolarization` to `true` and the `Model` property to `'Nonfluctuating'`. The values specified in the `ShhPattern`, `SvvPattern`, and `ShvPattern` properties are used to compute the scattering matrices for the incident and reflected directions, `ang`.

`refl_sig = step(target,sig,ang,laxes,update)` uses the `update` argument to control whether to update the scattering matrix values. This syntax applies when you set the `EnablePolarization` property to `true` and the `Model` property to one of the fluctuating RCS models: `'Swerling1'`, `'Swerling2'`, `'Swerling3'`, or `'Swerling4'`. If `update` is `true`, a new RCS value is generated. If `update` is `false`, the previous RCS value is used.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`target` — Backscatter target

System object

Backscatter target, specified as a System object.

Example: `phased.BackscatterRadarTarget`

`sig` — Narrowband signal

N-by-*M* complex-valued matrix | *1*-by-*M* `struct` array containing complex-valued fields

- Narrowband nonpolarized signal, specified as an *N*-by-*M* complex-valued matrix. The quantity *N* is the number of signal samples and *M* is the number of signals reflecting off the target. Each column corresponds to an independent signal incident at a different reflecting angle.

  The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.
- Narrowband polarized signal, specified as a 1-by-*M* `struct` array containing complex-valued fields. Each `struct` element contains three *N*-by-1 column vectors of

electromagnetic field components `(sig.X,sig.Y,sig.Z)` representing the polarized signal that reflects from the target.

For polarized fields, the `struct` element contains three *N*-by-1 complex-valued column vectors, `sig.X`, `sig.Y`, and `sig.Z`. These vectors represent the *x*, *y*, and *z* Cartesian components of the polarized signal.

The size of the first dimension of the matrix fields within the `struct` can vary to simulate a changing signal length such as a pulse waveform with variable pulse repetition frequency.

Example: `[1,1;j,1;0.5,0]`

Data Types: `double`
Complex Number Support: Yes

`ang` — Incident signal direction

2-by-*1* positive real-valued column vector | *2*-by-*M* positive real-valued column matrix

Incident signal direction, specified as a *2*-by-*1* positive real-valued column vector or a *2*-by-*M* positive real-valued column matrix. Each column of `ang` specifies the incident direction of the corresponding signal in the form of an `[AzimuthAngle;ElevationAngle]` pair. Units are degrees. The number of columns in `ang` must match the number of independent signals in `sig`.

Example: `[30;45]`

Data Types: `double`

`update` — Update RCS

`false` (default) | `true`

Allow the RCS values for fluctuation models to update, specified as `false` or `true`. When `update` is `true`, a new RCS value is generated with each call to the `step` method. If `update` is `false`, the RCS remains unchanged with each call to `step`.

Example: `true`

Data Types: `logical`

`laxes` — Local coordinate matrix

`eye(3,3)` (default) | 3-by-3 real-valued orthonormal matrix | 3-by-3-by-*M* real-valued array

Local coordinate system matrix, specified as a 3-by-3 real-valued orthonormal matrix or a 3-by-3-by-*M* real-valued array. The matrix columns specify the local coordinate system orthonormal *x*-axis, *y*-axis, and *z*-axis, respectively. Each axis is a vector of the form *(x;y;z)* with respect to the global coordinate system. When `sig` has only one signal, `laxes` is a 3-by-3 matrix. When `sig` has multiple signals, you can use a single 3-by-3 matrix for multiple signals in `sig`. In this case, all targets have the same local coordinate systems. When you specify `laxes` as a 3-by-3-by-*M* MATLAB array, each page (third index) defines a 3-by-3 local coordinate matrix for the corresponding target.

Example: `[1,0,0;0,0.7071,-0.7071;0,0.7071,0.7071]`

Data Types: `double`

Output Arguments

`refl_sig` — Narrowband reflected signal

N-by-*M* complex-valued matrix | *1*-by-*M* `struct` array containing complex-valued fields

- Narrowband nonpolarized signal, specified as an *N*-by-*M* complex-valued matrix. Each column contains an independent signal reflected from the target.

  The quantity *N* is the number of signal samples and *M* is the number of signals reflecting off the target. Each column corresponds to a reflecting angle.

- Narrowband polarized signal, specified as a 1-by-*M* `struct` array containing complex-valued fields. Each `struct` element contains three *N*-by-1 column vectors of electromagnetic field components `(sig.X,sig.Y,sig.Z)` representing the polarized signal that reflects from the target.

  For polarized fields, the `struct` element contains three *N*-by-1 complex-valued column vectors, `sig.X`, `sig.Y`, and `sig.Z`. These vectors represent the *x*, *y*, and *z* Cartesian components of the polarized signal.

The output `refl_sig` contains signal samples arriving at the signal destination within the current input time frame. When the propagation time from source to destination exceeds the current time frame duration, the output will not contain all contributions from the input of the current time frame. The remaining output appears in the next call to `step`.

Examples

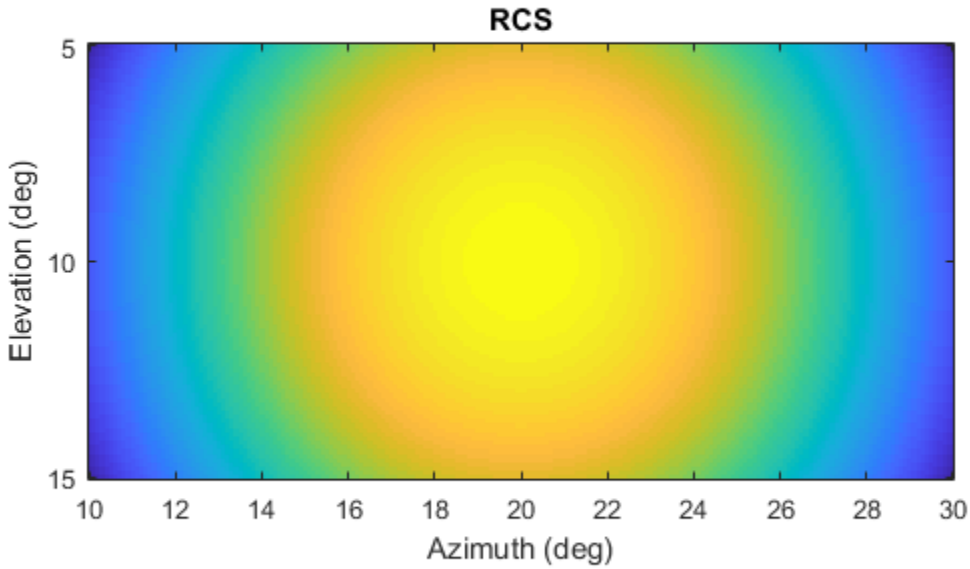
Backscatter Nonpolarized Signal

Calculate the reflected radar signal from a nonfluctuating point target with a peak RCS of 10.0 m^2. Use a simplified expression of an RCS pattern of a target for illustrative purposes. Real RCS patterns are more complicated. The RCS pattern covers a range of angles from 10°–30° in azimuth and 5°–15° in elevation. The RCS peaks at 20° azimuth and 10° elevation. Assume that the radar operating frequency is 1 GHz and that the signal is a sinusoid at 1 MHz.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

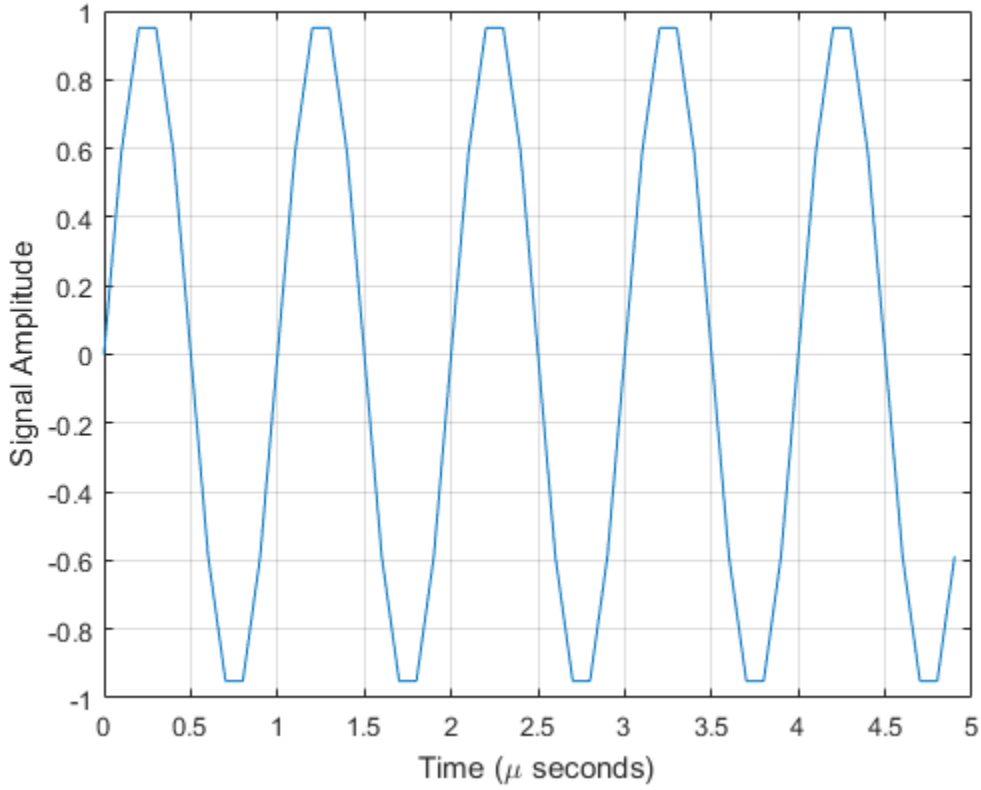
Create and plot the RCS pattern.

```
azmax = 20.0;
elmax = 10.0;
azpatangs = [10.0:0.1:30.0];
elpatangs = [5.0:0.1:15.0];
rcspattern = 10.0*cosd(4*(elpatangs - elmax))'*cosd(4*(azpatangs - azmax));
imagesc(azpatangs,elpatangs,rcspattern)
axis image
axis tight
title('RCS')
xlabel('Azimuth (deg)')
ylabel('Elevation (deg)')
```



Generate and plot 50 samples of the radar signal.

```
foper = 1.0e9;
freq = 1.0e6;
fs = 10*freq;
nsamp = 50;
t = [0:(nsamp-1)]'/fs;
sig = sin(2*pi*freq*t);
plot(t*1e6,sig)
xlabel('Time (\mu seconds)')
ylabel('Signal Amplitude')
grid
```



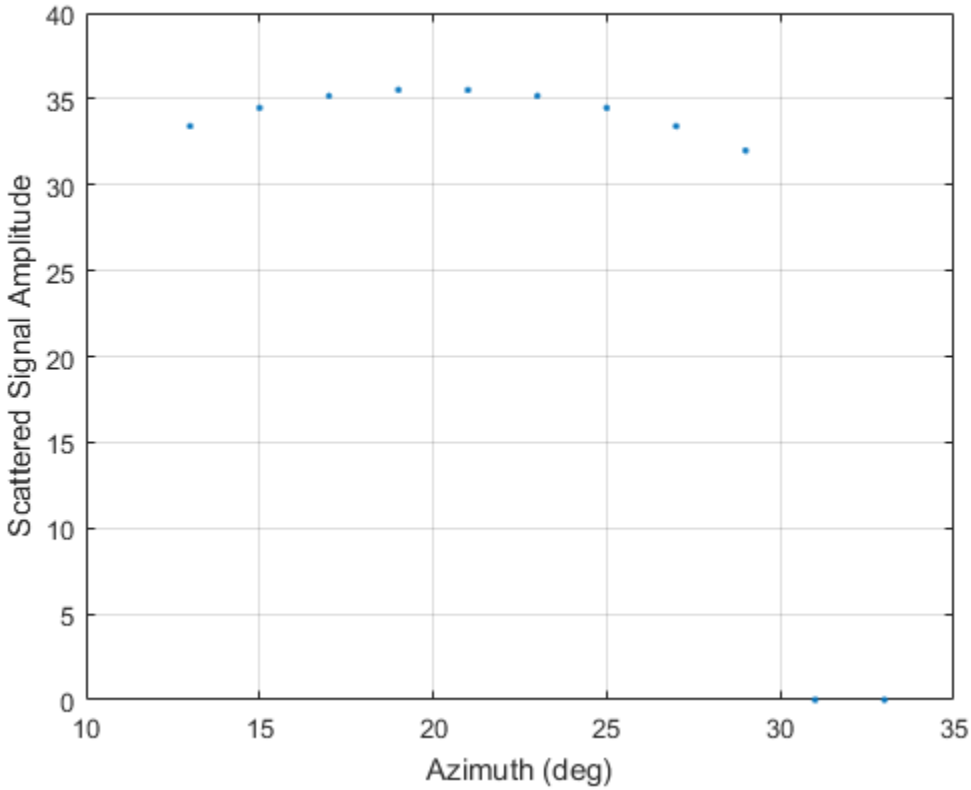
Create the `phased.BackscatterRadarTarget` System object™.

```
target = phased.BackscatterRadarTarget('Model','Nonfluctuating',...
    'AzimuthAngles',azpatangs,'ElevationAngles',elpatangs,...
    'RCSPattern',rcspattern,'OperatingFrequency',foper);
```

For a sequence of incident angles at constant elevation angle, find and plot the scattered signal amplitude.

```
az0 = 13.0;
el = 10.0;
naz = 20;
az = az0 + [0:2:20];
naz = length(az);
```

```
ss = zeros(1,naz);
for k = 1:naz
    y = target(sig,[az(k);el]);
    ss(k) = max(abs(y));
end
plot(az,ss,'.')
xlabel('Azimuth (deg)')
ylabel('Scattered Signal Amplitude')
grid
```



Backscatter Polarized Signal

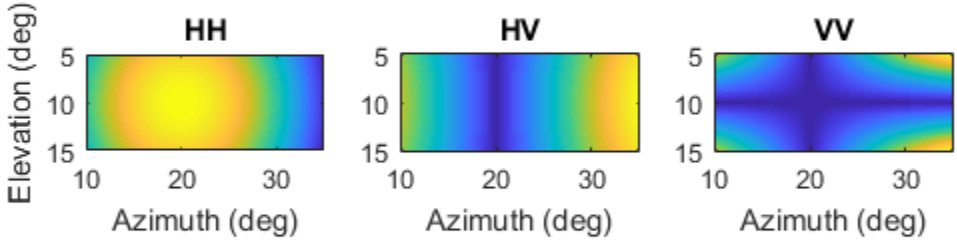
Calculate the polarized radar signal scattered from a Swerling1 fluctuating point target. Assume the target axis is rotated from the global coordinate system. Use simple

expressions for the scattering patterns for illustration. Real scattering patterns are more complicated. For polarized signals, you need to specify the *HH*, *HV*, and *VV* components of the scattering matrix for a range of incident angles. In this example, the patterns cover the range 10°–30° in azimuth and 5°–15° in elevation. Angles are with respect to the target local coordinate system. Assume that the radar operating frequency is 1 GHz and that the signal is a sinusoid with a frequency of 1 MHz. The incident angle is 13.0° azimuth and 14.0° elevation with respect to the target orientation.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Create and plot the scattering matrix patterns.

```
azmax = 20.0;
elmax = 10.0;
azpatangs = [10.0:0.1:35.0];
elpatangs = [5.0:0.1:15.0];
shhpat = cosd(4*(elpatangs - elmax))'*cosd(4*(azpatangs - azmax));
shvpat = 1i*cosd(4*(elpatangs - elmax))'*sind(4*(azpatangs - azmax));
svvpat = sind(4*(elpatangs - elmax))'*sind(4*(azpatangs - azmax));
subplot(1,3,1)
imagesc(azpatangs,elpatangs,abs(shhpat))
axis image
axis tight
title('HH')
xlabel('Azimuth (deg)')
ylabel('Elevation (deg)')
subplot(1,3,2)
imagesc(azpatangs,elpatangs,abs(shvpat))
axis image
axis tight
title('HV')
xlabel('Azimuth (deg)')
subplot(1,3,3)
imagesc(azpatangs,elpatangs,abs(svvpat))
axis image
axis tight
title('VV')
xlabel('Azimuth (deg)')
```



Create the `phased.BackscatterRadarTarget` System object™.

```
target = phased.BackscatterRadarTarget('EnablePolarization',true,...
    'Model','Swerling1','AzimuthAngles',azpatangs,...
    'ElevationAngles',elpatangs,'ShhPattern',shhpat,'ShvPattern',shvpat,...
    'SvvPattern',svvpat);
```

Generate 50 samples of a polarized radar signal.

```
foper = 1.0e9;
freq = 1.0e6;
fs = 10*freq;
nsamp = 50;
t = [0:(nsamp-1)]'/fs;
```

```
signal.X = exp(1i*2*pi*freq*t);
signal.Y = exp(1i*2*pi*freq*t + pi/3);
signal.Z = zeros(size(signal.X));
tgtaxes = azelaxes(60,10);
ang = [13.0;14.0];
```

Reflect the signal from the target and plot its components.

```
refl_signal = target(signal,ang,tgtaxes,true);
figure
plot(t*1e6,real(refl_signal.X))
hold on
plot(t*1e6,real(refl_signal.Y))
plot(t*1e6,real(refl_signal.Z))
hold off
xlabel('Time \mu seconds')
ylabel('Amplitude')
grid
```

phased.BackscatterSonarTarget System object

Package: phased

Sonar target backscatter

Description

The `phased.BackscatterSonarTarget` System object models the *backscattering* of a signal from an underwater or surface target. Backscattering is a special case of sonar target scattering when the incident and reflected angles are the same. This type of scattering applies to monostatic sonar configurations. The sonar target strength (TS) determines the backscattering response of a target to an incoming signal. This object lets you specify an angle-dependent sonar target strength model that covers a range of incident angles.

The object lets you specify the target strength as an array of values at discrete azimuth and elevation points. The object interpolates values for incident angles between array points.

You can employ one of four Swerling models to generate random fluctuations in the target strength. Choose the fluctuation model using the `Model` property. Then, use the `SeedSource` and `Seed` properties to control the fluctuations.

To model a backscattered reflected sonar signal:

1. Define and set up your sonar target. You can set `phased.BackscatterSonarTarget` System object properties at construction time or leave them to their default values. See "Construction" on page 1-75. Some properties that you set at construction time can be changed later. These properties are *tunable*.
2. To compute the reflected signal, call the `step` method of `phased.BackscatterSonarTarget`. The output of the method depends on the properties of the `phased.BackscatterSonarTarget` System object. You can change tunable properties at any time.

Note: Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`target = phased.BackscatterSonarTarget` creates a backscatter sonar target System object, `target`.

`target = phased.BackscatterSonarTarget(Name,Value)` creates a backscatter sonar target System object, `target`, with each specified property `Name` set to the specified `Value`. You can specify additional name and value pair arguments in any order as (`Name1,Value1,...,NameN,ValueN`).

Properties

`AzimuthAngles` — Target strength azimuth angles

`[-180:180]` (default) | real-valued 1-by-P row vector | real-valued P-by-1 column vector

Target strength azimuth angles, specified as a real-valued 1-by-P row vector or P-by-1 column vector. These angles define the azimuth coordinates of each column of the matrix specified by the `TSPattern` property. P must be greater than two. Angle units are in degrees.

Example: `[-45:0.1:45]`

Data Types: `double`

`ElevationAngles` — Elevation angles

`[-90:90]` (default) | real-valued 1-by-Q row vector | real-valued Q-by-1 column vector

Target strength elevation angles, specified as a real-valued 1-by-Q row vector or Q-by-1 column vector. These angles define the elevation coordinates of each row of the matrix specified by the `TSPattern` property. Q must be greater than two. Angle units are in degrees.

Example: `[-30:0.1:30]`

Data Types: `double`

`TSPattern` — Sonar target strength pattern

`zeros(181,361)` (default) | Q-by-P complex-valued matrix | Q-by-P-by-M complex-valued array | 1-by-P complex-valued vector | M-by-P complex-valued matrix

Sonar target strength (TS) pattern, specified as a real-valued Q-by-P matrix or Q-by-P-by-M array. Q is the length of the vector in the `ElevationAngles` property. P is the

length of the vector in the `AzimuthAngles` property. *M* is the number of target patterns. The number of patterns corresponds to the number of signals passed into the step method. You can, however, use a single pattern to model multiple signals reflecting from a single target. Pattern units are dB.

You can also specify the pattern as a function only of azimuth for a single elevation. In this case, specify the pattern as either a 1-by-*P* vector or an *M*-by-*P* matrix. Each row is a separate pattern.

Example: `[1,2;3,4]`

Data Types: `double`

`Model` — Target fluctuation model

`'Nonfluctuating'` (default) | `'Swerling1'` | `'Swerling2'` | `'Swerling3'` | `'Swerling4'`

Target fluctuation model, specified as `'Nonfluctuating'`, `'Swerling1'`, `'Swerling2'`, `'Swerling3'`, or `'Swerling4'`. If you set this property to a value other than `'Nonfluctuating'`, use the `update` input argument when calling the `step` method.

Example: `'Swerling3'`

Data Types: `char`

`SeedSource` — Seed source of random number generator for TS fluctuation model

`'Auto'` (default) | `'Property'`

Seed source of random number generator for TS fluctuation model, specified as `'Auto'` or `'Property'`. When you set this property to `'Auto'`, the System object generates random numbers using the default MATLAB random number generator. When you set this property to `'Property'`, you specify the random number generator seed using the `Seed` property. This property applies when you set the `Model` property to `'Swerling1'`, `'Swerling2'`, `'Swerling3'`, or `'Swerling4'`. When you use this object with Parallel Computing Toolbox software, you set this property to `'Auto'`.

Example: `'Property'`

Data Types: `char`

`Seed` — Random number generator seed

`0` (default) | nonnegative integer less than 2^{32}

Random number generator seed, specified as a nonnegative integer less than 2^{32}.

Example: 32301

Dependencies

To enable this property, set the `SeedSource` property to `'Property'`.

Data Types: `double`

Methods

reset	Reset states of System object
step	Backscatter incoming sonar signal

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

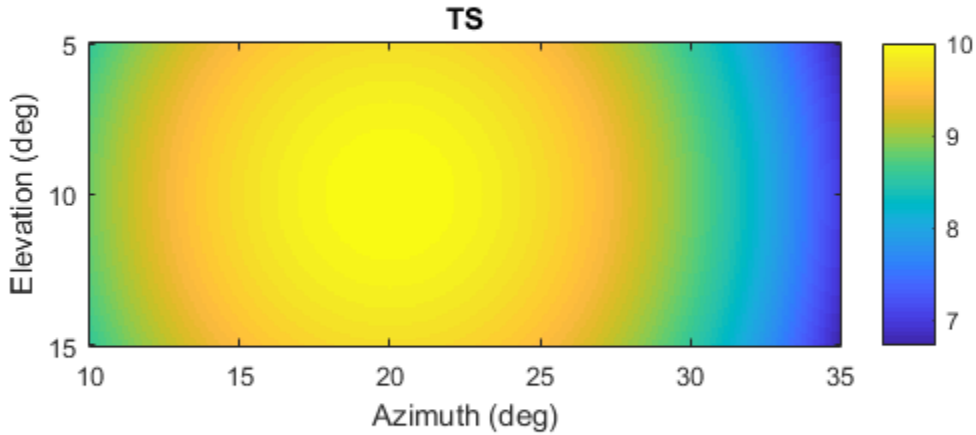
Backscatter Sonar Signal from Nonfluctuating Target

Calculate the reflected sonar signal from a nonfluctuating point target with a peak target strength (TS) of 10.0 db. For illustrative purposes, use a simplified expression for the TS pattern of a target. Real TS patterns are more complicated. The TS pattern covers a range of angles from 10° to 30° in azimuth and from 5° to 15° in elevation. The TS peaks at 20° azimuth and 10° elevation. Assume that the sonar operating frequency is 10 kHz and that the signal is a sinusoid at 9500 kHz.

Create and plot the TS pattern.

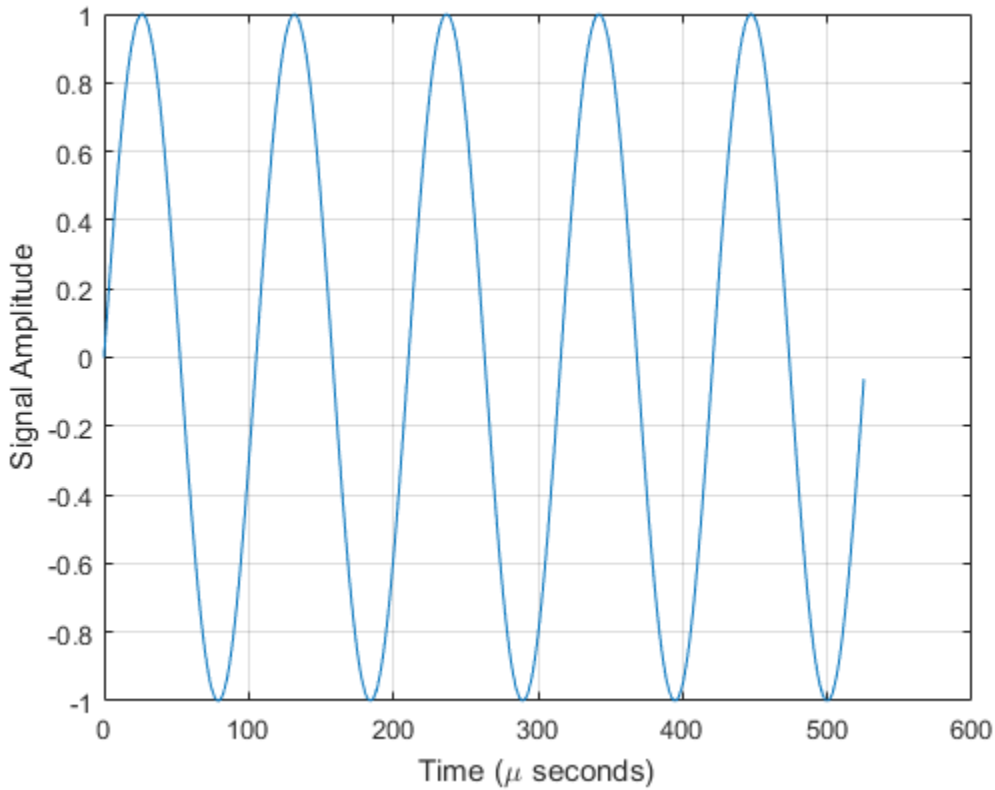
```
azmax = 20.0;
```

```
elmax = 10.0;
azpatangs = [10.0:0.1:35.0];
elpatangs = [5.0:0.1:15.0];
tspattern = 10.0*cosd(4*(elpatangs - elmax))'*cosd(4*(azpatangs - azmax));
tspatterndb = 10*log10(tspattern);
imagesc(azpatangs,elpatangs,tspatterndb)
colorbar
axis image
axis tight
title('TS')
xlabel('Azimuth (deg)')
ylabel('Elevation (deg)')
```



Generate and plot 50 samples of the sonar signal.

```
freq = 9.5e3;
fs = 100*freq;
nsamp = 500;
t = [0:(nsamp-1)]'/fs;
sig = sin(2*pi*freq*t);
plot(t*1e6,sig)
xlabel('Time (\mu seconds)')
ylabel('Signal Amplitude')
grid
```



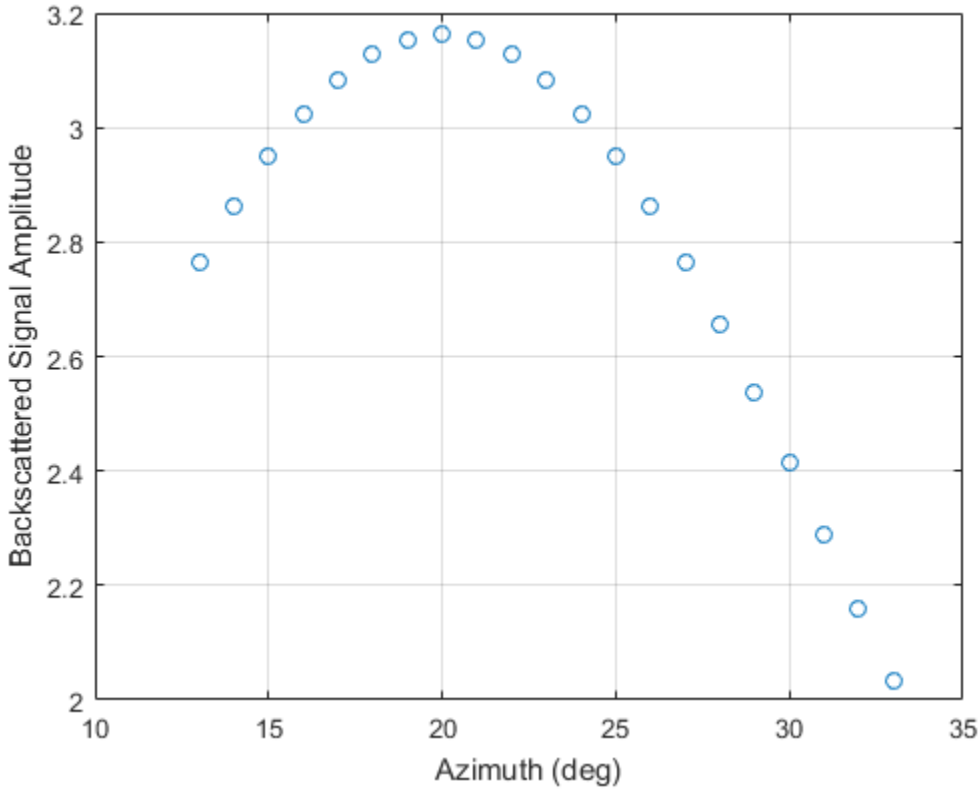
Create the `phased.BackscatterSonarTarget` System object™.

```
target = phased.BackscatterSonarTarget('Model','Nonfluctuating', ...
```

```
    'AzimuthAngles',azpatangs,'ElevationAngles',elpatangs, ...
    'TSPattern',tspattern);
```

For a sequence of different azimuth incident angles (at constant elevation angle), plot the maximum scattered signal amplitude.

```
az0 = 13.0;
el = 10.0;
naz = 20;
az = az0 + [0:1:20];
naz = length(az);
ss = zeros(1,naz);
for k = 1:naz
    y = target(sig,[az(k);el]);
    ss(k) = max(abs(y));
end
plot(az,ss,'o')
xlabel('Azimuth (deg)')
ylabel('Backscattered Signal Amplitude')
grid
```



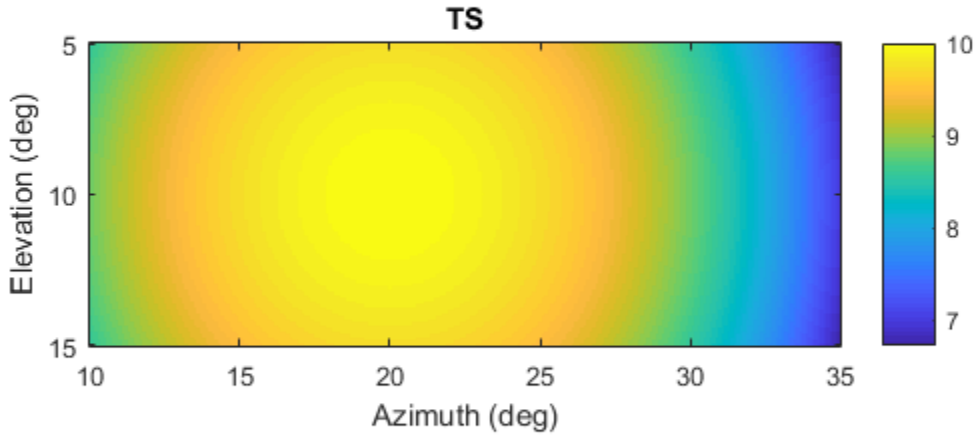
Backscatter Sonar Signal from Fluctuating Target

Calculate the reflected sonar signal from a Swerling2 fluctuating point target with a peak target strength (TS) of 10.0 db. For illustrative purposes, use a simplified expression for the TS pattern of a target. Real TS patterns are more complicated. The TS pattern covers a range of angles from 10°to 30° in azimuth and from 5° ro 15° in elevation. The TS peaks at 20° azimuth and 10° elevation. Assume that the sonar operating frequency is 10 kHz and that the signal is a sinusoid at 9500 kHz.

Create and plot the TS pattern.

```
azmax = 20.0;
elmax = 10.0;
azpatangs = [10.0:0.1:35.0];
```

```
elpatangs = [5.0:0.1:15.0];
tspattern = 10.0*cosd(4*(elpatangs - elmax))'*cosd(4*(azpatangs - azmax));
tspatterndb = 10*log10(tspattern);
imagesc(azpatangs,elpatangs,tspatterndb)
colorbar
axis image
axis tight
title('TS')
xlabel('Azimuth (deg)')
ylabel('Elevation (deg)')
```



Generate the sonar signal.

```
freq = 9.5e3;
```

```
fs = 10*freq;
nsamp = 50;
t = [0:(nsamp-1)]'/fs;
sig = sin(2*pi*freq*t);
```

Create the `phased.BackscatterSonarTarget` System object™.

```
target = phased.BackscatterSonarTarget('Model','Nonfluctuating',...
    'AzimuthAngles',azpatangs,'ElevationAngles',elpatangs,...
    'TSPattern',tspattern,'Model','Swerling2');
```

Compute and plot the fluctuating signal amplitude for 20 time steps.

```
az = 20.0;
el = 10.0;
nsteps = 20;
ss = zeros(1,nsteps);
for k = 1:nsteps
    y = target(sig,[az;el],true);
    ss(k) = max(abs(y));
end
plot([0:(nsteps-1)]*1000/fs,ss,'o')
xlabel('Time (msec)')
ylabel('Backscattered Signal Amplitude')
grid

- “Underwater Target Detection with an Active Sonar System”
- “Locating an Acoustic Beacon with a Passive Sonar System”

Definitions

Backscattered Sound Radiation

For narrowband acoustic signals, the reflected signal, Y, is given by

$$Y = \sqrt{G} \cdot X,$$

where

- X is the incoming signal.
- G is the target gain factor given by $10^{TS/10}$ where TS is the target strength in dB. Specify target strength using the `TSPattern` property.

For a more detailed explanation of target strength, see [1].

Introduced in R2017a

reset

System object: phased.BackscatterSonarTarget
Package: phased

Reset states of System object

Syntax

```
reset(target)
```

Description

`reset(target)` resets the internal state of the `phased.BackscatterSonarTarget` object, `target`. This method resets the random number generator state if `SeedSource` is a property of this System object and has the value `'Property'`.

Input Arguments

`target` — Backscatter sonar target

`phased.BackscatterSonarTarget` System object

Backscatter sonar target, specified as a `phased.BackscatterSonarTarget` System object.

Example: `phased.BackscatterSonarTarget`

Introduced in R2017a

step

System object: phased.BackscatterSonarTarget
Package: phased

Backscatter incoming sonar signal

Syntax

```
refl_sig = step(target,sig,ang)
refl_sig = step(target,sig,ang,update)
```

Description

Note: Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`refl_sig = step(target,sig,ang)` returns the reflected signal, `refl_sig`, of an incident sonar signal, `sig`, arriving at the target from the angle, `ang`.

`refl_sig = step(target,sig,ang,update)` uses `update` to control whether to update the target strength (TS) values. This syntax applies when you set the `Model` property to one of the fluctuating TS models: `'Swerling1'`, `'Swerling2'`, `'Swerling3'`, or `'Swerling4'`. If `update` is `true`, a new TS value is generated. If `update` is `false`, the previous TS value is used.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`target` — Backscatter sonar target

`phased.BackscatterSonarTarget` System object

Backscatter sonar target, specified as a `phased.BackscatterSonarTarget` System object.

`sig` — Sonar signal

N-by-*M* complex-valued matrix

Sonar signal, specified as an *N*-by-*M* complex-valued matrix. The quantity *N* is the number of signal samples and *M* is the number of signals reflecting off the target. Each column corresponds to an independent signal incident at a different reflecting angle.

When you specify the `TSPattern` property as a *Q*-by-*P*-by-*M*, a separate pattern is used for each signal. When you specify `TSPattern` as a *Q*-by-*P*matrix, the same pattern is used for every signal.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Example: `[1,1;j,1;0.5,0]`

Data Types: `double`
Complex Number Support: Yes

`ang` — Incident signal direction

2-by-*1* positive real-valued column vector | *2*-by-*M* positive real-valued column matrix

Incident signal direction, specified as a *2*-by-*1* positive real-valued column vector or a *2*-by-*M* positive real-valued column matrix. Each column of `ang` specifies the incident direction of the corresponding signal in the form of an `[AzimuthAngle;ElevationAngle]` pair. Units are degrees. The number of columns in `ang` must match the number of independent signals in `sig`.

Example: `[30;45]`

Data Types: `double`

`update` — Update target strength

`false` (default) | `true`

Allow the TS values for fluctuation models to update, specified as `false` or `true`. When `update` is `true`, a new TS value is generated with each call to the `step` method. If `update` is `false`, TS remains unchanged with each call to `step`.

Example: `true`

Data Types: `logical`

Output Arguments

`refl_sig` — Narrowband reflected sonar signal

N-by-*M* complex-valued matrix

Narrowband reflected sonar signal, specified as an *N*-by-*M* complex-valued matrix. Each column contains an independent signal reflected from the target.

The quantity *N* is the number of signal samples and *M* is the number of signals reflecting off the target. Each column corresponds to a reflecting angle.

The output `refl_sig` contains signal samples arriving at the signal destination within the current input time frame. When the propagation time from source to destination exceeds the current time frame duration, the output will not contain all contributions from the input of the current time frame. The remaining output appears in the next call to `step`.

Examples

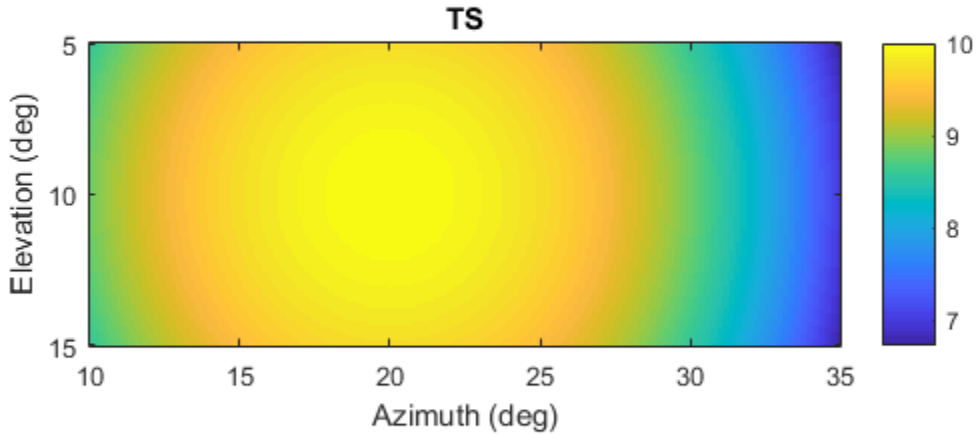
Backscatter Sonar Signal from Nonfluctuating Target

Calculate the reflected sonar signal from a nonfluctuating point target with a peak target strength (TS) of 10.0 db. For illustrative purposes, use a simplified expression for the TS pattern of a target. Real TS patterns are more complicated. The TS pattern covers a range of angles from 10° to 30° in azimuth and from 5° to 15° in elevation. The TS peaks at 20° azimuth and 10° elevation. Assume that the sonar operating frequency is 10 kHz and that the signal is a sinusoid at 9500 kHz.

Create and plot the TS pattern.

```
azmax = 20.0;
elmax = 10.0;
azpatangs = [10.0:0.1:35.0];
```

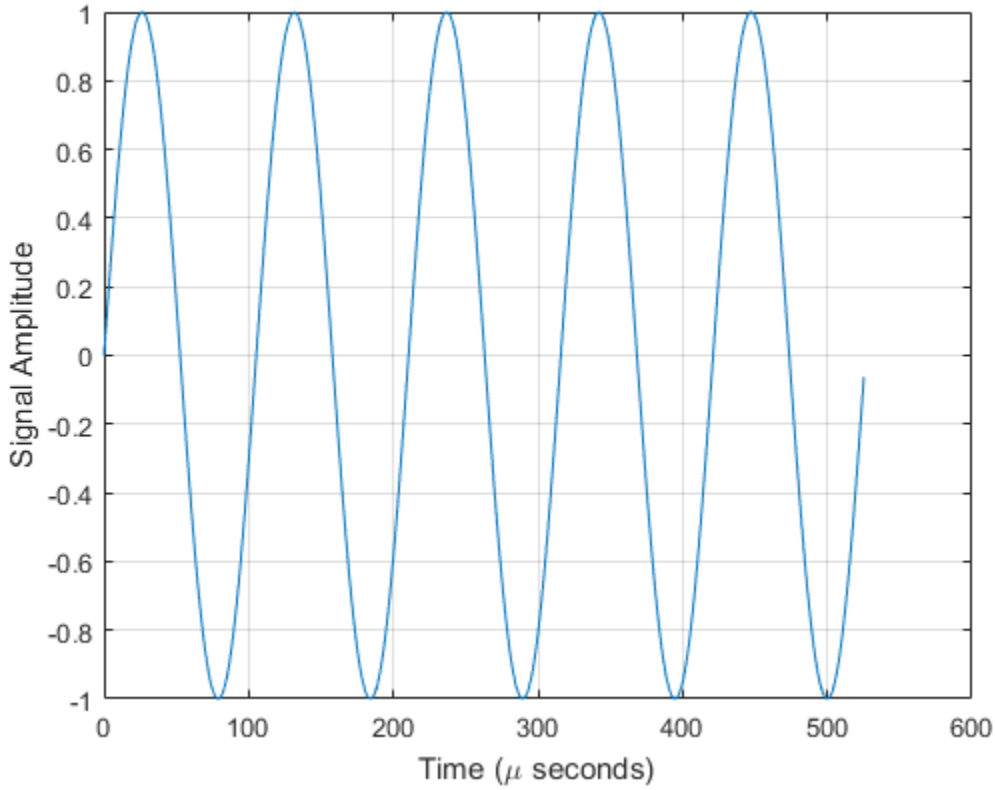
```
elpatangs = [5.0:0.1:15.0];
tspattern = 10.0*cosd(4*(elpatangs - elmax))'*cosd(4*(azpatangs - azmax));
tspatterndb = 10*log10(tspattern);
imagesc(azpatangs,elpatangs,tspatterndb)
colorbar
axis image
axis tight
title('TS')
xlabel('Azimuth (deg)')
ylabel('Elevation (deg)')
```



Generate and plot 50 samples of the sonar signal.

```
freq = 9.5e3;
```

```
fs = 100*freq;
nsamp = 500;
t = [0:(nsamp-1)]'/fs;
sig = sin(2*pi*freq*t);
plot(t*1e6,sig)
xlabel('Time (\mu seconds)')
ylabel('Signal Amplitude')
grid
```

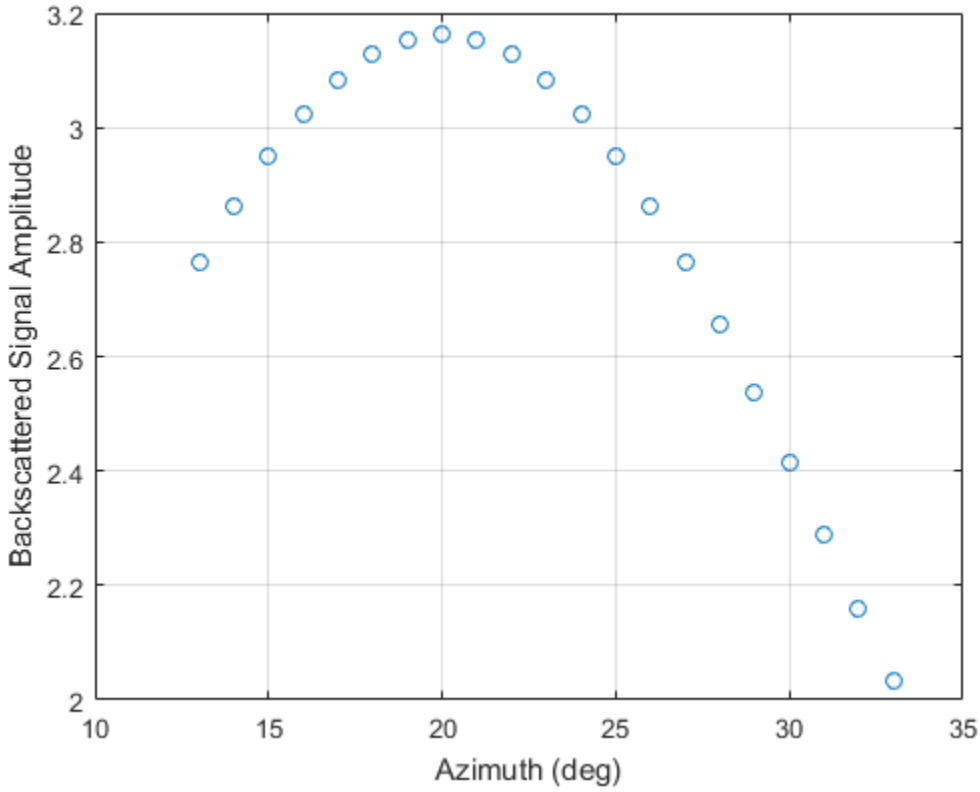


Create the `phased.BackscatterSonarTarget` System object™.

```
target = phased.BackscatterSonarTarget('Model','Nonfluctuating', ...
    'AzimuthAngles',azpatangs,'ElevationAngles',elpatangs, ...
    'TSPattern',tspattern);
```

For a sequence of different azimuth incident angles (at constant elevation angle), plot the maximum scattered signal amplitude.

```
az0 = 13.0;
el = 10.0;
naz = 20;
az = az0 + [0:1:20];
naz = length(az);
ss = zeros(1,naz);
for k = 1:naz
    y = target(sig,[az(k);el]);
    ss(k) = max(abs(y));
end
plot(az,ss,'o')
xlabel('Azimuth (deg)')
ylabel('Backscattered Signal Amplitude')
grid
```



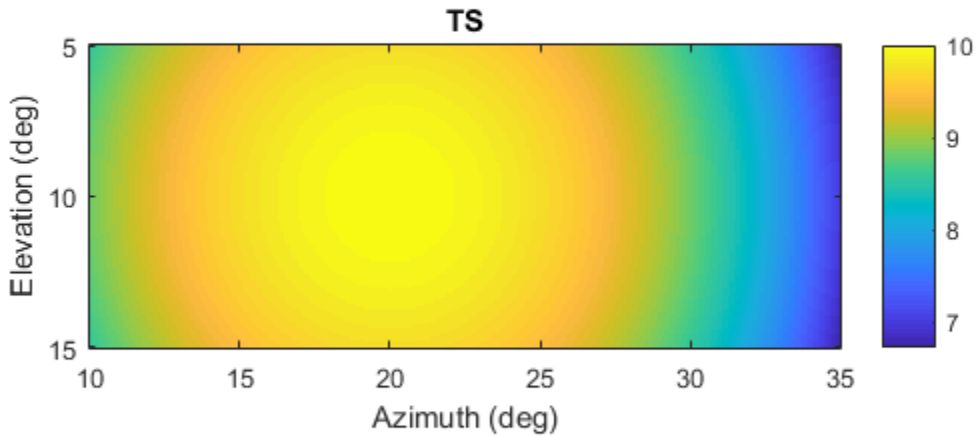
Backscatter Sonar Signal from Fluctuating Target

Calculate the reflected sonar signal from a Swerling2 fluctuating point target with a peak target strength (TS) of 10.0 db. For illustrative purposes, use a simplified expression for the TS pattern of a target. Real TS patterns are more complicated. The TS pattern covers a range of angles from 10°to 30° in azimuth and from 5° ro 15° in elevation. The TS peaks at 20° azimuth and 10° elevation. Assume that the sonar operating frequency is 10 kHz and that the signal is a sinusoid at 9500 kHz.

Create and plot the TS pattern.

```
azmax = 20.0;
elmax = 10.0;
azpatangs = [10.0:0.1:35.0];
```

```
elpatangs = [5.0:0.1:15.0];
tspattern = 10.0*cosd(4*(elpatangs - elmax))'*cosd(4*(azpatangs - azmax));
tspatterndb = 10*log10(tspattern);
imagesc(azpatangs,elpatangs,tspatterndb)
colorbar
axis image
axis tight
title('TS')
xlabel('Azimuth (deg)')
ylabel('Elevation (deg)')
```



Generate the sonar signal.

```
freq = 9.5e3;
```

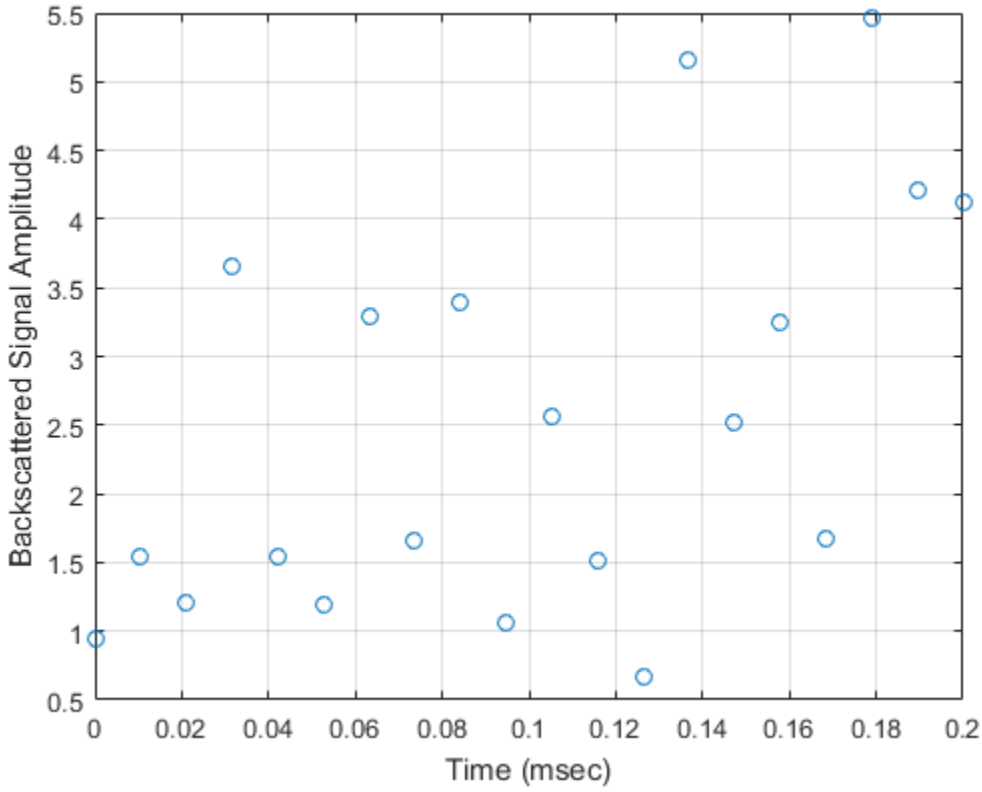
```
fs = 10*freq;
nsamp = 50;
t = [0:(nsamp-1)]'/fs;
sig = sin(2*pi*freq*t);
```

Create the `phased.BackscatterSonarTarget` System object™.

```
target = phased.BackscatterSonarTarget('Model','Nonfluctuating',...
    'AzimuthAngles',azpatangs,'ElevationAngles',elpatangs,...
    'TSPattern',tspattern,'Model','Swerling2');
```

Compute and plot the fluctuating signal amplitude for 20 time steps.

```
az = 20.0;
el = 10.0;
nsteps = 20;
ss = zeros(1,nsteps);
for k = 1:nsteps
    y = target(sig,[az;el],true);
    ss(k) = max(abs(y));
end
plot([0:(nsteps-1)]*1000/fs,ss,'o')
xlabel('Time (msec)')
ylabel('Backscattered Signal Amplitude')
grid
```



Introduced in R2017a

phased.BarrageJammer System object

Package: phased

Barrage jammer

Description

The `BarrageJammer` object implements a white Gaussian noise jammer.

To obtain the jamming signal:

1. Define and set up your barrage jammer. See "Construction" on page 1-98.
2. Call step to compute the jammer output according to the properties of `phased.BarrageJammer`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.BarrageJammer` creates a barrage jammer System object, `H`. This object generates a complex white Gaussian noise jamming signal.

`H = phased.BarrageJammer(Name,Value)` creates object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

`H = phased.BarrageJammer(E,Name,Value)` creates a barrage jammer object, `H`, with the `ERP` property set to `E` and other specified property Names set to the specified Values.

Properties

ERP

Effective radiated power

Specify the effective radiated power (ERP) (in watts) of the jamming signal as a positive scalar.

Default: `5000`

SamplesPerFrameSource

Source of number of samples per frame

Specify whether the number of samples of the jamming signal comes from the `SamplesPerFrame` property of this object or from an input argument in step. Values of this property are:

`'Property'`	The `SamplesPerFrame` property of this object specifies the number of samples of the jamming signal.
`'Input port'`	An input argument in each invocation of `step` specifies the number of samples of the jamming signal.

Default: `'Property'`

SamplesPerFrame

Number of samples per frame

Specify the number of samples in the output jamming signal as a positive integer. This property applies when you set the `SamplesPerFrameSource` property to `'Property'`.

Default: `100`

SeedSource

Source of seed for random number generator

Specify how the object generates random numbers. Values of this property are:

`'Auto'`	The default MATLAB random number generator produces the random numbers. Use `'Auto'` if you are using this object with Parallel Computing Toolbox software.
`'Property'`	The object uses its own private random number generator to produce random numbers. The `Seed` property of this object specifies the seed of the random number generator. Use `'Property'` if you want repeatable results and are not using this object with Parallel Computing Toolbox software.

Default: `'Auto'`

`Seed`

Seed for random number generator

Specify the seed for the random number generator as a scalar integer between 0 and 2^{32}–1. This property applies when you set the `SeedSource` property to `'Property'`.

Default: `0`

Methods

reset	Reset random number generator for noise generation
step	Generate noise jamming signal

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Plot Barrage Jammer Output

Create a barrage jammer with an effective radiated power of 1000W. Then plot the magnitude of the jammer output. Your plot might vary because of random numbers.

```
Hjammer = phased.BarrageJammer('ERP',1000);
x = step(Hjammer);
plot(abs(x)); xlabel('Samples'); ylabel('Magnitude');
```

reset

System object: phased.BarrageJammer
Package: phased

Reset random number generator for noise generation

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `BarrageJammer` object, `H`. This method resets the random number generator state if the `SeedSource` property is set to `'Property'`.

step

System object: phased.BarrageJammer
Package: phased

Generate noise jamming signal

Syntax

```
Y = step(H)
Y = step(H,N)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H)` returns a column vector, `Y`, that is a complex white Gaussian noise jamming signal. The power of the jamming signal is specified by the `ERP` property. The length of the jamming signal is specified by the `SamplesPerFrame` property. This syntax is available when the `SamplesPerFrameSource` property is `'Property'`.

`Y = step(H,N)` returns the jamming signal with length `N`. This syntax is available when the `SamplesPerFrameSource` property is `'Input port'`.

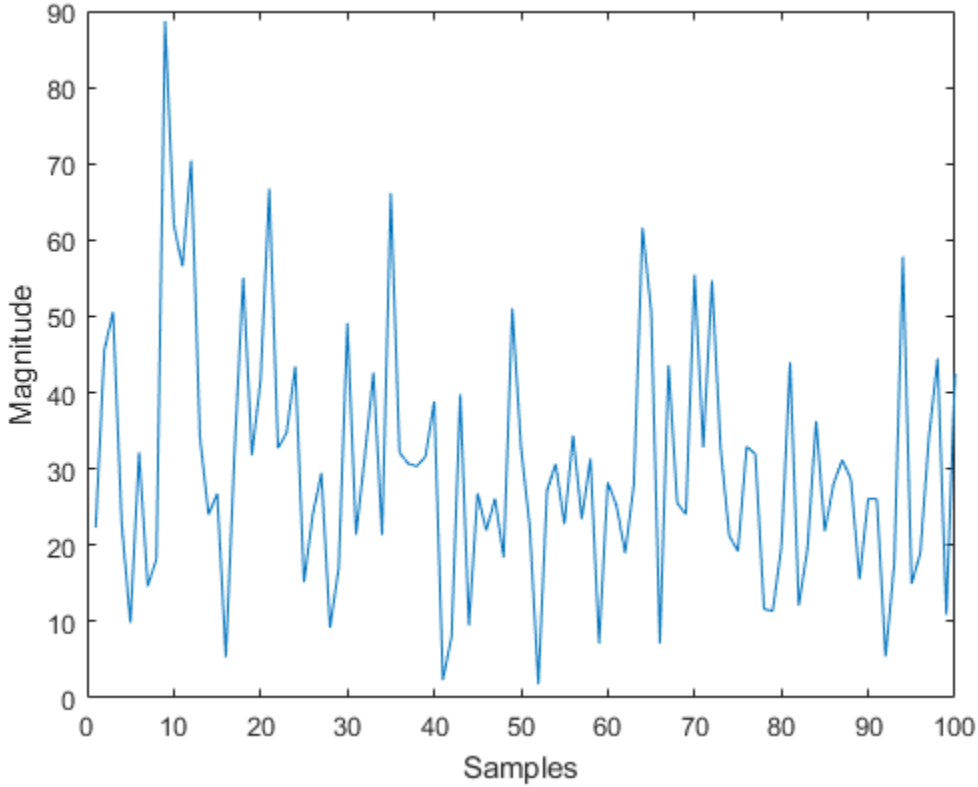
Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Examples

Plot Barrage Jammer Output

Create a barrage jammer with an effective radiated power of 1000W. Then plot the magnitude of the jammer output. Your plot might vary because of random numbers.

```
Hjammer = phased.BarrageJammer('ERP',1000);
x = step(Hjammer);
plot(abs(x)); xlabel('Samples'); ylabel('Magnitude');
```



phased.BeamscanEstimator System object

Package: phased

Beamscan spatial spectrum estimator for ULA

Description

The `BeamscanEstimator` object calculates a beamscan spatial spectrum estimate for a uniform linear array.

To estimate the spatial spectrum:

1. Define and set up your beamscan spatial spectrum estimator. See "Construction" on page 1-107.
2. Call step to estimate the spatial spectrum according to the properties of `phased.BeamscanEstimator`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.BeamscanEstimator` creates a beamscan spatial spectrum estimator System object, `H`. The object estimates the incoming signal's spatial spectrum using a narrowband conventional beamformer for a uniform linear array (ULA).

`H = phased.BeamscanEstimator(Name,Value)` creates object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`SensorArray`

Handle to sensor array

Specify the sensor array as a handle. The sensor array must be a `phased.ULA` object.

Default: phased.ULA with default property values

`PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

Default: Speed of light

`OperatingFrequency`

System operating frequency

Specify the operating frequency of the system in hertz as a positive scalar. The default value corresponds to 300 MHz.

Default: `3e8`

`NumPhaseShifterBits`

Number of phase shifter quantization bits

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

Default: `0`

`ForwardBackwardAveraging`

Perform forward-backward averaging

Set this property to `true` to use forward-backward averaging to estimate the covariance matrix for sensor arrays with conjugate symmetric array manifold.

Default: `false`

`SpatialSmoothing`

Spatial smoothing

Specify the number of averaging used by spatial smoothing to estimate the covariance matrix as a nonnegative integer. Each additional smoothing handles one extra coherent source, but reduces the effective number of elements by 1. The maximum value of this property is M–2, where M is the number of sensors.

Default: `0`, indicating no spatial smoothing

`ScanAngles`

Scan angles

Specify the scan angles (in degrees) as a real vector. The angles are broadside angles and must be between –90 and 90, inclusive. You must specify the angles in ascending order.

Default: `-90:90`

`DOAOutputPort`

Enable DOA output

To obtain the signal's direction of arrival (DOA), set this property to `true` and use the corresponding output argument when invoking step. If you do not want to obtain the DOA, set this property to `false`.

Default: `false`

`NumSignals`

Number of signals

Specify the number of signals for DOA estimation as a positive scalar integer. This property applies when you set the `DOAOutputPort` property to `true`.

Default: 1

Methods

plotSpectrum	Plot spatial spectrum
reset	Reset states of beamscan spatial spectrum estimator object
step	Perform spatial spectrum estimation

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Estimate Directions of Arrival of Two Signals

Estimate the DOA's of two signals received by a 10-element ULA with element spacing of 1 meter. The antenna operating frequency is 150 MHz. The actual direction of the first signal is 10° in azimuth and 20° in elevation. The direction of the second signal is 60° in azimuth and -5° in elevation.

Create the signals and array.

```
fs = 8000;
t = (0:1/fs:1).';
x1 = cos(2*pi*t*300);
x2 = cos(2*pi*t*400);
array = phased.ULA('NumElements',10,'ElementSpacing',1);
array.Element.FrequencyRange = [100e6 300e6];
```

```
fc = 150e6;
x = collectPlaneWave(array,[x1 x2],[10 20;60 -5]',fc);
noise = 0.1*(randn(size(x)) + 1i*randn(size(x)));
```

Solve for the DOAs.

```
estimator = phased.BeamscanEstimator('SensorArray',array, ...
    'OperatingFrequency',fc,...
    'DOAOutputPort',true,'NumSignals',2);
[y,doas] = estimator(x + noise);
doas = broadside2az(sort(doas),[20 -5])
```

```
doas =

    9.5829   60.3813
```

Plot the beamscan spectrum

```
plotSpectrum(estimator);
```

plotSpectrum

System object: phased.BeamscanEstimator
Package: phased

Plot spatial spectrum

Syntax

```
plotSpectrum(H)
plotSpectrum(H,Name,Value)
h = plotSpectrum( ___ )
```

Description

`plotSpectrum(H)` plots the spatial spectrum resulting from the last call of the `step` method.

`plotSpectrum(H,Name,Value)` plots the spatial spectrum with additional options specified by one or more `Name,Value` pair arguments.

`h = plotSpectrum( ___ )` returns the line handle in the figure.

Input Arguments

`H`

Spatial spectrum estimator object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'NormalizeResponse'`

Set this value to `true` to plot the normalized spectrum. Setting this value to `false` plots the spectrum without normalization.

Default: `false`

`'Title'`

Character vector to use as figure title.

Default: `''`

`'Unit'`

Plot units, specified as `'db'`, `'mag'`, or `'pow'`.

Default: `'db'`

Examples

Estimate Directions of Arrival of Two Signals

Estimate the DOA's of two signals received by a 10-element ULA with element spacing of 1 meter. The antenna operating frequency is 150 MHz. The actual direction of the first signal is 10° in azimuth and 20° in elevation. The direction of the second signal is 60° in azimuth and -5° in elevation.

Create the signals and array.

```
fs = 8000;
t = (0:1/fs:1).';
x1 = cos(2*pi*t*300);
x2 = cos(2*pi*t*400);
array = phased.ULA('NumElements',10,'ElementSpacing',1);
array.Element.FrequencyRange = [100e6 300e6];
fc = 150e6;
x = collectPlaneWave(array,[x1 x2],[10 20;60 -5]',fc);
noise = 0.1*(randn(size(x)) + 1i*randn(size(x)));
```

Solve for the DOAs.

```
estimator = phased.BeamscanEstimator('SensorArray',array, ...
```

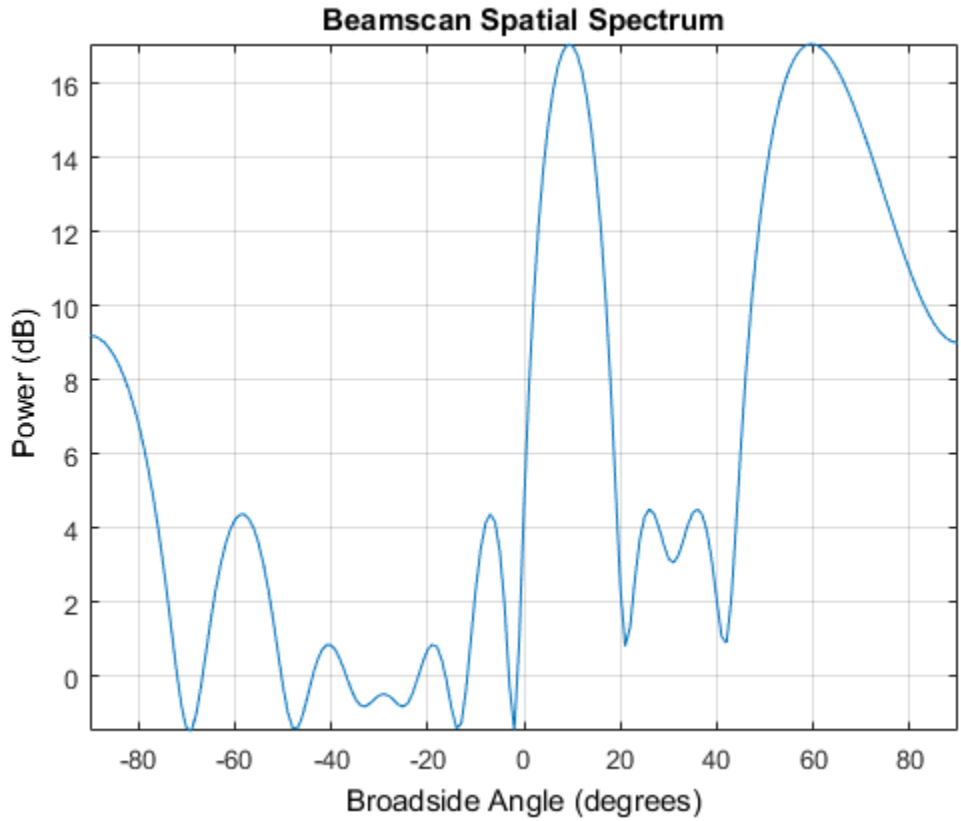
```
    'OperatingFrequency',fc,...
    'DOAOutputPort',true,'NumSignals',2);
[y,doas] = estimator(x + noise);
doas = broadside2az(sort(doas),[20 -5])
```

```
doas =

    9.5829   60.3813
```

Plot the beamscan spectrum

```
plotSpectrum(estimator);
```



reset

System object: phased.BeamscanEstimator
Package: phased

Reset states of beamscan spatial spectrum estimator object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `BeamscanEstimator` object, `H`.

step

System object: phased.BeamscanEstimator
Package: phased

Perform spatial spectrum estimation

Syntax

```
Y = step(H,X)
[Y,ANG] = step(H,X)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` estimates the spatial spectrum from `X` using the estimator, `H`. `X` is a matrix whose columns correspond to channels. `Y` is a column vector representing the magnitude of the estimated spatial spectrum.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

`[Y,ANG] = step(H,X)` returns additional output `ANG` as the signal's direction of arrival (DOA) when the `DOAOutputPort` property is `true`. `ANG` is a row vector of the estimated broadside angles (in degrees).

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To

change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Examples

Estimate Directions of Arrival of Two Signals

phased.BeamscanEstimator2D System object

Package: phased

2-D beamscan spatial spectrum estimator

Description

The `BeamscanEstimator2D` object calculates a 2-D beamscan spatial spectrum estimate.

To estimate the spatial spectrum:

1. Define and set up your 2-D beamscan spatial spectrum estimator. See "Construction" on page 1-121.
2. Call step to estimate the spatial spectrum according to the properties of `phased.BeamscanEstimator2D`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.BeamscanEstimator2D` creates a 2-D beamscan spatial spectrum estimator System object, `H`. The object estimates the signal's spatial spectrum using a narrowband conventional beamformer.

`H = phased.BeamscanEstimator2D(Name,Value)` creates object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`SensorArray`

Handle to sensor array

Specify the sensor array as a handle. The sensor array must be an array object in the `phased` package. The array cannot contain subarrays.

Default: phased.ULA with default property values

`PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

Default: Speed of light

`OperatingFrequency`

System operating frequency

Specify the operating frequency of the system in hertz as a positive scalar. The default value corresponds to 300 MHz.

Default: `3e8`

`NumPhaseShifterBits`

Number of phase shifter quantization bits

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

Default: `0`

`ForwardBackwardAveraging`

Perform forward-backward averaging

Set this property to `true` to use forward-backward averaging to estimate the covariance matrix for sensor arrays with conjugate symmetric array manifold.

Default: false

`AzimuthScanAngles`

Azimuth scan angles

Specify the azimuth scan angles (in degrees) as a real vector. The angles must be between –180 and 180, inclusive. You must specify the angles in ascending order.

Default: `-90:90`

`ElevationScanAngles`

Elevation scan angles

Specify the elevation scan angles (in degrees) as a real vector or scalar. The angles must be within [–90 90]. You must specify the angles in an ascending order.

Default: `0`

`DOAOutputPort`

Enable DOA output

To obtain the signal's direction of arrival (DOA), set this property to `true` and use the corresponding output argument when invoking step. If you do not want to obtain the DOA, set this property to `false`.

Default: `false`

`NumSignals`

Number of signals

Specify the number of signals for DOA estimation as a positive scalar integer. This property applies when you set the `DOAOutputPort` property to `true`.

Default: `1`

Methods

plotSpectrum	Plot spatial spectrum

reset	Reset states of 2-D beamscan spatial spectrum estimator object
step	Perform 2-D spatial spectrum estimation

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Estimate the DOAs of Two Signals

Create the signals and solve for the DOA's

Estimate the DOAs of two signals received by a 50-element URA with a rectangular lattice. The antenna operating frequency is 150 MHz. The actual direction of the first signal is -37° in azimuth and 0° in elevation. The direction of the second signal is 17° in azimuth and 20° in elevation.

```
ha = phased.URA('Size',[5 10],'ElementSpacing',[1 0.6]);
ha.Element.FrequencyRange = [100e6 300e6];
fc = 150e6;
lambda = physconst('LightSpeed')/fc;
ang1 = [-37; 0]; ang2 = [17; 20];
x = sensorsig(getElementPosition(ha)/lambda,8000,[ang1 ang2],0.2);
estimator = phased.BeamscanEstimator2D('SensorArray',ha,...
    'OperatingFrequency',fc,...
    'DOAOutputPort',true,'NumSignals',2,...
    'AzimuthScanAngles',-50:50,...
    'ElevationScanAngles',-30:30);
[~,doas] = estimator(x)

doas =
```

```
   -37    17
     0    20
```

Plot the beamscan spatial spectrum

```
plotSpectrum(estimator);

phased.BeamscanEstimator | `phitheta2azel` | `uv2azel`

Introduced in R2012a

plotSpectrum

System object: phased.BeamscanEstimator2D
Package: phased

Plot spatial spectrum

Syntax

```
plotSpectrum(H)
plotSpectrum(H,Name,Value)
h = plotSpectrum( ___ )
```

Description

`plotSpectrum(H)` plots the spatial spectrum resulting from the last call of the `step` method.

`plotSpectrum(H,Name,Value)` plots the spatial spectrum with additional options specified by one or more `Name,Value` pair arguments.

`h = plotSpectrum( ___ )` returns the line handle in the figure.

Input Arguments

`H`

Spatial spectrum estimator object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'NormalizeResponse'`

Set this value to `true` to plot the normalized spectrum. Setting this value to `false` plots the spectrum without normalization.

Default: `false`

`'Title'`

Character vector to use as figure title.

Default: `''`

`'Unit'`

Plot units, specified as `'db'`, `'mag'`, or `'pow'`.

Default: `'db'`

Examples

Estimate the DOAs of Two Signals

Create the signals and solve for the DOA's

Estimate the DOAs of two signals received by a 50-element URA with a rectangular lattice. The antenna operating frequency is 150 MHz. The actual direction of the first signal is -37° in azimuth and 0° in elevation. The direction of the second signal is 17° in azimuth and 20° in elevation.

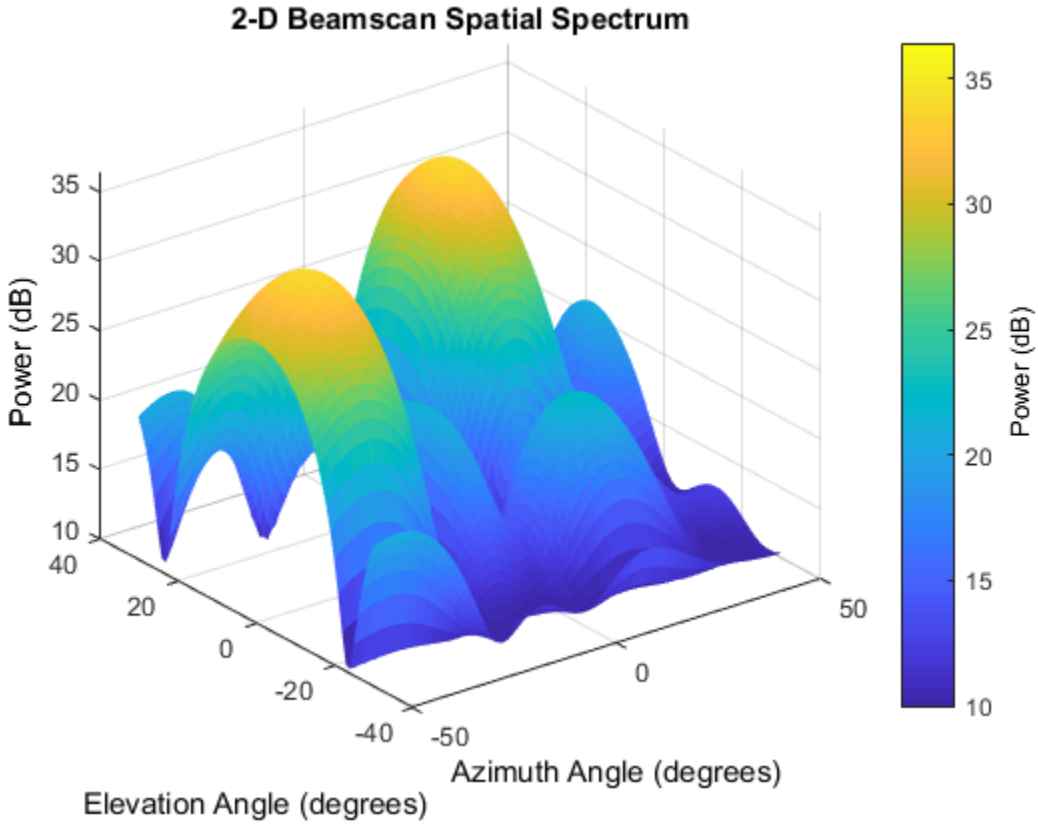
```
ha = phased.URA('Size',[5 10],'ElementSpacing',[1 0.6]);
ha.Element.FrequencyRange = [100e6 300e6];
fc = 150e6;
lambda = physconst('LightSpeed')/fc;
ang1 = [-37; 0]; ang2 = [17; 20];
x = sensorsig(getElementPosition(ha)/lambda,8000,[ang1 ang2],0.2);
estimator = phased.BeamscanEstimator2D('SensorArray',ha,...
    'OperatingFrequency',fc,...
    'DOAOutputPort',true,'NumSignals',2,...
    'AzimuthScanAngles',-50:50,...
    'ElevationScanAngles',-30:30);
[~,doas] = estimator(x)
```

```
doas =

   -37    17
     0    20
```

Plot the beamscan spatial spectrum

```
plotSpectrum(estimator);
```



reset

System object: phased.BeamscanEstimator2D
Package: phased

Reset states of 2-D beamscan spatial spectrum estimator object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `BeamscanEstimator2D` object, `H`.

step

System object: phased.BeamscanEstimator2D
Package: phased

Perform 2-D spatial spectrum estimation

Syntax

```
Y = step(H,X)
[Y,ANG] = step(H,X)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` estimates the spatial spectrum from `X` using the estimator `H`. `X` is a matrix whose columns correspond to channels. `Y` is a matrix representing the magnitude of the estimated 2-D spatial spectrum. `Y` has a row dimension equal to the number of elevation angles specified in `ElevationScanAngles` and a column dimension equal to the number of azimuth angles specified in `AzimuthScanAngles`.

`[Y,ANG] = step(H,X)` returns additional output `ANG` as the signal's direction of arrival (DOA) when the `DOAOutputPort` property is `true`. `ANG` is a two row matrix where the first row represents the estimated azimuth and the second row represents the estimated elevation (in degrees).

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications,

such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Examples

Estimate DOAs of Two Sinusoidal Signals

Estimate the DOAs of two sinusoidal signals received by a 50-element URA with a rectangular lattice. The antenna operating frequency is 150 MHz. The actual direction of the first signal is -37° in azimuth and 0° in elevation. The direction of the second signal is 17° in azimuth and 20° in elevation.

Create the signals and solve for the DOA's.

```
fs = 8000;
t = (0:1/fs:1).';
x1 = cos(2*pi*t*300);
x2 = cos(2*pi*t*400);
array = phased.URA('Size',[5 10],'ElementSpacing',[1 0.6]);
array.Element.FrequencyRange = [100e6 300e6];
fc = 150e6;
x = collectPlaneWave(array,[x1 x2],[-37 0; 17 20]',fc);
noise = 0.1*(randn(size(x)) + 1i*randn(size(x)));
estimator = phased.BeamscanEstimator2D('SensorArray',array, ...
    'OperatingFrequency',fc, ...
    'DOAOutputPort',true,'NumSignals',2, ...
    'AzimuthScanAngles',-50:50, ...
    'ElevationScanAngles',-30:30);
[~,doas] = estimator(x + noise)
```

```
doas =

   -37    17
     0    20

phased.BeamspaceESPRITEstimator System object

Package: phased

Beamspace ESPRIT direction of arrival (DOA) estimator for ULA

Description

The `BeamspaceESPRITEstimator` object computes a DOA estimate for a uniform linear array. The computation uses the estimation of signal parameters via rotational invariance techniques (ESPRIT) algorithm in beamspace.

To estimate the direction of arrival (DOA):

1. Define and set up your DOA estimator. See "Construction" on page 1-134.
2. Call step to estimate the DOA according to the properties of `phased.BeamspaceESPRITEstimator`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.BeamspaceESPRITEstimator` creates a beamspace ESPRIT DOA estimator System object, `H`. The object estimates the signal's direction of arrival using the beamspace ESPRIT algorithm with a uniform linear array (ULA).

`H = phased.BeamspaceESPRITEstimator(Name,Value)` creates object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`SensorArray`

Handle to sensor array

Specify the sensor array as a handle. The sensor array must be a `phased.ULA` object.

Default: phased.ULA with default property values

`PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

Default: Speed of light

`OperatingFrequency`

System operating frequency

Specify the operating frequency of the system in hertz as a positive scalar. The default value corresponds to 300 MHz.

Default: `3e8`

`SpatialSmoothing`

Spatial smoothing

Specify the number of averaging used by spatial smoothing to estimate the covariance matrix as a nonnegative integer. Each additional smoothing handles one extra coherent source, but reduces the effective number of element by 1. The maximum value of this property is M–2, where M is the number of sensors.

Default: `0`, indicating no spatial smoothing

`NumSignalsSource`

Source of number of signals

Specify the source of the number of signals as one of `'Auto'` or `'Property'`. If you set this property to `'Auto'`, the number of signals is estimated by the method specified by the `NumSignalsMethod` property.

Default: `'Auto'`

`NumSignalsMethod`

Method to estimate number of signals

Specify the method to estimate the number of signals as one of `'AIC'` or `'MDL'`. `'AIC'` uses the Akaike Information Criterion and `'MDL'` uses Minimum Description Length Criterion. This property applies when you set the `NumSignalsSource` property to `'Auto'`.

Default: `'AIC'`

`NumSignals`

Number of signals

Specify the number of signals as a positive integer scalar. This property applies when you set the `NumSignalsSource` property to `'Property'`.

Default: `1`

`Method`

Type of least square method

Specify the least squares method used for ESPRIT as one of `'TLS'` or `'LS'`. `'TLS'` refers to total least squares and `'LS'` refers to least squares.

Default: `'TLS'`

`BeamFanCenter`

Beam fan center direction (in degrees)

Specify the direction of the center of the beam fan (in degrees) as a real scalar value between –90 and 90. This property is tunable.

Default: `0`

`NumBeamsSource`

Source of number of beams

Specify the source of the number of beams as one of `'Auto'` or `'Property'`. If you set this property to `'Auto'`, the number of beams equals N–L, where N is the number of array elements and L is the value of the `SpatialSmoothing` property.

Default: `'Auto'`

`NumBeams`

Number of beams

Specify the number of beams as a positive scalar integer. The lower the number of beams, the greater the reduction in computational cost. This property applies when you set the `NumBeamsSource` to `'Property'`.

Default: 2

Methods

step	Perform DOA estimation

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Estimate DOA of Two Signals Using Beamspace ESPRIT

Estimate the directions of arrival (DOA) of two signals received by a standard 10-element ULA with element spacing 1 meter. The antenna operating frequency is 150 MHz. The

actual direction of the first signal is 10° in azimuth and 20° in elevation. The direction of the second signal is 45° in azimuth and 60° in elevation.

Create the two signals arriving at the array.

```
fs = 8000;
t = (0:1/fs:1).';
x1 = cos(2*pi*t*300);
x2 = cos(2*pi*t*400);
array = phased.ULA('NumElements',10,'ElementSpacing',1);
array.Element.FrequencyRange = [100e6 300e6];
fc = 150e6;
x = collectPlaneWave(array,[x1 x2],[10 20;45 60]',fc);
noise = 0.1/sqrt(2)*(randn(size(x)) + 1i*randn(size(x)));
```

Set up the beamspace ESPRIT estimator and solve for the DOAs.

```
estimator = phased.BeamspaceESPRITEstimator('SensorArray',array, ...
    'OperatingFrequency',fc,'NumSignalsSource','Property','NumSignals',2);
doas = estimator(x + noise);
az = broadside2az(sort(doas),[20 60])
```

```
az =

    9.9972   45.0061
```

```

```
az =

    9.9972   45.0061
```

phased.CFARDetector System object

Package: phased

Constant false alarm rate (CFAR) detector

Description

The `CFARDetector` object implements a one-dimensional constant false-alarm rate (CFAR) detector. Detection processing is performed on selected elements (called cells) of the input data. A detection is declared when an image cell value exceeds a threshold. To maintain a constant false alarm-rate, the threshold is set to a multiple of the image noise power. The detector estimates noise power for a cell-under-test *(CUT)* from surrounding cells using one of three cell averaging methods, or an order statistics method. The cell-averaging methods are cell averaging (CA), greatest-of cell averaging (GOCA), or smallest-of cell averaging (SOCA).

For each test cell, the detector:

1. estimates the noise statistic from the cell values in the training band surrounding the CUT cell.
2. computes the threshold by multiplying the noise estimate by the threshold factor.
3. compares the CUT cell value to the threshold to determine whether a target is present or absent. If the value is greater than the threshold, a target is present.

To run the detector

1. Define and set up your CFAR detector. See “Construction” on page 1-143.
2. Call step to perform CFAR detection according to the properties of `phased.CFARDetector`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.CFARDetector` creates a CFAR detector System object, `H`. The object performs CFAR detection on input data.

`H = phased.CFARDetector(Name,Value)` creates the object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`Method`

CFAR algorithm

Specify the CFAR detector algorithm as one of

`'CA'`	Cell-averaging CFAR
`'GOCA'`	Greatest-of cell-averaging CFAR
`'OS'`	Order statistic CFAR
`'SOCA'`	Smallest-of cell-averaging CFAR

Default: `'CA'`

`Rank`

Rank of order statistic

Specify the rank of the order statistic as a positive integer scalar. The value must be less than or equal to the value of the `NumTrainingCells` property. This property applies only when you set the `Method` property to `'OS'`.

Default: 1

`NumGuardCells`

Number of guard cells

Specify the number of guard cells used in training as an even integer. This property specifies the total number of cells on both sides of the cell under test.

Default: 2, indicating that there is one guard cell at both the front and back of the cell under test

`NumTrainingCells`

Number of training cells

Specify the number of training cells used in training as an even integer. Whenever possible, the training cells are equally divided before and after the cell under test.

Default: 2, indicating that there is one training cell at both the front and back of the cell under test

`ThresholdFactor`

Methods of obtaining threshold factor

Specify whether the threshold factor comes from an automatic calculation, the `CustomThresholdFactor` property of this object, or an input argument in step. Values of this property are:

`'Auto'`	The application calculates the threshold factor automatically based on the desired probability of false alarm specified in the `ProbabilityFalseAlarm` property. The calculation assumes each independent signal in the input is a single pulse coming out of a square law detector with no pulse integration. The calculation also assumes the noise is white Gaussian.
`'Custom'`	The `CustomThresholdFactor` property of this object specifies the threshold factor.
`'Input port'`	An input argument in each invocation of `step` specifies the threshold factor.

Default: `'Auto'`

`ProbabilityFalseAlarm`

Desired probability of false alarm

Specify the desired probability of false alarm as a scalar between 0 and 1 (not inclusive). This property applies only when you set the `ThresholdFactor` property to `'Auto'`.

Default: `0.1`

`CustomThresholdFactor`

Custom threshold factor

Specify the custom threshold factor as a positive scalar. This property applies only when you set the `ThresholdFactor` property to `'Custom'`. This property is tunable.

Default: `1`

`OutputFormat`

Format of detection results

Format of detection results returned by the step method, specified as `'CUT result'` or `'Detection index'`.

- When set to `'CUT result'`, the results are logical detection values (`1` or `0`) for each tested cell. `1` indicates that the value of the tested cell exceeds a detection threshold.
- When set to `'Detection index'`, the results form a vector or matrix containing the indices of tested cells which exceed a detection threshold. You can use this format as input to the phased.RangeEstimator and phased.DopplerEstimator System objects.

Default: `'CUT result'`

`ThresholdOutputPort`

Output detection threshold

To obtain the detection threshold, set this property to `true` and use the corresponding output argument when invoking step. If you do not want to obtain the detection threshold, set this property to `false`.

Default: `false`

`NoiseOutputPort`

Output estimated noise

To obtain the estimated noise, set this property to `true` and use the corresponding output argument when invoking step. If you do not want to obtain the estimated noise, set this property to `false`.

Default: `false`

Methods

step	Perform CFAR detection

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Compute PFA Using CFAR Detector On Noise

Perform cell-averaging CFAR detection on a given Gaussian noise vector with a desired probability of false alarm (pfa) of 0.1. Assume that the data comes from a square law detector and no pulse integration is performed. Use 50 cells to estimate the noise level and 1 cell to separate the test cell and training cells. Perform the detection on all cells of the input.

```
detector = phased.CFARDetector('NumTrainingCells',50,...
    'NumGuardCells',2,'ProbabilityFalseAlarm',0.1);
N = 1000;
x = 1/sqrt(2)*(randn(N,1) + 1i*randn(N,1));
dets = detector(abs(x).^2,1:N);
pfa = sum(dets)/N
```

```
pfa =
```

```
    0.1140
```

Compute CFAR Detection Indices

Perform cell-averaging CFAR detection on a given Gaussian noise vector with a desired probability of false alarm (pfa) of 0.005. Assume that the data comes from a square law detector and no pulse integration is performed. Perform the detection on all cells of the input. Use 50 cells to estimate the noise level and 1 cell to separate the test cell and training cells. Display the detection indices.

```
rng default;
detector = phased.CFARDetector('NumTrainingCells',50,'NumGuardCells',2, ...
    'ProbabilityFalseAlarm',0.005,'OutputFormat','Detection index');
N = 1000;
x1 = 1/sqrt(2)*(randn(N,1) + 1i*randn(N,1));
x2 = 1/sqrt(2)*(randn(N,1) + 1i*randn(N,1));
x = [x1,x2];
cutidx = 1:N;
dets = detector(abs(x).^2,cutidx)
```

```
dets =

   339   537   538   734   786   827   979   136   418   539   874
     1     1     1     1     1     1     1     2     2     2     2
```

Algorithms

`phased.CFARDetector` uses cell averaging in three steps:

1 Identify the training cells from the input, and form the noise estimate. The next table indicates how the detector forms the noise estimate, depending on the `Method` property value.

Method	Noise Estimate
`'CA'`	Use the average of the values in all the training cells.
`'GOCA'`	Select the greater of the averages in the front training cells and rear training cells.

Method	Noise Estimate
`'OS'`	Sort the values in the training cells in ascending order. Select the *N*th item, where *N* is the value of the `Rank` property.
`'SOCA'`	Select the smaller of the averages in the front training cells and rear training cells.

2 Multiply the noise estimate by the threshold factor to form the threshold.

3 Compare the value in the test cell against the threshold to determine whether the target is present or absent. If the value is greater than the threshold, the target is present.

For further details, see [1].

`npwgnthresh` | phased.MatchedFilter | phased.TimeVaryingGain

Introduced in R2012a

step

System object: phased.CFARDetector
Package: phased

Perform CFAR detection

Syntax

```
Y = step(H,X,cutidx)
[Y,th] = step( ___ )
[Y,noise] = step( ___ )
Y = step(H,X,cutidx,thfac)
[Y,TH,N] = step(H,X,cutidx,thfac)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X,cutidx)` performs CFAR detection on specified elements of the input data, `X`. `X` can either be a real-valued *M*-by-1 column vector or a real-valued *M*-by-*N* matrix. `cutidx` is a length-*D* vector of indices specifying the input elements or cells under test (CUT) on which to perform detection processing. When `X` is a vector, `cutidx` specifies the element. When `X` is a matrix, `cutidx` specifies the row of the element. The same index applies to all columns of the matrix. Detection is performed independently along each column of `X` for the indices specified in `cutidx`.

The output argument `Y` contains detection results. The format of `Y` depends on the `OutputFormat` property

- When `OutputFormat` is `'Cut result'`, `Y` is a *D*-by-1 vector or a *D*-by-*N* matrix containing logical detection results. *D* is the length of `cutidx` and *N* is the number

of columns of X. The rows of Y correspond to the rows in cutidx. For each row, Y contains 1 in a column if there is a detection in the corresponding column of X. Otherwise, Y contains a 0.

- When OutputFormat is 'Detection report', Y is a *1*-by-*L* vector or a 2-by-*L* matrix containing detections indices. *L* is the number of detections found in the input data. When X is a column vector, Y contains the index for each detection in X. When X is a matrix, Y contains the row and column indices of each detection in X. Each column of Y has the form [detrow;detcol]. When the NumDetectionsSource property is set to 'Property', *L* equals the value of the NumDetections property. If the number of actual detections is less than this value, columns without detections are set to NaN.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

[Y,th] = step(___) also returns the detection threshold, th, applied to detected cells under test.

- When OutputFormat is 'CUT result', th returns the detection threshold whenever an element of Y is 1 and NaN whenever an element of Y is 0. th has the same size as Y.
- When OutputFormat is 'Detection index', th returns a detection threshold for each corresponding detection in Y. When the NumDetectionsSource property is set to 'Property', *L* equals the value of the NumDetections property. If the number of actual detections is less than this value, columns without detections are set to NaN.

To enable this syntax, set the ThresholdOutputPort property to true.

[Y,noise] = step(___) also returns the estimated noise power, noise, for each detected cell under test in X.

- When OutputFormat is 'CUT result', noise returns a noise power estimate when Y is 1 and NaN whenever Y is zero. noise has the same size as Y.
- When OutputFormat is 'Detection index', noise returns a noise power estimate for each corresponding detection in Y. When the NumDetectionsSource property is set to 'Property', *L* equals the value of the NumDetections property. If the number of actual detections is less than this value, columns without detections are set to NaN.

To enable this syntax, set the NoisePowerOutputPort property to true.

`Y = step(H,X,cutidx,thfac)`, in addition, specifies `thfac` as the threshold factor used to calculate the detection threshold. `thfac` must be a positive scalar. To enable this syntax, set the `ThresholdFactor` property to `'Input port'`.

You can combine optional input and output arguments when their enabling properties are set. Optional inputs and outputs must be listed in the same order as the order of the enabling properties. For example, `[Y,TH,N] = step(H,X,cutidx,thfac)`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Examples

Compute PFA Using CFAR Detector On Noise

Perform cell-averaging CFAR detection on a given Gaussian noise vector with a desired probability of false alarm (pfa) of 0.1. Assume that the data comes from a square law detector and no pulse integration is performed. Use 50 cells to estimate the noise level and 1 cell to separate the test cell and training cells. Perform the detection on all cells of the input.

```
detector = phased.CFARDetector('NumTrainingCells',50,...
    'NumGuardCells',2,'ProbabilityFalseAlarm',0.1);
N = 1000;
x = 1/sqrt(2)*(randn(N,1) + 1i*randn(N,1));
dets = detector(abs(x).^2,1:N);
pfa = sum(dets)/N
```

```
pfa =

    0.1140
```

Compute CFAR Detection Indices

Perform cell-averaging CFAR detection on a given Gaussian noise vector with a desired probability of false alarm (pfa) of 0.005. Assume that the data comes from a square law detector and no pulse integration is performed. Perform the detection on all cells of the input. Use 50 cells to estimate the noise level and 1 cell to separate the test cell and training cells. Display the detection indices.

```
rng default;
detector = phased.CFARDetector('NumTrainingCells',50,'NumGuardCells',2, ...
    'ProbabilityFalseAlarm',0.005,'OutputFormat','Detection index');
N = 1000;
x1 = 1/sqrt(2)*(randn(N,1) + 1i*randn(N,1));
x2 = 1/sqrt(2)*(randn(N,1) + 1i*randn(N,1));
x = [x1,x2];
cutidx = 1:N;
dets = detector(abs(x).^2,cutidx)
```

```
dets =

   339   537   538   734   786   827   979   136   418   539   874
     1     1     1     1     1     1     1     2     2     2     2
```

Algorithms

`phased.CFARDetector` uses cell averaging in three steps:

1. Identify the training cells from the input, and form the noise estimate. The next table indicates how the detector forms the noise estimate, depending on the `Method` property value.

Method	Noise Estimate
`'CA'`	Use the average of the values in all the training cells.
`'GOCA'`	Select the greater of the averages in the front training cells and rear training cells.
`'OS'`	Sort the values in the training cells in ascending order. Select the *N*th item, where *N* is the value of the `Rank` property.

Method	Noise Estimate
'SOCA'	Select the smaller of the averages in the front training cells and rear training cells.

2 Multiply the noise estimate by the threshold factor to form the threshold.

3 Compare the value in the test cell against the threshold to determine whether the target is present or absent. If the value is greater than the threshold, the target is present.

For details, see [1].

phased.CFARDetector2D System object

Package: phased

Two-dimensional CFAR detector

Description

The phased.CFARDetector2D System object implements a constant false-alarm rate detector (CFAR) for selected elements (called cells) of two-dimensional image data. A detection is declared when an image cell value exceeds a threshold. To maintain a constant false alarm-rate, the threshold is set to a multiple of the image noise power. The detector estimates noise power for a cell-under-test *(CUT)* from surrounding cells using one of three cell averaging methods, or an order statistics method. The cell-averaging methods are cell averaging (CA), greatest-of cell averaging (GOCA), or smallest-of cell averaging (SOCA).

For each test cell, the detector:

1. estimates the noise statistic from the cell values in the training band surrounding the CUT cell.
2. computes the threshold by multiplying the noise estimate by the threshold factor.
3. compares the CUT cell value to the threshold to determine whether a target is present or absent. If the value is greater than the threshold, a target is present.

To run the detector

1. Define and set up your 2-D CFAR detector. You can set the phased.CFARDetector2D System object properties when you create the object, or leave them set to their default values. See “Construction” on page 1-155. Some properties that you set at construction time can be changed later. These properties are *tunable*.
2. Find the detections by calling the step method. The output of this method depends on the properties of the phased.CFARDetector2D System object.

Note: Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`detector = phased.CFARDetector2D` creates a 2-D CFAR detector System object, `detector`.

`detector = phased.CFARDetector2D(Name,Value)` creates a 2-D CFAR System object, `detector`, with each specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`Method` — Two-dimensional CFAR averaging method

`'CA'` (default) | `'GOCA'` | `'SOCA'` | `'OS'`

Two-dimensional CFAR averaging method, specified as `'CA'`, `'GOCA'`, `'SOCA'`, or `'OS'`. For `'CA'`, `'GOCA'`, `'SOCA'`, the noise power is the sample mean derived from the training band. For `'OS'`, the noise power is the *k*th cell value obtained from numerically ordering all training cell values. Set *k* using the `Rank` property.

Averaging Method	Description
`CA` — Cell-averaging algorithm	Computes the sample mean of all training cells surrounding the CUT cell.
`GOCA` — Greatest-of cell-averaging algorithm	Splits the 2-D training window surrounding the CUT cell into left and right halves. Then, the algorithm computes the sample mean for each half and selects the largest mean.
`SOCA` — Smallest-of cell-averaging algorithm	Splits the 2-D training window surrounding the CUT cell into left and right halves. Then, the algorithm computes the sample mean for each half and selects the smallest mean.
`OS` — Order statistic algorithm	Sorts training cells in ascending order of numeric values. Then the algorithm selects the *k*th value from the list. *k* is the rank specified by the `Rank` parameter.

Example: `'OS'`

Data Types: `char`

`GuardBandSize` — Widths of guard band

`[1 1]` (default) | nonnegative integer | 2-element vector of nonnegative integers

The number of rows and columns of the guard band cells on each side of the CUT cell, specified as nonnegative integers. The first element specifies the guard band size along the row dimension. The second element specifies the guard band size along the column dimension. Specifying this property as a single integer is equivalent to specifying a guard band with the same value for both dimensions. For example, a value of `[1 1]`, indicates that there is a one guard-cell-wide region surrounding each CUT cell. A value of zero indicates there are no guard cells.

Example: `[2 3]`

Data Types: `double`

`TrainingBandSize` — Widths of training band

`[1 1]` (default) | positive integer | 2-element vector of positive integers

The number of rows and columns of the training band cells on each side of the CUT cell, specified as a positive integer or a 1-by-2 matrix of positive integers. The first element specifies the training band size along the row dimension. The second element specifies the training band size along the column dimension. Specifying this property as a scalar is equivalent to specifying a training band with the same value for both dimensions. For example, a value of `[1 1]` indicates a 1 training-cell-wide region surrounding the CUT cell.

Example: `[-30:0.1:30]`

Data Types: `double`

`Rank` — Rank of order statistic

1 (default) | positive integer

Rank of the order statistic used in the 2-D CFAR algorithm, specified as a positive integer. The value of this property must lie between 1 and N_{train}, where N_{train} is the number of training cells. A value of 1 selects the smallest value in the training region.

Example: `5`

Dependencies

To enable this property, set the `Method` property to `'OS'`.

Data Types: `double`

`ThresholdFactor` — Threshold factor method

`'Auto'` (default) | `'Input port'` | `'Custom'`

Threshold factor method, specified as `'Auto'`, `'Input port'`, or `'Custom'`.

When you set the `ThresholdFactor` property to `'Auto'`, the threshold factor is calculated from the desired probability of false alarm set in the `ProbabilityFalseAlarm` property. The calculation assumes that each independent signal in the input is a single pulse coming out of a square law detector with no pulse integration. In addition, the noise is assumed to be white Gaussian.

When you set the `ThresholdFactor` property to `'Input port'`, the threshold factor is obtained from an input argument of the `step` method.

When you set the `ThresholdFactor` property to `'Custom'`, the threshold factor is obtained from the value of the `CustomThresholdFactor` property.

Example: `'Custom'`

Data Types: `char`

`ProbabilityFalseAlarm` — Required probability of false alarm

`0.1` (default) | positive scalar between 0 and 1

Required probability of false alarm, specified as a real positive scalar between 0 and 1. The algorithm calculates the threshold factor from the required probability of false alarm.

Example: `0.001`

Dependencies

To enable this property, set the `ThresholdFactor` property to `'Auto'`.

Data Types: `double`

`CustomThresholdFactor` — Custom threshold factor

`1` (default) | positive scalar

Custom threshold factor, specified as a real positive scalar. This property is tunable.

Dependencies

To enable this property, set the `ThresholdFactor` property to `'Custom'`.

Data Types: `double`

`OutputFormat` — Format of detection results

`'CUT result'` (default) | `'Detection index'`

Format of detection results returned by the step method, specified as `'CUT result'` or `'Detection index'`.

- When set to `'CUT result'`, the results are logical detection values (`1` or `0`) for each tested cell.
- When set to `'Detection index'`, the results form a vector or matrix containing the indices of tested cells that exceed a detection threshold. You can use this format as input to the phased.RangeEstimator and phased.DopplerEstimator System objects.

Data Types: `char`

`ThresholdOutputPort` — Enable detection threshold output

`false` (default) | `true`

Option to enable detection threshold output, specified as `false` or `true`. Setting this property to `true` returns the detection threshold via an output argument, `th`, of the `step` method.

Data Types: `logical`

`NoiseOutputPort` — Enable noise power output

`false` (default) | `true`

Option to enable output of noise power, specified as `false` or `true`. Setting this property to `true` returns the noise power via the output argument, `noise`, of the `step` method.

Data Types: `logical`

Methods

reset	Reset states of System object
step	Two-dimensional CFAR detection

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Set 2-D CFAR Threshold for Noise-Only Data

This example shows how to set a 2-D CFAR threshold based upon a required probability of false alarm (pfa).

Note: You can replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Perform cell-averaging CFAR detection on a 41-by-41 matrix of cells containing Gaussian noise. Estimate the empirical pfa and compare it to the required pfa. To get a good estimate, perform this simulation on 1000 similar matrices. First, set a threshold using the required pfa. In this case, there are no targets and the pfa can be estimated from the number of cells that exceed the threshold. Assume that the data is processed throught a square-law detector and that no pulse integration is performed. Use a training-cell band of 3 cells in width and 4 cells in height. Use a guard band of 3 cells in width and 2 cells in height to separate the cells under test (CUT) from the training cells. Specify a required pfa of 5.0e-4.

```
p = 5e-4;
rs = RandStream.create('mt19937ar','Seed',5);
N = 41;
ntrials = 1000;
detector = phased.CFARDetector2D('TrainingBandSize',[4,3], ...
    'ThresholdFactor','Auto','GuardBandSize',[2,3], ...
    'ProbabilityFalseAlarm',p,'Method','SOCA','ThresholdOutputPort',true);
```

Create a 41-by-41 image containing random complex data. Then, square the data to simulate a square-law detector.

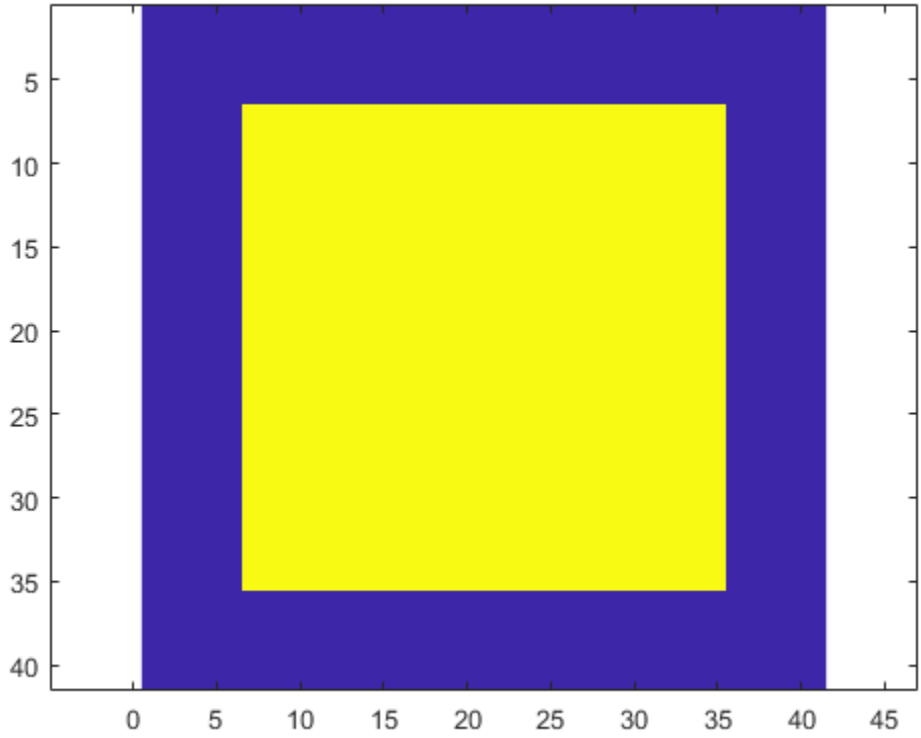
```
x = 2/sqrt(2)*(randn(rs,N,N,ntrials) + 1i*randn(rs,N,N,ntrials));
x2 = abs(x).^2;
```

Process all the cells in each image. To do this, find the row and column of each CUT cell whose training region falls entirely within each image.

```
Ngc = detector.GuardBandSize(2);
Ngr = detector.GuardBandSize(1);
Ntc = detector.TrainingBandSize(2);
Ntr = detector.TrainingBandSize(1);
cutidx = [];
colstart = Ntc + Ngc + 1;
colend = N - ( Ntc + Ngc);
rowstart = Ntr + Ngr + 1;
rowend = N - ( Ntr + Ngr);
for m = colstart:colend
    for n = rowstart:rowend
        cutidx = [cutidx,[n;m]];
    end
end
ncutcells = size(cutidx,2);
```

Display the CUT cells.

```
cutimage = zeros(N,N);
for k = 1:ncutcells
    cutimage(cutidx(1,k),cutidx(2,k)) = 1;
end
imagesc(cutimage)
axis equal
```



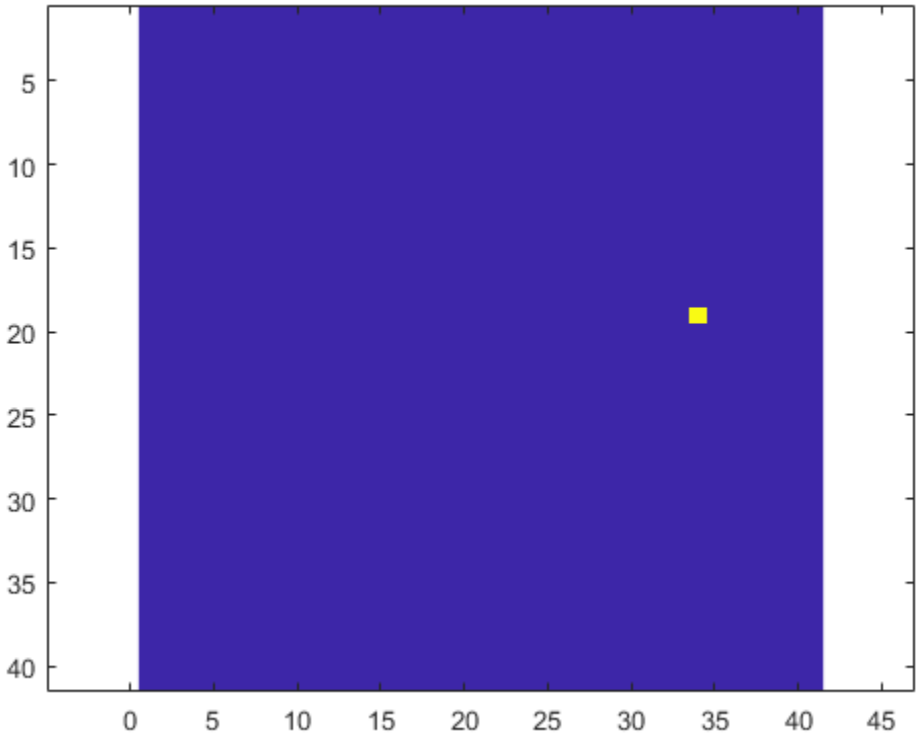
Perform the detection on all CUT cells. Return the detection classification and the threshold used to classify the cell.

```
[dets,th] = detector(x2,cutidx);
```

Find and display an image with a false alarm for illustration.

```
di = [];
for k = 1:ntrials
    d = dets(:,k);
    if (any(d) > 0)
        di = [di,k];
    end
end
```

```
idx = di(1);
detimg = zeros(N,N);
for k = 1:ncutcells
    detimg(cutidx(1,k),cutidx(2,k)) = dets(k,idx);
end
imagesc(detimg)
axis equal
```



Compute the empirical pfa.

```
pfa = sum(dets(:))/ntrials/ncutcells
```

```
pfa =
```

```
   4.5898e-04
```

The empirical and specified pfa agree.

Display the average empirical threshold value over all images.

```
mean(th(:))
```

```
ans =

   31.7139
```

Compute the theoretical threshold factor for the required pfa.

```
threshfactor = npwgnthresh(p,1,'noncoherent');
threshfactor = 10^(threshfactor/10);
disp(threshfactor)
```

```
    7.6009
```

The theoretical threshold factor multiplied by the noise variance should agree with the measured threshold.

```
noisevar = mean(x2(:));
disp(threshfactor*noisevar);
```

```
   30.4118
```

The theoretical threshold and empirical threshold agree to within an acceptable difference.

Detect Targets in Background Noise

Perform cell-averaging CFAR detection on a 41-by-41 matrix of cells containing five closely-spaced targets in Gaussian noise. Perform this detection on a simulation of 1000 images. Use two detectors with different guard band regions. Set the thresholds manually using the `Custom` threshold factor. Assume that the data is processed throught

a square law-detector and that no pulse integration is performed. Use a training cell band of 2 cells in width and 2 cells in height. For the first detector, use a guard band of 1 cell all around to separate the CUT cells from the training cells. For the second detector, use a guard band of 8 cells all around.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
p = 5e-4;
rs = RandStream.create('mt19937ar','Seed',5);
N = 41;
ntrials = 1000;
```

Create 1000 41-by-41 images of complex random noise with standard deviation of 1.

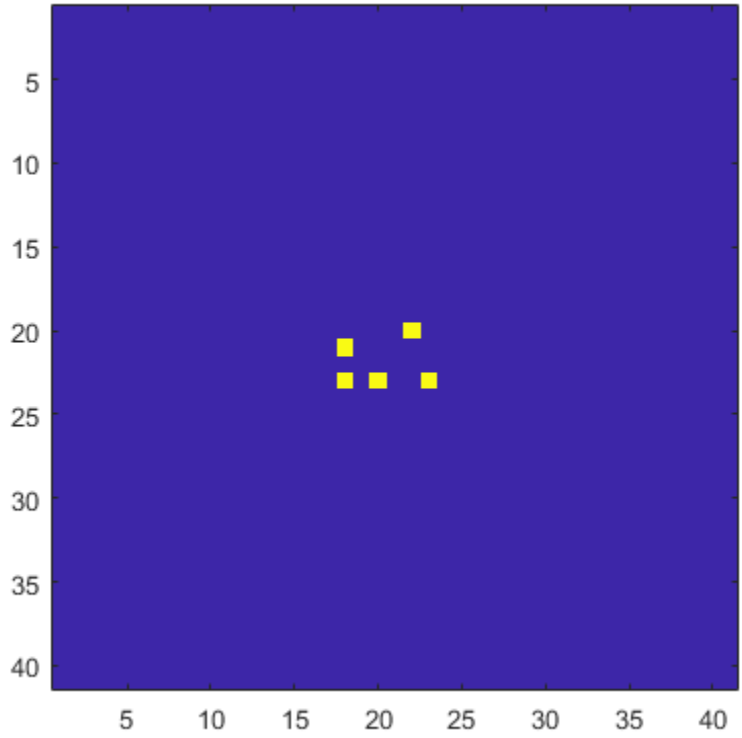
```
s = 1;
x = s/sqrt(2)*(randn(rs,N,N,ntrials) + 1i*randn(rs,N,N,ntrials));
```

Set the target cells values to 1.5. Then, square the cell values.

```
A = 1.5;
x(23,20,:) = A;
x(23,18,:) = A;
x(23,23,:) = A;
x(20,22,:) = A;
x(21,18,:) = A;
x2 = abs(x).^2;
```

Display the target cells.

```
xtgt = zeros(N,N);
xtgt(23,20,:) = A;
xtgt(23,18,:) = A;
xtgt(23,23,:) = A;
xtgt(20,22,:) = A;
xtgt(21,18,:) = A;
imagesc(xtgt)
axis equal
axis tight
```



Set the CUT cells to be the target cells.

```
cutidx(1,1) = 23;
cutidx(2,1) = 20;
cutidx(1,2) = 23;
cutidx(2,2) = 18;
cutidx(1,3) = 23;
cutidx(2,3) = 23;
cutidx(1,4) = 20;
cutidx(2,4) = 22;
cutidx(1,5) = 21;
cutidx(2,5) = 18;
```

Perform the detection on all CUT cells using two CFAR 2-D detectors. The first detector has a small guard band region. The training region can include neighboring targets which can affect the computation of the noise power. The second detector has a larger guard band region, which precludes target cells from being used in the noise computation.

Create the two CFAR detectors.

```
detector1 = phased.CFARDetector2D('TrainingBandSize',[2,2], ...
    'GuardBandSize',[1,1],'ThresholdFactor','Custom','Method','CA', ...
    'CustomThresholdFactor',2,'ThresholdOutputPort',true);
detector2 = phased.CFARDetector2D('TrainingBandSize',[2,2], ...
    'GuardBandSize',[8,8],'ThresholdFactor','Custom','Method','CA', ...
    'CustomThresholdFactor',2,'ThresholdOutputPort',true);
```

Return the detection classifications and the thresholds used to classify the cells. Then, compute the probabilities of detection.

```
[dets1,th1] = detector1(x2,cutidx);
ndets = numel(dets1(:));
pd1 = sum(dets1(:))/ndets
[dets2,th2] = detector2(x2,cutidx);
pd2 = sum(dets2(:))/ndets
```

```
pd1 =

    0.6416

pd2 =

    0.9396
```

The detector with the larger guard-band region has a higher pfa because the noise is more accurately estimated.

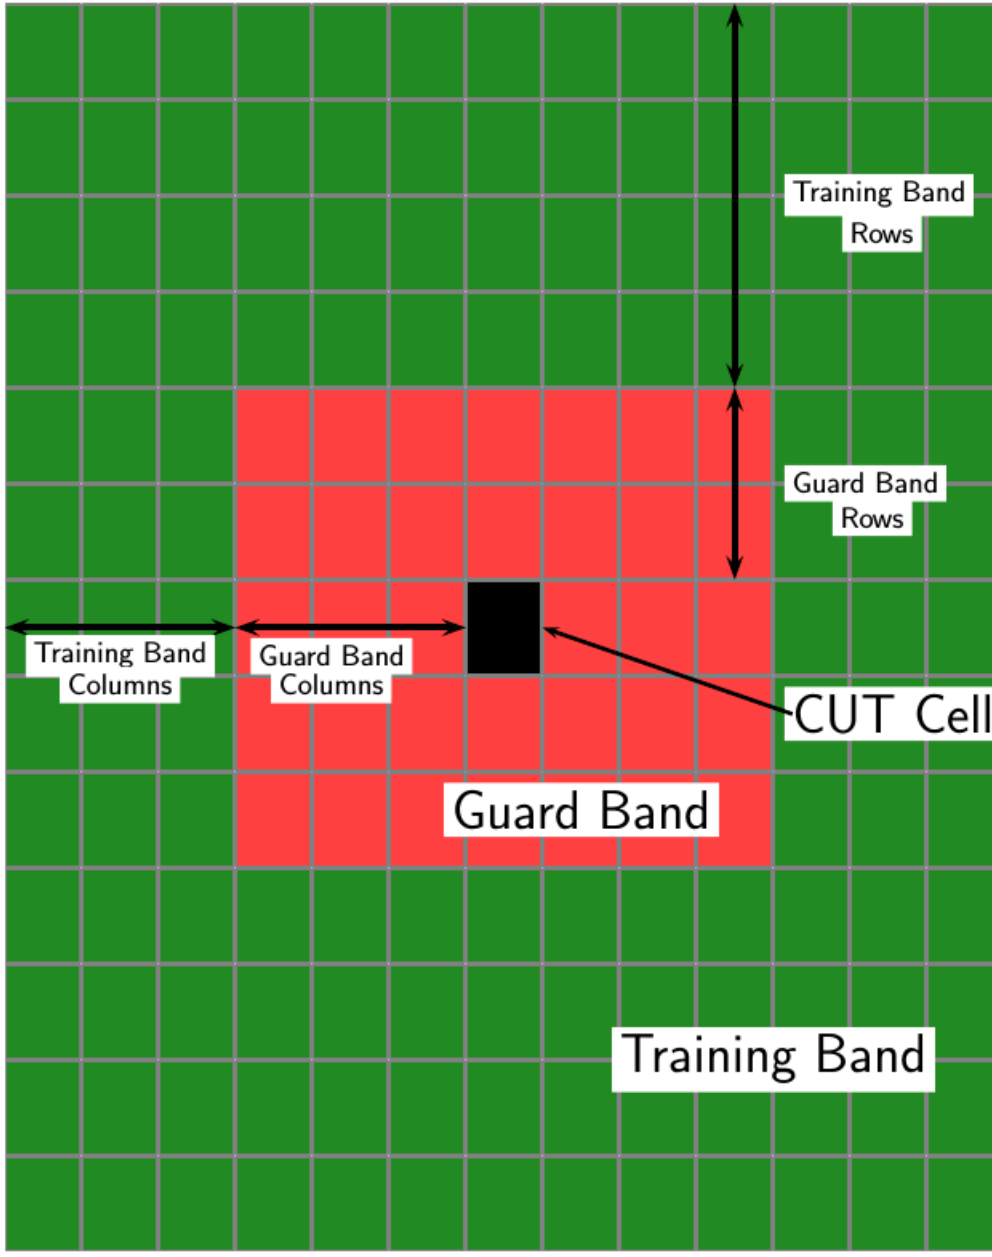
Definitions

Training Cells

CFAR 2-D requires an estimate of the noise power. Noise power is computed from cells that are assumed not to contain any target signal. These cells are the *training cells*. Training cells form a band around the cell-under-test (CUT) cell but may be separated from the CUT cell by a guard band. The detection threshold is computed by multiplying the noise power by the threshold factor.



Training Band
Rows
Guard Band
Rows
Training Band
Columns
Guard Band
Columns
CUT Cell
Guard Band
Training Band

For GOCA and SOCA averaging, the noise power is derived from the mean value of one of the left or right halves of the training cell region.

Because the number of columns in the training region is odd, the cells in the middle column are assigned equally to either the left or right half.

When using the order-statistic method, the rank cannot be larger than the number of cells in the training cell region, N_{train}. You can compute N_{train}.

- N_{TC} is the number of training band columns.
- N_{TR} is the number of training band rows.
- N_{GC} is the number of guard band columns.
- N_{GR} is the number of guard band rows.

The total number of cells in the combined training region, guard region, and CUT cell is $N_{total} = (2N_{TC} + 2N_{GC} + 1)(2N_{TR} + 2N_{GR} + 1)$.

The total number of cells in the combined guard region and CUT cell is $N_{guard} = (2N_{GC} + 1)(2N_{GR} + 1)$.

The number of training cells is $N_{train} = N_{total} - N_{guard}$.

By construction, the number of training cells is always even. Therefore, to implement a median filter, you can choose a rank of $N_{train}/2$ or $N_{train}/2 + 1$.

reset

System object: phased.CFARDetector2D
Package: phased

Reset states of System object

Syntax

```
reset(detector)
```

Description

`reset(detector)` resets the internal state of the `phased.CFARDetector2D`object, `detector`.

Input Arguments

`detector` — Two-dimensional CFAR detector

`phased.CFARDetector2D` System object

Two-dimensional CFAR detector, specified as a phased.CFARDetector2D System object.

Introduced in R2016b

step

System object: phased.CFARDetector2D
Package: phased

Two-dimensional CFAR detection

Syntax

```
Y = step(detector,X,cutidx)
Y = step(detector,X,cutidx,K)
[Y,th] = step( ___ )
[Y,noise] = step( ___ )
```

Description

Note: Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(detector,X,cutidx)` performs 2-D CFAR detection on input image data, `X`, for the image cells under test (CUT) specified by `cutidx`. `Y` contains the detection results for the CUT cells.

`Y = step(detector,X,cutidx,K)` also specifies a threshold factor, `K`, for setting the detection threshold. This syntax applies when the `ThresholdFactor` property of the detector is set to `'Input port'`.

`[Y,th] = step( ___ )` also returns the detection threshold, `th`, applied to detected cells under test. To enable this syntax, set the `ThresholdOutputPort` property to `true`.

`[Y,noise] = step( ___ )` also returns the estimated noise power, `noise`, applied to detected cells under test. To enable this syntax, set the `NoisePowerOutputPort` property to `true`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`detector` — Two-dimensional CFAR detector

`phased.CFARDetector2D` System object

Two-dimensional CFAR detector, specified as a phased.CFARDetector2D System object.

`X` — Input image

real *M*-by-*N* matrix | real *M*-by-*N*-by-*P* array

Input image, specified as a real *M*-by-*N* matrix or a real *M*-by-*N*-by-*P* array. *M* and *N* represent the rows and columns of a matrix. Each page is an independent 2-D signal.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Example: `[1,1;2.5,1;0.5,0.1]`

Data Types: `double`

`cutidx` — Test cells

2-by-*D* matrix of positive integers

Test cells, specified as a *2*-by-*D* matrix of positive integers, where *D* is the number of test cells. Each column of `cutidx` specifies the row and column indices of a CUT cell. The same indices apply to all pages in the input array. You must restrict the locations of CUT cells so that their training regions lie completely within the input images.

Example: `[10,15;11,15;12,15]`

Data Types: `double`

`K` — Detection threshold factor

positive scalar

Threshold factor used to calculate the detection threshold, specified as a positive scalar.

Dependencies

To enable this input argument, set the `ThresholdFactor` property of the detector object to `'Input port'`

Data Types: `double`

Output Arguments

`Y` — Detection results

L-by-*P* logical matrix

Detection results, whose format depends on the `OutputFormat` property

- When `OutputFormat` is `'Cut result'`, `Y` is a *D*-by-*P* matrix containing logical detection results for cells under test. *D* is the length of `cutidx` and *P* is the number of pages of `X`. The rows of `Y` correspond to the rows of `cutidx`. For each row, `Y` contains `1` in a column if there is a detection in the corresponding cell in `X`. Otherwise, `Y` contains a `0`.
- When `OutputFormat` is `'Detection report'`, `Y` is a *K*-by-*L* matrix containing detections indices. *K* is the number of dimensions of `X`. *L* is the number of detections found in the input data. When `X` is a matrix, `Y` contains the row and column indices of each detection in `X` in the form `[detrow;detcol]`. When `X` is an array, `Y` contains the row, column, and page indices of each detection in `X` in the form `[detrow;detcol;detpage]`. When the `NumDetectionsSource` property is set to `'Property'`, *L* equals the value of the `NumDetections` property. If the number of actual detections is less than this value, columns without detections are set to `NaN`.

Data Types: `double`

`th` — Computed detection threshold

real-valued matrix

Computed detection threshold for each detected cell, returned as a real-valued matrix. `Th` has the same dimensions as `Y`.

- When `OutputFormat` is `'CUT result'`, `Th` returns the detection threshold whenever an element of `Y` is `1` and `NaN` whenever an element of `Y` is `0`.
- When `OutputFormat` is `'Detection index'`, `th` returns a detection threshold for each corresponding detection in `Y`. When the `NumDetectionsSource` property is set

to `'Property'`, L equals the value of the `NumDetections` property. If the number of actual detections is less than this value, columns without detections are set to `NaN`.

Dependencies

To enable this output argument, set the `ThresholdOutputPort` to `true`.

Data Types: `double`

`noise` — Estimated noise power

real-valued matrix

Estimated noise power for each detected cell, returned as a real-valued matrix. `noise` has the same dimensions as `Y`.

- When `OutputFormat` is `'CUT result'`, `noise` returns the noise power whenever an element of `Y` is `1` and `NaN` whenever an element of `Y` is `0`.
- When `OutputFormat` is `'Detection index'`, `noise` returns a noise power for each corresponding detection in `Y`. When the `NumDetectionsSource` property is set to `'Property'`, L equals the value of the `NumDetections` property. If the number of actual detections is less than this value, columns without detections are set to `NaN`.

Dependencies

To enable this output argument, set the `NoisePowerOutputPort` to `true`.

Data Types: `double`

Examples

Set 2-D CFAR Threshold for Noise-Only Data

This example shows how to set a 2-D CFAR threshold based upon a required probability of false alarm (pfa).

Note: You can replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Perform cell-averaging CFAR detection on a 41-by-41 matrix of cells containing Gaussian noise. Estimate the empirical pfa and compare it to the required pfa. To get a good estimate, perform this simulation on 1000 similar matrices. First, set a threshold using the required pfa. In this case, there are no targets and the pfa can be estimated from the number of cells that exceed the threshold. Assume that the data is processed throught a square-law detector and that no pulse integration is performed. Use a training-cell band of 3 cells in width and 4 cells in height. Use a guard band of 3 cells in width and 2 cells in height to separate the cells under test (CUT) from the training cells. Specify a required pfa of 5.0e-4.

```
p = 5e-4;
rs = RandStream.create('mt19937ar','Seed',5);
N = 41;
ntrials = 1000;
detector = phased.CFARDetector2D('TrainingBandSize',[4,3], ...
    'ThresholdFactor','Auto','GuardBandSize',[2,3], ...
    'ProbabilityFalseAlarm',p,'Method','SOCA','ThresholdOutputPort',true);
```

Create a 41-by-41 image containing random complex data. Then, square the data to simulate a square-law detector.

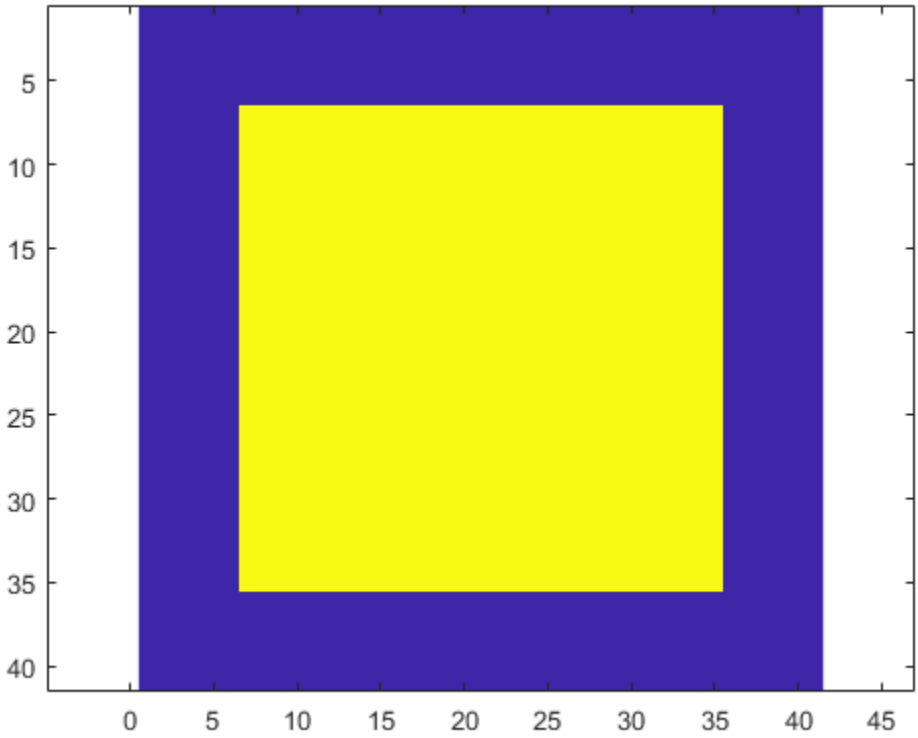
```
x = 2/sqrt(2)*(randn(rs,N,N,ntrials) + 1i*randn(rs,N,N,ntrials));
x2 = abs(x).^2;
```

Process all the cells in each image. To do this, find the row and column of each CUT cell whose training region falls entirely within each image.

```
Ngc = detector.GuardBandSize(2);
Ngr = detector.GuardBandSize(1);
Ntc = detector.TrainingBandSize(2);
Ntr = detector.TrainingBandSize(1);
cutidx = [];
colstart = Ntc + Ngc + 1;
colend = N - ( Ntc + Ngc);
rowstart = Ntr + Ngr + 1;
rowend = N - ( Ntr + Ngr);
for m = colstart:colend
    for n = rowstart:rowend
        cutidx = [cutidx,[n;m]];
    end
end
ncutcells = size(cutidx,2);
```

Display the CUT cells.

```
cutimage = zeros(N,N);
for k = 1:ncutcells
    cutimage(cutidx(1,k),cutidx(2,k)) = 1;
end
imagesc(cutimage)
axis equal
```

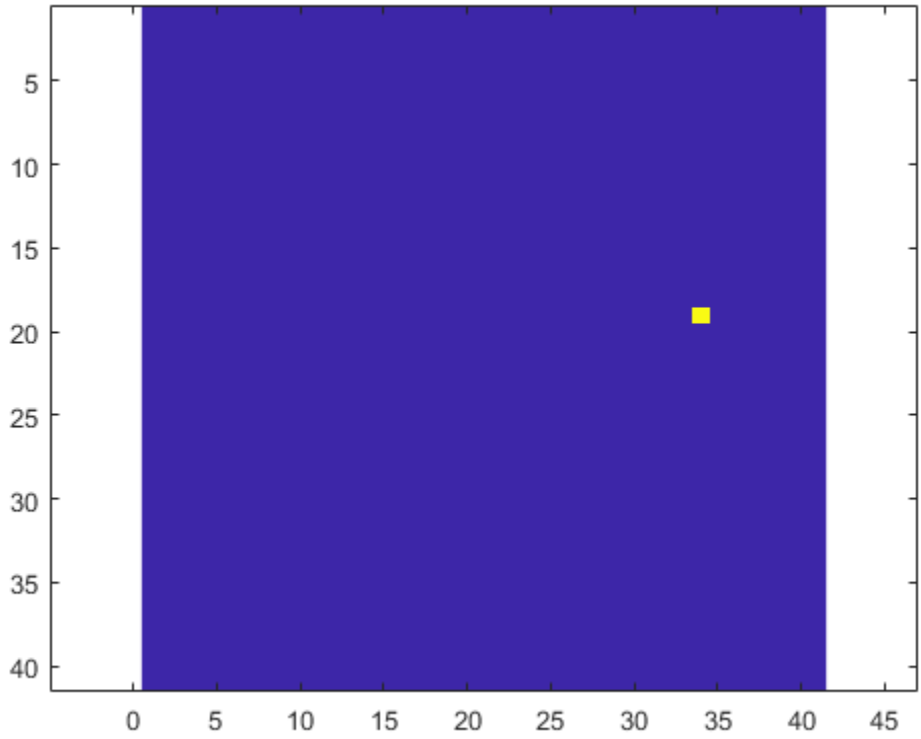


Perform the detection on all CUT cells. Return the detection classification and the threshold used to classify the cell.

```
[dets,th] = detector(x2,cutidx);
```

Find and display an image with a false alarm for illustration.

```
di = [];
for k = 1:ntrials
    d = dets(:,k);
    if (any(d) > 0)
        di = [di,k];
    end
end
idx = di(1);
detimg = zeros(N,N);
for k = 1:ncutcells
    detimg(cutidx(1,k),cutidx(2,k)) = dets(k,idx);
end
imagesc(detimg)
axis equal
```



Compute the empirical pfa.

```
pfa = sum(dets(:))/ntrials/ncutcells
```

```
pfa =

   4.5898e-04
```

The empirical and specified pfa agree.

Display the average empirical threshold value over all images.

```
mean(th(:))
```

```
ans =

   31.7139
```

Compute the theoretical threshold factor for the required pfa.

```
threshfactor = npwgnthresh(p,1,'noncoherent');
threshfactor = 10^(threshfactor/10);
disp(threshfactor)
```

```
    7.6009
```

The theoretical threshold factor multiplied by the noise variance should agree with the measured threshold.

```
noisevar = mean(x2(:));
disp(threshfactor*noisevar);
```

```
   30.4118
```

The theoretical threshold and empirical threshold agree to within an acceptable difference.

Detect Targets in Background Noise

Perform cell-averaging CFAR detection on a 41-by-41 matrix of cells containing five closely-spaced targets in Gaussian noise. Perform this detection on a simulation of

1000 images. Use two detectors with different guard band regions. Set the thresholds manually using the `Custom` threshold factor. Assume that the data is processed throught a square law-detector and that no pulse integration is performed. Use a training cell band of 2 cells in width and 2 cells in height. For the first detector, use a guard band of 1 cell all around to separate the CUT cells from the training cells. For the second detector, use a guard band of 8 cells all around.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
p = 5e-4;
rs = RandStream.create('mt19937ar','Seed',5);
N = 41;
ntrials = 1000;
```

Create 1000 41-by-41 images of complex random noise with standard deviation of 1.

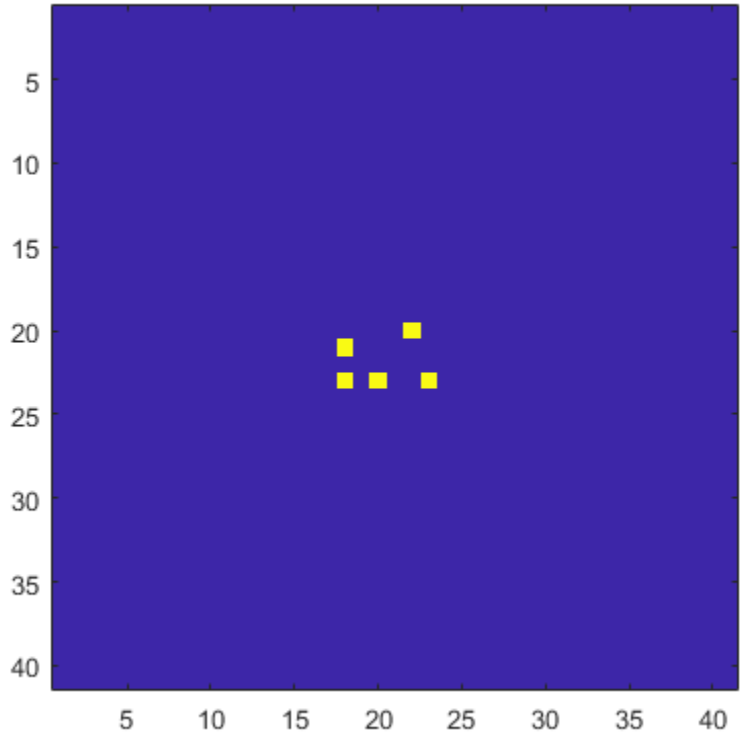
```
s = 1;
x = s/sqrt(2)*(randn(rs,N,N,ntrials) + 1i*randn(rs,N,N,ntrials));
```

Set the target cells values to 1.5. Then, square the cell values.

```
A = 1.5;
x(23,20,:) = A;
x(23,18,:) = A;
x(23,23,:) = A;
x(20,22,:) = A;
x(21,18,:) = A;
x2 = abs(x).^2;
```

Display the target cells.

```
xtgt = zeros(N,N);
xtgt(23,20,:) = A;
xtgt(23,18,:) = A;
xtgt(23,23,:) = A;
xtgt(20,22,:) = A;
xtgt(21,18,:) = A;
imagesc(xtgt)
axis equal
axis tight
```



Set the CUT cells to be the target cells.

```
cutidx(1,1) = 23;
cutidx(2,1) = 20;
cutidx(1,2) = 23;
cutidx(2,2) = 18;
cutidx(1,3) = 23;
cutidx(2,3) = 23;
cutidx(1,4) = 20;
cutidx(2,4) = 22;
cutidx(1,5) = 21;
cutidx(2,5) = 18;
```

Perform the detection on all CUT cells using two CFAR 2-D detectors. The first detector has a small guard band region. The training region can include neighboring targets which can affect the computation of the noise power. The second detector has a larger guard band region, which precludes target cells from being used in the noise computation.

Create the two CFAR detectors.

```
detector1 = phased.CFARDetector2D('TrainingBandSize',[2,2], ...
    'GuardBandSize',[1,1],'ThresholdFactor','Custom','Method','CA', ...
    'CustomThresholdFactor',2,'ThresholdOutputPort',true);
detector2 = phased.CFARDetector2D('TrainingBandSize',[2,2], ...
    'GuardBandSize',[8,8],'ThresholdFactor','Custom','Method','CA', ...
    'CustomThresholdFactor',2,'ThresholdOutputPort',true);
```

Return the detection classifications and the thresholds used to classify the cells. Then, compute the probabilities of detection.

```
[dets1,th1] = detector1(x2,cutidx);
ndets = numel(dets1(:));
pd1 = sum(dets1(:))/ndets
[dets2,th2] = detector2(x2,cutidx);
pd2 = sum(dets2(:))/ndets
```

```
pd1 =

    0.6416

pd2 =

    0.9396
```

The detector with the larger guard-band region has a higher pfa because the noise is more accurately estimated.

phased.CFARDetector.step

Introduced in R2016b

phased.Collector System object

Package: phased

Narrowband signal collector

Description

The `Collector` object implements a narrowband signal collector.

To compute the collected signal at the sensor(s):

1. Define and set up your signal collector. See "Construction" on page 1-184.
2. Call step to collect the signal according to the properties of `phased.Collector`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.Collector` creates a narrowband signal collector System object, `H`. The object collects incident narrowband signals from given directions using a sensor array or a single element.

`H = phased.Collector(Name,Value)` creates a collector object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`Sensor`

Sensor element or sensor array

Sensor element or sensor array specified as a System object in the Phased Array System Toolbox™. A sensor array can contain subarrays.

Antenna Toolbox™ antenna

Default: phased.ULA with default property values

`PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

Default: Speed of light

`OperatingFrequency`

System operating frequency

Specify the operating frequency of the system in hertz as a positive scalar. The default value corresponds to 300 MHz.

Default: `3e8`

`WeightsInputPort`

Enable weights input

To specify weights, set this property to `true` and use the corresponding input argument when you invoke step. If you do not want to specify weights, set this property to `false`.

Default: `false`

`EnablePolarization`

EnablePolarization

Set this property to `true` to simulate the collection of polarized waves. Set this property to `false` to ignore polarization. This property applies when the sensor specified in the `Sensor` property is capable of simulating polarization.

Default: `false`

`Wavefront`

Type of incoming wavefront

Specify the type of incoming wavefront as one of `'Plane'`, or `'Unspecified'`:

- If you set the `Wavefront` property to `'Plane'`, the input signals are multiple plane waves impinging on the entire array. Each plane wave is received by all collecting elements. If the `Sensor` property is an array that contains subarrays, the `Wavefront` property must be `'Plane'`.
- If you set the `Wavefront` property to `'Unspecified'`, the input signals are individual waves impinging on individual sensors.

Default: `'Plane'`

Methods

step	Collect signals

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Collect Wideband Signal at Single Antenna

Use the `phased.Collector` System object™ to construct a signal arriving at a single isotropic antenna from 10° azimuth and 30° elevation.

```
antenna = phased.IsotropicAntennaElement;
collector = phased.Collector('Sensor',antenna);
x = [1;0;-1];
```

```
incidentAngle = [10;30];
y = collector(x,incidentAngle)

y =

     1
     0
    -1
```

Collect Signal at Uniform Linear Array

Collect a far-field signal arriving at a 3-element uniform linear array (ULA) of isotropic antenna elements.

```
antenna = phased.ULA('NumElements',3);
collector = phased.Collector('Sensor',antenna,'OperatingFrequency',1e9);
x = [1;0;-1];
incidentAngle = [10 30]';
y = collector(x,incidentAngle)

y =

  -0.0051 - 1.0000i   1.0000 + 0.0000i  -0.0051 + 1.0000i
   0.0000 + 0.0000i   0.0000 + 0.0000i   0.0000 + 0.0000i
   0.0051 + 1.0000i  -1.0000 + 0.0000i   0.0051 - 1.0000i
```

Collect Different Signals at Array Elements

Collect different signals at a three-element array. Each input signal comes from a different direction.

```
array = phased.ULA('NumElements',3);
collector = phased.Collector('Sensor',array,'OperatingFrequency',1e9,...
    'Wavefront','Unspecified');
```

Each column is a signal for one element

```
x = rand(10,3)

x =
```

```
    0.8147    0.1576    0.6557
    0.9058    0.9706    0.0357
    0.1270    0.9572    0.8491
    0.9134    0.4854    0.9340
    0.6324    0.8003    0.6787
    0.0975    0.1419    0.7577
    0.2785    0.4218    0.7431
    0.5469    0.9157    0.3922
    0.9575    0.7922    0.6555
    0.9649    0.9595    0.1712
```

Specify three incident angles.

```
incidentAngles = [10 0; 20 5; 45 2]';
y = collector(x,incidentAngles)
```

```
y =

    0.8147    0.1576    0.6557
    0.9058    0.9706    0.0357
    0.1270    0.9572    0.8491
    0.9134    0.4854    0.9340
    0.6324    0.8003    0.6787
    0.0975    0.1419    0.7577
    0.2785    0.4218    0.7431
    0.5469    0.9157    0.3922
    0.9575    0.7922    0.6555
    0.9649    0.9595    0.1712
```

Algorithms

If the `Wavefront` property value is `'Plane'`, `phased.Collector` collects each plane wave signal using the phase approximation of the time delays across collecting elements in the far field.

If the `Wavefront` property value is `'Unspecified'`, `phased.Collector` collects each channel independently.

For further details, see [1].

phased.WidebandCollector

Introduced in R2012a

step

System object: phased.Collector
Package: phased

Collect signals

Syntax

```
Y = step(H,X,ANG)
Y = step(H,X,ANG,LAXES)
Y = step(H,X,ANG,WEIGHTS)
Y = step(H,X,ANG,STEERANGLE)
Y = step(H,X,ANG,LAXES,WEIGHTS,STEERANGLE)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X,ANG)` collects signals `X` arriving from directions `ANG`. The collection process depends on the `Wavefront` property of `H`, as follows:

- If `Wavefront` has the value `'Plane'`, each collecting element collects all the far field signals in `X`. Each column of `Y` contains the output of the corresponding element in response to all the signals in `X`.
- If `Wavefront` has the value `'Unspecified'`, each collecting element collects only one impinging signal from `X`. Each column of `Y` contains the output of the corresponding element in response to the corresponding column of `X`. The `'Unspecified'` option is available when the `Sensor` property of `H` does not contain subarrays.

`Y = step(H,X,ANG,LAXES)` uses `LAXES` as the local coordinate system axes directions. This syntax is available when you set the `EnablePolarization` property to `true`.

`Y = step(H,X,ANG,WEIGHTS)` uses `WEIGHTS` as the weight vector. This syntax is available when you set the `WeightsInputPort` property to `true`.

`Y = step(H,X,ANG,STEERANGLE)` uses `STEERANGLE` as the subarray steering angle. This syntax is available when you configure `H` so that `H.Sensor` is an array that contains subarrays and `H.Sensor.SubarraySteering` is either `'Phase'` or `'Time'`.

`Y = step(H,X,ANG,LAXES,WEIGHTS,STEERANGLE)` combines all input arguments. This syntax is available when you configure `H` so that `H.WeightsInputPort` is `true`, `H.Sensor` is an array that contains subarrays, and `H.Sensor.SubarraySteering` is either `'Phase'` or `'Time'`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`H`

Collector object.

`X`

Arriving signals. Each column of `X` represents a separate signal. The specific interpretation of `X` depends on the `Wavefront` property of `H`.

Wavefront Property Value	Description
`'Plane'`	Each column of `X` is a far field signal.
`'Unspecified'`	Each column of `X` is the signal impinging on the corresponding element. In this case, the number of columns in `X` must equal the number of collecting elements in the `Sensor` property.

- If the `EnablePolarization` property value is set to `false`, `X` is a matrix. The number of columns of the matrix equals the number of separate signals.

  The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.
- If the `EnablePolarization` property value is set to `true`, `X` is a row vector of MATLAB `struct` type. The dimension of the `struct` array equals the number of separate signals. Each `struct` member contains three column-vector fields, `X`, `Y`, and `Z`, representing the *x*, *y*, and *z* components of the polarized wave vector signals in the global coordinate system.

  The size of the first dimension of the matrix fields within the `struct` can vary to simulate a changing signal length such as a pulse waveform with variable pulse repetition frequency.

ANG

Incident directions of signals, specified as a two-row matrix. Each column specifies the incident direction of the corresponding column of `X`. Each column of `ANG` has the form [azimuth; elevation], in degrees. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

LAXES

Local coordinate system. `LAXES` is a 3-by-3 matrix whose columns specify the local coordinate system's orthonormal *x*, *y*, and *z* axes, respectively. Each axis is specified in terms of `[x;y;z]` with respect to the global coordinate system. This argument is only used when the `EnablePolarization` property is set to `true`.

WEIGHTS

Vector of weights. `WEIGHTS` is a column vector of length M, where M is the number of collecting elements.

Default: `ones(M,1)`

STEERANGLE

Subarray steering angle, specified as a length-2 column vector. The vector has the form [azimuth; elevation], in degrees. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

Output Arguments

Y

Collected signals. Each column of `Y` contains the output of the corresponding element. The output is the response to all the signals in `X`, or one signal in `X`, depending on the `Wavefront` property of `H`.

Examples

Collect Plane Wave at ULA

Construct a 4-element uniform linear array (ULA). The array operating frequency is 1 GHz. The array element spacing is one half the corresponding wavelength. Model the collection of a 200 Hz sinusoid from the far field incident on the array at 45° azimuth and 10° elevation.

Create the array.

```
fc = 1e9;
lambda = physconst('LightSpeed')/fc;
array = phased.ULA('NumElements',4,'ElementSpacing',lambda/2);
```

Create the sinusoid signal.

```
t = linspace(0,1,1e3);
x = cos(2*pi*200*t)';
```

Construct the collector object and obtain the received signal.

```
collector = phased.Collector('Sensor',array, ...
    'PropagationSpeed',physconst('LightSpeed'),'Wavefront','Plane', ...
    'OperatingFrequency',fc);
incidentangle = [45;10];
receivedsig = collector(x,incidentangle);
```

Algorithms

If the `Wavefront` property value is `'Plane'`, `phased.Collector` collects each plane wave signal using the phase approximation of the time delays across collecting elements in the far field.

If the `Wavefront` property value is `'Unspecified'`, `phased.Collector` collects each channel independently.

For further details, see [1].

phased.ConformalArray System object

Package: phased

Conformal array

Description

The `ConformalArray` object constructs a conformal array. A conformal array can have elements in any position pointing in any direction.

To compute the response for each element in the array for specified directions:

1. Define and set up your conformal array. See "Construction" on page 1-195.
2. Call step to compute the response according to the properties of `phased.ConformalArray`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.ConformalArray` creates a conformal array System object, `H`. The object models a conformal array formed with identical sensor elements.

`H = phased.ConformalArray(Name,Value)` creates object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

`H = phased.ConformalArray(POS,NV,Name,Value)` creates a conformal array object, `H`, with the `ElementPosition` property set to `POS`, the `ElementNormal` property set to `NV`, and other specified property Names set to the specified Values. `POS` and `NV`

are value-only arguments. When specifying a value-only argument, specify all preceding value-only arguments. You can specify name-value arguments in any order.

Properties

`Element`

Element of array

Specify the element of the sensor array as a handle. The element must be an element object in the `phased` package.

Default: Isotropic antenna element with default properties

`ElementPosition`

Element positions

`ElementPosition` specifies the positions of the elements in the conformal array. `ElementPosition` must be a 3-by-N matrix, where N indicates the number of elements in the conformal array. Each column of `ElementPosition` represents the position, in the form `[x; y; z]` (in meters), of a single element in the local coordinate system of the array. The local coordinate system has its origin at an arbitrary point. The default value of this property represents a single element at the origin of the local coordinate system.

Default: `[0; 0; 0]`

`ElementNormal`

Element normal directions

`ElementNormal` specifies the normal directions of the elements in the conformal array. Angle units are degrees. The value assigned to `ElementNormal` must be either a 2-by-N matrix or a 2-by-1 column vector. The variable N indicates the number of elements in the array. If the value of `ElementNormal` is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]` with respect to the local coordinate system. The local coordinate system aligns the positive x-axis with the direction normal to the conformal array. If the value of `ElementNormal` is a 2-by-1 column vector, it specifies the same pointing direction for all elements in the array.

You can use the `ElementPosition` and `ElementNormal` properties to represent any arrangement in which pairs of elements differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal.

Default: `[0; 0]`

`Taper`

Element taper or weighting

Element tapering or weighting, specified as a complex-valued scalar, 1-by-*N* row vector, or *N*-by-1 column vector. Weights are applied to each element in the sensor array. *N* is the number of elements along in the array as determined by the size of the `ElementPosition` property. If the `Taper` parameter is a scalar, the same taper value is applied to all elements. If the value of `Taper` is a vector, each taper values is applied to the corresponding element.

Default: 1

Methods

directivity	Directivity of conformal array
collectPlaneWave	Simulate received plane waves
getElementNormal	Normal vector to array elements
getElementPosition	Positions of array elements
getNumElements	Number of elements in array
getTaper	Array element tapers
isPolarizationCapable	Polarization capability
pattern	Plot conformal array pattern
patternAzimuth	Plot conformal array directivity or pattern versus azimuth
patternElevation	Plot conformal array array directivity or pattern versus elevation
plotResponse	Plot response pattern of array

step	Output responses of array elements
viewArray	View array geometry

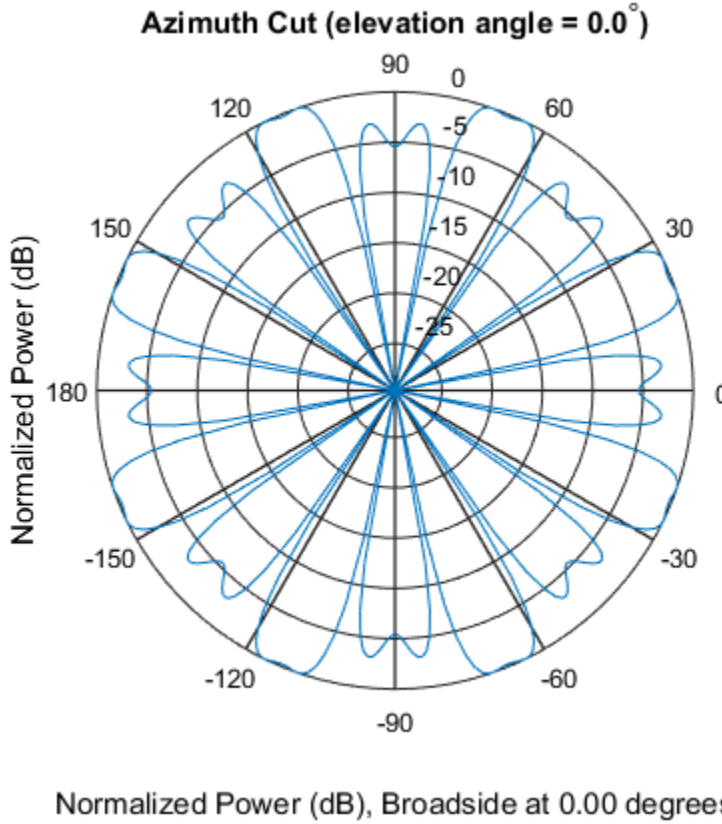
Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Plot Power Pattern of 8-Element Uniform Circular Array

Using the ConformalArray System object, construct an 8-element uniform circular array (UCA) of isotropic antenna elements. Plot a normalized azimuth power pattern at 0 degrees elevation. Assume the operating frequency is 1 GHz and the wave propagation speed is the speed of light.

```
N = 8;
azang = (0:N-1)*360/N-180;
sCA = phased.ConformalArray(...
    'ElementPosition',[cosd(azang);sind(azang);zeros(1,N)],...
    'ElementNormal',[azang;zeros(1,N)]);
fc = 1e9;
c = physconst('LightSpeed');
pattern(sCA,fc,[-180:180],0,...
    'PropagationSpeed',c,'Type','powerdb',...
    'CoordinateSystem','polar')
```



Plot Pattern of 31-Element Uniform Circular Sonar Array

Construct a 31-element acoustic uniform circular sonar array (UCA) using the ConformalArray System object. Assume the array is one meter in diameter. Using the `ElevationAngles` parameter, restrict the display to +/-40 degrees in 0.1 degree increments. Assume the operating frequency is 4 kHz. A typical value for the speed of sound in seawater is 1500.0 m/s.

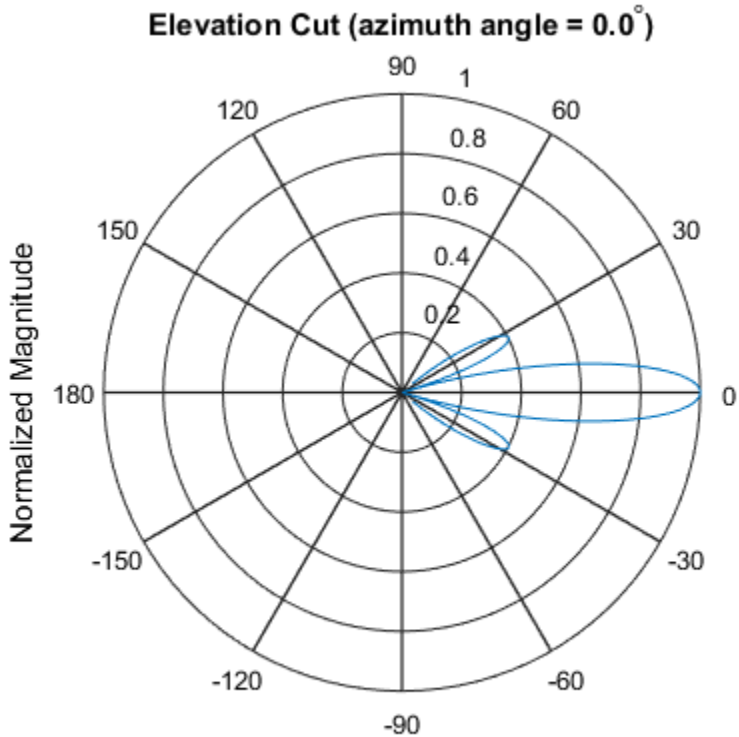
Construct the array

```
N = 31;
theta = (0:N-1)*360/N-180;
Radius = 0.5;
sMic = phased.OmnidirectionalMicrophoneElement(...
```

```
    'FrequencyRange',[0,10000],'BackBaffled',true);
sArray = phased.ConformalArray('Element',sMic,...
    'ElementPosition',Radius*[zeros(1,N);cosd(theta);sind(theta)],...
    'ElementNormal',[ones(1,N);zeros(1,N)]);
```

Plot the magnitude pattern

```
fc = 4000;
c = 1500.0;
pattern(sArray,fc,0,[-40:0.1:40],...
    'PropagationSpeed',c,...
    'CoordinateSystem','polar',...
    'Type','efield')
```



Normalized Magnitude, Broadside at 0.00 degrees

Plot the directivity pattern

```
pattern(sArray,fc,0,[-40:0.1:40],...
    'PropagationSpeed',c,...
    'CoordinateSystem','polar',...
    'Type','directivity')
```

directivity

System object: phased.ConformalArray
Package: phased

Directivity of conformal array

Syntax

```
D = directivity(H,FREQ,ANGLE)
D = directivity(H,FREQ,ANGLE,Name,Value)
```

Description

`D = directivity(H,FREQ,ANGLE)` computes the "Directivity" on page 1-207 of a conformal array of antenna or microphone elements, `H`, at frequencies specified by the `FREQ` and in angles of direction specified by the `ANGLE`.

`D = directivity(H,FREQ,ANGLE,Name,Value)` computes the directivity with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`H` — Conformal array

System object

Conformal array specified as a phased.ConformalArray System object.

Example: `H = phased.ConformalArray;`

`FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-L real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-L real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `-Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `-Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

`ANGLE` — Angles for computing directivity

1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Angles for computing directivity, specified as a 1-by-*M* real-valued row vector or a 2-by-*M* real-valued matrix, where *M* is the number of angular directions. Angle units are in degrees. If `ANGLE` is a 2-by-*M* matrix, then each column specifies a direction in azimuth and elevation, `[az;el]`. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°.

If `ANGLE` is a 1-by-*M* vector, then each entry represents an azimuth angle, with the elevation angle assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis.

Example: `[45 60; 0 10]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'PropagationSpeed'` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

`'Weights'` — Array weights

1 (default) | *N*-by-1 complex-valued column vector | *N*-by-*L* complex-valued matrix

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *N*-by-1 complex-valued column vector or *N*-by-*L* complex-valued matrix. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *N* is the number of elements in the array. The dimension *L* is the number of frequencies specified by `FREQ`.

Weights Dimension	FREQ Dimension	Purpose
N-by-1 complex-valued column vector	Scalar or 1-by-*L* row vector	Applies a set of weights for the single frequency or for all *L* frequencies.
N-by-*L* complex-valued matrix	1-by-*L* row vector	Applies each of the *L* columns of `'Weights'` for the corresponding frequency in `FREQ`.

Note: Use complex weights to steer the array response toward different directions. You can create weights using the phased.SteeringVector System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as phased.Radiator or phased.Collector. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(N,M)`

Data Types: `double`

Complex Number Support: Yes

Output Arguments

D — Directivity

M-by-*L* matrix

Directivity, returned as an *M*-by-*L* matrix whose columns contain the directivities at the *M* angles specified by `ANGLE`. Each column corresponds to one of the *L* frequency values specified in `FREQ`. Directivity units are in dBi.

Examples

Directivity of Conformal Array

Compute the directivity of a circular array constructed using a conformal array System object™.

Construct a 21-element uniform circular sonar array (UCA) of backbaffled omnidirectional microphones. The array is one meter in diameter. Set the operating frequency to 4 kHz. A typical value for the speed of sound in seawater is 1500.0 m/s.

```
N = 21;
theta = (0:N-1)*360/N-180;
Radius = 0.5;
myMic = phased.OmnidirectionalMicrophoneElement;
myMicFrequencyRange = [0,5000];
myMic.BackBaffled = true;
myArray = phased.ConformalArray;
myArray.Element = myMic;
myArray.ElementPosition = Radius*[zeros(1,N);cosd(theta);sind(theta)];
myArray.ElementNormal = [ones(1,N);zeros(1,N)];
c = 1500.0;
fc = 4000;
```

Steer the array to 30 degrees in azimuth and compute the directivity in the steering direction.

```
lambda = c/fc;
ang = [30;0];
```

```
w = steervec(getElementPosition(myArray)/lambda,ang);
d = directivity(myArray,fc,ang,...
    'PropagationSpeed',c,...
    'Weights',w)

d =

   15.1633
```

Definitions

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element directivity” and “Array directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular

mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

collectPlaneWave

System object: phased.ConformalArray
Package: phased

Simulate received plane waves

Syntax

```
Y = collectPlaneWave(H,X,ANG)
Y = collectPlaneWave(H,X,ANG,FREQ)
Y = collectPlaneWave(H,X,ANG,FREQ,C)
```

Description

`Y = collectPlaneWave(H,X,ANG)` returns the received signals at the sensor array, `H`, when the input signals indicated by `X` arrive at the array from the directions specified in `ANG`.

`Y = collectPlaneWave(H,X,ANG,FREQ)`, in addition, specifies the incoming signal carrier frequency in `FREQ`.

`Y = collectPlaneWave(H,X,ANG,FREQ,C)`, in addition, specifies the signal propagation speed in `C`.

Input Arguments

`H`

Array object.

`X`

Incoming signals, specified as an M-column matrix. Each column of `X` represents an individual incoming signal.

ANG

Directions from which incoming signals arrive, in degrees. ANG can be either a 2-by-M matrix or a row vector of length M.

If ANG is a 2-by-M matrix, each column specifies the direction of arrival of the corresponding signal in X. Each column of ANG is in the form `[azimuth; elevation]`. The azimuth angle must be between –180° and 180°, inclusive. The elevation angle must be between –90° and 90°, inclusive.

If ANG is a row vector of length M, each entry in ANG specifies the azimuth angle. In this case, the corresponding elevation angle is assumed to be 0°.

FREQ

Carrier frequency of signal in hertz. FREQ must be a scalar.

Default: `3e8`

C

Propagation speed of signal in meters per second.

Default: Speed of light

Output Arguments

Y

Received signals. Y is an N-column matrix, where N is the number of elements in the array H. Each column of Y is the received signal at the corresponding array element, with all incoming signals combined.

Examples

Simulate Received Signals at Conformal Array

Simulate two received signals at an 8-element uniform circular array. The signals arrive from 10° and 30° azimuth, respectively. Both signals have an elevation angle of 0°.

Assume the propagation speed is the speed of light and the carrier frequency of the signal is 100 MHz.

```
N = 8;
azang = (0:N-1)*360/N-180;
array = phased.ConformalArray('ElementPosition', ...
    [cosd(azang);sind(azang);zeros(1,N)],'ElementNormal',[azang;zeros(1,N)]);
y = collectPlaneWave(array,randn(4,2),[10 30],100e6);
```

Algorithms

`collectPlaneWave` modulates the input signal with a phase corresponding to the delay caused by the direction of arrival. The method does not account for the response of individual elements in the array.

For further details, see [1].

getElementNormal

System object: phased.ConformalArray
Package: phased

Normal vector to array elements

Syntax

```
normvec = getElementNormal(sConfArray)
normvec = getElementNormal(sConfArray,elemidx)
```

Description

`normvec = getElementNormal(sConfArray)` returns the normal vectors of the array elements of the `phased.sConfArray` System object, `sConfArray`. The output argument `normvec` is a 2-by-*N* matrix, where *N* is the number of elements in array, `sConfArray`. Each column of `normvec` defines the normal direction of an element in the local coordinate system in the form `[az;el]`. Units are degrees. The origin of the local coordinate system is defined by the phase center of the array.

`normvec = getElementNormal(sConfArray,elemidx)` returns only the normal vectors of the elements specified in the element index vector, `elemidx`. This syntax can use any of the input arguments in the previous syntax.

Input Arguments

`sConfArray` — Conformal array

`phased.ConformalArray` System object

Conformal array, specified as a `phased.ConformalArray` System object.

Example: `phased.ConformalArray`

`elemidx` — Element indices

all array elements (default) | integer-valued 1-by-*M* row vector | integer-valued *M*-by-1 column vector

Element indices , specified as a 1-by-*M* or *M*-by-1 vector. Index values lie in the range 1 to *N* where *N* is the number of elements of the array. When `elemidx` is specified, `getElementNormal` returns the normal vectors of the elements contained in `elemidx`.

Example: `[1,5,4]`

Output Arguments

`normvec` — Element normal vectors

2-by-*P* real-valued vector

Element normal vectors, specified as a 2-by-*P* real-valued vector. Each column of `normvec` takes the form `[az,el]`. When `elemidx` is not specified, *P* equals the array dimension. When `elemidx` is specified, *P* equals the length of `elemidx`, *M*.

Examples

Conformal Array Element Normals

Construct a 5-element acoustic cross array (UCA) using the ConformalArray System object. Assume the operating frequency is 4 kHz. A typical value for the speed of sound in seawater is 1500.0 m/s. Display the array normal vectors.

```
N = 5;
fc = 4000;
c = 1500.0;
lam = c/fc;
x = zeros(1,N);
y = [-1,0,1,0,0]*lam/2;
z = [0,0,0,-1,1]*lam/2;
sMic = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[0,10000],'BackBaffled',true);
sConformArray = phased.ConformalArray('Element',sMic,...
    'ElementPosition',[x;y;z],...
    'ElementNormal',[45*ones(1,N);zeros(1,N)]);
pos = getElementPosition(sConformArray)
normvec = getElementNormal(sConformArray)
```

```
pos =
```

```
         0         0         0         0         0
   -0.1875         0    0.1875         0         0
         0         0         0   -0.1875    0.1875

normvec =

    45    45    45    45    45
     0     0     0     0     0
```

Introduced in R2016a

getElementPosition

System object: phased.ConformalArray
Package: phased

Positions of array elements

Syntax

```
POS = getElementPosition(H)
POS = getElementPosition(H,ELEIDX)
```

Description

`POS = getElementPosition(H)` returns the element positions of the conformal array `H`. `POS` is an 3xN matrix where N is the number of elements in `H`. Each column of `POS` defines the position of an element in the local coordinate system, in meters, using the form [x; y; z].

For details regarding the local coordinate system of the conformal array, enter `phased.ConformalArray.coordinateSystemInfo`.

`POS = getElementPosition(H,ELEIDX)` returns the positions of the elements that are specified in the element index vector `ELEIDX`.

Examples

Element Positions of Conformal Array

Construct a three-element conformal array and obtain the element positions.

```
array = phased.ConformalArray('ElementPosition',[-1,0,1;0,0,0;0,0,0]);
pos = getElementPosition(array)
```

```
pos =
```

```
-1     0     1
 0     0     0
 0     0     0
```

getNumElements

System object: phased.ConformalArray
Package: phased

Number of elements in array

Syntax

```
N = getNumElements(H)
```

Description

`N = getNumElements(H)` returns the number of elements, N, in the conformal array object `H`.

Examples

Number of Elements of Conformal Array

Construct a three-element conformal array and obtain the number of elements.

```
array = phased.ConformalArray('ElementPosition',[-1,0,1;0,0,0;0,0,0]);
N = getNumElements(array)
```

```
N =

     3
```

getTaper

System object: phased.ConformalArray
Package: phased

Array element tapers

Syntax

```
wts = getTaper(h)
```

Description

`wts = getTaper(h)` returns the tapers applied to each element of a conformal array, `h`. Tapers are often referred to as weights.

Input Arguments

h — Conformal array

`phased.ConformalArray` System object

Conformal array specified as a phased.ConformalArray System object.

Output Arguments

wts — Array element tapers

N-by-1 complex-valued vector

Array element tapers returned as an *N*-by-1, complex-valued vector, where *N* is the number of elements in the array.

Examples

Create and View a Tapered Array

Create a two-ring tapered disk array

Create a two-ring disk array and set the taper values on the outer ring to be smaller than those on the inner ring.

```
elemAngles = ([0:5]*360/6);
elemPosInner = 0.5*[zeros(size(elemAngles));...
    cosd(elemAngles);...
    sind(elemAngles)];
elemPosOuter = [zeros(size(elemAngles));...
    cosd(elemAngles);...
    sind(elemAngles)];
elemNorms = repmat([0;0],1,12);
taper =  [ones(size(elemAngles)),0.3*ones(size(elemAngles))];
ha = phased.ConformalArray(...
    [elemPosInner,elemPosOuter],elemNorms,'Taper',taper);
```

Display the taper values

```
w = getTaper(ha)
```

```
w =

isPolarizationCapable

System object: phased.ConformalArray
Package: phased

Polarization capability

Syntax

```
flag = isPolarizationCapable(h)
```

Description

`flag = isPolarizationCapable(h)` returns a Boolean value, `flag`, indicating whether the array supports polarization. An array supports polarization if all of its constituent sensor elements support polarization.

Input Arguments

`h` — Conformal array

Conformal array specified as a phased.ConformalArray System object.

Output Arguments

`flag` — Polarization-capability flag

Polarization-capability returned as a Boolean value `true` if the array supports polarization or `false` if it does not.

Examples

Conformal Array of Short-Dipole Antennas Supports Polarization

Show that a circular conformal array of `phased.ShortDipoleAntennaElement` antenna elements supports polarization.

```
N = 8;
azang = (0:N-1)*360/N-180;
antenna = phased.ShortDipoleAntennaElement;
array = phased.ConformalArray(...
    'Element',antenna,'ElementPosition',[cosd(azang);sind(azang);zeros(1,N)],...
    'ElementNormal',[azang;zeros(1,N)]);
isPolarizationCapable(array)
```

```
ans =

  logical

   1
```

The returned value 1 shows that this array supports polarization.

pattern

System object: phased.ConformalArray
Package: phased

Plot conformal array pattern

Syntax

```
pattern(sArray,FREQ)
pattern(sArray,FREQ,AZ)
pattern(sArray,FREQ,AZ,EL)
pattern( ___ ,Name,Value)
[PAT,AZ_ANG,EL_ANG] = pattern( ___ )
```

Description

`pattern(sArray,FREQ)` plots the 3-D array directivity pattern (in dBi) for the array specified in `sArray`. The operating frequency is specified in `FREQ`.

`pattern(sArray,FREQ,AZ)` plots the array directivity pattern at the specified azimuth angle.

`pattern(sArray,FREQ,AZ,EL)` plots the array directivity pattern at specified azimuth and elevation angles.

`pattern( ___ ,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`[PAT,AZ_ANG,EL_ANG] = pattern( ___ )` returns the array pattern in `PAT`. The `AZ_ANG` output contains the coordinate values corresponding to the rows of `PAT`. The `EL_ANG` output contains the coordinate values corresponding to the columns of `PAT`. If the `'CoordinateSystem'` parameter is set to `'uv'`, then `AZ_ANG` contains the *U* coordinates of the pattern and `EL_ANG` contains the *V* coordinates of the pattern. Otherwise, they are in angular units in degrees. *UV* units are dimensionless.

Note: This method replaces the `plotResponse` method. See "Convert plotResponse to pattern" on page 1-234 for guidelines on how to use `pattern` in place of `plotResponse`.

Input Arguments

`sArray` — Conformal array

System object

Conformal array, specified as a phased.ConformalArray System object.

Example: `sArray= phased.ConformalArray;`

`FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `-Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `-Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

`AZ` — Azimuth angles

`[-180:180]` (default) | 1-by-*M* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a 1-by-*M* real-valued row vector where *M* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, this angle is positive.

Example: `[-45:2:45]`

Data Types: `double`

`EL` — Elevation angles

`[-90:90]` (default) | 1-by-*N* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a 1-by-*N* real-valued row vector where *N* is the number of desired elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and *xy*-plane. When measured towards the *z*-axis, this angle is positive.

Example: `[-75:1:70]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'CoordinateSystem'` — Plotting coordinate system

`'polar'` (default) | `'rectangular'` | `'uv'`

Plotting coordinate system of the pattern, specified as the comma-separated pair consisting of `'CoordinateSystem'` and one of `'polar'`, `'rectangular'`, or `'uv'`. When `'CoordinateSystem'` is set to `'polar'` or `'rectangular'`, the `AZ` and `EL` arguments specify the pattern azimuth and elevation, respectively. `AZ` values must lie between –180° and 180°. `EL` values must lie between –90° and 90°. If `'CoordinateSystem'` is set to `'uv'`, `AZ` and `EL` then specify *U* and *V* coordinates, respectively. `AZ` and `EL` must lie between -1 and 1.

Example: `'uv'`

Data Types: `char`

'Type' — Displayed pattern type
'directivity' (default) | 'efield' | 'power' | 'powerdb'

Displayed pattern type, specified as the comma-separated pair consisting of 'Type' and one of

- 'directivity' — directivity pattern measured in dBi.
- 'efield' — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- 'power' — power pattern of the sensor or array defined as the square of the field pattern.
- 'powerdb' — power pattern converted to dB.

Example: 'powerdb'

Data Types: char

'Normalize' — Display normalize pattern
true (default) | false

Display normalized pattern, specified as the comma-separated pair consisting of 'Normalize' and a Boolean. Set this parameter to true to display a normalized pattern. When you set 'Type' to 'directivity', this parameter does not apply. Directivity patterns are already normalized.

Example:

Data Types: logical

'PlotStyle' — Plotting style
'overlay' (default) | 'waterfall'

Plotting style, specified as the comma-separated pair consisting of 'Plotstyle' and either 'overlay' or 'waterfall'. This parameter applies when you specify multiple frequencies in FREQ in 2-D plots. You can draw 2-D plots by setting one of the arguments AZ or EL to a scalar.

Example:

Data Types: char

'Polarization' — Polarized field component
'combined' (default) | 'H' | 'V'

Polarized field component to display, specified as the comma-separated pair consisting of 'Polarization' and `'combined'`, `'H'`, or `'V'`. This parameter applies only when the sensors are polarization-capable and when the `'Type'` parameter is not set to `'directivity'`. This table shows the meaning of the display options

`'Polarization'`	Display
`'combined'`	Combined *H* and *V* polarization components
`'H'`	*H* polarization component
`'V'`	*V* polarization component

Example: `'V'`

Data Types: `char`

`'PropagationSpeed'` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

`'Weights'` — Array weights

1 (default) | *N*-by-1 complex-valued column vector | *N*-by-*L* complex-valued matrix

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *N*-by-1 complex-valued column vector or *N*-by-*L* complex-valued matrix. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *N* is the number of elements in the array. The dimension *L* is the number of frequencies specified by `FREQ`.

Weights Dimension	FREQ Dimension	Purpose
N-by-1 complex-valued column vector	Scalar or 1-by-*L* row vector	Applies a set of weights for the single frequency or for all *L* frequencies.
N-by-*L* complex-valued matrix	1-by-*L* row vector	Applies each of the *L* columns of `'Weights'` for

Weights Dimension	FREQ Dimension	Purpose
		the corresponding frequency in FREQ.

Note: Use complex weights to steer the array response toward different directions. You can create weights using the phased.SteeringVector System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as phased.Radiator or phased.Collector. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(N,M)`

Data Types: `double`
Complex Number Support: Yes

Output Arguments

PAT — Array pattern

M-by-*N* real-valued matrix

Array pattern, returned as an *M*-by-*N* real-valued matrix. The dimensions of PAT correspond to the dimensions of the output arguments AZ_ANG and EL_ANG.

AZ_ANG — Azimuth angles

scalar | 1-by-*M* real-valued row vector

Azimuth angles for displaying directivity or response pattern, returned as a scalar or 1-by-*M* real-valued row vector corresponding to the dimension set in AZ. The rows of PAT correspond to the values in AZ_ANG.

EL_ANG — Elevation angles

scalar | 1-by-*N* real-valued row vector

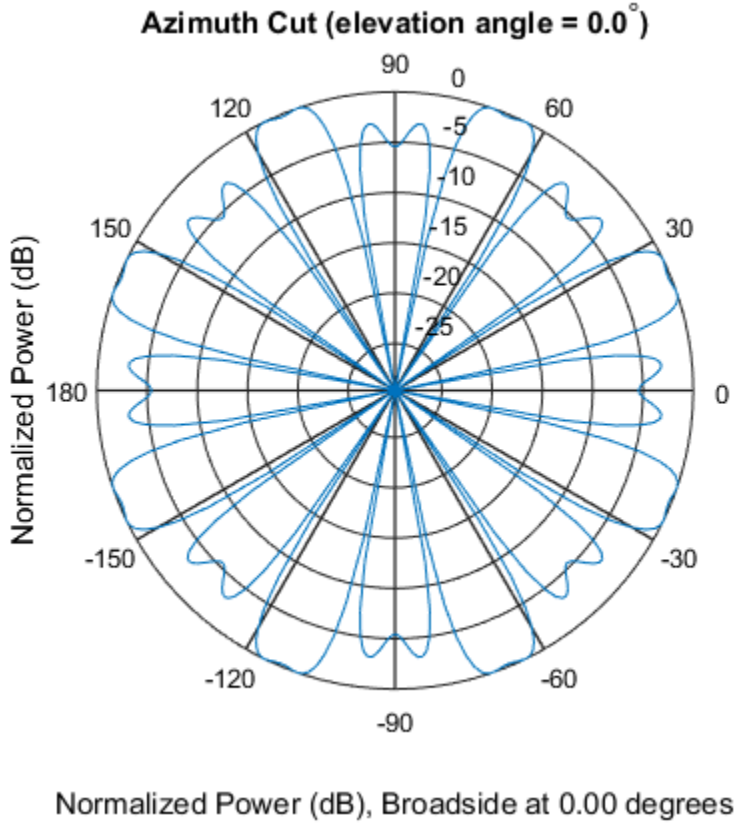
Elevation angles for displaying directivity or response, returned as a scalar or 1-by-*N* real-valued row vector corresponding to the dimension set in EL. The columns of PAT correspond to the values in EL_ANG.

Examples

Plot Power Pattern of 8-Element Uniform Circular Array

Using the ConformalArray System object, construct an 8-element uniform circular array (UCA) of isotropic antenna elements. Plot a normalized azimuth power pattern at 0 degrees elevation. Assume the operating frequency is 1 GHz and the wave propagation speed is the speed of light.

```
N = 8;
azang = (0:N-1)*360/N-180;
sCA = phased.ConformalArray(...
    'ElementPosition',[cosd(azang);sind(azang);zeros(1,N)],...
    'ElementNormal',[azang;zeros(1,N)]);
fc = 1e9;
c = physconst('LightSpeed');
pattern(sCA,fc,[-180:180],0,...
    'PropagationSpeed',c,'Type','powerdb',...
    'CoordinateSystem','polar')
```



Plot Pattern of 31-Element Uniform Circular Sonar Array

Construct a 31-element acoustic uniform circular sonar array (UCA) using the ConformalArray System object. Assume the array is one meter in diameter. Using the `ElevationAngles` parameter, restrict the display to +/-40 degrees in 0.1 degree increments. Assume the operating frequency is 4 kHz. A typical value for the speed of sound in seawater is 1500.0 m/s.

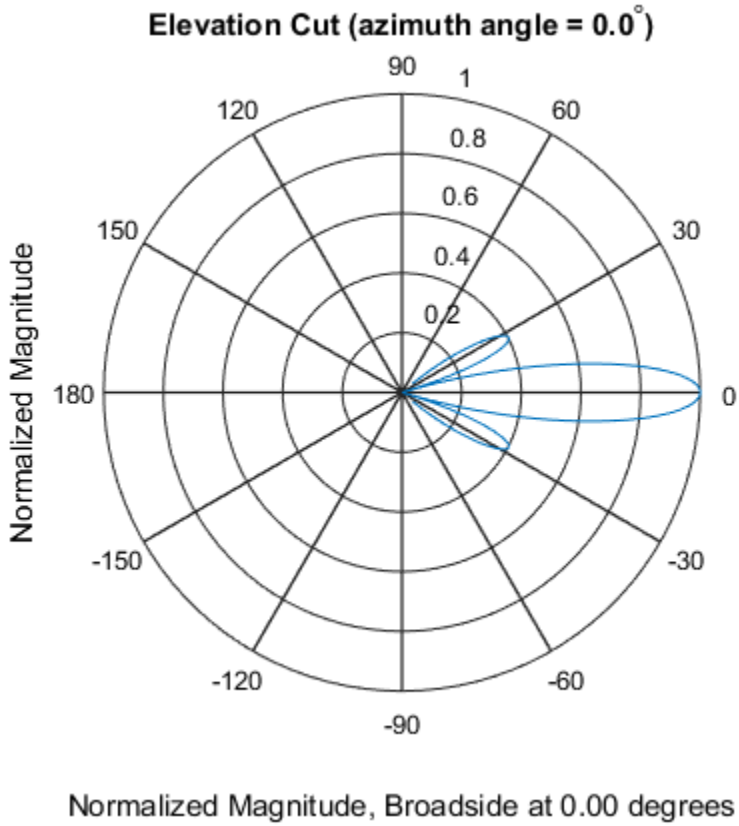
Construct the array

```
N = 31;
theta = (0:N-1)*360/N-180;
Radius = 0.5;
sMic = phased.OmnidirectionalMicrophoneElement(...
```

```
    'FrequencyRange',[0,10000],'BackBaffled',true);
sArray = phased.ConformalArray('Element',sMic,...
    'ElementPosition',Radius*[zeros(1,N);cosd(theta);sind(theta)],...
    'ElementNormal',[ones(1,N);zeros(1,N)]);
```

Plot the magnitude pattern

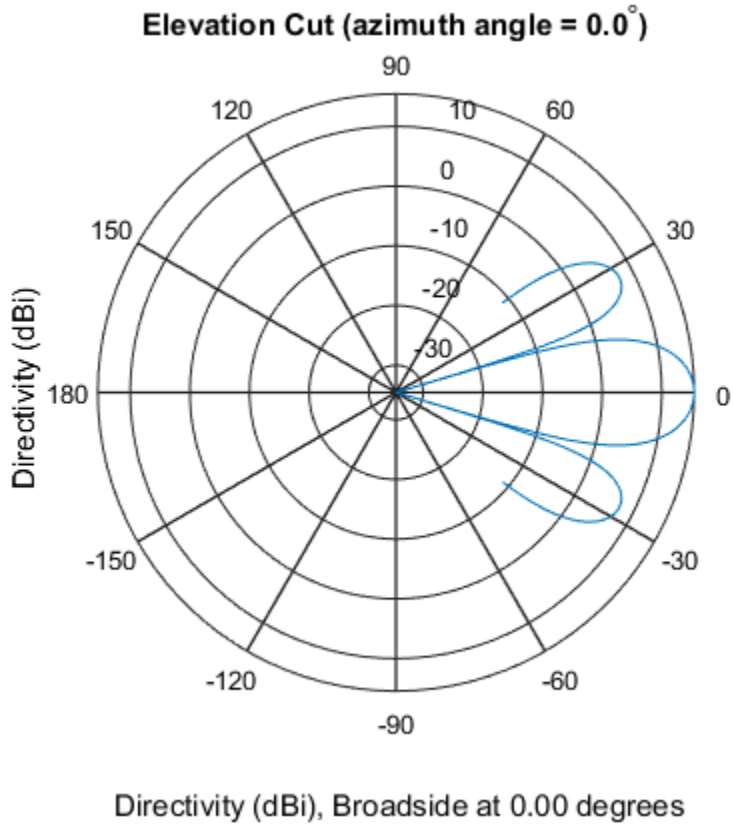
```
fc = 4000;
c = 1500.0;
pattern(sArray,fc,0,[-40:0.1:40],...
    'PropagationSpeed',c,...
    'CoordinateSystem','polar',...
    'Type','efield')
```



Normalized Magnitude, Broadside at 0.00 degrees

Plot the directivity pattern

```
pattern(sArray,fc,0,[-40:0.1:40],...
    'PropagationSpeed',c,...
    'CoordinateSystem','polar',...
    'Type','directivity')
```



More About

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on "Element directivity" and "Array directivity".

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

Convert plotResponse to pattern

For antenna, microphone, and array System objects, the `pattern` method replaces the `plotResponse` method. In addition, two new simplified methods exist just to draw 2-D azimuth and elevation pattern plots. These methods are `azimuthPattern` and `elevationPattern`.

The following table is a guide for converting your code from using `plotResponse` to `pattern`. Notice that some of the inputs have changed from *input arguments* to *Name-Value* pairs and conversely. The general `pattern` method syntax is

```
pattern(H,FREQ,AZ,EL,'Name1','Value1',...,'NameN','ValueN')
```

plotResponse Inputs	plotResponse Description	pattern Inputs
`H` argument	Antenna, microphone, or array System object.	`H` argument (no change)
`FREQ` argument	Operating frequency.	`FREQ` argument (no change)

plotResponse Inputs	plotResponse Description	pattern Inputs
`V` argument	Propagation speed. This argument is used only for arrays.	`'PropagationSpeed'` name-value pair. This parameter is only used for arrays.

<table>
<tr><th>plotResponse Inputs</th><th>plotResponse Description</th><th>pattern Inputs</th></tr>
<tr>
<td>'Format' and 'RespCut' name-value pairs</td>
<td>These options work together to let you create a plot in angle space (line or polar style) or UV space. They also determine whether the plot is 2-D or 3-D. This table shows you how to create different types of plots using plotResponse.
<table>
<tr><th>Display space</th><th></th></tr>
<tr><td>Angle space (2D)</td><td>Set 'RespCut' to 'Az' or 'El'. Set 'Format' to 'line' or 'polar'.

phased.ConformalArray.patternAzimuth | phased.ConformalArray.patternElevation

Introduced in R2015a

patternAzimuth

System object: phased.ConformalArray
Package: phased

Plot conformal array directivity or pattern versus azimuth

Syntax

```
patternAzimuth(sArray,FREQ)
patternAzimuth(sArray,FREQ,EL)
patternAzimuth(sArray,FREQ,EL,Name,Value)
PAT = patternAzimuth( ___ )
```

Description

`patternAzimuth(sArray,FREQ)` plots the 2-D array directivity pattern versus azimuth (in dBi) for the array `sArray` at zero degrees elevation angle. The argument `FREQ` specifies the operating frequency.

`patternAzimuth(sArray,FREQ,EL)`, in addtion, plots the 2-D array directivity pattern versus azimuth (in dBi) for the array `sArray` at the elevation angle specified by `EL`. When `EL` is a vector, multiple overlaid plots are created.

`patternAzimuth(sArray,FREQ,EL,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternAzimuth( ___ )` returns the array pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Azimuth'` parameter and the `EL` input argument.

Input Arguments

`sArray` — Conformal array

System object

Conformal array, specified as a phased.ConformalArray System object.

Example: `sArray= phased.ConformalArray;`

`FREQ` — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

`EL` — Elevation angles

1-by-*N* real-valued row vector

Elevation angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector. The quantity *N* is the number of requested elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and the *xy* plane. When measured toward the *z*-axis, this angle is positive.

Example: `[0,10,20]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'Type' — Displayed pattern type

'directivity' (default) | 'efield' | 'power' | 'powerdb'

Displayed pattern type, specified as the comma-separated pair consisting of 'Type' and one of

- 'directivity' — directivity pattern measured in dBi.
- 'efield' — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- 'power' — power pattern of the sensor or array defined as the square of the field pattern.
- 'powerdb' — power pattern converted to dB.

Example: 'powerdb'

Data Types: char

'PropagationSpeed' — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of 'PropagationSpeed' and a positive scalar in meters per second.

Example: 'PropagationSpeed',physconst('LightSpeed')

Data Types: double

'Weights' — Array weights

M-by-1 complex-valued column vector

Array weights, specified as the comma-separated pair consisting of 'Weights' and an *M*-by-1 complex-valued column vector. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *M* is the number of elements in the array.

Note: Use complex weights to steer the array response toward different directions. You can create weights using the phased.SteeringVector System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as phased.Radiator or phased.Collector. However, for the directivity, pattern, patternAzimuth, and patternElevation methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(10,1)`

Data Types: `double`
Complex Number Support: Yes

`'Azimuth'` — Azimuth angles

`[-180:180]` (default) | 1-by-*P* real-valued row vector

Azimuth angles, specified as the comma-separated pair consisting of `'Azimuth'` and a 1-by-*P* real-valued row vector. Azimuth angles define where the array pattern is calculated.

Example: `'Azimuth',[-90:2:90]`

Data Types: `double`

Output Arguments

`PAT` — Array directivity or pattern

L-by-*N* real-valued matrix

Array directivity or pattern, returned as an *L*-by-*N* rea-valued matrix. The dimension *L* is the number of azimuth values determined by the `'Azimuth'` name-value pair argument. The dimension *N* is the number of elevation angles, as determined by the `EL` input argument.

Examples

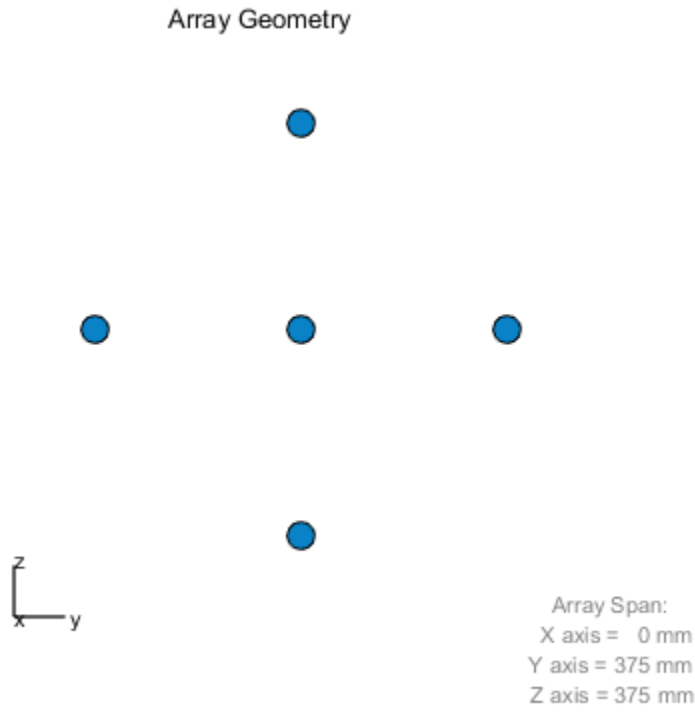
Plot Azimuth Pattern of 5-Element Cross Sonar Array

Construct a 5-element acoustic cross array (UCA) using the ConformalArray System object. Assume the operating frequency is 4 kHz. A typical value for the speed of sound in seawater is 1500.0 m/s. Plot the array patterns at two different elevation angles.

Construct and view array

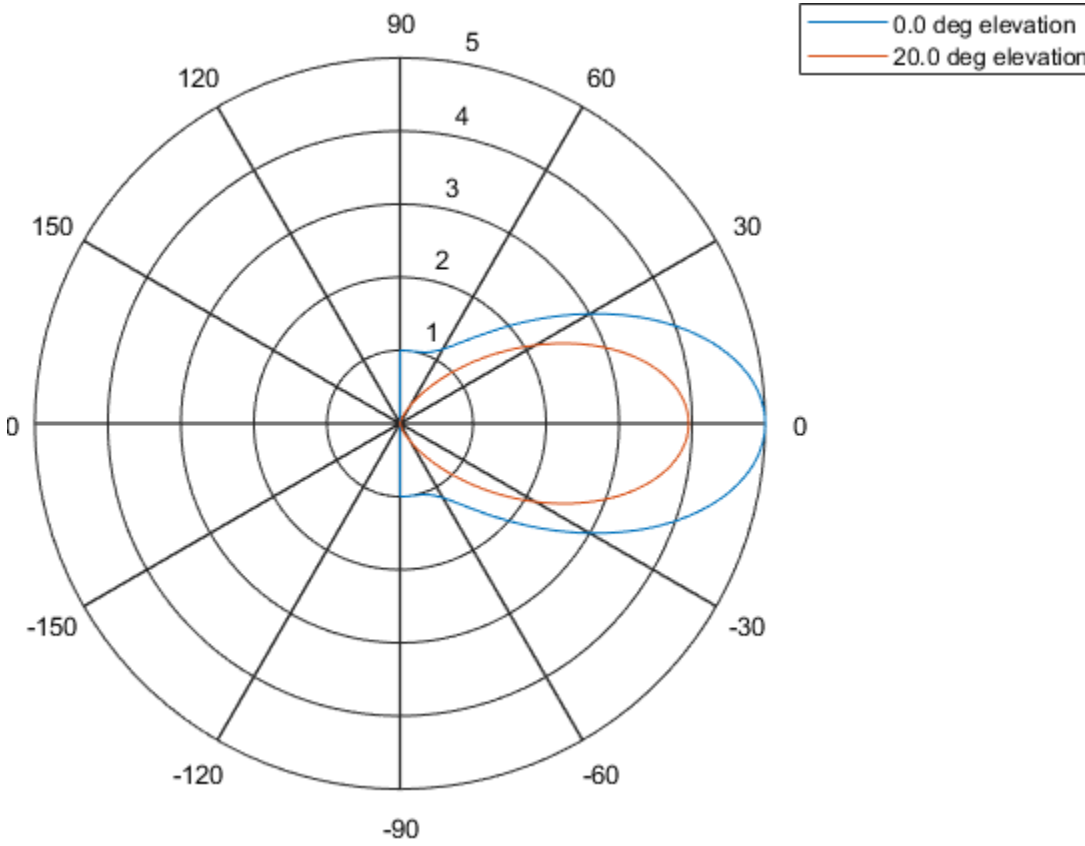
```
N = 5;
fc = 4000;
c = 1500.0;
lam = c/fc;
x = zeros(1,N);
y = [-1,0,1,0,0]*lam/2;
z = [0,0,0,-1,1]*lam/2;
```

```
sMic = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[0,10000],'BackBaffled',true);
sArray = phased.ConformalArray('Element',sMic,...
    'ElementPosition',[x;y;z],...
    'ElementNormal',[zeros(1,N);zeros(1,N)]);
viewArray(sArray)
```



Plot azimuth pattern for magnitude

```
fc = 4000;
c = 1500.0;
patternAzimuth(sArray,fc,[0,20],...
    'PropagationSpeed',c,...
    'Type','efield')
```



Plot azimuth pattern for directivity

```
patternAzimuth(sArray,fc,[0,20],...
    'PropagationSpeed',c,...
    'Type','directivity')
```

phased.UCA.pattern | phased.UCA.patternElevation

Introduced in R2015a

patternElevation

System object: phased.ConformalArray
Package: phased

Plot conformal array array directivity or pattern versus elevation

Syntax

```
patternElevation(sArray,FREQ)
patternElevation(sArray,FREQ,AZ)
patternElevation(sArray,FREQ,AZ,Name,Value)
PAT = patternElevation( ___ )
```

Description

`patternElevation(sArray,FREQ)` plots the 2-D array directivity pattern versus elevation (in dBi) for the array `sArray` at zero degrees azimuth angle. When `AZ` is a vector, multiple overlaid plots are created. The argument `FREQ` specifies the operating frequency.

`patternElevation(sArray,FREQ,AZ)`, in addition, plots the 2-D element directivity pattern versus elevation (in dBi) at the azimuth angle specified by `AZ`. When `AZ` is a vector, multiple overlaid plots are created.

`patternElevation(sArray,FREQ,AZ,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternElevation( ___ )` returns the array pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Elevation'` parameter and the `AZ` input argument.

Input Arguments

`sArray` — Conformal array

System object

Conformal array, specified as a phased.ConformalArray System object.

Example: `sArray= phased.ConformalArray;`

`FREQ` — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

`AZ` — Azimuth angles for computing directivity and pattern

1-by-*N* real-valued row vector

Azimuth angles for computing sensor or array directivities and patterns, specified as a 1-by-*M* real-valued row vector where *N* is the number of desired azimuth directions. Angle units are in degrees. The azimuth angle must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `[0,10,20]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'Type' — Displayed pattern type

'directivity' (default) | 'efield' | 'power' | 'powerdb'

Displayed pattern type, specified as the comma-separated pair consisting of 'Type' and one of

- 'directivity' — directivity pattern measured in dBi.
- 'efield' — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- 'power' — power pattern of the sensor or array defined as the square of the field pattern.
- 'powerdb' — power pattern converted to dB.

Example: 'powerdb'

Data Types: char

'PropagationSpeed' — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of 'PropagationSpeed' and a positive scalar in meters per second.

Example: 'PropagationSpeed',physconst('LightSpeed')

Data Types: double

'Weights' — Array weights

M-by-1 complex-valued column vector

Array weights, specified as the comma-separated pair consisting of 'Weights' and an *M*-by-1 complex-valued column vector. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *M* is the number of elements in the array.

Note: Use complex weights to steer the array response toward different directions. You can create weights using the phased.SteeringVector System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as phased.Radiator or phased.Collector. However, for the directivity, pattern, patternAzimuth, and patternElevation methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(10,1)`

Data Types: `double`
Complex Number Support: Yes

`'Elevation'` — Elevation angles

`[-90:90]` (default) | 1-by-*P* real-valued row vector

Elevation angles, specified as the comma-separated pair consisting of `'Elevation'` and a 1-by-*P* real-valued row vector. Elevation angles define where the array pattern is calculated.

Example: `'Elevation',[-90:2:90]`

Data Types: `double`

Output Arguments

`PAT` — Array directivity or pattern

L-by-*N* real-valued matrix

Array directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of elevation angles determined by the `'Elevation'` name-value pair argument. The dimension *N* is the number of azimuth angles determined by the `AZ` argument.

Examples

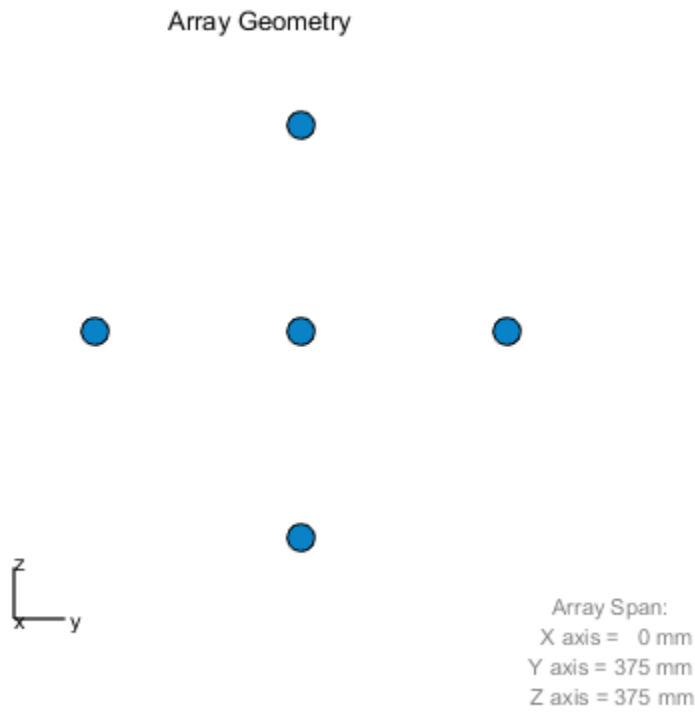
Plot Elevation Pattern of 5-Element Cross Sonar Array

Construct a 5-element acoustic cross array (UCA) using the ConformalArray System object. Assume the operating frequency is 4 kHz. A typical value for the speed of sound in seawater is 1500.0 m/s. Plot the array patterns at two different azimuth angles.

Construct and view array

```
N = 5;
fc = 4000;
c = 1500.0;
lam = c/fc;
```

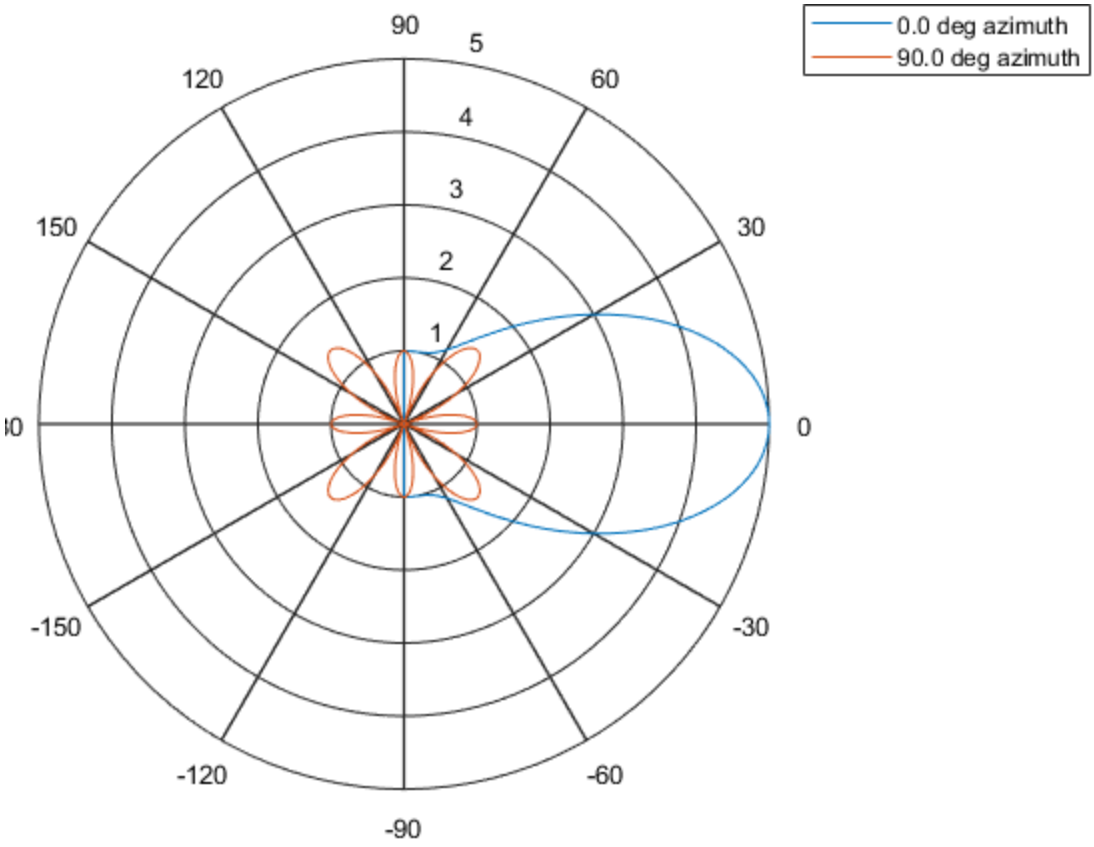
```
x = zeros(1,N);
y = [-1,0,1,0,0]*lam/2;
z = [0,0,0,-1,1]*lam/2;
sMic = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[0,10000],'BackBaffled',true);
sArray = phased.ConformalArray('Element',sMic,...
    'ElementPosition',[x;y;z],...
    'ElementNormal',[zeros(1,N);zeros(1,N)]);
viewArray(sArray)
```



Plot magnitude elevation pattern

```
fc = 4000;
```

```
c = 1500.0;
patternElevation(sArray,fc,[0,90],...
    'PropagationSpeed',c,...
    'Type','efield')
```



Plot directivity elevation pattern

Plot the pattern for elevation angles between -60 and 6- degrees at 0.1 degree resolution.

```
patternElevation(sArray,fc,[0,90],...
    'PropagationSpeed',c,...
    'Type','directivity',...
    'Elevation',[-60:0.1:60])
```

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on "Element directivity" and "Array directivity".

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

Introduced in R2015a

plotResponse

System object: phased.ConformalArray
Package: phased

Plot response pattern of array

Syntax

```
plotResponse(H,FREQ,V)
plotResponse(H,FREQ,V,Name,Value)
hPlot = plotResponse(___)
```

Description

`plotResponse(H,FREQ,V)` plots the array response pattern along the azimuth cut, where the elevation angle is 0. The operating frequency is specified in `FREQ`. The propagation speed is specified in `V`.

`plotResponse(H,FREQ,V,Name,Value)` plots the array response with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = plotResponse(___)` returns handles of the lines or surface in the figure window, using any of the input arguments in the previous syntaxes.

Input Arguments

`H`

Array object

`FREQ`

Operating frequency in Hertz specified as a scalar or 1-by-*K* row vector. Values must lie within the range specified by a property of `H`. That property is named `FrequencyRange` or `FrequencyVector`, depending on the type of element in the array. The element has no response at frequencies outside that range. If you set the `'RespCut'` property of `H` to

`'3D'`, `FREQ` must be a scalar. When `FREQ` is a row vector, `plotResponse` draws multiple frequency responses on the same axes.

`V`

Propagation speed in meters per second.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'CutAngle'`

Cut angle as a scalar. This argument is applicable only when `RespCut` is `'Az'` or `'El'`. If `RespCut` is `'Az'`, `CutAngle` must be between –90 and 90. If `RespCut` is `'El'`, `CutAngle` must be between –180 and 180.

Default: `0`

`'Format'`

Format of the plot, using one of `'Line'`, `'Polar'`, or `'UV'`. If you set `Format` to `'UV'`, `FREQ` must be a scalar.

Default: `'Line'`

`'NormalizeResponse'`

Set this value to `true` to normalize the response pattern. Set this value to `false` to plot the response pattern without normalizing it. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

Default: `true`

`'OverlayFreq'`

Set this value to `true` to overlay pattern cuts in a 2-D line plot. Set this value to `false` to plot pattern cuts against frequency in a 3-D waterfall plot. If this value is `false`, `FREQ` must be a vector with at least two entries.

This parameter applies only when `Format` is not `'Polar'` and RespCut is not `'3D'`.

Default: `true`

`'Polarization'`

Specify the polarization options for plotting the array response pattern. The allowable values are `|'None' | 'Combined' | 'H' | 'V' |` where

- `'None'` specifies plotting a nonpolarized response pattern
- `'Combined'` specifies plotting a combined polarization response pattern
- `'H'` specifies plotting the horizontal polarization response pattern
- `'V'` specifies plotting the vertical polarization response pattern

For arrays that do not support polarization, the only allowed value is `'None'`. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

Default: `'None'`

`'RespCut'`

Cut of the response. Valid values depend on `Format`, as follows:

- If `Format` is `'Line'` or `'Polar'`, the valid values of `RespCut` are `'Az'`, `'El'`, and `'3D'`. The default is `'Az'`.
- If `Format` is `'UV'`, the valid values of `RespCut` are `'U'` and `'3D'`. The default is `'U'`.

If you set `RespCut` to `'3D'`, `FREQ` must be a scalar.

`'Unit'`

The unit of the plot. Valid values are `'db'`, `'mag'`, `'pow'`, or `'dbi'`. This parameter determines the type of plot that is produced.

Unit value	Plot type
`db`	power pattern in dB scale
`mag`	field pattern
`pow`	power pattern
`dbi`	directivity

Default: `'db'`

`'Weights'`

Weight values applied to the array, specified as a length-*N* column vector or *N*-by-*M* matrix. The dimension *N* is the number of elements in the array. The interpretation of *M* depends upon whether the input argument `FREQ` is a scalar or row vector.

Weights Dimensions	FREQ Dimension	Purpose
N-by-1 column vector	Scalar or 1-by-*M* row vector	Apply one set of weights for the same single frequency or all *M* frequencies.
N-by-*M* matrix	Scalar	Apply all of the *M* different columns in `Weights` for the same single frequency.
	1-by-*M* row vector	Apply each of the *M* different columns in `Weights` for the corresponding frequency in `FREQ`.

`'AzimuthAngles'`

Azimuth angles for plotting array response, specified as a row vector. The `AzimuthAngles` parameter sets the display range and resolution of azimuth angles for visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'Az'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of azimuth angles should lie between –180° and 180° and must be in nondecreasing order. When you set the `RespCut` parameter to `'3D'`, you can set the `AzimuthAngles` and `ElevationAngles` parameters simultaneously.

Default: `[-180:180]`

`'ElevationAngles'`

Elevation angles for plotting array response, specified as a row vector. The `ElevationAngles` parameter sets the display range and resolution of elevation angles for visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'El'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of elevation angles should lie between –90° and 90° and must be in nondecreasing order. When yous set the `RespCut` parameter to `'3D'`, you can set the `ElevationAngles` and `AzimuthAngles` parameters simultaneously.

Default: `[-90:90]`

`'UGrid'`

U coordinate values for plotting array response, specified as a row vector. The `UGrid` parameter sets the display range and resolution of the *U* coordinates for visualizing the radiation pattern in *U*/*V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'U'` or `'3D'`. The values of `UGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set the `UGrid` and `VGrid` parameters simultaneously.

Default: `[-1:0.01:1]`

`'VGrid'`

V coordinate values for plotting array response, specified as a row vector. The `VGrid` parameter sets the display range and resolution of the *V* coordinates for visualizing the radiation pattern in *U*/*V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'3D'`. The values of `VGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set `VGrid` and `UGrid` parameters simultaneously.

Default: `[-1:0.01:1]`

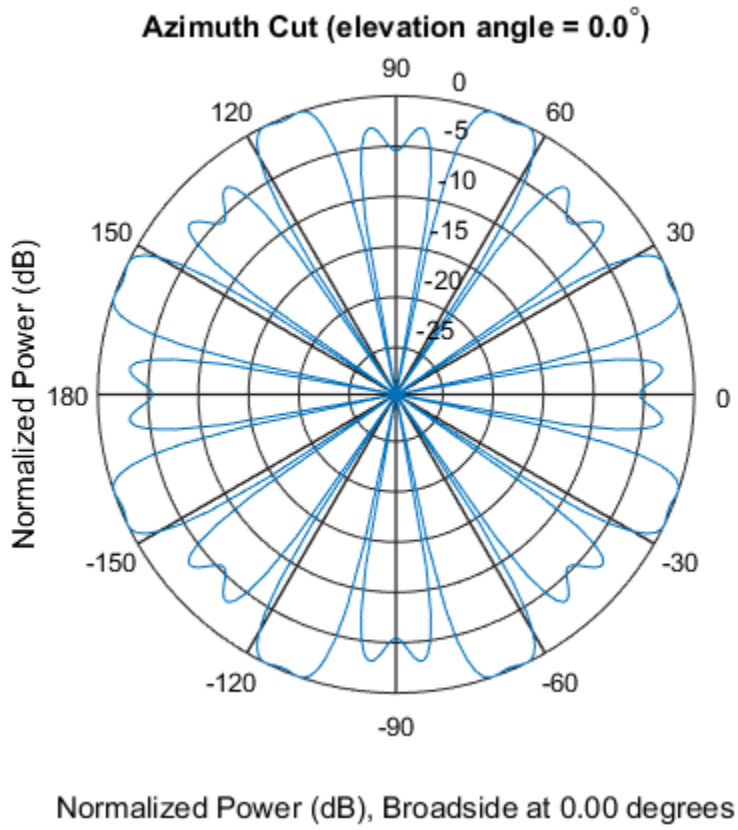
Examples

Plot Power Pattern of 8-Element Uniform Circular Array

Using the ConformalArray System object, construct an 8-element uniform circular array (UCA) of isotropic antenna elements. Plot a normalized azimuth power pattern at 0 degrees elevation. Assume the operating frequency is 1 GHz and the wave propagation speed is the speed of light.

```
N = 8;
azang = (0:N-1)*360/N-180;
sCA = phased.ConformalArray(...
    'ElementPosition',[cosd(azang);sind(azang);zeros(1,N)],...
    'ElementNormal',[azang;zeros(1,N)]);
fc = 1e9;
c = physconst('LightSpeed');
pattern(sCA,fc,[-180:180],0,...
    'PropagationSpeed',c,'Type','powerdb',...
```

```
'CoordinateSystem','polar')
```



Plot Pattern of 31-Element Uniform Circular Sonar Array

Construct a 31-element acoustic uniform circular sonar array (UCA) using the ConformalArray System object. Assume the array is one meter in diameter. Using the `ElevationAngles` parameter, restrict the display to +/-40 degrees in 0.1 degree increments. Assume the operating frequency is 4 kHz. A typical value for the speed of sound in seawater is 1500.0 m/s.

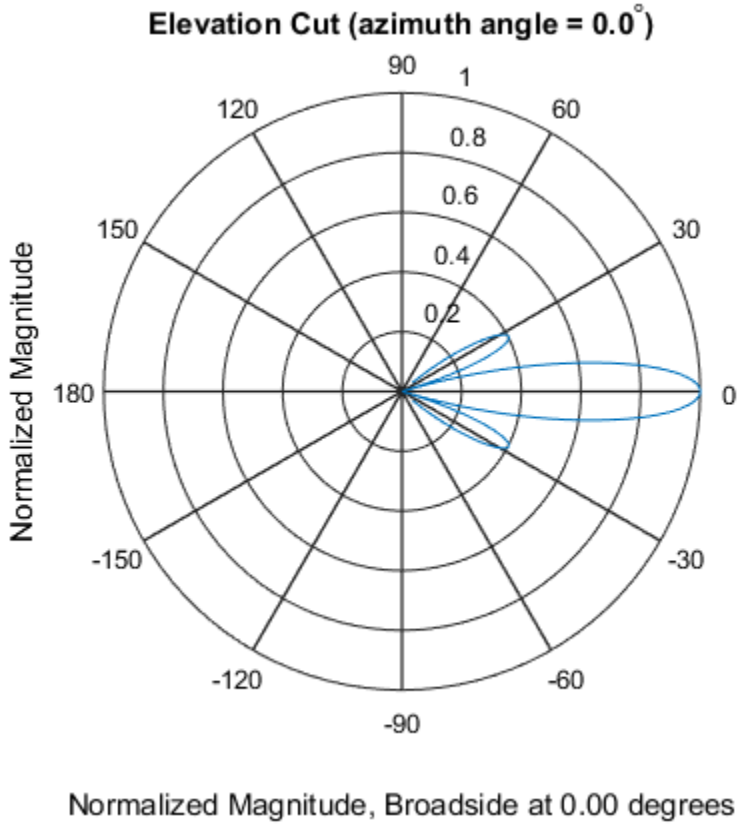
Construct the array

```
N = 31;
theta = (0:N-1)*360/N-180;
```

```
Radius = 0.5;
sMic = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[0,10000],'BackBaffled',true);
sArray = phased.ConformalArray('Element',sMic,...
    'ElementPosition',Radius*[zeros(1,N);cosd(theta);sind(theta)],...
    'ElementNormal',[ones(1,N);zeros(1,N)]);
```

Plot the magnitude pattern

```
fc = 4000;
c = 1500.0;
pattern(sArray,fc,0,[-40:0.1:40],...
    'PropagationSpeed',c,...
    'CoordinateSystem','polar',...
    'Type','efield')
```



Plot the directivity pattern

```
pattern(sArray,fc,0,[-40:0.1:40],...
    'PropagationSpeed',c,...
    'CoordinateSystem','polar',...
    'Type','directivity')
```

azel2uv | uv2azel

step

System object: phased.ConformalArray
Package: phased

Output responses of array elements

Syntax

```
RESP = step(H,FREQ,ANG)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`RESP = step(H,FREQ,ANG)` returns the response of the array elements, `RESP`, at operating frequencies specified in `FREQ` and directions specified in `ANG`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`H`

Array object

FREQ

Operating frequencies of array in hertz. `FREQ` is a row vector of length *L*. Typical values are within the range specified by a property of `H.Element`. That property is named `FrequencyRange` or `FrequencyVector`, depending on the type of element in the array. The element has zero response at frequencies outside that range.

ANG

Directions in degrees. `ANG` is either a 2-by-*M* matrix or a row vector of length *M*.

If `ANG` is a 2-by-*M* matrix, each column of the matrix specifies the direction in the form `[azimuth; elevation]`. The azimuth angle must lie between –180° and 180°, inclusive. The elevation angle must lie between –90° and 90°, inclusive.

If `ANG` is a row vector of length *M*, each element specifies the azimuth angle of the direction. In this case, the corresponding elevation angle is assumed to be 0°.

Output Arguments

RESP

Voltage responses of the phased array. The output depends on whether the array supports polarization or not.

- If the array is not capable of supporting polarization, the voltage response, `RESP`, has the dimensions *N*-by-*M*-by-*L*. *N* is the number of elements in the array. The dimension *M* is the number of angles specified in `ANG`. *L* is the number of frequencies specified in `FREQ`. For any element, the columns of `RESP` contain the responses of the array elements for the corresponding direction specified in `ANG`. Each of the *L* pages of `RESP` contains the responses of the array elements for the corresponding frequency specified in `FREQ`.
- If the array is capable of supporting polarization, the voltage response, `RESP`, is a MATLAB `struct` containing two fields, `RESP.H` and `RESP.V`. The field, `RESP.H`, represents the array's horizontal polarization response, while `RESP.V` represents the array's vertical polarization response. Each field has the dimensions *N*-by-*M*-by-*L*. *N* is the number of elements in the array, and *M* is the number of angles specified in `ANG`. *L* is the number of frequencies specified in `FREQ`. Each column of `RESP` contains the responses of the array elements for the corresponding direction specified in `ANG`.

Each of the L pages of RESP contains the responses of the array elements for the corresponding frequency specified in FREQ.

Examples

Response of 8-Element Uniform Circular Array

Using the ConformalArray System object, construct an 8-element uniform circular array (UCA) of isotropic antenna elements. The radius of the array is one meter. Assume the operating frequency is 1 GHz and the wave propagation speed is the speed of light.

```
N = 8;
azang = (0:N-1)*360/N-180;
sCA = phased.ConformalArray(...
    'ElementPosition',[cosd(azang);sind(azang);zeros(1,N)],...
    'ElementNormal',[azang;zeros(1,N)]);
```

Get the element response at 35 degrees azimuth and 5 degrees elevation.

```
fc = 1e9;
ang = [30;5];
resp = step(sCA,fc,ang)
```

```
resp =

     1
     1
     1
     1
     1
     1
     1
     1
```

viewArray

System object: phased.ConformalArray
Package: phased

View array geometry

Syntax

```
viewArray(H)
viewArray(H,Name,Value)
hPlot = viewArray( ___ )
```

Description

`viewArray(H)` plots the geometry of the array specified in `H`.

`viewArray(H,Name,Value)` plots the geometry of the array, with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = viewArray( ___ )` returns the handle of the array elements in the figure window. All input arguments described for the previous syntaxes also apply here.

Input Arguments

`H`

Array object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'ShowIndex'

Vector specifying the element indices to show in the figure. Each number in the vector must be an integer between 1 and the number of elements. You can also specify the value `'All'` to show the indices of all elements of the array or `'None'` to suppress indices.

Default: `'None'`

'ShowNormals'

Set this value to `true` to show the normal directions of all elements of the array. Set this value to `false` to plot the elements without showing normal directions.

Default: `false`

'ShowTaper'

Set this value to `true` to specify whether to change the element color brightness in proportion to the element taper magnitude. When this value is set to `false`, all elements are drawn with the same color.

Default: `false`

'Title'

Character vector specifying the title of the plot.

Default: `'Array Geometry'`

Output Arguments

hPlot

Handle of array elements in figure window.

Examples

View Uniform Circular Array

Display the element positions and normal directions of all elements of an 8-element uniform circular array.

Create the uniform circular array

```
N = 8;
azang = (0:N-1)*360/N - 180;
ha = phased.ConformalArray(...
    'ElementPosition',[cosd(azang);sind(azang);zeros(1,N)],...
    'ElementNormal',[azang;zeros(1,N)]);
```

Display the positions and normal directions of the elements

```
viewArray(ha,'ShowNormals',true);
```

phased.ConstantGammaClutter System object

Package: phased

Constant gamma clutter simulation

Description

The `ConstantGammaClutter` object simulates clutter.

To compute the clutter return:

1. Define and set up your clutter simulator. See "Construction" on page 1-272.
2. Call step to simulate the clutter return for your system according to the properties of `phased.ConstantGammaClutter`. The behavior of `step` is specific to each object in the toolbox.

The clutter simulation that `ConstantGammaClutter` provides is based on these assumptions:

- The radar system is monostatic.
- The propagation is in free space.
- The terrain is homogeneous.
- The clutter patch is stationary during the coherence time. *Coherence time* indicates how frequently the software changes the set of random numbers in the clutter simulation.
- The signal is narrowband. Thus, the spatial response can be approximated by a phase shift. Similarly, the Doppler shift can be approximated by a phase shift.
- The radar system maintains a constant height during simulation.
- The radar system maintains a constant speed during simulation.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.ConstantGammaClutter` creates a constant gamma clutter simulation System object, `H`. This object simulates the clutter return of a monostatic radar system using the constant gamma model.

`H = phased.ConstantGammaClutter(Name,Value)` creates a constant gamma clutter simulation object, `H`, with additional options specified by one or more `Name,Value` pair arguments. `Name` is a property name, and `Value` is the corresponding value. `Name` must appear inside single quotes (`''`). You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

Properties

`Sensor`

Handle of sensor

Specify the sensor as an antenna element object or as an array object whose `Element` property value is an antenna element object. If the sensor is an array, it can contain subarrays.

Default: phased.ULA with default property values

`PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

Default: Speed of light

`OperatingFrequency`

System operating frequency

Specify the operating frequency of the system in hertz as a positive scalar. The default value corresponds to 300 MHz.

Default: `3e8`

`SampleRate`

Sample rate

Specify the sample rate, in hertz, as a positive scalar. The default value corresponds to 1 MHz.

Default: `1e6`

`PRF`

Pulse repetition frequency

Specify the pulse repetition frequency in hertz as a positive scalar or a row vector. The default value of this property corresponds to 10 kHz. When `PRF` is a vector, it represents a staggered PRF. In this case, the output pulses use elements in the vector as their PRFs, one after another, in a cycle.

Default: `1e4`

`Gamma`

Terrain gamma value

Specify the γ value used in the constant γ clutter model, as a scalar in decibels. The γ value depends on both terrain type and the operating frequency.

Default: `0`

`EarthModel`

Earth model

Specify the earth model used in clutter simulation as one of `| 'Flat' | 'Curved' |`. When you set this property to `'Flat'`, the earth is assumed to be a flat plane. When you set this property to `'Curved'`, the earth is assumed to be a sphere.

Default: `'Flat'`

`PlatformHeight`

Radar platform height from surface

Specify the radar platform height (in meters) measured upward from the surface as a nonnegative scalar.

Default: 300

`PlatformSpeed`

Radar platform speed

Specify the radar platform's speed as a nonnegative scalar in meters per second.

Default: 300

`PlatformDirection`

Direction of radar platform motion

Specify the direction of radar platform motion as a 2-by-1 vector in the form [AzimuthAngle; ElevationAngle] in degrees. The default value of this property indicates that the platform moves perpendicular to the radar antenna array's broadside.

Both azimuth and elevation angle are measured in the local coordinate system of the radar antenna or antenna array. Azimuth angle must be between –180 and 180 degrees. Elevation angle must be between –90 and 90 degrees.

Default: `[90;0]`

`BroadsideDepressionAngle`

Depression angle of array broadside

Specify the depression angle in degrees of the broadside of the radar antenna array. This value is a scalar. The broadside is defined as zero degrees azimuth and zero degrees elevation. The depression angle is measured downward from horizontal.

Default: 0

`MaximumRange`

Maximum range for clutter simulation

Specify the maximum range in meters for the clutter simulation as a positive scalar. The maximum range must be greater than the value specified in the `PlatformHeight` property.

Default: `5000`

`AzimuthCoverage`

Azimuth coverage for clutter simulation

Specify the azimuth coverage in degrees as a positive scalar. The clutter simulation covers a region having the specified azimuth span, symmetric to 0 degrees azimuth. Typically, all clutter patches have their azimuth centers within the region, but the `PatchAzimuthWidth` value can cause some patches to extend beyond the region.

Default: `60`

`PatchAzimuthWidth`

Azimuth span of each clutter patch

Specify the azimuth span of each clutter patch in degrees as a positive scalar.

Default: `1`

`TransmitSignalInputPort`

Add input to specify transmit signal

Set this property to `true` to add input to specify the transmit signal in the `step` syntax. Set this property to `false` omit the transmit signal in the `step` syntax. The `false` option is less computationally expensive; to use this option, you must also specify the `TransmitERP` property.

Default: `false`

`TransmitERP`

Effective transmitted power

Specify the transmitted effective radiated power (ERP) of the radar system in watts as a positive scalar. This property applies only when you set the `TransmitSignalInputPort` property to `false`.

Default: 5000

`CoherenceTime`

Clutter coherence time

Specify the coherence time in seconds for the clutter simulation as a positive scalar. After the coherence time elapses, the `step` method updates the random numbers it uses for the clutter simulation at the next pulse. A value of `inf` means the random numbers are never updated.

Default: `inf`

`OutputFormat`

Output signal format

Specify the format of the output signal as one of `| 'Pulses' | 'Samples' |`. When you set the `OutputFormat` property to `'Pulses'`, the output of the `step` method is in the form of multiple pulses. In this case, the number of pulses is the value of the `NumPulses` property.

When you set the `OutputFormat` property to `'Samples'`, the output of the `step` method is in the form of multiple samples. In this case, the number of samples is the value of the `NumSamples` property. In staggered PRF applications, you might find the `'Samples'` option more convenient because the `step` output always has the same matrix size.

Default: `'Pulses'`

`NumPulses`

Number of pulses in output

Specify the number of pulses in the output of the `step` method as a positive integer. This property applies only when you set the `OutputFormat` property to `'Pulses'`.

Default: 1

`NumSamples`

Number of samples in output

Specify the number of samples in the output of the `step` method as a positive integer. Typically, you use the number of samples in one pulse. This property applies only when you set the `OutputFormat` property to `'Samples'`.

Default: `100`

`SeedSource`

Source of seed for random number generator

Specify how the object generates random numbers. Values of this property are:

`'Auto'`	The default MATLAB random number generator produces the random numbers. Use `'Auto'` if you are using this object with Parallel Computing Toolbox software.
`'Property'`	The object uses its own private random number generator to produce random numbers. The `Seed` property of this object specifies the seed of the random number generator. Use `'Property'` if you want repeatable results and are not using this object with Parallel Computing Toolbox software.

Default: `'Auto'`

`Seed`

Seed for random number generator

Specify the seed for the random number generator as a scalar integer between 0 and $2^{32}-1$. This property applies when you set the `SeedSource` property to `'Property'`.

Default: `0`

Methods

reset	Reset random numbers and time count for clutter simulation

step	Simulate clutter using constant gamma model

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Simulate Clutter for System with Known Power

Simulate the clutter return from terrain with a gamma value of 0 dB. The effective transmitted power of the radar system is 5 kW.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Set up the characteristics of the radar system. This system uses a 4-element uniform linear array (ULA). The sample rate is 1 MHz, and the PRF is 10 kHz. The propagation speed is the speed of light, and the operating frequency is 300 MHz. The radar platform is flying 1 km above the ground with a path parallel to the ground along the array axis. The platform speed is 2 km/s. The mainlobe has a depression angle of 30°.

```
Nele = 4;
c = physconst('Lightspeed');
fc = 300.0e6;
lambda = c/fc;
array = phased.ULA('NumElements',Nele,'ElementSpacing',lambda/2);
fs = 1.0e6;
prf = 10.0e3;
height = 1000.0;
direction = [90;0];
speed = 2.0e3;
```

```
depang = 30.0;
```

Create the clutter simulation object. The configuration assumes the earth is flat. The maximum clutter range of interest is 5 km, and the maximum azimuth coverage is ±60°.

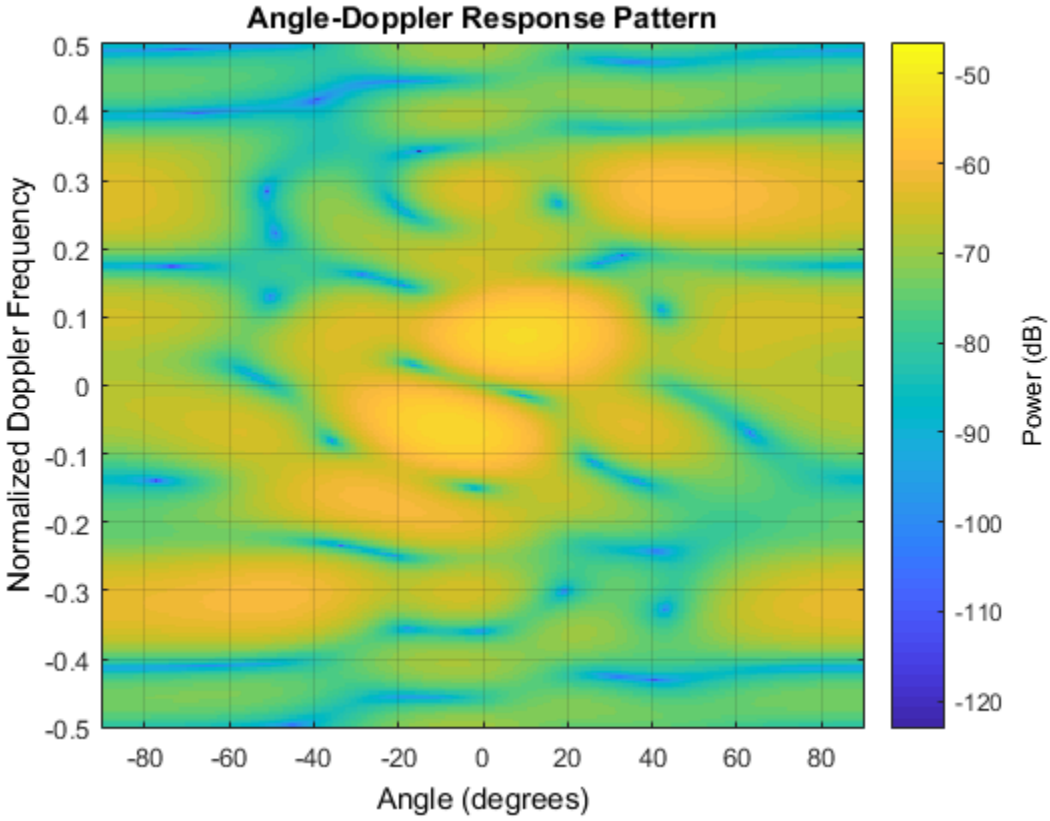
```
Rmax = 5000.0;
Azcov = 120.0;
tergamma = 0.0;
tpower = 5000.0;
clutter = phased.ConstantGammaClutter('Sensor',array,...
    'PropagationSpeed',c,'OperatingFrequency',fc,'PRF',prf,...
    'SampleRate',fs,'Gamma',tergamma,'EarthModel','Flat',...
    'TransmitERP',tpower,'PlatformHeight',height,...
    'PlatformSpeed',speed,'PlatformDirection',direction,...
    'BroadsideDepressionAngle',depang,'MaximumRange',Rmax,...
    'AzimuthCoverage',Azcov,'SeedSource','Property',...
    'Seed',40547);
```

Simulate the clutter return for 10 pulses.

```
Nsamp = fs/prf;
Npulse = 10;
sig = zeros(Nsamp,Nele,Npulse);
for m = 1:Npulse
    sig(:,:,m) = clutter();
end
```

Plot the angle-Doppler response of the clutter at the 20th range bin.

```
response = phased.AngleDopplerResponse('SensorArray',array,...
    'OperatingFrequency',fc,'PropagationSpeed',c,'PRF',prf);
plotResponse(response,shiftdim(sig(20,:,:)),'NormalizeDoppler',true)
```



Simulate Clutter Using Known Transmit Signal

Simulate the clutter return from terrain with a gamma value of 0 dB. You input the transmit signal of the radar system when creating clutter. In this case, you do not use the `TransmitERP` property.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Set up the characteristics of the radar system. This system has a 4-element uniform linear array (ULA). The sample rate is 1 MHz, and the PRF is 10 kHz. The propagation speed is the speed of light, and the operating frequency is 300 MHz. The radar platform

is flying 1 km above the ground with a path parallel to the ground along the array axis. The platform speed is 2 km/s. The mainlobe has a depression angle of 30°.

```
Nele = 4;
c = physconst('Lightspeed');
fc = 300.0e6;
lambda = c/fc;
ula = phased.ULA('NumElements',Nele,'ElementSpacing',lambda/2);
fs = 1.0e6;
prf = 10.0e3;
height = 1.0e3;
direction = [90;0];
speed = 2.0e3;
depang = 30;
```

Create the clutter simulation object and configure it to accept an transmit signal as an input argument. The configuration assumes the earth is flat. The maximum clutter range of interest is 5 km, and the maximum azimuth coverage is ±60°.

```
Rmax = 5000.0;
Azcov = 120.0;
tergamma = 0.0;
clutter = phased.ConstantGammaClutter('Sensor',ula,...
    'PropagationSpeed',c,'OperatingFrequency',fc,'PRF',prf,...
    'SampleRate',fs,'Gamma',tergamma,'EarthModel','Flat',...
    'TransmitSignalInputPort',true,'PlatformHeight',height,...
    'PlatformSpeed',speed,'PlatformDirection',direction,...
    'BroadsideDepressionAngle',depang,'MaximumRange',Rmax,...
    'AzimuthCoverage',Azcov,'SeedSource','Property',...
    'Seed',40547);
```

Simulate the clutter return for 10 pulses. At each step, pass the transmit signal as an input argument. The software computes the effective transmitted power of the signal. The transmit signal is a rectangular waveform with a pulse width of 2 µs.

```
tpower = 5.0e3;
pw = 2.0e-6;
X = tpower*ones(floor(pw*fs),1);
Nsamp = fs/prf;
Npulse = 10;
sig = zeros(Nsamp,Nele,Npulse);
for m = 1:Npulse
    sig(:,:,m) = step(clutter,X);
end
```

Plot the angle-Doppler response of the clutter at the 20th range bin.

```
response = phased.AngleDopplerResponse('SensorArray',ula,...
    'OperatingFrequency',fc,'PropagationSpeed',c,'PRF',prf);
plotResponse(response,shiftdim(sig(20,:,:)),'NormalizeDoppler',true)
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See "System Objects in MATLAB Code Generation" (MATLAB Coder).

Parallel Computing

Solve computationally and data-intensive problems using Parallel Computing Toolbox™.

You can use this System object to perform Monte Carlo simulations with Parallel Computing Toolbox constructs, such as `parfor`. In this situation, set the `SeedSource` property to `'Auto'` to ensure correct, automatic handling of random number streams on the workers.

Do not use this System object in a parallel construct whose iterations represent data from consecutive pulses. Because such iterations are not independent of each other, they must run sequentially.

To perform computations on a GPU instead of a CPU, use phased.gpu.ConstantGammaClutter instead of `phased.ConstantGammaClutter`.

Introduced in R2012a

reset

System object: phased.ConstantGammaClutter
Package: phased

Reset random numbers and time count for clutter simulation

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `ConstantGammaClutter` object, `H`. This method resets the random number generator state if the `SeedSource` property is set to `'Property'`. This method resets the elapsed coherence time. Also, if the `PRF` property is a vector, the next call to `step` uses the first PRF value in the vector.

step

System object: phased.ConstantGammaClutter
Package: phased

Simulate clutter using constant gamma model

Syntax

```
Y = step(H)
Y = step(H,X)
Y = step(H,STEERANGLE)
Y = step(H,X,STEERANGLE)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H)` computes the collected clutter return at each sensor. This syntax is available when you set the `TransmitSignalInputPort` property to `false`.

`Y = step(H,X)` specifies the transmit signal in `X`. *Transmit signal* refers to the output of the transmitter while it is on during a given pulse. This syntax is available when you set the `TransmitSignalInputPort` property to `true`.

`Y = step(H,STEERANGLE)` uses `STEERANGLE` as the subarray steering angle. This syntax is available when you configure `H` so that `H.Sensor` is an array that contains subarrays and `H.Sensor.SubarraySteering` is either `'Phase'` or `'Time'`.

`Y = step(H,X,STEERANGLE)` combines all input arguments. This syntax is available when you configure `H` so that `H.TransmitSignalInputPort` is `true`, `H.Sensor` is an array that contains subarrays, and `H.Sensor.SubarraySteering` is either `'Phase'` or `'Time'`.

Input Arguments

H

Constant gamma clutter object.

X

Transmit signal, specified as a column vector.

STEERANGLE

Subarray steering angle in degrees. `STEERANGLE` can be a length-2 column vector or a scalar.

If `STEERANGLE` is a length-2 vector, it has the form [azimuth; elevation]. The azimuth angle must be between –180 and 180 degrees, and the elevation angle must be between –90 and 90 degrees.

If `STEERANGLE` is a scalar, it represents the azimuth angle. In this case, the elevation angle is assumed to be 0.

Output Arguments

Y

Collected clutter return at each sensor. `Y` has dimensions N-by-M matrix. M is the number of subarrays in the radar system if `H.Sensor` contains subarrays, or the number of sensors, otherwise. When you set the `OutputFormat` property to `'Samples'`, N is specified in the `NumSamples` property. When you set the `OutputFormat` property to `'Pulses'`, N is the total number of samples in the next L pulses. In this case, L is specified in the `NumPulses` property.

Examples

Simulate Clutter for System with Known Power

Simulate the clutter return from terrain with a gamma value of 0 dB. The effective transmitted power of the radar system is 5 kW.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Set up the characteristics of the radar system. This system uses a 4-element uniform linear array (ULA). The sample rate is 1 MHz, and the PRF is 10 kHz. The propagation speed is the speed of light, and the operating frequency is 300 MHz. The radar platform is flying 1 km above the ground with a path parallel to the ground along the array axis. The platform speed is 2 km/s. The mainlobe has a depression angle of 30°.

```
Nele = 4;
c = physconst('Lightspeed');
fc = 300.0e6;
lambda = c/fc;
array = phased.ULA('NumElements',Nele,'ElementSpacing',lambda/2);
fs = 1.0e6;
prf = 10.0e3;
height = 1000.0;
direction = [90;0];
speed = 2.0e3;
depang = 30.0;
```

Create the clutter simulation object. The configuration assumes the earth is flat. The maximum clutter range of interest is 5 km, and the maximum azimuth coverage is ±60°.

```
Rmax = 5000.0;
Azcov = 120.0;
tergamma = 0.0;
tpower = 5000.0;
clutter = phased.ConstantGammaClutter('Sensor',array,...
    'PropagationSpeed',c,'OperatingFrequency',fc,'PRF',prf,...
    'SampleRate',fs,'Gamma',tergamma,'EarthModel','Flat',...
    'TransmitERP',tpower,'PlatformHeight',height,...
    'PlatformSpeed',speed,'PlatformDirection',direction,...
    'BroadsideDepressionAngle',depang,'MaximumRange',Rmax,...
    'AzimuthCoverage',Azcov,'SeedSource','Property',...
    'Seed',40547);
```

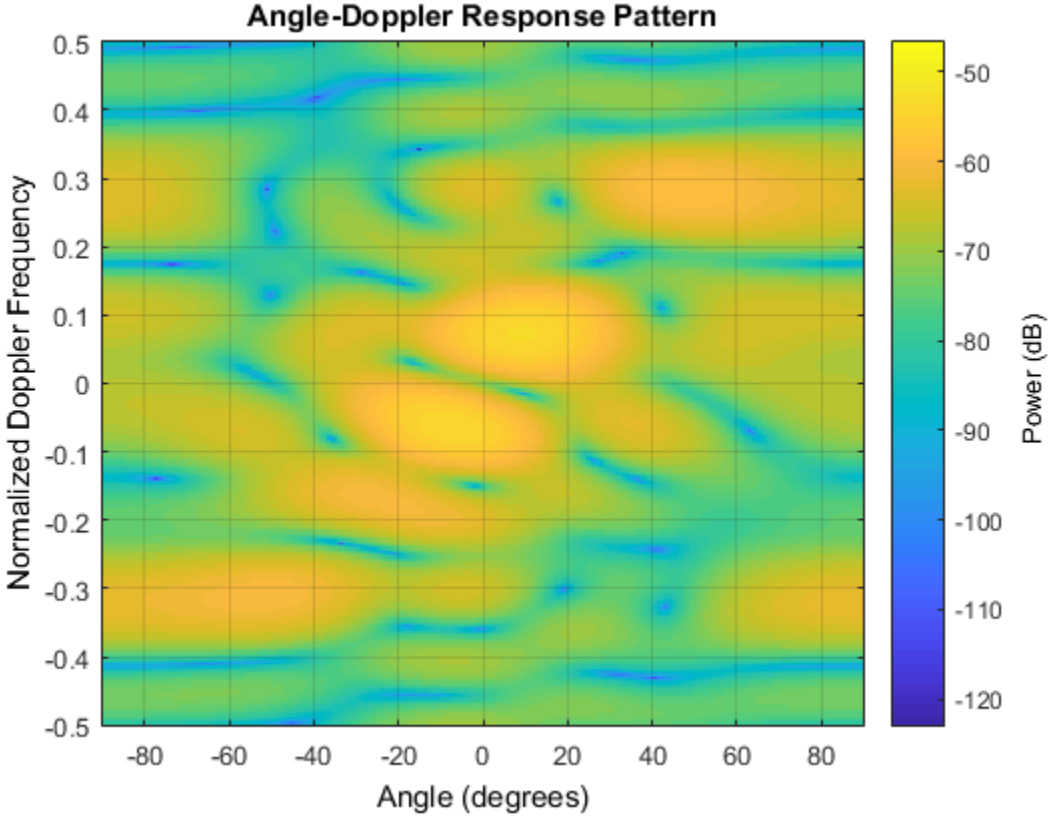
Simulate the clutter return for 10 pulses.

```
Nsamp = fs/prf;
Npulse = 10;
sig = zeros(Nsamp,Nele,Npulse);
for m = 1:Npulse
```

```
    sig(:,:,m) = clutter();
end
```

Plot the angle-Doppler response of the clutter at the 20th range bin.

```
response = phased.AngleDopplerResponse('SensorArray',array,...
    'OperatingFrequency',fc,'PropagationSpeed',c,'PRF',prf);
plotResponse(response,shiftdim(sig(20,:,:)),'NormalizeDoppler',true)
```



Simulate Clutter Using Known Transmit Signal

Simulate the clutter return from terrain with a gamma value of 0 dB. You input the transmit signal of the radar system when creating clutter. In this case, you do not use the `TransmitERP` property.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Set up the characteristics of the radar system. This system has a 4-element uniform linear array (ULA). The sample rate is 1 MHz, and the PRF is 10 kHz. The propagation speed is the speed of light, and the operating frequency is 300 MHz. The radar platform is flying 1 km above the ground with a path parallel to the ground along the array axis. The platform speed is 2 km/s. The mainlobe has a depression angle of 30°.

```
Nele = 4;
c = physconst('Lightspeed');
fc = 300.0e6;
lambda = c/fc;
ula = phased.ULA('NumElements',Nele,'ElementSpacing',lambda/2);
fs = 1.0e6;
prf = 10.0e3;
height = 1.0e3;
direction = [90;0];
speed = 2.0e3;
depang = 30;
```

Create the clutter simulation object and configure it to accept an transmit signal as an input argument. The configuration assumes the earth is flat. The maximum clutter range of interest is 5 km, and the maximum azimuth coverage is ±60°.

```
Rmax = 5000.0;
Azcov = 120.0;
tergamma = 0.0;
clutter = phased.ConstantGammaClutter('Sensor',ula,...
    'PropagationSpeed',c,'OperatingFrequency',fc,'PRF',prf,...
    'SampleRate',fs,'Gamma',tergamma,'EarthModel','Flat',...
    'TransmitSignalInputPort',true,'PlatformHeight',height,...
    'PlatformSpeed',speed,'PlatformDirection',direction,...
    'BroadsideDepressionAngle',depang,'MaximumRange',Rmax,...
    'AzimuthCoverage',Azcov,'SeedSource','Property',...
    'Seed',40547);
```

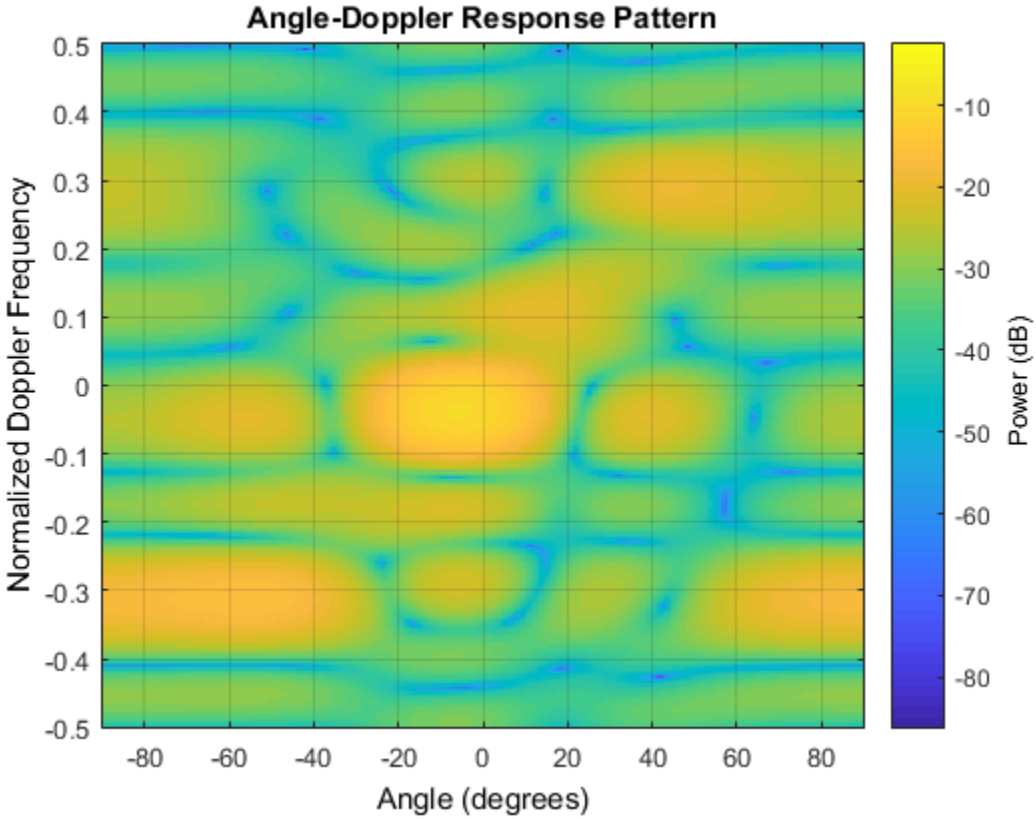
Simulate the clutter return for 10 pulses. At each step, pass the transmit signal as an input argument. The software computes the effective transmitted power of the signal. The transmit signal is a rectangular waveform with a pulse width of 2 µs.

```
tpower = 5.0e3;
pw = 2.0e-6;
```

```
X = tpower*ones(floor(pw*fs),1);
Nsamp = fs/prf;
Npulse = 10;
sig = zeros(Nsamp,Nele,Npulse);
for m = 1:Npulse
    sig(:,:,m) = step(clutter,X);
end
```

Plot the angle-Doppler response of the clutter at the 20th range bin.

```
response = phased.AngleDopplerResponse('SensorArray',ula,...
    'OperatingFrequency',fc,'PropagationSpeed',c,'PRF',prf);
plotResponse(response,shiftdim(sig(20,:,:)),'NormalizeDoppler',true)
```



- Ground Clutter Mitigation with Moving Target Indication (MTI) Radar

- “DPCA Pulse Canceller to Reject Clutter”

Tips

The clutter simulation that `ConstantGammaClutter` provides is based on these assumptions:

- The radar system is monostatic.
- The propagation is in free space.
- The terrain is homogeneous.
- The clutter patch is stationary during the coherence time. *Coherence time* indicates how frequently the software changes the set of random numbers in the clutter simulation.
- The signal is narrowband. Thus, the spatial response can be approximated by a phase shift. Similarly, the Doppler shift can be approximated by a phase shift.
- The radar system maintains a constant height during simulation.
- The radar system maintains a constant speed during simulation.

phased.CosineAntennaElement System object

Package: phased

Cosine antenna element

Description

The `CosineAntennaElement` object models an antenna with a cosine response in both azimuth and elevation. The main response axis (MRA) points to 0° azimuth and 0° elevation in the antenna coordinate system. When placed in a linear array, the MRA is normal to the array axis (see, for example, phased.ULA). When placed in a planar array, the MRA points along the array normal (see, for example, phased.URA).

To compute the response of the antenna element for specified directions:

1. Define and set up your cosine antenna element. See "Construction" on page 1-293.
2. Call step to compute the antenna response according to the properties of `phased.CosineAntennaElement`. The behavior of `step` is specific to each object in the toolbox.

This antenna element is not capable of supporting polarization.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.CosineAntennaElement` creates a cosine antenna system object, `H`, that models an antenna element whose response is cosine raised to a specified power greater than or equal to one in both the azimuth and elevation directions.

`H = phased.CosineAntennaElement(Name,Value)` creates a cosine antenna object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`FrequencyRange`

Operating frequency range

Specify the operating frequency range (in Hz) of the antenna element as a 1-by-2 row vector in the form `[LowerBound HigherBound]`. The antenna element has no response outside the specified frequency range.

Default: `[0 1e20]`

`CosinePower`

Exponent of cosine pattern

Specify the exponents of the cosine pattern as a scalar or a 1-by-2 vector. Exponent values must be real numbers greater than zero. When you set `CosinePower` to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the specified value. When you set `CosinePower` to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern and the second element is the exponent for the elevation direction cosine pattern.

Default: `[1.5 1.5]`

Methods

directivity	Directivity of cosine antenna element
isPolarizationCapable	Polarization capability
pattern	Plot cosine antenna element directivity and patterns
patternAzimuth	Plot cosine antenna element directivity or pattern versus azimuth
patternElevation	Plot cosine antenna element directivity or pattern versus elevation
step	Output response of antenna element

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

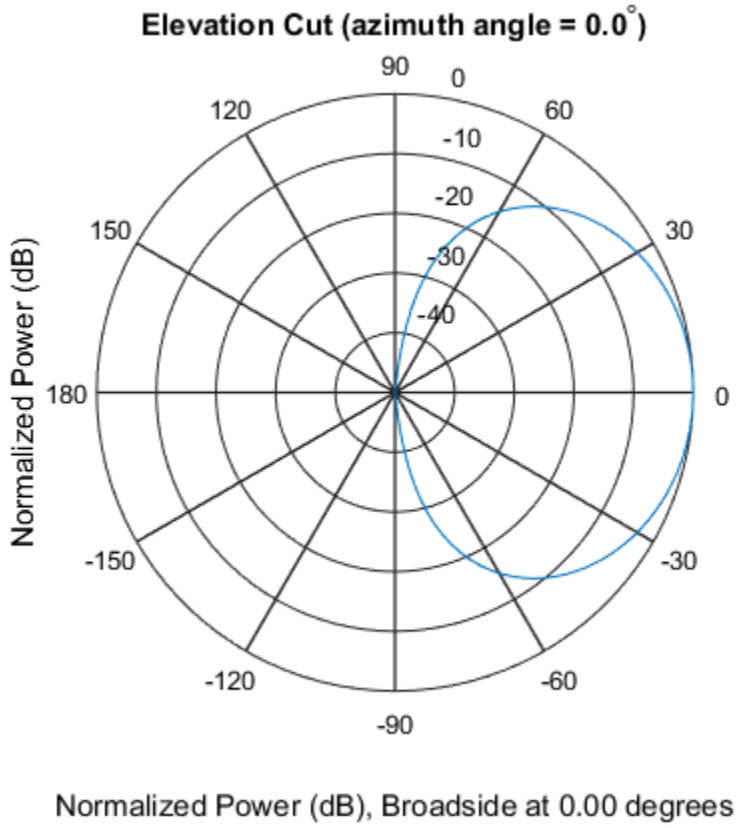
Calculate Response of Cosine Antenna

Construct a cosine pattern antenna and calculate its response at boresight (0 degrees azimuth and 0 degrees elevation). Then, plot the antenna pattern. Assume the antenna works between 800 MHz and 1.2 GHz and its operating frequency is 1 GHz.

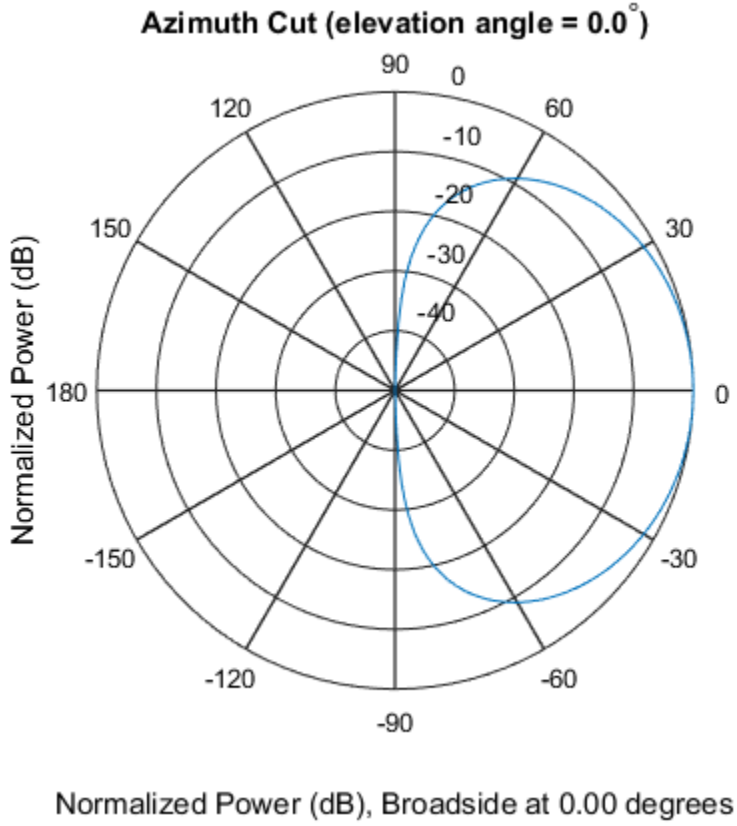
Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Set the azimuth exponent to 1.5 and elevation exponent to 2.5.

```
antenna = phased.CosineAntennaElement('FrequencyRange',[800e6 1.2e9],...
    'CosinePower',[1.5 2.5]);
fc = 1e9;
resp = antenna(fc,[0;0]);
pattern(antenna,fc,0,[-90:90],'Type','powerdb','CoordinateSystem','polar')
```



```
pattern(antenna,fc,[-180:180],0,'Type','powerdb','CoordinateSystem','polar')
```



Definitions

Cosine Response

The step method returns the *field response* (or *field pattern*)

$$f(az,el) = \cos^m(az)\cos^n(el)$$

of the cosine antenna element.

In this expression

- *az* is the azimuth angle.
- *el* is the elevation angle.
- The exponents *m* and *n* are real numbers greater than zero.

The response is defined for azimuth and elevation angles between –90° and 90°, inclusive, and is always positive. There is no response at the backside of a cosine antenna. The cosine response pattern achieves a maximum value of 1 at 0° azimuth and 0° elevation. Larger exponent values narrow the response pattern of the element and increase the directivity.

The *power response* (or *power pattern*) is the squared value of the field response.

$$P(az,el) = \cos^{2m}(az)\cos^{2n}(el)$$

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- `pattern`, `patternAzimuth`, `patternElevation`, and `plotResponse` methods are not supported.
- See "System Objects in MATLAB Code Generation" (MATLAB Coder).

Introduced in R2012a

directivity

System object: phased.CosineAntennaElement
Package: phased

Directivity of cosine antenna element

Syntax

```
D = directivity(H,FREQ,ANGLE)
```

Description

`D = directivity(H,FREQ,ANGLE)` returns the "Directivity (dBi)" on page 1-301 of a cosine antenna element, `H`, at frequencies specified by `FREQ` and in direction angles specified by `ANGLE`.

Input Arguments

`H` — Cosine antenna element

System object

Cosine antenna element specified as a phased.CosineAntennaElement System object.

Example: `H = phased.CosineAntennaElement;`

`FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the

directivity is returned as `-Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.

- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `-Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

`ANGLE` — Angles for computing directivity

1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Angles for computing directivity, specified as a 1-by-*M* real-valued row vector or a 2-by-*M* real-valued matrix, where *M* is the number of angular directions. Angle units are in degrees. If `ANGLE` is a 2-by-*M* matrix, then each column specifies a direction in azimuth and elevation, `[az;el]`. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°.

If `ANGLE` is a 1-by-*M* vector, then each entry represents an azimuth angle, with the elevation angle assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis.

Example: `[45 60; 0 10]`

Data Types: `double`

Output Arguments

`D` — Directivity

M-by-*L* matrix

Directivity, returned as an *M*-by-*L* matrix whose columns contain the directivities at the *M* angles specified by `ANGLE`. Each column corresponds to one of the *L* frequency values specified in `FREQ`. Directivity units are in dBi.

Examples

Directivity of Cosine Antenna Element

Compute the directivity of a cosine antenna element for a set of seven azimuth directions centered around boresight (zero degrees azimuth and zero degrees elevation). All elevation angles are set to zero degrees.

Create a cosine antenna element system object with the `CosinePower` exponents set to 1.8.

```
myAnt = phased.CosineAntennaElement('CosinePower',[1.8,1.8]);
```

Set the directivity angles so that the elevation angles are zero. Set the frequency to 1 GHz.

```
ang = [-30,-20,-10,0,10,20,30; 0,0,0,0,0,0,0];
freq = 1e9;
```

Compute the directivity

```
d = directivity(myAnt,freq,ang)
```

```
d =

    7.3890
    8.6654
    9.3985
    9.6379
    9.3985
    8.6654
    7.3890
```

The maximum directivity is at boresight.

Definitions

Directivity (dBi)

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit

more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element directivity” and “Array directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

phased.CosineAntennaElement.pattern

isPolarizationCapable

System object: phased.CosineAntennaElement
Package: phased

Polarization capability

Syntax

```
flag = isPolarizationCapable(h)
```

Description

`flag = isPolarizationCapable(h)` returns a Boolean value, `flag`, indicating whether the phased.CosineAntennaElement System object supports polarization. An antenna element supports polarization if it can create or respond to polarized fields. This object does not support polarization.

Input Arguments

h — Cosine antenna element

Cosine antenna element specified as a phased.CosineAntennaElement System object.

Output Arguments

flag — Polarization-capability flag

Polarization-capability flag returned as a Boolean value `true` if the antenna element supports polarization or `false` if it does not. Because the phased.CosineAntennaElement object does not support polarization, `flag` is always returned as `false`.

Examples

Cosine Antenna Does Not Support Polarization

Create a cosine antenna element using the `phased.CosineAntennaElement` System object™ and show that it does not support polarization.

```
antenna = phased.CosineAntennaElement('FrequencyRange',[1.0,10]*1e9);
isPolarizationCapable(antenna)
```

```
ans =

  logical

   0
```

The returned value `0` shows that the antenna element does not support polarization.

pattern

System object: phased.CosineAntennaElement
Package: phased

Plot cosine antenna element directivity and patterns

Syntax

```
pattern(sElem,FREQ)
pattern(sElem,FREQ,AZ)
pattern(sElem,FREQ,AZ,EL)
pattern( ___ ,Name,Value)
[PAT,AZ_ANG,EL_ANG] = pattern( ___ )
```

Description

`pattern(sElem,FREQ)` plots the 3-D array directivity pattern (in dBi) for the element specified in `sElem`. The operating frequency is specified in `FREQ`.

`pattern(sElem,FREQ,AZ)` plots the element directivity pattern at the specified azimuth angle.

`pattern(sElem,FREQ,AZ,EL)` plots the element directivity pattern at specified azimuth and elevation angles.

`pattern( ___ ,Name,Value)` plots the element pattern with additional options specified by one or more `Name,Value` pair arguments.

`[PAT,AZ_ANG,EL_ANG] = pattern( ___ )` returns the element pattern in `PAT`. The `AZ_ANG` output contains the coordinate values corresponding to the rows of `PAT`. The `EL_ANG` output contains the coordinate values corresponding to the columns of `PAT`. If the `'CoordinateSystem'` parameter is set to `'uv'`, then `AZ_ANG` contains the *U* coordinates of the pattern and `EL_ANG` contains the *V* coordinates of the pattern. Otherwise, they are in angular units in degrees. *UV* units are dimensionless.

Note: This method replaces the `plotResponse` method. See "Convert plotResponse to pattern" on page 1-313 for guidelines on how to use `pattern` in place of `plotResponse`.

Input Arguments

`sElem` — Cosine antenna element

System object

Cosine antenna element, specified as a phased.CosineAntennaElement System object.

Example: `sElem = phased.CosineAntennaElement;`

`FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `-Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `-Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

`AZ` — Azimuth angles

`[-180:180]` (default) | 1-by-*M* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a 1-by-*M* real-valued row vector where *M* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, this angle is positive.

Example: `[-45:2:45]`

Data Types: `double`

`EL` — Elevation angles

`[-90:90]` (default) | 1-by-*N* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a 1-by-*N* real-valued row vector where *N* is the number of desired elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and *xy*-plane. When measured towards the *z*-axis, this angle is positive.

Example: `[-75:1:70]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'CoordinateSystem'` — Plotting coordinate system

`'polar'` (default) | `'rectangular'` | `'uv'`

Plotting coordinate system of the pattern, specified as the comma-separated pair consisting of `'CoordinateSystem'` and one of `'polar'`, `'rectangular'`, or `'uv'`. When `'CoordinateSystem'` is set to `'polar'` or `'rectangular'`, the `AZ` and `EL` arguments specify the pattern azimuth and elevation, respectively. `AZ` values must lie between –180° and 180°. `EL` values must lie between –90° and 90°. If `'CoordinateSystem'` is set to `'uv'`, `AZ` and `EL` then specify *U* and *V* coordinates, respectively. `AZ` and `EL` must lie between -1 and 1.

Example: `'uv'`

Data Types: `char`

'Type' — Displayed pattern type

'directivity' (default) | 'efield' | 'power' | 'powerdb'

Displayed pattern type, specified as the comma-separated pair consisting of 'Type' and one of

- 'directivity' — directivity pattern measured in dBi.
- 'efield' — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- 'power' — power pattern of the sensor or array defined as the square of the field pattern.
- 'powerdb' — power pattern converted to dB.

Example: 'powerdb'

Data Types: char

'Normalize' — Display normalize pattern

true (default) | false

Display normalized pattern, specified as the comma-separated pair consisting of 'Normalize' and a Boolean. Set this parameter to true to display a normalized pattern. When you set 'Type' to 'directivity', this parameter does not apply. Directivity patterns are already normalized.

Example:

Data Types: logical

'PlotStyle' — Plotting style

'overlay' (default) | 'waterfall'

Plotting style, specified as the comma-separated pair consisting of 'Plotstyle' and either 'overlay' or 'waterfall'. This parameter applies when you specify multiple frequencies in FREQ in 2-D plots. You can draw 2-D plots by setting one of the arguments AZ or EL to a scalar.

Example:

Data Types: char

Output Arguments

PAT — Element pattern

M-by-*N* real-valued matrix

Element pattern, returned as an *M*-by-*N* real-valued matrix. The dimensions of PAT correspond to the dimensions of the output arguments AZ_ANG and EL_ANG.

AZ_ANG — Azimuth angles

scalar | 1-by-*M* real-valued row vector

Azimuth angles for displaying directivity or response pattern, returned as a scalar or 1-by-*M* real-valued row vector corresponding to the dimension set in AZ. The rows of PAT correspond to the values in AZ_ANG.

EL_ANG — Elevation angles

scalar | 1-by-*N* real-valued row vector

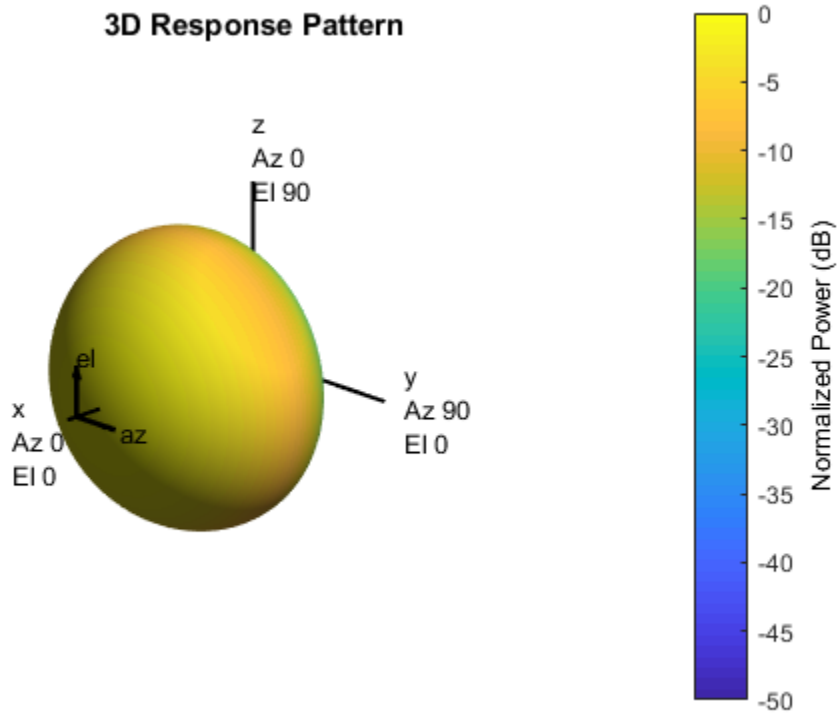
Elevation angles for displaying directivity or response, returned as a scalar or 1-by-*N* real-valued row vector corresponding to the dimension set in EL. The columns of PAT correspond to the values in EL_ANG.

Examples

Plot 3-D Polar Pattern of Cosine Antenna

Construct a cosine antenna element using default parameters. Then, plot the 3-D polar power pattern. Assume the antenna operating frequency is 1 GHz. Then, plot the antenna's response in 3-D polar format.

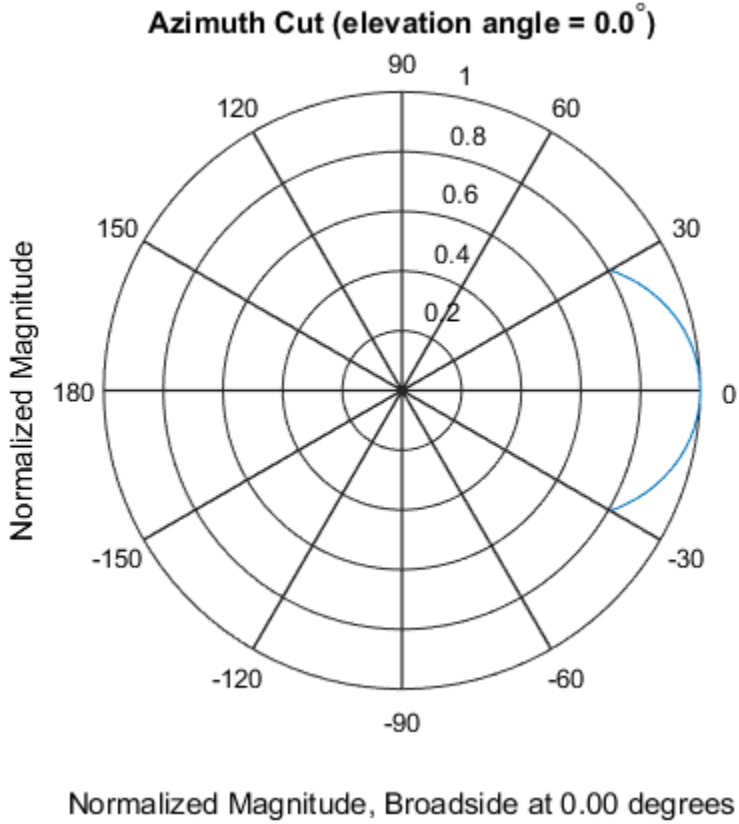
```
sCos = phased.CosineAntennaElement;
fc = 1e9;
pattern(sCos,fc,[-180:180],[-90:90],...
    'Type','powerdb',...
    'CoordinateSystem','polar')
```



Plot Azimuth-Cut of Cosine Antenna Response

Construct a cosine antenna element using default parameters. Then, plot the pattern of field magnitude. Assume the antenna operating frequency is 1 GHz. Restrict the response to the range of azimuth angles from -30 to 30 degrees in 0.1 degree increments. The default elevation angle is 0 degrees.

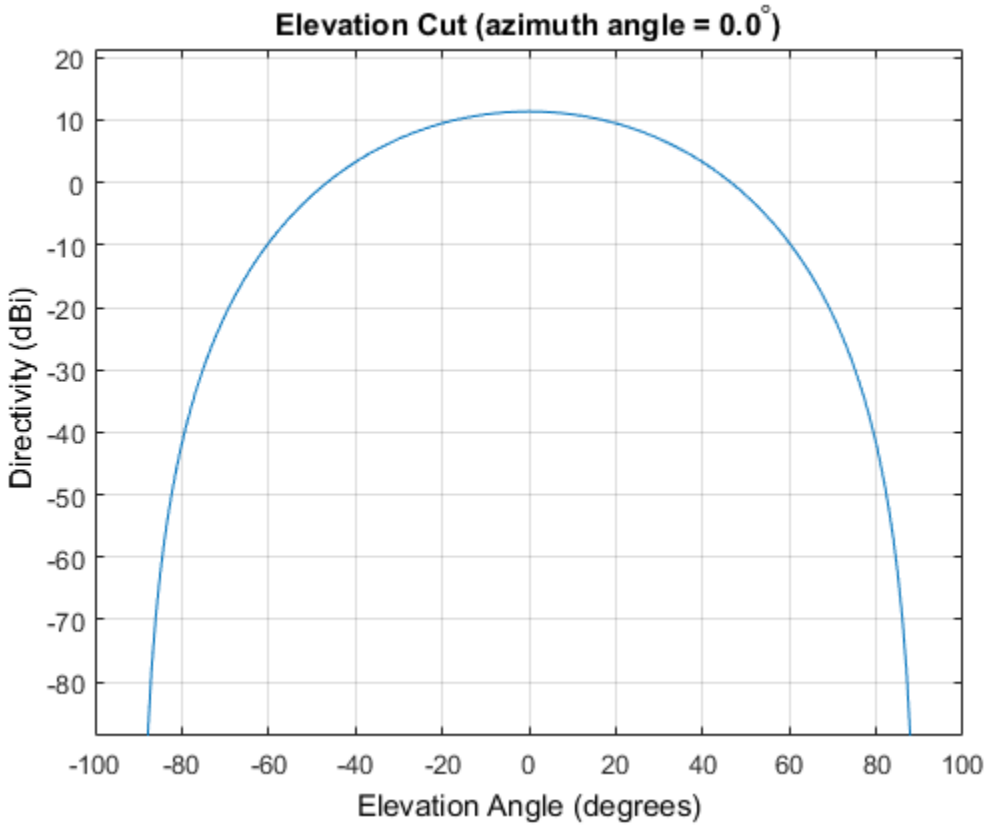
```
sCos = phased.CosineAntennaElement;
fc = 1e9;
pattern(sCos,fc,[-30:0.1:30],0,...
    'Type','efield',...
    'CoordinateSystem','polar')
```



Directivity of Cosine Antenna

Construct a cosine-pattern antenna. Assume the antenna works between 1 and 2 GHz and its operating frequency is 1.5 GHz. Set the azimuth angle cosine power to 2.5 and the elevation angle cosine power to 3.5. Then, plot an elevation cut of its directivity.

```
sCos = phased.CosineAntennaElement('FrequencyRange',...
    [1e9 2e9],'CosinePower',[2.5,3.5]);
fc = 1.5e9;
pattern(sCos,fc,0,[-90:90],...
    'Type','directivity',...
    'CoordinateSystem','rectangular')
```



The directivity is maximum at 0 degrees elevation and attains a value of approximately 12 dB.

More About

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant

intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on "Element directivity" and "Array directivity".

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

Convert plotResponse to pattern

For antenna, microphone, and array System objects, the `pattern` method replaces the `plotResponse` method. In addition, two new simplified methods exist just to draw 2-D azimuth and elevation pattern plots. These methods are `azimuthPattern` and `elevationPattern`.

The following table is a guide for converting your code from using `plotResponse` to `pattern`. Notice that some of the inputs have changed from *input arguments* to *Name-Value* pairs and conversely. The general `pattern` method syntax is

```
pattern(H,FREQ,AZ,EL,'Name1','Value1',...,'NameN','ValueN')
```

plotResponse Inputs	plotResponse Description	pattern Inputs
`H` argument	Antenna, microphone, or array System object.	`H` argument (no change)

plotResponse Inputs	plotResponse Description	pattern Inputs
FREQ argument	Operating frequency.	FREQ argument (no change)
V argument	Propagation speed. This argument is used only for arrays.	'PropagationSpeed' name-value pair. This parameter is only used for arrays.

<table>
<tr><th>plotResponse Inputs</th><th>plotResponse Description</th><th>pattern Inputs</th></tr>

If you set CoordinateSystem to 'uv', enter the UV grid values using AZ and EL.</td></tr>
<tr><td>'CutAngle' name-value pair</td><td>Constant angle at to take an azimuth or elevation cut. When producing a 2-D plot and when 'RespCut' is set to 'Az' or 'El', use 'CutAngle' to set the slice across which to view the plot.</td><td>No equivalent name-value pair. To create a cut, specify either AZ or EL as a scalar, not a vector.</td></tr>
</table>

plotResponse Inputs	plotResponse Description	pattern Inputs
`'NormalizeResponse'` name-value pair	Normalizes the plot. When `'Unit'` is set to `'dbi'`, you cannot specify `'NormalizeResponse'`.	`'Normalize'` name-value pair. When `'Type'` is set to `'directivity'`, you cannot specify `'Normalize'`. .
`'OverlayFreq'` name-value pair	Plot multiple frequencies on the same 2-D plot. Available only when `'Format'` is set to `'line'` or `'uv'` and `'RespCut'` is not set to `'3D'`. The value `true` produces an overlay plot and the value `false` produces a waterfall plot.	`'PlotStyle'` name-value pair plots multiple frequencies on the same 2-D plot. The values `'overlay'` and `'waterfall'` correspond to `'OverlayFreq'` values of `true` and `false`. The option `'waterfall'` is allowed only when `'CoordinateSystem'` is set to `'rectangular'` or `'uv'`.
`'Polarization'` name-value pair	Determines how to plot polarized fields. Options are `'None'`, `'Combined'`, `'H'`, or `'V'`.	`'Polarization'` name-value pair determines how to plot polarized fields. The `'None'` option is removed. The options `'Combined'`, `'H'`, or `'V'` are unchanged.

`'Unit'` name-value pair	Determines the plot units. Choose `'db'`, `'mag'`, `'pow'`, or `'dbi'`, where the default is `'db'`.	`'Type'` name-value pair, uses equivalent options with different names
		
		plotResponse pattern
		`'db'` `'powerdb'`
		`'mag'` `'efield'`
		`'pow'` `'power'`
		`'dbi'` `'directivity'`

`'Weights'` name-value pair	Array element tapers (or weights).	`'Weights'` name-value pair (no change).

plotResponse Inputs	plotResponse Description	pattern Inputs
`'AzimuthAngles'` name-value pair	Azimuth angles used to display the antenna or array response.	`AZ` argument
`'ElevationAngles'` name-value pair	Elevation angles used to display the antenna or array response.	`EL` argument
`'UGrid'` name-value pair	Contains *U* coordinates in *UV*-space.	`AZ` argument when `'CoordinateSystem'` name-value pair is set to `'uv'`
`'VGrid'` name-value pair	Contains *V*-coordinates in *UV*-space.	`EL` argument when `'CoordinateSystem'` name-value pair is set to `'uv'`

System Objects

phased.CosineAntennaElement.patternAzimuth | phased.CosineAntennaElement.patternElevation | phased.CosineAntennaElement.plotResponse

Introduced in R2015a

patternAzimuth

System object: phased.CosineAntennaElement
Package: phased

Plot cosine antenna element directivity or pattern versus azimuth

Syntax

```
patternAzimuth(sElem,FREQ)
patternAzimuth(sElem,FREQ,EL)
patternAzimuth(sElem,FREQ,EL,Name,Value)
PAT = patternAzimuth( ___ )
```

Description

`patternAzimuth(sElem,FREQ)` plots the 2-D element directivity pattern versus azimuth (in dBi) for the element `sElem` at zero degrees elevation angle. The argument `FREQ` specifies the operating frequency.

`patternAzimuth(sElem,FREQ,EL)`, in addition, plots the 2-D element directivity pattern versus azimuth (in dBi) at the elevation angle specified by `EL`. When `EL` is a vector, multiple overlaid plots are created.

`patternAzimuth(sElem,FREQ,EL,Name,Value)` plots the element pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternAzimuth( ___ )` returns the element pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Azimuth'` parameter and the `EL` input argument.

Input Arguments

`sElem` — Cosine antenna element

System object

Cosine antenna element, specified as a phased.CosineAntennaElement System object.

Example: `sElem = phased.CosineAntennaElement;`

FREQ — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

EL — Elevation angles

1-by-*N* real-valued row vector

Elevation angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector. The quantity *N* is the number of requested elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and the *xy* plane. When measured toward the *z*-axis, this angle is positive.

Example: `[0,10,20]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Type'` — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

`'Azimuth'` — Azimuth angles

`[-180:180]` (default) | 1-by-*P* real-valued row vector

Azimuth angles, specified as the comma-separated pair consisting of `'Azimuth'` and a 1-by-*P* real-valued row vector. Azimuth angles define where the array pattern is calculated.

Example: `'Azimuth',[-90:2:90]`

Data Types: `double`

Output Arguments

`PAT` — Element directivity or pattern

L-by-*N* real-valued matrix

Element directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of azimuth values determined by the `'Azimuth'` name-value pair argument. The dimension *N* is the number of elevation angles, as determined by the `EL` input argument.

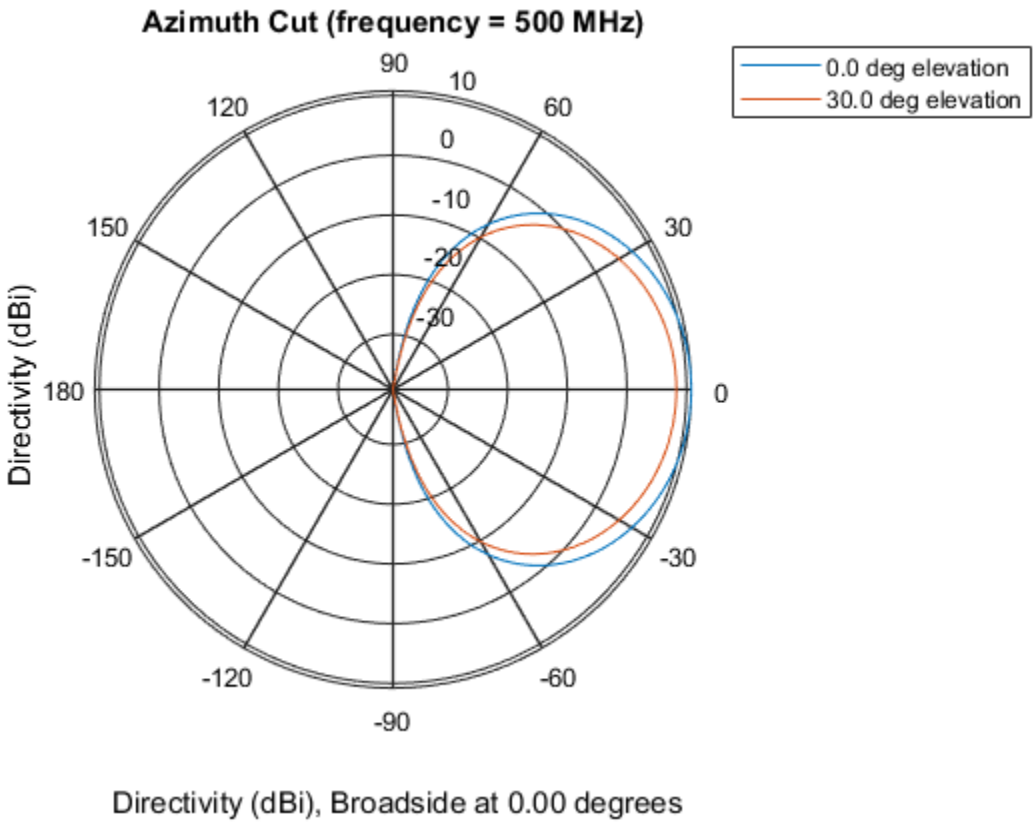
Examples

Reduced Azimuth Pattern of Cosine Antenna Element

Plot an azimuth cut of directivity of a cosine antenna element at 0 and 10 degrees elevation. Assume the operating frequency is 500 MHz.

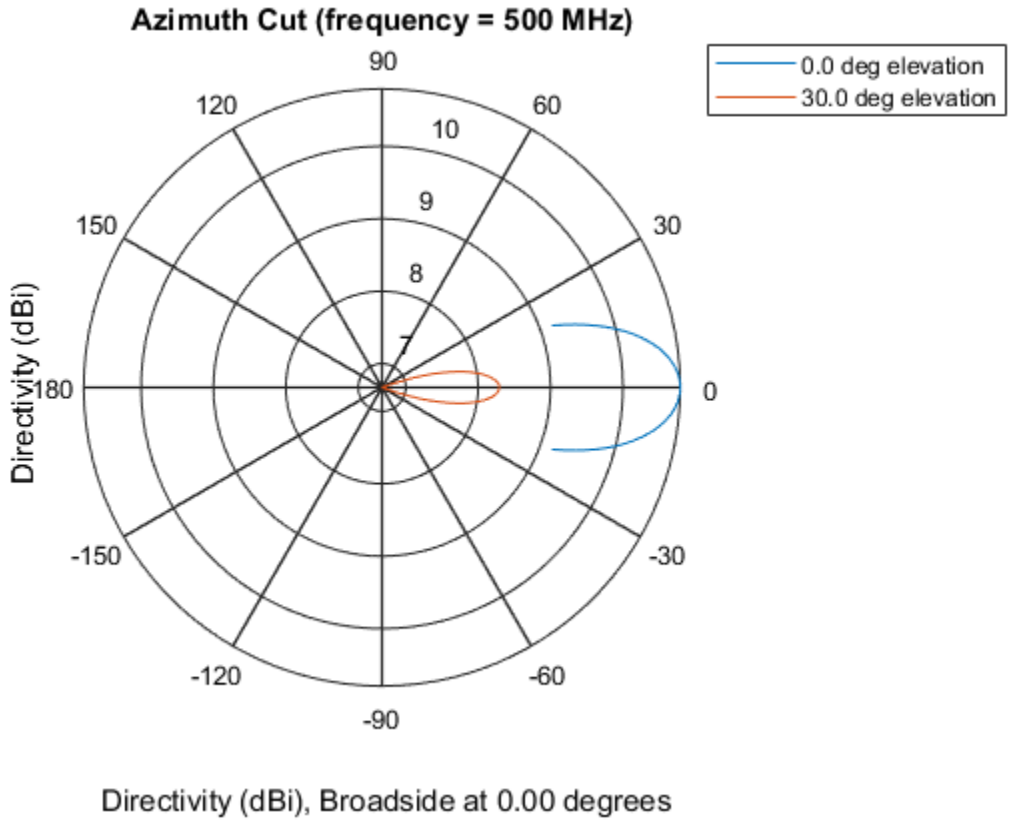
Create the Antenna Element

```
fc = 500e6;
sCos = phased.CosineAntennaElement('FrequencyRange',[100,900]*1e6,...
    'CosinePower',[3,2]);
patternAzimuth(sCos,fc,[0 30])
```



Plot a reduced range of azimuth angles using the `Azimuth` parameter. Notice the change in scale.

```
patternAzimuth(sCos,fc,[0 30],'Azimuth',[-20:20])
```



Definitions

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit

more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element directivity” and “Array directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

Introduced in R2015a

patternElevation

System object: phased.CosineAntennaElement
Package: phased

Plot cosine antenna element directivity or pattern versus elevation

Syntax

```
patternElevation(sElem,FREQ)
patternElevation(sElem,FREQ,AZ)
patternElevation(sElem,FREQ,AZ,Name,Value)
PAT = patternElevation( ___ )
```

Description

`patternElevation(sElem,FREQ)` plots the 2-D element directivity pattern versus elevation (in dBi) for the element `sElem` at zero degrees azimuth angle. The argument `FREQ` specifies the operating frequency.

`patternElevation(sElem,FREQ,AZ)`, in addition, plots the 2-D element directivity pattern versus elevation (in dBi) at the azimuth angle specified by `AZ`. When `AZ` is a vector, multiple overlaid plots are created.

`patternElevation(sElem,FREQ,AZ,Name,Value)` plots the element pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternElevation( ___ )` returns the element pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Elevation'` parameter and the `AZ` input argument.

Input Arguments

`sElem` — Cosine antenna element

System object

Cosine antenna element, specified as a phased.CosineAntennaElement System object.

Example: `sElem = phased.CosineAntennaElement;`

FREQ — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `-Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `-Inf`.

Example: `1e8`

Data Types: `double`

AZ — Azimuth angles for computing directivity and pattern

1-by-*N* real-valued row vector

Azimuth angles for computing sensor or array directivities and patterns, specified as a 1-by-*M* real-valued row vector where *N* is the number of desired azimuth directions. Angle units are in degrees. The azimuth angle must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `[0,10,20]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Type'` — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

`'Elevation'` — Elevation angles

`[-90:90]` (default) | 1-by-*P* real-valued row vector

Elevation angles, specified as the comma-separated pair consisting of `'Elevation'` and a 1-by-*P* real-valued row vector. Elevation angles define where the array pattern is calculated.

Example: `'Elevation',[-90:2:90]`

Data Types: `double`

Output Arguments

`PAT` — Element directivity or pattern

L-by-*N* real-valued matrix

Element directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of elevation angles determined by the `'Elevation'` name-value pair argument. The dimension *N* is the number of azimuth angles determined by the `AZ` argument.

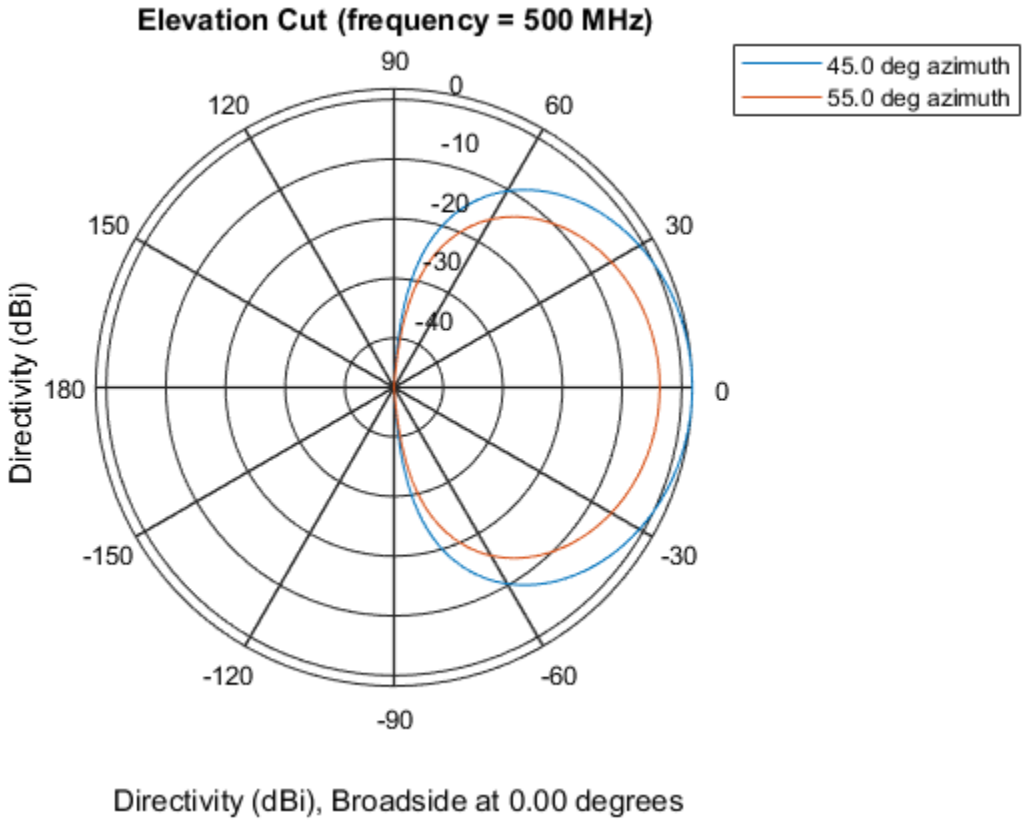
Examples

Reduced Elevation Pattern of Cosine Antenna Element

Plot an elevation cut of directivity of a cosine antenna element at 45 and 55 degrees azimuth. Assume the operating frequency is 500 MHz.

Create the Antenna Element

```
fc = 500e6;
sCos = phased.CosineAntennaElement('FrequencyRange',[100,900]*1e6,...
    'CosinePower',[3,2]);
patternElevation(sCos,fc,[45 55])
```



Plot a reduced range of azimuth angles using the `Azimuth` parameter. Notice the change in scale.

```
patternElevation(sCos,fc,[45 55],'Elevation',[-20:20])
```

phased.CosineAntennaElement.pattern |
phased.CosineAntennaElement.patternAzimuth

Introduced in R2015a

plotResponse

System object: phased.CosineAntennaElement
Package: phased

Plot response pattern of antenna

Syntax

```
plotResponse(H,FREQ)
plotResponse(H,FREQ,Name,Value)
hPlot = plotResponse( ___ )
```

Description

`plotResponse(H,FREQ)` plots the element response pattern along the azimuth cut, where the elevation angle is 0. The operating frequency is specified in `FREQ`.

`plotResponse(H,FREQ,Name,Value)` plots the element response with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = plotResponse( ___ )` returns handles of the lines or surface in the figure window, using any of the input arguments in the previous syntaxes.

Input Arguments

`H`

Element System object

`FREQ`

Operating frequency in Hertz specified as a scalar or 1–by-*K* row vector. `FREQ` must lie within the range specified by the `FrequencyVector` property of `H`. If you set the `'RespCut'` property of `H` to `'3D'`, `FREQ` must be a scalar. When `FREQ` is a row vector, `plotResponse` draws multiple frequency responses on the same axes.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'CutAngle'`

Cut angle specified as a scalar. This argument is applicable only when `RespCut` is `'Az'` or `'El'`. If `RespCut` is `'Az'`, `CutAngle` must be between –90 and 90. If `RespCut` is `'El'`, `CutAngle` must be between –180 and 180.

Default: `0`

`'Format'`

Format of the plot, using one of `'Line'`, `'Polar'`, or `'UV'`. If you set `Format` to `'UV'`, `FREQ` must be a scalar.

Default: `'Line'`

`'NormalizeResponse'`

Set this value to `true` to normalize the response pattern. Set this value to `false` to plot the response pattern without normalizing it. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

Default: `true`

`'OverlayFreq'`

Set this value to `true` to overlay pattern cuts in a 2-D line plot. Set this value to `false` to plot pattern cuts against frequency in a 3-D waterfall plot. If this value is `false`, `FREQ` must be a vector with at least two entries.

This parameter applies only when `Format` is not `'Polar'` and RespCut is not `'3D'`.

Default: `true`

`'Polarization'`

Specify the polarization options for plotting the antenna response pattern. The allowable values are `|'None' | 'Combined' | 'H' | 'V' |` where

- `'None'` specifies plotting a nonpolarized response pattern
- `'Combined'` specifies plotting a combined polarization response pattern
- `'H'` specifies plotting the horizontal polarization response pattern
- `'V'` specifies plotting the vertical polarization response pattern

For antennas that do not support polarization, the only allowed value is `'None'`. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

Default: `'None'`

`'RespCut'`

Cut of the response. Valid values depend on `Format`, as follows:

- If `Format` is `'Line'` or `'Polar'`, the valid values of `RespCut` are `'Az'`, `'El'`, and `'3D'`. The default is `'Az'`.
- If `Format` is `'UV'`, the valid values of `RespCut` are `'U'` and `'3D'`. The default is `'U'`.

If you set `RespCut` to `'3D'`, `FREQ` must be a scalar.

`'Unit'`

The unit of the plot. Valid values are `'db'`, `'mag'`, `'pow'`, or `'dbi'`. This parameter determines the type of plot that is produced.

Unit value	Plot type
`db`	power pattern in dB scale
`mag`	field pattern
`pow`	power pattern
`dbi`	directivity

Default: `'db'`

`'AzimuthAngles'`

Azimuth angles for plotting element response, specified as a row vector. The `AzimuthAngles` parameter sets the display range and resolution of azimuth angles for

visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'Az'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of azimuth angles should lie between –180° and 180° and must be in nondecreasing order. When you set the `RespCut` parameter to `'3D'`, you can set the `AzimuthAngles` and `ElevationAngles` parameters simultaneously.

Default: `[-180:180]`

`'ElevationAngles'`

Elevation angles for plotting element response, specified as a row vector. The `ElevationAngles` parameter sets the display range and resolution of elevation angles for visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'El'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of elevation angles should lie between –90° and 90° and must be in nondecreasing order. When you set the `RespCut` parameter to `'3D'`, you can set the `ElevationAngles` and `AzimuthAngles` parameters simultaneously.

Default: `[-90:90]`

`'UGrid'`

U coordinate values for plotting element response, specified as a row vector. The `UGrid` parameter sets the display range and resolution of the *U* coordinates for visualizing the radiation pattern in *U*/*V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'U'` or `'3D'`. The values of `UGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set the `UGrid` and `VGrid` parameters simultaneously.

Default: `[-1:0.01:1]`

`'VGrid'`

V coordinate values for plotting element response, specified as a row vector. The `VGrid` parameter sets the display range and resolution of the *V* coordinates for visualizing the radiation pattern in *U*/*V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'3D'`. The values of `VGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set the `VGrid` and `UGrid` parameters simultaneously.

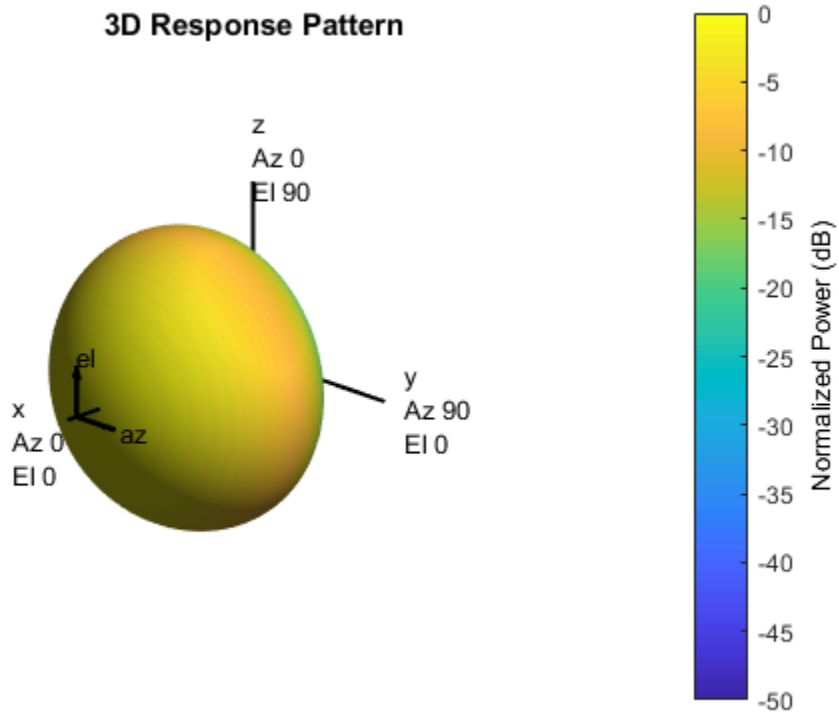
Default: `[-1:0.01:1]`

Examples

Plot 3-D Polar Response of Cosine Antenna

This example shows how to plot the 3-D polar response of a cosine antenna element. Construct a cosine antenna element using default parameters. Assume the antenna operating frequency is 1 GHz. Then, plot the antenna's response in 3-D polar format.

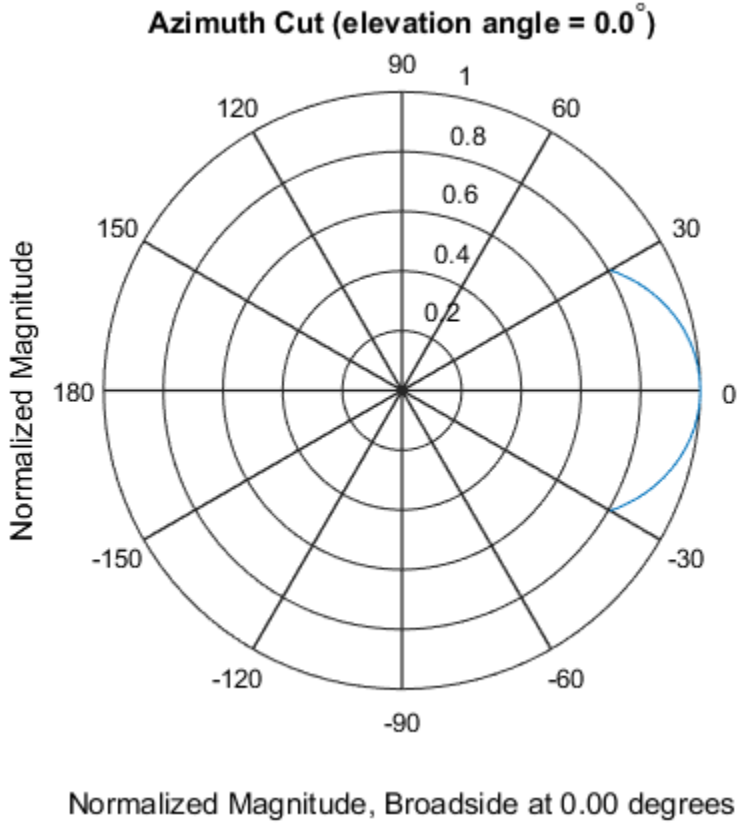
```
hcos = phased.CosineAntennaElement;
plotResponse(hcos,1e9,'Format','Polar','RespCut','3D');
```



Plot Azimuth-Cut of Cosine Antenna Response

This example shows how to plot an azimuth-cut of the cosine antenna response. Construct a cosine antenna element using default parameters. Assume the antenna operating frequency is 1 GHz. Restrict the response to the range of azimuth angles from -30 to 30 degrees in 0.1 degree increments. The default elevation angle is 0 degrees.

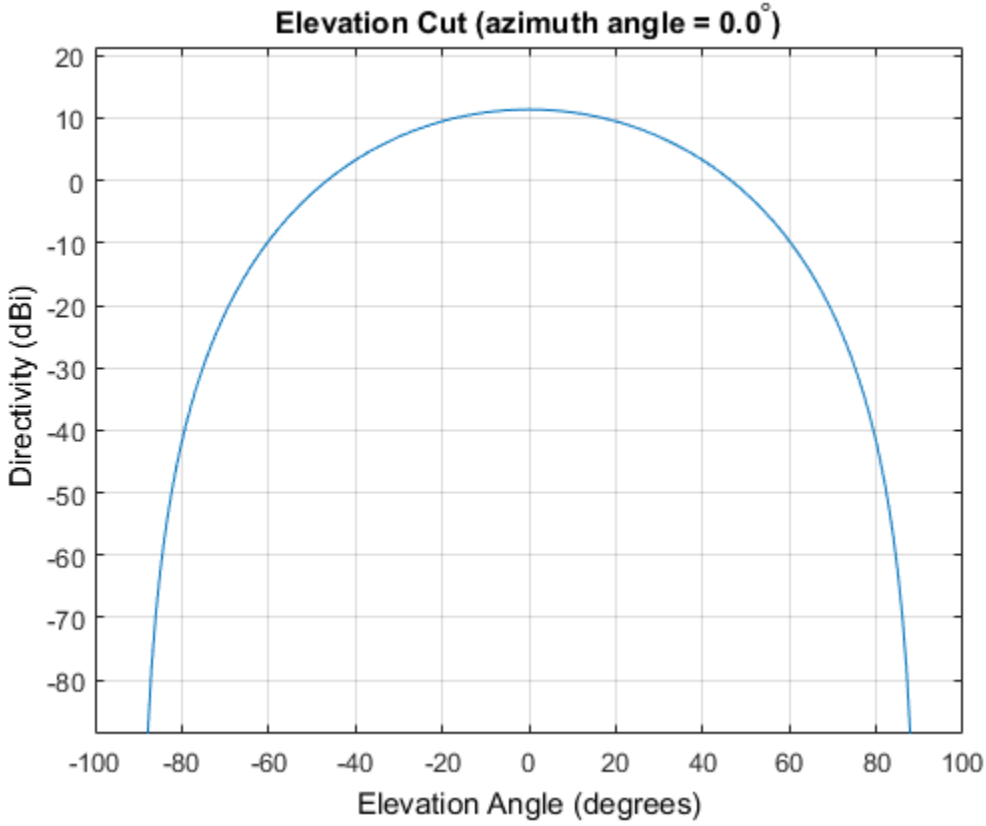
```
hcos = phased.CosineAntennaElement;
plotResponse(hcos,1e9,'Format','Polar','RespCut','Az',...
    'AzimuthAngles',[-30:0.1:30],'Unit','mag');
```



Plot Directivity of Cosine Antenna

This example shows how to construct a cosine-pattern antenna and plot an elevation cut of its directivity. Assume the antenna works between 1 and 2 GHz and its operating frequency is 1.5 GHz. Set the azimuth angle cosine power to 2.5 and the elevation angle cosine power to 3.5.

```
sCos = phased.CosineAntennaElement('FrequencyRange',...
    [1e9 2e9],'CosinePower',[2.5,3.5]);
plotResponse(sCos,1.5e9,'RespCut','El','Unit','dbi');
```



The directivity is maximum at 0 degrees elevation and attains a value of approximately 12 dB.

step

System object: phased.CosineAntennaElement
Package: phased

Output response of antenna element

Syntax

```
RESP = step(H,FREQ,ANG)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`RESP = step(H,FREQ,ANG)` returns the antenna's voltage response `RESP` at operating frequencies specified in `FREQ` and directions specified in `ANG`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`H`

Antenna element object.

FREQ

Operating frequencies of antenna in hertz. FREQ is a row vector of length L.

ANG

Directions in degrees. ANG can be either a 2-by-M matrix or a row vector of length M.

If ANG is a 2-by-M matrix, each column of the matrix specifies the direction in the form [azimuth; elevation]. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

If ANG is a row vector of length M, each element specifies a direction's azimuth angle. In this case, the corresponding elevation angle is assumed to be 0.

Output Arguments

RESP

Voltage response of antenna element specified as an *M*-by-*L*, complex-valued matrix. In this matrix, *M* represents the number of angles specified in ANG while *L* represents the number of frequencies specified in FREQ.

Examples

Cosine Antenna Response

Construct a cosine antenna element. The cosine response is raised to a power of 1.5 in both azimuth and elevation. The antenna frequency range lies in the X band (from 8 to 12 GHz) at 10 GHz. Obtain the antenna's response for an incident angle of 30° azimuth and 5° elevation.

```
antenna = phased.CosineAntennaElement('FrequencyRange',[8e9 12e9], ...
    'CosinePower',1.5);
fc = 10.0e9;
ang = [30;5];
resp = antenna(fc,ang)

resp =
```

```
0.8013
```

Definitions

Cosine Response

The step method returns the *field response* (or *field pattern*)

$$f(az,el) = \cos^m(az)\cos^n(el)$$

of the cosine antenna element.

In this expression

- az is the azimuth angle.
- el is the elevation angle.
- The exponents m and n are real numbers greater than zero.

The response is defined for azimuth and elevation angles between –90° and 90°, inclusive, and is always positive. There is no response at the backside of a cosine antenna. The cosine response pattern achieves a maximum value of 1 at 0° azimuth and 0° elevation. Larger exponent values narrow the response pattern of the element and increase the directivity.

The *power response* (or *power pattern*) is the squared value of the field response.

$$P(az,el) = \cos^{2m}(az)\cos^{2n}(el)$$

phased.CrossedDipoleAntennaElement System object

Package: phased

Crossed-dipole antenna element

Description

The `phased.CrossedDipoleAntennaElement` System object models a *crossed-dipole antenna element*. A crossed-dipole antenna is often used for generating circularly polarized fields. A crossed-dipole antenna is formed from two orthogonal short-dipole antennas, one along y-axis and the other along the z-axis in the antenna's local coordinate system. This antenna object generates right-handed circularly polarized fields along the *x*-axis (defined by 0° azimuth and 0° elevation angles).

To compute the response of the antenna element for specified directions:

1. Define and set up your crossed-dipole antenna element. See "Construction" on page 1-342.
2. Call step to compute the antenna response according to the properties of `phased.CrossedDipoleAntennaElement`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`h = phased.CrossedDipoleAntennaElement` creates the system object, `h`, to model a crossed-dipole antenna element.

`h = phased.CrossedDipoleAntennaElement(Name,Value)` creates the system object, `h`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`FrequencyRange`

Antenna operating frequency range

Antenna operating frequency range specified as a 1-by-2 row vector in the form of `[LowerBound HigherBound]`. This defines the frequency range over which the antenna has a response. The antenna element has no response outside the specified frequency range.

Default: `[0 1e20]`

Methods

directivity	Directivity of crossed-dipole antenna element
isPolarizationCapable	Polarization capability
pattern	Plot crossed-dipole antenna element directivity and patterns
patternAzimuth	Plot crossed-dipole antenna element directivity or pattern versus azimuth
patternElevation	Plot crossed-dipole antenna element directivity or pattern versus elevation
plotResponse	Plot response pattern of antenna
step	Output response of antenna element

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Plot Response of a Crossed-Dipole Antenna

Examine the response patterns of a crossed-dipole antenna used in an L-band radar with a frequency range between 1-2 GHz.

First, set up the radar parameters, and obtain the vertical and horizontal polarization responses at five different directions: elevation angles -30, -15, 0, 15 and 30 degrees, all at 0 degrees azimuth angle. The responses are computed at an operating frequency of 1.5 GHz.

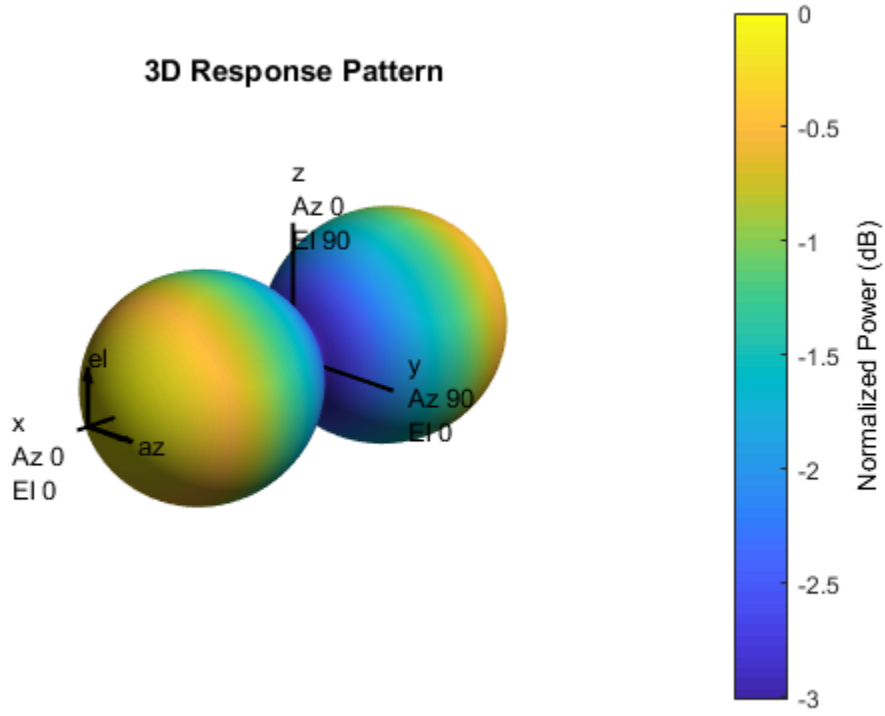
```
sCD = phased.CrossedDipoleAntennaElement(...
    'FrequencyRange',[1,2]*1e9);
fc = 1.5e9;
resp = step(sCD,fc,[0,0,0,0,0;-30,-15,0,15,30]);
[resp.V, resp.H]
```

```
ans =

  -1.0607 + 0.0000i   0.0000 - 1.2247i
  -1.1830 + 0.0000i   0.0000 - 1.2247i
  -1.2247 + 0.0000i   0.0000 - 1.2247i
  -1.1830 + 0.0000i   0.0000 - 1.2247i
  -1.0607 + 0.0000i   0.0000 - 1.2247i
```

Next, draw a 3-D plot of the combined polarization response.

```
pattern(sCD,fc,[-180:180],[-90:90],...
    'CoordinateSystem','polar',...
    'Type','powerdb',...
    'Polarization','combined')
```



Algorithms

The total response of a crossed-dipole antenna element is a combination of its frequency response and spatial response. `phased.CrossedDipoleAntennaElement` calculates both responses using nearest neighbor interpolation, and then multiplies the responses to form the total response.

directivity

System object: phased.CrossedDipoleAntennaElement
Package: phased

Directivity of crossed-dipole antenna element

Syntax

```
D = directivity(H,FREQ,ANGLE)
```

Description

`D = directivity(H,FREQ,ANGLE)` returns the "Directivity" on page 1-349 of a crossed-dipole antenna element, `H`, at frequencies specified by `FREQ` and in direction angles specified by `ANGLE`.

Input Arguments

`H` — Crossed-dipole antenna element

System object

Crossed-dipole antenna element specified as a phased.CrossedDipoleAntennaElement System object.

Example: `H = phased.CrossedDipoleAntennaElement;`

`FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the

directivity is returned as –Inf. Most elements use the FrequencyRange property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the FrequencyVector property.

- For an array of elements, FREQ must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as –Inf.

Example: [1e8 2e6]

Data Types: double

ANGLE — Angles for computing directivity

1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Angles for computing directivity, specified as a 1-by-*M* real-valued row vector or a 2-by-*M* real-valued matrix, where *M* is the number of angular directions. Angle units are in degrees. If ANGLE is a 2-by-*M* matrix, then each column specifies a direction in azimuth and elevation, [az;el]. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°.

If ANGLE is a 1-by-*M* vector, then each entry represents an azimuth angle, with the elevation angle assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis.

Example: [45 60; 0 10]

Data Types: double

Output Arguments

D — Directivity

M-by-*L* matrix

Directivity, returned as an *M*-by-*L* matrix whose columns contain the directivities at the *M* angles specified by ANGLE. Each column corresponds to one of the *L* frequency values specified in FREQ. Directivity units are in dBi.

Examples

Directivity of Crossed-Dipole Antenna Element

Compute the directivity of a crossed-dipole antenna element in several different directions.

Create a crossed-dipole antenna element system object.

```
myAnt = phased.CrossedDipoleAntennaElement;
```

Set the angles of interest to be at zero-degrees constant elevation angle. The seven azimuth angles are centered around boresight (zero degrees azimuth and zero degrees elevation). Set the desired frequency to 1 GHz.

```
ang = [-30,-20,-10,0,10,20,30; 0,0,0,0,0,0,0];
freq = 1e9;
```

Compute the directivity along the constant elevation cut.

```
d = directivity(myAnt,freq,ang)
```

```
d =

    1.1811
    1.4992
    1.6950
    1.7610
    1.6950
    1.4992
    1.1811
```

Definitions

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant

intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element directivity” and “Array directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

phased.CrossedDipoleAntennaElement.pattern

isPolarizationCapable

System object: phased.CrossedDipoleAntennaElement
Package: phased

Polarization capability

Syntax

```
flag = isPolarizationCapable(h)
```

Description

`flag = isPolarizationCapable(h)` returns a Boolean value, `flag`, indicating whether the phased.CrossedDipoleAntennaElement System object supports polarization. An antenna element supports polarization if it can create or respond to polarized fields. This object supports only polarized fields.

Input Arguments

h — Crossed-dipole antenna element

`phased.CrossedDipoleAntennaElement`System object

Crossed-dipole antenna element specified as a phased.CrossedDipoleAntennaElementSystem object.

Output Arguments

`flag` — Polarization-capability flag

Polarization-capability returned as a Boolean value `true` if the antenna element supports polarization or `false` if it does not. Because the phased.CrossedDipoleAntennaElement antenna element supports polarization, the returned value is always `true`.

Examples

Crossed-Dipole Antenna Supports Polarization

Show that the `phased.CrossedDipoleAntennaElement` antenna element supports polarization.

```
antenna = phased.CrossedDipoleAntennaElement;
isPolarizationCapable(antenna)
```

```
ans =

  logical

   1
```

The returned value of `1` shows that the crossed-dipole antenna element supports polarization.

pattern

System object: phased.CrossedDipoleAntennaElement
Package: phased

Plot crossed-dipole antenna element directivity and patterns

Syntax

```
pattern(sElem,FREQ)
pattern(sElem,FREQ,AZ)
pattern(sElem,FREQ,AZ,EL)
pattern( ___ ,Name,Value)
[PAT,AZ_ANG,EL_ANG] = pattern( ___ )
```

Description

`pattern(sElem,FREQ)` plots the 3-D array directivity pattern (in dBi) for the element specified in `sElem`. The operating frequency is specified in `FREQ`.

`pattern(sElem,FREQ,AZ)` plots the element directivity pattern at the specified azimuth angle.

`pattern(sElem,FREQ,AZ,EL)` plots the element directivity pattern at specified azimuth and elevation angles.

`pattern( ___ ,Name,Value)` plots the element pattern with additional options specified by one or more `Name,Value` pair arguments.

`[PAT,AZ_ANG,EL_ANG] = pattern( ___ )` returns the element pattern in `PAT`. The `AZ_ANG` output contains the coordinate values corresponding to the rows of `PAT`. The `EL_ANG` output contains the coordinate values corresponding to the columns of `PAT`. If the `'CoordinateSystem'` parameter is set to `'uv'`, then `AZ_ANG` contains the *U* coordinates of the pattern and `EL_ANG` contains the *V* coordinates of the pattern. Otherwise, they are in angular units in degrees. *UV* units are dimensionless.

Note: This method replaces the `plotResponse` method. See "Convert plotResponse to pattern" on page 1-362 for guidelines on how to use `pattern` in place of `plotResponse`.

Input Arguments

`sElem` — Crossed-dipole antenna element

System object

Crossed-dipole antenna element, specified as a phased.CrossedDipoleAntennaElement System object.

Example: `sElem = phased.CrossedDipoleAntennaElement;`

`FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `-Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `-Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

`AZ` — Azimuth angles

`[-180:180]` (default) | 1-by-*M* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a 1-by-*M* real-valued row vector where *M* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, this angle is positive.

Example: `[-45:2:45]`

Data Types: `double`

`EL` — Elevation angles

`[-90:90]` (default) | 1-by-*N* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a 1-by-*N* real-valued row vector where *N* is the number of desired elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and *xy*-plane. When measured towards the *z*-axis, this angle is positive.

Example: `[-75:1:70]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'CoordinateSystem'` — Plotting coordinate system

`'polar'` (default) | `'rectangular'` | `'uv'`

Plotting coordinate system of the pattern, specified as the comma-separated pair consisting of `'CoordinateSystem'` and one of `'polar'`, `'rectangular'`, or `'uv'`. When `'CoordinateSystem'` is set to `'polar'` or `'rectangular'`, the `AZ` and `EL` arguments specify the pattern azimuth and elevation, respectively. `AZ` values must lie between –180° and 180°. `EL` values must lie between –90° and 90°. If `'CoordinateSystem'` is set to `'uv'`, `AZ` and `EL` then specify *U* and *V* coordinates, respectively. `AZ` and `EL` must lie between -1 and 1.

Example: `'uv'`

Data Types: `char`

'Type' — Displayed pattern type
'directivity' (default) | 'efield' | 'power' | 'powerdb'

Displayed pattern type, specified as the comma-separated pair consisting of 'Type' and one of

- 'directivity' — directivity pattern measured in dBi.
- 'efield' — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- 'power' — power pattern of the sensor or array defined as the square of the field pattern.
- 'powerdb' — power pattern converted to dB.

Example: 'powerdb'

Data Types: char

'Normalize' — Display normalize pattern
true (default) | false

Display normalized pattern, specified as the comma-separated pair consisting of 'Normalize' and a Boolean. Set this parameter to true to display a normalized pattern. When you set 'Type' to 'directivity', this parameter does not apply. Directivity patterns are already normalized.

Example:

Data Types: logical

'PlotStyle' — Plotting style
'overlay' (default) | 'waterfall'

Plotting style, specified as the comma-separated pair consisting of 'Plotstyle' and either 'overlay' or 'waterfall'. This parameter applies when you specify multiple frequencies in FREQ in 2-D plots. You can draw 2-D plots by setting one of the arguments AZ or EL to a scalar.

Example:

Data Types: char

'Polarization' — Polarized field component
'combined' (default) | 'H' | 'V'

Polarized field component to display, specified as the comma-separated pair consisting of 'Polarization' and `'combined'`, `'H'`, or `'V'`. This parameter applies only when the sensors are polarization-capable and when the `'Type'` parameter is not set to `'directivity'`. This table shows the meaning of the display options

`'Polarization'`	Display
`'combined'`	Combined *H* and *V* polarization components
`'H'`	*H* polarization component
`'V'`	*V* polarization component

Example: `'V'`

Data Types: `char`

Output Arguments

PAT — Element pattern

M-by-*N* real-valued matrix

Element pattern, returned as an *M*-by-*N* real-valued matrix. The dimensions of PAT correspond to the dimensions of the output arguments AZ_ANG and EL_ANG.

AZ_ANG — Azimuth angles

scalar | 1-by-*M* real-valued row vector

Azimuth angles for displaying directivity or response pattern, returned as a scalar or 1-by-*M* real-valued row vector corresponding to the dimension set in AZ. The rows of PAT correspond to the values in AZ_ANG.

EL_ANG — Elevation angles

scalar | 1-by-*N* real-valued row vector

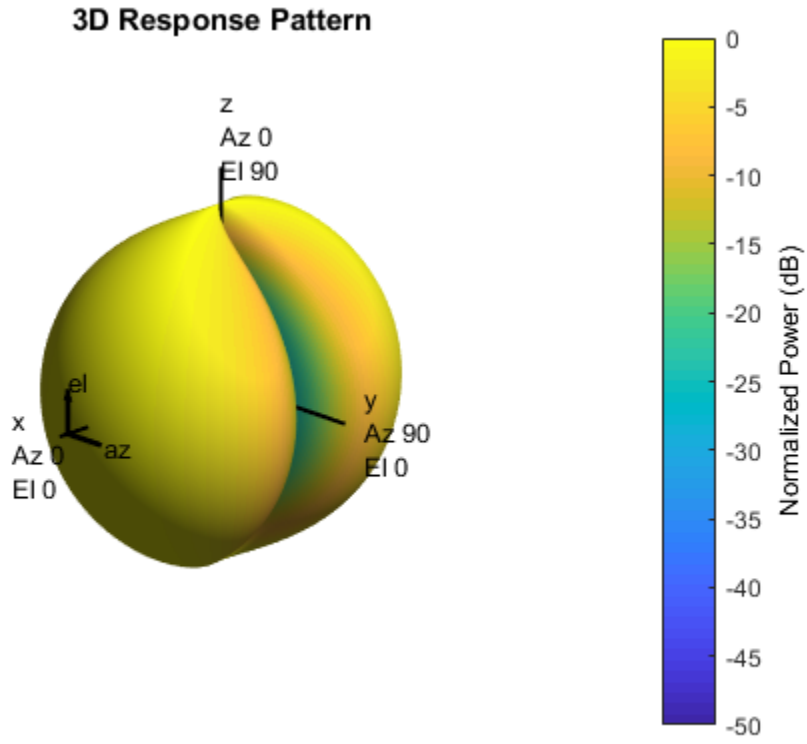
Elevation angles for displaying directivity or response, returned as a scalar or 1-by-*N* real-valued row vector corresponding to the dimension set in EL. The columns of PAT correspond to the values in EL_ANG.

Examples

Plot 3-D Polar Patterns of Crossed-Dipole Antenna

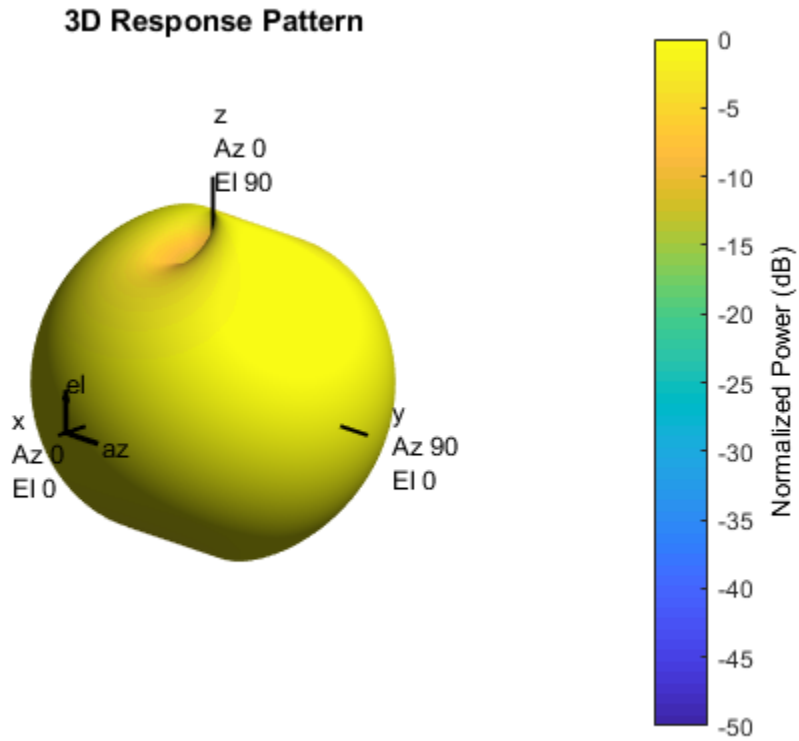
Construct a crossed-dipole antenna element that operates in the frequency range from 100 MHz to 1.5 GHz. Then, plot the 3-D polar power pattern for the horizontal polarization component. Assume the antenna operating operates at 1 GHz.

```
sCD = phased.CrossedDipoleAntennaElement('FrequencyRange',[100 1500]*1e6);
fc = 1e9;
pattern(sCD,fc,[-180:180],[-90:90],...
    'Type','powerdb',...
    'CoordinateSystem','polar',...
    'Polarization','H')
```



Next, plot the vertical polarization component.

```
pattern(sCD,fc,[-180:180],[-90:90],...
    'Type','powerdb',...
    'CoordinateSystem','polar',...
    'Polarization','V')
```

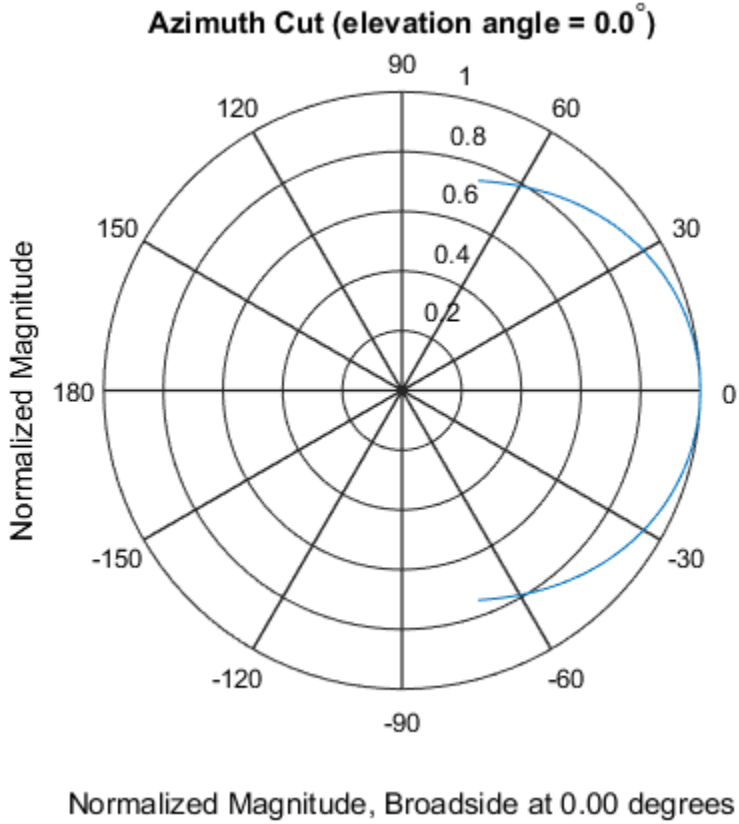


Azimuth-Cut of Crossed-Dipole Antenna Pattern

Construct a crossed-dipole antenna element. Then, plot the pattern of the horizontal component of the field magnitude. Assume the antenna operating frequency is 1 GHz. Restrict the response to the range of azimuth angles from -70 to 70 degrees in 0.1 degree increments. Set the elevation angle to 0 degrees.

```
sCD = phased.CrossedDipoleAntennaElement('FrequencyRange',[0.5 1.5]*1e9);
```

```
fc = 1e9;
pattern(sCD,fc,[-70:0.1:70],0,...
    'Type','efield',...
    'CoordinateSystem','polar',...
    'Polarization','combined')
```

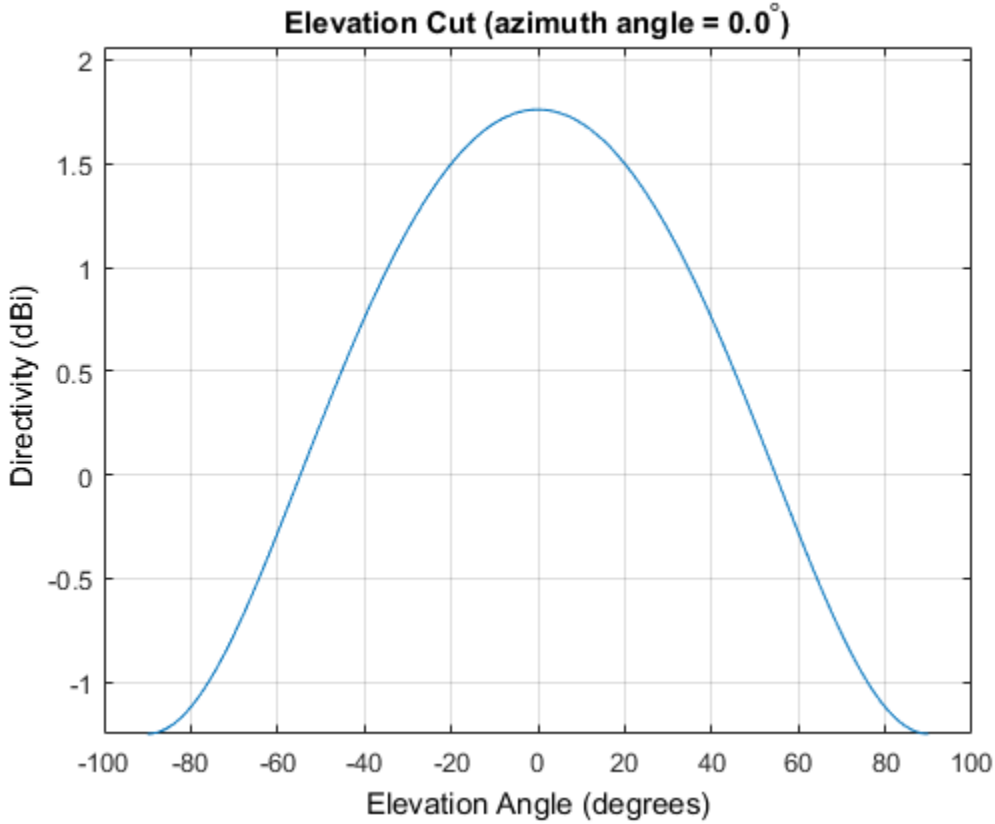


Directivity of Crossed-Dipole Antenna

Create a crossed-dipole antenna. Assume the antenna works between 1 and 2 GHz and its operating frequency is 1.5 GHz. Then, plot an elevation cut of its directivity.

```
sCD = phased.CrossedDipoleAntennaElement('FrequencyRange',[1e9 2e9]);
fc = 1.5e9;
pattern(sCD,fc,0,[-90:90],...
```

```
'Type','directivity',...
'CoordinateSystem','rectangular')
```



The directivity is maximum at 0 degrees elevation and attains a value of approximately 1.75 dB.

More About

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit

more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element directivity” and “Array directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

Convert plotResponse to pattern

For antenna, microphone, and array System objects, the `pattern` method replaces the `plotResponse` method. In addition, two new simplified methods exist just to draw 2-D azimuth and elevation pattern plots. These methods are `azimuthPattern` and `elevationPattern`.

The following table is a guide for converting your code from using `plotResponse` to `pattern`. Notice that some of the inputs have changed from *input arguments* to *Name-Value* pairs and conversely. The general `pattern` method syntax is

```
pattern(H,FREQ,AZ,EL,'Name1','Value1',...,'NameN','ValueN')
```

plotResponse Inputs	plotResponse Description	pattern Inputs
`H` argument	Antenna, microphone, or array System object.	`H` argument (no change)

plotResponse Inputs	plotResponse Description	pattern Inputs
`FREQ` argument	Operating frequency.	`FREQ` argument (no change)
`V` argument	Propagation speed. This argument is used only for arrays.	`'PropagationSpeed'` name-value pair. This parameter is only used for arrays.

<table>
<tr><th>plotResponse Inputs</th><th>plotResponse Description</th><th>pattern Inputs</th></tr>

plotResponse Inputs	plotResponse Description	pattern Inputs
`'NormalizeResponse'` name-value pair	Normalizes the plot. When `'Unit'` is set to `'dbi'`, you cannot specify `'NormalizeResponse'`.	`'Normalize'` name-value pair. When `'Type'` is set to `'directivity'`, you cannot specify `'Normalize'`. .
`'OverlayFreq'` name-value pair	Plot multiple frequencies on the same 2-D plot. Available only when `'Format'` is set to `'line'` or `'uv'` and `'RespCut'` is not set to `'3D'`. The value `true` produces an overlay plot and the value `false` produces a waterfall plot.	`'PlotStyle'` name-value pair plots multiple frequencies on the same 2-D plot. The values `'overlay'` and `'waterfall'` correspond to `'OverlayFreq'` values of `true` and `false`. The option `'waterfall'` is allowed only when `'CoordinateSystem'` is set to `'rectangular'` or `'uv'`.
`'Polarization'` name-value pair	Determines how to plot polarized fields. Options are `'None'`, `'Combined'`, `'H'`, or `'V'`.	`'Polarization'` name-value pair determines how to plot polarized fields. The `'None'` option is removed. The options `'Combined'`, `'H'`, or `'V'` are unchanged.

`'Unit'` name-value pair	Determines the plot units. Choose `'db'`, `'mag'`, `'pow'`, or `'dbi'`, where the default is `'db'`.	`'Type'` name-value pair, uses equivalent options with different names
		
		plotResponse pattern
		`'db'` `'powerdb'`
		`'mag'` `'efield'`
		`'pow'` `'power'`
		`'dbi'` `'directivity'`

`'Weights'` name-value pair	Array element tapers (or weights).	`'Weights'` name-value pair (no change).

plotResponse Inputs	plotResponse Description	pattern Inputs
`'AzimuthAngles'` name-value pair	Azimuth angles used to display the antenna or array response.	`AZ` argument
`'ElevationAngles'` name-value pair	Elevation angles used to display the antenna or array response.	`EL` argument
`'UGrid'` name-value pair	Contains *U* coordinates in *UV*-space.	`AZ` argument when `'CoordinateSystem'` name-value pair is set to `'uv'`
`'VGrid'` name-value pair	Contains *V*-coordinates in *UV*-space.	`EL` argument when `'CoordinateSystem'` name-value pair is set to `'uv'`

phased.CrossedDipoleAntennaElement.patternAzimuth | phased.CrossedDipoleAntennaElement.patternElevation

Introduced in R2015a

patternAzimuth

System object: phased.CrossedDipoleAntennaElement
Package: phased

Plot crossed-dipole antenna element directivity or pattern versus azimuth

Syntax

```
patternAzimuth(sElem,FREQ)
patternAzimuth(sElem,FREQ,EL)
patternAzimuth(sElem,FREQ,EL,Name,Value)
PAT = patternAzimuth( ___ )
```

Description

`patternAzimuth(sElem,FREQ)` plots the 2-D element directivity pattern versus azimuth (in dBi) for the element `sElem` at zero degrees elevation angle. The argument `FREQ` specifies the operating frequency.

`patternAzimuth(sElem,FREQ,EL)`, in addition, plots the 2-D element directivity pattern versus azimuth (in dBi) at the elevation angle specified by `EL`. When `EL` is a vector, multiple overlaid plots are created.

`patternAzimuth(sElem,FREQ,EL,Name,Value)` plots the element pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternAzimuth( ___ )` returns the element pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Azimuth'` parameter and the `EL` input argument.

Input Arguments

`sElem` — Crossed-dipole antenna element

System object

Crossed-dipole antenna element, specified as a phased.CrossedDipoleAntennaElement System object.

Example: `sElem = phased.CrossedDipoleAntennaElement;`

`FREQ` — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `-Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `-Inf`.

Example: `1e8`

Data Types: `double`

`EL` — Elevation angles

1-by-*N* real-valued row vector

Elevation angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector. The quantity *N* is the number of requested elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and the *xy* plane. When measured toward the *z*-axis, this angle is positive.

Example: `[0,10,20]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'Type' — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

'Azimuth' — Azimuth angles

`[-180:180]` (default) | 1-by-*P* real-valued row vector

Azimuth angles, specified as the comma-separated pair consisting of `'Azimuth'` and a 1-by-*P* real-valued row vector. Azimuth angles define where the array pattern is calculated.

Example: `'Azimuth',[-90:2:90]`

Data Types: `double`

Output Arguments

PAT — Element directivity or pattern

L-by-*N* real-valued matrix

Element directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of azimuth values determined by the `'Azimuth'` name-value pair argument. The dimension *N* is the number of elevation angles, as determined by the `EL` input argument.

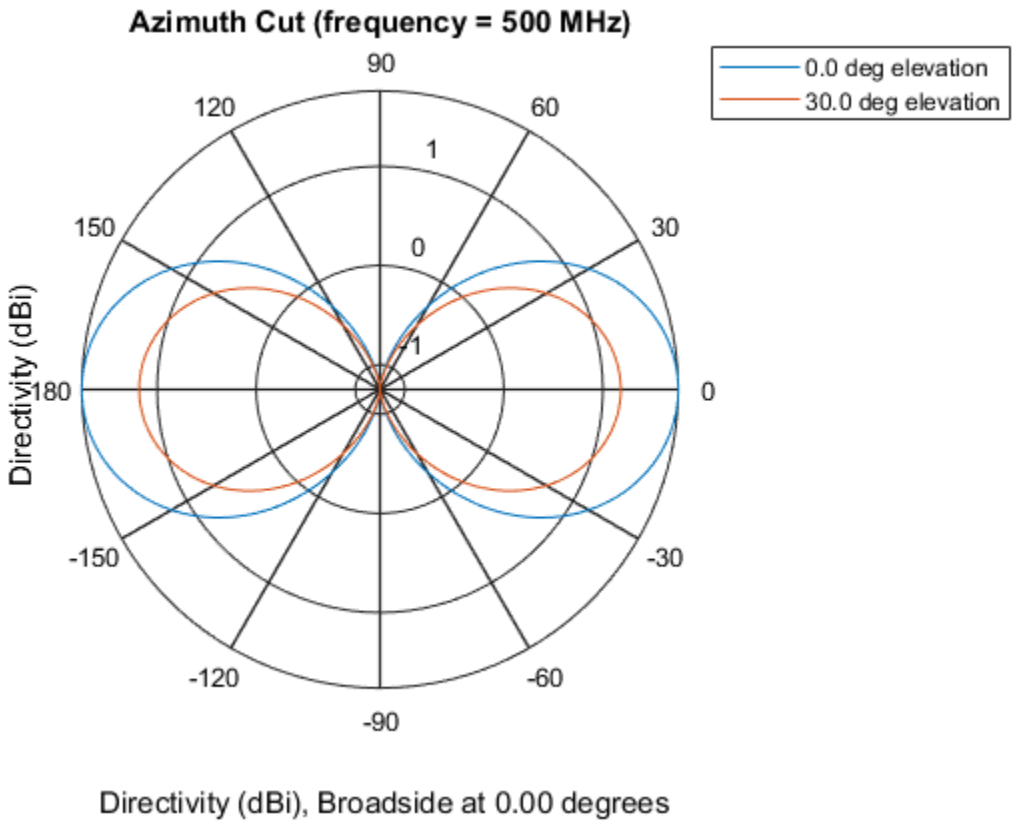
Examples

Reduced Azimuth Pattern of Crossed-Dipole Antenna Element

Plot an azimuth cut of the directivity of a crossed-dipole antenna element at 0 and 30 degrees elevation. Assume the operating frequency is 500 MHz.

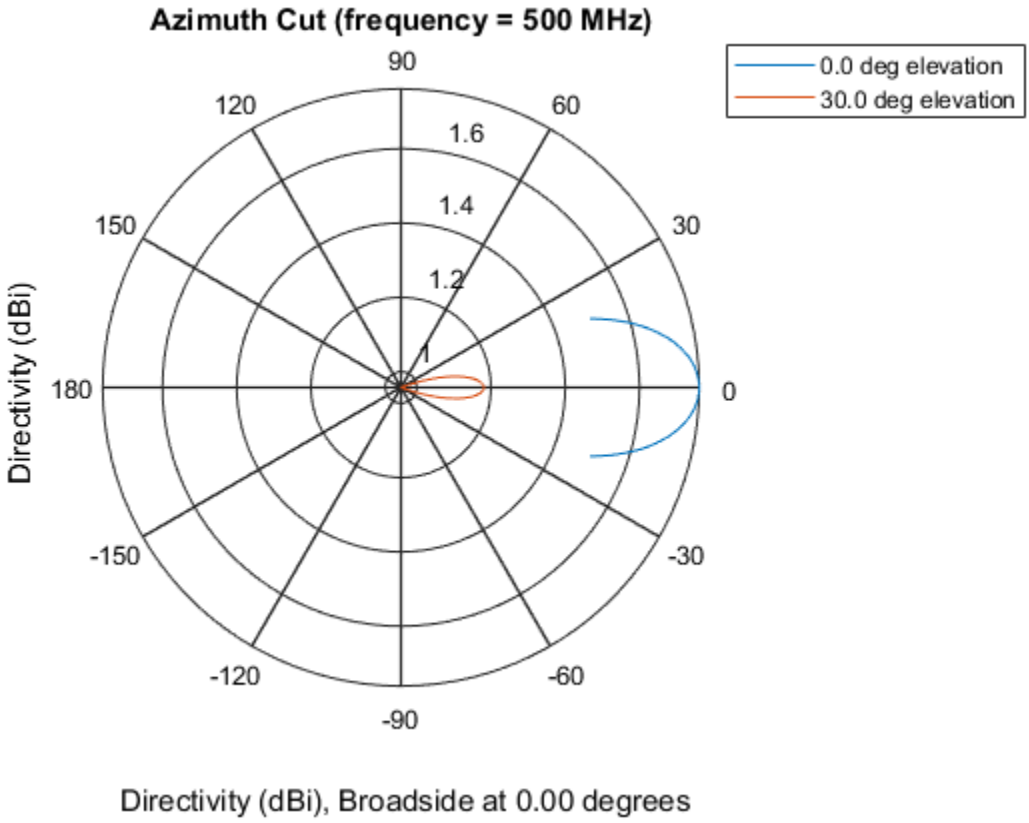
Create the antenna element.

```
fc = 500e6;
sCD = phased.CrossedDipoleAntennaElement('FrequencyRange',[100,900]*1e6);
patternAzimuth(sCD,fc,[0 30])
```



Plot a reduced range of azimuth angles using the `Azimuth` parameter. Notice the change in scale.

```
patternAzimuth(sCD,fc,[0 30],'Azimuth',[-20:20])
```



Definitions

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit

more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on "Element directivity" and "Array directivity".

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

phased.CrossedDipoleAntennaElement.patternElevation

Introduced in R2015a

patternElevation

System object: phased.CrossedDipoleAntennaElement
Package: phased

Plot crossed-dipole antenna element directivity or pattern versus elevation

Syntax

```
patternElevation(sElem,FREQ)
patternElevation(sElem,FREQ,AZ)
patternElevation(sElem,FREQ,AZ,Name,Value)
PAT = patternElevation( ___ )
```

Description

`patternElevation(sElem,FREQ)` plots the 2-D element directivity pattern versus elevation (in dBi) for the element `sElem` at zero degrees azimuth angle. The argument `FREQ` specifies the operating frequency.

`patternElevation(sElem,FREQ,AZ)`, in addition, plots the 2-D element directivity pattern versus elevation (in dBi) at the azimuth angle specified by `AZ`. When `AZ` is a vector, multiple overlaid plots are created.

`patternElevation(sElem,FREQ,AZ,Name,Value)` plots the element pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternElevation( ___ )` returns the element pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Elevation'` parameter and the `AZ` input argument.

Input Arguments

`sElem` — Crossed-dipole antenna element

System object

Crossed-dipole antenna element, specified as a phased.CrossedDipoleAntennaElement System object.

Example: `sElem = phased.CrossedDipoleAntennaElement;`

`FREQ` — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

`AZ` — Azimuth angles for computing directivity and pattern

1-by-*N* real-valued row vector

Azimuth angles for computing sensor or array directivities and patterns, specified as a 1-by-*M* real-valued row vector where *N* is the number of desired azimuth directions. Angle units are in degrees. The azimuth angle must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `[0,10,20]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Type'` — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

`'Elevation'` — Elevation angles

`[-90:90]` (default) | 1-by-*P* real-valued row vector

Elevation angles, specified as the comma-separated pair consisting of `'Elevation'` and a 1-by-*P* real-valued row vector. Elevation angles define where the array pattern is calculated.

Example: `'Elevation',[-90:2:90]`

Data Types: `double`

Output Arguments

`PAT` — Element directivity or pattern

L-by-*N* real-valued matrix

Element directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of elevation angles determined by the `'Elevation'` name-value pair argument. The dimension *N* is the number of azimuth angles determined by the `AZ` argument.

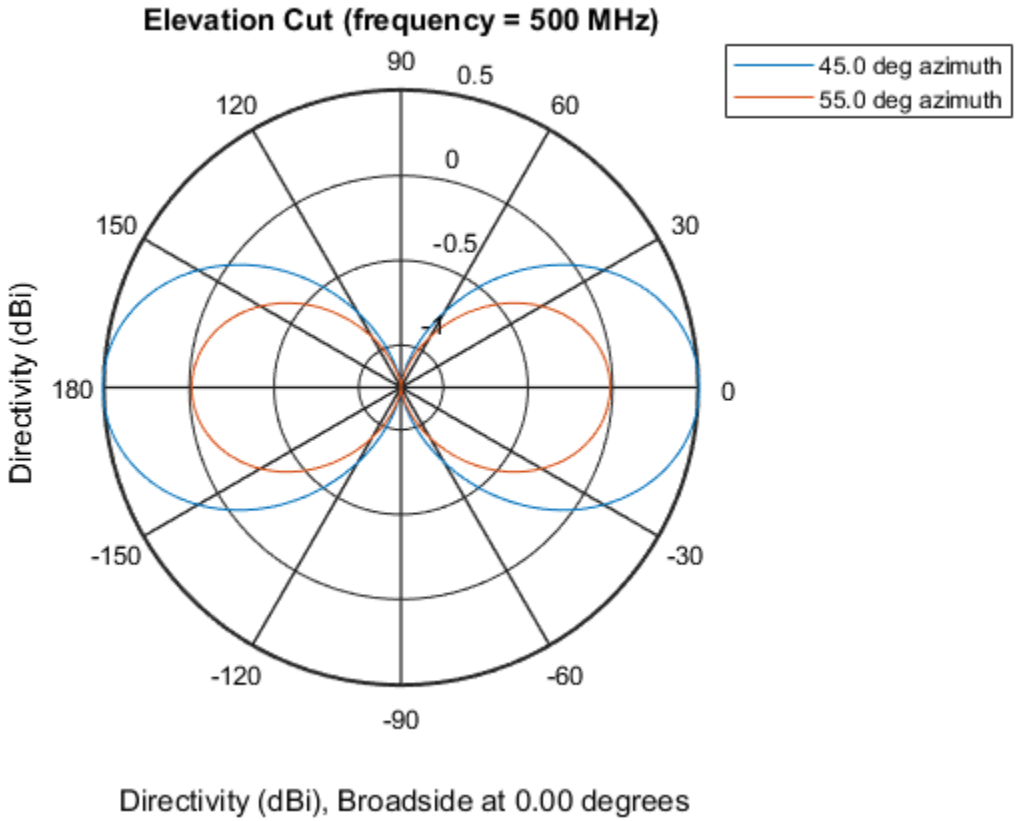
Examples

Reduced Elevation Pattern of Crossed-Dipole Antenna Element

Plot an elevation cut of directivity of a crossed dipole antenna element at 45 and 55 degrees azimuth. Assume the operating frequency is 500 MHz.

Create the antenna element

```
fc = 500e6;
sCD = phased.CrossedDipoleAntennaElement('FrequencyRange',[100,900]*1e6);
patternElevation(sCD,fc,[45 55])
```



Plot a reduced range of elevation angles using the `Elevation` parameter. Notice the change in scale.

```
patternElevation(sCD,fc,[45 55],'Elevation',[-20:20])
```

phased.CrossedDipoleAntennaElement.pattern |
phased.CrossedDipoleAntennaElement.patternAzimuth

Introduced in R2015a

plotResponse

System object: phased.CrossedDipoleAntennaElement
Package: phased

Plot response pattern of antenna

Syntax

```
plotResponse(H,FREQ)
plotResponse(H,FREQ,Name,Value)
hPlot = plotResponse( ___ )
```

Description

`plotResponse(H,FREQ)` plots the element response pattern along the azimuth cut, where the elevation angle is 0. The operating frequency is specified in `FREQ`.

`plotResponse(H,FREQ,Name,Value)` plots the element response with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = plotResponse( ___ )` returns handles of the lines or surface in the figure window, using any of the input arguments in the previous syntaxes.

Input Arguments

`H`

Element System object

`FREQ`

Operating frequency in Hertz specified as a scalar or 1–by-*K* row vector. `FREQ` must lie within the range specified by the `FrequencyVector` property of `H`. If you set the `'RespCut'` property of `H` to `'3D'`, `FREQ` must be a scalar. When `FREQ` is a row vector, `plotResponse` draws multiple frequency responses on the same axes.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'CutAngle'`

Cut angle specified as a scalar. This argument is applicable only when `RespCut` is `'Az'` or `'El'`. If `RespCut` is `'Az'`, `CutAngle` must be between –90 and 90. If `RespCut` is `'El'`, `CutAngle` must be between –180 and 180.

Default: `0`

`'Format'`

Format of the plot, using one of `'Line'`, `'Polar'`, or `'UV'`. If you set `Format` to `'UV'`, `FREQ` must be a scalar.

Default: `'Line'`

`'NormalizeResponse'`

Set this value to `true` to normalize the response pattern. Set this value to `false` to plot the response pattern without normalizing it. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

Default: `true`

`'OverlayFreq'`

Set this value to `true` to overlay pattern cuts in a 2-D line plot. Set this value to `false` to plot pattern cuts against frequency in a 3-D waterfall plot. If this value is `false`, `FREQ` must be a vector with at least two entries.

This parameter applies only when `Format` is not `'Polar'` and RespCut is not `'3D'`.

Default: `true`

`'Polarization'`

Specify the polarization options for plotting the antenna response pattern. The allowable values are `|'None' | 'Combined' | 'H' | 'V' |` where

- `'None'` specifies plotting a nonpolarized response pattern
- `'Combined'` specifies plotting a combined polarization response pattern
- `'H'` specifies plotting the horizontal polarization response pattern
- `'V'` specifies plotting the vertical polarization response pattern

For antennas that do not support polarization, the only allowed value is `'None'`. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

Default: `'None'`

`'RespCut'`

Cut of the response. Valid values depend on `Format`, as follows:

- If `Format` is `'Line'` or `'Polar'`, the valid values of `RespCut` are `'Az'`, `'El'`, and `'3D'`. The default is `'Az'`.
- If `Format` is `'UV'`, the valid values of `RespCut` are `'U'` and `'3D'`. The default is `'U'`.

If you set `RespCut` to `'3D'`, `FREQ` must be a scalar.

`'Unit'`

The unit of the plot. Valid values are `'db'`, `'mag'`, `'pow'`, or `'dbi'`. This parameter determines the type of plot that is produced.

Unit value	Plot type
`db`	power pattern in dB scale
`mag`	field pattern
`pow`	power pattern
`dbi`	directivity

Default: `'db'`

`'AzimuthAngles'`

Azimuth angles for plotting element response, specified as a row vector. The `AzimuthAngles` parameter sets the display range and resolution of azimuth angles for

visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'Az'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of azimuth angles should lie between –180° and 180° and must be in nondecreasing order. When you set the `RespCut` parameter to `'3D'`, you can set the `AzimuthAngles` and `ElevationAngles` parameters simultaneously.

Default: `[-180:180]`

`'ElevationAngles'`

Elevation angles for plotting element response, specified as a row vector. The `ElevationAngles` parameter sets the display range and resolution of elevation angles for visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'El'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of elevation angles should lie between –90° and 90° and must be in nondecreasing order. When you set the `RespCut` parameter to `'3D'`, you can set the `ElevationAngles` and `AzimuthAngles` parameters simultaneously.

Default: `[-90:90]`

`'UGrid'`

U coordinate values for plotting element response, specified as a row vector. The `UGrid` parameter sets the display range and resolution of the *U* coordinates for visualizing the radiation pattern in *U*/*V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'U'` or `'3D'`. The values of `UGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set the `UGrid` and `VGrid` parameters simultaneously.

Default: `[-1:0.01:1]`

`'VGrid'`

V coordinate values for plotting element response, specified as a row vector. The `VGrid` parameter sets the display range and resolution of the *V* coordinates for visualizing the radiation pattern in *U*/*V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'3D'`. The values of `VGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set the `VGrid` and `UGrid` parameters simultaneously.

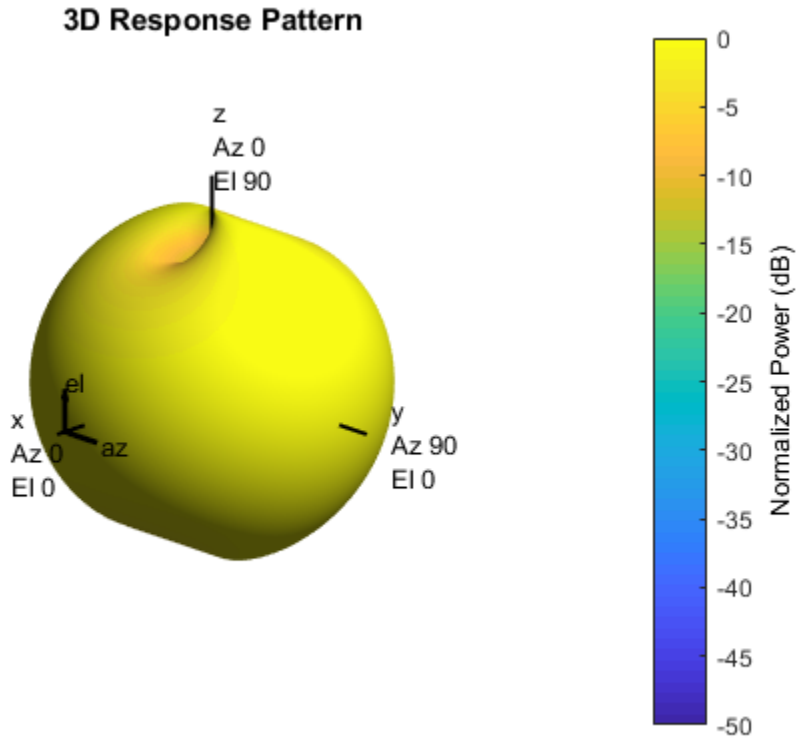
Default: `[-1:0.01:1]`

Examples

Vertical and Horizontal Responses of Crossed-Dipole Antenna

This example shows how to create a crossed-dipole antenna operating between 100 and 900 MHz and then how to plot its vertical polarization response at 250 MHz in the form of a 3-D polar plot.

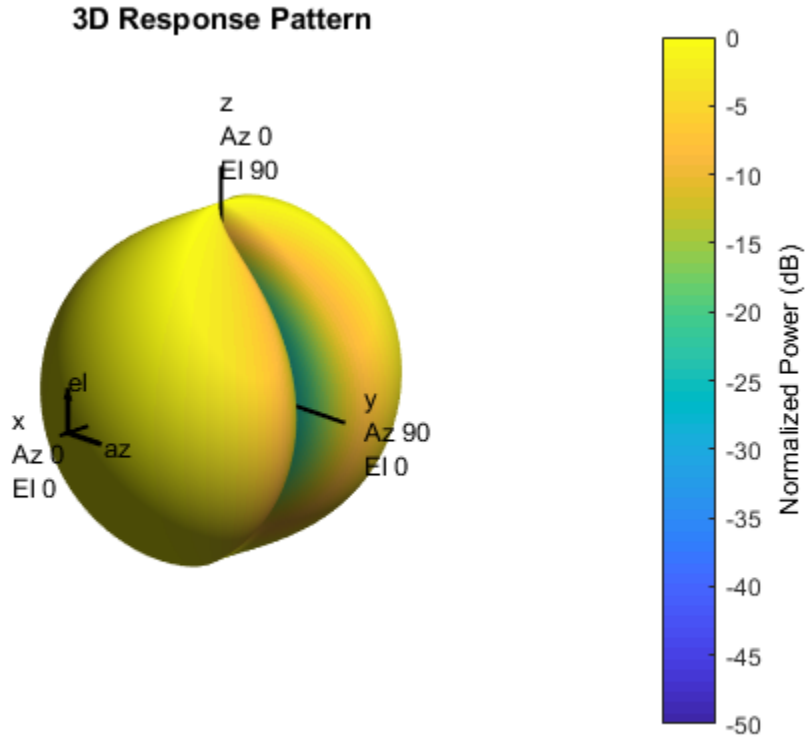
```
scd = phased.CrossedDipoleAntennaElement(...
    'FrequencyRange',[100 900]*1e6);
plotResponse(scd,250e6,'Format','Polar',...
    'RespCut','3D','Polarization','V');
```



The antenna pattern of the vertical-polarization component is almost isotropic and has a maximum at 0° elevation and 0° azimuth, as shown in the figure above.

Plot the antenna's horizontal polarization response. The pattern of the horizontal polarization response also has a maximum at 0° elevation and 0° azimuth but no response at $\pm 90^\circ$ azimuth.

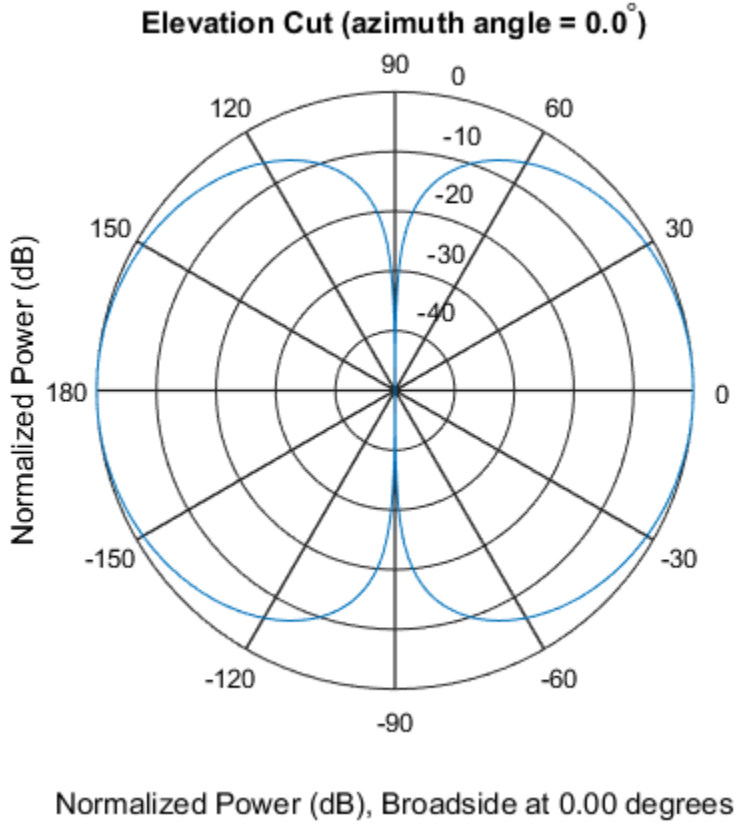
```
scd = phased.CrossedDipoleAntennaElement(...
    'FrequencyRange',[100 900]*1e6);
plotResponse(scd,250e6,'Format','Polar',...
    'RespCut','3D','Polarization','H');
```



Response and Directivity of Crossed-Dipole Antenna As Elevation-Cut

Create a crossed-dipole antenna operating between 100 and 900 MHz. Then, plot the antenna's vertical polarization response at 250 MHz as an elevation cut. Display the response from -90° to 90° elevation in 0.1° increments.

```
scd = phased.CrossedDipoleAntennaElement(...
    'FrequencyRange',[100 900]*1e6);
plotResponse(scd,250e6,'Format','Polar',...
    'RespCut','El','ElevationAngles',[-90:0.1:90],...
    'Polarization','V');
```



Plot the antenna's directivity at 250 MHz as an elevation cut.

```
plotResponse(scd,250e6,'Format','Polar','Unit','dbi',...
    'RespCut','El','ElevationAngles',[-90:0.1:90]);
```

`azel2uv` | `uv2azel`

step

System object: phased.CrossedDipoleAntennaElement
Package: phased

Output response of antenna element

Syntax

```
RESP = step(H,FREQ,ANG)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`RESP = step(H,FREQ,ANG)` returns the antenna's voltage response, `RESP`, at the operating frequencies specified in `FREQ` and in the directions specified in `ANG`. For the crossed-dipole antenna element object, `RESP` is a MATLAB `struct` containing two fields, `RESP.H` and `RESP.V`, representing the horizontal and vertical polarization components of the antenna's response. Each field is an *M*-by-*L* matrix containing the antenna response at the *M* angles specified in `ANG` and at the *L* frequencies specified in `FREQ`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

H

Antenna element object.

FREQ

Operating frequencies of antenna in hertz. FREQ is a row vector of length L.

ANG

Directions in degrees. ANG can be either a 2-by-M matrix or a row vector of length M.

If ANG is a 2-by-M matrix, each column of the matrix specifies the direction in the form [azimuth; elevation]. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

If ANG is a row vector of length M, each element specifies a direction's azimuth angle. In this case, the corresponding elevation angle is assumed to be 0.

Output Arguments

RESP

Voltage response of antenna element returned as a MATLAB `struct` with fields `RESP.H` and `RESP.V`. Both `RESP.H` and `RESP.V` contain responses for the horizontal and vertical polarization components of the antenna radiation pattern. Both `RESP.H` and `RESP.V` are *M*-by-*L* matrices. In these matrices, *M* represents the number of angles specified in ANG, and *L* represents the number of frequencies specified in FREQ.

Examples

Compute Crossed-Dipole Antenna Response

Find the response of a crossed-dipole antenna at boresight, 0° azimuth and 0° elevation, and off-boresight at 30° azimuth and 0° elevation. The antenna operates at 250 MHz.

```
antenna = phased.CrossedDipoleAntennaElement('FrequencyRange',[100 900]*1e6);
```

```
ang = [0 30;0 0];
fc = 250e6;
resp = antenna(fc,ang);
disp(resp.H)
```

```
   0.0000 - 1.2247i
   0.0000 - 1.0607i
```

```
disp(resp.V)
```

```
   -1.2247
   -1.2247
```

Algorithms

The total response of a crossed-dipole antenna element is a combination of its frequency response and spatial response. `phased.CrossedDipoleAntennaElement` calculates both responses using nearest neighbor interpolation, and then multiplies the responses to form the total response.

phased.CustomAntennaElement System object

Package: phased

Custom antenna element

Description

The `phased.CustomAntennaElement` object models an antenna element with a custom response pattern. The response pattern may be defined for polarized or non-polarized fields.

To compute the response of the antenna element for specified directions:

1. Define and set up your custom antenna element. See "Construction" on page 1-392.
2. Call step to compute the antenna response according to the properties of `phased.CustomAntennaElement`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.CustomAntennaElement` creates a system object, `H`, to model an antenna element with a custom response pattern. How the response pattern is specified depends upon whether polarization is desired or not. The default pattern has an isotropic spatial response.

- To create a nonpolarized response pattern, set the `SpecifyPolarizationPattern` property to `false` (default). Then, use the `MagnitudePattern` property to set the response pattern.

- To create a polarized response pattern, set the `SpecifyPolarizationPattern` property to `true`. Then, use any or all of the `HorizontalMagnitudePattern`, `HorizontalPhasePattern`, `VerticalMagnitudePattern`, and `VerticalPhasePattern` properties to set the response pattern.

The output response of the step method depends on whether polarization is set or not.

`H = phased.CustomAntennaElement(Name,Value)` creates a custom antenna object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`FrequencyVector`

Response and pattern frequency vector

Specify the frequencies (in Hz) at which the frequency response and antenna patterns are to be returned, as a 1-by-L row vector. The elements of the vector must be in increasing order. The antenna element has no response outside the frequency range specified by the minimum and maximum elements of the frequency vector.

Default: `[0 1e20]`

`AzimuthAngles`

Azimuth angles

Specify the azimuth angles (in degrees) as a length-P vector. These values are the azimuth angles where the custom radiation pattern is to be specified. P must be greater than 2. The azimuth angles should lie between –180 and 180 degrees and be in strictly increasing order.

Default: `[-180:180]`

`ElevationAngles`

Elevation angles

Specify the elevation angles (in degrees) as a length-Q vector. These values are the elevation angles where the custom radiation pattern is to be specified. Q must be greater than 2. The elevation angles should lie between –90 and 90 degrees and be in strictly increasing order.

Default: `[-90:90]`

`FrequencyResponse`

Frequency responses of antenna element

Specify the frequency responses in decibels measured at the frequencies defined in `FrequencyVector` property as a 1-by-L row vector where L must equal the length of the vector specified in the `FrequencyVector` property.

Default: `[0 0]`

`SpecifyPolarizationPattern`

Polarized array response

- When the `SpecifyPolarizationPattern` property is set to `false`, nonpolarized radiation is transmitted or received by the antenna element. In this case, use the `MagnitudePattern` property to set the antenna response pattern.
- When the `SpecifyPolarizationPattern` property is set to `true`, polarized radiation is transmitted or received by the antenna element. In this case, use the `HorizontalMagnitudePattern` and `HorizontalPhasePattern` properties to set the horizontal polarization response pattern and the `VerticalMagnitudePattern` and `VerticalPhasePattern` properties to set the vertical polarization response pattern.

Default: `false`

`MagnitudePattern`

Magnitude of combined antenna radiation pattern

The magnitude of the combined polarization antenna radiation pattern specified as a Q-by-P matrix or a Q-by-P-by-L array. This property is used only when the `SpecifyPolarizationPattern` property is set to `false`. Magnitude units are in dB.

- If the value of this property is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the `FrequencyVector` property.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the `FrequencyVector` property.

If the pattern contains a `NaN` at any azimuth and elevation direction, it is converted to `-Inf`, indicating zero response in that direction. The custom antenna object uses interpolation to estimate the response of the antenna at a given direction. To avoid interpolation errors, the custom response pattern should contain azimuth angles in the range`[-180,180]` degrees. You should also set the range of elevation angles to `[-90,90]` degrees.

Default: A 181-by-361 matrix with all elements equal to 0 dB

`PhasePattern`

Phase of combined antenna radiation pattern

The phase of the combined polarization antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. This property is used only when the `SpecifyPolarizationPattern` property is set to `false`. Phase units are in degrees.

- If the value of this property is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the `FrequencyVector` property.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the `FrequencyVector` property.

The custom antenna object uses interpolation to estimate the response of the antenna at a given direction. To avoid interpolation errors, the custom response pattern should contain azimuth angles in the range *[–180°,180°]*. You should also set the range of elevation angles to *[–90°,90°]*.

Default: A 181-by-361 matrix with all elements equal to 0

`HorizontalMagnitudePattern`

Magnitude of horizontal polarization component of antenna radiation pattern

The magnitude of the horizontal polarization component of the antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. This property is used only when the `SpecifyPolarizationPattern` property is set to `true`. Magnitude units are in dB.

- If the value of this property is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the `FrequencyVector` property.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the `FrequencyVector` property.

If the magnitude pattern contains a `NaN` at any azimuth and elevation direction, it is converted to `-Inf`, indicating zero response in that direction. The custom antenna object uses interpolation to estimate the response of the antenna at a given direction. To avoid interpolation errors, the custom response pattern should contain azimuth angles in the range `[–180,180]°` nd elevation angles in the range `[–90,90]°`.

Default: A 181-by-361 matrix with all elements equal to 0 dB

`HorizontalPhasePattern`

Phase of horizontal polarization component of antenna radiation pattern

The phase of the horizontal polarization component of the antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. This property is used only when the `SpecifyPolarizationPattern` property is set to `true`. Phase units are in degrees.

- If the value of this property is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the `FrequencyVector` property.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the `FrequencyVector` property.

The custom antenna object uses interpolation to estimate the response of the antenna at a given direction. To avoid interpolation errors, the custom response pattern should contain azimuth angles in the range`[–180,180]°` and elevation angles in the range `[–90,90]°`.

Default: A 181-by-361 matrix with all elements equal to 0°

`VerticalMagnitudePattern`

Magnitude of vertical polarization component of antenna radiation pattern

The magnitude of the vertical polarization component of the antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. This property is used only when the `SpecifyPolarizationPattern` property is set to `true`. Magnitude units are in dB.

- If the value of this property is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the `FrequencyVector` property.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the `FrequencyVector` property.

If the pattern contains a `NaN` at any azimuth and elevation direction, it is converted to `-Inf`, indicating zero response in that direction. The custom antenna object uses interpolation to estimate the response of the antenna at a given direction. To avoid interpolation errors, the custom response pattern should contain azimuth angles in the range`[–180,180]°` and elevation angles in the range `[–90,90]°`.

Default: A 181-by-361 matrix with all elements equal to 0 dB

`VerticalPhasePattern`

Phase of vertical polarization component of antenna radiation pattern

The phase of the vertical polarization component of the antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. This property is used only when the `SpecifyPolarizationPattern` property is set to `true`. Phase units are in degrees.

- If the value of this property is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the `FrequencyVector` property.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the `FrequencyVector` property.

The custom antenna object uses interpolation to estimate the response of the antenna at a given direction. To avoid interpolation errors, the custom response pattern should contain azimuth angles in the range`[–180,180]°` and elevation angles in the range `[–90,90]°`.

Default: A 181-by-361 matrix with all elements equal to 0°

Methods

directivity	Directivity of custom antenna element
isPolarizationCapable	Polarization capability

pattern	Plot custom antenna element directivity and patterns
patternAzimuth	Plot custom antenna element directivity or pattern versus azimuth
patternElevation	Plot custom antenna element directivity or pattern versus elevation
plotResponse	Plot response pattern of antenna
step	Output response of antenna element

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Response and Directivity of Custom Antenna

Create a user-defined antenna with a cosine pattern. Then, plot an elevation cut of the antenna's power response.

The user-defined pattern is omnidirectional in the azimuth direction and has a cosine pattern in the elevation direction. Assume the antenna operates at 1 GHz. Obtain the response at 20° azimuth and 30° elevation.

```
fc = 1e9;
azang = [-180:180];
elang = [-90:90];
magpattern = mag2db(repmat(cosd(elang)',1,numel(azang)));
phasepattern = zeros(size(magpattern));
antenna = phased.CustomAntennaElement('AzimuthAngles',azang, ...
    'ElevationAngles',elang,'MagnitudePattern',magpattern, ...
    'PhasePattern',phasepattern);
```

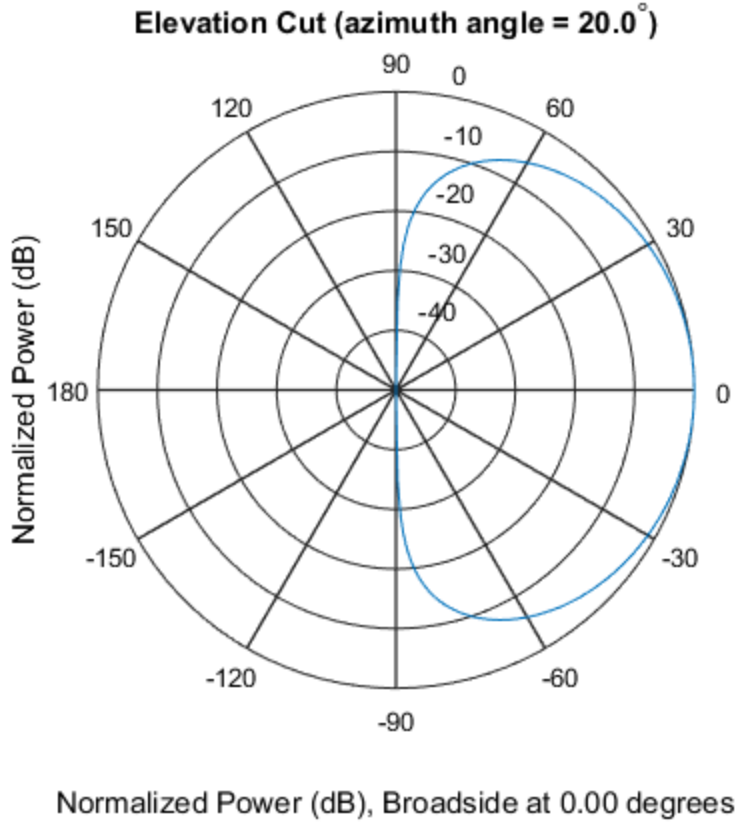
```
resp = antenna(fc,[20;30])
```

```
resp =

    0.8660
```

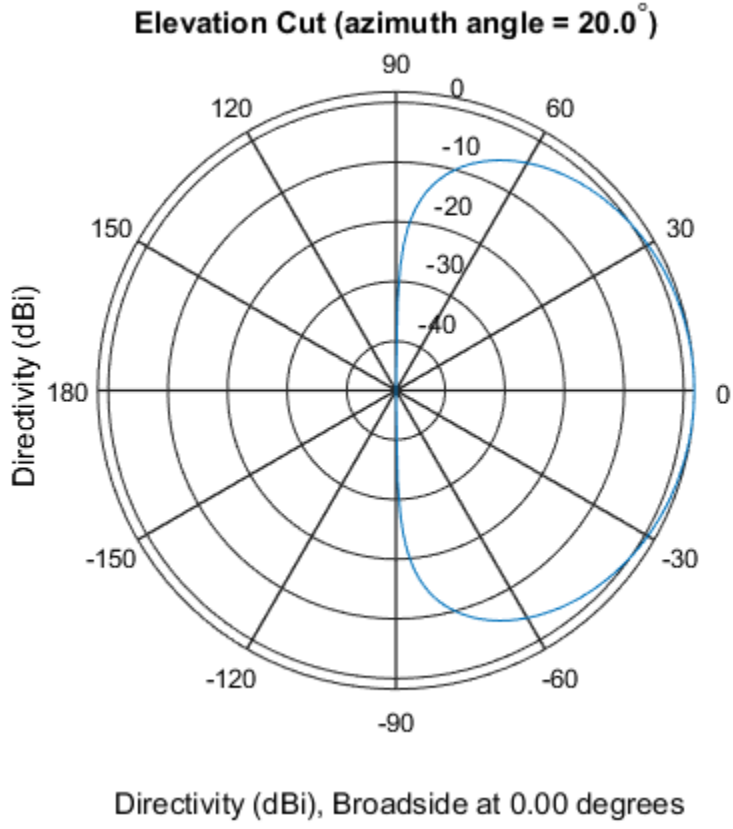
Plot an elevation cut of the power response.

```
pattern(antenna,fc,20,[-90:90],'CoordinateSystem','polar','Type','powerdb')
```



Plot an elevation cut of the directivity.

```
pattern(antenna,fc,20,[-90:90],'CoordinateSystem','polar','Type','directivity')
```



Antenna Radiation Pattern in U-V Coordinates

Define a custom antenna in *u*-*v* space. Then, calculate and plot the response.

Define the radiation pattern (in dB) of an antenna in terms of *u* and *v* coordinates within the unit circle.

```
u = -1:0.01:1;
v = -1:0.01:1;
[u_grid,v_grid] = meshgrid(u,v);
pat_uv = sqrt(1 - u_grid.^2 - v_grid.^2);
pat_uv(hypot(u_grid,v_grid) >= 1) = 0;
```

Create an antenna with this radiation pattern. Convert u-v coordinates to azimuth and elevation coordinates.

```
[pat_azel,az,el] = uv2azelpat(pat_uv,u,v);
array = phased.CustomAntennaElement('AzimuthAngles',az,'ElevationAngles',el, ...
    'MagnitudePattern',mag2db(pat_azel),'PhasePattern',45*ones(size(pat_azel)));
```

Calculate the response in the direction $u = 0.5$, $v = 0$. Assume the antenna operates at 1 GHz. The output of the step method is in linear units.

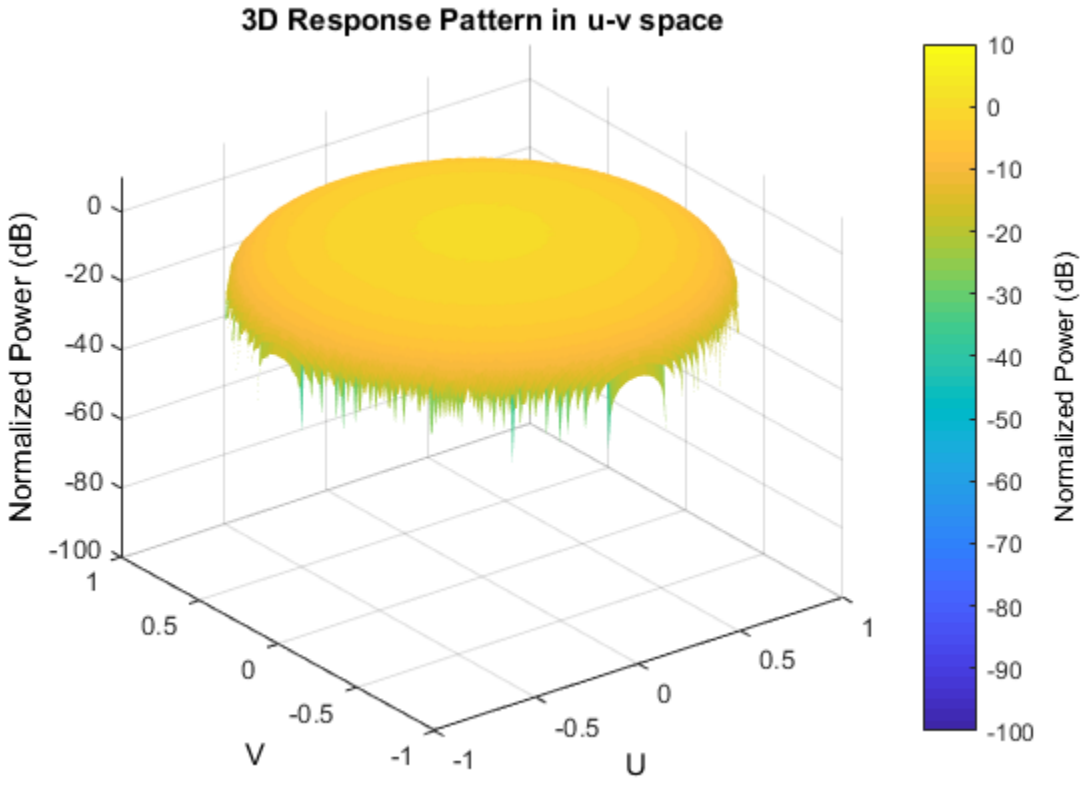
```
dir_uv = [0.5;0];
dir_azel = uv2azel(dir_uv);
fc = 1e9;
resp = array(fc,dir_azel)
```

```
resp =

   0.6124 + 0.6124i
```

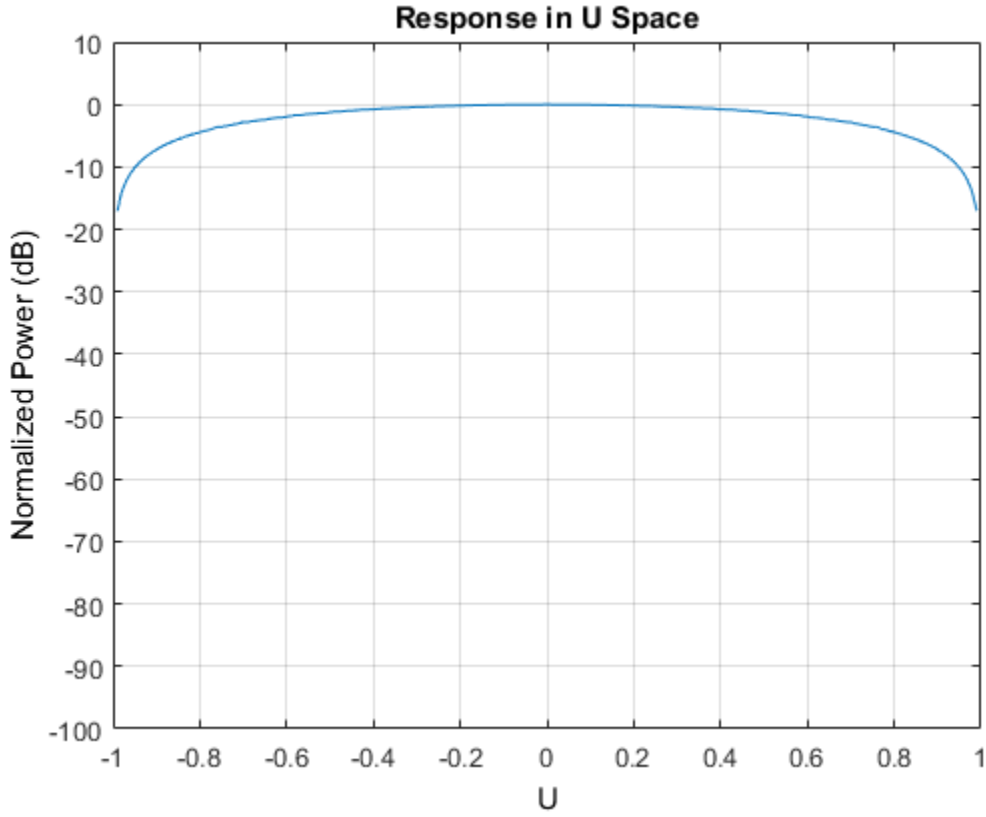
Plot the 3D response in u-v coordinates.

```
pattern(array,fc,[-1:.01:1],[-1:.01:1],'CoordinateSystem','uv','Type','powerdb')
```



Display the antenna response as a line plot in *u*-*v* coordinates.

```
pattern(array,fc,[-1:.01:1],0,'CoordinateSystem','uv','Type','powerdb')
```



Polarized Antenna Radiation Patterns

Model a short dipole antenna oriented along the x-axis of the local antenna coordinate system. For this type of antenna, the horizontal and vertical components of the electric field are given by $E_H = \frac{j\omega\mu IL}{4\pi r}\sin(\text{az})$ and $E_V = -\frac{j\omega\mu IL}{4\pi r}\sin(\text{el})\cos(\text{az})$.

Specify a normalized radiation pattern of a short dipole antenna terms of azimuth, az, and elevation, el, coordinates. The vertical and horizontal radiation patterns are normalized to a maximum of unity.

```
az = [-180:180];
el = [-90:90];
[az_grid,el_grid] = meshgrid(az,el);
```

```
horz_pat_azel = ...
    mag2db(abs(sind(az_grid)));
vert_pat_azel = ...
    mag2db(abs(sind(el_grid).*cosd(az_grid)));
```

Set up the antenna. Specify the `SpecifyPolarizationPattern` property to produce polarized radiation. In addition, use the `HorizontalMagnitudePattern` and `VerticalMagnitudePattern` properties to specify the pattern magnitude values. The `HorizontalPhasePattern` and `VerticalPhasePattern` properties take default values of zero.

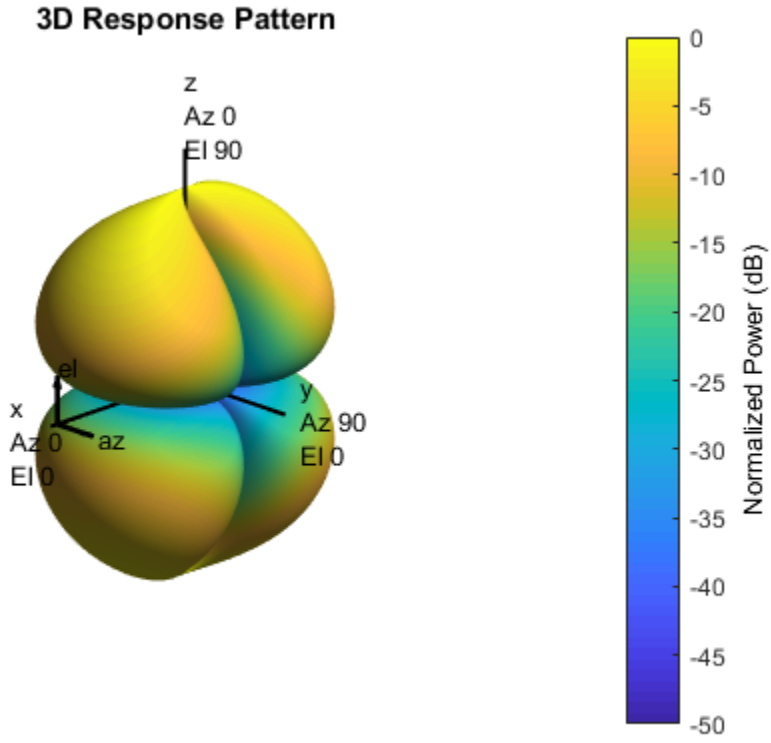
```
sCust = phased.CustomAntennaElement(...
    'AzimuthAngles',az,'ElevationAngles',el,...
    'SpecifyPolarizationPattern',true,...
    'HorizontalMagnitudePattern',horz_pat_azel,...
    'VerticalMagnitudePattern',vert_pat_azel);
```

Assume the antenna operates at 1 GHz.

```
fc = 1e9;
```

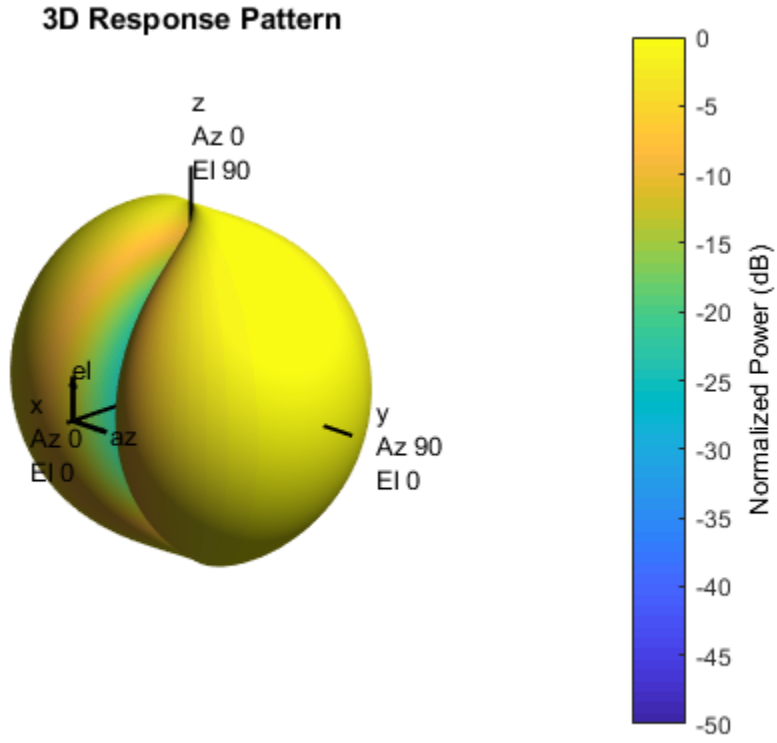
Display the vertical response pattern.

```
pattern(sCust,fc,[-180:180],[-90:90],...
    'CoordinateSystem','polar',...
    'Type','powerdb',...
    'Polarization','V')
```



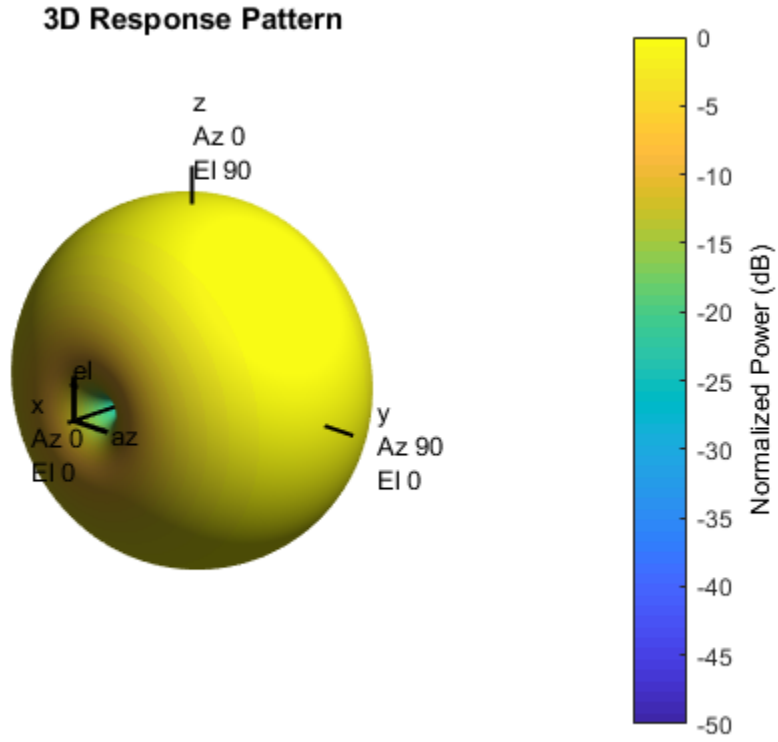
Display the horizontal response pattern.

```
pattern(sCust,fc,[-180:180],[-90:90],...
    'CoordinateSystem','polar',...
    'Type','powerdb',...
    'Polarization','H')
```



The combined polarization response, shown below, illustrates the x-axis null of the dipole.

```
pattern(sCust,fc,[-180:180],[-90:90],...
    'CoordinateSystem','polar',...
    'Type','powerdb',...
    'Polarization','combined')
```



Algorithms

The total response of a custom antenna element is a combination of its frequency response and spatial response. `phased.CustomAntennaElement` calculates both responses using nearest neighbor interpolation, and then multiplies the responses to form the total response.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- `pattern`, `patternAzimuth`, `patternElevation`, and `plotResponse` methods are not supported.
- See "System Objects in MATLAB Code Generation" (MATLAB Coder).

Introduced in R2012a

directivity

System object: phased.CustomAntennaElement
Package: phased

Directivity of custom antenna element

Syntax

```
D = directivity(H,FREQ,ANGLE)
```

Description

`D = directivity(H,FREQ,ANGLE)` returns the "Directivity" on page 1-412 of a custom antenna element, `H`, at frequencies specified by `FREQ` and in direction angles specified by `ANGLE`.

Input Arguments

`H` — Custom antenna element

System object

Custom antenna element specified as a phased.CustomAntennaElement System object.

Example: `H = phased.CustomAntennaElement;`

`FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the

directivity is returned as `-Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.

- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `-Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

`ANGLE` — Angles for computing directivity

1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Angles for computing directivity, specified as a 1-by-*M* real-valued row vector or a 2-by-*M* real-valued matrix, where *M* is the number of angular directions. Angle units are in degrees. If `ANGLE` is a 2-by-*M* matrix, then each column specifies a direction in azimuth and elevation, `[az;el]`. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°.

If `ANGLE` is a 1-by-*M* vector, then each entry represents an azimuth angle, with the elevation angle assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis.

Example: `[45 60; 0 10]`

Data Types: `double`

Output Arguments

`D` — Directivity

M-by-*L* matrix

Directivity, returned as an *M*-by-*L* matrix whose columns contain the directivities at the *M* angles specified by `ANGLE`. Each column corresponds to one of the *L* frequency values specified in `FREQ`. Directivity units are in dBi.

Examples

Directivity of Custom Antenna Element

Compute the directivity of a custom antenna element.

Define an antenna pattern for a custom antenna element in azimuth-elevation space. The pattern is omnidirectional in the azimuth direction and has a cosine pattern in the elevation direction. Assume the antenna operates at 1 GHz. Get the response at zero degrees azimuth and from -30 to 30 degrees elevation.

```
fc = 1e9;
azang = [-180:180];
elang = [-90:90];
magpattern = mag2db(repmat(cosd(elang)',1,numel(azang)));
phasepattern = zeros(size(magpattern));
antenna = phased.CustomAntennaElement('AzimuthAngles',azang, ...
    'ElevationAngles',elang,'MagnitudePattern',magpattern, ...
    'PhasePattern',phasepattern);
```

Calculate the directivities as a function of elevation for 0° azimuth angle.

```
angs = [0,0,0,0,0,0,0;-30,-20,-10,0,10,20,30];
freq = 1e9;
d = directivity(antenna,freq,angs)
```

```
d =

    0.5115
    1.2206
    1.6279
    1.7609
    1.6279
    1.2206
    0.5115
```

The directivity is maximum at 0° elevation.

Definitions

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element directivity” and “Array directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

phased.CustomAntennaElement.pattern

isPolarizationCapable

System object: phased.CustomAntennaElement
Package: phased

Polarization capability

Syntax

```
flag = isPolarizationCapable(antenna)
```

Description

`flag = isPolarizationCapable(antenna)` returns a Boolean value, `flag`, indicating whether the phased.CustomAntennaElement System object supports polarization. An antenna element supports polarization if it can create or respond to polarized fields. This antenna object supports both polarized and nonpolarized fields.

Input Arguments

`antenna` — Custom antenna element

`phased.CustomAntennaElement` System object

Custom antenna element, specified as a phased.CustomAntennaElement System object.

Output Arguments

`flag` — Polarization-capability flag

Polarization-capability returned as a Boolean value `true` if the antenna element supports polarization or `false` if it does not. The returned value depends upon the value of the `SpecifyPolarizationPattern` property. If `SpecifyPolarizationPattern` is `true`, then `flag` is `true`. Otherwise it is `false`.

Examples

Custom Antenna Element Supports Polarization

Show that the `CustomAntennaElement` antenna element supports polarization when the `SpecifyPolarizationPattern` property is set to `true`.

```
antenna = phased.CustomAntennaElement('SpecifyPolarizationPattern',true);
isPolarizationCapable(antenna)
```

```
ans =

  logical

   1
```

The returned value `1` shows that this antenna element supports polarization.

pattern

System object: phased.CustomAntennaElement
Package: phased

Plot custom antenna element directivity and patterns

Syntax

```
pattern(sElem,FREQ)
pattern(sElem,FREQ,AZ)
pattern(sElem,FREQ,AZ,EL)
pattern( ___ ,Name,Value)
[PAT,AZ_ANG,EL_ANG] = pattern( ___ )
```

Description

`pattern(sElem,FREQ)` plots the 3-D array directivity pattern (in dBi) for the element specified in `sElem`. The operating frequency is specified in `FREQ`.

`pattern(sElem,FREQ,AZ)` plots the element directivity pattern at the specified azimuth angle.

`pattern(sElem,FREQ,AZ,EL)` plots the element directivity pattern at specified azimuth and elevation angles.

`pattern( ___ ,Name,Value)` plots the element pattern with additional options specified by one or more `Name,Value` pair arguments.

`[PAT,AZ_ANG,EL_ANG] = pattern( ___ )` returns the element pattern in `PAT`. The `AZ_ANG` output contains the coordinate values corresponding to the rows of `PAT`. The `EL_ANG` output contains the coordinate values corresponding to the columns of `PAT`. If the `'CoordinateSystem'` parameter is set to `'uv'`, then `AZ_ANG` contains the *U* coordinates of the pattern and `EL_ANG` contains the *V* coordinates of the pattern. Otherwise, they are in angular units in degrees. *UV* units are dimensionless.

Note: This method replaces the `plotResponse` method. See "Convert plotResponse to pattern" on page 1-425 for guidelines on how to use `pattern` in place of `plotResponse`.

Input Arguments

`sElem` — Custom antenna element

System object

Custom antenna element, specified as a phased.CustomAntennaElement System object.

Example: `sElem = phased.CustomAntennaElement;`

`FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `-Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `-Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

`AZ` — Azimuth angles

`[-180:180]` (default) | 1-by-*M* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a 1-by-*M* real-valued row vector where *M* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, this angle is positive.

Example: `[-45:2:45]`

Data Types: `double`

`EL` — Elevation angles

`[-90:90]` (default) | 1-by-*N* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a 1-by-*N* real-valued row vector where *N* is the number of desired elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and *xy*-plane. When measured towards the *z*-axis, this angle is positive.

Example: `[-75:1:70]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'CoordinateSystem'` — Plotting coordinate system

`'polar'` (default) | `'rectangular'` | `'uv'`

Plotting coordinate system of the pattern, specified as the comma-separated pair consisting of `'CoordinateSystem'` and one of `'polar'`, `'rectangular'`, or `'uv'`. When `'CoordinateSystem'` is set to `'polar'` or `'rectangular'`, the `AZ` and `EL` arguments specify the pattern azimuth and elevation, respectively. `AZ` values must lie between –180° and 180°. `EL` values must lie between –90° and 90°. If `'CoordinateSystem'` is set to `'uv'`, `AZ` and `EL` then specify *U* and *V* coordinates, respectively. `AZ` and `EL` must lie between -1 and 1.

Example: `'uv'`

Data Types: `char`

'Type' — Displayed pattern type
'directivity' (default) | 'efield' | 'power' | 'powerdb'

Displayed pattern type, specified as the comma-separated pair consisting of 'Type' and one of

- 'directivity' — directivity pattern measured in dBi.
- 'efield' — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- 'power' — power pattern of the sensor or array defined as the square of the field pattern.
- 'powerdb' — power pattern converted to dB.

Example: 'powerdb'

Data Types: char

'Normalize' — Display normalize pattern
true (default) | false

Display normalized pattern, specified as the comma-separated pair consisting of 'Normalize' and a Boolean. Set this parameter to true to display a normalized pattern. When you set 'Type' to 'directivity', this parameter does not apply. Directivity patterns are already normalized.

Example:

Data Types: logical

'PlotStyle' — Plotting style
'overlay' (default) | 'waterfall'

Plotting style, specified as the comma-separated pair consisting of 'Plotstyle' and either 'overlay' or 'waterfall'. This parameter applies when you specify multiple frequencies in FREQ in 2-D plots. You can draw 2-D plots by setting one of the arguments AZ or EL to a scalar.

Example:

Data Types: char

'Polarization' — Polarized field component
'combined' (default) | 'H' | 'V'

Polarized field component to display, specified as the comma-separated pair consisting of 'Polarization' and `'combined'`, `'H'`, or `'V'`. This parameter applies only when the sensors are polarization-capable and when the `'Type'` parameter is not set to `'directivity'`. This table shows the meaning of the display options

`'Polarization'`	Display
`'combined'`	Combined *H* and *V* polarization components
`'H'`	*H* polarization component
`'V'`	*V* polarization component

Example: `'V'`

Data Types: `char`

Output Arguments

PAT — Element pattern

M-by-*N* real-valued matrix

Element pattern, returned as an *M*-by-*N* real-valued matrix. The dimensions of PAT correspond to the dimensions of the output arguments AZ_ANG and EL_ANG.

AZ_ANG — Azimuth angles

scalar | 1-by-*M* real-valued row vector

Azimuth angles for displaying directivity or response pattern, returned as a scalar or 1-by-*M* real-valued row vector corresponding to the dimension set in AZ. The rows of PAT correspond to the values in AZ_ANG.

EL_ANG — Elevation angles

scalar | 1-by-*N* real-valued row vector

Elevation angles for displaying directivity or response, returned as a scalar or 1-by-*N* real-valued row vector corresponding to the dimension set in EL. The columns of PAT correspond to the values in EL_ANG.

Examples

Power and Directivity Patterns of Custom Antenna

Create a custom antenna with a cosine pattern. Show the response at boresight. Then, plot the antenna's field and directivity patterns.

Create the antenna and calculate the response. The user-defined pattern is omnidirectional in the azimuth direction and has a cosine pattern in the elevation direction. Assume the antenna works at 1 GHz.

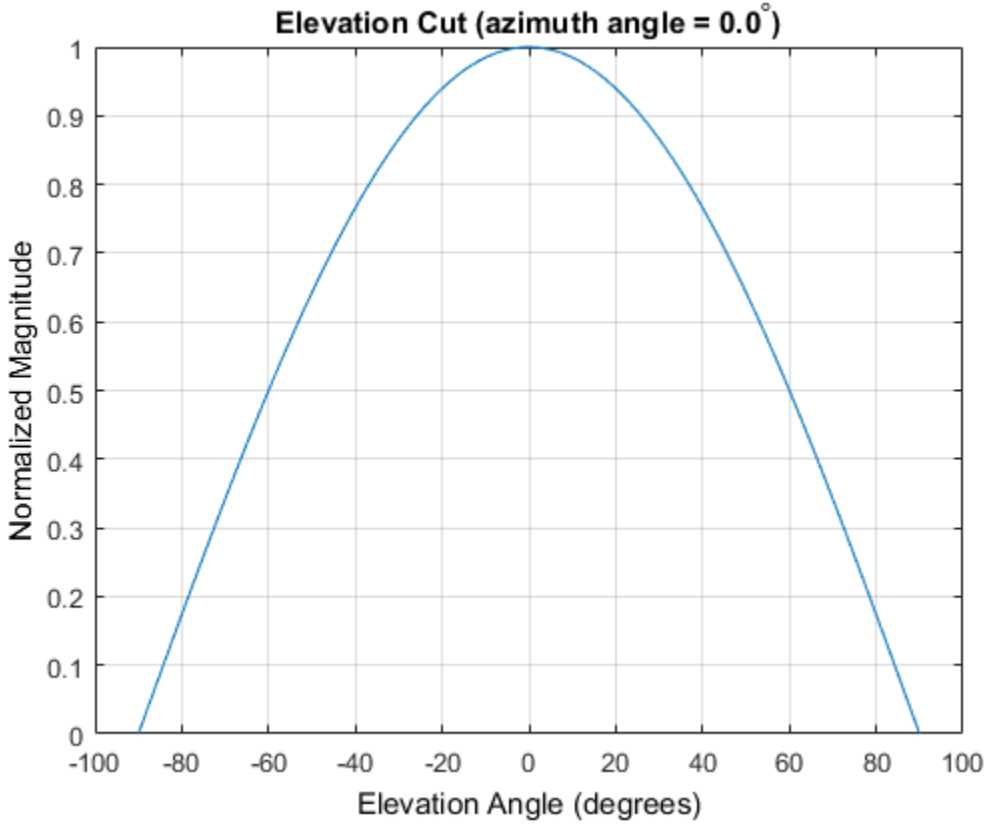
```
fc = 1e9;
antenna = phased.CustomAntennaElement;
antenna.AzimuthAngles = -180:180;
antenna.ElevationAngles = -90:90;
antenna.MagnitudePattern = mag2db(repmat(cosd(antenna.ElevationAngles)', ...
    1,numel(antenna.AzimuthAngles)));
resp = antenna(fc,[0;0])
```

```
resp =

     1
```

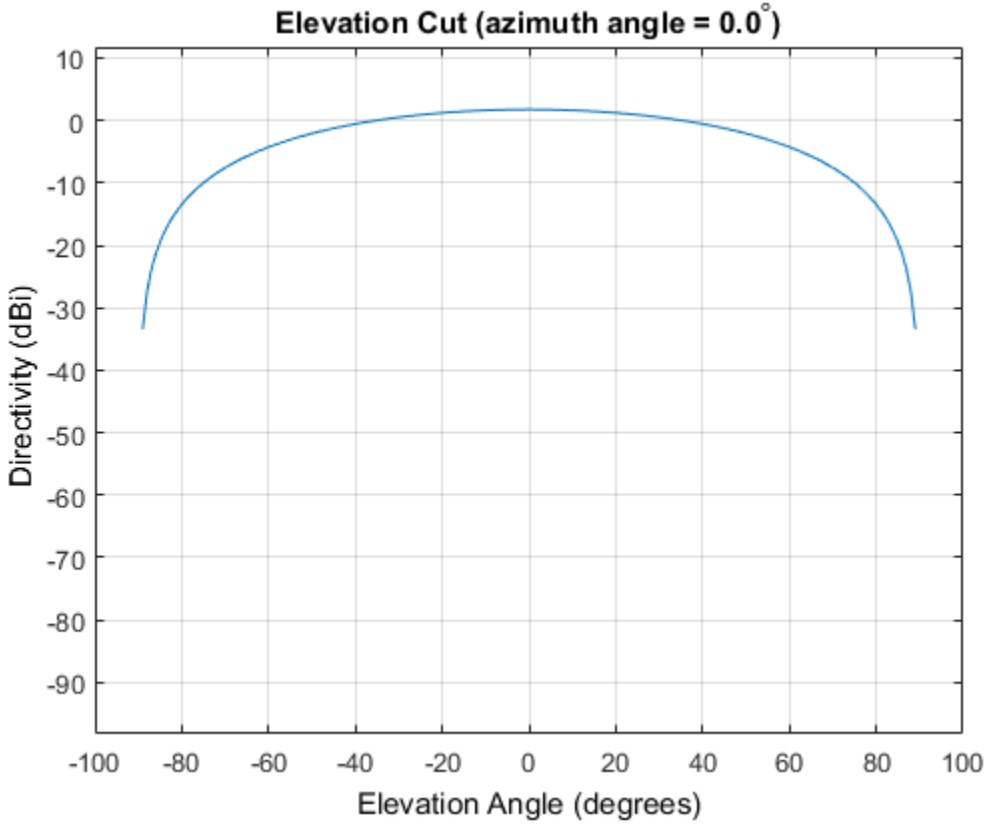
Plot an elevation cut of the magnitude response as a line plot.

```
pattern(antenna,fc,0,[-90:90],'CoordinateSystem','rectangular', ...
    'Type','efield')
```



Plot an elevation cut of the directivity as a line plot, showing that the maximum directivity is approximately 2 dB.

```
pattern(antenna,fc,0,[-90:90],'CoordinateSystem','rectangular', ...
    'Type','directivity')
```



Pattern of Custom Antenna Over Selected Range of Angles

Create an custom antenna System object. The user-defined pattern is omnidirectional in the azimuth direction and has a cosine pattern in the elevation direction. Assume the antenna operates at a frequency of 1 GHz. First show the response at boresight. Display the 3-D pattern for a 60 degree range of azimuth and elevation angles centered at 0 degrees azimuth and 0 degrees elevation in 0.1 degree increments.

```
fc = 1e9;
azang = -180:180;
elang = -90:90;
magpattern = mag2db(repmat(cosd(elang)',1,numel(azang)));
antenna = phased.CustomAntennaElement('AzimuthAngles',azang, ...
    'ElevationAngles',elang,'MagnitudePattern',magpattern);
```

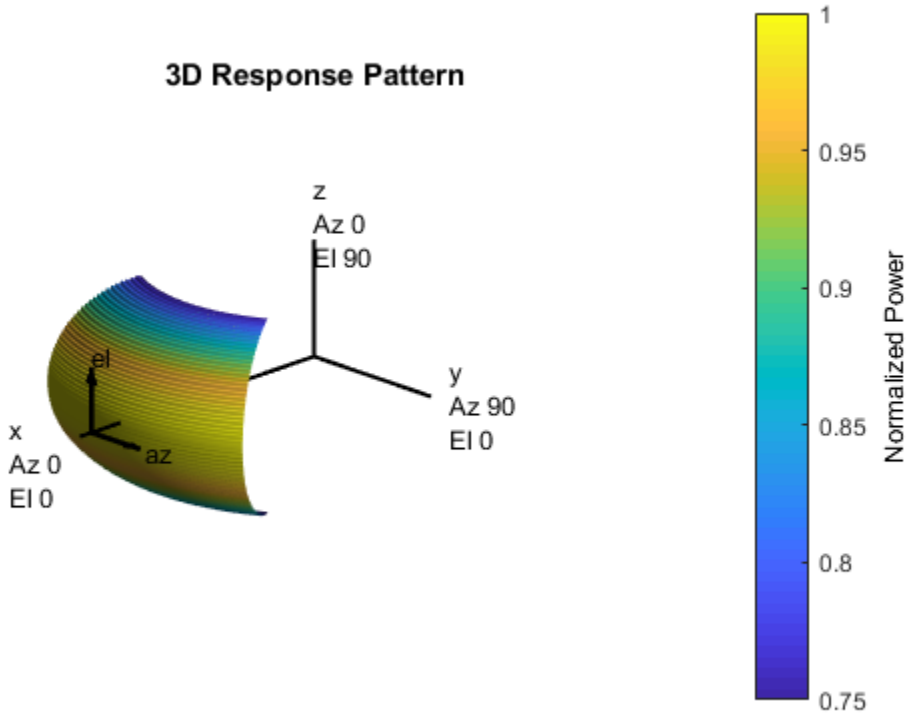
```
resp = antenna(fc,[0;0])
```

```
resp =

     1
```

Plot the power pattern for a range of angles.

```
pattern(antenna,fc,[-30:0.1:30],[-30:0.1:30],'CoordinateSystem','polar', ...
    'Type','power')
```



More About

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on "Element directivity" and "Array directivity".

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

Convert plotResponse to pattern

For antenna, microphone, and array System objects, the `pattern` method replaces the `plotResponse` method. In addition, two new simplified methods exist just to draw 2-D azimuth and elevation pattern plots. These methods are `azimuthPattern` and `elevationPattern`.

The following table is a guide for converting your code from using `plotResponse` to `pattern`. Notice that some of the inputs have changed from *input arguments* to *Name-Value* pairs and conversely. The general `pattern` method syntax is

```
pattern(H,FREQ,AZ,EL,'Name1','Value1',...,'NameN','ValueN')
```

plotResponse Inputs	plotResponse Description	pattern Inputs
`H` argument	Antenna, microphone, or array System object.	`H` argument (no change)
`FREQ` argument	Operating frequency.	`FREQ` argument (no change)

plotResponse Inputs	plotResponse Description	pattern Inputs
`V` argument	Propagation speed. This argument is used only for arrays.	`'PropagationSpeed'` name-value pair. This parameter is only used for arrays.

<table>
<tr><th>plotResponse Inputs</th><th>plotResponse Description</th><th>pattern Inputs</th></tr>
<tr>
<td>'Format' and 'RespCut' name-value pairs</td>
<td>These options work together to let you create a plot in angle space (line or polar style) or UV space. They also determine whether the plot is 2-D or 3-D. This table shows you how to create different types of plots using plotResponse.
<table>
<tr><th>Display space</th><th></th></tr>
<tr><td>Angle space (2D)</td><td>Set 'RespCut' to 'Az' or 'El'. Set 'Format' to 'line' or 'polar'.

<tr><td>UV space (3D)</td><td>Set 'CoordinateSystem' to 'uv'. Use AZ to specify a U-space vector. Use EL to specify a V-space vector.</td></tr>
</table>
If you set CoordinateSystem to 'uv', enter the UV grid values using AZ and EL.</td></tr>
<tr><td>'CutAngle' name-value pair</td><td>Constant angle at to take an azimuth or elevation cut. When producing a 2-D plot and when 'RespCut' is set to 'Az' or 'El', use 'CutAngle' to set the slice across which to view the plot.</td><td>No equivalent name-value pair. To create a cut, specify either AZ or EL as a scalar, not a vector.</td></tr>
</table>

plotResponse Inputs	plotResponse Description	pattern Inputs
`'NormalizeResponse'` name-value pair	Normalizes the plot. When `'Unit'` is set to `'dbi'`, you cannot specify `'NormalizeResponse'`.	`'Normalize'` name-value pair. When `'Type'` is set to `'directivity'`, you cannot specify `'Normalize'`. .
`'OverlayFreq'` name-value pair	Plot multiple frequencies on the same 2-D plot. Available only when `'Format'` is set to `'line'` or `'uv'` and `'RespCut'` is not set to `'3D'`. The value `true` produces an overlay plot and the value `false` produces a waterfall plot.	`'PlotStyle'` name-value pair plots multiple frequencies on the same 2-D plot. The values `'overlay'` and `'waterfall'` correspond to `'OverlayFreq'` values of `true` and `false`. The option `'waterfall'` is allowed only when `'CoordinateSystem'` is set to `'rectangular'` or `'uv'`.
`'Polarization'` name-value pair	Determines how to plot polarized fields. Options are `'None'`, `'Combined'`, `'H'`, or `'V'`.	`'Polarization'` name-value pair determines how to plot polarized fields. The `'None'` option is removed. The options `'Combined'`, `'H'`, or `'V'` are unchanged.

`'Unit'` name-value pair	Determines the plot units. Choose `'db'`, `'mag'`, `'pow'`, or `'dbi'`, where the default is `'db'`.	`'Type'` name-value pair, uses equivalent options with different names
		
		plotResponse pattern
		`'db'` `'powerdb'`
		`'mag'` `'efield'`
		`'pow'` `'power'`
		`'dbi'` `'directivity'`

`'Weights'` name-value pair	Array element tapers (or weights).	`'Weights'` name-value pair (no change).

plotResponse Inputs	plotResponse Description	pattern Inputs
`'AzimuthAngles'` name-value pair	Azimuth angles used to display the antenna or array response.	`AZ` argument
`'ElevationAngles'` name-value pair	Elevation angles used to display the antenna or array response.	`EL` argument
`'UGrid'` name-value pair	Contains *U* coordinates in *UV*-space.	`AZ` argument when `'CoordinateSystem'` name-value pair is set to `'uv'`
`'VGrid'` name-value pair	Contains *V*-coordinates in *UV*-space.	`EL` argument when `'CoordinateSystem'` name-value pair is set to `'uv'`

phased.CustomAntennaElement.patternAzimuth | phased.CustomAntennaElement.patternElevation

Introduced in R2015a

patternAzimuth

System object: phased.CustomAntennaElement
Package: phased

Plot custom antenna element directivity or pattern versus azimuth

Syntax

```
patternAzimuth(sElem,FREQ)
patternAzimuth(sElem,FREQ,EL)
patternAzimuth(sElem,FREQ,EL,Name,Value)
PAT = patternAzimuth( ___ )
```

Description

`patternAzimuth(sElem,FREQ)` plots the 2-D element directivity pattern versus azimuth (in dBi) for the element `sElem` at zero degrees elevation angle. The argument `FREQ` specifies the operating frequency.

`patternAzimuth(sElem,FREQ,EL)`, in addition, plots the 2-D element directivity pattern versus azimuth (in dBi) at the elevation angle specified by `EL`. When `EL` is a vector, multiple overlaid plots are created.

`patternAzimuth(sElem,FREQ,EL,Name,Value)` plots the element pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternAzimuth( ___ )` returns the element pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Azimuth'` parameter and the `EL` input argument.

Input Arguments

`sElem` — Custom antenna element

System object

Custom antenna element, specified as a phased.CustomAntennaElement System object.

Example: `sElem = phased.CustomAntennaElement;`

`FREQ` — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

`EL` — Elevation angles

1-by-*N* real-valued row vector

Elevation angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector. The quantity *N* is the number of requested elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and the *xy* plane. When measured toward the *z*-axis, this angle is positive.

Example: `[0,10,20]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Type'` — Displayed pattern type
`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

`'Azimuth'` — Azimuth angles
`[-180:180]` (default) | 1-by-*P* real-valued row vector

Azimuth angles, specified as the comma-separated pair consisting of `'Azimuth'` and a 1-by-*P* real-valued row vector. Azimuth angles define where the array pattern is calculated.

Example: `'Azimuth',[-90:2:90]`

Data Types: `double`

Output Arguments

`PAT` — Element directivity or pattern
L-by-*N* real-valued matrix

Element directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of azimuth values determined by the `'Azimuth'` name-value pair argument. The dimension *N* is the number of elevation angles, as determined by the `EL` input argument.

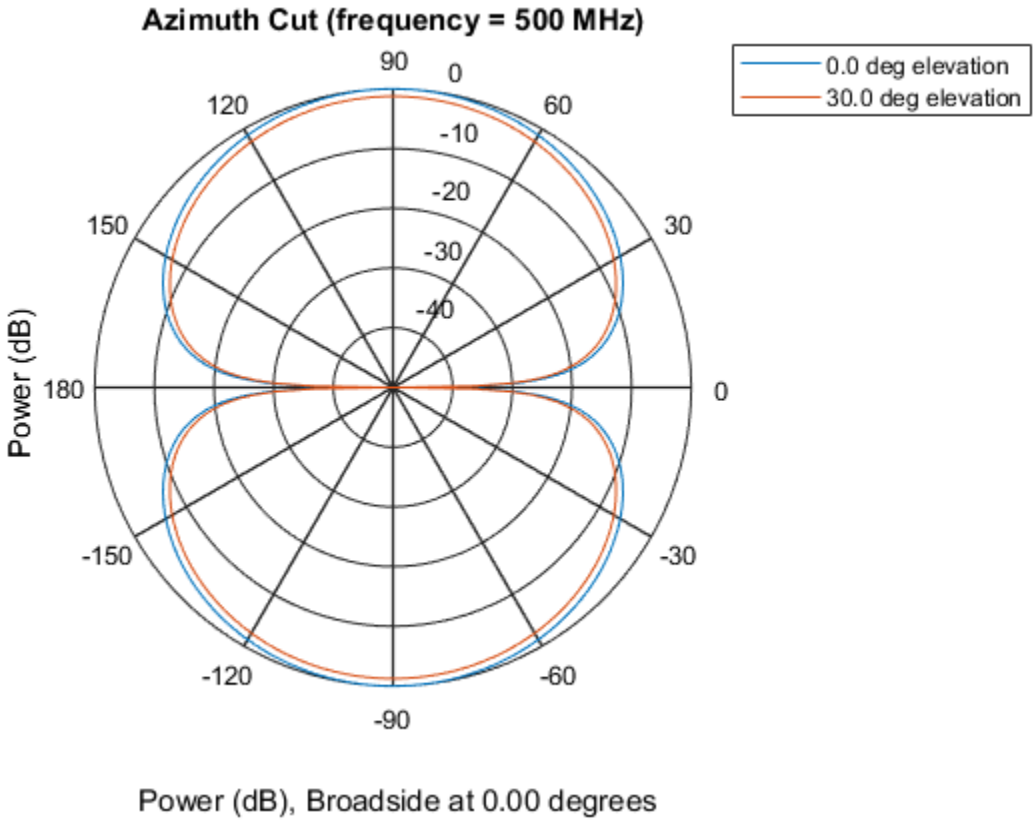
Examples

Reduced Azimuth Pattern of Custom Antenna Element

Create an antenna with a custom response. The user-defined pattern has a sine pattern in the azimuth direction and a cosine pattern in the elevation direction. Assume the antenna operates at a frequency of 500 MHz. Plot an azimuth cut of the power pattern of the custom antenna element at 0 and 30 degrees elevation. Assume the operating frequency is 500 MHz.

Create the antenna element.

```
fc = 500e6;
antenna = phased.CustomAntennaElement;
antenna.AzimuthAngles = -180:180;
antenna.ElevationAngles = -90:90;
antenna.MagnitudePattern = mag2db(abs(cosd(antenna.ElevationAngles)'*sind(antenna.Azimu
patternAzimuth(antenna,fc,[0 30],'Type','powerdb')
```



Plot a reduced range of azimuth angles using the `Azimuth` parameter.

```
patternAzimuth(antenna,fc,[0 30],'Azimuth',[-45:45],'Type','powerdb')
```

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on "Element directivity" and "Array directivity".

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

Introduced in R2015a

patternElevation

System object: phased.CustomAntennaElement
Package: phased

Plot custom antenna element directivity or pattern versus elevation

Syntax

```
patternElevation(sElem,FREQ)
patternElevation(sElem,FREQ,AZ)
patternElevation(sElem,FREQ,AZ,Name,Value)
PAT = patternElevation( ___ )
```

Description

`patternElevation(sElem,FREQ)` plots the 2-D element directivity pattern versus elevation (in dBi) for the element `sElem` at zero degrees azimuth angle. The argument `FREQ` specifies the operating frequency.

`patternElevation(sElem,FREQ,AZ)`, in addition, plots the 2-D element directivity pattern versus elevation (in dBi) at the azimuth angle specified by `AZ`. When `AZ` is a vector, multiple overlaid plots are created.

`patternElevation(sElem,FREQ,AZ,Name,Value)` plots the element pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternElevation( ___ )` returns the element pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Elevation'` parameter and the `AZ` input argument.

Input Arguments

`sElem` — Custom antenna element

System object

Custom antenna element, specified as a phased.CustomAntennaElement System object.

Example: `sElem = phased.CustomAntennaElement;`

FREQ — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

AZ — Azimuth angles for computing directivity and pattern

1-by-*N* real-valued row vector

Azimuth angles for computing sensor or array directivities and patterns, specified as a 1-by-*M* real-valued row vector where *N* is the number of desired azimuth directions. Angle units are in degrees. The azimuth angle must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `[0,10,20]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'Type' — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

'Elevation' — Elevation angles

`[-90:90]` (default) | 1-by-*P* real-valued row vector

Elevation angles, specified as the comma-separated pair consisting of `'Elevation'` and a 1-by-*P* real-valued row vector. Elevation angles define where the array pattern is calculated.

Example: `'Elevation',[-90:2:90]`

Data Types: `double`

Output Arguments

PAT — Element directivity or pattern

L-by-*N* real-valued matrix

Element directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of elevation angles determined by the `'Elevation'` name-value pair argument. The dimension *N* is the number of azimuth angles determined by the `AZ` argument.

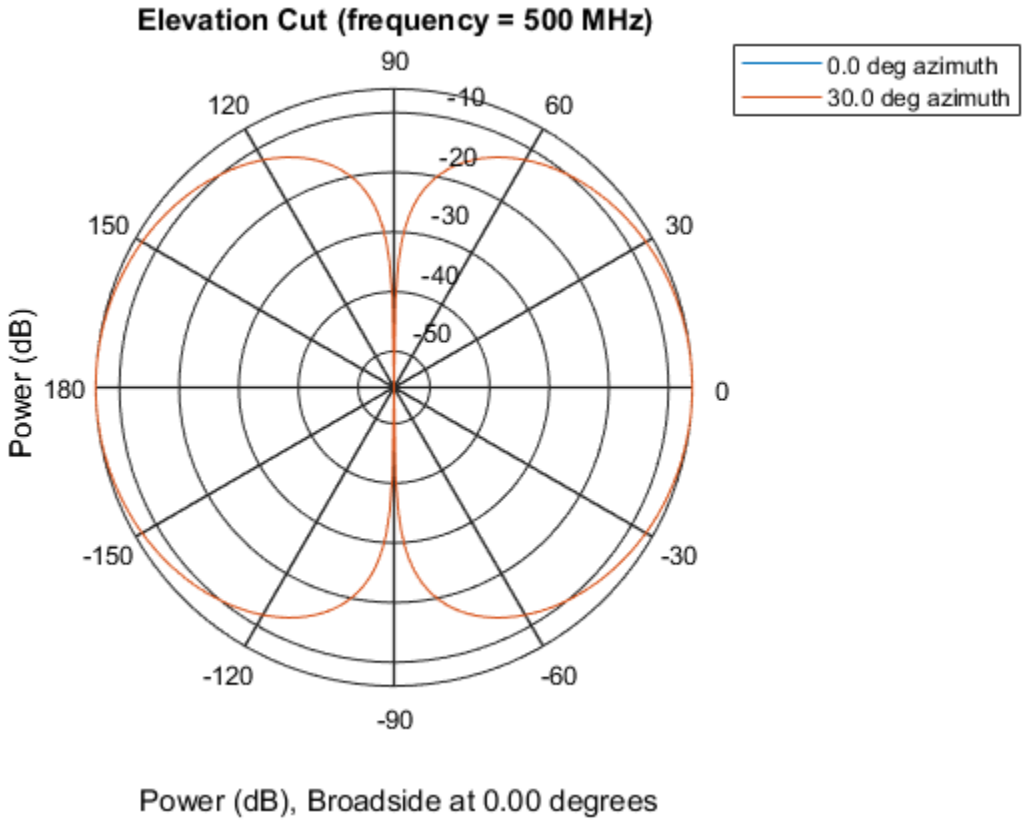
Examples

Reduced Elevation Pattern of Custom Antenna Element

Create an antenna with a custom response. The user-defined pattern has a sine pattern in the azimuth direction and a cosine pattern in the elevation direction. Assume the antenna operates at a frequency of 500 MHz. Plot an elevation cut of the power of the custom antenna element at 0 and 30 degrees elevation. Assume the operating frequency is 500 MHz.

Create the antenna element.

```
fc = 500e6;
antenna = phased.CustomAntennaElement;
antenna.AzimuthAngles = -180:180;
antenna.ElevationAngles = -90:90;
antenna.MagnitudePattern = mag2db(abs(cosd(antenna.ElevationAngles)'*sind(antenna.Azimu
patternElevation(antenna,fc,[0 30],'Type','powerdb')
```



Plot a reduced range of elevation angles using the `Azimuth` parameter.

```
patternElevation(antenna,fc,[0 30],'Elevation',[-45:45],'Type','powerdb')
```

phased.CustomAntennaElement.pattern |
phased.CustomAntennaElement.patternAzimuth

Introduced in R2015a

plotResponse

System object: phased.CustomAntennaElement
Package: phased

Plot response pattern of antenna

Syntax

```
plotResponse(H,FREQ)
plotResponse(H,FREQ,Name,Value)
hPlot = plotResponse( ___ )
```

Description

`plotResponse(H,FREQ)` plots the element response pattern along the azimuth cut, where the elevation angle is 0. The operating frequency is specified in `FREQ`.

`plotResponse(H,FREQ,Name,Value)` plots the element response with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = plotResponse( ___ )` returns handles of the lines or surface in the figure window, using any of the input arguments in the previous syntaxes.

Input Arguments

`H`

Element System object

`FREQ`

Operating frequency in Hertz specified as a scalar or 1–by-*K* row vector. `FREQ` must lie within the range specified by the `FrequencyVector` property of `H`. If you set the `'RespCut'` property of `H` to `'3D'`, `FREQ` must be a scalar. When `FREQ` is a row vector, `plotResponse` draws multiple frequency responses on the same axes.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'CutAngle'`

Cut angle specified as a scalar. This argument is applicable only when `RespCut` is `'Az'` or `'El'`. If `RespCut` is `'Az'`, `CutAngle` must be between –90 and 90. If `RespCut` is `'El'`, `CutAngle` must be between –180 and 180.

Default: `0`

`'Format'`

Format of the plot, using one of `'Line'`, `'Polar'`, or `'UV'`. If you set `Format` to `'UV'`, `FREQ` must be a scalar.

Default: `'Line'`

`'NormalizeResponse'`

Set this value to `true` to normalize the response pattern. Set this value to `false` to plot the response pattern without normalizing it. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

Default: `true`

`'OverlayFreq'`

Set this value to `true` to overlay pattern cuts in a 2-D line plot. Set this value to `false` to plot pattern cuts against frequency in a 3-D waterfall plot. If this value is `false`, `FREQ` must be a vector with at least two entries.

This parameter applies only when `Format` is not `'Polar'` and RespCut is not `'3D'`.

Default: `true`

`'Polarization'`

Specify the polarization options for plotting the antenna response pattern. The allowable values are `|'None' | 'Combined' | 'H' | 'V' |` where

- `'None'` specifies plotting a nonpolarized response pattern
- `'Combined'` specifies plotting a combined polarization response pattern
- `'H'` specifies plotting the horizontal polarization response pattern
- `'V'` specifies plotting the vertical polarization response pattern

For antennas that do not support polarization, the only allowed value is `'None'`. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

Default: `'None'`

`'RespCut'`

Cut of the response. Valid values depend on `Format`, as follows:

- If `Format` is `'Line'` or `'Polar'`, the valid values of `RespCut` are `'Az'`, `'El'`, and `'3D'`. The default is `'Az'`.
- If `Format` is `'UV'`, the valid values of `RespCut` are `'U'` and `'3D'`. The default is `'U'`.

If you set `RespCut` to `'3D'`, `FREQ` must be a scalar.

`'Unit'`

The unit of the plot. Valid values are `'db'`, `'mag'`, `'pow'`, or `'dbi'`. This parameter determines the type of plot that is produced.

Unit value	Plot type
`db`	power pattern in dB scale
`mag`	field pattern
`pow`	power pattern
`dbi`	directivity

Default: `'db'`

`'AzimuthAngles'`

Azimuth angles for plotting element response, specified as a row vector. The `AzimuthAngles` parameter sets the display range and resolution of azimuth angles for

visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'Az'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of azimuth angles should lie between –180° and 180° and must be in nondecreasing order. When you set the `RespCut` parameter to `'3D'`, you can set the `AzimuthAngles` and `ElevationAngles` parameters simultaneously.

Default: `[-180:180]`

`'ElevationAngles'`

Elevation angles for plotting element response, specified as a row vector. The `ElevationAngles` parameter sets the display range and resolution of elevation angles for visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'El'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of elevation angles should lie between –90° and 90° and must be in nondecreasing order. When you set the `RespCut` parameter to `'3D'`, you can set the `ElevationAngles` and `AzimuthAngles` parameters simultaneously.

Default: `[-90:90]`

`'UGrid'`

U coordinate values for plotting element response, specified as a row vector. The `UGrid` parameter sets the display range and resolution of the *U* coordinates for visualizing the radiation pattern in *U*/*V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'U'` or `'3D'`. The values of `UGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set the `UGrid` and `VGrid` parameters simultaneously.

Default: `[-1:0.01:1]`

`'VGrid'`

V coordinate values for plotting element response, specified as a row vector. The `VGrid` parameter sets the display range and resolution of the *V* coordinates for visualizing the radiation pattern in *U*/*V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'3D'`. The values of `VGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set the `VGrid` and `UGrid` parameters simultaneously.

Default: `[-1:0.01:1]`

Examples

Plot Response and Directivity of Custom Antenna

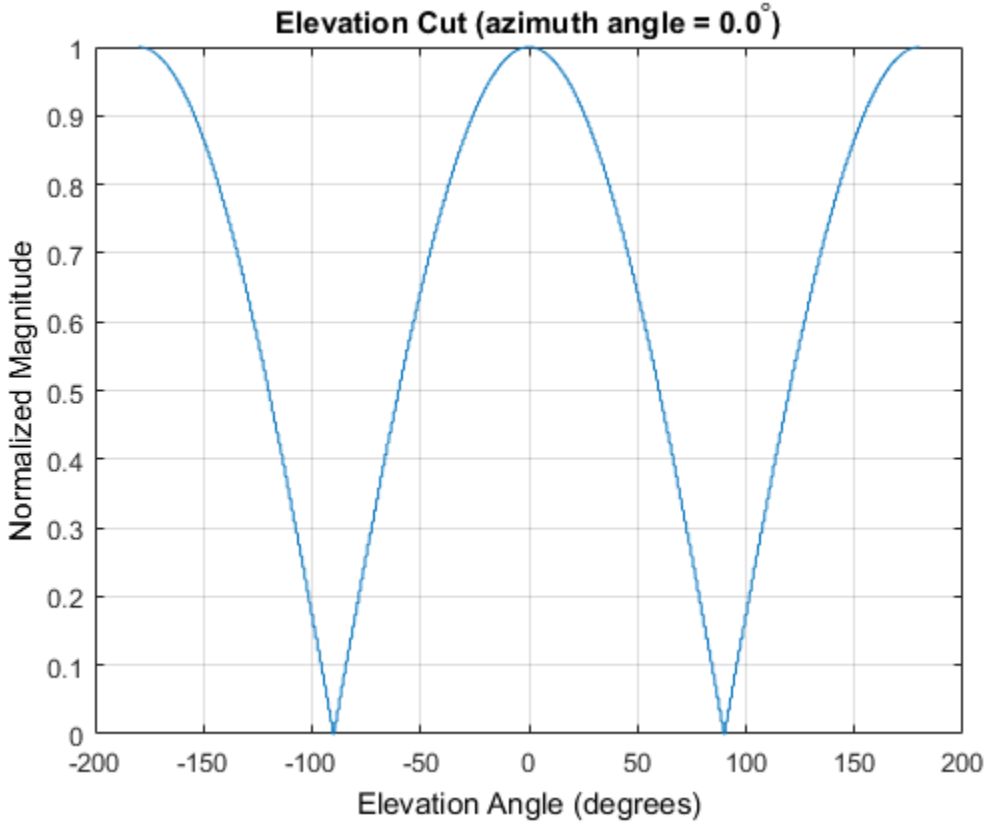
Create a custom antenna with a cosine pattern. Then, plot the antenna's response.

Create the antenna and calculate the response. The user-defined pattern is omnidirectional in the azimuth direction and has a cosine pattern in the elevation direction. Assume the antenna works at 1 GHz.

```
fc = 1e9;
azang = [-180:180];
elang = [-90:90];
magpattern = mag2db(repmat(cosd(elang)',1,numel(azang)));
phasepattern = zeros(size(magpattern));
antenna = phased.CustomAntennaElement('AzimuthAngles',azang, ...
    'ElevationAngles',elang,'MagnitudePattern',magpattern, ...
    'PhasePattern',phasepattern);
```

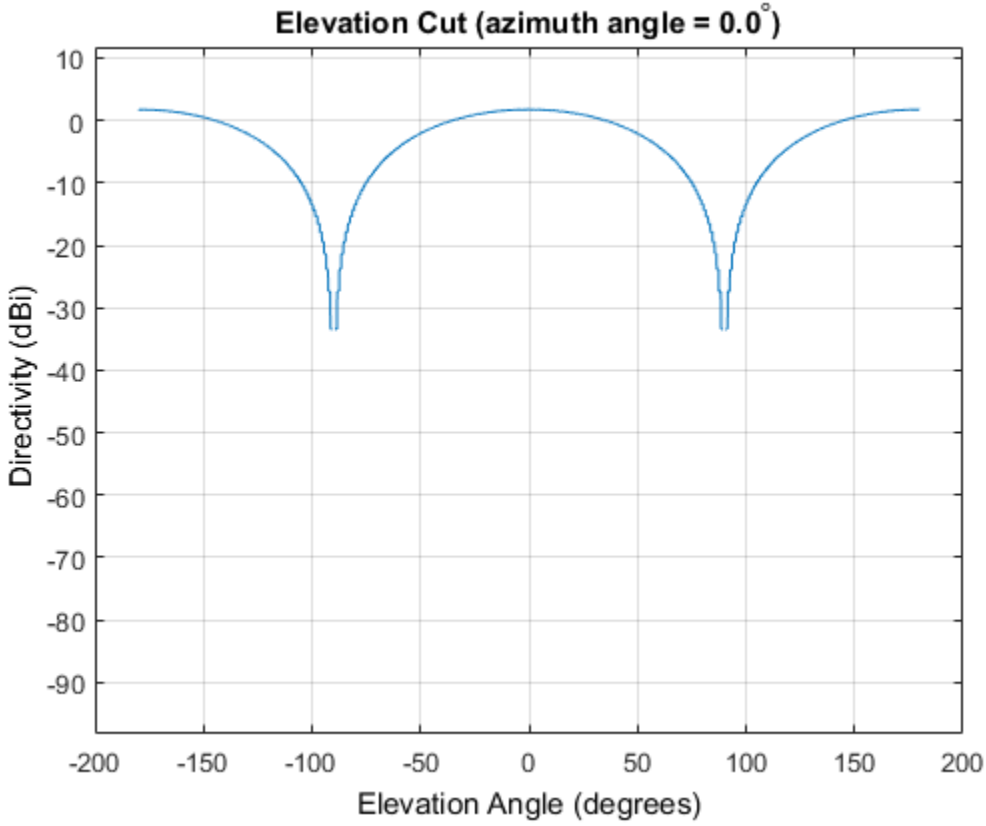
Plot an elevation cut of the magnitude response as a line plot.

```
plotResponse(antenna,fc,'RespCut','El','ElevationAngles',[-90:0.1:90],...
    'Format','Line','Unit','mag')
```



Plot an elevation cut of the directivity as a line plot, showing that the maximum directivity is approximately 2 dB.

```
plotResponse(antenna,fc,'RespCut','El','ElevationAngles',[-90:0.1:90],...
    'Format','Line','Unit','dbi')
```



Plot Response of Custom Antenna Over Selected Range of Angles

Create an antenna with a custom response. The user-defined pattern is omnidirectional in the azimuth direction and has a cosine pattern in the elevation direction. Assume the antenna operates at a frequency of 1 GHz. Display the 3-D response for a 60 degree range of azimuth and elevation angles centered at 0 degrees azimuth and 0 degrees elevation in 0.1 degree increments.

```
fc = 1e9;
azang = [-180:180];
elang = [-90:90];
magpattern = mag2db(repmat(cosd(elang)',1,numel(azang)));
phasepattern = zeros(size(magpattern));
antenna = phased.CustomAntennaElement('AzimuthAngles',azang, ...
```

```
    'ElevationAngles',elang,'MagnitudePattern',magpattern, ...
    'PhasePattern',phasepattern);
resp = antenna(fc,[0;0]);
plotResponse(antenna,fc,'RespCut','3D','AzimuthAngles',[-30:0.1:30],...
    'ElevationAngles',[-30:0.1:30],'Format','Polar','Unit','pow')
```

step

System object: phased.CustomAntennaElement
Package: phased

Output response of antenna element

Syntax

```
RESP = step(H,FREQ,ANG)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`RESP = step(H,FREQ,ANG)` returns the antenna's voltage response `RESP` at operating frequencies specified in `FREQ` and directions specified in `ANG`. The form of `RESP` depends upon whether the antenna element supports polarization as determined by the `SpecifyPolarizationPattern` property. If `SpecifyPolarizationPattern` is set to `false`, `RESP` is an *M*-by-*L* matrix containing the antenna response at the *M* angles specified in `ANG` and at the *L* frequencies specified in `FREQ`. If `SpecifyPolarizationPattern` is set to `true`, `RESP` is a MATLAB `struct` containing two fields, `RESP.H` and `RESP.V`, representing the antenna's response in horizontal and vertical polarization, respectively. Each field is an *M*-by-*L* matrix containing the antenna response at the *M* angles specified in `ANG` and at the *L* frequencies specified in `FREQ`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

H

Antenna element object.

FREQ

Operating frequencies of antenna in hertz. FREQ is a row vector of length L.

ANG

Directions in degrees. ANG can be either a 2-by-M matrix or a row vector of length M.

If ANG is a 2-by-M matrix, each column of the matrix specifies the direction in the form [azimuth; elevation]. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

If ANG is a row vector of length M, each element specifies a direction's azimuth angle. In this case, the corresponding elevation angle is assumed to be 0.

Output Arguments

RESP

Voltage response of antenna element. The output depends on whether the antenna element supports polarization or not.

- If the antenna element does not support polarization, RESP is an *M*-by-*L* matrix. In this matrix, *M* represents the number of angles specified in ANG while *L* represents the number of frequencies specified in FREQ.
- If the antenna element supports polarization, RESP is a MATLAB `struct` with fields RESP.H and RESP.V containing responses for the horizontal and vertical polarization components of the antenna radiation pattern. RESP.H and RESP.V are *M*-by-*L* matrices. In these matrices, *M* represents the number of angles specified in ANG while *L* represents the number of frequencies specified in FREQ.

Examples

Custom Antenna Element Response at 30° Elevation

Construct a user-defined antenna with an omnidirectional response in azimuth and a cosine pattern in elevation. The antenna operates at 1 GHz. Plot the response pattern. Then, find the antenna response at 30°

```
antenna = phased.CustomAntennaElement;
antenna.AzimuthAngles = -180:180;
antenna.ElevationAngles = -90:90;
antenna.MagnitudePattern = mag2db(repmat(cosd(antenna.ElevationAngles)',...
    1,numel(antenna.AzimuthAngles)));
```

Find the response at 30° elevation for an operating frequency of 1 GHz.

```
fc = 1.0e9;
resp = antenna(fc,[0;30])
```

```
resp =

    0.8660
```

Antenna with Custom Radiation Pattern

Create a custom antenna element object. The radiation pattern has a cosine dependence on elevation angle but is independent of azimuth angle.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
az = -180:90:180;
el = -90:45:90;
elresp = cosd(el);
magpattern = mag2db(repmat(elresp',1,numel(az)));
phasepattern = zeros(size(magpattern));
antenna = phased.CustomAntennaElement('AzimuthAngles',az,...
    'ElevationAngles',el,'MagnitudePattern',magpattern, ...
    'PhasePattern',phasepattern);
```

Display the radiation pattern.

```
disp(antenna.MagnitudePattern)
```

```
      -Inf      -Inf      -Inf      -Inf      -Inf
   -3.0103   -3.0103   -3.0103   -3.0103   -3.0103
         0         0         0         0         0
   -3.0103   -3.0103   -3.0103   -3.0103   -3.0103
      -Inf      -Inf      -Inf      -Inf      -Inf
```

Calculate the antenna response at the azimuth-elevation pairs *(-30,0)* and *(-45,0)* at 500 Mhz.

```
ang = [-30 0; -45 0];
resp = antenna(500.0e6,ang);
disp(resp)
```

```
    0.7071
    1.0000
```

The following code illustrates how nearest-neighbor interpolation method is used to find the antenna voltage response in the two directions. The total response is the product of the angular response and the frequency response.

```
g = interp2(deg2rad(antenna.AzimuthAngles),...
    deg2rad(antenna.ElevationAngles),...
    db2mag(antenna.MagnitudePattern),...
    deg2rad(ang(1,:))', deg2rad(ang(2,:))','nearest',0);
h = interp1(antenna.FrequencyVector,...
    db2mag(antenna.FrequencyResponse),500e6,'nearest',0);
antresp = h.*g;
```

Compare the value of `antresp` to the response of the antenna.

```
disp(mag2db(antresp))
```

```
   -3.0103
         0
```

Algorithms

The total response of a custom antenna element is a combination of its frequency response and spatial response. `phased.CustomAntennaElement` calculates both

responses using nearest neighbor interpolation, and then multiplies the responses to form the total response.

phased.CustomMicrophoneElement System object

Package: phased

Custom microphone

Description

The `CustomMicrophoneElement` object creates a custom microphone element.

To compute the response of the microphone element for specified directions:

1. Define and set up your custom microphone element. See "Construction" on page 1-458.
2. Call step to compute the response according to the properties of `phased.CustomMicrophoneElement`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.CustomMicrophoneElement` creates a custom microphone system object, `H`, that models a custom microphone element.

`H = phased.CustomMicrophoneElement(Name,Value)` creates a custom microphone object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`FrequencyVector`

Operating frequency vector

Specify the frequencies in hertz where the frequency responses of element are measured as a vector. The elements of the vector must be increasing. The microphone element has no response outside the specified frequency range.

Default: `[0 1e20]`

`FrequencyResponse`

Frequency responses

Specify the frequency responses in decibels measured at the frequencies defined in the `FrequencyVector` property as a row vector. The length of the vector must equal the length of the frequency vector specified in the `FrequencyVector` property.

Default: `[0 0]`

`PolarPatternFrequencies`

Polar pattern measuring frequencies

Specify the measuring frequencies in hertz of the polar patterns as a row vector of length M. The measuring frequencies must be within the frequency range specified in the `FrequencyVector` property.

Default: `1e3`

`PolarPatternAngles`

Polar pattern measuring angles

Specify the measuring angles in degrees of the polar patterns as a row vector of length N. The angles are measured from the central pickup axis of the microphone, and must be between –180 and 180, inclusive.

Default: `[-180:180]`

`PolarPattern`

Polar pattern

Specify the polar patterns of the microphone element as an M-by-N matrix. M is the number of measuring frequencies specified in the `PolarPatternFrequencies` property. N is the number of measuring angles specified in the `PolarPatternAngles` property. Each row of the matrix represents the magnitude of the polar pattern (in decibels) measured at the corresponding frequency specified in the `PolarPatternFrequencies` property and corresponding angles specified in the `PolarPatternAngles` property. The pattern is assumed to be measured in the azimuth plane where the elevation angle is 0 and where the central pickup axis is assumed to be 0 degrees azimuth and 0 degrees elevation. The polar pattern is assumed to be symmetric around the central axis and therefore the microphone's response pattern in 3-D space can be constructed from the polar pattern.

Default: An omnidirectional pattern with 0 dB response everywhere

Methods

directivity	Directivity of custom microphone element
isPolarizationCapable	Polarization capability
pattern	Plot custom microphone element directivity and patterns
patternAzimuth	Plot custom microphone element directivity or pattern versus azimuth
patternElevation	Plot custom microphone element directivity or pattern versus elevation
plotResponse	Plot response pattern of microphone
step	Output response of microphone

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Custom Cardioid Microphone Response

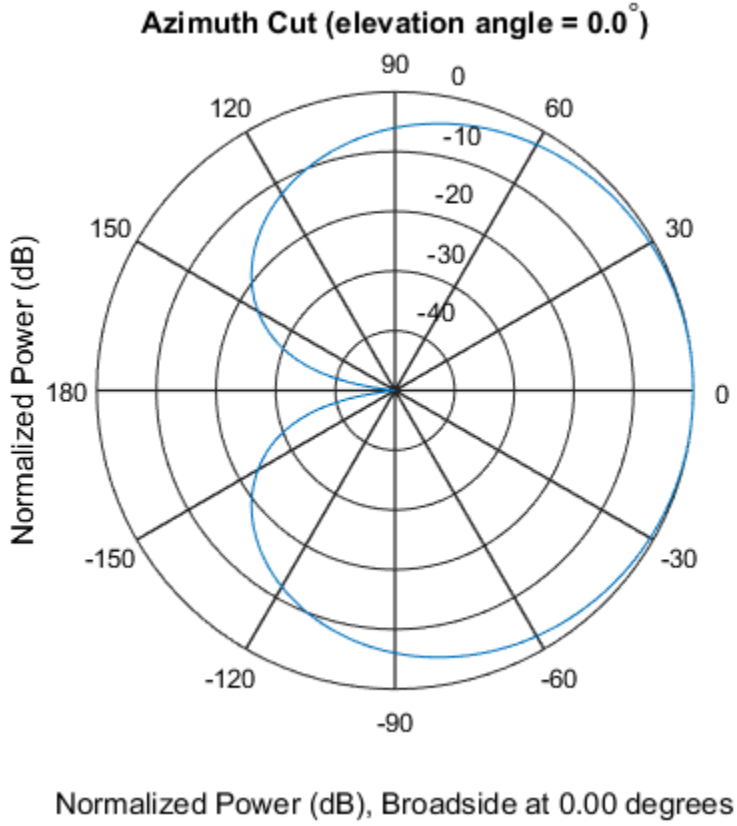
Create a custom cardioid microphone, and calculate the microphone response at 500, 1500, and 2000 Hz in two directions: *(0,0)* azimuth and elevation, and *(40,50)* azimuth and elevation.

```
sCustMic = phased.CustomMicrophoneElement;
sCustMic.PolarPatternFrequencies = [500 1000];
sCustMic.PolarPattern = mag2db([...
    0.5+0.5*cosd(sCustMic.PolarPatternAngles);...
    0.6+0.4*cosd(sCustMic.PolarPatternAngles)]);
resp = step(sCustMic,[500 1500 2000],[0 0; 40 50]')
```

```
resp =

    1.0000    1.0000    1.0000
    0.7424    0.7939    0.7939
```

```
pattern(sCustMic,500,[-180:180],0,'Type','powerdb')
```



Algorithms

The total response of a custom microphone element is a combination of its frequency response and spatial response. `phased.CustomMicrophoneElement` calculates both responses using nearest neighbor interpolation and then multiplies them to form the total response. When the `PolarPatternFrequencies` property value is nonscalar, the object specifies multiple polar patterns. In this case, the interpolation uses the polar pattern that is measured closest to the specified frequency.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- `pattern`, `patternAzimuth`, `patternElevation`, and `plotResponse` methods are not supported.
- See "System Objects in MATLAB Code Generation" (MATLAB Coder).

Introduced in R2012a

directivity

System object: phased.CustomMicrophoneElement
Package: phased

Directivity of custom microphone element

Syntax

```
D = directivity(H,FREQ,ANGLE)
```

Description

`D = directivity(H,FREQ,ANGLE)` returns the "Directivity (dBi)" on page 1-467 of a custom microphone element, `H`, at frequencies specified by `FREQ` and in direction angles specified by `ANGLE`.

Input Arguments

`H` — Custom microphone element

System object

Custom microphone element specified as a phased.CustomMicrophoneElement System object.

Example: `H = phased.CustomMicrophoneElement;`

`FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the

directivity is returned as –Inf. Most elements use the FrequencyRange property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the FrequencyVector property.

- For an array of elements, FREQ must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as –Inf.

Example: [1e8 2e6]

Data Types: double

ANGLE — Angles for computing directivity

1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Angles for computing directivity, specified as a 1-by-*M* real-valued row vector or a 2-by-*M* real-valued matrix, where *M* is the number of angular directions. Angle units are in degrees. If ANGLE is a 2-by-*M* matrix, then each column specifies a direction in azimuth and elevation, [az;el]. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°.

If ANGLE is a 1-by-*M* vector, then each entry represents an azimuth angle, with the elevation angle assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis.

Example: [45 60; 0 10]

Data Types: double

Output Arguments

D — Directivity

M-by-*L* matrix

Directivity, returned as an *M*-by-*L* matrix whose columns contain the directivities at the *M* angles specified by ANGLE. Each column corresponds to one of the *L* frequency values specified in FREQ. Directivity units are in dBi.

Examples

Directivity of Custom Microphone Element

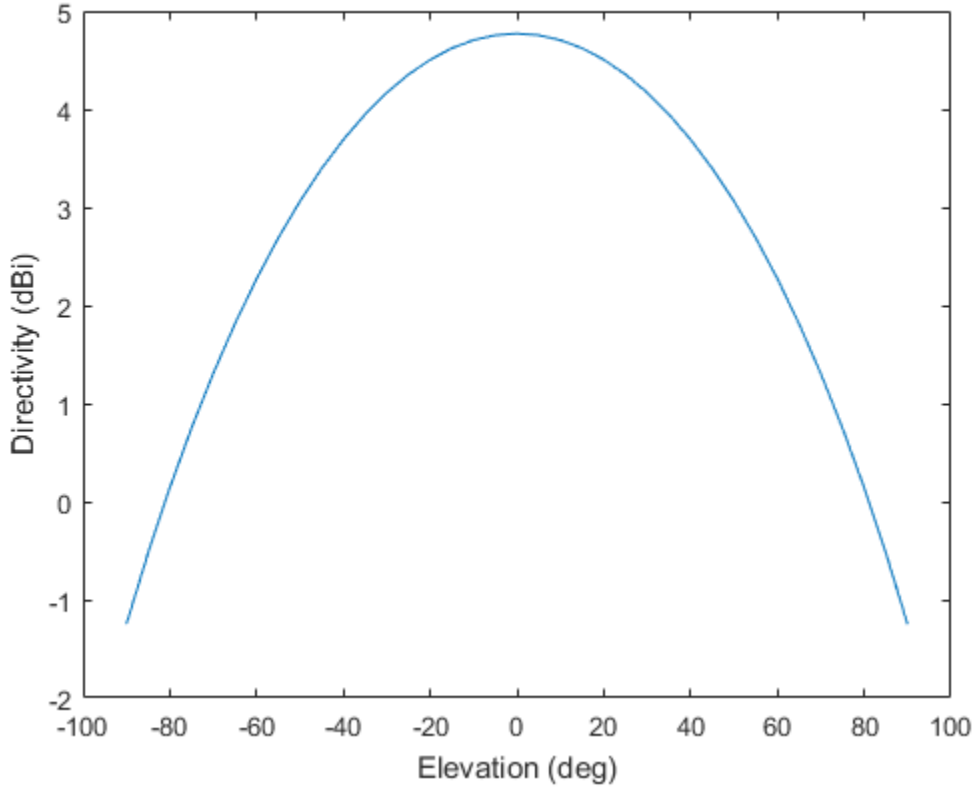
Compute the directivity of a custom microphone element. Create a custom cardioid microphone, and plot the microphone's response at 700 Hz for elevations between -90 and +90 degrees.

Define the pattern for the custom microphone element. The System object's `PolarPatternAngles` property has default value of `[-180:180]` degrees.

```
myAnt = phased.CustomMicrophoneElement;
myAnt.PolarPatternFrequencies = [500 1000];
myAnt.PolarPattern = mag2db([...
    0.5+0.5*cosd(myAnt.PolarPatternAngles);...
    0.6+0.4*cosd(myAnt.PolarPatternAngles)]);
```

Calculate the directivity as a function of elevation at zero degrees azimuth.

```
elev = [-90:5:90];
azm = zeros(size(elev));
ang = [azm;elev];
freq = 700;
d = directivity(myAnt,freq,ang);
plot(elev,d)
xlabel('Elevation (deg)')
ylabel('Directivity (dBi)')
```



The directivity is maximum at 0° elevation.

Definitions

Directivity (dBi)

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on "Element directivity" and "Array directivity".

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

phased.CustomAntennaElement.plotResponse

isPolarizationCapable

System object: phased.CustomMicrophoneElement
Package: phased

Polarization capability

Syntax

```
flag = isPolarizationCapable(h)
```

Description

`flag = isPolarizationCapable(h)` returns a Boolean value, `flag`, indicating whether the phased.CustomMicrophoneElement supports polarization. An element supports polarization if it can create or respond to polarized fields. This microphone element, as with all microphone elements, does not support polarization.

Input Arguments

h — Custom microphone element

Custom microphone element specified as a phased.CustomMicrophoneElement System object.

Output Arguments

flag — Polarization-capability flag

Polarization-capability returned as a Boolean value `true` if the microphone element supports polarization or `false` if it does not. Because the phased.CustomMicrophoneElement object does not support polarization, `flag` is always returned as `false`.

Examples

Custom Microphone Does Not Support Polarization

Show that the `phased.CustomMicrophoneElement` microphone element does not support polarization.

```
microphone = phased.CustomMicrophoneElement;
isPolarizationCapable(microphone)
```

```
ans =

  logical

   0
```

The returned value `0` shows that the custom microphone element does not support polarization.

pattern

System object: phased.CustomMicrophoneElement
Package: phased

Plot custom microphone element directivity and patterns

Syntax

```
pattern(sElem,FREQ)
pattern(sElem,FREQ,AZ)
pattern(sElem,FREQ,AZ,EL)
pattern( ___ ,Name,Value)
[PAT,AZ_ANG,EL_ANG] = pattern( ___ )
```

Description

`pattern(sElem,FREQ)` plots the 3-D array directivity pattern (in dBi) for the element specified in `sElem`. The operating frequency is specified in `FREQ`.

`pattern(sElem,FREQ,AZ)` plots the element directivity pattern at the specified azimuth angle.

`pattern(sElem,FREQ,AZ,EL)` plots the element directivity pattern at specified azimuth and elevation angles.

`pattern( ___ ,Name,Value)` plots the element pattern with additional options specified by one or more `Name,Value` pair arguments.

`[PAT,AZ_ANG,EL_ANG] = pattern( ___ )` returns the element pattern in `PAT`. The `AZ_ANG` output contains the coordinate values corresponding to the rows of `PAT`. The `EL_ANG` output contains the coordinate values corresponding to the columns of `PAT`. If the `'CoordinateSystem'` parameter is set to `'uv'`, then `AZ_ANG` contains the *U* coordinates of the pattern and `EL_ANG` contains the *V* coordinates of the pattern. Otherwise, they are in angular units in degrees. *UV* units are dimensionless.

Note: This method replaces the `plotResponse` method. See "Convert plotResponse to pattern" on page 1-481 for guidelines on how to use `pattern` in place of `plotResponse`.

Input Arguments

`sElem` — Custom microphone element

System object

Custom microphone element, specified as a phased.CustomMicrophoneElement System object.

Example: `sElem = phased.CustomMicrophoneElement;`

`FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `-Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `-Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

`AZ` — Azimuth angles

`[-180:180]` (default) | 1-by-*M* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a 1-by-*M* real-valued row vector where *M* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, this angle is positive.

Example: `[-45:2:45]`

Data Types: `double`

`EL` — Elevation angles

`[-90:90]` (default) | 1-by-*N* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a 1-by-*N* real-valued row vector where *N* is the number of desired elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and *xy*-plane. When measured towards the *z*-axis, this angle is positive.

Example: `[-75:1:70]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'CoordinateSystem'` — Plotting coordinate system

`'polar'` (default) | `'rectangular'` | `'uv'`

Plotting coordinate system of the pattern, specified as the comma-separated pair consisting of `'CoordinateSystem'` and one of `'polar'`, `'rectangular'`, or `'uv'`. When `'CoordinateSystem'` is set to `'polar'` or `'rectangular'`, the `AZ` and `EL` arguments specify the pattern azimuth and elevation, respectively. `AZ` values must lie between –180° and 180°. `EL` values must lie between –90° and 90°. If `'CoordinateSystem'` is set to `'uv'`, `AZ` and `EL` then specify *U* and *V* coordinates, respectively. `AZ` and `EL` must lie between -1 and 1.

Example: `'uv'`

Data Types: `char`

'Type' — Displayed pattern type

'directivity' (default) | 'efield' | 'power' | 'powerdb'

Displayed pattern type, specified as the comma-separated pair consisting of 'Type' and one of

- 'directivity' — directivity pattern measured in dBi.
- 'efield' — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- 'power' — power pattern of the sensor or array defined as the square of the field pattern.
- 'powerdb' — power pattern converted to dB.

Example: 'powerdb'

Data Types: char

'Normalize' — Display normalize pattern

true (default) | false

Display normalized pattern, specified as the comma-separated pair consisting of 'Normalize' and a Boolean. Set this parameter to true to display a normalized pattern. When you set 'Type' to 'directivity', this parameter does not apply. Directivity patterns are already normalized.

Example:

Data Types: logical

'PlotStyle' — Plotting style

'overlay' (default) | 'waterfall'

Plotting style, specified as the comma-separated pair consisting of 'Plotstyle' and either 'overlay' or 'waterfall'. This parameter applies when you specify multiple frequencies in FREQ in 2-D plots. You can draw 2-D plots by setting one of the arguments AZ or EL to a scalar.

Example:

Data Types: char

Output Arguments

PAT — Element pattern

M-by-*N* real-valued matrix

Element pattern, returned as an *M*-by-*N* real-valued matrix. The dimensions of PAT correspond to the dimensions of the output arguments AZ_ANG and EL_ANG.

AZ_ANG — Azimuth angles

scalar | 1-by-*M* real-valued row vector

Azimuth angles for displaying directivity or response pattern, returned as a scalar or 1-by-*M* real-valued row vector corresponding to the dimension set in AZ. The rows of PAT correspond to the values in AZ_ANG.

EL_ANG — Elevation angles

scalar | 1-by-*N* real-valued row vector

Elevation angles for displaying directivity or response, returned as a scalar or 1-by-*N* real-valued row vector corresponding to the dimension set in EL. The columns of PAT correspond to the values in EL_ANG.

Examples

Azimuth Power Pattern and Directivity of Cardioid Microphone

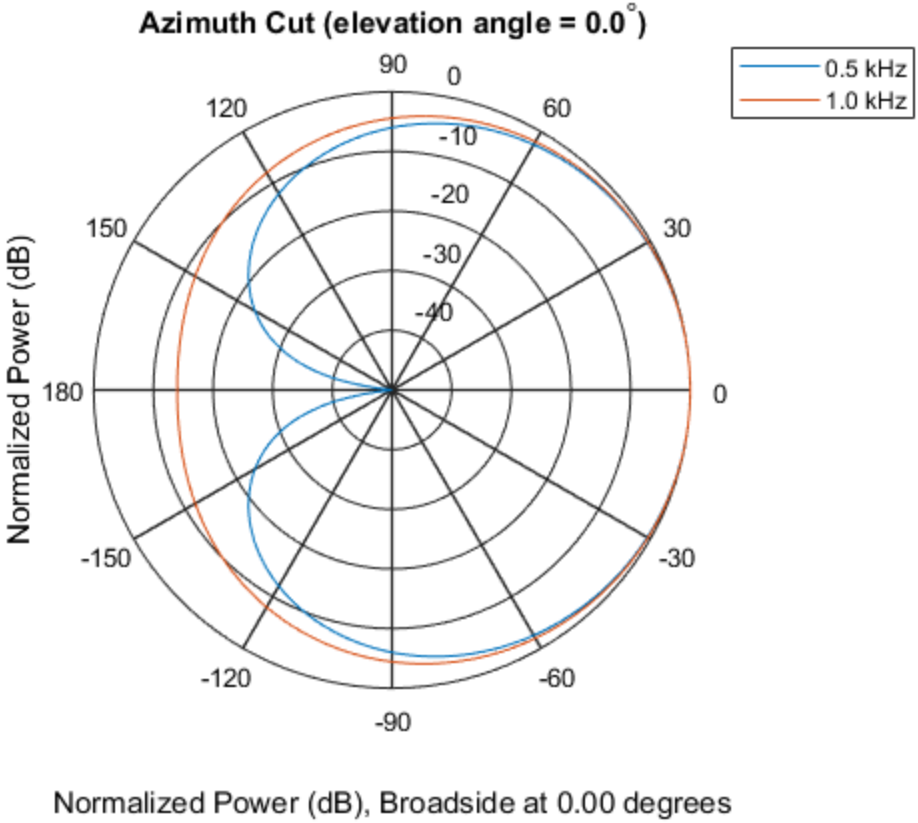
Design a cardioid microphone to operate in the frequency range between 500 and 1000 Hz.

```
sCustMike = phased.CustomMicrophoneElement;
sCustMike.PolarPatternFrequencies = [500 1000];
sCustMike.PolarPattern = mag2db([...
    0.5+0.5*cosd(sCustMike.PolarPatternAngles);...
    0.6+0.4*cosd(sCustMike.PolarPatternAngles)]);
```

Display a polar plot of an azimuth cut of the response at 500 Hz and 1000 Hz.

```
fc = 500;
pattern(sCustMike,[fc 2*fc],[-180:180],0,...
```

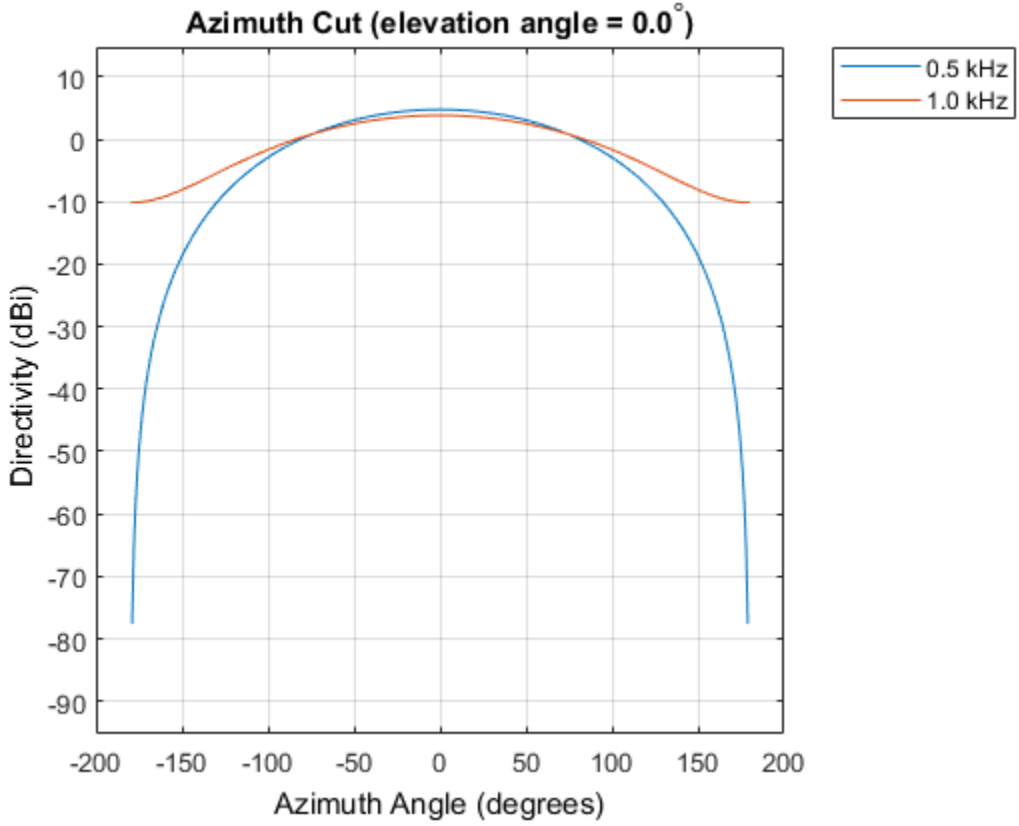
```
    'CoordinateSystem','polar',...
    'Type','powerdb');
```



Normalized Power (dB), Broadside at 0.00 degrees

Plot the directivity as a line plot for the same two frequencies.

```
pattern(sCustMike,[fc 2*fc],[-180:180],0,...
    'CoordinateSystem','rectangular',...
    'Type','directivity');
```



Power Pattern of Cardioid Microphone in U/V Space

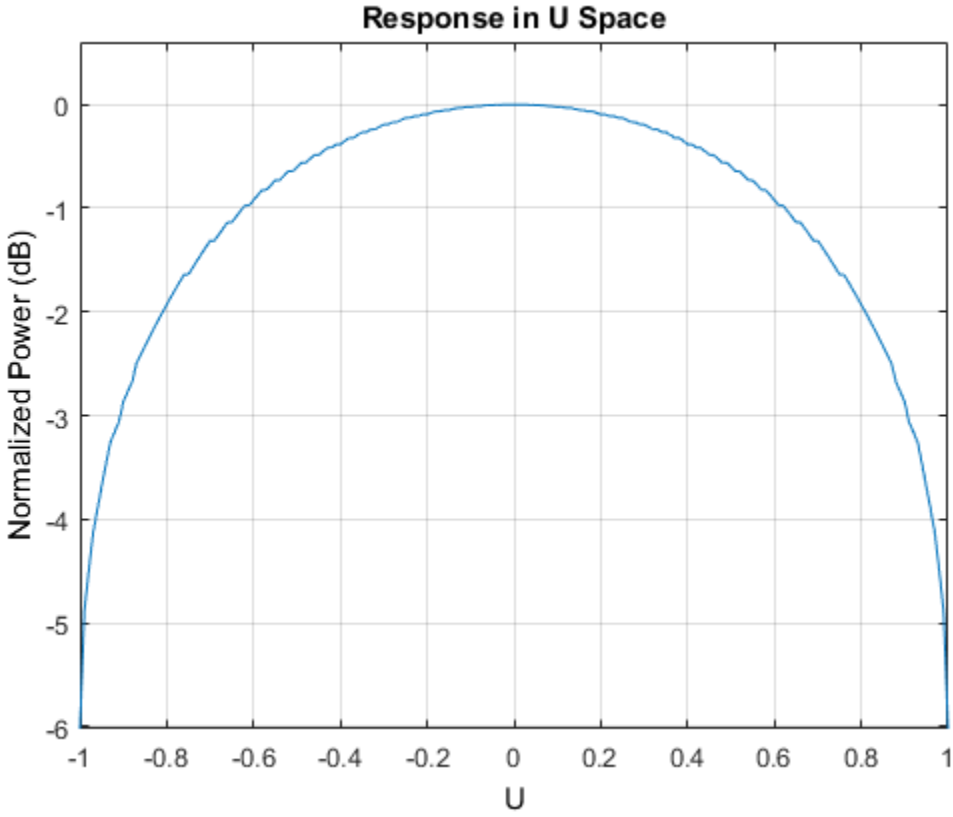
Plot a u-cut of the power pattern of a custom cardioid microphone designed to operate in the frequency range 500-1000 Hz.

Create a cardioid microphone.

```
sCustMike = phased.CustomMicrophoneElement;
sCustMike.PolarPatternFrequencies = [500 1000];
sCustMike.PolarPattern = mag2db([...
    0.5+0.5*cosd(sCustMike.PolarPatternAngles);...
    0.6+0.4*cosd(sCustMike.PolarPatternAngles)]);
```

Plot the power pattern.

```
fc = 500;
pattern(sCustMike,fc,[-1:.01:1],0,...
    'CoordinateSystem','uv',...
    'Type','powerdb');
```



3-D Pattern of Cardioid Microphone Over Restricted Range of Angles

Plot the 3-D magnitude pattern of a custom cardioid microphone with both the azimuth and elevation angles restricted to the range -40 to 40 degrees in 0.1 degree increments.

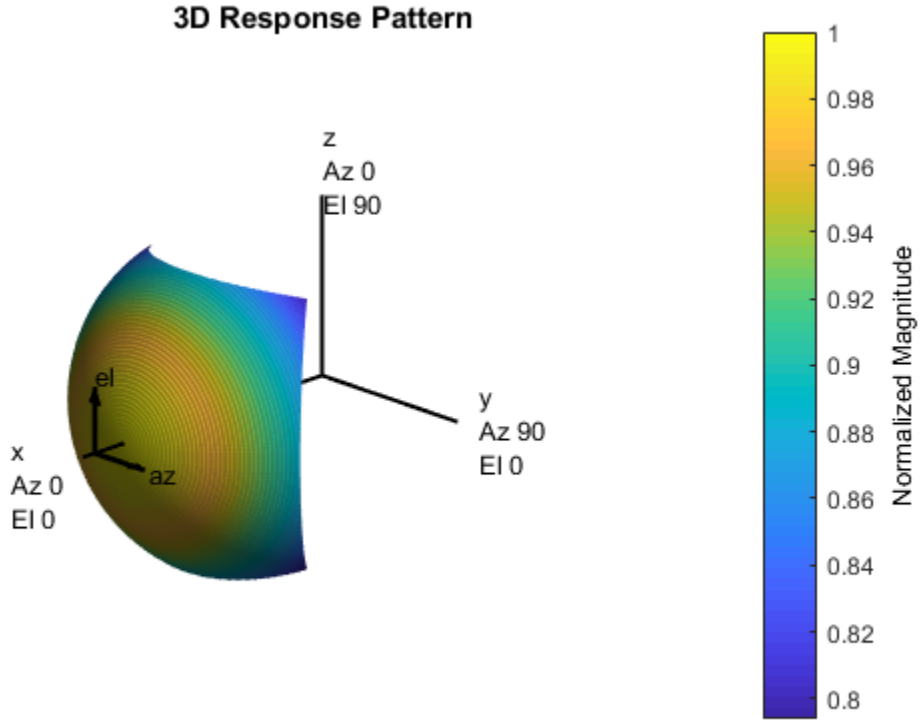
Create a custom microphone element with a cardioid pattern.

```
sCustMike = phased.CustomMicrophoneElement;
```

```
sCustMike.PolarPatternFrequencies = [500 1000];
sCustMike.PolarPattern = mag2db([...
    0.5+0.5*cosd(sCustMike.PolarPatternAngles);...
    0.6+0.4*cosd(sCustMike.PolarPatternAngles)]);
```

Plot the 3-D magnitude pattern.

```
fc = 500;
pattern(sCustMike,fc,[-40:0.1:40],[-40:0.1:40],...
    'CoordinateSystem','polar',...
    'Type','efield');
```



More About

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on "Element directivity" and "Array directivity".

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

Convert plotResponse to pattern

For antenna, microphone, and array System objects, the `pattern` method replaces the `plotResponse` method. In addition, two new simplified methods exist just to draw 2-D azimuth and elevation pattern plots. These methods are `azimuthPattern` and `elevationPattern`.

The following table is a guide for converting your code from using `plotResponse` to `pattern`. Notice that some of the inputs have changed from *input arguments* to *Name-Value* pairs and conversely. The general `pattern` method syntax is

```
pattern(H,FREQ,AZ,EL,'Name1','Value1',...,'NameN','ValueN')
```

plotResponse Inputs	plotResponse Description	pattern Inputs
`H` argument	Antenna, microphone, or array System object.	`H` argument (no change)
`FREQ` argument	Operating frequency.	`FREQ` argument (no change)

plotResponse Inputs	plotResponse Description	pattern Inputs
`V` argument	Propagation speed. This argument is used only for arrays.	`'PropagationSpeed'` name-value pair. This parameter is only used for arrays.

<table>
<tr><th>plotResponse Inputs</th><th>plotResponse Description</th><th>pattern Inputs</th></tr>
<tr>
<td>'Format' and 'RespCut' name-value pairs</td>
<td>These options work together to let you create a plot in angle space (line or polar style) or UV space. They also determine whether the plot is 2-D or 3-D. This table shows you how to create different types of plots using plotResponse.
<table>
<tr><th>Display space</th><th></th></tr>
<tr><td>Angle space (2D)</td><td>Set 'RespCut' to 'Az' or 'El'. Set 'Format' to 'line' or 'polar'.

</table>
If you set CoordinateSystem to 'uv', enter the UV grid values using AZ and EL.</td></tr>
<tr><td>'CutAngle' name-value pair</td><td>Constant angle at to take an azimuth or elevation cut. When producing a 2-D plot and when 'RespCut' is set to 'Az' or 'El', use 'CutAngle' to set the slice across which to view the plot.</td><td>No equivalent name-value pair. To create a cut, specify either AZ or EL as a scalar, not a vector.</td></tr>
</table>

plotResponse Inputs	plotResponse Description	pattern Inputs
`'NormalizeResponse'` name-value pair	Normalizes the plot. When `'Unit'` is set to `'dbi'`, you cannot specify `'NormalizeResponse'`.	`'Normalize'` name-value pair. When `'Type'` is set to `'directivity'`, you cannot specify `'Normalize'`. .
`'OverlayFreq'` name-value pair	Plot multiple frequencies on the same 2-D plot. Available only when `'Format'` is set to `'line'` or `'uv'` and `'RespCut'` is not set to `'3D'`. The value `true` produces an overlay plot and the value `false` produces a waterfall plot.	`'PlotStyle'` name-value pair plots multiple frequencies on the same 2-D plot. The values `'overlay'` and `'waterfall'` correspond to `'OverlayFreq'` values of `true` and `false`. The option `'waterfall'` is allowed only when `'CoordinateSystem'` is set to `'rectangular'` or `'uv'`.
`'Polarization'` name-value pair	Determines how to plot polarized fields. Options are `'None'`, `'Combined'`, `'H'`, or `'V'`.	`'Polarization'` name-value pair determines how to plot polarized fields. The `'None'` option is removed. The options `'Combined'`, `'H'`, or `'V'` are unchanged.

`'Unit'` name-value pair	Determines the plot units. Choose `'db'`, `'mag'`, `'pow'`, or `'dbi'`, where the default is `'db'`.	`'Type'` name-value pair, uses equivalent options with different names
		
		plotResponse pattern
		`'db'` `'powerdb'`
		`'mag'` `'efield'`
		`'pow'` `'power'`
		`'dbi'` `'directivity'`

`'Weights'` name-value pair	Array element tapers (or weights).	`'Weights'` name-value pair (no change).

plotResponse Inputs	plotResponse Description	pattern Inputs
`'AzimuthAngles'` name-value pair	Azimuth angles used to display the antenna or array response.	`AZ` argument
`'ElevationAngles'` name-value pair	Elevation angles used to display the antenna or array response.	`EL` argument
`'UGrid'` name-value pair	Contains *U* coordinates in *UV*-space.	`AZ` argument when `'CoordinateSystem'` name-value pair is set to `'uv'`
`'VGrid'` name-value pair	Contains *V*-coordinates in *UV*-space.	`EL` argument when `'CoordinateSystem'` name-value pair is set to `'uv'`

phased.CustomMicrophoneElement.patternAzimuth | phased.CustomMicrophoneElement.patternElevation

Introduced in R2015a

patternAzimuth

System object: phased.CustomMicrophoneElement
Package: phased

Plot custom microphone element directivity or pattern versus azimuth

Syntax

```
patternAzimuth(sElem,FREQ)
patternAzimuth(sElem,FREQ,EL)
patternAzimuth(sElem,FREQ,EL,Name,Value)
PAT = patternAzimuth( ___ )
```

Description

`patternAzimuth(sElem,FREQ)` plots the 2-D element directivity pattern versus azimuth (in dBi) for the element `sElem` at zero degrees elevation angle. The argument `FREQ` specifies the operating frequency.

`patternAzimuth(sElem,FREQ,EL)`, in addition, plots the 2-D element directivity pattern versus azimuth (in dBi) at the elevation angle specified by `EL`. When `EL` is a vector, multiple overlaid plots are created.

`patternAzimuth(sElem,FREQ,EL,Name,Value)` plots the element pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternAzimuth( ___ )` returns the element pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Azimuth'` parameter and the `EL` input argument.

Input Arguments

`sElem` — Custom microphone element

System object

Custom microphone element, specified as a phased.CustomMicrophoneElement System object.

Example: `sElem = phased.CustomMicrophoneElement;`

`FREQ` — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `-Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `-Inf`.

Example: `1e8`

Data Types: `double`

`EL` — Elevation angles

1-by-*N* real-valued row vector

Elevation angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector. The quantity *N* is the number of requested elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and the *xy* plane. When measured toward the *z*-axis, this angle is positive.

Example: `[0,10,20]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Type'` — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

`'Azimuth'` — Azimuth angles

`[-180:180]` (default) | 1-by-*P* real-valued row vector

Azimuth angles, specified as the comma-separated pair consisting of `'Azimuth'` and a 1-by-*P* real-valued row vector. Azimuth angles define where the array pattern is calculated.

Example: `'Azimuth',[-90:2:90]`

Data Types: `double`

Output Arguments

`PAT` — Element directivity or pattern

L-by-*N* real-valued matrix

Element directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of azimuth values determined by the `'Azimuth'` name-value pair argument. The dimension *N* is the number of elevation angles, as determined by the `EL` input argument.

Examples

Azimuth Pattern of Cardioid Microphone Over Reduced Angular Range

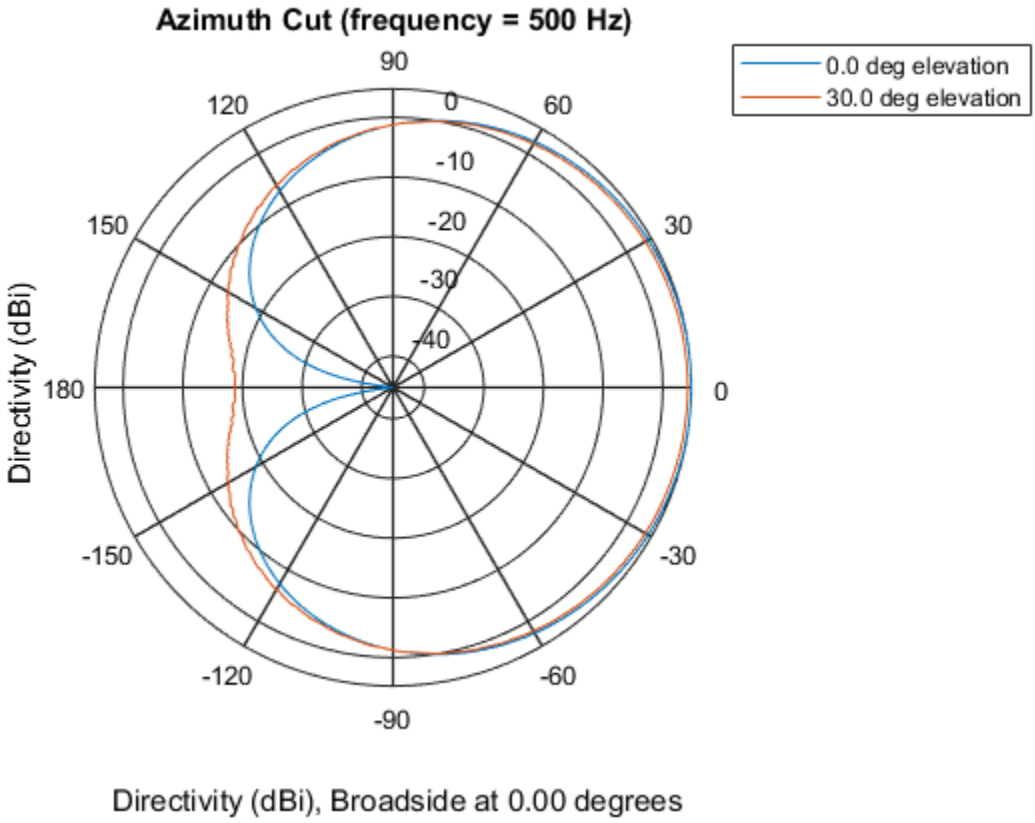
Plot the azimuth directivity pattern of a custom cardioid microphone at both 0 and 30 degrees elevation.

Create a custom microphone element with a cardioid pattern.

```
sCustMike = phased.CustomMicrophoneElement;
sCustMike.PolarPatternFrequencies = [500 1000];
sCustMike.PolarPattern = mag2db([...
    0.5+0.5*cosd(sCustMike.PolarPatternAngles);...
    0.6+0.4*cosd(sCustMike.PolarPatternAngles)]);
```

Plot the directivity at 500 Hz.

```
fc = 500;
patternAzimuth(sCustMike,fc,[0 30])
```



Plot the directivity for a reduced range of azimuth angles using the `Azimuth` parameter. Notice the change in scale.

```
fc = 500;
patternAzimuth(sCustMike,fc,[0 30],...
    'Azimuth',[-40:.1:40])
```

Introduced in R2015a

patternElevation

System object: phased.CustomMicrophoneElement
Package: phased

Plot custom microphone element directivity or pattern versus elevation

Syntax

```
patternElevation(sElem,FREQ)
patternElevation(sElem,FREQ,AZ)
patternElevation(sElem,FREQ,AZ,Name,Value)
PAT = patternElevation( ___ )
```

Description

`patternElevation(sElem,FREQ)` plots the 2-D element directivity pattern versus elevation (in dBi) for the element `sElem` at zero degrees azimuth angle. The argument `FREQ` specifies the operating frequency.

`patternElevation(sElem,FREQ,AZ)`, in addition, plots the 2-D element directivity pattern versus elevation (in dBi) at the azimuth angle specified by `AZ`. When `AZ` is a vector, multiple overlaid plots are created.

`patternElevation(sElem,FREQ,AZ,Name,Value)` plots the element pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternElevation( ___ )` returns the element pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Elevation'` parameter and the `AZ` input argument.

Input Arguments

`sElem` — Custom microphone element

System object

Custom microphone element, specified as a phased.CustomMicrophoneElement System object.

Example: `sElem = phased.CustomMicrophoneElement;`

`FREQ` — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

`AZ` — Azimuth angles for computing directivity and pattern

1-by-*N* real-valued row vector

Azimuth angles for computing sensor or array directivities and patterns, specified as a 1-by-*M* real-valued row vector where *N* is the number of desired azimuth directions. Angle units are in degrees. The azimuth angle must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `[0,10,20]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Type'` — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

`'Elevation'` — Elevation angles

`[-90:90]` (default) | 1-by-*P* real-valued row vector

Elevation angles, specified as the comma-separated pair consisting of `'Elevation'` and a 1-by-*P* real-valued row vector. Elevation angles define where the array pattern is calculated.

Example: `'Elevation',[-90:2:90]`

Data Types: `double`

Output Arguments

`PAT` — Element directivity or pattern

L-by-*N* real-valued matrix

Element directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of elevation angles determined by the `'Elevation'` name-value pair argument. The dimension *N* is the number of azimuth angles determined by the `AZ` argument.

Examples

Elevation Pattern of Cardioid Microphone Over Reduced Angular Range

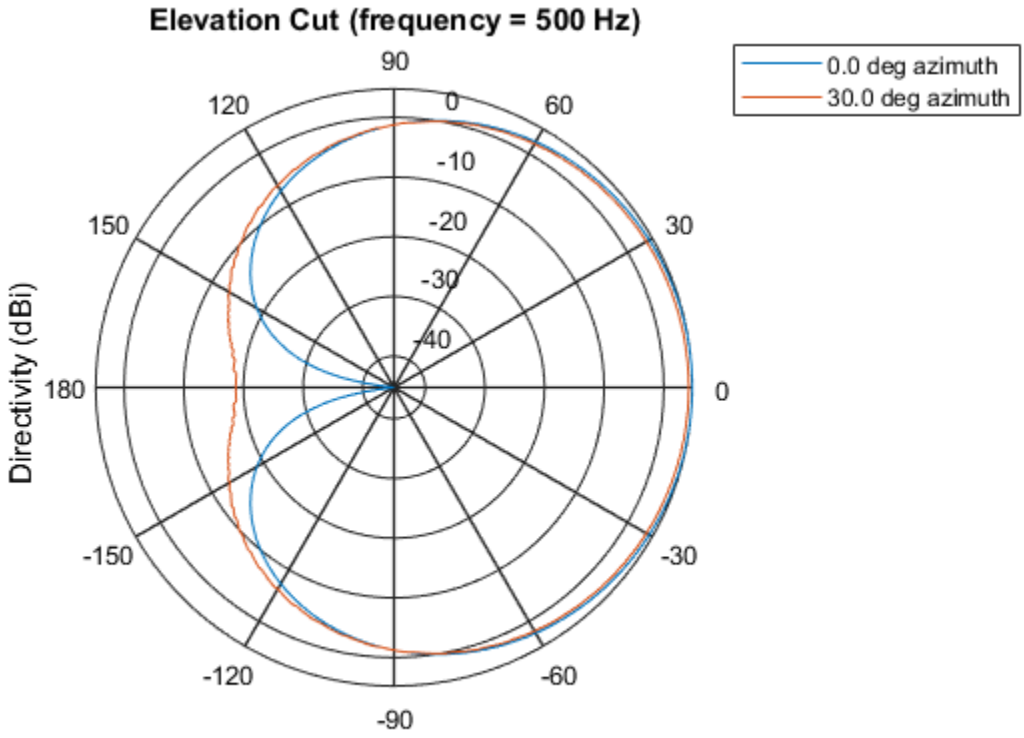
Plot the elevation directivity pattern of a custom cardioid microphone at both 0 and 45 degrees azimuth.

Create a custom microphone element with a cardioid pattern.

```
sCustMike = phased.CustomMicrophoneElement;
sCustMike.PolarPatternFrequencies = [500 1000];
sCustMike.PolarPattern = mag2db([...
    0.5+0.5*cosd(sCustMike.PolarPatternAngles);...
    0.6+0.4*cosd(sCustMike.PolarPatternAngles)]);
```

Plot the directivity at 500 Hz.

```
fc = 500;
patternElevation(sCustMike,fc,[0 30])
```



Plot the directivity for a reduced range of azimuth angles using the `Azimuth` parameter. Notice the change in scale.

```
fc = 500;
patternElevation(sCustMike,fc,[0 45],...
    'Elevation',[-40:.1:40])
```

phased.CustomMicrophoneElement.pattern |
phased.CustomMicrophoneElement.patternAzimuth

Introduced in R2015a

plotResponse

System object: phased.CustomMicrophoneElement
Package: phased

Plot response pattern of microphone

Syntax

```
plotResponse(H,FREQ)
plotResponse(H,FREQ,Name,Value)
hPlot = plotResponse( ___ )
```

Description

`plotResponse(H,FREQ)` plots the element response pattern along the azimuth cut, where the elevation angle is 0. The operating frequency is specified in `FREQ`.

`plotResponse(H,FREQ,Name,Value)` plots the element response with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = plotResponse( ___ )` returns handles of the lines or surface in the figure window, using any of the input arguments in the previous syntaxes.

Input Arguments

`H`

Element System object

`FREQ`

Operating frequency in Hertz specified as a scalar or 1–by-*K* row vector. `FREQ` must lie within the range specified by the `FrequencyVector` property of `H`. If you set the `'RespCut'` property of `H` to `'3D'`, `FREQ` must be a scalar. When `FREQ` is a row vector, `plotResponse` draws multiple frequency responses on the same axes.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'CutAngle'`

Cut angle specified as a scalar. This argument is applicable only when `RespCut` is `'Az'` or `'El'`. If `RespCut` is `'Az'`, `CutAngle` must be between –90 and 90. If `RespCut` is `'El'`, `CutAngle` must be between –180 and 180.

Default: `0`

`'Format'`

Format of the plot, using one of `'Line'`, `'Polar'`, or `'UV'`. If you set `Format` to `'UV'`, `FREQ` must be a scalar.

Default: `'Line'`

`'NormalizeResponse'`

Set this value to `true` to normalize the response pattern. Set this value to `false` to plot the response pattern without normalizing it. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

Default: `true`

`'OverlayFreq'`

Set this value to `true` to overlay pattern cuts in a 2-D line plot. Set this value to `false` to plot pattern cuts against frequency in a 3-D waterfall plot. If this value is `false`, `FREQ` must be a vector with at least two entries.

This parameter applies only when `Format` is not `'Polar'` and RespCut is not `'3D'`.

Default: `true`

`'Polarization'`

Specify the polarization options for plotting the antenna response pattern. The allowable values are `|'None' | 'Combined' | 'H' | 'V' |` where

- `'None'` specifies plotting a nonpolarized response pattern
- `'Combined'` specifies plotting a combined polarization response pattern
- `'H'` specifies plotting the horizontal polarization response pattern
- `'V'` specifies plotting the vertical polarization response pattern

For antennas that do not support polarization, the only allowed value is `'None'`. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

Default: `'None'`

`'RespCut'`

Cut of the response. Valid values depend on `Format`, as follows:

- If `Format` is `'Line'` or `'Polar'`, the valid values of `RespCut` are `'Az'`, `'El'`, and `'3D'`. The default is `'Az'`.
- If `Format` is `'UV'`, the valid values of `RespCut` are `'U'` and `'3D'`. The default is `'U'`.

If you set `RespCut` to `'3D'`, `FREQ` must be a scalar.

`'Unit'`

The unit of the plot. Valid values are `'db'`, `'mag'`, `'pow'`, or `'dbi'`. This parameter determines the type of plot that is produced.

Unit value	Plot type
`db`	power pattern in dB scale
`mag`	field pattern
`pow`	power pattern
`dbi`	directivity

Default: `'db'`

`'AzimuthAngles'`

Azimuth angles for plotting element response, specified as a row vector. The `AzimuthAngles` parameter sets the display range and resolution of azimuth angles for

visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'Az'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of azimuth angles should lie between –180° and 180° and must be in nondecreasing order. When you set the `RespCut` parameter to `'3D'`, you can set the `AzimuthAngles` and `ElevationAngles` parameters simultaneously.

Default: `[-180:180]`

`'ElevationAngles'`

Elevation angles for plotting element response, specified as a row vector. The `ElevationAngles` parameter sets the display range and resolution of elevation angles for visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'El'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of elevation angles should lie between –90° and 90° and must be in nondecreasing order. When you set the `RespCut` parameter to `'3D'`, you can set the `ElevationAngles` and `AzimuthAngles` parameters simultaneously.

Default: `[-90:90]`

`'UGrid'`

U coordinate values for plotting element response, specified as a row vector. The `UGrid` parameter sets the display range and resolution of the *U* coordinates for visualizing the radiation pattern in *U*/*V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'U'` or `'3D'`. The values of `UGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set the `UGrid` and `VGrid` parameters simultaneously.

Default: `[-1:0.01:1]`

`'VGrid'`

V coordinate values for plotting element response, specified as a row vector. The `VGrid` parameter sets the display range and resolution of the *V* coordinates for visualizing the radiation pattern in *U*/*V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'3D'`. The values of `VGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set the `VGrid` and `UGrid` parameters simultaneously.

Default: `[-1:0.01:1]`

Examples

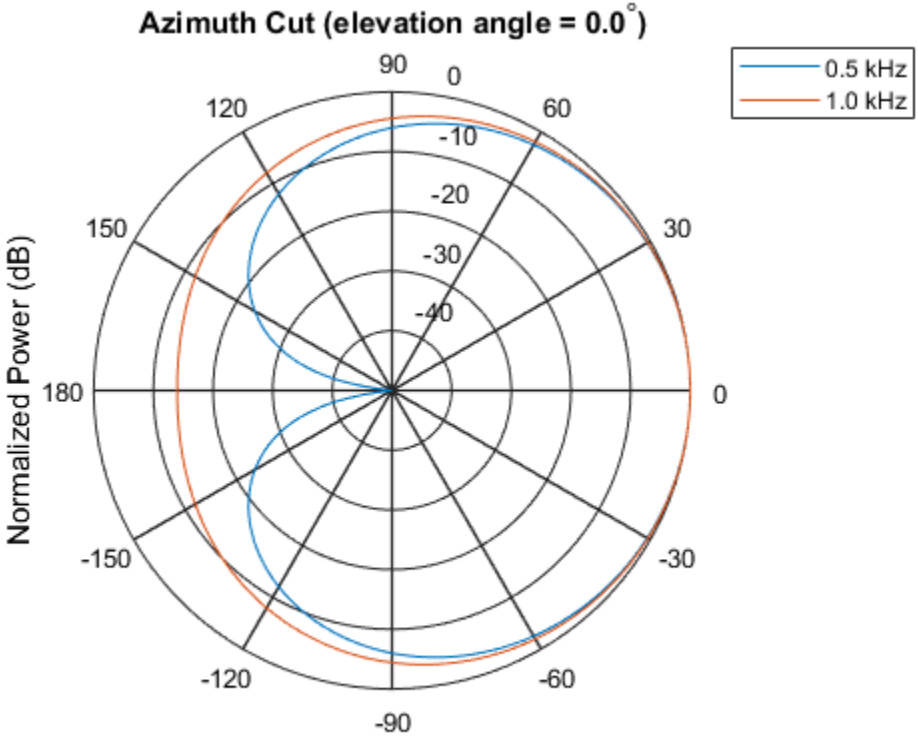
Azimuth Response and Directivity of Cardioid Microphone

Design a cardioid microphone to operate in the frequency range between 500 and 1000 Hz.

```
h = phased.CustomMicrophoneElement;
h.PolarPatternFrequencies = [500 1000];
h.PolarPattern = mag2db([...
    0.5+0.5*cosd(h.PolarPatternAngles);...
    0.6+0.4*cosd(h.PolarPatternAngles)]);
```

Display a polar plot of an azimuth cut of the response at 500 Hz and 1000 Hz.

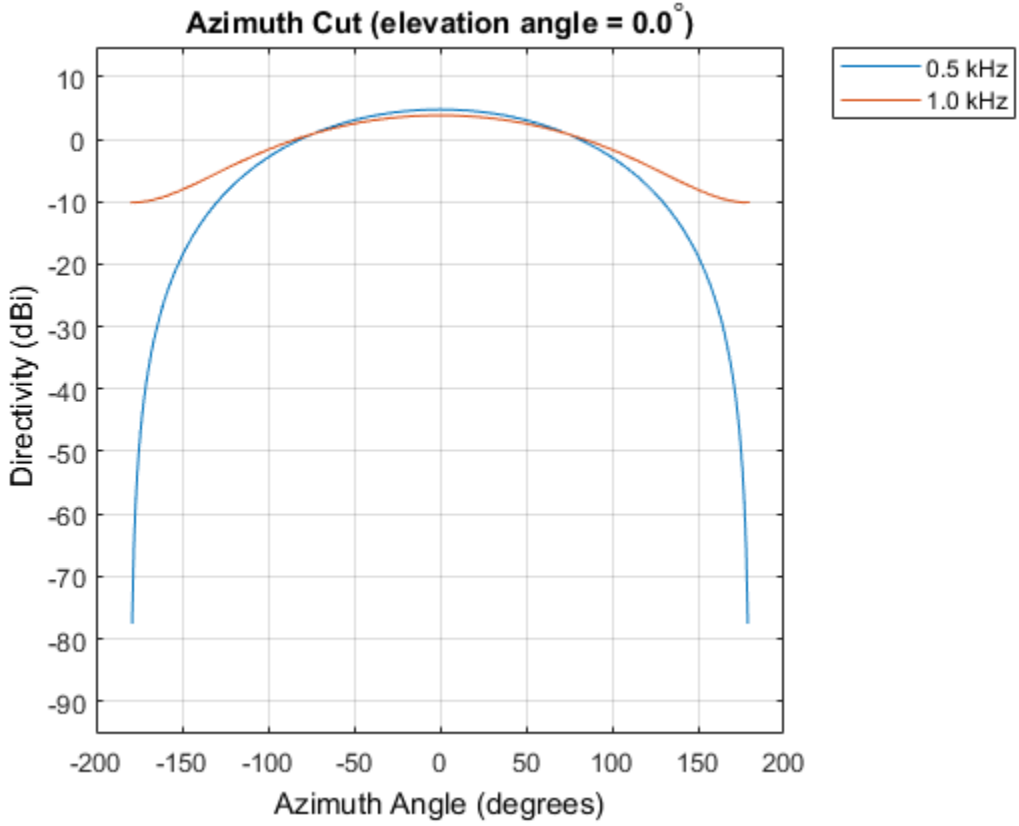
```
fc = 500;
plotResponse(h,[fc 2*fc],'RespCut','Az','Format','Polar');
```



Normalized Power (dB), Broadside at 0.00 degrees

Plot the directivity as a line plot for the same two frequencies.

```
plotResponse(h,[fc 2*fc],'RespCut','Az','Format','Line','Unit','dbi');
```



Response of Cardioid Microphone in U/V Space

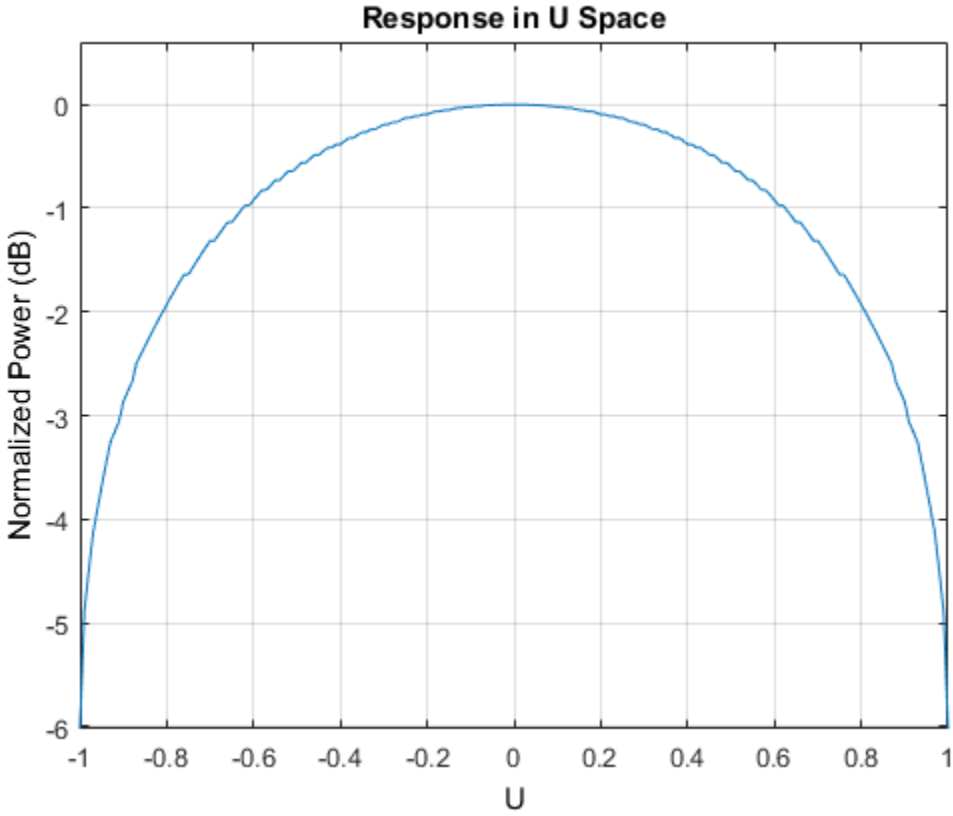
Plot a u-cut of the response of a custom cardioid microphone that is designed to operate in the frequency range 500-1000 Hz.

Create a cardioid microphone.

```
h = phased.CustomMicrophoneElement;
h.PolarPatternFrequencies = [500 1000];
h.PolarPattern = mag2db([...
    0.5+0.5*cosd(h.PolarPatternAngles);...
    0.6+0.4*cosd(h.PolarPatternAngles)]);
```

Plot the response.

```
fc = 500;
plotResponse(h,fc,'Format','UV');
```



3-D Response of Cardioid Microphone Over Restricted Range of Angles

Plot the 3-D response of a custom cardioid microphone in space but with both the azimuth and elevation angles restricted to the range -40 to 40 degrees in 0.1 degree increments.

Create a custom microphone element with a cardioid pattern.

```
h = phased.CustomMicrophoneElement;
h.PolarPatternFrequencies = [500 1000];
```

```
h.PolarPattern = mag2db([...
    0.5+0.5*cosd(h.PolarPatternAngles);...
    0.6+0.4*cosd(h.PolarPatternAngles)]);
```

Plot the 3-D response.

```
fc = 500;
plotResponse(h,fc,'Format','polar','RespCut','3D',...
    'Unit','mag','AzimuthAngles',[-40:0.1:40],...
    'ElevationAngles',[-40:0.1:40]);
```

`azel2uv` | `uv2azel`

step

System object: phased.CustomMicrophoneElement
Package: phased

Output response of microphone

Syntax

```
RESP = step(H,FREQ,ANG)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`RESP = step(H,FREQ,ANG)` returns the microphone's magnitude response, `RESP`, at frequencies specified in `FREQ` and directions specified in `ANG`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`H`

Microphone object.

FREQ

Frequencies in hertz. FREQ is a row vector of length L.

ANG

Directions in degrees. ANG can be either a 2-by-M matrix or a row vector of length M.

If ANG is a 2-by-M matrix, each column of the matrix specifies the direction in the form [azimuth; elevation]. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

If ANG is a row vector of length M, each element specifies a direction's azimuth angle. In this case, the corresponding elevation angle is assumed to be 0.

Output Arguments

RESP

Response of microphone. RESP is an M-by-L matrix that contains the responses of the microphone element at the M angles specified in ANG and the L frequencies specified in FREQ.

Examples

Custom Microphone Response

Construct a custom cardioid microphone with an operating frequency of 500 Hz. Find the microphone response in the directions: *(0,0)* degrees azimuth and elevation and *(40,50)* degrees azimuth and elevation.

```
sCustMic = phased.CustomMicrophoneElement;
sCustMic.PolarPatternFrequencies = [500 1000];
sCustMic.PolarPattern = mag2db([...
    0.5+0.5*cosd(sCustMic.PolarPatternAngles);...
    0.6+0.4*cosd(sCustMic.PolarPatternAngles)]);
fc = 700;
ang = [0 0; 40 50]';
resp = step(sCustMic,fc,ang)
```

```
resp =

    1.0000
    0.7424
```

Algorithms

The total response of a custom microphone element is a combination of its frequency response and spatial response. `phased.CustomMicrophoneElement` calculates both responses using nearest neighbor interpolation and then multiplies them to form the total response. When the `PolarPatternFrequencies` property value is nonscalar, the object specifies multiple polar patterns. In this case, the interpolation uses the polar pattern that is measured closest to the specified frequency.

phased.DopplerEstimator System object

Package: phased

Doppler estimation

Description

The `phased.DopplerEstimator` System object estimates Doppler frequencies of targets. Input to the estimator consists of detection locations output from a detector, and a range-Doppler response data cube. When detections are clustered, the Doppler frequencies are computed using cluster information. Clustering associates multiple detections into one extended detection.

To compute Doppler values for detections:

1. Define and set up your Doppler estimator using the "Construction" on page 1-514 procedure that follows.
2. Call the `step` method to compute the Doppler of detections, using the properties you specify for the `phased.DopplerEstimator` System object.

Note: Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`estimator = phased.DopplerEstimator` creates a Doppler estimator System object, `estimator`.

`estimator = phased.DopplerEstimator(Name,Value)` creates a System object, `estimator`, with each specified property `Name` set to the specified `Value`. You can specify additional name and value pair arguments in any order as (`Name1,Value1,...,NameN,ValueN`).

Properties

`NumEstimatesSource` — Source of requested number of Doppler estimates

`'Auto'` (default) | `'Property'`

Source of the number of requested Doppler estimates, specified as `'Auto'` or `'Property'`.

If you set this property to `'Auto'`, the number of estimates equals the number of columns in the `detidx` input argument of the `step` method. If cluster IDs are provided, the number of estimates equals the number of unique cluster IDs.

If you set this property to `'Property'`, the number of reported estimates is obtained from the value of the `NumEstimates` property.

Data Types: `char`

`NumEstimates` — Maximum number of estimates

1 (default) | positive integer

The maximum number of estimates to report, specified as a positive integer. When the number of requested estimates is greater than the number of columns in the `detidx` argument of the `step` method, the remainder is filled with `NaN`.

Dependencies

To enable this property, set the `NumEstimatesSource` property to `'Property'`.

Data Types: `double`

`ClusterInputPort` — Accept `clusterids` as input

`false` (default) | `true`

Option to accept `clusterids` as an input argument to the `step` method, specified as `false` or `true`. Setting this property to `true` enables the `clusterid` input argument of the `step` method.

Data Types: `logical`

`VarianceOutputPort` — Enable output of Doppler variance estimates

`false` (default) | `true`

Option to enable output of Doppler variance estimate, specified as `false` or `true`. Doppler variances estimates are returned in the `dopvar` output argument of the `step` method.

Data Types: `logical`

`NumPulses` — Number of pulses in Doppler-processed waveform

`2` (default) | positive integer

The number of pulses in the Doppler processed data cube, specified as a positive integer.

Dependencies

To enable this property, set the `VarianceOutputPort` property to `true`.

Data Types: `double`

`NoisePowerSource` — Source of noise power values

`'Property'` (default) | `'Input port'`

Source of noise power values, specified as `'Property'` or `'Input port'`. Noise power is used to compute Doppler estimation variance and SNR. If you set this property to `'Property'`, the value of the `NoisePower` property represents the noise power at the detection locations. If you set this property to `'Input port'`, you can specify noise power using the `noisepower` input argument ofargument of the `step` method.

Data Types: `char`

`NoisePower` — Noise power

`1.0` (default) | positive scalar

Constant noise power value over the range-Doppler data cube, specified as a positive scalar. Noise power units are linear. The same noise power value is applied to all detections.

Dependencies

To enable this property, set the `VarianceOutputPort` property to `true` and set `NoisePowerSource` to `'Property'`.

Data Types: `double`

Methods

step	Estimate target Doppler

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Estimate Range and Speed of Three Targets

To estimate the range and speed of three targets, create a range-Doppler map using the `phased.RangeDopplerResponse` System object™. Then use the `phased.RangeEstimator` and `phased.DopplerEstimator` System objects to estimate range and speed. The transmitter and receiver are collocated isotropic antenna elements forming a monostatic radar system.

The transmitted signal is a linear FM waveform with a pulse repetition interval (PRI) of 7.0 μs and a duty cycle of 2%. The operating frequency is 77 GHz and the sample rate is 150 MHz.

```
fs = 150e6;
c = physconst('LightSpeed');
fc = 77.0e9;
pri = 7e-6;
prf = 1/pri;
```

Set up the scenario parameters. The transmitter and receiver are stationary and located at the origin. The targets are 500, 530, and 750 meters from the radar along the *x*-axis.

The targets move along the *x*-axis at speeds of –60, 20, and 40 m/s. All three targets have a nonfluctuating radar cross-section (RCS) of 10 dB. Create the target and radar platforms.

```
Numtgts = 3;
tgtpos = zeros(Numtgts);
tgtpos(1,:) = [500 530 750];
tgtvel = zeros(3,Numtgts);
tgtvel(1,:) = [-60 20 40];
tgtrcs = db2pow(10)*[1 1 1];
tgtmotion = phased.Platform(tgtpos,tgtvel);
target = phased.RadarTarget('PropagationSpeed',c,'OperatingFrequency',fc, ...
    'MeanRCS',tgtrcs);
radarpos = [0;0;0];
radarvel = [0;0;0];
radarmotion = phased.Platform(radarpos,radarvel);
```

Create the transmitter and receiver antennas.

```
txantenna = phased.IsotropicAntennaElement;
rxantenna = clone(txantenna);
```

Set up the transmitter-end signal processing. Create an upsweep linear FM signal with a bandwidth of one half the sample rate. Find the length of the PRI in samples and then estimate the rms bandwidth and range resolution.

```
bw = fs/2;
waveform = phased.LinearFMWaveform('SampleRate',fs, ...
    'PRF',prf,'OutputFormat','Pulses','NumPulses',1,'SweepBandwidth',fs/2, ...
    'DurationSpecification','Duty cycle','DutyCycle',0.02);
sig = waveform();
Nr = length(sig);
bwrms = bandwidth(waveform)/sqrt(12);
rngrms = c/bwrms;
```

Set up the transmitter and radiator System object properties. The peak output power is 10 W and the transmitter gain is 36 dB.

```
peakpower = 10;
txgain = 36.0;
txgain = 36.0;
transmitter = phased.Transmitter( ...
    'PeakPower',peakpower, ...
    'Gain',txgain, ...
```

```
    'InUseOutputPort',true);
radiator = phased.Radiator( ...
    'Sensor',txantenna,...
    'PropagationSpeed',c,...
    'OperatingFrequency',fc);
```

Set up the free-space channel in two-way propagation mode.

```
channel = phased.FreeSpace( ...
    'SampleRate',fs, ...
    'PropagationSpeed',c, ...
    'OperatingFrequency',fc, ...
    'TwoWayPropagation',true);
```

Set up the receiver-end processing. Set the receiver gain and noise figure.

```
collector = phased.Collector( ...
    'Sensor',rxantenna, ...
    'PropagationSpeed',c, ...
    'OperatingFrequency',fc);
rxgain = 42.0;
noisefig = 1;
receiver = phased.ReceiverPreamp( ...
    'SampleRate',fs, ...
    'Gain',rxgain, ...
    'NoiseFigure',noisefig);
```

Loop over the pulses to create a data cube of 128 pulses. For each step of the loop, move the target and propagate the signal. Then put the received signal into the data cube. The data cube contains the received signal per pulse. Ordinarily, a data cube has three dimensions where the last dimension corresponds to antennas or beams. Because only one sensor is used, the cube has only two dimensions.

The processing steps are:

1. Move the radar and targets.
2. Transmit a waveform.
3. Propagate the waveform signal to the target.
4. Reflect the signal from the target.
5. Propagate the waveform back to the radar. Two-way propagation enables enables you to combine the return propagation with the outbound propagation.

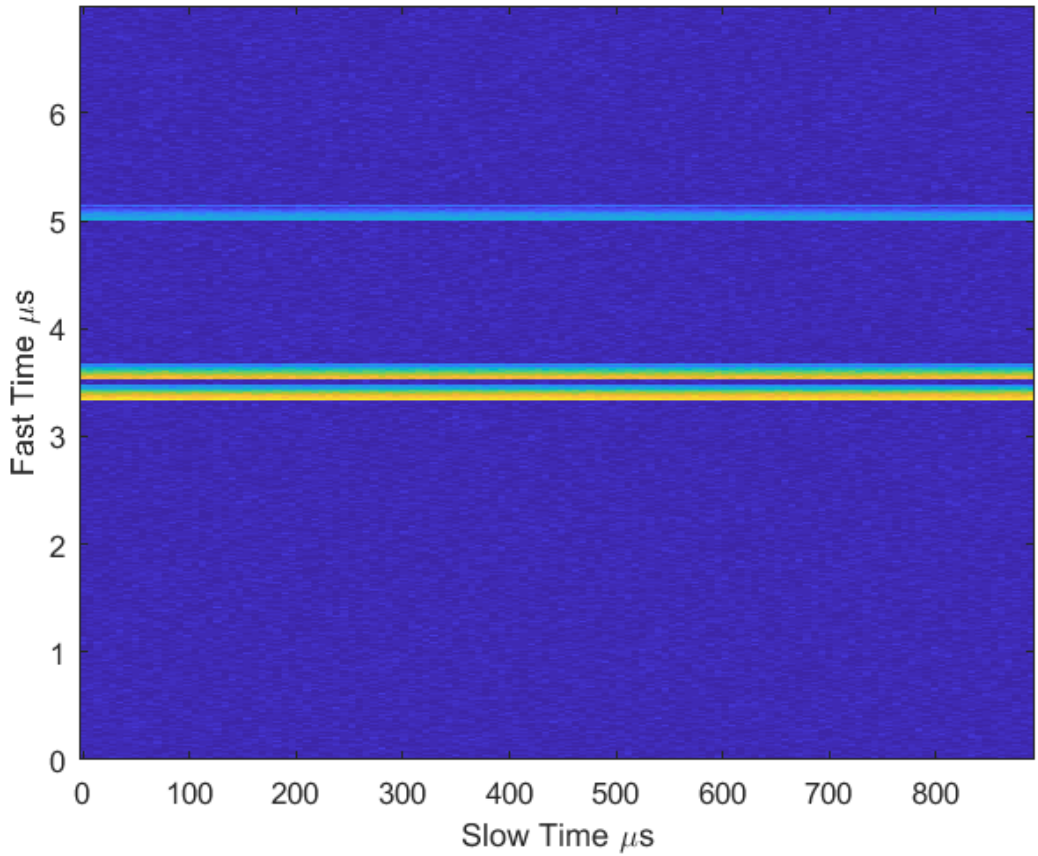
6 Receive the signal at the radar.

7 Load the signal into the data cube.

```
Np = 128;
dt = pri;
cube = zeros(Nr,Np);
for n = 1:Np
    [sensorpos,sensorvel] = radarmotion(dt);
    [tgtpos,tgtvel] = tgtmotion(dt);
    [tgtrng,tgtang] = rangeangle(tgtpos,sensorpos);
    sig = waveform();
    [txsig,txstatus] = transmitter(sig);
    txsig = radiator(txsig,tgtang);
    txsig = channel(txsig,sensorpos,tgtpos,sensorvel,tgtvel);
    tgtsig = target(txsig);
    rxcol = collector(tgtsig,tgtang);
    rxsig = receiver(rxcol);
    cube(:,n) = rxsig;
end
```

Display the data cube containing signals per pulse.

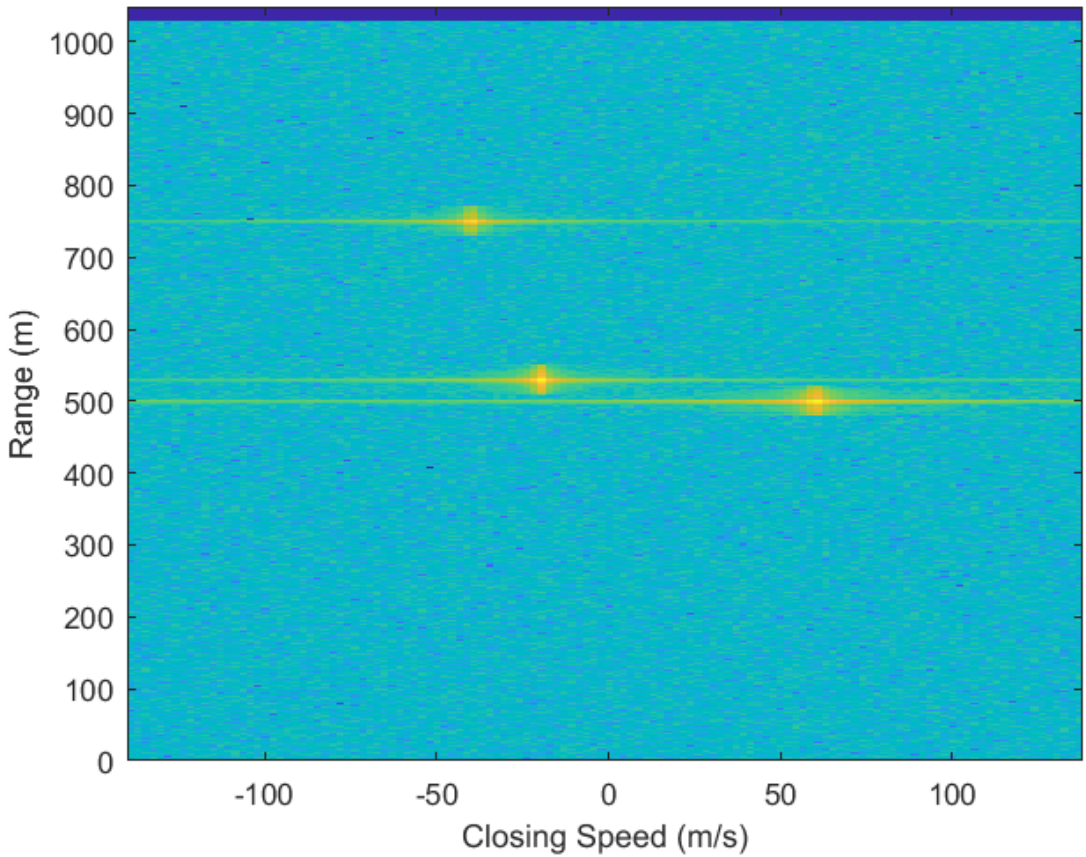
```
imagesc([0:(Np-1)]*pri*1e6,[0:(Nr-1)]/fs*1e6,abs(cube))
xlabel('Slow Time {\mu}s')
ylabel('Fast Time {\mu}s')
axis xy
```



Create and display the range-Doppler image for 128 Doppler bins. The image shows range vertically and speed horizontally. Use the linear FM waveform for match filtering. The image is here is the range-Doppler map.

```
ndop = 128;
rangedopresp = phased.RangeDopplerResponse('SampleRate',fs, ...
    'PropagationSpeed',c,'DopplerFFTLengthSource','Property', ...
    'DopplerFFTLength',ndop,'DopplerOutput','Speed', ...
    'OperatingFrequency',fc);
matchingcoeff = getMatchedFilter(waveform);
[rngdopresp,rnggrid,dopgrid] = rangedopresp(cube,matchingcoeff);
```

```
imagesc(dopgrid,rnggrid,10*log10(abs(rngdopresp)))
xlabel('Closing Speed (m/s)')
ylabel('Range (m)')
axis xy
```



Because the targets lie along the positive *x*-axis, positive velocity in the global coordinate system corresponds to negative closing speed. Negative velocity in the global coordinate system corresponds to positive closing speed.

Estimate the noise power after matched filtering. Create a constant noise background image for simulation purposes.

```
mfgain = matchingcoeff'*matchingcoeff;
dopgain = Np;
noisebw = fs;
noisepower = noisepow(noisebw,receiver.NoiseFigure,receiver.ReferenceTemperature);
noisepowerprc = mfgain*dopgain*noisepower;
noise = noisepowerprc*ones(size(rngdopresp));
```

Create the range and Doppler estimator objects.

```
rangeestimator = phased.RangeEstimator('NumEstimatesSource','Auto', ...
    'VarianceOutputPort',true,'NoisePowerSource','Input port', ...
    'RMSResolution',rngrms);
dopestimator = phased.DopplerEstimator('VarianceOutputPort',true, ...
    'NoisePowerSource','Input port','NumPulses',Np);
```

Locate the target indices in the range-Doppler image. Instead of using a CFAR detector, for simplicity, use the known locations and speeds of the targets to obtain the corresponding index in the range-Doppler image.

```
detidx = NaN(2,Numtgts);
tgtrng = rangeangle(tgtpos,radarpos);
tgtspd = radialspeed(tgtpos,tgtvel,radarpos,radarvel);
tgtdop = 2*speed2dop(tgtspd,c/fc);
for m = 1:numel(tgtrng)
    [~,iMin] = min(abs(rnggrid-tgtrng(m)));
    detidx(1,m) = iMin;
    [~,iMin] = min(abs(dopgrid-tgtspd(m)));
    detidx(2,m) = iMin;
end
```

Find the noise power at the detection locations.

```
ind = sub2ind(size(noise),detidx(1,:),detidx(2,:));
```

Estimate the range and range variance at the detection locations. The estimated ranges agree with the postulated ranges.

```
[rngest,rngvar] = rangeestimator(rngdopresp,rnggrid,detidx,noise(ind))
```

```
rngest =

  499.7911
  529.8380
  750.0983
```

```
rngvar =

   1.0e-04 *

    0.0273
    0.0276
    0.2094
```

Estimate the speed and speed variance at the detection locations. The estimated speeds agree with the predicted speeds.

```
[spdest,spdvar] = dopestimator(rngdopresp,dopgrid,detidx,noise(ind))
```

```
spdest =

   60.5241
  -19.6167
  -39.5838

spdvar =

   1.0e-05 *

    0.0806
    0.0816
    0.6188
```

Algorithms

The `phased.DopplerEstimator` System object estimates the Doppler frequency of a detection by following these steps of the Doppler estimator are

1. Input a Doppler-processed response data cube obtained from the phased.RangeDopplerResponse System object. The first dimension of the cube represents the fast-time or equivalent range of the returned signal samples. The second dimension represents the spatial information, such as sensors or beams. The

last dimension represents the response as a function of Doppler frequency. Only this dimension is used to estimate detection Doppler frequency. All others are ignored. See “Radar Data Cube”.

2 Input the matrix of detection indices that specify the location of detections in the data cube. Each column denotes a separate detection. The row entries designate indices into the data cube. To return these detection indices as an output of the phased.CFARDetector or phased.CFARDetector2D detectors. To return these indices, set the detector `OutputFormat` property of either CFAR detector to `'Detection index'`.

3 Optionally input a row vector of cluster IDs. This vector is equal in length to the number of detections. Each element of this vector assigns an ID to a corresponding detection. To form clusters of detections, the same ID can be assigned to more than one detection. To enable this option, set the `ClusterInputPort` property to `true`.

4 When `ClusterInputPort` is `false`, the object computes Doppler frequencies for each detection. The algorithm finds the response values at the detection index and at two adjacent indices in the cube along the Doppler dimension. Then, the algorithm fits a quadratic curve to the magnitudes of the Doppler response at these three indices. The peak of the curve indicates the detection location. When detections occur at the first or last sample in the Doppler dimension, the object estimates the detection location from a two-point centroid. The centroid is formed using the location of the detection index and the sample next to the detection index.

   When the object computes Doppler frequencies for each cluster. The algorithm finds the indices of the largest response value in the cluster. Then, the algorithm fits a quadratic curve to that detection in the same way as for individual detections.

5 The objct converts the fractional index values to Doppler frequency or speed by using appropriate units from the `dopgrid` input argument of the `step` method. You can obtain values for `dopgrid` using the phased.RangeDopplerResponse System object.

Estimate target Doppler

Syntax

```
dopest = step(estimator,resp,dopgrid,detidx)
[dopest,dopvar] = step(estimator,resp,dopgrid,detidx,noisepower)
[dopest,dopvar] = step(estimator,resp,dopgrid,detidx,clusterids)
[dopest,dopvar] = step(estimator,resp,dopgrid,detidx,noisepower,
clusterids)
```

Description

Note: Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`dopest = step(estimator,resp,dopgrid,detidx)` estimates Doppler frequencies of detections derived from the range-Doppler response data, `resp`. Doppler estimates are computed for each detection position reported in `detidx`. The `dopgrid` argumen sets the units for the Doppler dimension of the response data cube.

`[dopest,dopvar] = step(estimator,resp,dopgrid,detidx,noisepower)` also specifies the noise power. This syntax applies when you set `VarianceOutputPort` property to `true` and `NoisePowerSource` property to `'Input port'`.

`[dopest,dopvar] = step(estimator,resp,dopgrid,detidx,clusterids)` also specifies the `clusterids` for the detections. This syntax applies when you set the `ClusterInputPort` property to `true`.

You can combine optional input and output arguments when their enabling properites are set. Optional inputs and outputs must be listed in the same order as the order of

the enabling properties. For example, `[dopest,dopvar] = step(estimator,resp, dopgrid,detidx,noisepower,clusterids)`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`estimator` — Doppler estimator

`phased.DopplerEstimator` System object

Doppler estimator, specified as a `phased.DopplerEstimator` System object.

Example: `phased.DopplerEstimator`

`resp` — Doppler-processed response data cube

complex-valued *P*-by-1 column vector | complex-valued *M*-by-*P* matrix | complex-valued *M*-by-*N*-by-*P* array

Doppler-processed response data cube, specified as a complex-valued *P*-by-1 column vector, a complex-valued *M*-by-*P* matrix, or a complex-valued *M*-by-*N*-by-*P* array. *M* represents the number of fast-time or range samples. *N* is the number of spatial elements, such as sensor elements or beams. *P* is the number of Doppler bins.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Data Types: `double`
Complex Number Support: Yes

`dopgrid` — Doppler grid values along Doppler dimension

real-valued *P*-by-1 column vector

Doppler grid values along the Doppler dimension of the `resp` argument, specified as a real-valued *P*-by-1 column vector. `dopgrid` defines the Doppler values corresponding to the Doppler dimension of the `resp` argument. Doppler values must be monotonically

increasing and equally spaced. You can specify the grid values to be velocity or frequency. Units are in hertz or meters/sec.

Example: `[-0.3,-0.2,-0.1,0,0.1,0.2,0.3]`

Data Types: `double`

`detidx` — Detection indices

real-valued N_d-by-Q matrix

Detection indices, specified as a real-valued N_d-by-Q matrix. Q is the number of detections and N_d is the number of dimensions of the response data cube, `resp`. Each column of `detidx` contains the N_d indices of the detection in the response data cube.

To generate detection indices, you can use the phased.CFARDetector or phased.CFARDetector2D objects.

Data Types: `double`

`noisepower` — Noise power at detection locations

positive scalar | real-valued 1-by-Q row vector of positive values

Noise power at detection locations, specified as a positive scalar or real-valued 1-by-Q row vector of positive values. Q is the number of detections specified in `detidx`.

Dependencies

To enable this input argument, set the `NoisePowerSource` property to `Input port`.

Data Types: `double`

`clusterids` — Cluster IDs

real-valued 1-by-Q row vector of positive values

Cluster IDs, specified as a real-valued 1-by-Q row vector where Q is the number of detections specified in `detidx`. Each element of `clusterids` corresponds to a column in `detidx`. Detections with the same cluster ID belong to the same cluster.

Dependencies

To enable this input argument, set the `ClusterInputPort` property to `true`.

Data Types: `double`

Output Arguments

`dopest` — Doppler estimates

real-valued *K*-by-1 column vector

Doppler estimates, returned as a real-valued *K*-by-1 column vector.

- When `ClusterInputPort` is `false`, Doppler estimates are computed for each detection location in the `detidx` argument. Then *K* equals the column dimension, *Q*, of `detidx`.
- When `ClusterInputPort` is `true`, Doppler estimates are computed for each cluster ID in the `clusterids` argument. Then *K* equals the number of unique cluster IDs, *Q*.

Data Types: `double`

`dopvar` — Doppler estimation variance

positive, real-valued *K*-by-1 column vector

Doppler estimation variance, returned as a positive, real-valued *K*-by-1 column vector, where *K* is the dimension of `dopest`. Each element of `dopvar` corresponds to an element of `dopest`. The estimator variance is computed using the Ziv-Zakai bound.

Data Types: `double`

Examples

Estimate Range and Speed of Three Targets

To estimate the range and speed of three targets, create a range-Doppler map using the `phased.RangeDopplerResponse` System object™. Then use the `phased.RangeEstimator` and `phased.DopplerEstimator` System objects to estimate range and speed. The transmitter and receiver are collocated isotropic antenna elements forming a monostatic radar system.

The transmitted signal is a linear FM waveform with a pulse repetition interval (PRI) of 7.0 μs and a duty cycle of 2%. The operating frequency is 77 GHz and the sample rate is 150 MHz.

```
fs = 150e6;
c = physconst('LightSpeed');
fc = 77.0e9;
pri = 7e-6;
prf = 1/pri;
```

Set up the scenario parameters. The transmitter and receiver are stationary and located at the origin. The targets are 500, 530, and 750 meters from the radar along the *x*-axis. The targets move along the *x*-axis at speeds of –60, 20, and 40 m/s. All three targets have a nonfluctuating radar cross-section (RCS) of 10 dB. Create the target and radar platforms.

```
Numtgts = 3;
tgtpos = zeros(Numtgts);
tgtpos(1,:) = [500 530 750];
tgtvel = zeros(3,Numtgts);
tgtvel(1,:) = [-60 20 40];
tgtrcs = db2pow(10)*[1 1 1];
tgtmotion = phased.Platform(tgtpos,tgtvel);
target = phased.RadarTarget('PropagationSpeed',c,'OperatingFrequency',fc, ...
    'MeanRCS',tgtrcs);
radarpos = [0;0;0];
radarvel = [0;0;0];
radarmotion = phased.Platform(radarpos,radarvel);
```

Create the transmitter and receiver antennas.

```
txantenna = phased.IsotropicAntennaElement;
rxantenna = clone(txantenna);
```

Set up the transmitter-end signal processing. Create an upsweep linear FM signal with a bandwidth of one half the sample rate. Find the length of the PRI in samples and then estimate the rms bandwidth and range resolution.

```
bw = fs/2;
waveform = phased.LinearFMWaveform('SampleRate',fs, ...
    'PRF',prf,'OutputFormat','Pulses','NumPulses',1,'SweepBandwidth',fs/2, ...
    'DurationSpecification','Duty cycle','DutyCycle',0.02);
sig = waveform();
Nr = length(sig);
bwrms = bandwidth(waveform)/sqrt(12);
rngrms = c/bwrms;
```

Set up the transmitter and radiator System object properties. The peak output power is 10 W and the transmitter gain is 36 dB.

```
peakpower = 10;
txgain = 36.0;
txgain = 36.0;
transmitter = phased.Transmitter( ...
    'PeakPower',peakpower, ...
    'Gain',txgain, ...
    'InUseOutputPort',true);
radiator = phased.Radiator( ...
    'Sensor',txantenna,...
    'PropagationSpeed',c,...
    'OperatingFrequency',fc);
```

Set up the free-space channel in two-way propagation mode.

```
channel = phased.FreeSpace( ...
    'SampleRate',fs, ...
    'PropagationSpeed',c, ...
    'OperatingFrequency',fc, ...
    'TwoWayPropagation',true);
```

Set up the receiver-end processing. Set the receiver gain and noise figure.

```
collector = phased.Collector( ...
    'Sensor',rxantenna, ...
    'PropagationSpeed',c, ...
    'OperatingFrequency',fc);
rxgain = 42.0;
noisefig = 1;
receiver = phased.ReceiverPreamp( ...
    'SampleRate',fs, ...
    'Gain',rxgain, ...
    'NoiseFigure',noisefig);
```

Loop over the pulses to create a data cube of 128 pulses. For each step of the loop, move the target and propagate the signal. Then put the received signal into the data cube. The data cube contains the received signal per pulse. Ordinarily, a data cube has three dimensions where the last dimension corresponds to antennas or beams. Because only one sensor is used, the cube has only two dimensions.

The processing steps are:

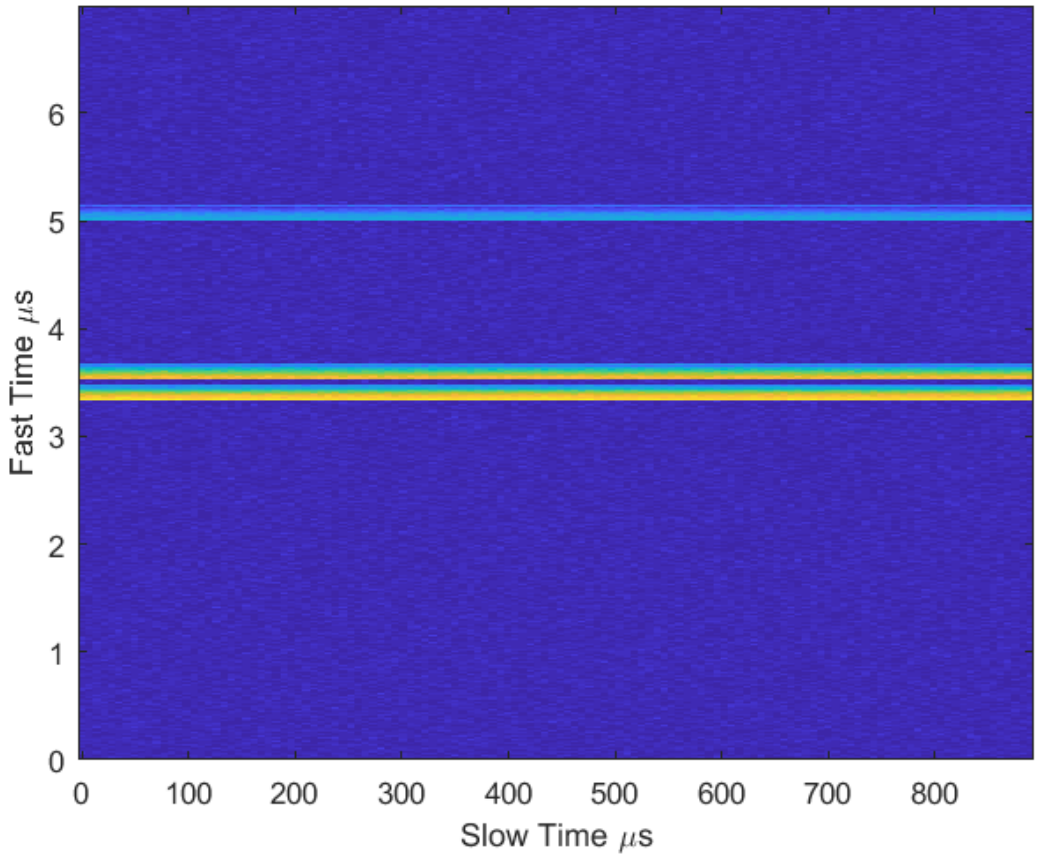
1. Move the radar and targets.
2. Transmit a waveform.

3. Propagate the waveform signal to the target.
4. Reflect the signal from the target.
5. Propagate the waveform back to the radar. Two-way propagation enables enables you to combine the return propagation with the outbound propagation.
6. Receive the signal at the radar.
7. Load the signal into the data cube.

```
Np = 128;
dt = pri;
cube = zeros(Nr,Np);
for n = 1:Np
    [sensorpos,sensorvel] = radarmotion(dt);
    [tgtpos,tgtvel] = tgtmotion(dt);
    [tgtrng,tgtang] = rangeangle(tgtpos,sensorpos);
    sig = waveform();
    [txsig,txstatus] = transmitter(sig);
    txsig = radiator(txsig,tgtang);
    txsig = channel(txsig,sensorpos,tgtpos,sensorvel,tgtvel);
    tgtsig = target(txsig);
    rxcol = collector(tgtsig,tgtang);
    rxsig = receiver(rxcol);
    cube(:,n) = rxsig;
end
```

Display the data cube containing signals per pulse.

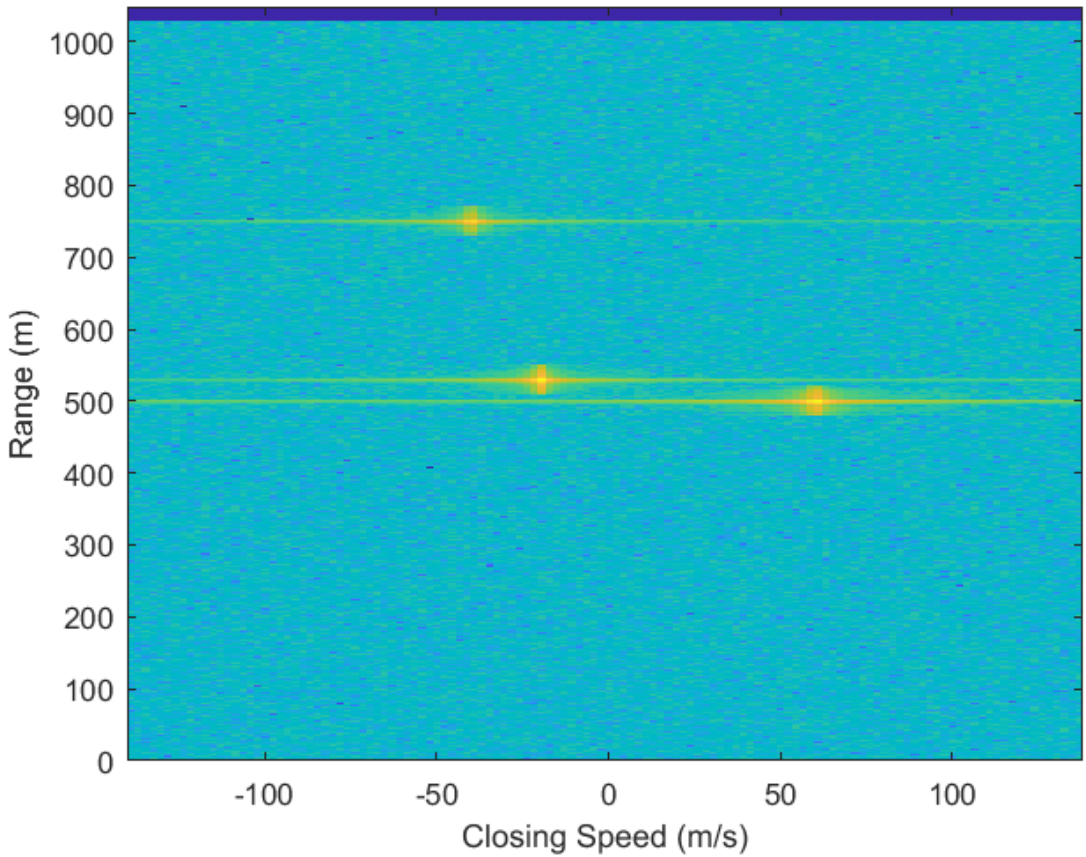
```
imagesc([0:(Np-1)]*pri*1e6,[0:(Nr-1)]/fs*1e6,abs(cube))
xlabel('Slow Time {\mu}s')
ylabel('Fast Time {\mu}s')
axis xy
```



Create and display the range-Doppler image for 128 Doppler bins. The image shows range vertically and speed horizontally. Use the linear FM waveform for match filtering. The image is here is the range-Doppler map.

```
ndop = 128;
rangedopresp = phased.RangeDopplerResponse('SampleRate',fs, ...
    'PropagationSpeed',c,'DopplerFFTLengthSource','Property', ...
    'DopplerFFTLength',ndop,'DopplerOutput','Speed', ...
    'OperatingFrequency',fc);
matchingcoeff = getMatchedFilter(waveform);
[rngdopresp,rnggrid,dopgrid] = rangedopresp(cube,matchingcoeff);
```

```
imagesc(dopgrid,rnggrid,10*log10(abs(rngdopresp)))
xlabel('Closing Speed (m/s)')
ylabel('Range (m)')
axis xy
```



Because the targets lie along the positive *x*-axis, positive velocity in the global coordinate system corresponds to negative closing speed. Negative velocity in the global coordinate system corresponds to positive closing speed.

Estimate the noise power after matched filtering. Create a constant noise background image for simulation purposes.

```
mfgain = matchingcoeff'*matchingcoeff;
dopgain = Np;
noisebw = fs;
noisepower = noisepow(noisebw,receiver.NoiseFigure,receiver.ReferenceTemperature);
noisepowerprc = mfgain*dopgain*noisepower;
noise = noisepowerprc*ones(size(rngdopresp));
```

Create the range and Doppler estimator objects.

```
rangeestimator = phased.RangeEstimator('NumEstimatesSource','Auto', ...
    'VarianceOutputPort',true,'NoisePowerSource','Input port', ...
    'RMSResolution',rngrms);
dopestimator = phased.DopplerEstimator('VarianceOutputPort',true, ...
    'NoisePowerSource','Input port','NumPulses',Np);
```

Locate the target indices in the range-Doppler image. Instead of using a CFAR detector, for simplicity, use the known locations and speeds of the targets to obtain the corresponding index in the range-Doppler image.

```
detidx = NaN(2,Numtgts);
tgtrng = rangeangle(tgtpos,radarpos);
tgtspd = radialspeed(tgtpos,tgtvel,radarpos,radarvel);
tgtdop = 2*speed2dop(tgtspd,c/fc);
for m = 1:numel(tgtrng)
    [~,iMin] = min(abs(rnggrid-tgtrng(m)));
    detidx(1,m) = iMin;
    [~,iMin] = min(abs(dopgrid-tgtspd(m)));
    detidx(2,m) = iMin;
end
```

Find the noise power at the detection locations.

```
ind = sub2ind(size(noise),detidx(1,:),detidx(2,:));
```

Estimate the range and range variance at the detection locations. The estimated ranges agree with the postulated ranges.

```
[rngest,rngvar] = rangeestimator(rngdopresp,rnggrid,detidx,noise(ind))
```

```
rngest =

  499.7911
  529.8380
  750.0983
```

```
rngvar =

   1.0e-04 *

    0.0273
    0.0276
    0.2094
```

Estimate the speed and speed variance at the detection locations. The estimated speeds agree with the predicted speeds.

```
[spdest,spdvar] = dopestimator(rngdopresp,dopgrid,detidx,noise(ind))
```

```
spdest =

   60.5241
  -19.6167
  -39.5838

spdvar =

   1.0e-05 *

    0.0806
    0.0816
    0.6188
```

Introduced in R2017a

phased.DPCACanceller System object

Package: phased

Displaced phase center array (DPCA) pulse canceller

Description

The `DPCACanceller` object implements a displaced phase center array pulse canceller for a uniform linear array (ULA).

To compute the output signal of the space time pulse canceller:

1. Define and set up your DPCA pulse canceller. See "Construction" on page 1-538.
2. Call step to execute the DPCA algorithm according to the properties of `phased.DPCACanceller`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.DPCACanceller` creates a displaced phase center array (DPCA) canceller System object, `H`. The object performs two-pulse DPCA processing on the input data.

`H = phased.DPCACanceller(Name,Value)` creates a DPCA object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`SensorArray`

Uniform linear array

Uniform linear array, specified as a phased.ULA System object.

Default: phased.ULA with default property values

`PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

Default: Speed of light

`OperatingFrequency`

System operating frequency

Specify the operating frequency of the system in hertz as a positive scalar. The default value corresponds to 300 MHz.

Default: `3e8`

`PRF`

Pulse repetition frequency

Specify the pulse repetition frequency (PRF) of the received signal in hertz as a scalar.

Default: `1`

`DirectionSource`

Source of receiving mainlobe direction

Specify whether the targeting direction for the STAP processor comes from the `Direction` property of this object or from an input argument in step. Values of this property are:

`'Property'`	The `Direction` property of this object specifies the targeting direction.
`'Input port'`	An input argument in each invocation of `step` specifies the targeting direction.

Default: `'Property'`

`Direction`

Receiving mainlobe direction

Specify the receiving mainlobe direction of the receiving sensor array as a column vector of length 2. The direction is specified in the format of `[AzimuthAngle;ElevationAngle]` (in degrees). The azimuth angle should be between –180° and 180°. The elevation angle should be between –90° and 90°. This property applies when you set the `DirectionSource` property to `'Property'`.

Default: `[0; 0]`

`NumPhaseShifterBits`

Number of phase shifter quantization bits

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

Default: `0`

`DopplerSource`

Source of targeting Doppler

Specify whether the targeting Doppler for the STAP processor comes from the `Doppler` property of this object or from an input argument in step. Values of this property are:

`'Property'`	The `Doppler` property of this object specifies the Doppler.
`'Input port'`	An input argument in each invocation of `step` specifies the Doppler.

Default: `'Property'`

`Doppler`

Targeting Doppler frequency (hertz)

Specify the targeting Doppler of the STAP processor as a scalar. This property applies when you set the `DopplerSource` property to `'Property'`.

Default: `0`

`WeightsOutputPort`

Output processing weights

To obtain the weights used in the STAP processor, set this property to `true` and use the corresponding output argument when invoking step. If you do not want to obtain the weights, set this property to `false`.

Default: `false`

`PreDopplerOutput`

Output pre-Doppler result

Set this property to `true` to output the processing result before applying the Doppler filtering. Set this property to `false` to output the processing result after the Doppler filtering.

Default: `false`

Methods

step	Perform DPCA processing on input data

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Process Data Cube Using DPCA

Process a data cube using a DPCA processor. The weights are calculated for the 71st cell of the collected data cube. The look direction is *(0,0)* degrees and the Doppler shift is 12.980 kHz.

```
load STAPExampleData;
Hs = phased.DPCACanceller('SensorArray',STAPEx_HArray,...
    'PRF',STAPEx_PRF,...
    'PropagationSpeed',STAPEx_PropagationSpeed,...
    'OperatingFrequency',STAPEx_OperatingFrequency,...
    'WeightsOutputPort',true,...
    'DirectionSource','Input port',...
    'DopplerSource','Input port');
[y,w] = step(Hs,STAPEx_ReceivePulse,71,[0;0],12.980e3);

sAngDop = phased.AngleDopplerResponse(...
    'SensorArray',Hs.SensorArray,...
    'OperatingFrequency',Hs.OperatingFrequency,...
    'PRF',Hs.PRF,...
    'PropagationSpeed',Hs.PropagationSpeed);
plotResponse(sAngDop,w)
```

phased.ADPCACanceller | phased.AngleDopplerResponse | phased.STAPSMIBeamformer | `phitheta2azel` | `uv2azel`

Introduced in R2012a

step

System object: phased.DPCACanceller
Package: phased

Perform DPCA processing on input data

Syntax

```
Y = step(H,X,CUTIDX)
Y = step(H,X,CUTIDX,ANG)
Y = step(___,DOP)
[Y,W] = step(___)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X,CUTIDX)` applies the DPCA pulse cancellation algorithm to the input data `X`. The algorithm calculates the processing weights according to the range cell specified by `CUTIDX`. This syntax is available when the `DirectionSource` property is `'Property'` and the `DopplerSource` property is `'Property'`. The receiving mainlobe direction is the `Direction` property value. The output `Y` contains the result of pulse cancellation either before or after Doppler filtering, depending on the `PreDopplerOutput` property value.

`Y = step(H,X,CUTIDX,ANG)` uses `ANG` as the receiving mainlobe direction. This syntax is available when the `DirectionSource` property is `'Input port'` and the `DopplerSource` property is `'Property'`.

`Y = step(___,DOP)` uses `DOP` as the targeting Doppler frequency. This syntax is available when the `DopplerSource` property is `'Input port'`.

`[Y,W] = step( ___ )` returns the additional output, `W`, as the processing weights. This syntax is available when the `WeightsOutputPort` property is `true`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`H`

Pulse canceller object.

`X`

Input data. `X` must be a 3-dimensional M-by-N-by-P numeric array whose dimensions are (range, channels, pulses).

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

`CUTIDX`

Range cell.

`ANG`

Receiving mainlobe direction. `ANG` must be a 2-by-1 vector in the form `[AzimuthAngle; ElevationAngle]`, in degrees. The azimuth angle must be between –180 and 180. The elevation angle must be between –90 and 90.

Default: `Direction` property of `H`

`DOP`

Targeting Doppler frequency in hertz. `DOP` must be a scalar.

Default: `Doppler` property of `H`

Output Arguments

Y

Result of applying pulse cancelling to the input data. The meaning and dimensions of `Y` depend on the `PreDopplerOutput` property of `H`:

- If `PreDopplerOutput` is `true`, `Y` contains the pre-Doppler data. `Y` is an M-by-(P–1) matrix. Each column in `Y` represents the result obtained by cancelling the two successive pulses.
- If `PreDopplerOutput` is `false`, `Y` contains the result of applying an FFT-based Doppler filter to the pre-Doppler data. The targeting Doppler is the `Doppler` property value. `Y` is a column vector of length M.

W

Processing weights the pulse canceller used to obtain the pre-Doppler data. The dimensions of `W` depend on the `PreDopplerOutput` property of `H`:

- If `PreDopplerOutput` is `true`, `W` is a 2N-by-(P-1) matrix. The columns in `W` correspond to successive pulses in `X`.
- If `PreDopplerOutput` is `false`, `W` is a column vector of length (N*P).

Examples

Process Data Cube Using DPCA

Process a data cube using a DPCA processor. The weights are calculated for the 71st cell of the collected data cube. The look direction is *(0,0)* degrees and the Doppler shift is 12.980 kHz.

```
load STAPExampleData;
Hs = phased.DPCACanceller('SensorArray',STAPEx_HArray,...
    'PRF',STAPEx_PRF,...
    'PropagationSpeed',STAPEx_PropagationSpeed,...
    'OperatingFrequency',STAPEx_OperatingFrequency,...
    'WeightsOutputPort',true,...
    'DirectionSource','Input port',...
    'DopplerSource','Input port');
[y,w] = step(Hs,STAPEx_ReceivePulse,71,[0;0],12.980e3);
```

```
sAngDop = phased.AngleDopplerResponse(...
    'SensorArray',Hs.SensorArray,...
    'OperatingFrequency',Hs.OperatingFrequency,...
    'PRF',Hs.PRF,...
    'PropagationSpeed',Hs.PropagationSpeed);
plotResponse(sAngDop,w)
```

phased.ElementDelay System object

Package: phased

Sensor array element delay estimator

Description

The `ElementDelay` object calculates the signal delay for elements in an array.

To compute the signal delay across the array elements:

1. Define and set up your element delay estimator. See "Construction" on page 1-549.
2. Call step to estimate the delay according to the properties of `phased.ElementDelay`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.ElementDelay` creates an element delay estimator System object, `H`. The object calculates the signal delay for elements in an array when the signal arrives the array from specified directions. By default, a 2-element uniform linear array (ULA) is used.

`H = phased.ElementDelay(Name,Value)` creates object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

SensorArray

Handle to sensor array used to calculate the delay

Specify the sensor array as a handle. The sensor array must be an array object in the `phased` package. The array cannot contain subarrays.

Default: phased.ULA with default property values

PropagationSpeed

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

Default: Speed of light

Methods

step	Calculate delay for elements

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Element Delay for Uniform Linear Array

Calculate the element delay for a uniform linear array when the input is impinging on the array from 30° azimuth and 20° elevation.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
array = phased.ULA('NumElements',4);
delay = phased.ElementDelay('SensorArray',array);
tau = delay([30;20])
```

```
tau =

   1.0e-08 *

    0.1175
    0.0392
   -0.0392
   -0.1175
```

phased.ArrayGain | phased.ArrayResponse | phased.SteeringVector

Introduced in R2012a

step

System object: phased.ElementDelay
Package: phased

Calculate delay for elements

Syntax

```
TAU = step(H,ANG)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`TAU = step(H,ANG)` returns the delay `TAU` of each element relative to the array's phase center for the signal incident directions specified by `ANG`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`H`

Element delay object.

ANG

Signal incident directions in degrees. ANG can be either a 2-by-M matrix or a row vector of length M.

If ANG is a 2-by-M matrix, each column of the matrix specifies the direction in the form [azimuth; elevation]. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

If ANG is a row vector of length M, each element specifies a direction's azimuth angle. In this case, the corresponding elevation angle is assumed to be 0.

Output Arguments

TAU

Delay in seconds.TAU is an N-by-M matrix, where N is the number of elements in the array. Each column of TAU contains the delays of the array elements for the corresponding direction specified in ANG.

Examples

Element Delay for Uniform Linear Array

Calculate the element delay for a uniform linear array when the input is impinging on the array from 30° azimuth and 20° elevation.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
array = phased.ULA('NumElements',4);
delay = phased.ElementDelay('SensorArray',array);
tau = delay([30;20])
```

```
tau =

   1.0e-08 *
```

```
    0.1175
    0.0392
   -0.0392
   -0.1175
```

phased.ESPRITEstimator System object

Package: phased

ESPRIT direction of arrival (DOA) estimator for ULA

Description

The `phased.ESPRITEstimator` System object estimate the direction of arrival of signals parameters via rotational invariance (ESPRIT) direction of arrival estimate.

To estimate the direction of arrival (DOA):

1. Define and set up your DOA estimator. See "Construction" on page 1-556.
2. Call step to estimate the DOA according to the properties of `phased.ESPRITEstimator`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.ESPRITEstimator` creates an ESPRIT DOA estimator System object, `H`. The object estimates the signal's direction-of-arrival (DOA) using the ESPRIT algorithm with a uniform linear array (ULA).

`H = phased.ESPRITEstimator(Name,Value)` creates object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`SensorArray`

Handle to sensor array

Specify the sensor array as a handle. The sensor array must be a `phased.ULA` object.

Default: phased.ULA with default property values

`PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

Default: Speed of light

`OperatingFrequency`

System operating frequency

Specify the operating frequency of the system in hertz as a positive scalar. The default value corresponds to 300 MHz.

Default: `3e8`

`ForwardBackwardAveraging`

Perform forward-backward averaging

Set this property to `true` to use forward-backward averaging to estimate the covariance matrix for sensor arrays with conjugate symmetric array manifold.

Default: `false`

`SpatialSmoothing`

Spatial smoothing

Specify the number of averaging used by spatial smoothing to estimate the covariance matrix as a nonnegative integer. Each additional smoothing handles one extra coherent source, but reduces the effective number of element by 1. The maximum value of this property is M–2, where M is the number of sensors.

Default: 0, indicating no spatial smoothing

NumSignalsSource

Source of number of signals

Specify the source of the number of signals as one of 'Auto' or 'Property'. If you set this property to 'Auto', the number of signals is estimated by the method specified by the NumSignalsMethod property.

Default: 'Auto'

NumSignalsMethod

Method to estimate number of signals

Specify the method to estimate the number of signals as one of 'AIC' or 'MDL'. The 'AIC' uses the Akaike Information Criterion and the 'MDL' uses Minimum Description Length criterion. This property applies when you set the NumSignalsSource property to 'Auto'.

Default: 'AIC'

NumSignals

Number of signals

Specify the number of signals as a positive integer scalar. This property applies when you set the NumSignalsSource property to 'Property'. The number of signals, N_{sig}, must be smaller than the number of elements, N_{sub}, in the subarray derived from the array specified in the SensorArray property. See "ESPRIT Subarrays" on page 1-560.

Default: 1

Method

Type of least squares method

Specify the least squares method used for ESPRIT as one of 'TLS' or 'LS'. 'TLS' refers to total least squares and 'LS'refers to least squares.

Default: 'TLS'

`RowWeighting`

Row weighting factor

Specify the row weighting factor for signal subspace eigenvectors as a positive integer scalar. This property controls the weights applied to the selection matrices. In most cases the higher value the better. However, it can never be greater than *(Nsub – 1)/2* where *Nsub* is the number of elements in the subarray derived from the array specified in the `SensorArray` property. See "ESPRIT Subarrays" on page 1-560.

Default: 1

Methods

step Perform DOA estimation

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Estimate DOAs of Two Signals

Estimate the directions-of-arrival (DOA) of two signals received by a standard 10-element ULA with element spacing 1 m. The antenna operating frequency is 150 MHz. The actual direction of the first signal is 10° in azimuth and 20° in elevation. The direction of the second signal is 45° in azimuth and 60° in elevation.

Create the signals.

```
fs = 8.0e3;
t = (0:1/fs:1).';
x1 = cos(2*pi*t*300);
x2 = cos(2*pi*t*400);
```

```
array = phased.ULA('NumElements',10,'ElementSpacing',1);
array.Element.FrequencyRange = [100e6 300e6];
fc = 150e6;
```

Create the plane waves and add noise.

```
x = collectPlaneWave(array,[x1 x2],[10 20;45 60]',fc);
noise = 0.1/sqrt(2)*(randn(size(x)) + 1i*randn(size(x)));
```

Estimate the arrival angles.

```
estimator = phased.ESPRITEstimator('SensorArray',array,...
    'OperatingFrequency',fc);
doas = estimator(x + noise);
az = broadside2az(sort(doas),[20 60])
```

```
az =

   10.0000   45.0126
```

ESPRIT Subarrays

The ESPRIT algorithm, as implemented in the `phased.ESPRITEstimator` System object, reorganizes the ULA elements into two overlapping subarrays. For an original N-element array, the first subarray consist of elements *1,...,N - 1* of the original array. The second subarray consist of elements *2,...,N* of the original array. There are $N_{sub} = N - 1$ elements in each subarray.

```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`ANG = step(H,X)` estimates the DOAs from `X` using the DOA estimator, `H`. `X` is a matrix whose columns correspond to channels. `ANG` is a row vector of the estimated broadside angles (in degrees).

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Examples

Estimate DOAs of Two Signals

Estimate the directions-of-arrival (DOA) of two signals received by a standard 10-element ULA with element spacing 1 m. The antenna operating frequency is 150 MHz. The actual direction of the first signal is 10° in azimuth and 20° in elevation. The direction of the second signal is 45° in azimuth and 60° in elevation.

Create the signals.

```
fs = 8.0e3;
t = (0:1/fs:1).';
x1 = cos(2*pi*t*300);
x2 = cos(2*pi*t*400);
array = phased.ULA('NumElements',10,'ElementSpacing',1);
array.Element.FrequencyRange = [100e6 300e6];
fc = 150e6;
```

Create the plane waves and add noise.

```
x = collectPlaneWave(array,[x1 x2],[10 20;45 60]',fc);
noise = 0.1/sqrt(2)*(randn(size(x)) + 1i*randn(size(x)));
```

Estimate the arrival angles.

```
estimator = phased.ESPRITEstimator('SensorArray',array,...
    'OperatingFrequency',fc);
doas = estimator(x + noise);
az = broadside2az(sort(doas),[20 60])
```

```
az =

   10.0000   45.0126
```

phased.FMCWWaveform System object

Package: phased

FMCW waveform

Description

The `FMCWWaveform` object creates an FMCW (frequency modulated continuous wave) waveform.

To obtain waveform samples:

1. Define and set up your FMCW waveform. See "Construction" on page 1-564.
2. Call step to generate the FMCW waveform samples according to the properties of `phased.FMCWWaveform`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations. When the only argument to the `step` method is the System object itself, replace `y = step(obj)` by `y = obj()`.

Construction

`H = phased.FMCWWaveform` creates an FMCW waveform System object, `H`. The object generates samples of an FMCW waveform.

`H = phased.FMCWWaveform(Name,Value)` creates an FMCW waveform object, `H`, with additional options specified by one or more `Name,Value` pair arguments. `Name` is a property name, and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

Properties

`SampleRate`

Sample rate

Specify the same rate, in hertz, as a positive scalar. The default value of this property corresponds to 1 MHz.

The quantity `(SampleRate .* SweepTime)` is a scalar or vector that must contain only integers.

Default: `1e6`

`SweepTime`

Duration of each linear FM sweep

Specify the duration of the upsweep or downsweep, in seconds, as a row vector of positive, real numbers. The default value corresponds to 100 μs.

If `SweepDirection` is `'Triangle'`, the sweep time is half the sweep period because each period consists of an upsweep and a downsweep. If `SweepDirection` is `'Up'` or `'Down'`, the sweep time equals the sweep period.

The quantity `(SampleRate .* SweepTime)` is a scalar or vector that must contain only integers.

To implement a varying sweep time, specify `SweepTime` as a nonscalar row vector. The waveform uses successive entries of the vector as the sweep time for successive periods of the waveform. If the last element of the vector is reached, the process continues cyclically with the first entry of the vector.

If `SweepTime` and `SweepBandwidth` are both nonscalar, they must have the same length.

Default: `1e-4`

`SweepBandwidth`

FM sweep bandwidth

Specify the bandwidth of the linear FM sweeping, in hertz, as a row vector of positive, real numbers. The default value corresponds to 100 kHz.

To implement a varying bandwidth, specify `SweepBandwidth` as a nonscalar row vector. The waveform uses successive entries of the vector as the sweep bandwidth for successive periods of the waveform. If the last element of the `SweepBandwidth` vector is reached, the process continues cyclically with the first entry of the vector.

If `SweepTime` and `SweepBandwidth` are both nonscalar, they must have the same length.

Default: `1e5`

`SweepDirection`

FM sweep direction

Specify the direction of the linear FM sweep as one of `'Up' | 'Down' | 'Triangle'`.

Default: `'Up'`

`SweepInterval`

Location of FM sweep interval

If you set this property value to `'Positive'`, the waveform sweeps in the interval between 0 and B, where B is the `SweepBandwidth` property value. If you set this property value to `'Symmetric'`, the waveform sweeps in the interval between $-B/2$ and $B/2$.

Default: `'Positive'`

`OutputFormat`

Output signal format

Specify the format of the output signal as one of `'Sweeps'` or `'Samples'`. When you set the `OutputFormat` property to `'Sweeps'`, the output of the `step` method is in the form of multiple sweeps. In this case, the number of sweeps is the value of the `NumSweeps` property. If the `SweepDirection` property is `'Triangle'`, each sweep is half a period.

When you set the `OutputFormat` property to `'Samples'`, the output of the `step` method is in the form of multiple samples. In this case, the number of samples is the value of the `NumSamples` property.

Default: `'Sweeps'`

NumSamples

Number of samples in output

Specify the number of samples in the output of the `step` method as a positive integer. This property applies only when you set the `OutputFormat` property to `'Samples'`.

Default: `100`

NumSweeps

Number of sweeps in output

Specify the number of sweeps in the output of the `step` method as a positive integer. This property applies only when you set the `OutputFormat` property to `'Sweeps'`.

Default: `1`

Methods

plot	Plot FMCW waveform
reset	Reset states of FMCW waveform object
step	Samples of FMCW waveform

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

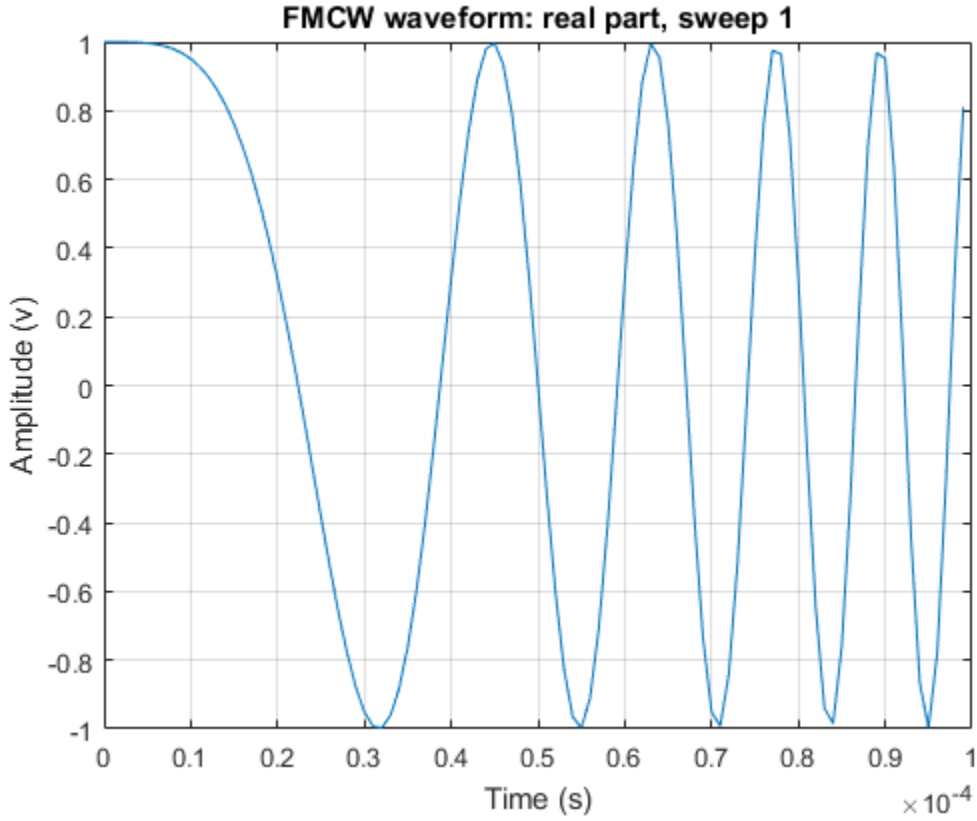
Examples

Plot FMCW Waveform

Create and plot an upsweep FMCW waveform.

```
waveform = phased.FMCWWaveform('SweepBandwidth',100.0e3,...
```

```
    'OutputFormat','Sweeps','NumSweeps',2);
plot(waveform)
```

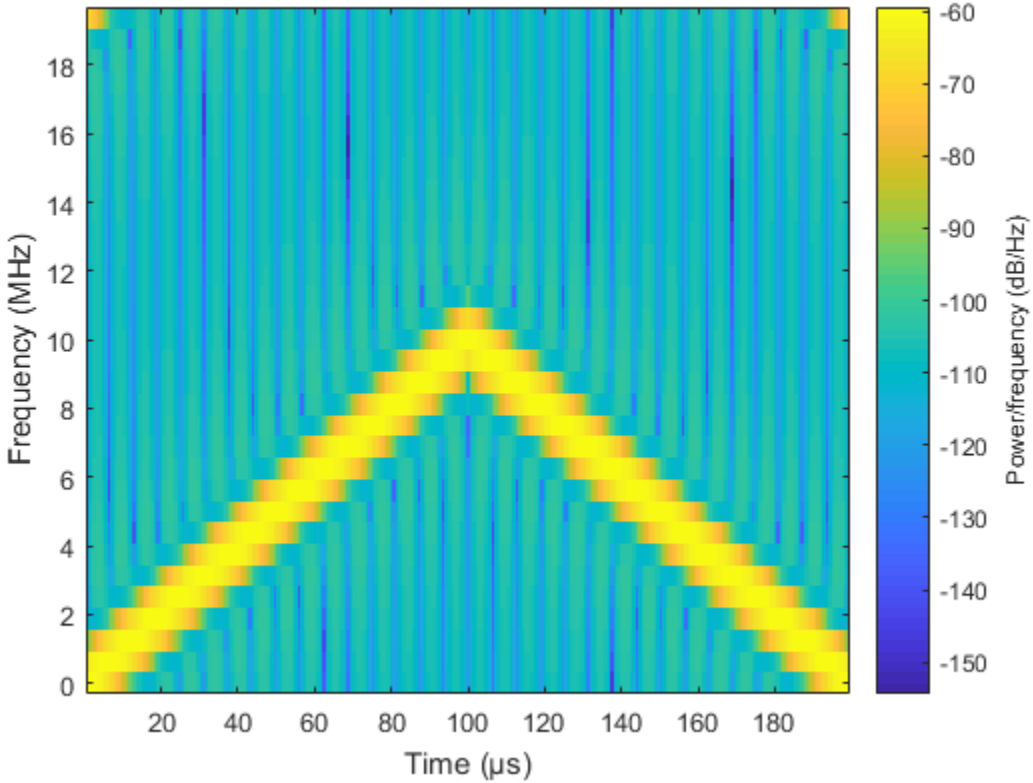


Spectrogram of Triangle Sweep FMCW Waveform

Generate samples of a triangle sweep FMCW Waveform. Then, plot the spectrogram of the sweep. The sweep has a 10 MHz bandwidth.

```
sFMCW = phased.FMCWWaveform('SweepBandwidth',10.0e6,...
   'SampleRate',20.0e6,'SweepDirection','Triangle',...
   'NumSweeps',2);
sig = step(sFMCW);
windowlength = 32;
noverlap = 16;
```

```
nfft = 32;
spectrogram(sig,windowlength,noverlap,nfft,sFMCW.SampleRate,'yaxis')
```

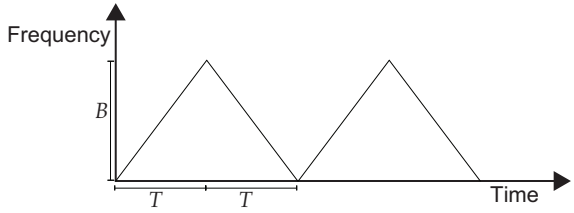


- Automotive Adaptive Cruise Control Using FMCW Technology

Definitions

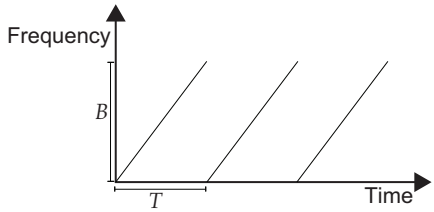
Triangle Sweep

In each period of a triangle sweep, the waveform sweeps up with a slope of B/T and then down with a slope of $-B/T$. B is the sweep bandwidth, and T is the sweep time. The sweep period is $2T$.



Upsweep

In each period of an upsweep, the waveform sweeps with a slope of B/T. B is the sweep bandwidth, and T is the sweep time.



Downsweep

In each period of a downsweep, the waveform sweeps with a slope of $-B/T$. B is the sweep bandwidth, and T is the sweep time.

plot

System object: phased.FMCWWaveform
Package: phased

Plot FMCW waveform

Syntax

```
plot(Hwav)
plot(Hwav,Name,Value)
plot(Hwav,Name,Value,LineSpec)
h = plot( ___ )
```

Description

`plot(Hwav)` plots the real part of the waveform specified by `Hwav`.

`plot(Hwav,Name,Value)` plots the waveform with additional options specified by one or more `Name,Value` pair arguments.

`plot(Hwav,Name,Value,LineSpec)` specifies the same line color, line style, or marker options as are available in the MATLAB `plot` function.

`h = plot( ___ )` returns the line handle in the figure.

Input Arguments

`Hwav`

Waveform object. This variable must be a scalar that represents a single waveform object.

`LineSpec`

Character vector to specifies the same line color, style, or marker options as are available in the MATLAB `plot` function. If you specify a `PlotType` value of `'complex'`, then `LineSpec` applies to both the real and imaginary subplots.

Default: `'b'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'PlotType'`

Specifies whether the function plots the real part, imaginary part, or both parts of the waveform. Valid values are `'real'`, `'imag'`, and `'complex'`.

Default: `'real'`

`'SweepIdx'`

Index of the sweep to plot. This value must be a positive integer scalar.

Default: 1

Output Arguments

`h`

Handle to the line or lines in the figure. For a `PlotType` value of `'complex'`, `h` is a column vector. The first and second elements of this vector are the handles to the lines in the real and imaginary subplots, respectively.

Examples

Plot FMCW Waveform

Create and plot an upsweep FMCW waveform.

```
waveform = phased.FMCWWaveform('SweepBandwidth',100.0e3,...
    'OutputFormat','Sweeps','NumSweeps',2);
plot(waveform)
```

reset

System object: phased.FMCWWaveform
Package: phased

Reset states of FMCW waveform object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `FMCWWaveform` object, `H`. Afterward, the next call to `step` restarts the sweep of the waveform.

step

System object: phased.FMCWWaveform
Package: phased

Samples of FMCW waveform

Syntax

```
Y = step(H)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations. When the only argument to the `step` method is the System object itself, replace `y = step(obj)` by `y = obj()`.

`Y = step(H)` returns samples of the FMCW waveform in a column vector, `Y`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`H`

FMCW waveform object.

Output Arguments

Y

Column vector containing the waveform samples.

If `H.OutputFormat` is `'Samples'`, `Y` consists of `H.NumSamples` samples.

If `H.OutputFormat` is `'Sweeps'`, `Y` consists of `H.NumSweeps` sweeps. Also, if `H.SweepDirection` is `'Triangle'`, each sweep is half a period.

Examples

Spectrogram of Triangle Sweep FMCW Waveform

Generate samples of a triangle sweep FMCW Waveform. Then, plot the spectrogram of the sweep. The sweep has a 10 MHz bandwidth.

```
sFMCW = phased.FMCWWaveform('SweepBandwidth',10.0e6,...
   'SampleRate',20.0e6,'SweepDirection','Triangle',...
   'NumSweeps',2);
sig = step(sFMCW);
windowlength = 32;
noverlap = 16;
nfft = 32;
spectrogram(sig,windowlength,noverlap,nfft,sFMCW.SampleRate,'yaxis')

phased.FreeSpace System object

Package: phased

Free space environment

Description

The `phased.FreeSpace` System object models narrowband signal propagation from one point to another in a free-space environment. The object applies range-dependent time delay, gain and phase shift to the input signal. The object accounts for doppler shift when either the source or destination is moving. A free-space environment is a boundaryless medium with a speed of signal propagation independent of position and direction. The signal propagates along a straight line from source to destination. For example, you can use this object to model the propagation of a signal from a radar to a target and back to the radar.

For non-polarized signals, the `FreeSpace` System object lets you propagate signals from a single point to multiple points or from multiple points to a single point. Multiple-point to multiple-point propagation is not supported.

To compute the propagated signal in free space:

1. Define and set up your free space environment. See "Construction" on page 1-580.
2. Call step to propagate the signal through a free space environment according to the properties of `phased.FreeSpace`. The behavior of `step` is specific to each object in the toolbox.

When propagating a round trip signal in free-space, you can either use one `FreeSpace` System object to compute the two-way propagation delay or two separate `FreeSpace` System objects to compute one-way propagation delays in each direction. Due to filter distortion, the total round trip delay when you employ two-way propagation can differ from the delay when you use two one-way `phased.FreeSpace` System objects. It is more accurate to use a single two-way `phased.FreeSpace` System object. This option is set by the `TwoWayPropagation` property.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were

a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.FreeSpace` creates a free space environment System object, `H`.

`H = phased.FreeSpace(Name,Value)` creates a free space environment object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`PropagationSpeed`

Signal propagation speed

Specify signal wave propagation speed in free space as a real positive scalar. Units are meters per second.

Default: Speed of light

`OperatingFrequency`

Signal carrier frequency

A scalar containing the carrier frequency of the narrowband signal. Units are hertz.

Default: `3e8`

`TwoWayPropagation`

Perform two-way propagation

Set this property to `true` to perform round-trip propagation between the origin and destination that you specify in the `step` command. Set this property to `false` to perform one-way propagation from the origin to the destination.

Default: `false`

SampleRate

Sample rate

A scalar containing the sample rate. Units of sample rate are hertz. The algorithm uses this value to determine the propagation delay in number of samples.

Default: `1e6`

MaximumDistanceSource

Source of maximum distance value

Source of maximum distance value, specified as `'Auto'` or `'Property'`. This choice selects how the maximum one-way propagation distance is determined. The maximum one-way propagation distance is used to allocate sufficient memory for delay computation. When you set this property to `'Auto`, the System object automatically allocates memory. When you set this property to `'Property'`, you specify the maximum one-way propagation distance using the value of the `MaximumDistance` property.

Default: `'Auto'`

MaximumDistance

Maximum one-way propagation distance

Maximum one-way propagation distance, specified as a real-valued positive scalar. Units are meters. This property applies when you set the `MaximumDistanceSource` property to `'Property'`. Any signal that propagates more than the maximum one-way distance is ignored. The maximum distance should be greater than or equal to the largest position-to-position distance.

Default: `10000`

MaximumNumInputSamplesSource

Source of maximum number of samples

The source of the maximum number of samples of the input signal, specified as `'Auto'` or `'Property'`. When you set this property to `'Auto'`, the propagation model automatically allocates enough memory to buffer the input signal. When you set this property to `'Property'`, you specify the maximum number of samples in the input

signal using the `MaximumNumInputSamples` property. Any input signal longer than that value is truncated.

This property applies when you set the `MaximumDistanceSource` property to `'Property'`.

When you use propagation models in MATLAB Function Block in Simulink® with variable-size signals, you must set the `MaximumNumInputSamples` parameter to `'Property'` and set the `MaximumNumInputSamples` parameter accordingly.

Default: `'Auto'`

`MaximumNumInputSamples`

Maximum number of input signal samples

Maximum number of samples in input signal, specified as a positive integer. This property limits the size of the input signal. Any input signal longer than this value is truncated. The input signal is the first argument to the `step` method. The number of samples is the number of rows in the input. This property applies only when you set the `MaximumNumInputSamplesSource` property to `'Property'`.

Default: `100`

Methods

reset	Reset internal states of propagation channel
step	Propagate signal from one location to another

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Signal Propagation from Stationary Radar to Stationary Target

Calculate the amplitude of a signal propagating in free-space from a radar at (1000,0,0) to a target at (300,200,50). Assume both the radar and the target are stationary. The sample rate is 8000 Hz while the operating frequency of the radar is 300 MHz. Transmit five samples of a unit amplitude signal. The signal propagation speed takes the default value of the speed of light. Examine the amplitude of the signal at the target.

```
fs = 8e3;
fop = 3e8;
henv = phased.FreeSpace('SampleRate',fs,...
    'OperatingFrequency',fop);
pos1 = [1000;0;0];
pos2 = [300;200;50];
vel1 = [0;0;0];
vel2 = [0;0;0];
```

Compute the received signal at the target.

```
x = ones(5,1);
y = step(henv,x,...
    pos1,...
    pos2,...
    vel1,...
    vel2);
disp(y)
```

```
   1.0e-03 *

   0.0126 - 0.1061i
   0.0129 - 0.1082i
   0.0129 - 0.1082i
   0.0129 - 0.1082i
   0.0129 - 0.1082i
```

The first sample is zero because the signal has not yet reached the target.

Manually compute the loss using the formula

$$L = (4\pi R/\lambda)^2$$

```
R = sqrt( (pos1-pos2)'*(pos1-pos2));
lambda = physconst('Lightspeed')/fop;
L = (4*pi*R/lambda)^2
```

```
L =

   8.4205e+07
```

Because the transmitted amplitude is unity, the square of the signal at the target equals the inverse of the loss.

```
disp(1/abs(y(2))^2)
```

```
   8.4205e+07
```

Signal Propagation from Moving Radar to Moving Target

Calculate the result of propagating a signal in free space from a radar at (1000,0,0) to a target at (300,200,50). Assume the radar moves at 10 m/s along the *x*-axis, while the target moves at 15 m/s along the *y*-axis. The sample rate is 8000 Hz while the operating frequency of the radar is 300 MHz. The signal propagation speed takes the default value of the speed of light. Transmit five samples of a unit amplitude signal and examine the amplitude of the signal at the target.

```
fs = 8000;
fop = 3e8;
sProp = phased.FreeSpace('SampleRate',fs,...
    'OperatingFrequency',fop);
pos1 = [1000;0;0];
pos2 = [300;200;50];
vel1 = [10;0;0];
vel2 = [0;15;0];
y = step(sProp,ones(5,1),...
    pos1,...
    pos2,...
    vel1,...
    vel2);
disp(y)
```

```
   1.0e-03 *

   0.0126 - 0.1061i
```

```
0.0117 - 0.1083i
0.0105 - 0.1085i
0.0094 - 0.1086i
0.0082 - 0.1087i
```

Because the transmitted amplitude is unity, the square of the signal at the target equals the inverse of the loss.

```
disp(1/abs(y(2))^2)
```

```
8.4206e+07
```

Definitions

Freespace Time Delay and Path Loss

When the origin and destination are stationary relative to each other, you can write the output signal of a free-space channel as $Y(t) = x(t-\tau)/L_{fsp}$. The quantity τ is the signal delay and L_{fsp} is the free-space path loss. The delay τ is given by R/c, where R is the propagation distance and c is the propagation speed. The free-space path loss is given by

$$L_{fsp} = \frac{(4\pi R)^2}{\lambda^2},$$

where λ is the signal wavelength.

This formula assumes that the target is in the far field of the transmitting element or array. In the near field, the free-space path loss formula is not valid and can result in a loss smaller than one, equivalent to a signal gain. Therefore, the loss is set to unity for range values, $R \le \lambda/4\pi$.

When the origin and destination have relative motion, the processing also introduces a Doppler frequency shift. The frequency shift is v/λ for one-way propagation and $2v/\lambda$ for two-way propagation. The quantity v is the relative speed of the destination with respect to the origin.

For more details on free space channel propagation, see [2].

Package: phased

Reset internal states of propagation channel

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `FreeSpace` object, `H`.

step

System object: phased.FreeSpace
Package: phased

Propagate signal from one location to another

Syntax

```
Y = step(SFS,F,origin_pos,dest_pos,origin_vel,dest_vel)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(SFS,F,origin_pos,dest_pos,origin_vel,dest_vel)` returns the resulting signal `Y` when the narrowband signal `F` propagates in free space from the position or positions specified in `origin_pos` to the position or positions specified in `dest_pos`. For non-polarized signals, either the `origin_pos` or `dest_pos` arguments can specify more than one point. Using both arguments to specify multiple points is not allowed. The velocity of the signal origin is specified in `origin_vel` and the velocity of the signal destination is specified in `dest_vel`. The dimensions of `origin_vel` and `dest_vel` must agree with the dimensions of `origin_pos` and `dest_pos`, respectively.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

SFS — Free-space propagator

System object

Free-space propagator, specified as a System object.

F — Narrowband signal

M-element complex-valued column vector, *M*-by-*N* complex-valued matrix or structure containing complex-valued fields.

Narrowband signal, specified as an *M*-element complex-valued column vector, *M*-by-*N* complex-valued matrix or structure containing complex-valued fields.

Polarization	Signal structure
Not enabled	The signal `X` can be a complex-valued 1-by-*M* column vector or complex-valued *M*-by-*N* matrix. The quantity *M* is the number of sample values of the signal and *N* is the number of signals to propagate. When you specify *N* signals, you need to specify *N* signal origins or *N* signal destinations. The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.
Enabled	The signal `X` is a MATLAB `struct` containing three matrix fields:`X.X`, `X.Y`, and `X.Z` representing the *x*, *y*, and *z* components of the polarized signals. The size of the first dimension of the matrix fields within the `struct` can vary to simulate a changing signal length such as a pulse waveform with variable pulse repetition frequency.

`origin_pos`

Origin of the signal or signals, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. Position units are meters. The quantity *N* is the number of signals arriving from *N* signal origins and matches the dimension specified in the signal `X`. If `origin_pos` is a column vector, it takes the form `[x; y; z]`. If `origin_pos` is a matrix, each column specifies a different signal origin and has the form `[x; y; z]`. `origin_pos` and `dest_pos` cannot both be specified as matrices — at least one must be a 3-by-1 column vector.

`dest_pos`

Destination of the signal or signals, specified as a 3-by-1 column vector or 3-by-*N* matrix. Position units are meters. The quantity *N* is the number of signals arriving at *N* signal destinations and matches the dimension specified in the signal `X`. If `dest_pos` is a column vector, it takes the form `[x; y; z]`. If `dest_pos` is a matrix, each column specifies a different destination and has the form `[x; y; z]`. `dest_pos` and `origin_pos` cannot both be specified as matrices — at least one must be a 3-by-1 column vector.

`origin_vel`

Velocity of signal origin, specified as a 3-by-1 column vector or 3-by-*N* matrix. Velocity units are meters/second. The dimensions of `origin_vel` must match the dimensions of `origin_pos`. If `origin_vel` is a column vector, it takes the form `[Vx; Vy; Vz]`. If `origin_vel` is a 3–by-*N* matrix, each column specifies a different origin velocity and has the form `[Vx; Vy; Vz]`.

`dest_vel`

Velocity of signal destinations, specified as a 3-by-1 column vector or 3–by-*N* matrix. Velocity units are meters/second. The dimensions of `dest_vel` must match the dimensions of `dest_pos`. If `dest_vel` is a column vector, it takes the form `[Vx; Vy; Vz]`. If `dest_vel` is a 3–by-*N* matrix, each column specifies a different destination velocity and has the form `[Vx; Vy; Vz]`.

Output Arguments

Y

Propagated signal, returned as a *M*-element complex-valued column vector, *M*-by-*N* complex-valued matrix or MATLAB structure containing complex-valued fields.

If `X` is a column vector or matrix, `Y` is also a column vector or matrix with the same dimensions.

If `X` is a `struct`, `Y` is also a `struct` with the same fields. Each field in `Y` contains the resulting signal of the corresponding field in `X`.

The output `Y` contains signal samples arriving at the signal destination within the current time frame. The current time frame is defined as the time spanned by the current input. Whenever it takes longer than the current time frame for the signal to propagate from the origin to the destination, the output contains no contribution from the input of the current time frame.

Examples

Signal Propagation from Stationary Radar to Stationary Target

Calculate the amplitude of a signal propagating in free-space from a radar at (1000,0,0) to a target at (300,200,50). Assume both the radar and the target are stationary. The sample rate is 8000 Hz while the operating frequency of the radar is 300 MHz. Transmit five samples of a unit amplitude signal. The signal propagation speed takes the default value of the speed of light. Examine the amplitude of the signal at the target.

```
fs = 8e3;
fop = 3e8;
henv = phased.FreeSpace('SampleRate',fs,...
    'OperatingFrequency',fop);
pos1 = [1000;0;0];
pos2 = [300;200;50];
vel1 = [0;0;0];
vel2 = [0;0;0];
```

Compute the received signal at the target.

```
x = ones(5,1);
```

```
y = step(henv,x,...
    pos1,...
    pos2,...
    vel1,...
    vel2);
disp(y)
```

```
   1.0e-03 *

   0.0126 - 0.1061i
   0.0129 - 0.1082i
   0.0129 - 0.1082i
   0.0129 - 0.1082i
   0.0129 - 0.1082i
```

The first sample is zero because the signal has not yet reached the target.

Manually compute the loss using the formula

$$L = (4\pi R/\lambda)^2$$

```
R = sqrt( (pos1-pos2)'*(pos1-pos2));
lambda = physconst('Lightspeed')/fop;
L = (4*pi*R/lambda)^2
```

```
L =

   8.4205e+07
```

Because the transmitted amplitude is unity, the square of the signal at the target equals the inverse of the loss.

```
disp(1/abs(y(2))^2)
```

```
   8.4205e+07
```

Signal Propagation from Moving Radar to Moving Target

Calculate the result of propagating a signal in free space from a radar at (1000,0,0) to a target at (300,200,50). Assume the radar moves at 10 m/s along the *x*-axis, while the

target moves at 15 m/s along the *y*-axis. The sample rate is 8000 Hz while the operating frequency of the radar is 300 MHz. The signal propagation speed takes the default value of the speed of light. Transmit five samples of a unit amplitude signal and examine the amplitude of the signal at the target.

```
fs = 8000;
fop = 3e8;
sProp = phased.FreeSpace('SampleRate',fs,...
    'OperatingFrequency',fop);
pos1 = [1000;0;0];
pos2 = [300;200;50];
vel1 = [10;0;0];
vel2 = [0;15;0];
y = step(sProp,ones(5,1),...
    pos1,...
    pos2,...
    vel1,...
    vel2);
disp(y)
```

```
   1.0e-03 *

   0.0126 - 0.1061i
   0.0117 - 0.1083i
   0.0105 - 0.1085i
   0.0094 - 0.1086i
   0.0082 - 0.1087i
```

Because the transmitted amplitude is unity, the square of the signal at the target equals the inverse of the loss.

```
disp(1/abs(y(2))^2)
```

```
   8.4206e+07
```

Propagation of Polarized Field from Source to Target

Create a uniform linear array (ULA) consisting of four short-dipole antenna elements that support polarization. Set the orientation of each dipole to the z-direction. Set the operating frequency to 300 MHz and the element spacing of the array to 0.4 meters. While the antenna element supports polarization, you must explicitly enable polarization in the Radiator System object.

Create the short-dipole antenna element, ULA array, and radiator System objects. Set the `CombineRadiatedSignals` property to `true` to coherently combine the radiated signals from all antennas and the `EnablePolarization` property to true to process polarized waves.

```
freq = 300e6;
nsensors = 4;
c = physconst('LightSpeed');
sAnt = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 900e6],...
    'AxisDirection','Z');
sArray = phased.ULA('Element',sAnt,...
    'NumElements',nsensors,...
    'ElementSpacing',0.4);
sRad = phased.Radiator('Sensor',sArray,...
    'PropagationSpeed',c,...
    'OperatingFrequency',freq,...
    'CombineRadiatedSignals',true,...
    'EnablePolarization',true,...
    'WeightsInputPort',true);
```

Create a signal to be radiated. In this case, the signal consists of one cycle of a 4 kHz sinusoid. Set the signal amplitude to unity. Set the sampling frequency to 8 kHz. Choose a radiating angles of 0 degrees azimuth and 20 degrees elevation. polarization, you must set a local axes - in this case chosen to coincide with the global axes. Set uniform weights on the elements of the array.

```
fsig = 4000;
fs = 8000;
A = 1;
t = [0:0.01:2]/fs;
signal = A*sin(2*pi*fsig*t');
radiatingAngles = [0;20];
laxes = ones(3,3);
y = step(sRad,signal,radiatingAngles,laxes,[1,1,1,1].');
disp(y)
```

```
    X: [201×1 double]
    Y: [201×1 double]
    Z: [201×1 double]
```

The radiated signal is a `struct` containing the polarized field.

Use a `FreeSpace` System object to propagate the field from the origin to the destination.

```
sFree = phased.FreeSpace('PropagationSpeed',c,...
    'OperatingFrequency',freq,...
    'TwoWayPropagation',false,...
    'SampleRate',fs);
```

Set the signal origin, signal origin velocity, signal destination, and signal destination velocity.

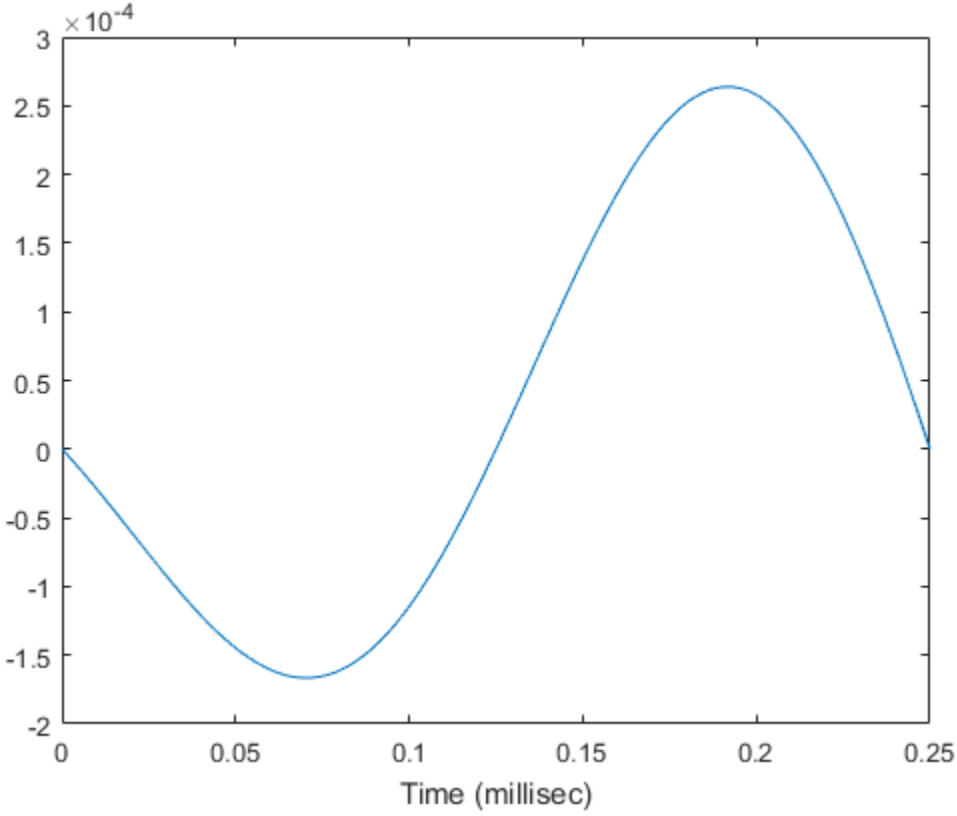
```
origin_pos = [0; 0; 0];
dest_pos = [500; 200; 50];
origin_vel = [10; 0; 0];
dest_vel = [0; 15; 0];
```

Call the FreeSpace object `step` method to propagate the signals.

```
yprop = step(sFree,y,origin_pos,dest_pos,...
    origin_vel,dest_vel);
```

Plot the x-component of the propagated signals.

```
figure
plot(1000*t,real(yprop.X))
xlabel('Time (millisec)')
```



Propagate Signal to Multiple Destinations

Create a FreeSpace System object to propagate a signal from one point to multiple points in space. Start by defining a signal origin and three destination points, all at different ranges.

Compute the propagation direction angles from the source to the destination locations. The source and destination are stationary.

```
pos1 = [0,0,0]';
vel1 = [0,0,0]';
pos2 = [[700;700;100],[1400;1400;200],2*[2100;2100;400]];
vel2 = zeros(size(pos2));
[rngs,radiatingAngles] = rangeangle(pos2,pos1);
```

Create the cosine antenna element, ULA array, and Radiator System objects.

```
fs = 8000;
freq = 300e6;
nsensors = 4;
sAnt = phased.CosineAntennaElement;
sArray = phased.ULA('Element',sAnt,'NumElements',nsensors);
sRad = phased.Radiator('Sensor',sArray,...
    'OperatingFrequency',freq,...
    'CombineRadiatedSignals',true,'WeightsInputPort',true);
```

Create a signal to be one cycle of a sinusoid of amplitude one and having a frequency of 4 kHz.

```
fsig = 4000;
t = [0:0.01:2]'/fs;
signal = sin(2*pi*fsig*t);
```

Radiate the signals in the destination directions. Apply a uniform weighting to the array.

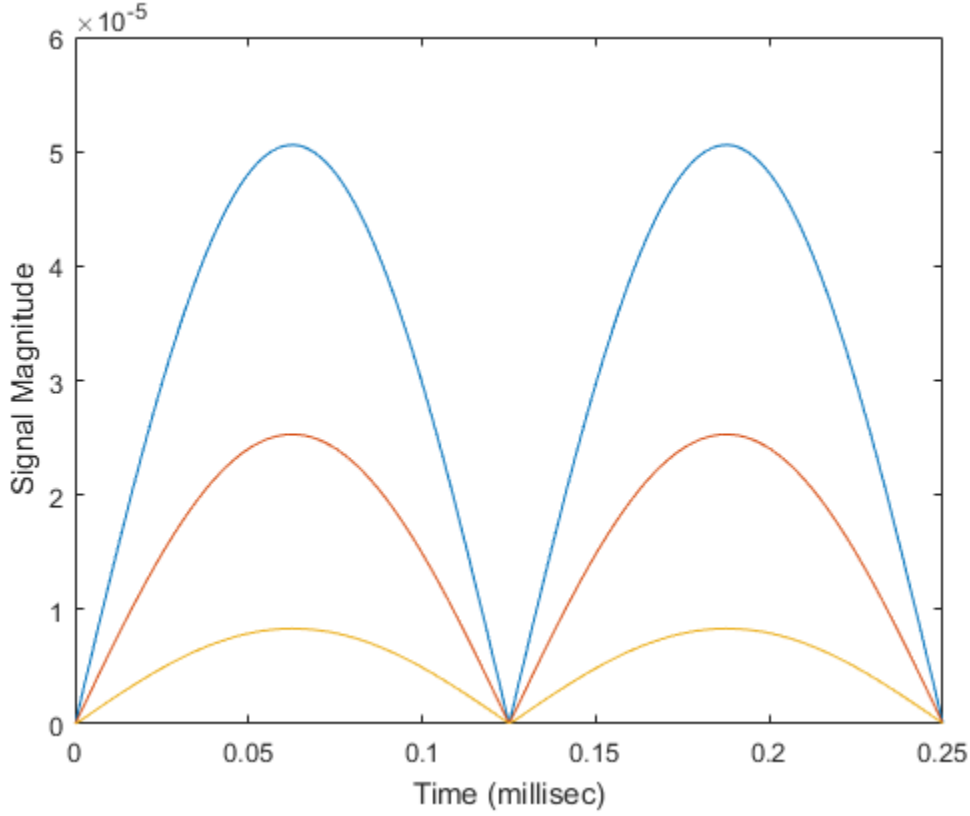
```
y = step(sRad,signal,radiatingAngles,[1,1,1,1].');
```

Propagate the signals to the destination points.

```
sFSp = phased.FreeSpace('OperatingFrequency',freq,'SampleRate',fs);
yprop = step(sFSp,y,pos1,pos2,vel1,vel2);
```

Plot the propagated signal magnitudes for each range.

```
figure
plot(1000*t,abs(yprop(:,1)),1000*t,abs(yprop(:,2)),1000*t,abs(yprop(:,3)))
ylabel('Signal Magnitude')
xlabel('Time (millisec)')
```



Algorithms

When the origin and destination are stationary relative to each other, you can write the output signal of a free-space channel as $Y(t) = x(t-\tau)/L_{fsp}$. The quantity τ is the signal delay and L_{fsp} is the free-space path loss. The delay τ is given by R/c, where R is the propagation distance and c is the propagation speed. The free-space path loss is given by

$$L_{fsp} = \frac{(4\pi R)^2}{\lambda^2},$$

where λ is the signal wavelength.

This formula assumes that the target is in the far field of the transmitting element or array. In the near field, the free-space path loss formula is not valid and can result in a loss smaller than one, equivalent to a signal gain. Therefore, the loss is set to unity for range values, $R \le \lambda/4\pi$.

When the origin and destination have relative motion, the processing also introduces a Doppler frequency shift. The frequency shift is v/λ for one-way propagation and $2v/\lambda$ for two-way propagation. The quantity v is the relative speed of the destination with respect to the origin.

For further details, see [2].

phased.TwoRayChannel.step

phased.FrostBeamformer System object

Package: phased

Frost beamformer

Description

The `phased.FrostBeamformer` object implements a Frost beamformer. A Frost beamformer consists of a time-domain MVDR beamformer combined with a bank of FIR filters. The beamformer steers the beam towards a given direction while the FIR filters preserve the input signal power.

To compute the beamformed signal:

1. Define and set up a Frost beamformer. See "Construction" on page 1-600.
2. Call step to perform the beamforming operation according to the properties of `phased.FrostBeamformer`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.FrostBeamformer` creates a Frost beamformer System object, `H`. The object performs Frost beamforming on the received signal.

`H = phased.FrostBeamformer(Name,Value)` creates a Frost beamformer object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`SensorArray`

Handle to sensor array

Specify the sensor array as a handle. The sensor array must be an array object in the `phased` package. The array cannot contain subarrays.

Default: phased.ULA with default property values

`PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

Default: Speed of light

`SampleRate`

Signal sampling rate

Specify the signal sampling rate (in hertz) as a positive scalar.

Default: `1e6`

`FilterLength`

FIR filter length

Specify the length of FIR filter behind each sensor element in the array as a positive integer.

Default: `2`

`DiagonalLoadingFactor`

Diagonal loading factor

Specify the diagonal loading factor as a positive scalar. Diagonal loading is a technique used to achieve robust beamforming performance, especially when the sample support is small. This property is tunable.

Default: `0`

`TrainingInputPort`

Add input to specify training data

To specify additional training data, set this property to `true` and use the corresponding input argument when you invoke step. To use the input signal as the training data, set this property to `false`.

Default: `false`

`DirectionSource`

Source of beamforming direction

Specify whether the beamforming direction comes from the `Direction` property of this object or from an input argument in step. Values of this property are:

`'Property'`	The `Direction` property of this object specifies the beamforming direction.
`'Input port'`	An input argument in each invocation of `step` specifies the beamforming direction.

Default: `'Property'`

`Direction`

Beamforming direction

Specify the beamforming direction of the beamformer as a column vector of length 2. The direction is specified in the format of `[AzimuthAngle; ElevationAngle]` (in degrees). The azimuth angle should be between –180 and 180. The elevation angle should be between –90 and 90. This property applies when you set the `DirectionSource` property to `'Property'`.

Default: `[0;0]`

`WeightsOutputPort`

Output beamforming weights

To obtain the weights used in the beamformer, set this property to `true` and use the corresponding output argument when invoking step. If you do not want to obtain the weights, set this property to `false`.

Default: `false`

Methods

step	Perform Frost beamforming

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Apply Frost Beamforming to ULA

Apply Frost beamforming to an 11-element acoustic ULA array. The incident angle of the incoming signal is -50 degrees in azimuth and 30 degrees in elevation. The speed of sound in air is assumed to be 340 m/sec. The signal has added gaussian white noise.

Simulate the signal.

```
array = phased.ULA('NumElements',11,'ElementSpacing',0.04);
array.Element.FrequencyRange = [20 20000];
fs = 8e3;
t = 0:1/fs:0.3;
x = chirp(t,0,1,500);
c = 340;
collector = phased.WidebandCollector('Sensor',array,...
```

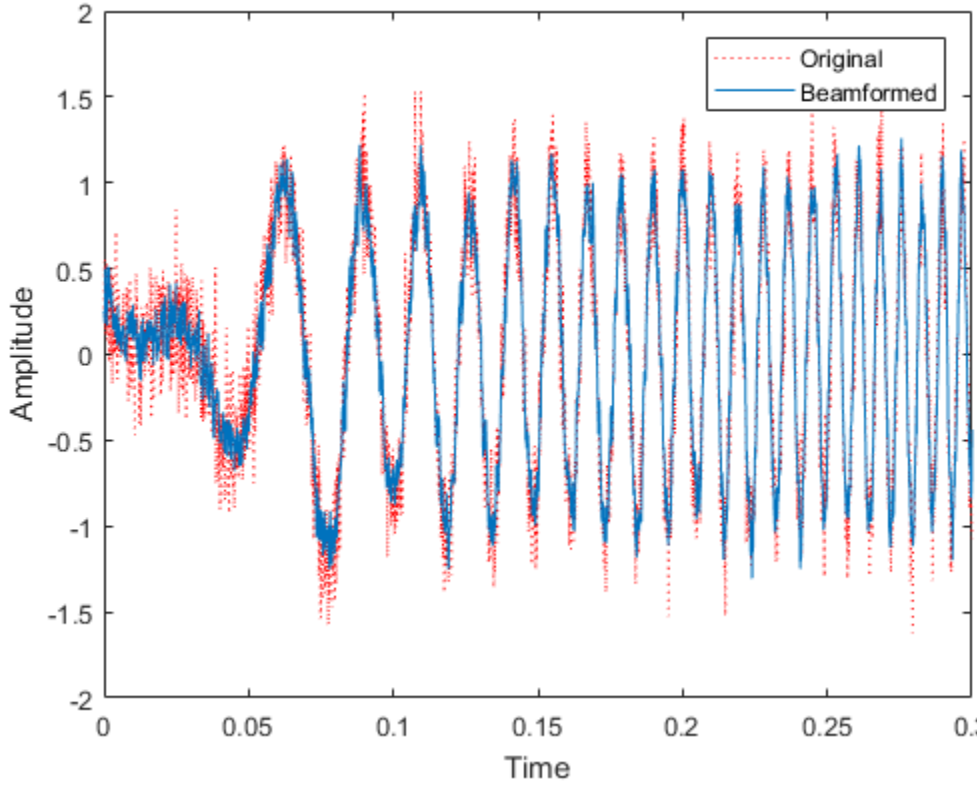
```
    'PropagationSpeed',c,'SampleRate',fs,...
    'ModulatedInput',false,'NumSubbands',8192);
incidentAngle = [-50;30];
x = collector(x.',incidentAngle);
noise = 0.2*randn(size(x));
rx = x + noise;
```

Beamform the signal.

```
beamformer = phased.FrostBeamformer('SensorArray',array,...
    'PropagationSpeed',c,'SampleRate',fs,...
    'Direction',incidentAngle,'FilterLength',5);
y = beamformer(rx);
```

Plot the beamformed output.

```
plot(t,rx(:,6),'r:',t,y)
xlabel('Time')
ylabel('Amplitude')
legend('Original','Beamformed')
```



Algorithms

`phased.FrostBeamformer` uses a beamforming algorithm proposed by Frost. It can be considered the time-domain counterpart of the minimum variance distortionless response (MVDR) beamformer. The algorithm does the following:

1. Steers the array to the beamforming direction.
2. Applies an FIR filter to the output of each sensor to achieve the distortionless response constraint. The filter is specific to each sensor.

For further details, see [1].

Introduced in R2012a

step

System object: phased.FrostBeamformer
Package: phased

Perform Frost beamforming

Syntax

```
Y = step(H,X)
Y = step(H,X,XT)
Y = step(H,X,ANG)
Y = step(H,X,XT,ANG)
[Y,W] = step( ___ )
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` performs Frost beamforming on the input, `X`, and returns the beamformed output in `Y`.

`Y = step(H,X,XT)` uses `XT` as the training samples to calculate the beamforming weights. This syntax is available when you set the `TrainingInputPort` property to `true`.

`Y = step(H,X,ANG)` uses `ANG` as the beamforming direction. This syntax is available when you set the `DirectionSource` property to `'Input port'`.

`Y = step(H,X,XT,ANG)` combines all input arguments. This syntax is available when you set the `TrainingInputPort` property to `true` and set the `DirectionSource` property to `'Input port'`.

`[Y,W] = step( ___ )` returns the beamforming weights, `W`. This syntax is available when you set the `WeightsOutputPort` property to `true`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`H`

Beamformer object.

`X`

Input signal, specified as an *M*-by-*N* matrix. *M* must be larger than the FIR filter length specified in the `FilterLength` property. *N* is the number of elements in the sensor array.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

`XT`

Training samples, specified as an *M*-by-*N* matrix. *M* and *N* have the same dimensions as `X`.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

`ANG`

Beamforming directions, specified as a length-2 column vector. The vector has the form `[AzimuthAngle; ElevationAngle]`, in degrees. The azimuth angle must be between –180 and 180 degrees, and the elevation angle must be between –90 and 90 degrees.

Output Arguments

Y

Beamformed output. Y is a column vector of length *M*, where *M* is the number of rows in X.

W

Beamforming weights. W is a column vector of length *L*, where *L* is the degrees of freedom of the beamformer. For a Frost beamformer, H, *L* is given by the product of the number of elements in the array and the FIR filter length.

Examples

Apply Frost Beamforming to ULA

Apply Frost beamforming to an 11-element acoustic ULA array. The incident angle of the incoming signal is -50 degrees in azimuth and 30 degrees in elevation. The speed of sound in air is assumed to be 340 m/sec. The signal has added gaussian white noise.

Simulate the signal.

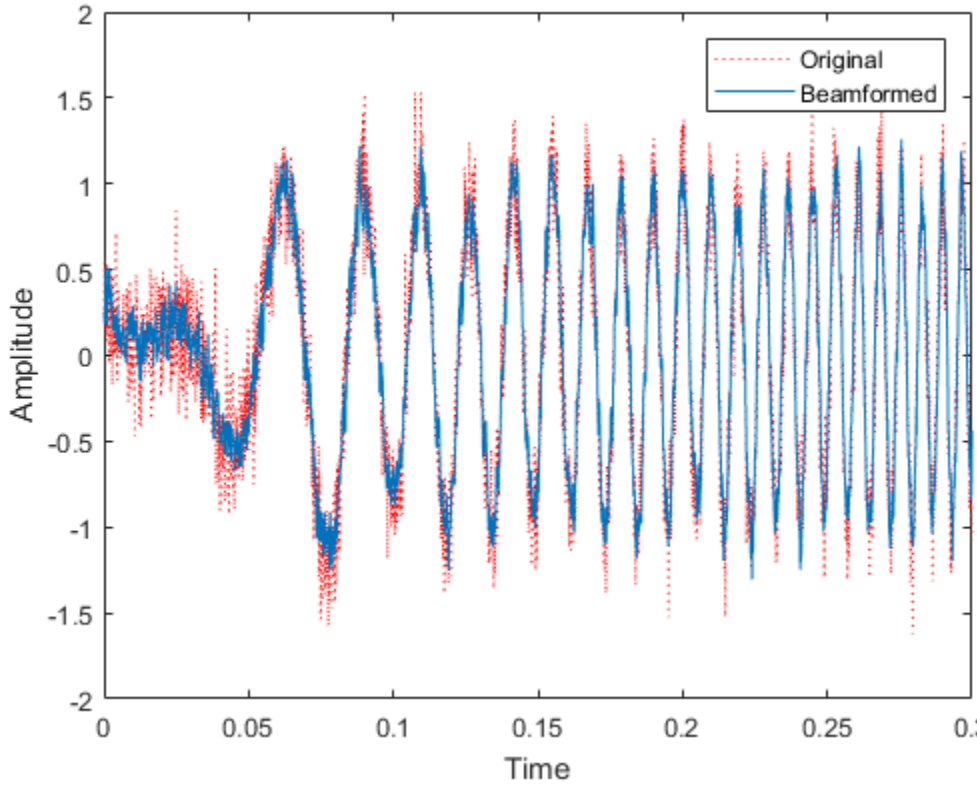
```
array = phased.ULA('NumElements',11,'ElementSpacing',0.04);
array.Element.FrequencyRange = [20 20000];
fs = 8e3;
t = 0:1/fs:0.3;
x = chirp(t,0,1,500);
c = 340;
collector = phased.WidebandCollector('Sensor',array,...
    'PropagationSpeed',c,'SampleRate',fs,...
    'ModulatedInput',false,'NumSubbands',8192);
incidentAngle = [-50;30];
x = collector(x.',incidentAngle);
noise = 0.2*randn(size(x));
rx = x + noise;
```

Beamform the signal.

```
beamformer = phased.FrostBeamformer('SensorArray',array,...
    'PropagationSpeed',c,'SampleRate',fs,...
    'Direction',incidentAngle,'FilterLength',5);
y = beamformer(rx);
```

Plot the beamformed output.

```
plot(t,rx(:,6),'r:',t,y)
xlabel('Time')
ylabel('Amplitude')
legend('Original','Beamformed')
```



Algorithms

`phased.FrostBeamformer` uses a beamforming algorithm proposed by Frost. It can be considered the time-domain counterpart of the minimum variance distortionless response (MVDR) beamformer. The algorithm does the following:

1. Steers the array to the beamforming direction.
2. Applies an FIR filter to the output of each sensor to achieve the distortionless response constraint. The filter is specific to each sensor.

For further details, see [1].

phased.gpu.ConstantGammaClutter System object

Package: phased.gpu

Constant gamma clutter simulation on GPU

Description

The `phased.gpu.ConstantGammaClutter` object simulates clutter, performing the computations on a GPU.

Note: To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see "GPU Computing" (Parallel Computing Toolbox) in the Parallel Computing Toolbox documentation.

To compute the clutter return:

1. Define and set up your clutter simulator. See "Construction" on page 1-613.
2. Call step to simulate the clutter return for your system according to the properties of `phased.gpu.ConstantGammaClutter`. The behavior of `step` is specific to each object in the toolbox.

The clutter simulation that `ConstantGammaClutter` provides is based on these assumptions:

- The radar system is monostatic.
- The propagation is in free space.
- The terrain is homogeneous.
- The clutter patch is stationary during the coherence time. *Coherence time* indicates how frequently the software changes the set of random numbers in the clutter simulation.
- The signal is narrowband. Thus, the spatial response can be approximated by a phase shift. Similarly, the Doppler shift can be approximated by a phase shift.
- The radar system maintains a constant height during simulation.

- The radar system maintains a constant speed during simulation.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.gpu.ConstantGammaClutter` creates a constant gamma clutter simulation System object, `H`. This object simulates the clutter return of a monostatic radar system using the constant gamma model.

`H = phased.gpu.ConstantGammaClutter(Name,Value)` creates a constant gamma clutter simulation object, `H`, with additional options specified by one or more `Name,Value` pair arguments. `Name` is a property name, and `Value` is the corresponding value. `Name` must appear inside single quotes (`''`). You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

Properties

`Sensor`

Handle of sensor

Specify the sensor as an antenna element object or as an array object whose `Element` property value is an antenna element object. If the sensor is an array, it can contain subarrays.

Default: phased.ULA with default property values

`PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

Default: Speed of light

`OperatingFrequency`

System operating frequency

Specify the operating frequency of the system in hertz as a positive scalar. The default value corresponds to 300 MHz.

Default: `3e8`

`SampleRate`

Sample rate

Specify the sample rate, in hertz, as a positive scalar. The default value corresponds to 1 MHz.

Default: `1e6`

`PRF`

Pulse repetition frequency

Specify the pulse repetition frequency in hertz as a positive scalar or a row vector. The default value of this property corresponds to 10 kHz. When `PRF` is a vector, it represents a staggered PRF. In this case, the output pulses use elements in the vector as their PRFs, one after another, in a cycle.

Default: `1e4`

`Gamma`

Terrain gamma value

Specify the γ value used in the constant γ clutter model, as a scalar in decibels. The γ value depends on both terrain type and the operating frequency.

Default: `0`

`EarthModel`

Earth model

Specify the earth model used in clutter simulation as one of | 'Flat' | 'Curved' |. When you set this property to 'Flat', the earth is assumed to be a flat plane. When you set this property to 'Curved', the earth is assumed to be a sphere.

Default: 'Flat'

PlatformHeight

Radar platform height from surface

Specify the radar platform height (in meters) measured upward from the surface as a nonnegative scalar.

Default: 300

PlatformSpeed

Radar platform speed

Specify the radar platform's speed as a nonnegative scalar in meters per second.

Default: 300

PlatformDirection

Direction of radar platform motion

Specify the direction of radar platform motion as a 2-by-1 vector in the form [AzimuthAngle; ElevationAngle] in degrees. The default value of this property indicates that the platform moves perpendicular to the radar antenna array's broadside.

Both azimuth and elevation angle are measured in the local coordinate system of the radar antenna or antenna array. Azimuth angle must be between –180 and 180 degrees. Elevation angle must be between –90 and 90 degrees.

Default: [90;0]

BroadsideDepressionAngle

Depression angle of array broadside

Specify the depression angle in degrees of the broadside of the radar antenna array. This value is a scalar. The broadside is defined as zero degrees azimuth and zero degrees elevation. The depression angle is measured downward from horizontal.

Default: 0

`MaximumRange`

Maximum range for clutter simulation

Specify the maximum range in meters for the clutter simulation as a positive scalar. The maximum range must be greater than the value specified in the `PlatformHeight` property.

Default: 5000

`AzimuthCoverage`

Azimuth coverage for clutter simulation

Specify the azimuth coverage in degrees as a positive scalar. The clutter simulation covers a region having the specified azimuth span, symmetric to 0 degrees azimuth. Typically, all clutter patches have their azimuth centers within the region, but the `PatchAzimuthWidth` value can cause some patches to extend beyond the region.

Default: 60

`PatchAzimuthWidth`

Azimuth span of each clutter patch

Specify the azimuth span of each clutter patch in degrees as a positive scalar.

Default: 1

`TransmitSignalInputPort`

Add input to specify transmit signal

Set this property to `true` to add input to specify the transmit signal in the `step` syntax. Set this property to `false` omit the transmit signal in the `step` syntax. The `false` option is less computationally expensive; to use this option, you must also specify the `TransmitERP` property.

Default: `false`

`TransmitERP`

Effective transmitted power

Specify the transmitted effective radiated power (ERP) of the radar system in watts as a positive scalar. This property applies only when you set the `TransmitSignalInputPort` property to `false`.

Default: `5000`

`CoherenceTime`

Clutter coherence time

Specify the coherence time in seconds for the clutter simulation as a positive scalar. After the coherence time elapses, the `step` method updates the random numbers it uses for the clutter simulation at the next pulse. A value of `inf` means the random numbers are never updated.

Default: `inf`

`OutputFormat`

Output signal format

Specify the format of the output signal as one of `| 'Pulses' | 'Samples' |`. When you set the `OutputFormat` property to `'Pulses'`, the output of the `step` method is in the form of multiple pulses. In this case, the number of pulses is the value of the `NumPulses` property.

When you set the `OutputFormat` property to `'Samples'`, the output of the `step` method is in the form of multiple samples. In this case, the number of samples is the value of the `NumSamples` property. In staggered PRF applications, you might find the `'Samples'` option more convenient because the `step` output always has the same matrix size.

Default: `'Pulses'`

`NumPulses`

Number of pulses in output

Specify the number of pulses in the output of the `step` method as a positive integer. This property applies only when you set the `OutputFormat` property to `'Pulses'`.

Default: 1

`NumSamples`

Number of samples in output

Specify the number of samples in the output of the `step` method as a positive integer. Typically, you use the number of samples in one pulse. This property applies only when you set the `OutputFormat` property to `'Samples'`.

Default: 100

`SeedSource`

Source of seed for random number generator

Specify how the object generates random numbers. Values of this property are:

`'Auto'`	Random numbers come from the global GPU random number stream. `'Auto'` is appropriate in a variety of situations. In particular, if you want to use a generator algorithm other than `mrg32k3a`, set `SeedSource` to `'Auto'`. Then, configure the global GPU random number stream to use the generator of your choice. You can configure the global GPU random number stream using `parallel.gpu.RandStream` and `parallel.gpu.RandStream.setGlobalStream`.
`'Property'`	Random numbers come from a private stream of random numbers. The stream uses the `mrg32k3a` generator algorithm, with a seed specified in the `Seed` property of this object. If you do not want clutter computations to affect the global GPU random number stream, set `SeedSource` to `'Property'`.

Default: `'Auto'`

`Seed`

Seed for random number generator

Specify the seed for the random number generator as a scalar integer between 0 and 2^{32}–1. This property applies when you set the `SeedSource` property to `'Property'`.

Default: `0`

Methods

reset	Reset random numbers and time count for clutter simulation
step	Simulate clutter using constant gamma model

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Clutter Simulation of System with Known Power

Simulate the clutter return from terrain with a gamma value of 0 dB. The effective transmitted power of the radar system is 5 kw.

Set up the characteristics of the radar system. This system has a 4-element uniform linear array (ULA). The sample rate is 1 MHz, and the PRF is 10 kHz. The propagation speed is 300,000 km/s, and the operating frequency is 300 MHz. The radar platform is flying 1 km above the ground with a path parallel to the ground along the array axis. The platform speed is 2000 m/s. The mainlobe has a depression angle of 30 degrees.

```
Nele = 4;
```

```
c = 3e8; fc = 3e8; lambda = c/fc;
ha = phased.ULA('NumElements',Nele,'ElementSpacing',lambda/2);

fs = 1e6; prf = 10e3;
height = 1000; direction = [90; 0];
speed = 2000; depang = 30;
```

Create the GPU clutter simulation object. The configuration assumes the earth is flat. The maximum clutter range of interest is 5 km, and the maximum azimuth coverage is +/– 60 degrees.

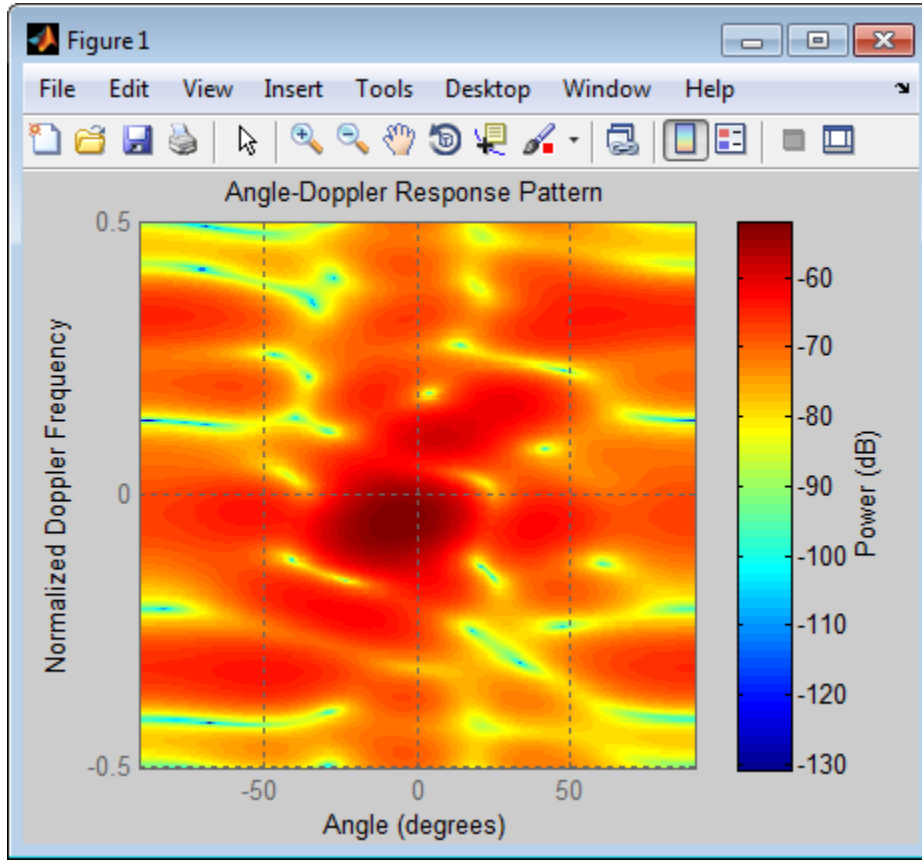
```
Rmax = 5000; Azcov = 120;
tergamma = 0; tpower = 5000;
hclutter = phased.gpu.ConstantGammaClutter('Sensor',ha,...
    'PropagationSpeed',c,'OperatingFrequency',fc,'PRF',prf,...
    'SampleRate',fs,'Gamma',tergamma,'EarthModel','Flat',...
    'TransmitERP',tpower,'PlatformHeight',height,...
    'PlatformSpeed',speed,'PlatformDirection',direction,...
    'BroadsideDepressionAngle',depang,'MaximumRange',Rmax,...
    'AzimuthCoverage',Azcov);
```

Simulate the clutter return for 10 pulses.

```
Nsamp = fs/prf; Npulse = 10;
csig = zeros(Nsamp,Nele,Npulse);
for m = 1:Npulse
    csig(:,:,m) = step(hclutter);
end
```

Plot the angle-Doppler response of the clutter at the 20th range bin.

```
hresp = phased.AngleDopplerResponse('SensorArray',ha,...
    'OperatingFrequency',fc,'PropagationSpeed',c,'PRF',prf);
plotResponse(hresp,shiftdim(csig(20,:,:)),...
    'NormalizeDoppler',true);
```



The results do not exactly match those achieved by using `phased.ConstantGammaClutter` instead of `phased.gpu.ConstantGammaClutter`. This discrepancy occurs because of differences between CPU and GPU computations.

Clutter Simulation Using Known Transmit Signal

Simulate the clutter return from terrain with a gamma value of 0 dB. The `step` syntax includes the transmit signal of the radar system as an input argument. In this case, you do not record the effective transmitted power of the signal in a property.

Set up the characteristics of the radar system. This system has a 4-element uniform linear array (ULA). The sample rate is 1 MHz, and the PRF is 10 kHz. The propagation speed is 300,000 km/s, and the operating frequency is 300 MHz. The radar platform is

flying 1 km above the ground with a path parallel to the ground along the array axis. The platform speed is 2000 m/s. The mainlobe has a depression angle of 30 degrees.

```
Nele = 4;
c = 3e8; fc = 3e8; lambda = c/fc;
ha = phased.ULA('NumElements',Nele,'ElementSpacing',lambda/2);

fs = 1e6; prf = 10e3;
height = 1000; direction = [90; 0];
speed = 2000; depang = 30;
```

Create the GPU clutter simulation object and configure it to take a transmit signal as an input argument to `step`. The configuration assumes the earth is flat. The maximum clutter range of interest is 5 km, and the maximum azimuth coverage is +/– 60 degrees.

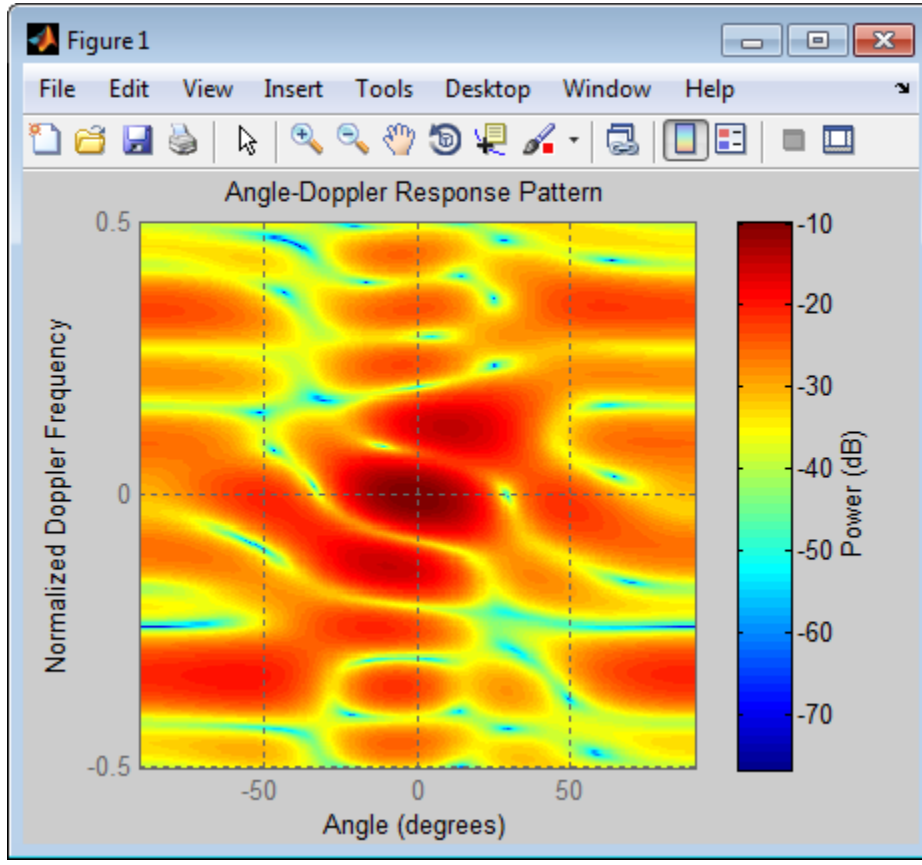
```
Rmax = 5000; Azcov = 120;
tergamma = 0;
hclutter = phased.gpu.ConstantGammaClutter('Sensor',ha,...
    'PropagationSpeed',c,'OperatingFrequency',fc,'PRF',prf,...
    'SampleRate',fs,'Gamma',tergamma,'EarthModel','Flat',...
    'TransmitSignalInputPort',true,'PlatformHeight',height,...
    'PlatformSpeed',speed,'PlatformDirection',direction,...
    'BroadsideDepressionAngle',depang,'MaximumRange',Rmax,...
    'AzimuthCoverage',Azcov);
```

Simulate the clutter return for 10 pulses. At each step, pass the transmit signal as an input argument. The software automatically computes the effective transmitted power of the signal. The transmit signal is a rectangular waveform with a pulse width of 2 μs.

```
tpower = 5000;
pw = 2e-6;
X = tpower*ones(floor(pw*fs),1);
Nsamp = fs/prf; Npulse = 10;
csig = zeros(Nsamp,Nele,Npulse);
for m = 1:Npulse
    csig(:,:,m) = step(hclutter,X);
end
```

Plot the angle-Doppler response of the clutter at the 20th range bin.

```
hresp = phased.AngleDopplerResponse('SensorArray',ha,...
    'OperatingFrequency',fc,'PropagationSpeed',c,'PRF',prf);
plotResponse(hresp,shiftdim(csig(20,:,:)),...
    'NormalizeDoppler',true);
```



The results do not exactly match those achieved by using `phased.ConstantGammaClutter` instead of `phased.gpu.ConstantGammaClutter`. This discrepancy occurs because of differences between CPU and GPU computations.

Random Number Comparison Between GPU and CPU

In most cases, it does not matter that the GPU and CPU use different random numbers. Sometimes, you may need to reproduce the same stream on both GPU and CPU. In such cases, you can set up the two global streams so they produce identical random numbers. Both GPU and CPU support the combined multiple recursive generator (`mrg32k3a`) with the `NormalTransform` parameter set to `'Inversion'`.

Define a seed value to use for the GPU stream and the CPU stream.

```
seed = 7151;
```

Create a CPU random number stream that uses the combined multiple recursive generator and the chosen seed value. Then, use this stream as the global stream for random number generation on the CPU.

```
stream_cpu = RandStream('CombRecursive','Seed',seed,...
   'NormalTransform','Inversion');
RandStream.setGlobalStream(stream_cpu);
```

Create a GPU random number stream that uses the combined multiple recursive generator and the same seed value. Then, use this stream as the global stream for random number generation on the GPU.

```
stream_gpu = parallel.gpu.RandStream('CombRecursive','Seed',seed);
parallel.gpu.RandStream.setGlobalStream(stream_gpu);
```

Generate clutter on both the CPU and the GPU, using the global stream on each platform.

```
h_cpu = phased.ConstantGammaClutter('SeedSource','Auto');
h_gpu = phased.gpu.ConstantGammaClutter('SeedSource','Auto');

y_cpu = step(h_cpu);
y_gpu = step(h_gpu);
```

Check that the element-wise differences between the CPU and GPU results are negligible.

```
maxdiff = max(max(abs(y_cpu - y_gpu)))
eps
```

```
maxdiff =

   2.9092e-18

ans =

   2.2204e-16
```

reset

System object: phased.gpu.ConstantGammaClutter
Package: phased.gpu

Reset random numbers and time count for clutter simulation

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `ConstantGammaClutter` object, `H`. This method resets the random number generator state if the `SeedSource` property is set to `'Property'`. This method resets the elapsed coherence time. Also, if the `PRF` property is a vector, the next call to `step` uses the first PRF value in the vector.

step

System object: phased.gpu.ConstantGammaClutter
Package: phased.gpu

Simulate clutter using constant gamma model

Syntax

```
Y = step(H)
Y = step(H,X)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H)` computes the collected clutter return at each sensor. This syntax is available when you set the `TransmitSignalInputPort` property to `false`.

`Y = step(H,X)` specifies the transmit signal in `X`. *Transmit signal* refers to the output of the transmitter while it is on during a given pulse. This syntax is available when you set the `TransmitSignalInputPort` property to `true`.

Input Arguments

`H`

Constant gamma clutter object.

`X`

Transmit signal, specified as a column vector of data type `double`. The System object handles data transfer between the CPU and GPU.

Output Arguments

Y

Collected clutter return at each sensor. The data types of `X` and `Y` are the same. `Y` has dimensions N-by-M matrix. M is the number of subarrays in the radar system if `H.Sensor` contains subarrays, or the number of sensors, otherwise. When you set the `OutputFormat` property to `'Samples'`, N is specified in the `NumSamples` property. When you set the `OutputFormat` property to `'Pulses'`, N is the total number of samples in the next L pulses. In this case, L is specified in the `NumPulses` property.

Examples

Clutter Simulation of System with Known Power

Simulate the clutter return from terrain with a gamma value of 0 dB. The effective transmitted power of the radar system is 5 kw.

Set up the characteristics of the radar system. This system has a 4-element uniform linear array (ULA). The sample rate is 1 MHz, and the PRF is 10 kHz. The propagation speed is 300,000 km/s, and the operating frequency is 300 MHz. The radar platform is flying 1 km above the ground with a path parallel to the ground along the array axis. The platform speed is 2000 m/s. The mainlobe has a depression angle of 30 degrees.

```
Nele = 4;
c = 3e8; fc = 3e8; lambda = c/fc;
ha = phased.ULA('NumElements',Nele,'ElementSpacing',lambda/2);

fs = 1e6; prf = 10e3;
height = 1000; direction = [90; 0];
speed = 2000; depang = 30;
```

Create the GPU clutter simulation object. The configuration assumes the earth is flat. The maximum clutter range of interest is 5 km, and the maximum azimuth coverage is +/– 60 degrees.

```
Rmax = 5000; Azcov = 120;
tergamma = 0; tpower = 5000;
hclutter = phased.gpu.ConstantGammaClutter('Sensor',ha,...
    'PropagationSpeed',c,'OperatingFrequency',fc,'PRF',prf,...
```

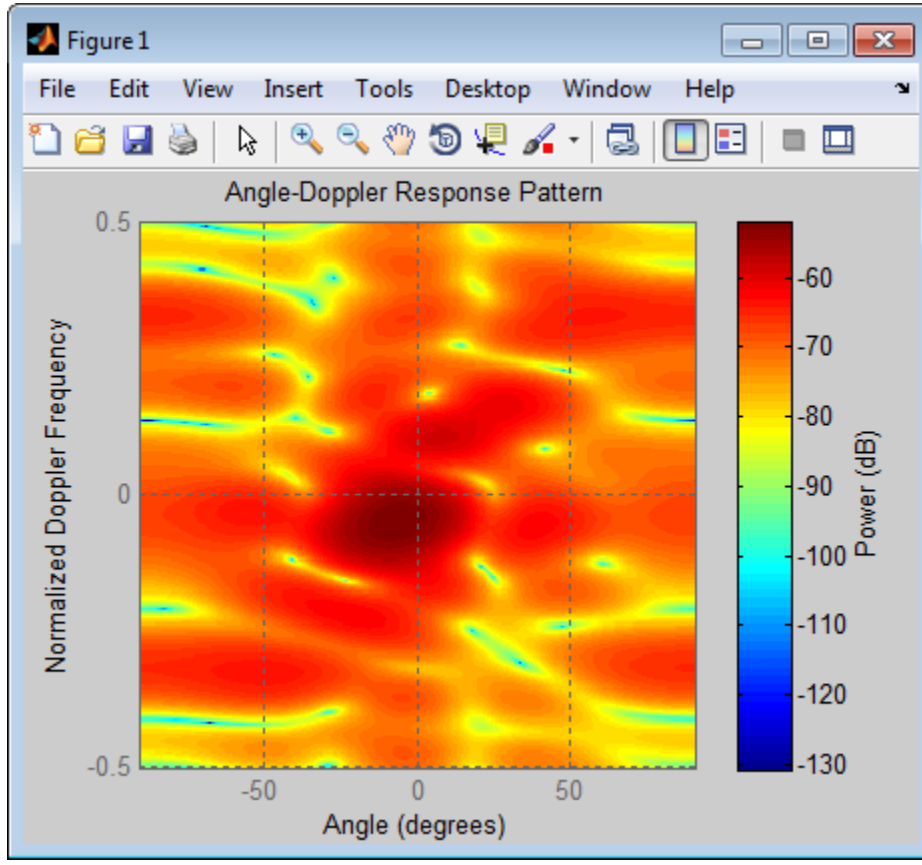
```
    'SampleRate',fs,'Gamma',tergamma,'EarthModel','Flat',...
    'TransmitERP',tpower,'PlatformHeight',height,...
    'PlatformSpeed',speed,'PlatformDirection',direction,...
    'BroadsideDepressionAngle',depang,'MaximumRange',Rmax,...
    'AzimuthCoverage',Azcov);
```

Simulate the clutter return for 10 pulses.

```
Nsamp = fs/prf; Npulse = 10;
csig = zeros(Nsamp,Nele,Npulse);
for m = 1:Npulse
    csig(:,:,m) = step(hclutter);
end
```

Plot the angle-Doppler response of the clutter at the 20th range bin.

```
hresp = phased.AngleDopplerResponse('SensorArray',ha,...
    'OperatingFrequency',fc,'PropagationSpeed',c,'PRF',prf);
plotResponse(hresp,shiftdim(csig(20,:,:)),...
    'NormalizeDoppler',true);
```



The results do not exactly match those achieved by using `phased.ConstantGammaClutter` instead of `phased.gpu.ConstantGammaClutter`. This discrepancy occurs because of differences between CPU and GPU computations.

Clutter Simulation Using Known Transmit Signal

Simulate the clutter return from terrain with a gamma value of 0 dB. The `step` syntax includes the transmit signal of the radar system as an input argument. In this case, you do not record the effective transmitted power of the signal in a property.

Set up the characteristics of the radar system. This system has a 4-element uniform linear array (ULA). The sample rate is 1 MHz, and the PRF is 10 kHz. The propagation speed is 300,000 km/s, and the operating frequency is 300 MHz. The radar platform is

flying 1 km above the ground with a path parallel to the ground along the array axis. The platform speed is 2000 m/s. The mainlobe has a depression angle of 30 degrees.

```
Nele = 4;
c = 3e8; fc = 3e8; lambda = c/fc;
ha = phased.ULA('NumElements',Nele,'ElementSpacing',lambda/2);

fs = 1e6; prf = 10e3;
height = 1000; direction = [90; 0];
speed = 2000; depang = 30;
```

Create the GPU clutter simulation object and configure it to take a transmit signal as an input argument to `step`. The configuration assumes the earth is flat. The maximum clutter range of interest is 5 km, and the maximum azimuth coverage is +/– 60 degrees.

```
Rmax = 5000; Azcov = 120;
tergamma = 0;
hclutter = phased.gpu.ConstantGammaClutter('Sensor',ha,...
    'PropagationSpeed',c,'OperatingFrequency',fc,'PRF',prf,...
    'SampleRate',fs,'Gamma',tergamma,'EarthModel','Flat',...
    'TransmitSignalInputPort',true,'PlatformHeight',height,...
    'PlatformSpeed',speed,'PlatformDirection',direction,...
    'BroadsideDepressionAngle',depang,'MaximumRange',Rmax,...
    'AzimuthCoverage',Azcov);
```

Simulate the clutter return for 10 pulses. At each step, pass the transmit signal as an input argument. The software automatically computes the effective transmitted power of the signal. The transmit signal is a rectangular waveform with a pulse width of 2 μs.

```
tpower = 5000;

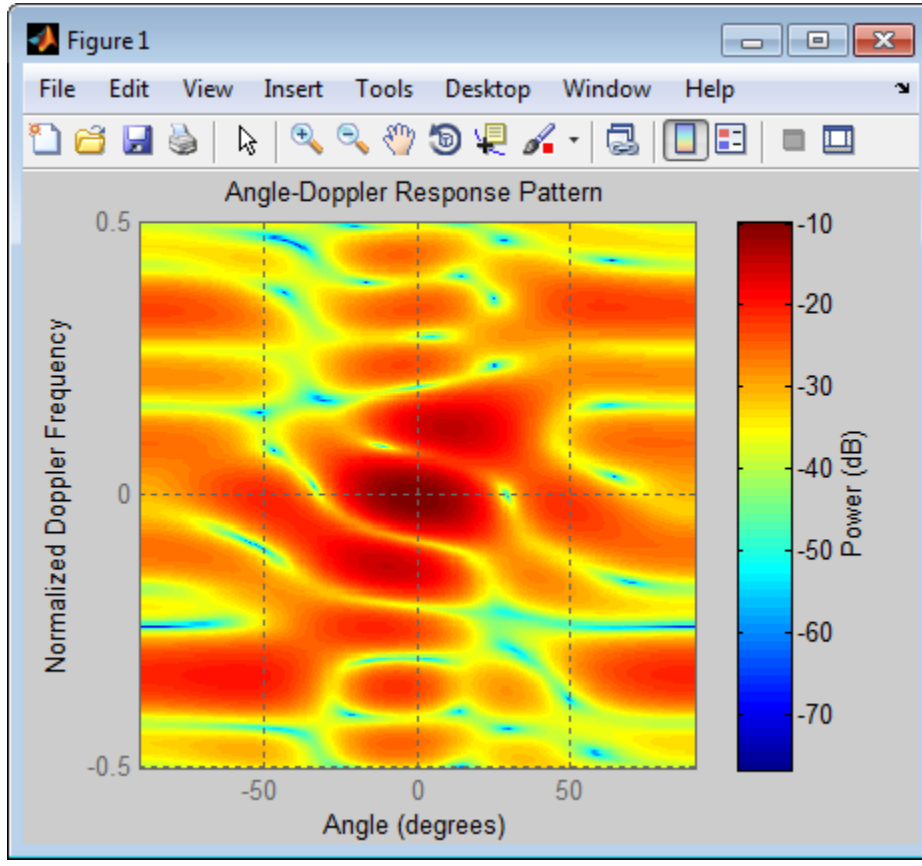
X = tpower*ones(floor(pw*fs),1);
Nsamp = fs/prf; Npulse = 10;
csig = zeros(Nsamp,Nele,Npulse);
for m = 1:Npulse
    csig(:,:,m) = step(hclutter,X);
end
```

Plot the angle-Doppler response of the clutter at the 20th range bin.

```
hresp = phased.AngleDopplerResponse('SensorArray',ha,...
    'OperatingFrequency',fc,'PropagationSpeed',c,'PRF',prf);
plotResponse(hresp,shiftdim(csig(20,:,:)),...
    'NormalizeDoppler',true);
```



The results do not exactly match those achieved by using `phased.ConstantGammaClutter` instead of `phased.gpu.ConstantGammaClutter`. This discrepancy occurs because of differences between CPU and GPU computations.

- Acceleration of Clutter Simulation Using GPU and Code Generation
- Ground Clutter Mitigation with Moving Target Indication (MTI) Radar

Tips

The clutter simulation that `ConstantGammaClutter` provides is based on these assumptions:

- The radar system is monostatic.
- The propagation is in free space.
- The terrain is homogeneous.
- The clutter patch is stationary during the coherence time. *Coherence time* indicates how frequently the software changes the set of random numbers in the clutter simulation.
- The signal is narrowband. Thus, the spatial response can be approximated by a phase shift. Similarly, the Doppler shift can be approximated by a phase shift.
- The radar system maintains a constant height during simulation.
- The radar system maintains a constant speed during simulation.

phased.GCCEstimator System object

Package: phased

Wideband direction of arrival estimation

Description

The `phased.GCCEstimator` System object creates a direction of arrival estimator for wideband signals. This System object estimates the direction of arrival or time of arrival among sensor array elements using the generalized cross-correlation with phase transform algorithm (GCC-PHAT). The algorithm assumes that all signals propagate from a single source lying in the array far field so the direction of arrival is the same for all sensors. The System object first estimates the correlations between all specified sensor pairs using GCC-PHAT and then finds the largest peak in each correlation. The peak identifies the delay between the signals arriving at each sensor pair. Finally, aleast-squares estimate is used to derive the direction of arrival from all estimated delays.

To compute the direction of arrival for pairs of element in the array:

1. Define and set up a GCC-PHAT estimator System object, `phased.GCCEstimator`, using the "Construction" on page 1-634 procedure.
2. Call `step` to compute the direction of arrival of a signal using the properties of the `phased.GCCEstimator` System object.

   The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`sGCC = phased.GCCEstimator` creates a GCC direction of arrival estimator System object, `sGCC`. This object estimates the direction of arrival or time of arrival between sensor array elements using the GCC-PHAT algorithm.

`sGCC = phased.GCCEstimator(Name,Value)` returns a GCC direction of arrival estimator object, `sGCC`, with the specified property `Name` set to the specified `Value`. `Name` must appear inside single quotes (`''`). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Properties

`SensorArray` — Sensor array

`phased.ULA` System object (default) | Phased Array System Toolbox sensor array

Sensor array, specified as a Phased Array System Toolbox System object. The array can also consist of subarrays. If you do not specify this property, the default sensor array is a phased.ULA System object with default array property values.

Example: `phased.URA`

`PropagationSpeed` — Signal propagation speed

speed of light (default) | positive real-valued scalar

Signal propagation speed, specified as a positive real-valued scalar. Units are in meters per second.

Example: `physconst('LightSpeed')`

Data Types: `double`

`SampleRate` — Sample rate

1e6 (default) | positive real-valued scalar

Sample rate, specified as a positive real-valued scalar. Units are in hertz.

Example: 1e6

Data Types: `double`

`SensorPairSource` — Source of sensor pairs

`'Auto'` (default) | `'Property'`

Source of sensor pairs, specified as either `'Auto'` or `'Property'`.

- `'Auto'` — choose this property value to compute correlations between the first sensor and all other sensors. The first sensor of the array is the reference channel.

- `'Property'` — choose this property value when you want to explicitly specify the sensor pairs to be used for computing correlations. Set the sensor pair indices using the `SensorPair` property. You can view the array indices using the `viewArray` method of any array System object.

Example: `'Auto'`

Data Types: `char`

`SensorPair` — Sensor pairs

`[2;1]` (default) | 2-by-*N* positive integer valued matrix

Sensor pairs used to compute correlations, specified as a 2-by-*N* positive integer-valued matrix. Each column of the matrix specifies a pair of sensors between which the correlation is computed. The second row specifies the reference sensors. Each entry in the matrix must be less than the number of array sensors or subarrays. To use the `SensorPair` property, you must also set the `SensorPairSource` value to `'Property'`.

Example: `[1,3,5;2,4,6]`

Data Types: `double`

`DelayOutputPort` — Option to enable delay output

`false` (default) | `true`

Option to enable output of time delay values, specified as a Boolean. Set this property to `true` to output the delay values as an output argument of the `step` method. The delays correspond to the arrival angles of a signal between sensor pairs. Set this property to `false` to disable the output of delays.

Example: `false`

Data Types: `logical`

`CorrelationOutputPort` — Option to enable correlation output

`false` (default) | `true`

Option to enable output of correlation values, specified as a Boolean. Set this property to `true` to output the correlations and lags between sensor pairs as output arguments of the `step` method. Set this property to `false` to disable output of correlations.

Example: false

Data Types: `logical`

Methods

reset	Reset states of phased.GCCEstimator System object
step	Estimate direction of arrival using generalized cross-correlation

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

GCC Estimate of Direction of Arrival at Microphone Array

Estimate the direction of arrival of a signal using the GCC-PHAT algorithm. The receiving array is a 5-by-5-element URA microphone array with elements spaced 0.25 meters apart. The arriving signal is a sequence of widebandand chirps. The signal arrives from 17° azimuth and 0° elevation. Assume the speed of sound in air is 340 m/s.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Load the chirp signal.

```
load chirp;
c = 340.0;
```

Create the 5-by-5 microphone URA.

```
d = 0.25;
N = 5;
mic = phased.OmnidirectionalMicrophoneElement;
array = phased.URA([N,N],[d,d],'Element',mic);
```

Simulate the incoming signal using the `WidebandCollector` System object™.

```
arrivalAng = [17;0];
collector = phased.WidebandCollector('Sensor',array,'PropagationSpeed',c,...
    'SampleRate',Fs,'ModulatedInput',false);
signal = collector(y,arrivalAng);
```

Estimate the direction of arrival.

```
estimator = phased.GCCEstimator('SensorArray',array,...
    'PropagationSpeed',c,'SampleRate',Fs);
ang = estimator(signal)
```

```
ang =

   16.4538
   -0.7145
```

Definitions

GCC-PHAT Cross-Correlation Algorithm

You can use generalized cross-correlation to estimate the time difference of arrival of a signal at two different sensors.

A model of a signal emitted by a source and received at two sensors is given by:

$$r_1(t) = s(t) + n_1(t)$$
$$r_2(t) = s(t - D) + n_2(t)$$

where D is the time difference of arrival (*TDOA*), or time lag, of the signal at one sensor with respect to the arrival time at a second sensor. You can estimate the time delay by finding the time lag that maximizes the cross-correlation between the two signals.

From the TDOA, you can estimate the broadside arrival angle of the plane wave with respect to the line connecting the two sensors. For two sensors separated by distance L, the broadside arrival angle, “Broadside Angles”, is related to the time lag by

$$\sin\beta = \frac{c\tau}{L}$$

where c is the propagation speed in the medium.

A common method of estimating time delay is to compute the cross-correlation between signals received at two sensors. To identify the time delay, locate the peak in the cross-correlation. When the signal-to-noise ratio (SNR) is large, the correlation peak, τ, corresponds to the actual time delay D.

$$R(\tau) = E\{r_1(t)r_2(t+\tau)\}$$
$$D = \arg\max_{\tau} R(\tau)$$

When the correlation function is more sharply peaked, performance improves. You can sharpen a cross correlation peak using a weighting function that whitens the input signals. This technique is called *generalized cross-correlation*(GCC). One particular weighting function normalizes the signal spectral density by the spectrum magnitude, leading to the *generalized cross-correlation phase transform* method (*GCC-PHAT*).

$$S(f) = \int_{-\infty}^{\infty} R(\tau)e^{-i2\pi f\tau}d\tau$$
$$\tilde{R}(\tau) = \int_{-\infty}^{\infty} \frac{S(f)}{|S(f)|}e^{+i2\pi f\tau}df$$
$$\tilde{D} = \arg\max_{\tau} \tilde{R}(\tau)$$

If you use just two sensor pairs, you can only estimate the broadside angle of arrival. However, if you use multiple pairs of non-collinear sensors, for example, in a URA, you can estimate the arrival azimuth and elevation angles of the plane wave using least-square estimation. For N sensors, you can write the delay time τ_{kj} of a signal arriving at the k^{th} sensor with respect to the j^{th} sensor by

$$c\tau_{kj} = -\left(\vec{x}_k - \vec{x}_j\right)\cdot\vec{u}$$
$$\vec{u} = \cos\alpha\sin\theta i + \sin\alpha\sin\theta j + \cos\theta k$$

where u is the unit propagation vector of the plane wave. The angles α and θ are the azimuth and elevation angles of the propagation vector. All angles and vectors are

defined with respect to the local axes. You can solve the first equation using least-squares to yield the three components of the unit propagation vector. Then, you can solve the second equation for the azimuth and elevation angles.

phased.BeamScanEstimator | phased.RootMUSICEstimator | `gccphat`

Introduced in R2015b

reset

System object: phased.GCCEstimator
Package: phased

Reset states of phased.GCCEstimator System object

Syntax

```
reset(S)
```

Description

`reset(S)` resets the internal state of the `phased.GCCEstimator` object, `S`. This method resets the random number generator state if the `SeedSource` property is applicable and has the value `'Property'`.

Input Arguments

S — GCC-PHAT estimator

`phased.GCCEstimator` System object

GCC-PHAT estimator, specified as a phased.GCCEstimator System object.

Example: `phased.GCCEstimator()`

Introduced in R2015b

step

System object: phased.GCCEstimator
Package: phased

Estimate direction of arrival using generalized cross-correlation

Syntax

```
ang = step(sGCC,sig)
[ang,tau] = step(sGCC,sig)
[ang,R,lag] = step(sGCC,sig)
[ang,tau,R,lag] = step(sGCC,sig)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`ang = step(sGCC,sig)` returns the direction of arrival, `ang`, of an input signal `sig`. The argument `sig` is a matrix specifying the received signals at the elements of the array specified in the `SensorArray` property. Signals propagate from a single source. Each column in `sig` corresponds to the elements in the array (if an array is used) or the number of subarrays (if a subarray is used). Each row of `sig` represents a single time snapshot.

`[ang,tau] = step(sGCC,sig)` returns the time delays, `tau`, estimated from the correlations between pairs of sensors. To use this syntax, set the `DelayOutputPort` property to `true`. The argument `tau` is a *P*-element row vector, where *P* is the number of sensor pairs, and where $P = N(N-1)$.

`[ang,R,lag] = step(sGCC,sig)` returns the estimated correlations, `R`, between pairs of sensors, when you set the `CorrelationOutputPort` property to true. `R` is a matrix

with P columns where P is the number of sensor pairs. Each column in `R` contains the correlation for the corresponding pair of sensors. `lag` is a column vector containing the time lags corresponding to the rows of the correlation matrix. The time lags are the same for all sensor pairs.

You can combine optional input arguments when their enabling properties are set. Optional inputs must be listed in the same order as their enabling properties. For example,`[ang,tau,R,lag] = step(sGCC,sig)` is valid when you set both `DelayOutputPort` and `CorrelationOutputPort` to `true`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

sGCC — GCC-PHAT estimator

`phased.GCCEstimator` System object

GCC-PHAT estimator, specified as a phased.GCCEstimator System object.

Example: `phased.GCCEstimator`

sig — Received signal

M-by-*N* complex-valued matrix

Received signal, specified as an *M*-by-*N* complex-valued matrix. The quantity *M* is the number of sample values (snapshots) of the signal and *N* is the number of sensor elements in the array. For subarrays, *N* is the number of subarrays.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Example: `[[0;1;2;3;4;3;2;1;0],[1;2;3;4;3;2;1;0;0]]`

Data Types: `double`

Complex Number Support: Yes

Output Arguments

`ang` — Direction of arrival

2-by-1 real-valued column vector | scalar

Direction of arrival of a signal, returned as a 2-by-1 real-valued column vector in the form `[azimuth;elevation]`. If the array is a uniform linear array, `ang` is a scalar representing the broadside angle. Angle units are in degrees, defined with respect to the local coordinate system of the array.

`tau` — Time delays of arrival

1-by-*P* real-valued row vector

Time delays of arrival, returned as 1-by-*P* real-valued row vector. *P* is the number of sensor pairs selected from the array.

- When `SensorPairSource` is set to `'Auto'`, *P* = *N* - *1*. *N* is the number of elements in the array.
- When `SensorPairSource` is set to `'Property'`, *P* is the number of sensor pairs specified by the `SensorPair` property.

Time units are seconds. This output is enabled when you set the `DelayOutputPort` property to `true`.

`R` — Estimated cross-correlation

(2*M*+1)-by-*P* complex-valued matrix

Estimated cross-correlation between pairs of sensors, returned as a (2*M*+1)-by-*P* complex-valued matrix, where *P* is the number of sensor pairs selected from the array.

- When `SensorPairSource` is set to `'Auto'`, *P* = *N* - *1*. *N* is the number of elements in the array. The columns in `R` contain the correlations between the first sensor and all other sensors.
- When `SensorPairSource` is set to `'Property'`, *P* is the number of sensor pairs specified by the `SensorPair` property. Each column in `R` contains the correlation for the corresponding pair of sensors.

M is the number of time samples in the input signal. This output is enabled when you set the `CorrelationOutputPort` property to `true`.

`lag` — Time lags

M-by-1 real-valued column vector

Time lags, returned as an (2*M*+1)-by-1 real-valued column vector. *M* is the number of time samples in the input signal. Each time lag applies to the corresponding row in the cross-correlation matrix.

Examples

Plot Correlations from GCC Estimator

Estimate the direction of arrival of a signal using GCC-PHAT. The receiving array is a 5-by-5-element URA microphone array with elements spaced 25 centimeters apart. Choose 10 element pairs to compute the arrival angle. Assume the speed of sound in air is 340 meters/second. The arriving signal is a sequence of wideband sounds. Assume the signal arrives from 54 degrees azimuth and five degrees elevation. Estimate the arrival angle, and then plot the correlation function versus lag for a pair of elements.

Load the signal and extract a small portion for computation.

```
load gong;
y1 = y(1:100);
```

Set up the receiving array.

```
N = 5;
d = 0.25;
sMic = phased.OmnidirectionalMicrophoneElement;
sURA = phased.URA([N,N],[d,d],'Element',sMic);
```

Simulate the arriving plane wave using the `WidebandCollector` System object™.

```
c = 340.0;
arrivalAng = [54;5];
sWBC = phased.WidebandCollector('Sensor',sURA,...
    'PropagationSpeed',c,...
    'SampleRate',Fs,...
    'ModulatedInput',false);
signal = step(sWBC,y1,arrivalAng);
```

Estimate direction of arrival. Choose 10 sensors to correlate with the first element of the URA.

```
sensorpairs = [[2,4,6,8,10,12,14,16,18,20];ones(1,10)];
sGCC = phased.GCCEstimator('SensorArray',sURA,...
    'PropagationSpeed',c,'SampleRate',Fs,...
    'SensorPairSource','Property',...
    'SensorPair',sensorpairs,...
    'DelayOutputPort',true','CorrelationOutputPort',true);
[estimatedAng,taus,R,lags] = step(sGCC,signal);
```

The estimated angle is:

```
disp(estimatedAng)
```

```
   11.6720
    4.2189
```

Plot the correlation between sensor 8 and sensor 1. This pair corresponds to the fourth column of the correlation matrix. The estimated value of tau (in milliseconds) for this pair is:

```
disp(1000*taus(4))
plot(1000*lags,real(R(:,4)))
xlabel('Time lags (msec)')
ylabel('Correlation')
```

```
    0.0238
```

Introduced in R2015b

phased.GSCBeamformer System object

Package: phased

Generalized sideband canceller

Description

The `phased.GSCBeamformer` System object implements a generalized sidelobe cancellation (GSC) beamformer. A GSC beamformer splits an array's incoming signals sends them through a conventional beamformer path and a sidelobe canceling path. The algorithm first presteers the array to the beamforming direction and then adaptively chooses filter weights to minimize power at the output of the sidelobe canceling path. The algorithm uses least mean squares (LMS) to compute the adaptive weights. The final beamformed signal is the difference between the outputs of the two paths.

To compute the beamformed signal:

1. Define and set up the GSC beamformer. See "Construction" on page 1-649.
2. Call step to perform the beamforming operation according to the properties of `phased.GSCBeamformer`.

Note: Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`beamformer = phased.GSCBeamformer` creates a GSC beamformer System object, `beamformer`, with default property values.

`beamformer = phased.GSCBeamformer(Name,Value)` creates a GSC beamformer System object with each specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Properties

`SensorArray` — Sensor array

`phased.ULA` (default) | Phased Array System Toolbox array System object

Sensor array, specified as a Phased Array System Toolbox array System object. The default value is a phased.ULA System object. When you use the default array, the ULA is created using the phased.ULA default values.

Example: `phased.URA`

`PropagationSpeed` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. Units are in m/s. The default value of the speed of light is the value returned by `physconst('LightSpeed')`.

Example: `3e8`

Data Types: `double`

`SampleRate` — Signal sample rate

`1e6` (default) | positive real-valued scalar

Signal sample rate, specified as a positive real-valued scalar. Units are in hertz.

Example: `1e6`

Data Types: `double`

`FilterLength` — Length of FIR filter

`1` (default) | positive integer

Length of the signal path FIR filters, specified as a positive integer. This property determines the adaptive filter size for the sidelobe cancelling path. The FIR filter for the conventional beamforming path is a delta function of the same length.

Example: `4`

Data Types: `double`

`LMSStepSize` — Adaptive filter step size factor

`0.1` (default) | positive real-valued scalar

The adaptive filter step size factor, specified as a positive real-valued scalar. This quantity, when divided by the total power in the sidelobe canceling path, sets the actual adaptive filter step size that is used in the LMS algorithm.

`Direction` — Beamforming directions

`[0;0]` (default) | 2-by-1 real-valued vector | 2-by-*L* real-valued matrix

Beamforming directions, specified as a 2-by-1 real-valued vector or 2-by-*L* real-valued matrix. *L*is the number of desired beamforming directions. Each column of the matrix has the form `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. Azimuth angles lie between –180° and 180°, inclusive, and elevation angles lie between –90° and 90°, inclusive. All angles are defined with respect to the local coordinate system of the array. This property applies only when you set the `DirectionSource` property to `'Property'`

Example: `[40;20]`

Dependencies

To enable this property, set `DirectionSource` to property.

Data Types: `double`

`DirectionSource` — Source of beamforming direction

`'Property'` (default) | `'Input port'`

Source of beamforming direction, specified as `'Property'` or `'Input port'`. When you set `DirectionSource` to `'Property'`, you then set the direction using the `Direction` property. When you select `'Input port'`, the direction is determined by the input argument to the step method.

Data Types: `char`

Methods

reset	Reset states of System object
step	Generalized sidelobe canceller

Common to All System Objects	
`clone`	Create System object with same property values

Common to All System Objects	
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Generalized Sidelobe Cancellation on Uniform Linear Array

Create a GSC beamformer for a 11-element acoustic array in air. A chirp signal is incident on the array at –50° in azimuth and 0° in elevation. Compare the GSC beamformed signal to a Frost beamformed signal. The signal propagation speed is 340 m/s. The sample rate is 8 kHz.

Create the microphone and array System objects. The array element spacing is one-half wavelength. Set the signal frequency to the one-half the Nyquist frequency.

```
c = 340.0;
fs = 8.0e3;
fc = fs/2;
lam = c/fc;
transducer = phased.OmnidirectionalMicrophoneElement('FrequencyRange',[20 20000]);
array = phased.ULA('Element',transducer,'NumElements',11,'ElementSpacing',lam/2);
```

Simulate a chirp signal with a 500 Hz bandwidth.

```
t = 0:1/fs:.4;
signal = chirp(t,0,1,500);
```

Create an incident wavefield hitting the array.

```
collector = phased.WidebandCollector('Sensor',array,'PropagationSpeed',c, ...
    'SampleRate',fs,'ModulatedInput',false,'NumSubbands',512);
incidentAngle = [-50;0];
signal = collector(signal.',incidentAngle);
noise = 0.1*randn(size(signal));
recsignal = signal + noise;
```

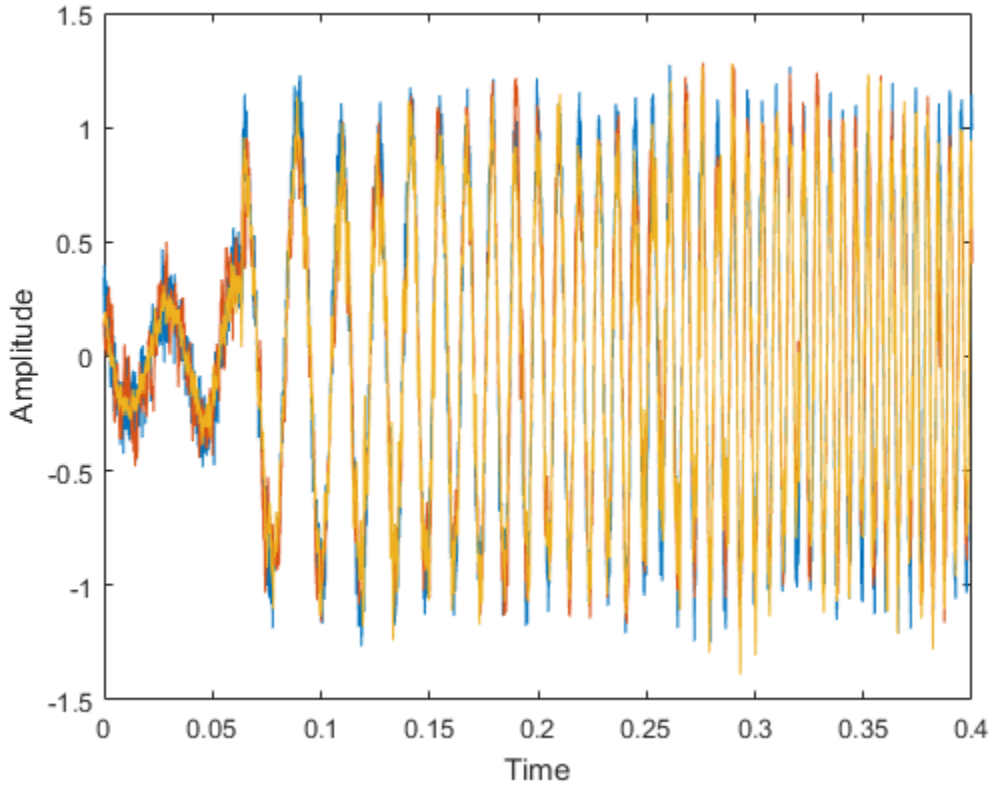
Perform Frost beamforming at the actual incident angle.

```
frostbeamformer = phased.FrostBeamformer('SensorArray',array,'PropagationSpeed', ...
```

```
    c,'SampleRate',fs,'Direction',incidentAngle,'FilterLength',10);
yfrost = frostbeamformer(recsignal);
```

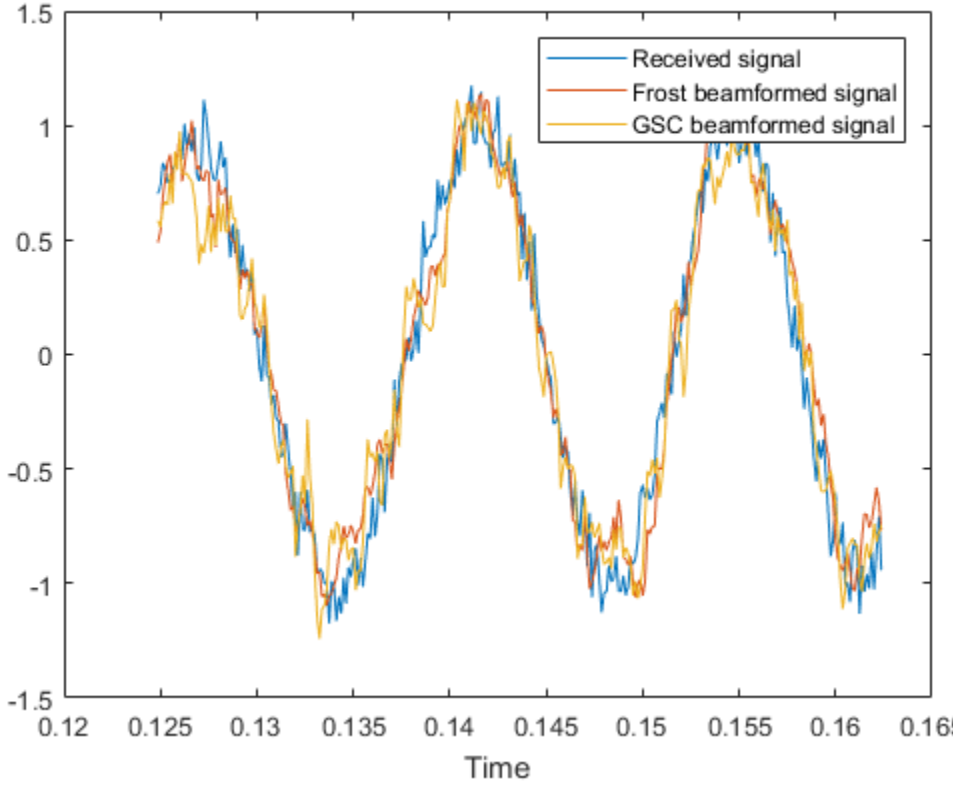
Perform GSC beamforming and plot the beamformer output against the Frost beamformer output. Also plot the nonbeamformed signal arriving at the middle element of the array.

```
gscbeamformer = phased.GSCBeamformer('SensorArray',array, ...
    'PropagationSpeed',c,'SampleRate',fs,'Direction',incidentAngle, ...
    'FilterLength',5);
ygsc = gscbeamformer(recsignal);
plot(t,recsignal(:,6),t,yfrost,t,ygsc)
xlabel('Time')
ylabel('Amplitude')
```



Zoom in on a small portion of the output.

```
idx = 1000:1300;
plot(t(idx),recsignal(idx,6),t(idx),yfrost(idx),t(idx),ygsc(idx))
xlabel('Time')
legend('Received signal','Frost beamformed signal','GSC beamformed signal')
```



Definitions

Generalized Sidelobe Cancellation

The *generalized sidelobe canceller* (GSC) is an efficient implementation of a *linear constraint minimum variance* (LCMV) beamformer. LCMV beamforming minimizes the output power of an array while preserving the power in one or more specified directions. This type of beamformer is called a *constrained beamformer*. You can compute exact weights for the constrained beamformer but the computation is costly when the number of elements is large. The computation requires the inversion of a large spatial covariance

matrix. The GSC formulation converts the adaptive constrained optimization LCMV problem into an adaptive unconstrained problem, which simplifies the implementation.

In the GSC algorithm, incoming sensor data is split into two signal paths as shown in the block diagram. The upper path is a conventional beamformer. The lower path is an adaptive unconstrained beamformer whose purpose is to minimize the GSC output power. The GSC algorithm consists of these steps:

1. Presteer the element sensor data by time-shifting the incoming signals. Presteering time-aligns all sensor element signals. The time shifts depend on the arrival angle of the signal.
2. Pass the presteered signals through the upper path into a conventional beamformer with fixed weights, $\mathbf{w}_{conv}$.
3. Also pass the presteered signals through the lower path into the blocking matrix, **B**. The blocking matrix is orthogonal to the signal and removes the signal from the lower path.
4. Filter the lower path signals through a bank of FIR filters. The `FilterLength` property sets the length of the filters. The filter coefficients are the adaptive filter weights, $\mathbf{w}_{ad}$.
5. Compute the difference between the upper and lower signal paths. This difference is the beamformed GSC output.
6. Feed the beamformed output back into the filter. The filter adapts its weights using a least mean-square (LMS) algorithm. The actual adaptive LMS step size is the quantity set by `LMSStepSize`, divided by the total signal power.

Introduced in R2016b

reset

System object: phased.GSCBeamformer
Package: phased

Reset states of System object

Syntax

```
reset(beamformer)
```

Description

`reset(beamformer)` resets the internal state of the `phased.GSCBeamformer` object, `beamformer`.

Input Arguments

`beamformer` — Generalized sidelobe canceller

`phased.GSCBeamformer` System object

Generalized sidelobe canceller, specified as a phased.GSCBeamformer System object.

Introduced in R2016b

step

System object: phased.GSCBeamformer
Package: phased

Generalized sidelobe canceller

Syntax

```
bfsig = step(beamformer,sig)
bfsig = step(beamformer,sig,ang)
```

Description

Note: Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`bfsig = step(beamformer,sig)` performs generalized sidelobe cancellation (GSC) using the beamformer, `beamformer`, on the input signal, `sig`, and returns the beamformed output in `bfsig`.

`bfsig = step(beamformer,sig,ang)` uses `ang` as the desired beamforming direction. This syntax applies only when you set the `DirectionSource` property of the input beamformer to `'Input port'`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`beamformer` — Generalized sidelobe canceller

`phased.GSCBeamformer` System object

Generalized sidelobe canceller, specified as a phased.GSCBeamformer System object.

`sig` — Input signal

M-by-*N* complex-valued matrix

Input signal, specified as an *M*-by-*N* matrix, where *M* is the number of samples in the data, and *N* is the number of array elements.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Example: `[1,1;j,1;0.5,0]`

Data Types: `double`
Complex Number Support: Yes

`ang` — Beamforming direction

2-by-*L* real-valued matrix

Beamforming direction, specified as a *2*-by-*L* real-valued matrix, where *L* is the number of beamforming directions. Each column takes the form of `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°, inclusive, and the elevation angle must lie between –90° and 90°, inclusive. Angles are defined with respect to the local coordinate system of the array.

Example: `F = [40 30; 0 10]`

Dependencies

To enable this argument, set the `DirectionSource` property to `'Input port'`.

Data Types: `double`

Output Arguments

`bfsig` — Beamformed output

M-by-*L* complex-valued matrix

Beamformed output, returned as an *M*-by-*L* complex-valued matrix. The quantity *M* is the number of signal samples, and *L* is the number of desired beamforming directions specified in `ang`.

Examples

Generalized Sidelobe Cancellation on Uniform Linear Array

Create a GSC beamformer for a 11-element acoustic array in air. A chirp signal is incident on the array at –50° in azimuth and 0° in elevation. Compare the GSC beamformed signal to a Frost beamformed signal. The signal propagation speed is 340 m/s. The sample rate is 8 kHz.

Create the microphone and array System objects. The array element spacing is one-half wavelength. Set the signal frequency to the one-half the Nyquist frequency.

```
c = 340.0;
fs = 8.0e3;
fc = fs/2;
lam = c/fc;
transducer = phased.OmnidirectionalMicrophoneElement('FrequencyRange',[20 20000]);
array = phased.ULA('Element',transducer,'NumElements',11,'ElementSpacing',lam/2);
```

Simulate a chirp signal with a 500 Hz bandwidth.

```
t = 0:1/fs:.4;
signal = chirp(t,0,1,500);
```

Create an incident wavefield hitting the array.

```
collector = phased.WidebandCollector('Sensor',array,'PropagationSpeed',c, ...
    'SampleRate',fs,'ModulatedInput',false,'NumSubbands',512);
incidentAngle = [-50;0];
signal = collector(signal.',incidentAngle);
noise = 0.1*randn(size(signal));
```

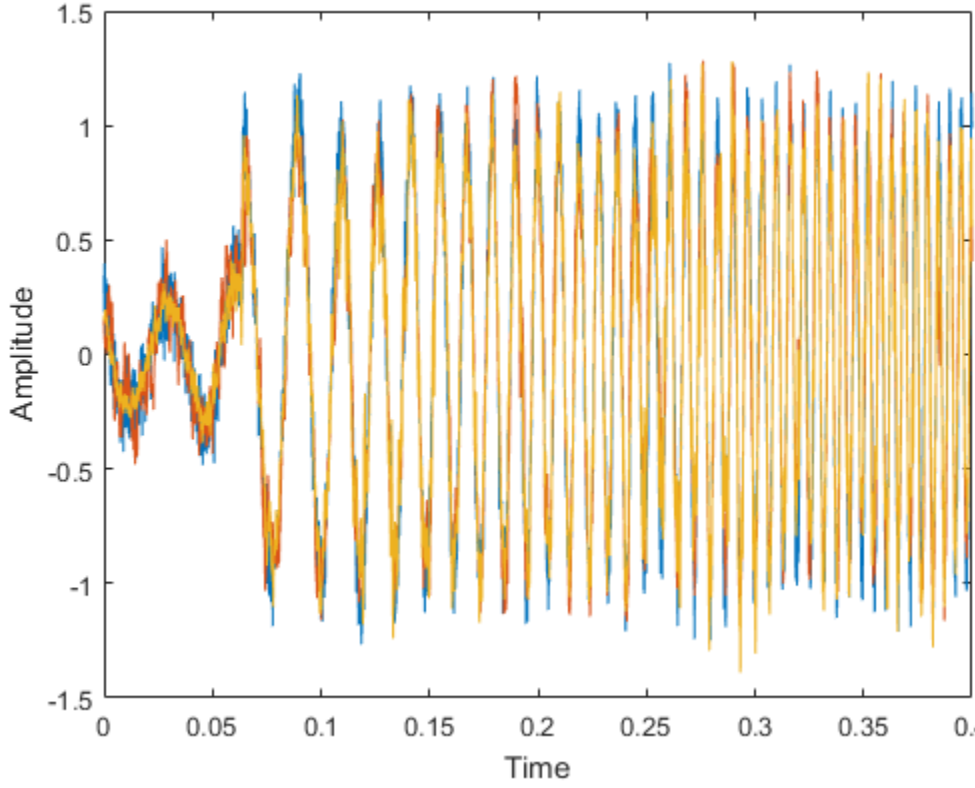
```
recsignal = signal + noise;
```

Perform Frost beamforming at the actual incident angle.

```
frostbeamformer = phased.FrostBeamformer('SensorArray',array,'PropagationSpeed', ...
    c,'SampleRate',fs,'Direction',incidentAngle,'FilterLength',10);
yfrost = frostbeamformer(recsignal);
```

Perform GSC beamforming and plot the beamformer output against the Frost beamformer output. Also plot the nonbeamformed signal arriving at the middle element of the array.

```
gscbeamformer = phased.GSCBeamformer('SensorArray',array, ...
    'PropagationSpeed',c,'SampleRate',fs,'Direction',incidentAngle, ...
    'FilterLength',5);
ygsc = gscbeamformer(recsignal);
plot(t,recsignal(:,6),t,yfrost,t,ygsc)
xlabel('Time')
ylabel('Amplitude')
```



Zoom in on a small portion of the output.

```
idx = 1000:1300;
plot(t(idx),recsignal(idx,6),t(idx),yfrost(idx),t(idx),ygsc(idx))
xlabel('Time')
legend('Received signal','Frost beamformed signal','GSC beamformed signal')
```

Introduced in R2016b

phased.HeterogeneousConformalArray System object

Package: phased

Heterogeneous conformal array

Description

The `HeterogeneousConformalArray` object constructs a conformal array from a heterogeneous set of antenna elements. A heterogeneous array is an array which consists of different kinds of antenna elements or an array of different kinds of microphone elements. A *conformal array* can have elements in any position pointing in any direction.

To compute the response for each element in the array for specified directions:

1. Define and set up your conformal array. See "Construction" on page 1-666.
2. Call step to compute the response according to the properties of `phased.HeterogeneousConformalArray`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.HeterogeneousConformalArray` creates a heterogeneous conformal array System object, `H`. This object models a heterogeneous conformal array formed with different kinds of sensor elements.

`H = phased.HeterogeneousConformalArray(Name,Value)` creates object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`ElementSet`

Set of elements used in the array

Specify the set of different elements used in the sensor array as a row MATLAB cell array. Each member of the cell array contains an element object in the phased package. Elements specified in the `ElementSet` property must be either all antennas or all microphones. In addition, all specified antenna elements must have the same polarization capability. Specify the element of the sensor array as a handle. The element must be an element object in the `phased` package.

Default: One cell containing one isotropic antenna element

`ElementIndices`

Elements location assignment

This property specifies the mapping of elements in the array. The property assigns elements to their locations in the array using the indices into the `ElementSet` property. The value of `ElementIndices` must be an length-*N* row vector. In this vector, *N* represents the number of elements in the array. The values in the vector specified by `ElementIndices` must be less than or equal to the number of entries in the `ElementSet` property.

Default: `[1 2 2 1]`

`ElementPosition`

Element positions

`ElementPosition` specifies the positions of the elements in the conformal array. The value of the `ElementPosition` property must be a 3-by-*N* matrix, where *N* indicates the number of elements in the conformal array. Each column of `ElementPosition` represents the position, in the form `[x; y; z]` (in meters), of a single element in the local coordinate system of the array. The local coordinate system has its origin at an arbitrary point.

Default: `[0; 0; 0]`

`ElementNormal`

Element normal directions

`ElementNormal` specifies the normal directions of the elements in the conformal array. Angle units are degrees. The value assigned to `ElementNormal` must be either a 2-by-*N* matrix or a 2-by-1 column vector. The variable *N* indicates the number of elements in the array. If the value of `ElementNormal` is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]` with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If the value of `ElementNormal` is a 2-by-1 column vector, it specifies the pointing direction of all elements in the array.

You can use the `ElementPosition` and `ElementNormal` properties to represent any arrangement in which pairs of elements differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal.

Default: `[0; 0]`

`Taper`

Element taper or weighting

Element tapering or weighting, specified as a complex-valued scalar, 1-by-*N* row vector, or *N*-by-1 column vector. The quantity *N* is the number of elements in the array as determined by the size of the `ElementIndices` property. Tapers, also known as weights, are applied to each sensor element in the sensor array and modify both the amplitude and phase of the received data. If `'Taper'` is a scalar, the same taper value is applied to all elements. If `'Taper'` is a vector, each taper value is applied to the corresponding sensor element.

Default: 1

Methods

directivity	Directivity of heterogeneous conformal array
collectPlaneWave	Simulate received plane waves
getElementNormal	Normal vector to array elements
getElementPosition	Positions of array elements
getNumElements	Number of elements in array

getTaper	Array element tapers
isPolarizationCapable	Polarization capability
pattern	Plot heterogeneous conformal array pattern
patternAzimuth	Plot heterogeneous conformal array directivity or pattern versus azimuth
patternElevation	Plot heterogeneous conformal array directivity or pattern versus elevation
plotResponse	Plot response pattern of array
step	Output responses of array elements
viewArray	View array geometry

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Heterogeneous Uniform Circular Array

Construct an 8-element heterogeneous uniform circular array (UCA) using the ConformalArray System object. Four of the elements have a cosine pattern with a power of 1.6 while the remaining elements have a cosine pattern with a power of 2.0. Plot the 3-D power response. Assume a 1 GHz operating frequency. The wave propagation speed is the speed of light.

Construct the array

```
sElement1 = phased.CosineAntennaElement('CosinePower',1.6);
sElement2 = phased.CosineAntennaElement('CosinePower',2.0);
N = 8;
azang = (0:N-1)*360/N-180;
sArray = phased.HeterogeneousConformalArray(...
```

```
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 1 1 2 2 2 2],...
    'ElementPosition',[cosd(azang);sind(azang);zeros(1,N)],...
    'ElementNormal',[azang;zeros(1,N)]);
c = physconst('LightSpeed');
fc = 1e9;
```

Create the 3-D power pattern

```
pattern(sArray,fc,[-180:180],[-90:90],...
    'CoordinateSystem','polar',...
    'Type','power')
```

directivity

System object: phased.HeterogeneousConformalArray
Package: phased

Directivity of heterogeneous conformal array

Syntax

```
D = directivity(H,FREQ,ANGLE)
D = directivity(H,FREQ,ANGLE,Name,Value)
```

Description

`D = directivity(H,FREQ,ANGLE)` computes the "Directivity" on page 1-676 of a heterogeneous conformal array of antenna or microphone elements, `H`, at frequencies specified by the `FREQ` and in angles of direction specified by the `ANGLE`.

`D = directivity(H,FREQ,ANGLE,Name,Value)` computes the directivity with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`H` — Heterogeneous conformal array

System object

Heterogeneous conformal array specified as a phased.HeterogeneousConformalArray System object.

Example: `H = phased.HeterogeneousConformalArray;`

`FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

`ANGLE` — Angles for computing directivity

1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Angles for computing directivity, specified as a 1-by-*M* real-valued row vector or a 2-by-*M* real-valued matrix, where *M* is the number of angular directions. Angle units are in degrees. If `ANGLE` is a 2-by-*M* matrix, then each column specifies a direction in azimuth and elevation, `[az;el]`. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°.

If `ANGLE` is a 1-by-*M* vector, then each entry represents an azimuth angle, with the elevation angle assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis.

Example: `[45 60; 0 10]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'PropagationSpeed' — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of 'PropagationSpeed' and a positive scalar in meters per second.

Example: 'PropagationSpeed',physconst('LightSpeed')

Data Types: double

'Weights' — Array weights

1 (default) | *N*-by-1 complex-valued column vector | *N*-by-*L* complex-valued matrix

Array weights, specified as the comma-separated pair consisting of 'Weights' and an *N*-by-1 complex-valued column vector or *N*-by-*L* complex-valued matrix. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *N* is the number of elements in the array. The dimension *L* is the number of frequencies specified by FREQ.

Weights Dimension	FREQ Dimension	Purpose
N-by-1 complex-valued column vector	Scalar or 1-by-*L* row vector	Applies a set of weights for the single frequency or for all *L* frequencies.
N-by-*L* complex-valued matrix	1-by-*L* row vector	Applies each of the *L* columns of 'Weights' for the corresponding frequency in FREQ.

Note: Use complex weights to steer the array response toward different directions. You can create weights using the phased.SteeringVector System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as phased.Radiator or phased.Collector. However, for the directivity, pattern, patternAzimuth, and patternElevation methods of any array System object use the steering vector without conjugation.

Example: 'Weights',ones(N,M)

Data Types: double

Complex Number Support: Yes

Output Arguments

`D` — Directivity

M-by-*L* matrix

Directivity, returned as an *M*-by-*L* matrix whose columns contain the directivities at the *M* angles specified by `ANGLE`. Each column corresponds to one of the *L* frequency values specified in `FREQ`. Directivity units are in dBi.

Examples

Directivity of Heterogeneous Conformal Array

Compute the directivity of a steered heterogeneous conformal array. Construct a 24-element heterogeneous disk array using elements having different antenna patterns and then show how to compute the array's directivity.

Set the signal speed to the speed of light and the signal frequency to 2GHz.

```
c = physconst('LightSpeed');
freq = 2e9;
```

Choose two different types of elements - both are cosine antenna elements with different powers.

```
myElement1 = phased.CosineAntennaElement('CosinePower',1.5);
myElement2 = phased.CosineAntennaElement('CosinePower',1.8);
```

Set up a three-ring disk array with 8 elements per ring. The inner ring has different elements from the outer rings.

```
N = 8;
azang = (0:N-1)*360/N-180;
p0 = [zeros(1,N);cosd(azang);sind(azang)];
posn = [0.6*p0, 0.4*p0, 0.2*p0];
myArray = phased.HeterogeneousConformalArray;
myArray.ElementPosition = posn;
myArray.ElementNormal = zeros(2,3*N);
```

```
myArray.ElementSet = {myElement1,myElement2};
myArray.ElementIndices = [1 1 1 1 1 1 1 1,...
    1 1 1 1 1 1 1 1,...
    2 2 2 2 2 2 2 2];
```

Set up the steering vector to point at 30 degrees azimuth and compute the directivity in that direction.

```
lambda = c/freq;
ang = [30;0];
w = steervec(getElementPosition(myArray)/lambda,ang);
d = directivity(myArray,freq,ang,'PropagationSpeed',c,...
            'Weights',w)
```

```
d =

   20.9519
```

Definitions

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element directivity” and “Array directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

collectPlaneWave

System object: phased.HeterogeneousConformalArray
Package: phased

Simulate received plane waves

Syntax

```
Y = collectPlaneWave(H,X,ANG)
Y = collectPlaneWave(H,X,ANG,FREQ)
Y = collectPlaneWave(H,X,ANG,FREQ,C)
```

Description

`Y = collectPlaneWave(H,X,ANG)` returns the received signals at the sensor array, `H`, when the input signals indicated by `X` arrive at the array from the directions specified in `ANG`.

`Y = collectPlaneWave(H,X,ANG,FREQ)`, in addition, specifies the incoming signal carrier frequency in `FREQ`.

`Y = collectPlaneWave(H,X,ANG,FREQ,C)`, in addition, specifies the signal propagation speed in `C`.

Input Arguments

`H`

Array object.

`X`

Incoming signals, specified as an M-column matrix. Each column of `X` represents an individual incoming signal.

ANG

Directions from which incoming signals arrive, in degrees. ANG can be either a 2-by-M matrix or a row vector of length M.

If ANG is a 2-by-M matrix, each column specifies the direction of arrival of the corresponding signal in X. Each column of ANG is in the form `[azimuth; elevation]`. The azimuth angle must be between –180° and 180°, inclusive. The elevation angle must be between –90° and 90°, inclusive.

If ANG is a row vector of length M, each entry in ANG specifies the azimuth angle. In this case, the corresponding elevation angle is assumed to be 0°.

FREQ

Carrier frequency of signal in hertz. FREQ must be a scalar.

Default: `3e8`

C

Propagation speed of signal in meters per second.

Default: Speed of light

Output Arguments

Y

Received signals. Y is an N-column matrix, where N is the number of elements in the array H. Each column of Y is the received signal at the corresponding array element, with all incoming signals combined.

Examples

Simulate Received Signal at Heterogeneous Conformal Array

Simulate the received signal at an 8-element heterogeneous uniform circular array created using the `phased.HeterogeneousConformalArray` System object™. The

signals arrive from 10° and 30° azimuth. Both signals have an elevation angle of 0°. Assume the propagation speed is the speed of light.

```
antenna1 = phased.CosineAntennaElement('CosinePower',1.5);
antenna2 = phased.CosineAntennaElement('CosinePower',1.8);
N = 8;
azang = (0:N-1)*360/N-180;
array = phased.HeterogeneousConformalArray('ElementPosition', ...
    [cosd(azang);sind(azang);zeros(1,N)],'ElementNormal',[azang;zeros(1,N)], ...
    'ElementSet',{antenna1,antenna2},'ElementIndices',[1 1 1 1 2 2 2 2]);
c = physconst('LightSpeed');
y = collectPlaneWave(array,randn(4,2),[10 30],c);
disp(y(:,1:2))
```

```
   0.7476 + 0.2890i   0.5378 + 0.5554i
   0.9544 - 0.8005i  -0.5059 + 1.3857i
  -2.5374 - 0.5387i  -1.3746 - 2.1411i
   1.0865 + 0.3377i   0.6977 + 0.8549i
```

Algorithms

`collectPlaneWave` modulates the input signal with a phase corresponding to the delay caused by the direction of arrival. The method does not account for the response of individual elements in the array.

For further details, see Van Trees [1].

getElementNormal

System object: phased.HeterogeneousConformalArray
Package: phased

Normal vector to array elements

Syntax

```
normvec = getElementNormal(sConfArray)
normvec = getElementNormal(sConfArray,elemidx)
```

Description

`normvec = getElementNormal(sConfArray)` returns the normal vectors of the array elements of the `phased.sConfArray` System object, `sConfArray`. The output argument `normvec` is a 2-by-*N* matrix, where *N* is the number of elements in array, `sConfArray`. Each column of `normvec` defines the normal direction of an element in the local coordinate system in the form `[az;el]`. Units are degrees. The origin of the local coordinate system is defined by the phase center of the array.

`normvec = getElementNormal(sConfArray,elemidx)` returns only the normal vectors of the elements specified in the element index vector, `elemidx`. This syntax can use any of the input arguments in the previous syntax.

Input Arguments

`sConfArray` — Heterogeneous conformal array

`phased.HeterogeneousConformalArray` System object

Heterogeneous conformal array, specified as a `phased.HeterogeneousConformalArray` System object.

Example: `phased.HeterogeneousConformalArray`

`elemidx` — Element indices

all array elements (default) | integer-valued 1-by-*M* row vector | integer-valued *M*-by-1 column vector

Element indices, specified as a 1-by-*M* or *M*-by-1 vector. Index values lie in the range 1 to *N* where *N* is the number of elements of the array. When `elemidx` is specified, `getElementNormal` returns the normal vectors of the elements contained in `elemidx`.

Example: `[1,5,4]`

Output Arguments

`normvec` — Element normal vectors

2-by-*P* real-valued vector

Element normal vectors, specified as a 2-by-*P* real-valued vector. Each column of `normvec` takes the form `[az,el]`. When `elemidx` is not specified, *P* equals the array dimension. When `elemidx` is specified, *P* equals the length of `elemidx`, *M*.

Examples

Display Heterogenous Conformal Array Element Normals

Construct a 5-element acoustic cross array (UCA) composed of two different types of cosine antenna elements. Use the Phased.HeterogeneousConformalArray System object. Assume the operating frequency is 4 kHz. A typical value for the speed of sound in seawater is 1500.0 m/s. Display the array normal vectors.

```
N = 5;
fc = 4000;
c = 1500.0;
lam = c/fc;
x = zeros(1,N);
y = [-1,0,1,0,0]*lam/2;
z = [0,0,0,-1,1]*lam/2;
sCos1 = phased.CosineAntennaElement('CosinePower',1.5);
sCos2 = phased.CosineAntennaElement('CosinePower',1.8);
sHCA = phased.HeterogeneousConformalArray('ElementSet',{sCos1,sCos2},...
    'ElementIndices',[1,2,2,2,1],...
    'ElementPosition',[x;y;z],...
    'ElementNormal',[[-20,-10,0,10,20];zeros(1,N)]);
pos = getElementPosition(sHCA)
normvec = getElementNormal(sHCA)
```

```
pos =

         0         0         0         0         0
   -0.1875         0    0.1875         0         0
         0         0         0   -0.1875    0.1875

normvec =

   -20   -10     0    10    20
     0     0     0     0     0
```

Introduced in R2016a

getElementPosition

System object: phased.HeterogeneousConformalArray
Package: phased

Positions of array elements

Syntax

```
pos = getElementPosition(sHCA)
pos = getElementPosition(sHCA,elemidx)
```

Description

`pos = getElementPosition(sHCA)` returns the element positions of the HeterogeneousConformalArray System object, `sHCA`. `POS` is an 3-by-*N* matrix where *N* is the number of elements in `H`. Each column of `pos` defines the position of an element in the local coordinate system, in meters, in the form `[x;y;z]`.

For details regarding the local coordinate system of the conformal or heterogeneous conformal array, enter `phased.ConformalArray.coordinateSystemInfo`.

`pos = getElementPosition(sHCA,elemidx)` returns the positions of the elements that are specified in the element index vector `elemidx`.

Examples

Element Positions of Heterogeneous Conformal Array

Construct an 8-element heterogeneous conformal array with oriented short-dipole antenna elements. Then, obtain the positions of the first four elements.

```
sElement1 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[100e6 1e9],...
    'AxisDirection','Z');
sElement2 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[100e6 1e9],...
```

```
    'AxisDirection','Y');
N = 8; azang = (0:N-1)*360/N-180;
sArray = phased.HeterogeneousConformalArray(...
    'ElementPosition',...
    [cosd(azang);sind(azang);zeros(1,N)],...
    'ElementNormal',[azang;zeros(1,N)],...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 1 1 2 2 2 2]);
pos = getElementPosition(sArray);
disp(pos(:,1:4));
```

```
   -1.0000   -0.7071         0    0.7071
         0   -0.7071   -1.0000   -0.7071
         0         0         0         0
```

getNumElements

System object: phased.HeterogeneousConformalArray
Package: phased

Number of elements in array

Syntax

```
N = getNumElements(H)
```

Description

`N = getNumElements(H)` returns the number of elements, N, in the conformal array object `H`.

Examples

Number of Elements in Heterogeneous Conformal Array

Construct a heterogeneous 8-element circular array and use the `getNumElements` method to return the number of elements.

```
antenna1 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Z');
antenna2 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Y');
N = 8;
azang = (0:N-1)*360/N-180;
array = phased.HeterogeneousConformalArray('ElementPosition', ...
    [cosd(azang);sind(azang);zeros(1,N)], ...
    'ElementNormal',[azang;zeros(1,N)], ...
    'ElementSet',{antenna1,antenna2}, ...
    'ElementIndices',[1 1 1 1 2 2 2 2]);
N = getNumElements(array)
```

```
N =
```

8

getTaper

System object: phased.HeterogeneousConformalArray
Package: phased

Array element tapers

Syntax

```
wts = getTaper(h)
```

Description

`wts = getTaper(h)` returns the tapers applied to each element of a conformal array, `h`. Tapers are often referred to as weights.

Input Arguments

h — Conformal array

`phased.HeterogeneousConformalArray` System object

Conformal array specified as a phased.HeterogeneousConformalArray System object.

Output Arguments

wts — Array element tapers

N-by-1 complex-valued vector

Array element tapers returned as an *N*-by-1, complex-valued vector, where *N* is the number of elements in the array.

Examples

Create Tapered Heterogeneous Conformal Disk Array

Create a 12-element, 2-ring tapered disk array where the outer ring is more heavily tapered than the inner ring.

```
antenna1 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Z');
antenna2 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Y');
elemAngles = ([0:5]*360/6);
elemPosInner = 0.5*[zeros(size(elemAngles));cosd(elemAngles); ...
    sind(elemAngles)];
elemPosOuter = [zeros(size(elemAngles));cosd(elemAngles); ...
    sind(elemAngles)];
elemNorms = repmat([0;0],1,12);
taper =  [ones(size(elemAngles)),0.3*ones(size(elemAngles))];
array = phased.HeterogeneousConformalArray('ElementSet',{antenna1,antenna2}, ...
    'ElementIndices',[1 1 1 1 1 1 2 2 2 2 2 2], ...
    'ElementPosition',[elemPosInner,elemPosOuter],'ElementNormal',elemNorms, ...
    'Taper',taper);
w = getTaper(array)
```

```
w =

isPolarizationCapable

System object: phased.HeterogeneousConformalArray
Package: phased

Polarization capability

Syntax

```
flag = isPolarizationCapable(h)
```

Description

`flag = isPolarizationCapable(h)` returns a Boolean value, `flag`, indicating whether the array supports polarization. An array supports polarization if all of its constituent sensor elements support polarization.

Input Arguments

`h` — Conformal array

Conformal array specified as a phased.HeterogeneousConformalArray System object.

Output Arguments

`flag` — Polarization-capability flag

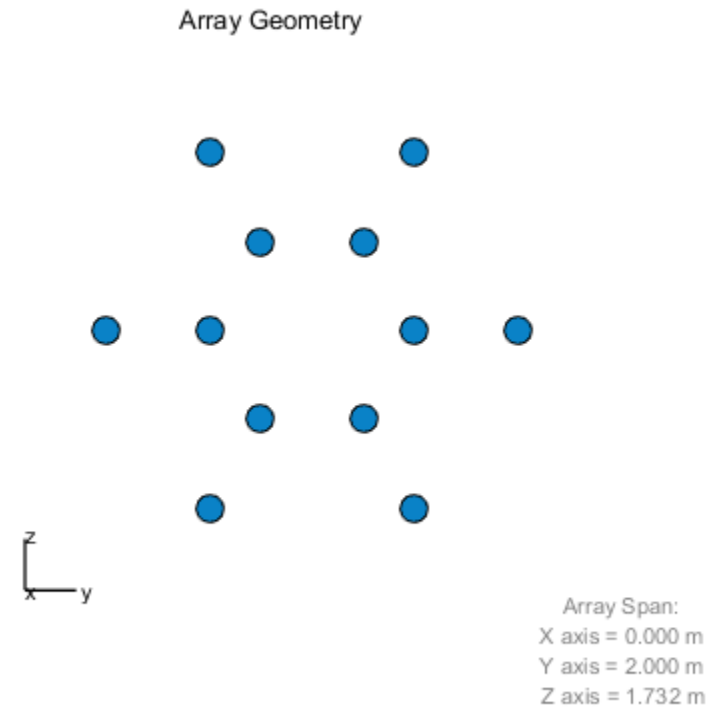
Polarization-capability returned as a Boolean value `true` if the array supports polarization or `false` if it does not.

Examples

Conformal Heterogeneous Array Supports Polarization

Show that a disk heterogeneous conformal array of short-dipole antennas supports polarization.

```
antenna1 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[100e6 1e9],...
    'AxisDirection','Z');
antenna2 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[100e6 1e9],...
    'AxisDirection','Y');
elemAngles = ([0:5]*360/6);
elemPosInner = 0.5*[zeros(size(elemAngles));...
    cosd(elemAngles); sind(elemAngles)];
elemPosOuter = [zeros(size(elemAngles));...
    cosd(elemAngles); sind(elemAngles)];
elemNorms = repmat([0;0],1,12);
array = phased.HeterogeneousConformalArray(...
    'ElementSet',{antenna1,antenna2},...
    'ElementIndices',[1 1 1 1 1 1 2 2 2 2 2 2],...
    'ElementPosition',[elemPosInner,elemPosOuter],...
    'ElementNormal',elemNorms);
viewArray(array)
```



```
isPolarizationCapable(array)

ans =

  logical

   1
```

The returned value of 1 shows that this array supports polarization when used with a polarized antenna.

pattern

System object: phased.HeterogeneousConformalArray
Package: phased

Plot heterogeneous conformal array pattern

Syntax

```
pattern(sArray,FREQ)
pattern(sArray,FREQ,AZ)
pattern(sArray,FREQ,AZ,EL)
pattern( ___ ,Name,Value)
[PAT,AZ_ANG,EL_ANG] = pattern( ___ )
```

Description

`pattern(sArray,FREQ)` plots the 3-D array directivity pattern (in dBi) for the array specified in `sArray`. The operating frequency is specified in `FREQ`.

`pattern(sArray,FREQ,AZ)` plots the array directivity pattern at the specified azimuth angle.

`pattern(sArray,FREQ,AZ,EL)` plots the array directivity pattern at specified azimuth and elevation angles.

`pattern( ___ ,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`[PAT,AZ_ANG,EL_ANG] = pattern( ___ )` returns the array pattern in `PAT`. The `AZ_ANG` output contains the coordinate values corresponding to the rows of `PAT`. The `EL_ANG` output contains the coordinate values corresponding to the columns of `PAT`. If the `'CoordinateSystem'` parameter is set to `'uv'`, then `AZ_ANG` contains the *U* coordinates of the pattern and `EL_ANG` contains the *V* coordinates of the pattern. Otherwise, they are in angular units in degrees. *UV* units are dimensionless.

Note: This method replaces the `plotResponse` method. See "Convert plotResponse to pattern" on page 1-706 for guidelines on how to use `pattern` in place of `plotResponse`.

Input Arguments

`sArray` — Heterogeneous conformal array

System object

Heterogeneous conformal array, specified as a phased.HeterogeneousConformalArray System object.

Example: `sArray= phased.HeterogeneousConformalArray;`

`FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `-Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `-Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

`AZ` — Azimuth angles

`[-180:180]` (default) | 1-by-*M* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a 1-by-*M* real-valued row vector where *M* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, this angle is positive.

Example: `[-45:2:45]`

Data Types: `double`

`EL` — Elevation angles

`[-90:90]` (default) | 1-by-*N* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a 1-by-*N* real-valued row vector where *N* is the number of desired elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and *xy*-plane. When measured towards the *z*-axis, this angle is positive.

Example: `[-75:1:70]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'CoordinateSystem'` — Plotting coordinate system

`'polar'` (default) | `'rectangular'` | `'uv'`

Plotting coordinate system of the pattern, specified as the comma-separated pair consisting of `'CoordinateSystem'` and one of `'polar'`, `'rectangular'`, or `'uv'`. When `'CoordinateSystem'` is set to `'polar'` or `'rectangular'`, the `AZ` and `EL` arguments specify the pattern azimuth and elevation, respectively. `AZ` values must lie between –180° and 180°. `EL` values must lie between –90° and 90°. If `'CoordinateSystem'` is set to `'uv'`, `AZ` and `EL` then specify *U* and *V* coordinates, respectively. `AZ` and `EL` must lie between -1 and 1.

Example: `'uv'`

Data Types: `char`

`'Type'` — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

`'Normalize'` — Display normalize pattern

`true` (default) | `false`

Display normalized pattern, specified as the comma-separated pair consisting of `'Normalize'` and a Boolean. Set this parameter to `true` to display a normalized pattern. When you set `'Type'` to `'directivity'`, this parameter does not apply. Directivity patterns are already normalized.

Example:

Data Types: `logical`

`'PlotStyle'` — Plotting style

`'overlay'` (default) | `'waterfall'`

Plotting style, specified as the comma-separated pair consisting of `'Plotstyle'` and either `'overlay'` or `'waterfall'`. This parameter applies when you specify multiple frequencies in `FREQ` in 2-D plots. You can draw 2-D plots by setting one of the arguments `AZ` or `EL` to a scalar.

Example:

Data Types: `char`

`'Polarization'` — Polarized field component

`'combined'` (default) | `'H'` | `'V'`

Polarized field component to display, specified as the comma-separated pair consisting of 'Polarization' and `'combined'`, `'H'`, or `'V'`. This parameter applies only when the sensors are polarization-capable and when the `'Type'` parameter is not set to `'directivity'`. This table shows the meaning of the display options

`'Polarization'`	Display
`'combined'`	Combined *H* and *V* polarization components
`'H'`	*H* polarization component
`'V'`	*V* polarization component

Example: `'V'`

Data Types: `char`

`'PropagationSpeed'` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

`'Weights'` — Array weights

1 (default) | *N*-by-1 complex-valued column vector | *N*-by-*L* complex-valued matrix

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *N*-by-1 complex-valued column vector or *N*-by-*L* complex-valued matrix. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *N* is the number of elements in the array. The dimension *L* is the number of frequencies specified by `FREQ`.

Weights Dimension	FREQ Dimension	Purpose
N-by-1 complex-valued column vector	Scalar or 1-by-*L* row vector	Applies a set of weights for the single frequency or for all *L* frequencies.
N-by-*L* complex-valued matrix	1-by-*L* row vector	Applies each of the *L* columns of `'Weights'` for

Weights Dimension	FREQ Dimension	Purpose
		the corresponding frequency in FREQ.

Note: Use complex weights to steer the array response toward different directions. You can create weights using the phased.SteeringVector System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as phased.Radiator or phased.Collector. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(N,M)`

Data Types: `double`
Complex Number Support: Yes

Output Arguments

PAT — Array pattern

M-by-*N* real-valued matrix

Array pattern, returned as an *M*-by-*N* real-valued matrix. The dimensions of PAT correspond to the dimensions of the output arguments AZ_ANG and EL_ANG.

AZ_ANG — Azimuth angles

scalar | 1-by-*M* real-valued row vector

Azimuth angles for displaying directivity or response pattern, returned as a scalar or 1-by-*M* real-valued row vector corresponding to the dimension set in AZ. The rows of PAT correspond to the values in AZ_ANG.

EL_ANG — Elevation angles

scalar | 1-by-*N* real-valued row vector

Elevation angles for displaying directivity or response, returned as a scalar or 1-by-*N* real-valued row vector corresponding to the dimension set in EL. The columns of PAT correspond to the values in EL_ANG.

Examples

Plot Power Patterns of 8-Element Heterogeneous Uniform Circular Array

Create an 8-element uniform circular array using the `HeterogeneousConformalArray` System object with two different types of short-dipole elements. Then, plot the 3-D and 2-D power patterns.

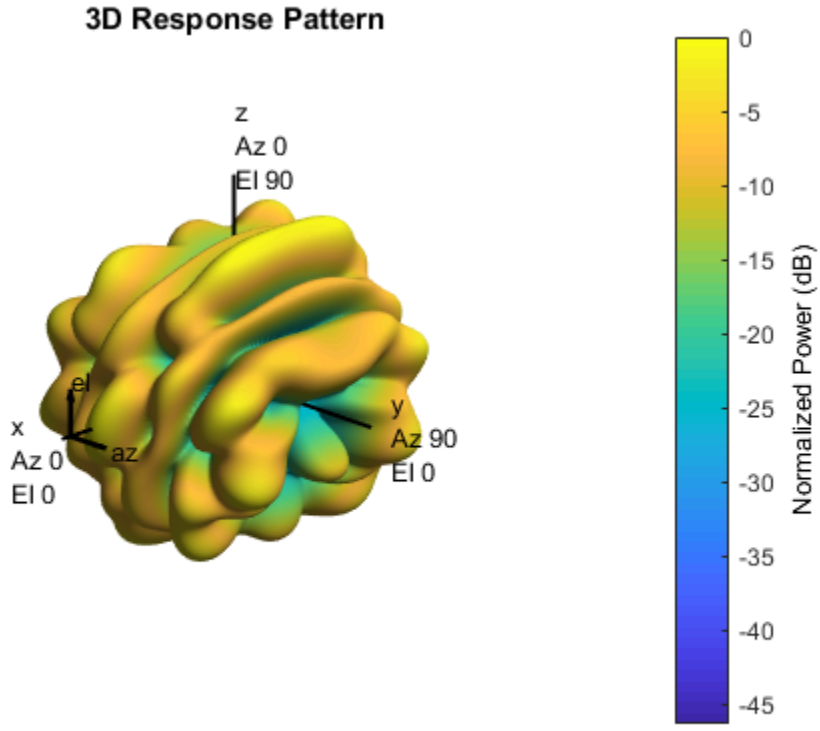
Create the array

```
sElement1 = phased.ShortDipoleAntennaElement('FrequencyRange',[1e9 5e9],...
    'AxisDirection','Z');
sElement2 = phased.ShortDipoleAntennaElement('FrequencyRange',[1e9 5e9],...
    'AxisDirection','Y');
N = 8;
azang = (0:N-1)*360/N-180;
sArray = phased.HeterogeneousConformalArray(...
    'ElementPosition',...
    0.4*[zeros(1,N);cosd(azang);sind(azang)],...
    'ElementNormal', zeros(2,N),...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 1 1 2 2 2 2]);
```

Plot 3-D power pattern

Assume the operating frequency is 1.5 GHz and the wave propagation speed is the speed of light.

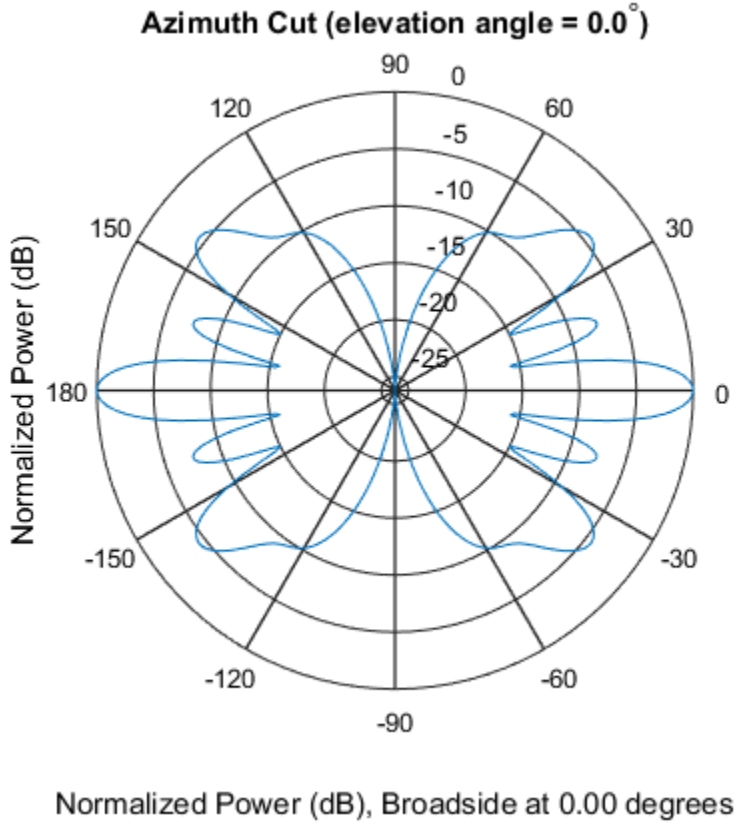
```
c = physconst('LightSpeed');
fc = 1.5e9;
pattern(sArray,fc,[-180:180],[-90:90],...
    'PropagationSpeed',c',...
    'CoordinateSystem','polar',...
    'Type','powerdb',...
    'Polarization','combined')
```



Plot 2-D power pattern

Take a cut of the 3-D power pattern at zero degrees elevation

```
pattern(sArray,fc,[-180:180],0,...
    'PropagationSpeed',c',...
    'CoordinateSystem','polar',...
    'Type','powerdb',...
    'Polarization','combined')
```



Plot pattern of disk array

Construct a 24-element disk array using elements with two different types of cosine antennas. Then, plot the array pattern.

Create the array

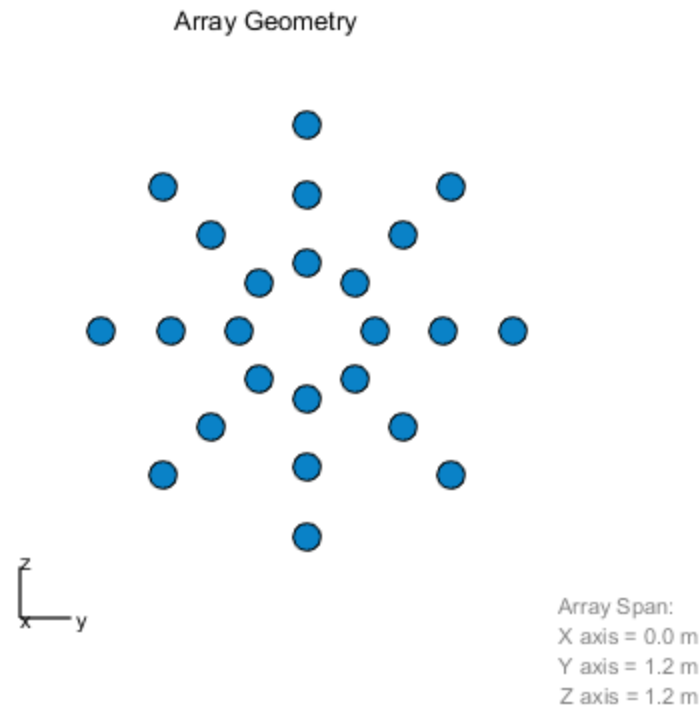
The array consists of cosine antenna elements with different power exponents.

```
sElement1 = phased.CosineAntennaElement('CosinePower',1.5);
sElement2 = phased.CosineAntennaElement('CosinePower',1.8);
N = 8;
azang = (0:N-1)*360/N-180;
p0 = [zeros(1,N);cosd(azang);sind(azang)];
```

```
posn = [0.6*p0, 0.4*p0, 0.2*p0];
sArray1 = phased.HeterogeneousConformalArray(...
    'ElementPosition',posn,...
    'ElementNormal', zeros(2,3*N),...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 1 1 1 1 1 1,...
    1 1 1 1 1 1 1 1,...
    2 2 2 2 2 2 2 2]);
```

View the disk array

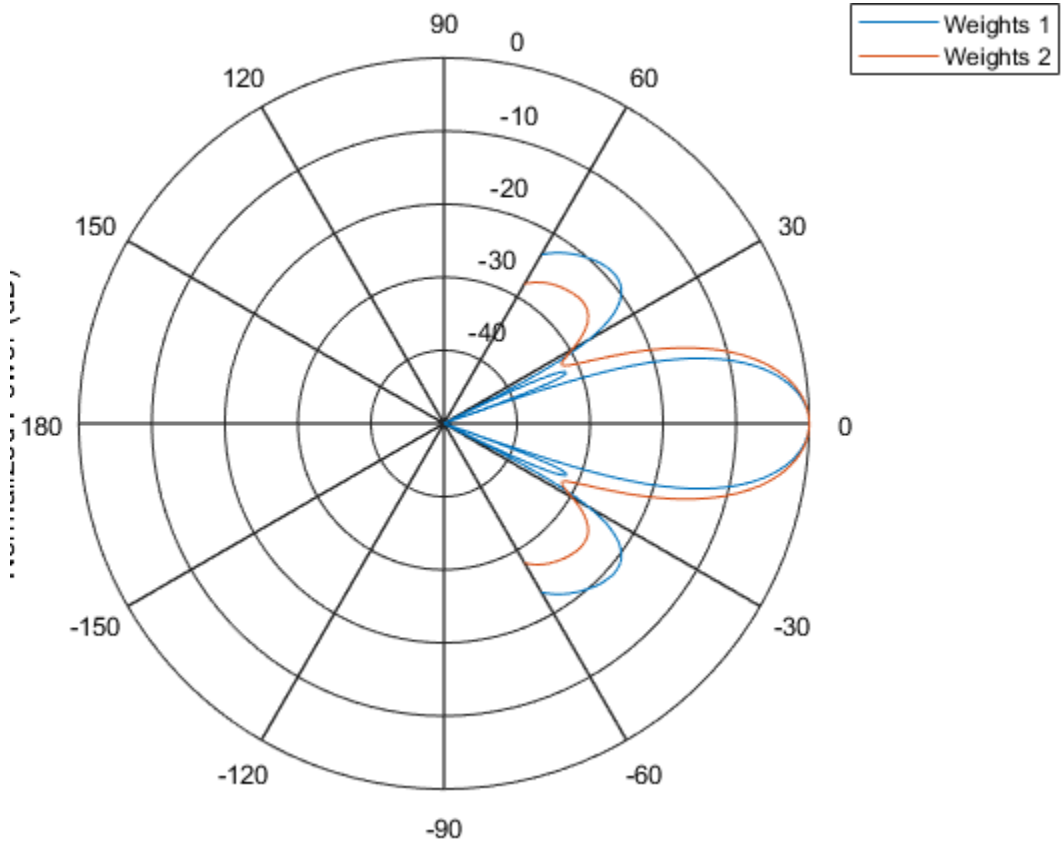
```
viewArray(sArray1)
```



Plot the power pattern

Plot the elevation power pattern of this array two different sets of element weights. The first set is uniform weights on the elements. The second set is a tapered set of weights set by the `Weights` parameter. Restrict the plot of the response from -60 to 60 degrees in 0.1 degree increments. Assume the operating frequency is 1 GHz and the wave propagation speed is the speed of light.

```
c = physconst('LightSpeed');
fc = 1e9;
wts1 = ones(3*N,1);
wts1 = wts1/sum(abs(wts1));
wts2 = [0.5*ones(N,1); 0.7*ones(N,1); 1*ones(N,1)];
wts2 = wts2/sum(abs(wts2));
pattern(sArray1,fc,0,[-60:0.1:60],'PropagationSpeed',c,...
    'CoordinateSystem','polar',...
    'Type','powerdb','Weights',[wts1,wts2])
```



As expected, the tapered weights broaden the mainlobe and reduce the sidelobes.

More About

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on "Element directivity" and "Array directivity".

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

Convert plotResponse to pattern

For antenna, microphone, and array System objects, the `pattern` method replaces the `plotResponse` method. In addition, two new simplified methods exist just to draw 2-D azimuth and elevation pattern plots. These methods are `azimuthPattern` and `elevationPattern`.

The following table is a guide for converting your code from using `plotResponse` to `pattern`. Notice that some of the inputs have changed from *input arguments* to *Name-Value* pairs and conversely. The general `pattern` method syntax is

```
pattern(H,FREQ,AZ,EL,'Name1','Value1',...,'NameN','ValueN')
```

plotResponse Inputs	plotResponse Description	pattern Inputs
`H` argument	Antenna, microphone, or array System object.	`H` argument (no change)
`FREQ` argument	Operating frequency.	`FREQ` argument (no change)

plotResponse Inputs	plotResponse Description	pattern Inputs
`V` argument	Propagation speed. This argument is used only for arrays.	`'PropagationSpeed'` name-value pair. This parameter is only used for arrays.

<table>
<tr><th>plotResponse Inputs</th><th>plotResponse Description</th><th>pattern Inputs</th></tr>
<tr>
<td>'Format' and 'RespCut' name-value pairs</td>
<td>These options work together to let you create a plot in angle space (line or polar style) or UV space. They also determine whether the plot is 2-D or 3-D. This table shows you how to create different types of plots using plotResponse.
<table>
<tr><th>Display space</th><th></th></tr>
<tr><td>Angle space (2D)</td><td>Set 'RespCut' to 'Az' or 'El'. Set 'Format' to 'line' or 'polar'.

phased.HeterogeneousConformalArray.patternAzimuth | phased.HeterogeneousConformalArray.patternElevation

Introduced in R2015a

patternAzimuth

System object: phased.HeterogeneousConformalArray
Package: phased

Plot heterogeneous conformal array directivity or pattern versus azimuth

Syntax

```
patternAzimuth(sArray,FREQ)
patternAzimuth(sArray,FREQ,EL)
patternAzimuth(sArray,FREQ,EL,Name,Value)
PAT = patternAzimuth( ___ )
```

Description

`patternAzimuth(sArray,FREQ)` plots the 2-D array directivity pattern versus azimuth (in dBi) for the array `sArray` at zero degrees elevation angle. The argument `FREQ` specifies the operating frequency.

`patternAzimuth(sArray,FREQ,EL)`, in addtion, plots the 2-D array directivity pattern versus azimuth (in dBi) for the array `sArray` at the elevation angle specified by `EL`. When `EL` is a vector, multiple overlaid plots are created.

`patternAzimuth(sArray,FREQ,EL,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternAzimuth( ___ )` returns the array pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Azimuth'` parameter and the `EL` input argument.

Input Arguments

`sArray` — Heterogeneous conformal array

System object

Heterogeneous conformal array, specified as a phased.HeterogeneousConformalArray System object.

Example: `sArray= phased.HeterogeneousConformalArray;`

`FREQ` — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

`EL` — Elevation angles

1-by-*N* real-valued row vector

Elevation angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector. The quantity *N* is the number of requested elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and the *xy* plane. When measured toward the *z*-axis, this angle is positive.

Example: `[0,10,20]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'Type' — Displayed pattern type

'directivity' (default) | 'efield' | 'power' | 'powerdb'

Displayed pattern type, specified as the comma-separated pair consisting of 'Type' and one of

- 'directivity' — directivity pattern measured in dBi.
- 'efield' — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- 'power' — power pattern of the sensor or array defined as the square of the field pattern.
- 'powerdb' — power pattern converted to dB.

Example: 'powerdb'

Data Types: char

'PropagationSpeed' — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of 'PropagationSpeed' and a positive scalar in meters per second.

Example: 'PropagationSpeed',physconst('LightSpeed')

Data Types: double

'Weights' — Array weights

M-by-1 complex-valued column vector

Array weights, specified as the comma-separated pair consisting of 'Weights' and an *M*-by-1 complex-valued column vector. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *M* is the number of elements in the array.

Note: Use complex weights to steer the array response toward different directions. You can create weights using the phased.SteeringVector System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as phased.Radiator or phased.Collector. However, for the directivity, pattern, patternAzimuth, and

`patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(10,1)`

Data Types: `double`
Complex Number Support: Yes

`'Azimuth'` — Azimuth angles

`[-180:180]` (default) | 1-by-*P* real-valued row vector

Azimuth angles, specified as the comma-separated pair consisting of `'Azimuth'` and a 1-by-*P* real-valued row vector. Azimuth angles define where the array pattern is calculated.

Example: `'Azimuth',[-90:2:90]`

Data Types: `double`

Output Arguments

`PAT` — Array directivity or pattern

L-by-*N* real-valued matrix

Array directivity or pattern, returned as an *L*-by-*N* rea-valued matrix. The dimension *L* is the number of azimuth values determined by the `'Azimuth'` name-value pair argument. The dimension *N* is the number of elevation angles, as determined by the `EL` input argument.

Examples

Plot azimuthal directivity pattern of disk array

Construct a 24-element disk array using elements with two different types of cosine antennas. Then, plot the array azimuthal directivity pattern.

Create the array

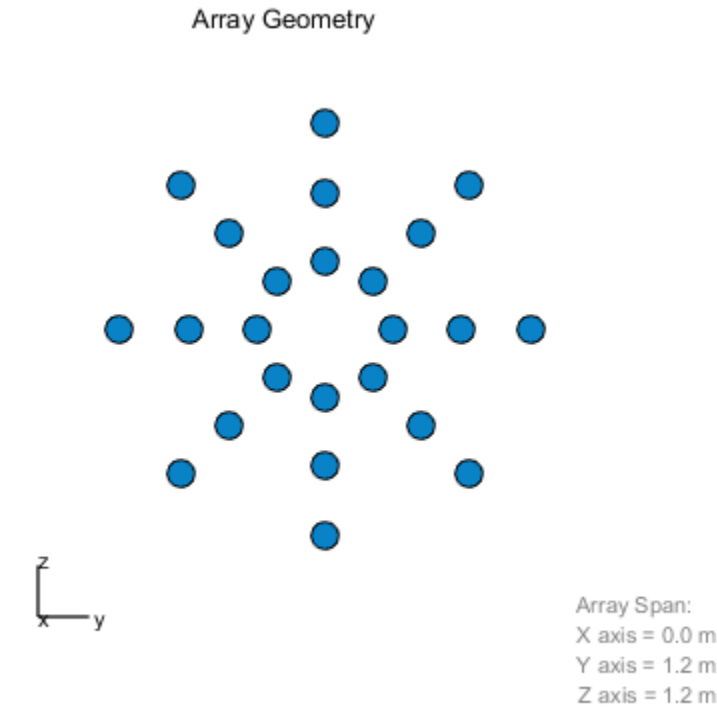
The array consists of cosine antenna elements with different power exponents.

```
sElement1 = phased.CosineAntennaElement('CosinePower',1.5);
sElement2 = phased.CosineAntennaElement('CosinePower',1.8);
```

```
N = 8;
azang = (0:N-1)*360/N-180;
p0 = [zeros(1,N);cosd(azang);sind(azang)];
posn = [0.6*p0, 0.4*p0, 0.2*p0];
sArray = phased.HeterogeneousConformalArray(...
    'ElementPosition',posn,...
    'ElementNormal', zeros(2,3*N),...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 1 1 1 1 1 1,...
    1 1 1 1 1 1 1 1,...
    2 2 2 2 2 2 2 2]);
```

View the disk array

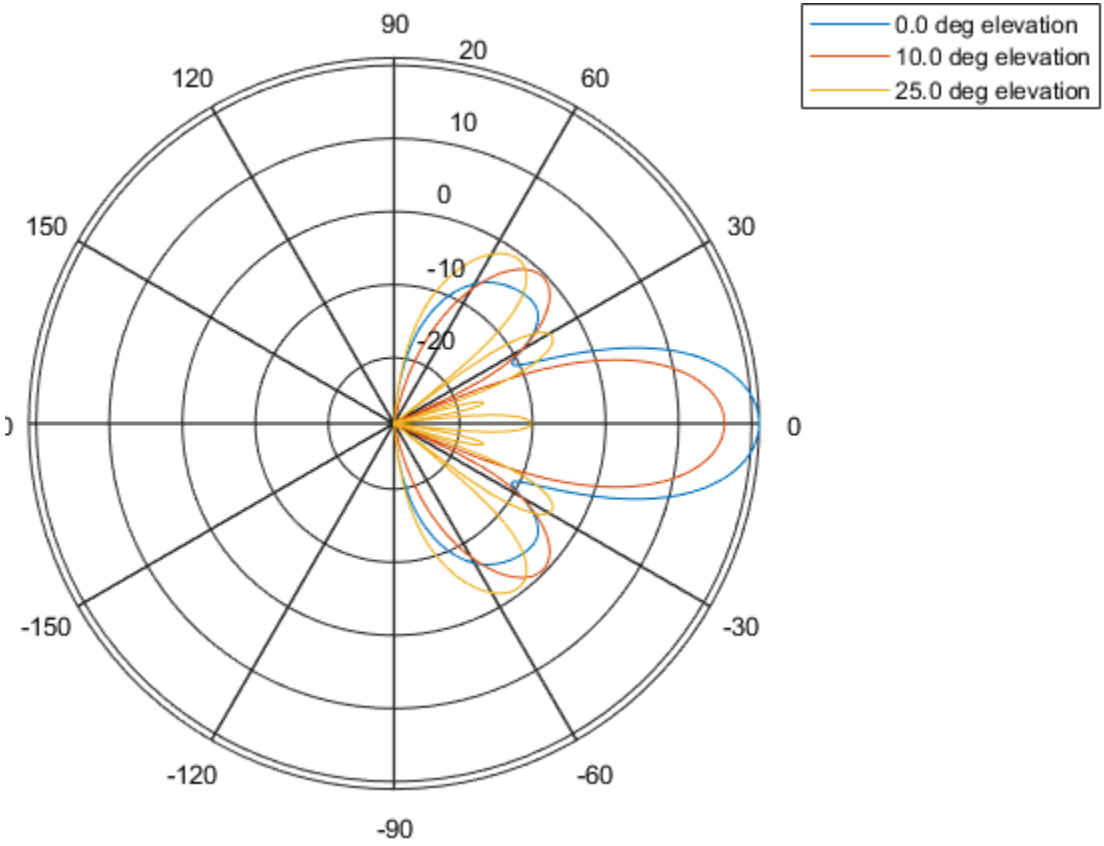
```
viewArray(sArray)
```



Plot the power pattern

Plot the azimuthal power pattern of this array for three different elevation angles: 0, 10 and 25 degrees. Apply radial tapering to the array. Assume the operating frequency is 1 GHz and the wave propagation speed is the speed of light.

```
c = physconst('LightSpeed');
fc = 1e9;
wts = [0.5*ones(N,1); 0.7*ones(N,1); 1.0*ones(N,1)];
wts = wts/sum(abs(wts));
patternAzimuth(sArray,fc,[0,10,25],'PropagationSpeed',c,...
    'Type','directivity','Weights',wts)
```



Definitions

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on "Element directivity" and "Array directivity".

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

phased.HeterogeneousConformalArray.patternElevation

Introduced in R2015a

patternElevation

System object: phased.HeterogeneousConformalArray
Package: phased

Plot heterogeneous conformal array directivity or pattern versus elevation

Syntax

```
patternElevation(sArray,FREQ)
patternElevation(sArray,FREQ,AZ)
patternElevation(sArray,FREQ,AZ,Name,Value)
PAT = patternElevation( ___ )
```

Description

`patternElevation(sArray,FREQ)` plots the 2-D array directivity pattern versus elevation (in dBi) for the array `sArray` at zero degrees azimuth angle. When `AZ` is a vector, multiple overlaid plots are created. The argument `FREQ` specifies the operating frequency.

`patternElevation(sArray,FREQ,AZ)`, in addition, plots the 2-D element directivity pattern versus elevation (in dBi) at the azimuth angle specified by `AZ`. When `AZ` is a vector, multiple overlaid plots are created.

`patternElevation(sArray,FREQ,AZ,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternElevation( ___ )` returns the array pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Elevation'` parameter and the `AZ` input argument.

Input Arguments

`sArray` — Heterogeneous conformal array

System object

Heterogeneous conformal array, specified as a phased.HeterogeneousConformalArray System object.

Example: `sArray= phased.HeterogeneousConformalArray;`

FREQ — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

AZ — Azimuth angles for computing directivity and pattern

1-by-*N* real-valued row vector

Azimuth angles for computing sensor or array directivities and patterns, specified as a 1-by-*M* real-valued row vector where *N* is the number of desired azimuth directions. Angle units are in degrees. The azimuth angle must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `[0,10,20]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'Type' — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

'PropagationSpeed' — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

'Weights' — Array weights

M-by-1 complex-valued column vector

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *M*-by-1 complex-valued column vector. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *M* is the number of elements in the array.

Note: Use complex weights to steer the array response toward different directions. You can create weights using the phased.SteeringVector System object or you can compute

your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as phased.Radiator or phased.Collector. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(10,1)`

Data Types: `double`
Complex Number Support: Yes

`'Elevation'` — Elevation angles

`[-90:90]` (default) | 1-by-*P* real-valued row vector

Elevation angles, specified as the comma-separated pair consisting of `'Elevation'` and a 1-by-*P* real-valued row vector. Elevation angles define where the array pattern is calculated.

Example: `'Elevation',[-90:2:90]`

Data Types: `double`

Output Arguments

`PAT` — Array directivity or pattern

L-by-*N* real-valued matrix

Array directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of elevation angles determined by the `'Elevation'` name-value pair argument. The dimension *N* is the number of azimuth angles determined by the `AZ` argument.

Examples

Plot elevation directivity pattern of disk array

Construct a 24-element disk array using elements with two different types of cosine antennas. Then, plot the array elevation directivity pattern.

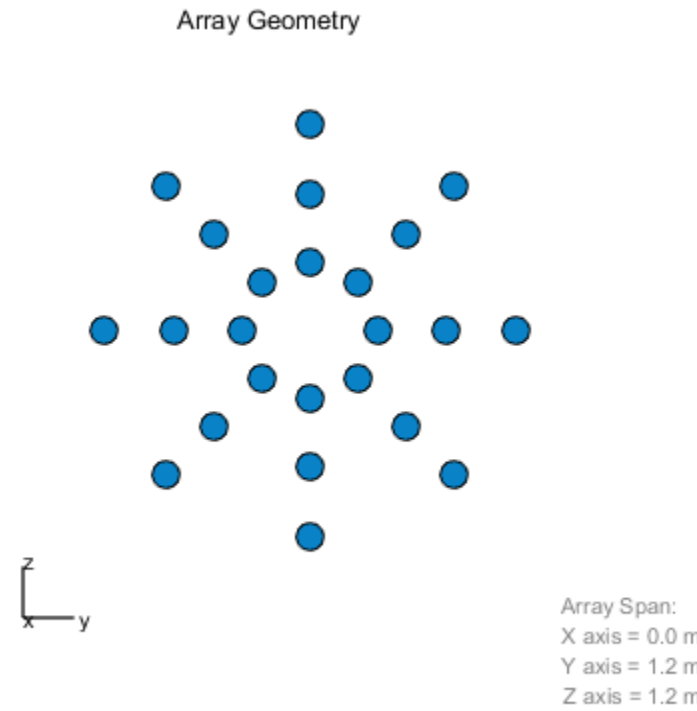
Create the array

The array consists of cosine antenna elements with different power exponents.

```
sElement1 = phased.CosineAntennaElement('CosinePower',1.5);
sElement2 = phased.CosineAntennaElement('CosinePower',1.8);
N = 8;
azang = (0:N-1)*360/N-180;
p0 = [zeros(1,N);cosd(azang);sind(azang)];
posn = [0.6*p0, 0.4*p0, 0.2*p0];
sArray = phased.HeterogeneousConformalArray(...
    'ElementPosition',posn,...
    'ElementNormal', zeros(2,3*N),...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 1 1 1 1 1 1,...
    1 1 1 1 1 1 1 1,...
    2 2 2 2 2 2 2 2]);
```

View the disk array

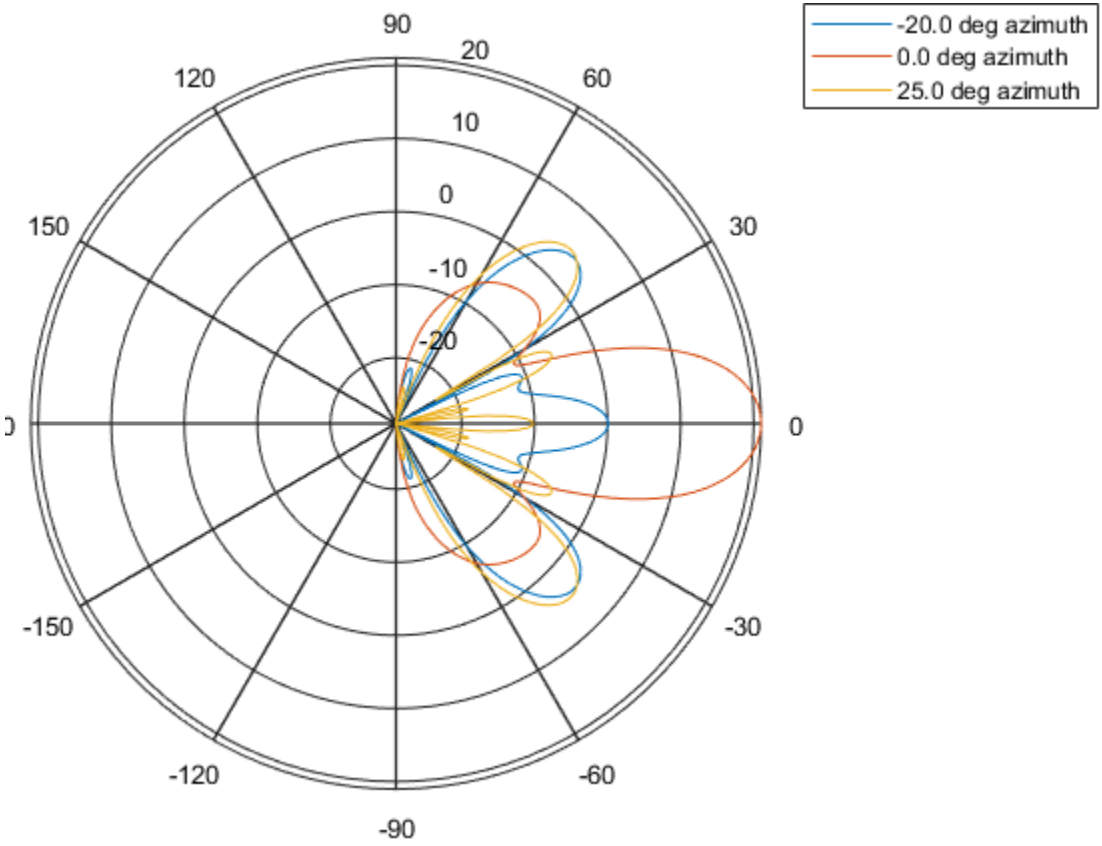
```
viewArray(sArray)
```



Plot the power pattern

Plot the elevation power pattern of this array for three different azimuth angles: 0, -20 and 25 degrees. Apply radial tapering to the array. Assume the operating frequency is 1 GHz and the wave propagation speed is the speed of light.

```
c = physconst('LightSpeed');
fc = 1e9;
wts = [0.5*ones(N,1); 0.7*ones(N,1); 1*ones(N,1)];
wts = wts/sum(abs(wts));
patternElevation(sArray,fc,[-20,0,25],'PropagationSpeed',c,...
    'Type','directivity','Weights',wts)
```



Definitions

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on "Element directivity" and "Array directivity".

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

Introduced in R2015a

plotResponse

System object: phased.HeterogeneousConformalArray
Package: phased

Plot response pattern of array

Syntax

```
plotResponse(H,FREQ,V)
plotResponse(H,FREQ,V,Name,Value)
hPlot = plotResponse(___)
```

Description

`plotResponse(H,FREQ,V)` plots the array response pattern along the azimuth cut, where the elevation angle is 0. The operating frequency is specified in `FREQ`. The propagation speed is specified in `V`.

`plotResponse(H,FREQ,V,Name,Value)` plots the array response with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = plotResponse(___)` returns handles of the lines or surface in the figure window, using any of the input arguments in the previous syntaxes.

Input Arguments

`H`

Array object

`FREQ`

Operating frequency in Hertz specified as a scalar or 1-by-*K* row vector. Values must lie within the range specified by a property of `H`. That property is named `FrequencyRange` or `FrequencyVector`, depending on the type of element in the array. The element has no response at frequencies outside that range. If you set the `'RespCut'` property of `H` to

`'3D'`, `FREQ` must be a scalar. When `FREQ` is a row vector, `plotResponse` draws multiple frequency responses on the same axes.

`V`

Propagation speed in meters per second.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'CutAngle'`

Cut angle as a scalar. This argument is applicable only when `RespCut` is `'Az'` or `'El'`. If `RespCut` is `'Az'`, `CutAngle` must be between –90 and 90. If `RespCut` is `'El'`, `CutAngle` must be between –180 and 180.

Default: `0`

`'Format'`

Format of the plot, using one of `'Line'`, `'Polar'`, or `'UV'`. If you set `Format` to `'UV'`, `FREQ` must be a scalar.

Default: `'Line'`

`'NormalizeResponse'`

Set this value to `true` to normalize the response pattern. Set this value to `false` to plot the response pattern without normalizing it. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

Default: `true`

`'OverlayFreq'`

Set this value to `true` to overlay pattern cuts in a 2-D line plot. Set this value to `false` to plot pattern cuts against frequency in a 3-D waterfall plot. If this value is `false`, `FREQ` must be a vector with at least two entries.

This parameter applies only when `Format` is not `'Polar'` and RespCut is not `'3D'`.

Default: `true`

`'Polarization'`

Specify the polarization options for plotting the array response pattern. The allowable values are `|'None' | 'Combined' | 'H' | 'V' |` where

- `'None'` specifies plotting a nonpolarized response pattern
- `'Combined'` specifies plotting a combined polarization response pattern
- `'H'` specifies plotting the horizontal polarization response pattern
- `'V'` specifies plotting the vertical polarization response pattern

For arrays that do not support polarization, the only allowed value is `'None'`. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

Default: `'None'`

`'RespCut'`

Cut of the response. Valid values depend on `Format`, as follows:

- If `Format` is `'Line'` or `'Polar'`, the valid values of `RespCut` are `'Az'`, `'El'`, and `'3D'`. The default is `'Az'`.
- If `Format` is `'UV'`, the valid values of `RespCut` are `'U'` and `'3D'`. The default is `'U'`.

If you set `RespCut` to `'3D'`, `FREQ` must be a scalar.

`'Unit'`

The unit of the plot. Valid values are `'db'`, `'mag'`, `'pow'`, or `'dbi'`. This parameter determines the type of plot that is produced.

Unit value	Plot type
`db`	power pattern in dB scale
`mag`	field pattern
`pow`	power pattern
`dbi`	directivity

Default: `'db'`

`'Weights'`

Weight values applied to the array, specified as a length-*N* column vector or *N*-by-*M* matrix. The dimension *N* is the number of elements in the array. The interpretation of *M* depends upon whether the input argument `FREQ` is a scalar or row vector.

Weights Dimensions	FREQ Dimension	Purpose
N-by-1 column vector	Scalar or 1-by-*M* row vector	Apply one set of weights for the same single frequency or all *M* frequencies.
N-by-*M* matrix	Scalar	Apply all of the *M* different columns in `Weights` for the same single frequency.
	1-by-*M* row vector	Apply each of the *M* different columns in `Weights` for the corresponding frequency in `FREQ`.

`'AzimuthAngles'`

Azimuth angles for plotting array response, specified as a row vector. The `AzimuthAngles` parameter sets the display range and resolution of azimuth angles for visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'Az'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of azimuth angles should lie between –180° and 180° and must be in nondecreasing order. When you set the `RespCut` parameter to `'3D'`, you can set the `AzimuthAngles` and `ElevationAngles` parameters simultaneously.

Default: `[-180:180]`

`'ElevationAngles'`

Elevation angles for plotting array response, specified as a row vector. The `ElevationAngles` parameter sets the display range and resolution of elevation angles for visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'El'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of elevation angles should lie between –90° and 90° and must be

in nondecreasing order. When yous set the `RespCut` parameter to `'3D'`, you can set the `ElevationAngles` and `AzimuthAngles` parameters simultaneously.

Default: `[-90:90]`

`'UGrid'`

U coordinate values for plotting array response, specified as a row vector. The `UGrid` parameter sets the display range and resolution of the *U* coordinates for visualizing the radiation pattern in *U*/*V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'U'` or `'3D'`. The values of `UGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set the `UGrid` and `VGrid` parameters simultaneously.

Default: `[-1:0.01:1]`

`'VGrid'`

V coordinate values for plotting array response, specified as a row vector. The `VGrid` parameter sets the display range and resolution of the *V* coordinates for visualizing the radiation pattern in *U*/*V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'3D'`. The values of `VGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set `VGrid` and `UGrid` parameters simultaneously.

Default: `[-1:0.01:1]`

Examples

Plot Response and Directivity of 8-Element Uniform Circular Array

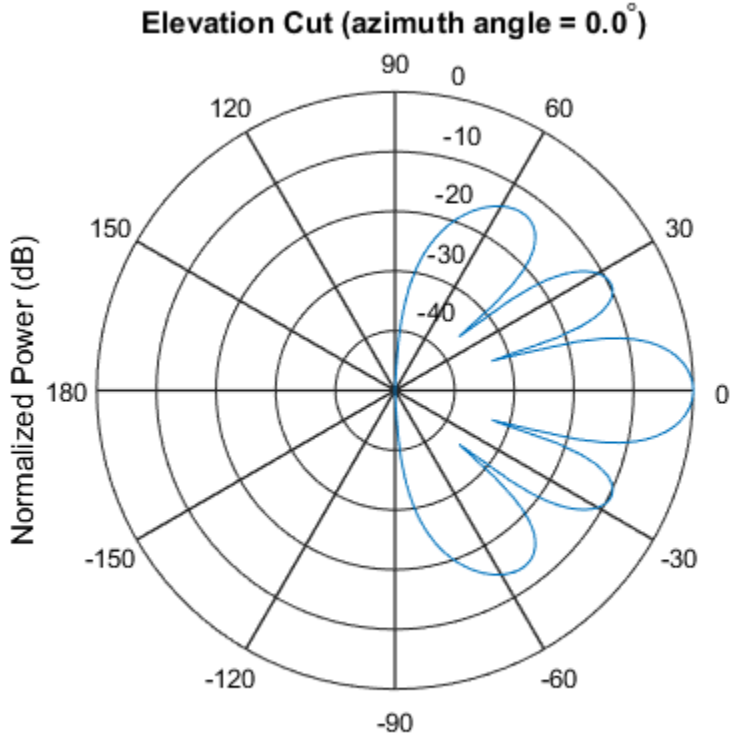
This example shows how to construct an 8-element uniform circular array (UCA) with two different antenna patterns.

```
sElement1 = phased.CosineAntennaElement('CosinePower',1.5);
sElement2 = phased.CosineAntennaElement('CosinePower',1.8);
N = 8; azang = (0:N-1)*360/N-180;
sArray = phased.HeterogeneousConformalArray(...
    'ElementPosition',...
    0.4*[zeros(1,N);cosd(azang);sind(azang)],...
    'ElementNormal', zeros(2,N),...
```

```
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 1 1 2 2 2 2]);
```

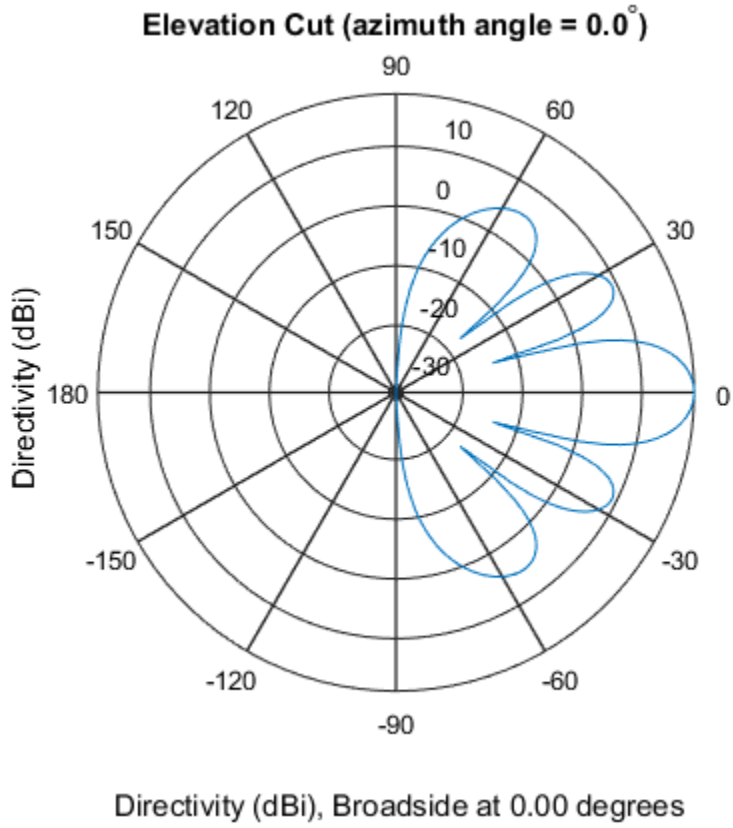
Plot its elevation response. Assume the operating frequency is 1 GHz and the wave propagation speed is the speed of light.

```
c = physconst('LightSpeed');
fc = 1e9;
plotResponse(sArray,fc,c,'RespCut','El','Format','Polar');
```



Plot the directivity.

```
plotResponse(sArray,fc,c,'RespCut','El','Format','Polar',...
    'Unit','dbi');
```



Plot Response of Disk Array

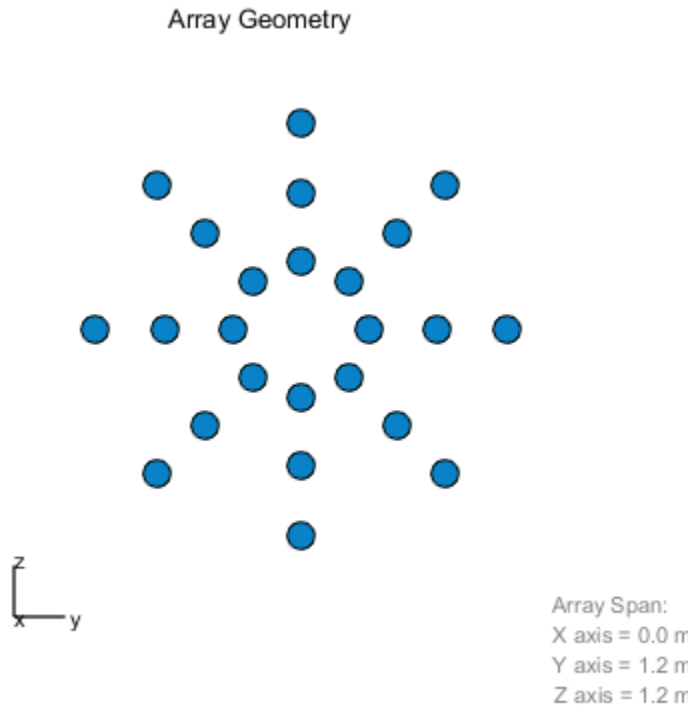
This example shows how to construct a 24-element disk array using elements with two different antenna patterns and plot its response.

```
sElement1 = phased.CosineAntennaElement('CosinePower',1.5);
sElement2 = phased.CosineAntennaElement('CosinePower',1.8);
N = 8; azang = (0:N-1)*360/N-180;
p0 = [zeros(1,N);cosd(azang);sind(azang)];
posn = [0.6*p0, 0.4*p0, 0.2*p0];
sArray1 = phased.HeterogeneousConformalArray(...
    'ElementPosition',posn,...
    'ElementNormal', zeros(2,3*N),...
    'ElementSet',{sElement1,sElement2},...
```

```
    'ElementIndices',[1 1 1 1 1 1 1 1,...
    1 1 1 1 1 1 1 1,...
    2 2 2 2 2 2 2 2]);
```

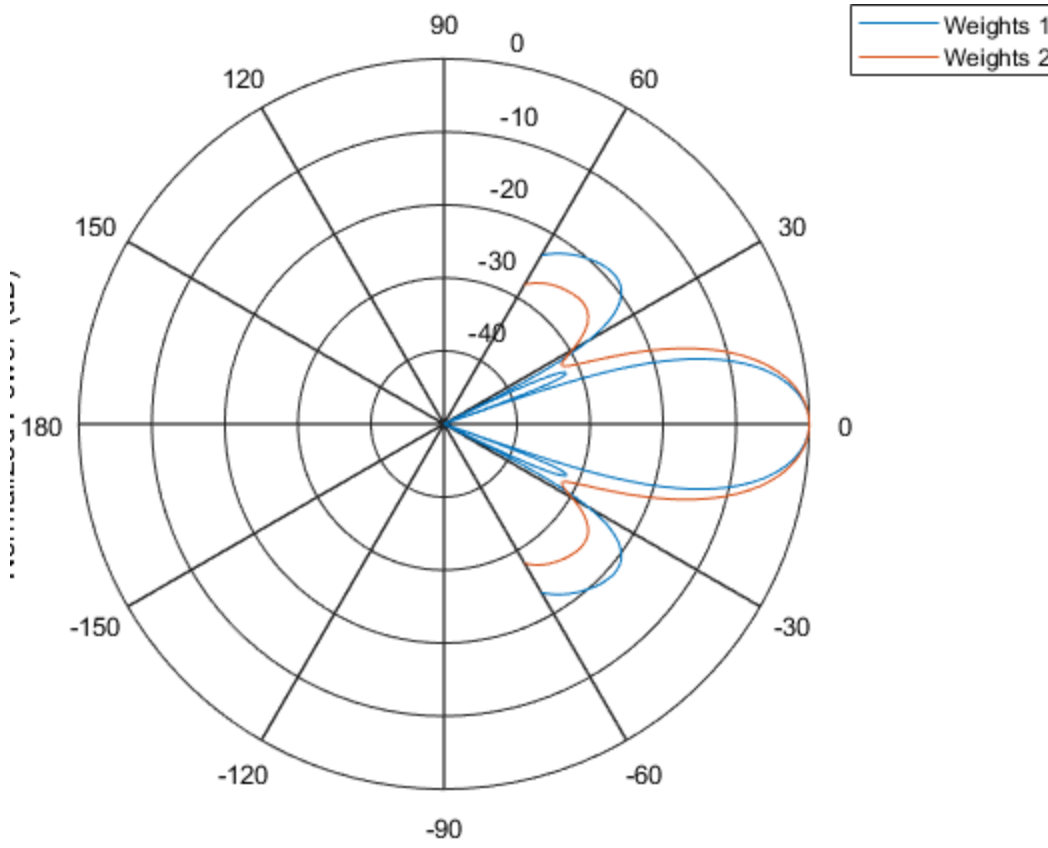
Show the array.

```
viewArray(sArray1);
```



Plot the elevation response of this array using uniform weights on the elements and also a tapered set of weights set by the `Weights` parameter. Using the `ElevationAngles` parameter, restrict the plot of the response from -60 to 60 degrees in 0.1 degree increments. Assume the operating frequency is 1 GHz and the wave propagation speed is the speed of light.

```
c = physconst('LightSpeed');
fc = 1e9;
wts1 = ones(3*N,1);
wts1 = wts1/sum(abs(wts1));
wts2 = [0.5*ones(N,1); 0.7*ones(N,1); 1*ones(N,1)];
wts2 = wts2/sum(abs(wts2));
plotResponse(sArray1,fc,c,'RespCut','El',...
    'Format','Polar',...
    'ElevationAngles',[-60:0.1:60],...
    'Weights',...
    [wts1,wts2],...
    'Unit','db');
```



As expected, the tapered weights broaden the mainlobe and reduce the sidelobes.

`azel2uv` | `uv2azel`

step

System object: phased.HeterogeneousConformalArray
Package: phased

Output responses of array elements

Syntax

```
RESP = step(H,FREQ,ANG)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`RESP = step(H,FREQ,ANG)` returns the array elements' responses `RESP` at operating frequencies specified in `FREQ` and directions specified in `ANG`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`H`

Array object

FREQ

Operating frequencies of array in hertz. FREQ is a row vector of length L. Typical values are within the range specified by a property of H.Element. That property is named FrequencyRange or FrequencyVector, depending on the type of element in the array. The element has zero response at frequencies outside that range.

ANG

Directions in degrees. ANG is either a 2-by-M matrix or a row vector of length M.

If ANG is a 2-by-M matrix, each column of the matrix specifies the direction in the form [azimuth; elevation]. The azimuth angle must lie between –180° and 180°, inclusive. The elevation angle must lie between –90° and 90°, inclusive.

If ANG is a row vector of length M, each element specifies the azimuth angle of the direction. In this case, the corresponding elevation angle is assumed to be 0°.

Output Arguments

RESP

Voltage responses of the phased array. The output depends on whether the array supports polarization or not.

- If the array is not capable of supporting polarization, the voltage response, RESP, has the dimensions N-by-M-by-L. N is the number of elements in the array. The dimension M is the number of angles specified in ANG. L is the number of frequencies specified in FREQ. For any element, the columns of RESP contain the responses of the array elements for the corresponding direction specified in ANG. Each of the L pages of RESP contains the responses of the array elements for the corresponding frequency specified in FREQ.
- If the array is capable of supporting polarization, the voltage response, RESP, is a MATLAB struct containing two fields, RESP.H and RESP.V. The field, RESP.H, represents the array's horizontal polarization response, while RESP.V represents the array's vertical polarization response. Each field has the dimensions N-by-M-by-L. N is the number of elements in the array, and M is the number of angles specified in ANG. L is the number of frequencies specified in FREQ. Each column of RESP contains the responses of the array elements for the corresponding direction specified in ANG. Each of the L pages of RESP contains the responses of the array elements for the corresponding frequency specified in FREQ.

Examples

Compute Response of Circular Conformal Array

Construct an 8-element uniform circular array using the `phased.HeterogeneousConformalArray` System object™. Assume the operating frequency is 1 GHz. Find the response of each element in this array in the direction of 30° azimuth and 5°.

```
antenna1 = phased.CosineAntennaElement('CosinePower',1.5);
antenna2 = phased.CosineAntennaElement('CosinePower',1.8);
N = 8;
azang = (0:N-1)*360/N-180;
array = phased.HeterogeneousConformalArray(...
    'ElementPosition',...
    [cosd(azang);sind(azang);zeros(1,N)],...
    'ElementNormal', zeros(2,N),...
    'ElementSet',{antenna1,antenna2},...
    'ElementIndices',[1 1 1 1 2 2 2 2]);
fc = 1e9;
ang = [30;5];
resp = array(fc,ang)
```

```
resp =

    0.8013
    0.8013
    0.8013
    0.8013
    0.7666
    0.7666
    0.7666
    0.7666
```

`phitheta2azel` | `uv2azel`

viewArray

System object: phased.HeterogeneousConformalArray
Package: phased

View array geometry

Syntax

```
viewArray(H)
viewArray(H,Name,Value)
hPlot = viewArray( ___ )
```

Description

`viewArray(H)` plots the geometry of the array specified in `H`.

`viewArray(H,Name,Value)` plots the geometry of the array, with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = viewArray( ___ )` returns the handle of the array elements in the figure window. All input arguments described for the previous syntaxes also apply here.

Input Arguments

`H`

Array object

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'ShowIndex'`

Vector specifying the element indices to show in the figure. Each number in the vector must be an integer between 1 and the number of elements. You can also specify the value `'All'` to show the indices of all elements of the array or `'None'` to suppress indices.

Default: `'None'`

`'ShowNormals'`

Set this value to `true` to show the normal directions of all elements of the array. Set this value to `false` to plot the elements without showing normal directions.

Default: `false`

`'ShowTaper'`

Set this value to `true` to specify whether to change the element color brightness in proportion to the element taper magnitude. When this value is set to `false`, all elements are drawn with the same color.

Default: `false`

`'Title'`

Character vector specifying the title of the plot.

Default: `'Array Geometry'`

Output Arguments

`hPlot`

Handle of array elements in figure window.

Examples

Element Positions and Normal Directions for Uniform Circular Array

Display the element positions and normal directions for all elements of an 8-element heterogeneous uniform circular array.

Create the elements and the array.

```
antenna1 = phased.CosineAntennaElement('CosinePower',1.5);
antenna2 = phased.CosineAntennaElement('CosinePower',1.8);
N = 8;
azang = (0:N-1)*360/N-180;
array = phased.HeterogeneousConformalArray(...
    'ElementPosition',...
    [cosd(azang);sind(azang);zeros(1,N)],...
    'ElementNormal', zeros(2,N),...
    'ElementSet',{antenna1,antenna2},...
    'ElementIndices',[1 1 1 1 2 2 2 2]);
viewArray(array,'ShowIndex','all','ShowNormal',true);
```

phased.HeterogeneousULA System object

Package: phased

Heterogeneous uniform linear array

Description

The `phased.HeterogeneousULA` object creates a uniform linear array from a heterogeneous set of antenna elements. A heterogeneous array is an array in which the antenna or microphone elements may be of different kinds or have different properties. An example would be an array of elements each having different antenna patterns.

To compute the response for each element in the array for specified directions:

1. Define and set up your uniform linear array. See "Construction" on page 1-745.
2. Call step to compute the response according to the properties of `phased.HeterogeneousULA`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.HeterogeneousULA` creates a heterogeneous uniform linear array (ULA) System object, `H`. The object models a heterogeneous ULA formed with generally different sensor elements. The origin of the local coordinate system is the phase center of the array. The positive *x*-axis is the direction normal to the array, and the elements of the array are located along the *y*-axis.

`H = phased.HeterogeneousULA(Name,Value)` creates object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`ElementSet`

Set of elements used in the array

Specify the set of different elements used in the sensor array as a row MATLAB cell array. Each member of the cell array contains an element object in the phased package. Elements specified in the `ElementSet` property must be either all antennas or all microphones. In addition, all specified antenna elements should have same polarization capability. Specify the element of the sensor array as a handle. The element must be an element object in the `phased` package.

Default: One cell containing one isotropic antenna element

`ElementIndices`

Elements location assignment

This property specifies the mapping of elements in the array. The property assigns elements to their locations in the array using indices into the `ElementSet` property. `ElementIndices` must be a 1-by-*N* row vector where *N* is greater than 1. *N* is the number of elements in the sensor array. The values in `ElementIndices` should be less than or equal to the number of entries in the `ElementSet` property.

Default: `[1 1]`

`ElementSpacing`

Element spacing

A scalar containing the spacing (in meters) between two adjacent elements in the array.

Default: `0.5`

`ArrayAxis`

Array axis

Array axis, specified as one of `'x'`, `'y'`, or `'z'`. ULA array elements are located along the selected coordinate system axis.

Element normal vectors are determined by the selected array axis

ArrayAxis Property Value	Element Normal Direction
`'x'`	azimuth = 90°, elevation = 0° (*y*-axis)
`'y'`	azimuth = 0°, elevation = 0° (*x*-axis)
`'z'`	azimuth = 0°, elevation = 0° (*x*-axis)

Default: `'y'`

`Taper`

Element tapering

Element tapering or weighting, specified as a complex-valued scalar, 1-by-*N* row vector, or *N*-by-1 column vector. The quantity *N* is the number of elements in the array as determined by the size of the `ElementIndices` property. Tapers, also known as weights, are applied to each sensor element in the sensor array and modify both the amplitude and phase of the received data. If `'Taper'` is a scalar, the same taper value is applied to all elements. If `'Taper'` is a vector, each taper value is applied to the corresponding sensor element.

Default: 1

Methods

directivity	Directivity of heterogeneous uniform linear array
collectPlaneWave	Simulate received plane waves
getElementNormal	Normal vector to array elements
getElementPosition	Positions of array elements
getNumElements	Number of elements in array
getTaper	Array element tapers
isPolarizationCapable	Polarization capability
pattern	Plot heterogeneous ULA pattern

patternAzimuth	Plot heterogeneous ULA directivity or pattern versus azimuth
patternElevation	Plot heterogeneous ULA directivity or pattern versus elevation
plotResponse	Plot response pattern of array
step	Output responses of array elements
viewArray	View array geometry

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Power pattern of 10-Element Heterogeneous ULA Array

Create a 10-element heterogeneous ULA consisting of cosine antenna elements with different power exponents. Two elements at each end have power values of 1.5 while the inside elements have power exponents of 1.8. Find the power pattern in dB of each element at boresight.

Construct the heterogeneous array and show the element responses at 1 GHz.

```
sElement1 = phased.CosineAntennaElement('CosinePower',1.5);
sElement2 = phased.CosineAntennaElement('CosinePower',1.8);
sArray = phased.HeterogeneousULA(...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 2 2 2 2 2 2 1 1 ]);
fc = 1e9;
ang = [0;0];
resp = step(sArray,fc,ang)
```

```
resp =

     1
     1

Pattern of Array of Polarized Short-Dipole Antennas

Construct a heterogeneous uniform line array of 10 short-dipole sensor elements. Because short dipoles support polarization, the array should also. Verify that the array supports polarization by looking at the output of `isPolarizationCapable`. Then, draw the array, showing the tapering.

Construct the array

Construct the array. Then, verify that it supports polarization by looking at the returned value of the `isPolarizationCapable` method.

```
sElement1 = phased.ShortDipoleAntennaElement(...
```

```
    'FrequencyRange',[100e6 1e9],...
    'AxisDirection','Z');
sElement2 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[100e6 1e9],...
    'AxisDirection','Y');
sArray = phased.HeterogeneousULA(...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 2 2 2 2 2 2 1 1 ],...
    'Taper',taylorwin(10)');
isPolarizationCapable(sArray)

directivity

System object: phased.HeterogeneousULA
Package: phased

Directivity of heterogeneous uniform linear array

Syntax

```
D = directivity(H,FREQ,ANGLE)
D = directivity(H,FREQ,ANGLE,Name,Value)
```

Description

`D = directivity(H,FREQ,ANGLE)` computes the "Directivity (dBi)" on page 1-760 of a heterogeneous uniform linear array of antenna or microphone elements, `H`, at frequencies specified by the `FREQ` and in angles of direction specified by the `ANGLE`.

`D = directivity(H,FREQ,ANGLE,Name,Value)` computes the directivity with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`H` — Heterogeneous uniform linear array

System object

Heterogeneous uniform linear array, specified as a phased.HeterogeneousULA System object.

Example: `H = phased.HeterogeneousULA;`

`FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

`ANGLE` — Angles for computing directivity

1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Angles for computing directivity, specified as a 1-by-*M* real-valued row vector or a 2-by-*M* real-valued matrix, where *M* is the number of angular directions. Angle units are in degrees. If `ANGLE` is a 2-by-*M* matrix, then each column specifies a direction in azimuth and elevation, `[az;el]`. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°.

If `ANGLE` is a 1-by-*M* vector, then each entry represents an azimuth angle, with the elevation angle assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis.

Example: `[45 60; 0 10]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'PropagationSpeed' — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of 'PropagationSpeed' and a positive scalar in meters per second.

Example: 'PropagationSpeed',physconst('LightSpeed')

Data Types: double

'Weights' — Array weights

1 (default) | *N*-by-1 complex-valued column vector | *N*-by-*L* complex-valued matrix

Array weights, specified as the comma-separated pair consisting of 'Weights' and an *N*-by-1 complex-valued column vector or *N*-by-*L* complex-valued matrix. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *N* is the number of elements in the array. The dimension *L* is the number of frequencies specified by FREQ.

Weights Dimension	FREQ Dimension	Purpose
N-by-1 complex-valued column vector	Scalar or 1-by-*L* row vector	Applies a set of weights for the single frequency or for all *L* frequencies.
N-by-*L* complex-valued matrix	1-by-*L* row vector	Applies each of the *L* columns of 'Weights' for the corresponding frequency in FREQ.

Note: Use complex weights to steer the array response toward different directions. You can create weights using the phased.SteeringVector System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as phased.Radiator or phased.Collector. However, for the directivity, pattern, patternAzimuth, and patternElevation methods of any array System object use the steering vector without conjugation.

Example: 'Weights',ones(N,M)

Data Types: double
Complex Number Support: Yes

Output Arguments

`D` — Directivity

M-by-*L* matrix

Directivity, returned as an *M*-by-*L* matrix whose columns contain the directivities at the *M* angles specified by `ANGLE`. Each column corresponds to one of the *L* frequency values specified in `FREQ`. Directivity units are in dBi.

Examples

Directivity of Heterogeneous Uniform Linear Array

Compute the directivity of a 10-element heterogeneous ULA consisting of cosine antenna elements with different power factors. The two elements at each end have power values of 1.5 while the inner elements have power values of 1.8.

Construct the heterogeneous array. Set the signal frequency to 1 GHz.

```
c = physconst('LightSpeed');
freq = 1e9;
ang = [30;0];
lambda = c/freq;
```

Create the cosine antenna elements.

```
myElement1 = phased.CosineAntennaElement;
myElement1.CosinePower = 1.5;
myElement2 = phased.CosineAntennaElement;
myElement2.CosinePower = 1.8;
```

Create the Heterogeneous ULA.

```
myArray = phased.HeterogeneousULA;
myArray.ElementSet = {myElement1,myElement2};
myArray.ElementIndices = [1 1 2 2 2 2 2 2 1 1 ];
myArray.ElementSpacing = 0.5*lambda;
```

Create the steering vector and compute the directivity in the same direction as the steering vector.

```
w = steervec(getElementPosition(myArray)/lambda,ang);
```

```
d = directivity(myArray,freq,ang,'PropagationSpeed',c,...
    'Weights',w)

d =

   17.0102
```

Definitions

Directivity (dBi)

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element directivity” and “Array directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

collectPlaneWave

System object: phased.HeterogeneousULA
Package: phased

Simulate received plane waves

Syntax

```
Y = collectPlaneWave(H,X,ANG)
Y = collectPlaneWave(H,X,ANG,FREQ)
Y = collectPlaneWave(H,X,ANG,FREQ,C)
```

Description

`Y = collectPlaneWave(H,X,ANG)` returns the received signals at the sensor array, `H`, when the input signals indicated by `X` arrive at the array from the directions specified in `ANG`.

`Y = collectPlaneWave(H,X,ANG,FREQ)`, in addition, specifies the incoming signal carrier frequency in `FREQ`.

`Y = collectPlaneWave(H,X,ANG,FREQ,C)`, in addition, specifies the signal propagation speed in `C`.

Input Arguments

`H`

Array object.

`X`

Incoming signals, specified as an M-column matrix. Each column of `X` represents an individual incoming signal.

ANG

Directions from which incoming signals arrive, in degrees. ANG can be either a 2-by-M matrix or a row vector of length M.

If ANG is a 2-by-M matrix, each column specifies the direction of arrival of the corresponding signal in X. Each column of ANG is in the form `[azimuth; elevation]`. The azimuth angle must be between –180° and 180°, inclusive. The elevation angle must be between –90° and 90°, inclusive.

If ANG is a row vector of length M, each entry in ANG specifies the azimuth angle. In this case, the corresponding elevation angle is assumed to be 0°.

FREQ

Carrier frequency of signal in hertz. FREQ must be a scalar.

Default: `3e8`

C

Propagation speed of signal in meters per second.

Default: Speed of light

Output Arguments

Y

Received signals. Y is an N-column matrix, where N is the number of elements in the array H. Each column of Y is the received signal at the corresponding array element, with all incoming signals combined.

Examples

Simulate Received Signals at Heterogeneous ULA

Simulate two received signal at a heterogeneous 4-element ULA. The signals arrive from 10° and 30° degrees azimuth. Both signals have an elevation angle of 0°. Assume the propagation speed is the speed of light and the carrier frequency of the signal is 100 MHz.

```
antenna1 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Z');
antenna2 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Y');
array = phased.HeterogeneousULA('ElementSet',{antenna1,antenna2}, ...
    'ElementIndices',[1 2 2 1]);
```

Create a random plane wave signals.

```
y = collectPlaneWave(array,randn(4,2),[10 30],1e8,physconst('LightSpeed'));
```

Display the signal at the first element.

```
y(:,1)
```

```
ans =

   0.7430 - 0.3705i
   0.8418 + 0.4308i
  -2.4817 + 0.9157i
   1.0724 - 0.4748i
```

Algorithms

`collectPlaneWave` modulates the input signal with a phase corresponding to the delay caused by the direction of arrival. The method does not account for the response of individual elements in the array.

For further details, see [1].

getElementNormal

System object: phased.HeterogeneousULA
Package: phased

Normal vector to array elements

Syntax

```
normvec = getElementNormal(sULA)
normvec = getElementNormal(sULA,elemidx)
```

Description

`normvec = getElementNormal(sULA)` returns the normal vectors of the array elements of the `phased.HeterogeneousULA` System object, `sULA`. The output argument `normvec` is a 2-by-*N* matrix, where *N* is the number of elements in array, `sULA`. Each column of `normvec` defines the normal direction of an element in the local coordinate system in the form `[az;el]`. Units are degrees. The origin of the local coordinate system is defined by the phase center of the array.

`normvec = getElementNormal(sULA,elemidx)` returns only the normal vectors of the elements specified in the element index vector, `elemidx`. This syntax can use any of the input arguments in the previous syntax.

Input Arguments

`sULA` — Uniform line array

`phased.HeterogeneousULA` System object

Uniform line array, specified as a `phased.HeterogeneousULA` System object.

Example: `sULA = phased.HeterogeneousULA`

`elemidx` — Element indices

all array elements (default) | integer-valued 1-by-*M* row vector | integer-valued *M*-by-1 column vector

Element indices , specified as a 1-by-*M* or *M*-by-1 vector. Index values lie in the range 1 to *N* where *N* is the number of elements of the array. When `elemidx` is specified, `getElementNormal` returns the normal vectors of the elements contained in `elemidx`.

Example: `[1,5,4]`

Output Arguments

`normvec` — Element normal vectors

2-by-*P* real-valued vector

Element normal vectors, specified as a 2-by-*P* real-valued vector. Each column of `normvec` takes the form `[az,el]`. When `elemidx` is not specified, *P* equals the array dimension. When `elemidx` is specified, *P* equals the length of `elemidx`, *M*.

Examples

Heterogeneous ULA Element Normals

Construct three 5-element heterogeneous ULA's with elements along the *x*-, *y*-, and *z*-axes. Obtain the element normals.

Create two types of cosine antennas.

```
sCosAnt1 = phased.CosineAntennaElement('CosinePower',[1.5,1.5]);
sCosAnt2 = phased.CosineAntennaElement('CosinePower',[1.8,1.8]);
```

First, choose the array axis to lie along the *x*-axis.

```
sULA1 = phased.HeterogeneousULA('ElementSet',{sCosAnt1,sCosAnt2},...
    'ElementIndices',[1 2 2 2 1],'ArrayAxis','x');
norm = getElementNormal(sULA1)
```

```
norm =

    90    90    90    90    90
     0     0     0     0     0
```

The element normal vectors point along the *y*-axis.

Next, choose the array axis along the *y*-axis.

```
sULA2 = phased.HeterogeneousULA('ElementSet',{sCosAnt1,sCosAnt2},...
    'ElementIndices',[1 2 2 2 1],'ArrayAxis','y');
norm = getElementNormal(sULA2)
```

```
norm =

     0     0     0     0     0
     0     0     0     0     0
```

The element normal vectors point along the *x*-axis.

Finally, set the array axis along the *z*-axis. Obtain the normal vectors of the odd-numbered elements.

```
sULA3 = phased.HeterogeneousULA('ElementSet',{sCosAnt1,sCosAnt2},...
    'ElementIndices',[1 2 2 2 1],'ArrayAxis','z');
norm = getElementNormal(sULA3,[1,3,5])
```

```
norm =

     0     0     0
     0     0     0
```

The element normal vectors also point along the *x*-axis.

Introduced in R2016a

getElementPosition

System object: phased.HeterogeneousULA
Package: phased

Positions of array elements

Syntax

```
pos = getElementPosition(sHULA)
pos = getElementPosition(sHULA,elemidx)
```

Description

`pos = getElementPosition(sHULA)` returns the element positions of the `phased.HeterogeneousULA` System object, `sHULA`. `pos` is a 3-by-*N* matrix, where *N* is the number of elements in `sHULA`. Each column of `pos` defines the position of an element in the local coordinate system, in meters, using the form `[x;y;z]`. The origin of the local coordinate system is the phase center of the array. The positions of the array elements depend upon the value of the `ArrayAxis` property.

`pos = getElementPosition(sHULA,elemidx)` returns only the positions of the elements that are specified in the element index vector `elemidx`. This syntax can use any of the input arguments in the previous syntax.

Examples

Position of Heterogeneous ULA Elements

Construct a 4-element heterogeneous ULA of different types of short-dipole antenna elements. Then, obtain the element positions.

```
sElement1 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[100e6 1e9],...
    'AxisDirection','Z');
sElement2 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[100e6 1e9],...
```

```
    'AxisDirection','Y');
sArray = phased.HeterogeneousULA(...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 2 2 1]);
pos = getElementPosition(sArray)

pos =

         0         0         0         0
   -0.7500   -0.2500    0.2500    0.7500
         0         0         0         0
```

getNumElements

System object: phased.HeterogeneousULA
Package: phased

Number of elements in array

Syntax

```
N = getNumElements(array)
```

Description

`N = getNumElements(array)` returns the number of elements, *N*, in the heterogeneous ULA object `array`.

Examples

Number of Elements of Heterogeneous ULA

Construct a 4-element heterogeneous ULA. Then verify the number of elements in the array.

```
antenna1 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Z');
antenna2 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Y');
array = phased.HeterogeneousULA('ElementSet',{antenna1,antenna2}, ...
    'ElementIndices',[1 2 2 1]);
N = getNumElements(array)
```

```
N =

     4
```

getTaper

System object: phased.HeterogeneousULA
Package: phased

Array element tapers

Syntax

```
wts = getTaper(array)
```

Description

`wts = getTaper(array)` returns the tapers, `wts`, applied to each element of the phased heterogeneous uniform line array (ULA), `h`. Tapers are often referred to as weights.

Input Arguments

`array` — Heterogeneous uniform line array

`phased.HeterogeneousULA` System object

Heterogeneous uniform line array, specified as a phased.HeterogeneousULA System object.

Output Arguments

`wts` — Array element tapers

N-by-1 complex-valued vector

Array element tapers returned as an *N*-by-1 complex-valued vector, where *N* is the number of elements in the array.

Examples

Heterogeneous ULA with Taylor Window Taper

Construct a 5-element heterogeneous ULA with a Taylor window taper. The array consists of short-dipole antenna elements with different orientations.Then, obtain the element taper values.

```
antenna1 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Z');
antenna2 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Y');
array = phased.HeterogeneousULA('ElementSet',{antenna1,antenna2}, ...
    'ElementIndices',[1 2 2 2 1],'Taper',taylorwin(5)');
w = getTaper(array)
```

```
w =

    0.5181
    1.2029
    1.5581
    1.2029
    0.5181
```

isPolarizationCapable

System object: phased.HeterogeneousULA
Package: phased

Polarization capability

Syntax

```
flag = isPolarizationCapable(array)
```

Description

`flag = isPolarizationCapable(array)` returns a Boolean value, `flag`, indicating whether the array supports polarization. An array supports polarization if all of its constituent sensor elements support polarization.

Input Arguments

`array` — Heterogeneous uniform line array

`phased.HeterogeneousULA` System object

Heterogeneous uniform line array, specified as a phased.HeterogeneousULA System object.

Output Arguments

`flag` — Polarization-capability flag

Polarization-capability flag, returned as a Boolean value `1` if the array supports polarization or `0` if it does not.

Examples

Heterogeneous ULA of Short-Dipole Antenna Elements Supports Polarization

Show that a heterogeneous array of short-dipole antenna elements supports polarization.

```
antenna1 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Z');
antenna2 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Y');
array = phased.HeterogeneousULA('ElementSet',{antenna1,antenna2}, ...
    'ElementIndices',[1 2 2 2 1]);
isPolarizationCapable(array)
```

```
ans =

  logical

   1
```

pattern

System object: phased.HeterogeneousULA
Package: phased

Plot heterogeneous ULA pattern

Syntax

```
pattern(sArray,FREQ)
pattern(sArray,FREQ,AZ)
pattern(sArray,FREQ,AZ,EL)
pattern( ___ ,Name,Value)
[PAT,AZ_ANG,EL_ANG] = pattern( ___ )
```

Description

`pattern(sArray,FREQ)` plots the 3-D array directivity pattern (in dBi) for the array specified in `sArray`. The operating frequency is specified in `FREQ`.

`pattern(sArray,FREQ,AZ)` plots the array directivity pattern at the specified azimuth angle.

`pattern(sArray,FREQ,AZ,EL)` plots the array directivity pattern at specified azimuth and elevation angles.

`pattern( ___ ,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`[PAT,AZ_ANG,EL_ANG] = pattern( ___ )` returns the array pattern in `PAT`. The `AZ_ANG` output contains the coordinate values corresponding to the rows of `PAT`. The `EL_ANG` output contains the coordinate values corresponding to the columns of `PAT`. If the `'CoordinateSystem'` parameter is set to `'uv'`, then `AZ_ANG` contains the *U* coordinates of the pattern and `EL_ANG` contains the *V* coordinates of the pattern. Otherwise, they are in angular units in degrees. *UV* units are dimensionless.

Note: This method replaces the `plotResponse` method. See "Convert plotResponse to pattern" on page 1-785 for guidelines on how to use `pattern` in place of `plotResponse`.

Input Arguments

`sArray` — Heterogeneous ULA

System object

Heterogeneous conformal array, specified as a phased.HeterogeneousULA System object.

Example: `sArray= phased.HeterogeneousULA;`

`FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `-Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `-Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

`AZ` — Azimuth angles

`[-180:180]` (default) | 1-by-*M* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a 1-by-*M* real-valued row vector where *M* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, this angle is positive.

Example: `[-45:2:45]`

Data Types: `double`

`EL` — Elevation angles

`[-90:90]` (default) | 1-by-*N* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a 1-by-*N* real-valued row vector where *N* is the number of desired elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and *xy*-plane. When measured towards the *z*-axis, this angle is positive.

Example: `[-75:1:70]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'CoordinateSystem'` — Plotting coordinate system

`'polar'` (default) | `'rectangular'` | `'uv'`

Plotting coordinate system of the pattern, specified as the comma-separated pair consisting of `'CoordinateSystem'` and one of `'polar'`, `'rectangular'`, or `'uv'`. When `'CoordinateSystem'` is set to `'polar'` or `'rectangular'`, the `AZ` and `EL` arguments specify the pattern azimuth and elevation, respectively. `AZ` values must lie between –180° and 180°. `EL` values must lie between –90° and 90°. If `'CoordinateSystem'` is set to `'uv'`, `AZ` and `EL` then specify *U* and *V* coordinates, respectively. `AZ` and `EL` must lie between -1 and 1.

Example: `'uv'`

Data Types: `char`

'Type' — Displayed pattern type
'directivity' (default) | 'efield' | 'power' | 'powerdb'

Displayed pattern type, specified as the comma-separated pair consisting of 'Type' and one of

- 'directivity' — directivity pattern measured in dBi.
- 'efield' — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- 'power' — power pattern of the sensor or array defined as the square of the field pattern.
- 'powerdb' — power pattern converted to dB.

Example: 'powerdb'

Data Types: char

'Normalize' — Display normalize pattern
true (default) | false

Display normalized pattern, specified as the comma-separated pair consisting of 'Normalize' and a Boolean. Set this parameter to true to display a normalized pattern. When you set 'Type' to 'directivity', this parameter does not apply. Directivity patterns are already normalized.

Example:

Data Types: logical

'PlotStyle' — Plotting style
'overlay' (default) | 'waterfall'

Plotting style, specified as the comma-separated pair consisting of 'Plotstyle' and either 'overlay' or 'waterfall'. This parameter applies when you specify multiple frequencies in FREQ in 2-D plots. You can draw 2-D plots by setting one of the arguments AZ or EL to a scalar.

Example:

Data Types: char

'Polarization' — Polarized field component
'combined' (default) | 'H' | 'V'

Polarized field component to display, specified as the comma-separated pair consisting of 'Polarization' and `'combined'`, `'H'`, or `'V'`. This parameter applies only when the sensors are polarization-capable and when the `'Type'` parameter is not set to `'directivity'`. This table shows the meaning of the display options

`'Polarization'`	Display
`'combined'`	Combined *H* and *V* polarization components
`'H'`	*H* polarization component
`'V'`	*V* polarization component

Example: `'V'`

Data Types: `char`

`'PropagationSpeed'` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

`'Weights'` — Array weights

1 (default) | *N*-by-1 complex-valued column vector | *N*-by-*L* complex-valued matrix

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *N*-by-1 complex-valued column vector or *N*-by-*L* complex-valued matrix. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *N* is the number of elements in the array. The dimension *L* is the number of frequencies specified by `FREQ`.

Weights Dimension	FREQ Dimension	Purpose
N-by-1 complex-valued column vector	Scalar or 1-by-*L* row vector	Applies a set of weights for the single frequency or for all *L* frequencies.
N-by-*L* complex-valued matrix	1-by-*L* row vector	Applies each of the *L* columns of `'Weights'` for

Weights Dimension	FREQ Dimension	Purpose
		the corresponding frequency in FREQ.

Note: Use complex weights to steer the array response toward different directions. You can create weights using the phased.SteeringVector System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as phased.Radiator or phased.Collector. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(N,M)`

Data Types: `double`
Complex Number Support: Yes

Output Arguments

PAT — Array pattern

M-by-*N* real-valued matrix

Array pattern, returned as an *M*-by-*N* real-valued matrix. The dimensions of PAT correspond to the dimensions of the output arguments AZ_ANG and EL_ANG.

AZ_ANG — Azimuth angles

scalar | 1-by-*M* real-valued row vector

Azimuth angles for displaying directivity or response pattern, returned as a scalar or 1-by-*M* real-valued row vector corresponding to the dimension set in AZ. The rows of PAT correspond to the values in AZ_ANG.

EL_ANG — Elevation angles

scalar | 1-by-*N* real-valued row vector

Elevation angles for displaying directivity or response, returned as a scalar or 1-by-*N* real-valued row vector corresponding to the dimension set in EL. The columns of PAT correspond to the values in EL_ANG.

Examples

Azimuth Power Pattern For Two Frequencies

Create a 5-element hetergeneous ULA from short-dipole antenna elements with different axis directions. Draw the azimuth power pattern for the horizontal polarization component at 0 degrees elevation for two frequencies, 300 MHz and 400 MHz.

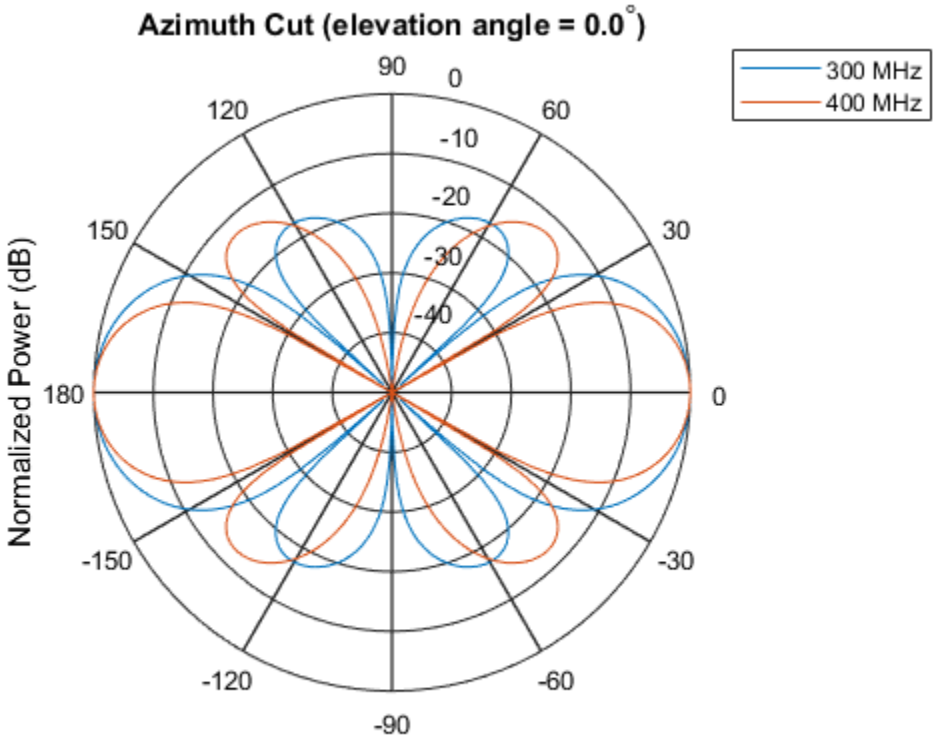
Construct Heterogeneous ULA

Construct the array from z-directed and y-directed short dipole antenna elements.

```
sElement1 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[2e8 5e8],...
    'AxisDirection','Z');
sElement2 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[2e8 5e8],...
    'AxisDirection','Y');
sArray = phased.HeterogeneousULA(...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 2 2 2 1]);
```

Plot the patterns

```
fc = [300e6 400e6];
c = physconst('LightSpeed');
pattern(sArray,fc,[-180:180],0,...
    'PropagationSpeed',c,...
    'CoordinateSystem','polar',...
    'Type','powerdb',...
    'PlotStyle','overlay',...
    'Polarization','H')
```



Normalized Power (dB), Broadside at 0.00 degrees

Directivity Pattern in UV Space

Create an 11-element hetergeneous ULA from short-dipole antenna elements with different axis directions. Draw the 3-D power pattern for the horizontal polarization component at 300 MHz.

Construct Heterogeneous ULA

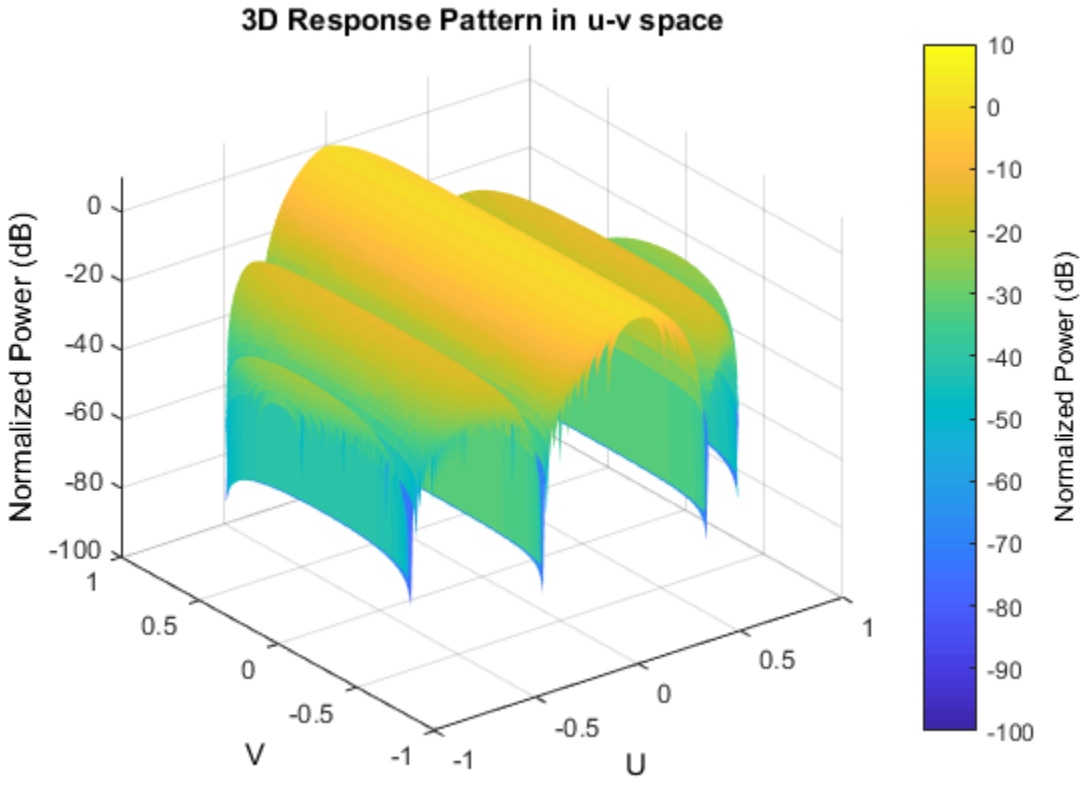
Construct the array from z-directed and y-directed short dipole antenna elements.

```
sElement1 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[2e8 5e8],...
    'AxisDirection','Z');
sElement2 = phased.ShortDipoleAntennaElement(...
```

```
    'FrequencyRange',[2e8 5e8],...
    'AxisDirection','Y');
sArray = phased.HeterogeneousULA(...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 1 2 2 2 2 2 1 1 1]);
```

Plot the patterns

```
fc = 300e6;
c = physconst('LightSpeed');
pattern(sArray,fc,[-1:.01:1],[-1:.01:1],...
    'PropagationSpeed',c,...
    'CoordinateSystem','uv',...
    'Type','powerdb',...
    'Polarization','H')
```



More About

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on "Element directivity" and "Array directivity".

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

Convert plotResponse to pattern

For antenna, microphone, and array System objects, the `pattern` method replaces the `plotResponse` method. In addition, two new simplified methods exist just to draw 2-D azimuth and elevation pattern plots. These methods are `azimuthPattern` and `elevationPattern`.

The following table is a guide for converting your code from using `plotResponse` to `pattern`. Notice that some of the inputs have changed from *input arguments* to *Name-Value* pairs and conversely. The general `pattern` method syntax is

```
pattern(H,FREQ,AZ,EL,'Name1','Value1',...,'NameN','ValueN')
```

plotResponse Inputs	plotResponse Description	pattern Inputs
`H` argument	Antenna, microphone, or array System object.	`H` argument (no change)
`FREQ` argument	Operating frequency.	`FREQ` argument (no change)

plotResponse Inputs	plotResponse Description	pattern Inputs
`V` argument	Propagation speed. This argument is used only for arrays.	`'PropagationSpeed'` name-value pair. This parameter is only used for arrays.

<table>
<tr><th>plotResponse Inputs</th><th>plotResponse Description</th><th>pattern Inputs</th></tr>
<tr>
<td>'Format' and 'RespCut' name-value pairs</td>
<td>These options work together to let you create a plot in angle space (line or polar style) or UV space. They also determine whether the plot is 2-D or 3-D. This table shows you how to create different types of plots using plotResponse.
<table>
<tr><th>Display space</th><th></th></tr>
<tr><td>Angle space (2D)</td><td>Set 'RespCut' to 'Az' or 'El'. Set 'Format' to 'line' or 'polar'.

Set the display axis using either the the 'AzimuthAngl or 'ElevationAn name-value pairs.</td></tr>

phased.HeterogeneousULA.patternAzimuth |
phased.HeterogeneousULA.patternElevation

Introduced in R2015a

patternAzimuth

System object: phased.HeterogeneousULA
Package: phased

Plot heterogeneous ULA directivity or pattern versus azimuth

Syntax

```
patternAzimuth(sArray,FREQ)
patternAzimuth(sArray,FREQ,EL)
patternAzimuth(sArray,FREQ,EL,Name,Value)
PAT = patternAzimuth( ___ )
```

Description

`patternAzimuth(sArray,FREQ)` plots the 2-D array directivity pattern versus azimuth (in dBi) for the array `sArray` at zero degrees elevation angle. The argument `FREQ` specifies the operating frequency.

`patternAzimuth(sArray,FREQ,EL)`, in addtion, plots the 2-D array directivity pattern versus azimuth (in dBi) for the array `sArray` at the elevation angle specified by `EL`. When `EL` is a vector, multiple overlaid plots are created.

`patternAzimuth(sArray,FREQ,EL,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternAzimuth( ___ )` returns the array pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Azimuth'` parameter and the `EL` input argument.

Input Arguments

`sArray` — Heterogeneous ULA

System object

Heterogeneous ULA, specified as a phased.HeterogeneousULA System object.

Example: `sArray= phased.HeterogeneousULA;`

FREQ — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `-Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `-Inf`.

Example: `1e8`

Data Types: `double`

EL — Elevation angles

1-by-*N* real-valued row vector

Elevation angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector. The quantity *N* is the number of requested elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and the *xy* plane. When measured toward the *z*-axis, this angle is positive.

Example: `[0,10,20]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Type'` — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

`'PropagationSpeed'` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

`'Weights'` — Array weights

M-by-1 complex-valued column vector

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *M*-by-1 complex-valued column vector. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *M* is the number of elements in the array.

Note: Use complex weights to steer the array response toward different directions. You can create weights using the phased.SteeringVector System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as phased.Radiator or phased.Collector. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(10,1)`

Data Types: `double`
Complex Number Support: Yes

`'Azimuth'` — Azimuth angles

`[-180:180]` (default) | 1-by-*P* real-valued row vector

Azimuth angles, specified as the comma-separated pair consisting of `'Azimuth'` and a 1-by-*P* real-valued row vector. Azimuth angles define where the array pattern is calculated.

Example: `'Azimuth',[-90:2:90]`

Data Types: `double`

Output Arguments

`PAT` — Array directivity or pattern

L-by-*N* real-valued matrix

Array directivity or pattern, returned as an *L*-by-*N* rea-valued matrix. The dimension *L* is the number of azimuth values determined by the `'Azimuth'` name-value pair argument. The dimension *N* is the number of elevation angles, as determined by the `EL` input argument.

Examples

Azimuth Directivity Pattern For Steered Array

Create an 11-element hetergeneous ULA from short-dipole antenna elements with different axis directions. The element spacing is 0.4 meters. Draw the azimuthal directivity pattern for 0 degrees elevation at an operating frequency of 300 MHz. Then, steer the array and draw the azimuthal directivity pattern.

Construct Heterogeneous ULA

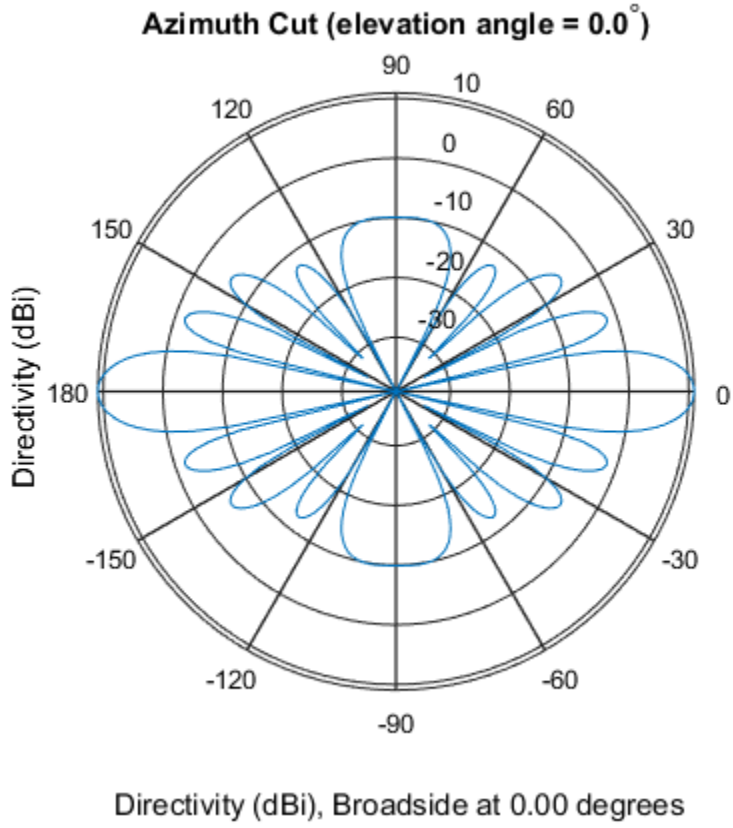
Construct the array from z-directed and y-directed short dipole antenna elements.

```
sElement1 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[200e6 500e6],...
    'AxisDirection','Z');
sElement2 = phased.ShortDipoleAntennaElement(...
```

```
    'FrequencyRange',[200e6 500e6],...
    'AxisDirection','Y');
sArray = phased.HeterogeneousULA(...
    'ElementSpacing',0.4,...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 1 2 2 2 2 2 1 1 1]);
```

Plot Directivity Pattern

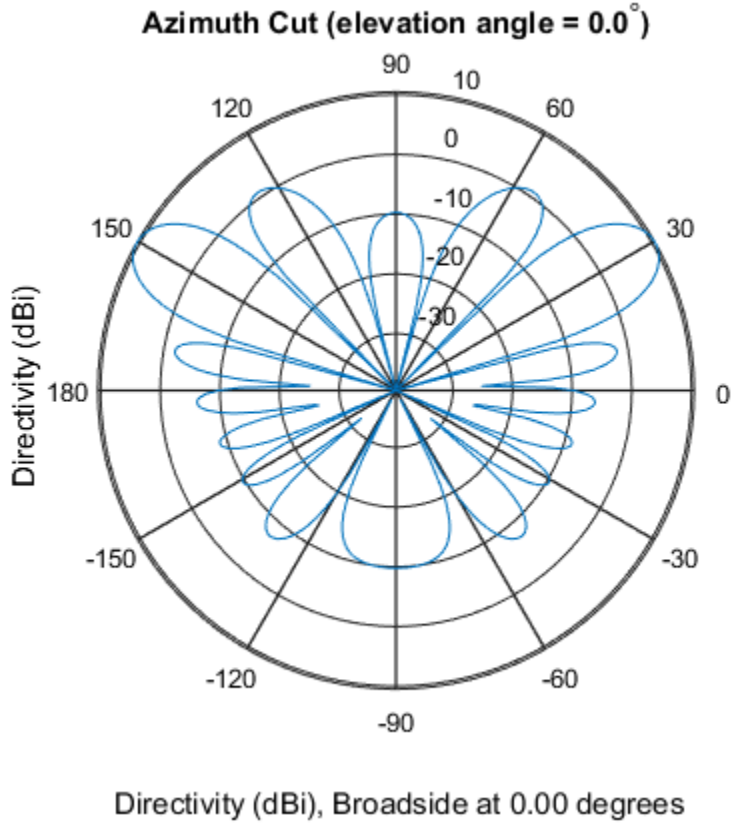
```
fc = 300e6;
c = physconst('LightSpeed');
lam = c/fc;
patternAzimuth(sArray,fc,0,...
    'PropagationSpeed',c,...
    'Type','directivity')
```



Steer Array and Plot Directivity Pattern

Steer the array to 30 degrees in azimuth by applying weights to achieve a linear phase shift.

```
theta = 30;
d = [0:10]*0.4;
ph = 2*pi*d'/lam*sind(theta);
wts = exp(1i*ph);
patternAzimuth(sArray,fc,0,...
    'PropagationSpeed',c,...
    'Type','directivity',....
    'Weights',wts)
```



Definitions

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on "Element directivity" and "Array directivity".

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

phased.HeterogeneousULA.pattern | phased.HeterogeneousULA.patternElevation

Introduced in R2015a

patternElevation

System object: phased.HeterogeneousULA
Package: phased

Plot heterogeneous ULA directivity or pattern versus elevation

Syntax

```
patternElevation(sArray,FREQ)
patternElevation(sArray,FREQ,AZ)
patternElevation(sArray,FREQ,AZ,Name,Value)
PAT = patternElevation( ___ )
```

Description

`patternElevation(sArray,FREQ)` plots the 2-D array directivity pattern versus elevation (in dBi) for the array `sArray` at zero degrees azimuth angle. When `AZ` is a vector, multiple overlaid plots are created. The argument `FREQ` specifies the operating frequency.

`patternElevation(sArray,FREQ,AZ)`, in addition, plots the 2-D element directivity pattern versus elevation (in dBi) at the azimuth angle specified by `AZ`. When `AZ` is a vector, multiple overlaid plots are created.

`patternElevation(sArray,FREQ,AZ,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternElevation( ___ )` returns the array pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Elevation'` parameter and the `AZ` input argument.

Input Arguments

`sArray` — Heterogeneous ULA

System object

Heterogeneous ULA array, specified as a phased.HeterogeneousULA System object.

Example: `sArray= phased.HeterogeneousULA;`

FREQ — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

AZ — Azimuth angles for computing directivity and pattern

1-by-*N* real-valued row vector

Azimuth angles for computing sensor or array directivities and patterns, specified as a 1-by-*M* real-valued row vector where *N* is the number of desired azimuth directions. Angle units are in degrees. The azimuth angle must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `[0,10,20]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Type'` — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

`'PropagationSpeed'` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

`'Weights'` — Array weights

M-by-1 complex-valued column vector

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *M*-by-1 complex-valued column vector. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *M* is the number of elements in the array.

Note: Use complex weights to steer the array response toward different directions. You can create weights using the phased.SteeringVector System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in

any Phased Array System Toolbox function or System object such as phased.Radiator or phased.Collector. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(10,1)`

Data Types: `double`
Complex Number Support: Yes

`'Elevation'` — Elevation angles

`[-90:90]` (default) | 1-by-*P* real-valued row vector

Elevation angles, specified as the comma-separated pair consisting of `'Elevation'` and a 1-by-*P* real-valued row vector. Elevation angles define where the array pattern is calculated.

Example: `'Elevation',[-90:2:90]`

Data Types: `double`

Output Arguments

`PAT` — Array directivity or pattern

L-by-*N* real-valued matrix

Array directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of elevation angles determined by the `'Elevation'` name-value pair argument. The dimension *N* is the number of azimuth angles determined by the `AZ` argument.

Examples

Elevation Power Pattern For Two Azimuth Directions

Create an 11-element hetergeneous ULA from short-dipole antenna elements with different axis directions. The element spacing is 0.4 meters. Draw the elevation power pattern for 0 and 30 degrees azimuth for 300 MHz.

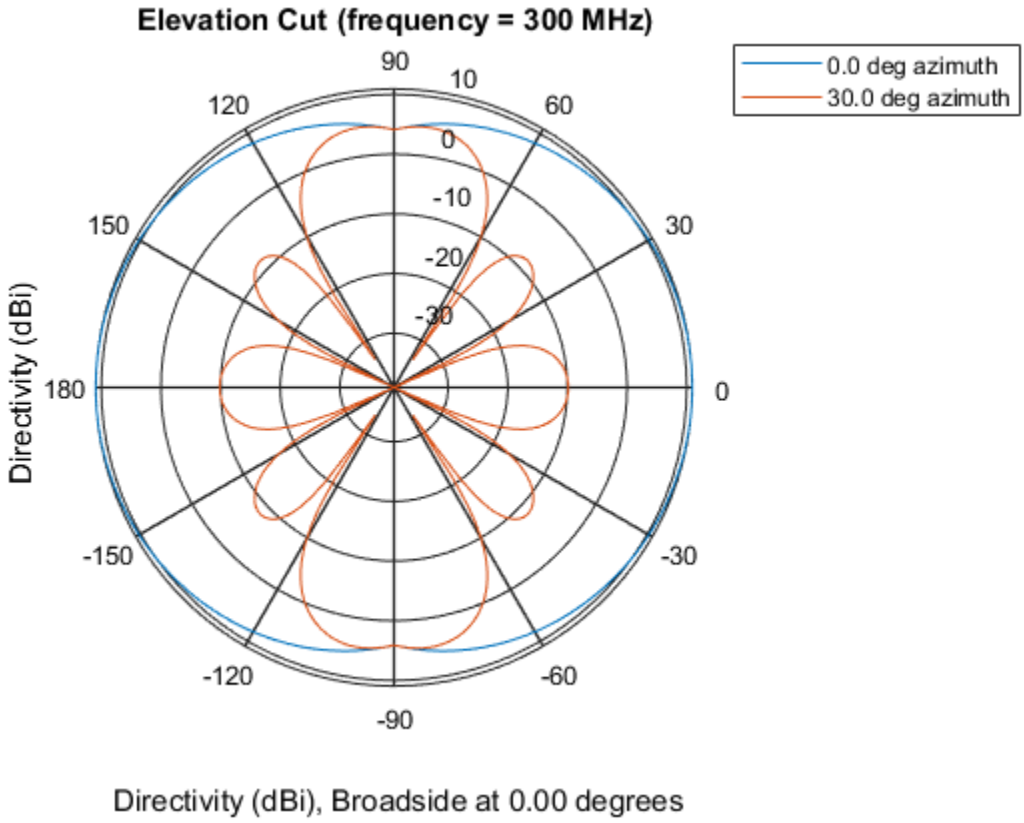
Construct Heterogeneous ULA

Construct the array from z-directed and y-directed short dipole antenna elements.

```
sElement1 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[200e6 500e6],...
    'AxisDirection','Z');
sElement2 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[200e6 500e6],...
    'AxisDirection','Y');
sArray = phased.HeterogeneousULA(...
    'ElementSpacing',0.4,...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 1 2 2 2 2 2 1 1 1]);
```

Plot Directivity Pattern

```
fc = 300e6;
c = physconst('LightSpeed');
patternElevation(sArray,fc,[0,30],...
    'PropagationSpeed',c,...
    'Type','directivity')
```



Definitions

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on "Element directivity" and "Array directivity".

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

Introduced in R2015a

plotResponse

System object: phased.HeterogeneousULA
Package: phased

Plot response pattern of array

Syntax

```
plotResponse(H,FREQ,V)
plotResponse(H,FREQ,V,Name,Value)
hPlot = plotResponse(___)
```

Description

`plotResponse(H,FREQ,V)` plots the array response pattern along the azimuth cut, where the elevation angle is 0. The operating frequency is specified in `FREQ`. The propagation speed is specified in `V`.

`plotResponse(H,FREQ,V,Name,Value)` plots the array response with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = plotResponse(___)` returns handles of the lines or surface in the figure window, using any of the input arguments in the previous syntaxes.

Input Arguments

`H`

Array object

`FREQ`

Operating frequency in Hertz specified as a scalar or 1-by-*K* row vector. Values must lie within the range specified by a property of `H`. That property is named `FrequencyRange` or `FrequencyVector`, depending on the type of element in the array. The element has no response at frequencies outside that range. If you set the `'RespCut'` property of `H` to

`'3D'`, `FREQ` must be a scalar. When `FREQ` is a row vector, `plotResponse` draws multiple frequency responses on the same axes.

`V`

Propagation speed in meters per second.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'CutAngle'`

Cut angle as a scalar. This argument is applicable only when `RespCut` is `'Az'` or `'El'`. If `RespCut` is `'Az'`, `CutAngle` must be between –90 and 90. If `RespCut` is `'El'`, `CutAngle` must be between –180 and 180.

Default: `0`

`'Format'`

Format of the plot, using one of `'Line'`, `'Polar'`, or `'UV'`. If you set `Format` to `'UV'`, `FREQ` must be a scalar.

Default: `'Line'`

`'NormalizeResponse'`

Set this value to `true` to normalize the response pattern. Set this value to `false` to plot the response pattern without normalizing it. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

Default: `true`

`'OverlayFreq'`

Set this value to `true` to overlay pattern cuts in a 2-D line plot. Set this value to `false` to plot pattern cuts against frequency in a 3-D waterfall plot. If this value is `false`, `FREQ` must be a vector with at least two entries.

This parameter applies only when `Format` is not `'Polar'` and RespCut is not `'3D'`.

Default: `true`

`'Polarization'`

Specify the polarization options for plotting the array response pattern. The allowable values are `|'None' | 'Combined' | 'H' | 'V' |` where

- `'None'` specifies plotting a nonpolarized response pattern
- `'Combined'` specifies plotting a combined polarization response pattern
- `'H'` specifies plotting the horizontal polarization response pattern
- `'V'` specifies plotting the vertical polarization response pattern

For arrays that do not support polarization, the only allowed value is `'None'`. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

Default: `'None'`

`'RespCut'`

Cut of the response. Valid values depend on `Format`, as follows:

- If `Format` is `'Line'` or `'Polar'`, the valid values of `RespCut` are `'Az'`, `'El'`, and `'3D'`. The default is `'Az'`.
- If `Format` is `'UV'`, the valid values of `RespCut` are `'U'` and `'3D'`. The default is `'U'`.

If you set `RespCut` to `'3D'`, `FREQ` must be a scalar.

`'Unit'`

The unit of the plot. Valid values are `'db'`, `'mag'`, `'pow'`, or `'dbi'`. This parameter determines the type of plot that is produced.

Unit value	Plot type
`db`	power pattern in dB scale
`mag`	field pattern
`pow`	power pattern
`dbi`	directivity

Default: `'db'`

`'Weights'`

Weight values applied to the array, specified as a length-*N* column vector or *N*-by-*M* matrix. The dimension *N* is the number of elements in the array. The interpretation of *M* depends upon whether the input argument `FREQ` is a scalar or row vector.

Weights Dimensions	FREQ Dimension	Purpose
N-by-1 column vector	Scalar or 1-by-*M* row vector	Apply one set of weights for the same single frequency or all *M* frequencies.
N-by-*M* matrix	Scalar	Apply all of the *M* different columns in `Weights` for the same single frequency.
	1-by-*M* row vector	Apply each of the *M* different columns in `Weights` for the corresponding frequency in `FREQ`.

`'AzimuthAngles'`

Azimuth angles for plotting array response, specified as a row vector. The `AzimuthAngles` parameter sets the display range and resolution of azimuth angles for visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'Az'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of azimuth angles should lie between –180° and 180° and must be in nondecreasing order. When you set the `RespCut` parameter to `'3D'`, you can set the `AzimuthAngles` and `ElevationAngles` parameters simultaneously.

Default: `[-180:180]`

`'ElevationAngles'`

Elevation angles for plotting array response, specified as a row vector. The `ElevationAngles` parameter sets the display range and resolution of elevation angles for visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'El'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of elevation angles should lie between –90° and 90° and must be in nondecreasing order. When yous set the `RespCut` parameter to `'3D'`, you can set the `ElevationAngles` and `AzimuthAngles` parameters simultaneously.

Default: `[-90:90]`

`'UGrid'`

U coordinate values for plotting array response, specified as a row vector. The `UGrid` parameter sets the display range and resolution of the *U* coordinates for visualizing the radiation pattern in *U*/*V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'U'` or `'3D'`. The values of `UGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set the `UGrid` and `VGrid` parameters simultaneously.

Default: `[-1:0.01:1]`

`'VGrid'`

V coordinate values for plotting array response, specified as a row vector. The `VGrid` parameter sets the display range and resolution of the *V* coordinates for visualizing the radiation pattern in *U*/*V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'3D'`. The values of `VGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set `VGrid` and `UGrid` parameters simultaneously.

Default: `[-1:0.01:1]`

Examples

Line Plot Showing Multiple Frequencies

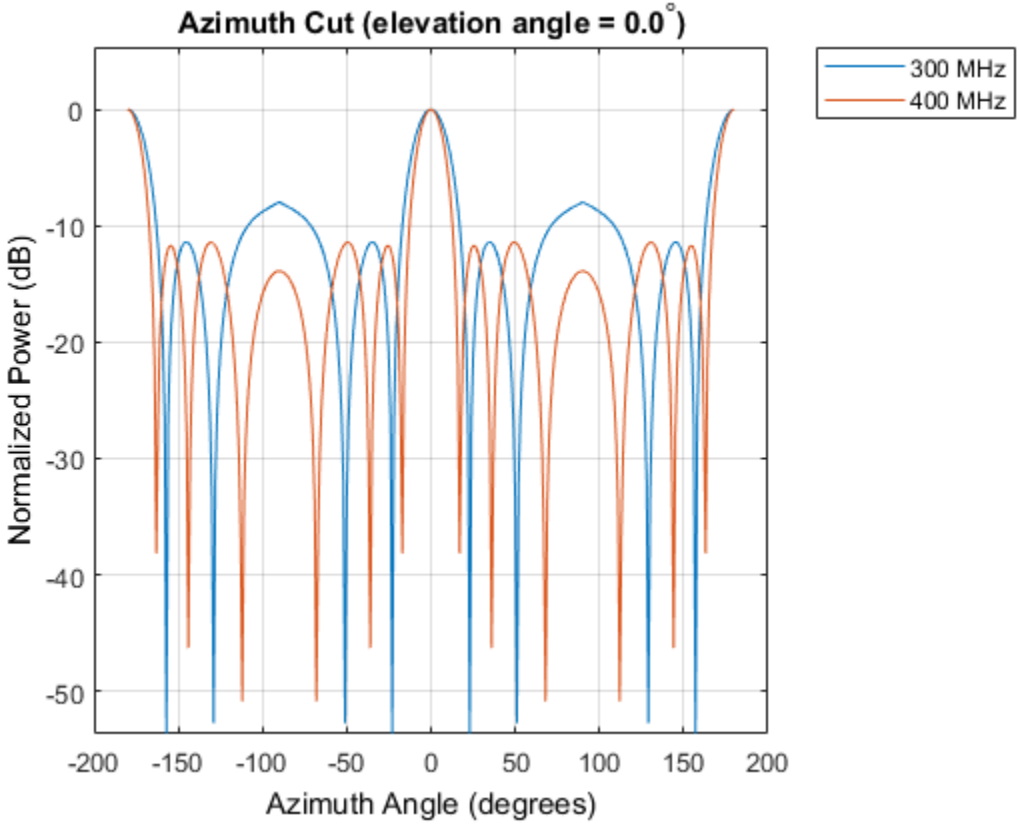
Using a line plot, show the azimuth cut response of a 5-element heterogeneous uniform linear array along 0 degrees elevation. The plot shows the responses at operating frequencies of 200 MHz and 400 MHz.

Construct the array from z-directed and y-directed short dipole antenna elements.

```
sElement1 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[2e8 5e8],...
    'AxisDirection','Z');
sElement2 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[2e8 5e8],...
    'AxisDirection','Y');
sArray = phased.HeterogeneousULA(...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 2 2 2 1]);
```

Plot the response.

```
fc = [3e8 4e8];
c = physconst('LightSpeed');
plotResponse(sArray,fc,c);
```



Plot Response and Directivity for 5-Element Array

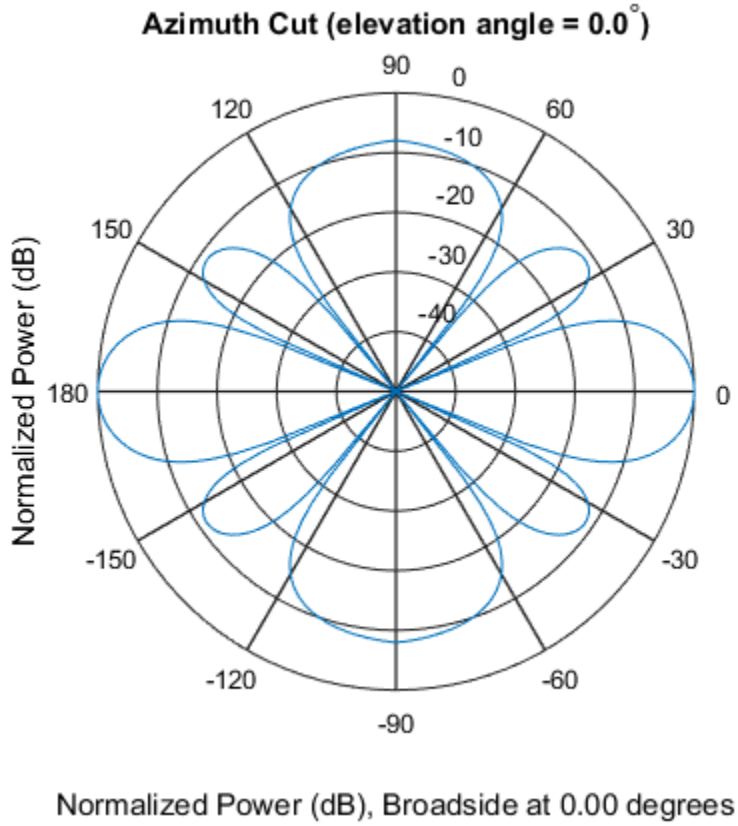
Construct a 5-element heterogeneous ULA of short-dipole antenna elements. Using the `plotResponse` method, plot the array's azimuth response in polar format. Assume each element's operating frequency spans 200-500 MHz and the wave propagation speed is the speed of light.

```
sElement1 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[2e8 5e8],...
    'AxisDirection','Z');
```

```
sElement2 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[2e8 5e8],...
    'AxisDirection','Y');
sArray = phased.HeterogeneousULA(...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 2 2 2 1]);
```

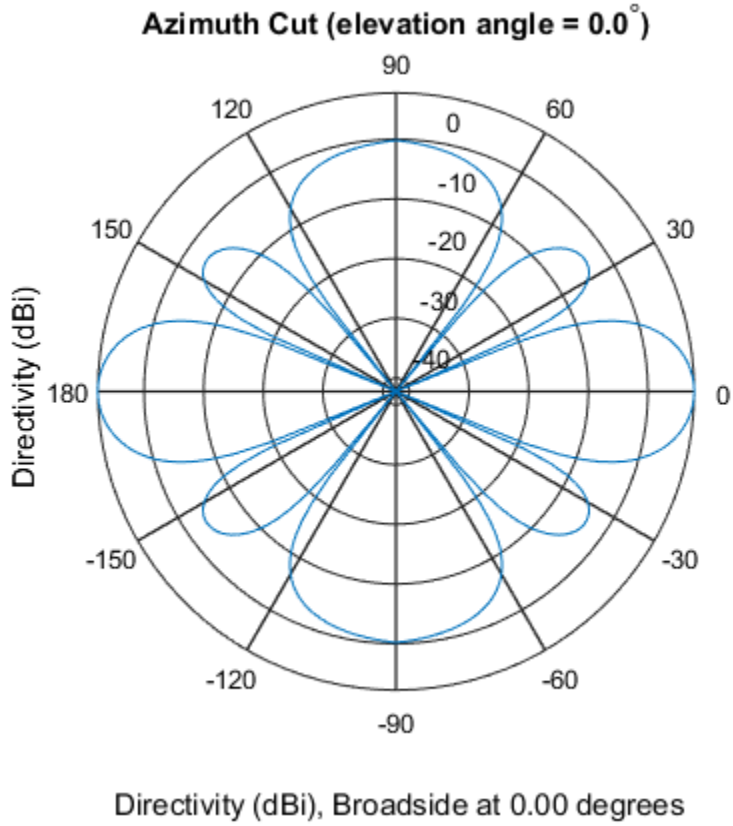
Plot the response at 300 MHz.

```
fc = 3e8;
c = physconst('LightSpeed');
plotResponse(sArray,fc,c,'RespCut','Az','Format','Polar');
```



Plot the directivity of the array at 300 MHz.

```
plotResponse(sArray,fc,c,'RespCut','Az','Format','Polar',...
    'Unit','dbi');
```



Plot Response for 9-Element Array with Two Weight Sets

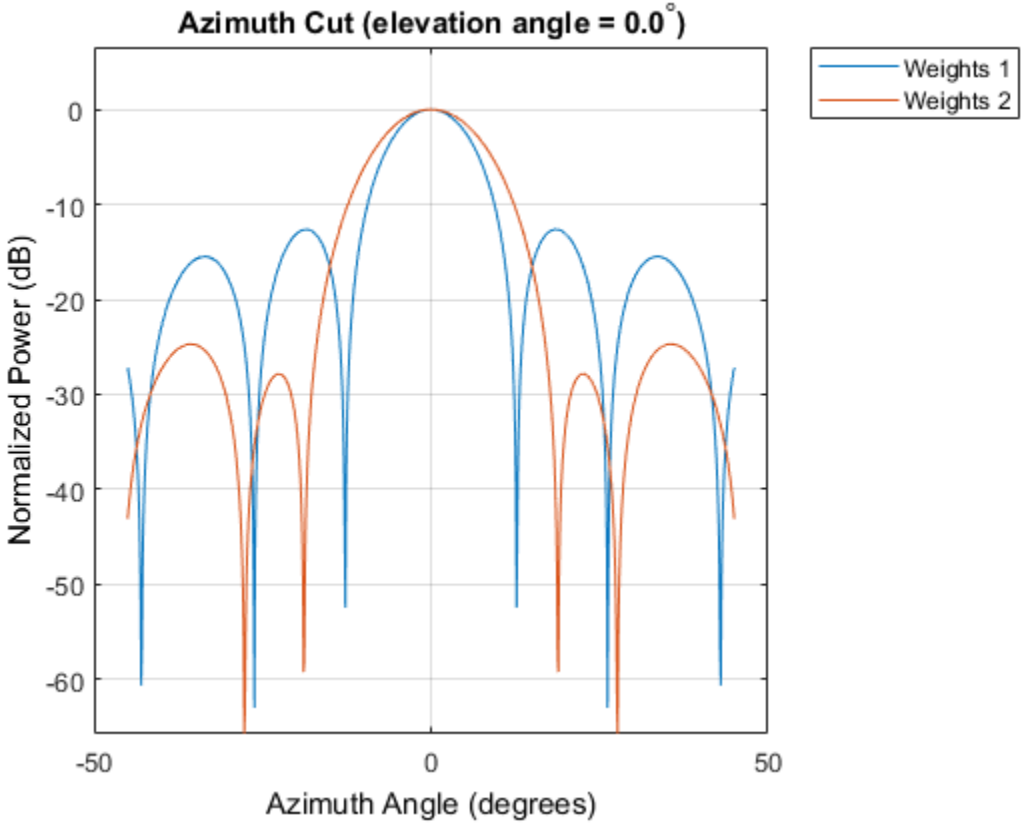
Construct a 9-element heterogeneous ULA of short-dipole antenna elements having different orientations. Assume each element response is in the frequency range 200-500 MHz. Using the `plotResponse` method, plot the array's azimuth response in polar format. Use the `Weights` parameter to set two different sets of tapering weights: a uniform tapering and a Taylor tapering. Use the `AzimuthAngles` parameter to restrict the display range from -45 to 45 degrees in 0.1 degree increments.

Construct the array.

```
sElement1 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[2e8 5e8],...
    'AxisDirection','Z');
sElement2 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[2e8 5e8],...
    'AxisDirection','Y');
sArray = phased.HeterogeneousULA(...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 2 2 2 2 2 1 1]);
```

Plot the response at 300 MHz.

```
fc = 3e8;
wts1 = ones(9,1);
wts2 = taylorwin(9);
c = physconst('LightSpeed');
plotResponse(sArray,fc,c,'RespCut','Az',...
    'AzimuthAngles',[-45:0.1:45],...
    'Weights',[wts1,wts2]);
```



As expected, the tapered weighting broadens the mainlobe and reduces the sidelobes.

`azel2uv` | `uv2azel`

step

System object: phased.HeterogeneousULA
Package: phased

Output responses of array elements

Syntax

```
RESP = step(H,FREQ,ANG)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`RESP = step(H,FREQ,ANG)` returns the array elements' responses `RESP` at operating frequencies specified in `FREQ` and directions specified in `ANG`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`H`

Array object

FREQ

Operating frequencies of array in hertz. `FREQ` is a row vector of length *L*. Typical values are within the range specified by a property of `H.Element`. That property is named `FrequencyRange` or `FrequencyVector`, depending on the type of element in the array. The element has zero response at frequencies outside that range.

ANG

Directions in degrees. `ANG` is either a 2-by-*M* matrix or a row vector of length *M*.

If `ANG` is a 2-by-*M* matrix, each column of the matrix specifies the direction in the form `[azimuth; elevation]`. The azimuth angle must lie between –180° and 180°, inclusive. The elevation angle must lie between –90° and 90°, inclusive.

If `ANG` is a row vector of length *M*, each element specifies the azimuth angle of the direction. In this case, the corresponding elevation angle is assumed to be 0°.

Output Arguments

RESP

Voltage responses of the phased array. The output depends on whether the array supports polarization or not.

- If the array is not capable of supporting polarization, the voltage response, `RESP`, has the dimensions *N*-by-*M*-by-*L*. *N* is the number of elements in the array. The dimension *M* is the number of angles specified in `ANG`. *L* is the number of frequencies specified in `FREQ`. For any element, the columns of `RESP` contain the responses of the array elements for the corresponding direction specified in `ANG`. Each of the *L* pages of `RESP` contains the responses of the array elements for the corresponding frequency specified in `FREQ`.
- If the array is capable of supporting polarization, the voltage response, `RESP`, is a MATLAB `struct` containing two fields, `RESP.H` and `RESP.V`. The field, `RESP.H`, represents the array's horizontal polarization response, while `RESP.V` represents the array's vertical polarization response. Each field has the dimensions *N*-by-*M*-by-*L*. *N* is the number of elements in the array, and *M* is the number of angles specified in `ANG`. *L* is the number of frequencies specified in `FREQ`. Each column of `RESP` contains the responses of the array elements for the corresponding direction specified in `ANG`.

Each of the L pages of RESP contains the responses of the array elements for the corresponding frequency specified in FREQ.

Examples

Heterogeneous ULA of Cosine Antenna Elements

Create a 5-element heterogeneous ULA of cosine antenna elements with difference responses, and find the response of each element at 30° azimuth.

```
antenna1 = phased.CosineAntennaElement('CosinePower',1.5);
antenna2 = phased.CosineAntennaElement('CosinePower',1.8);
array = phased.HeterogeneousULA(...
    'ElementSet',{antenna1,antenna2},...
    'ElementIndices',[1 2 2 2 1]);
fc = 1e9;
c = physconst('LightSpeed');
ang = [30;0];
resp = array(fc,ang)
```

```
resp =

    0.8059
    0.7719
    0.7719
    0.7719
    0.8059
```

Response of Heterogeneous Microphone ULA Array

Find the response of a heterogeneous ULA array of 7 custom microphone elements with different responses.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Create two microphones with different response patterns.

```
mic1 = phased.CustomMicrophoneElement(...
```

```
    'FrequencyResponse',[20 20e3]);
mic1.PolarPatternFrequencies = [500 1000];
mic1.PolarPattern = mag2db([...
    0.5+0.5*cosd(mic1.PolarPatternAngles);...
    0.6+0.4*cosd(mic1.PolarPatternAngles)]);
mic2 = phased.CustomMicrophoneElement(...
    'FrequencyResponse',[20 20e3]);
mic2.PolarPatternFrequencies = [500 1000];
mic2.PolarPattern = mag2db([...
    ones(size(mic2.PolarPatternAngles));...
    ones(size(mic2.PolarPatternAngles))]);
```

Create the heterogeneous ULA.

```
array = phased.HeterogeneousULA(...
    'ElementSet',{mic1,mic2},...
    'ElementIndices',[1 1 2 2 2 1 1]);
```

Find the array response at 40° and 50° azimuth.

```
fc = [1500, 2000];
ang = [40 50; 0 0];
resp = array(fc,ang)
```

```
resp(:,:,1) =

    9.0642    8.5712
    9.0642    8.5712
   10.0000   10.0000
   10.0000   10.0000
   10.0000   10.0000
    9.0642    8.5712
    9.0642    8.5712

resp(:,:,2) =

    9.0642    8.5712
    9.0642    8.5712
   10.0000   10.0000
   10.0000   10.0000
   10.0000   10.0000
    9.0642    8.5712
    9.0642    8.5712
```

`phitheta2azel` | `uv2azel`

viewArray

System object: phased.HeterogeneousULA
Package: phased

View array geometry

Syntax

```
viewArray(H)
viewArray(H,Name,Value)
hPlot = viewArray( ___ )
```

Description

`viewArray(H)` plots the geometry of the array specified in `H`.

`viewArray(H,Name,Value)` plots the geometry of the array, with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = viewArray( ___ )` returns the handle of the array elements in the figure window. All input arguments described for the previous syntaxes also apply here.

Input Arguments

`H`

Array object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'ShowIndex'`

Vector specifying the element indices to show in the figure. Each number in the vector must be an integer between 1 and the number of elements. You can also specify the value `'All'` to show the indices of all elements of the array or `'None'` to suppress indices.

Default: `'None'`

`'ShowNormals'`

Set this value to `true` to show the normal directions of all elements of the array. Set this value to `false` to plot the elements without showing normal directions.

Default: `false`

`'ShowTaper'`

Set this value to `true` to specify whether to change the element color brightness in proportion to the element taper magnitude. When this value is set to `false`, all elements are drawn with the same color.

Default: `false`

`'Title'`

Character vector specifying the title of the plot.

Default: `'Array Geometry'`

Output Arguments

`hPlot`

Handle of array elements in figure window.

Examples

Geometry and Indices of Heterogeneous ULA Elements

Display the geometry of a 5-element heterogeneous ULA of cosine antenna elements, showing the indices for the first three elements.

```
sElement1 = phased.CosineAntennaElement('CosinePower',1.5);
```

```
sElement2 = phased.CosineAntennaElement('CosinePower',1.8);
sArray = phased.HeterogeneousULA(...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 2 2 2 1]);
viewArray(sArray,'ShowIndex',[1:3])
```

phased.HeterogeneousURA System object

Package: phased

Heterogeneous uniform rectangular array

Description

The `HeterogeneousURA` object constructs a heterogeneous uniform rectangular array (URA).

To compute the response for each element in the array for specified directions:

1. Define and set up your uniform rectangular array. See "Construction" on page 1-825.
2. Call step to compute the response according to the properties of `phased.HeterogeneousURA`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.HeterogeneousURA` creates a heterogeneous uniform rectangular array (URA) System object, `H`. This object models a heterogeneous URA formed with sensor elements whose pattern may vary from element to element. Array elements are distributed in the *yz*-plane in a rectangular lattice. An *M*-by-*N* heterogeneous URA has *M* rows and *N* columns. The array boresight direction is along the positive *x*-axis. The default array is a 2-by-2 URA of isotropic antenna elements.

`H = phased.HeterogeneousURA(Name,Value)` creates the object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`ElementSet`

Set of elements used in the array

Specify the set of different elements used in the sensor array as a row MATLAB cell array. Each member of the cell array contains an element object in the phased package. Elements specified in the `ElementSet` property must be either all antennas or all microphones. In addition, all specified antenna elements should have same polarization capability. Specify the element of the sensor array as a handle. The element must be an element object in the `phased` package.

Default: One cell containing one isotropic antenna element

`ElementIndices`

Elements location assignment

This property specifies the mapping of elements in the array. The property assigns elements to their locations in the array using the indices into the `ElementSet` property. The value of `ElementIndices` must be an *M*-by-*N* matrix. In this matrix, *M* represents the number of rows and *N* represents the number of columns. Rows are along *y*-axis and columns are along *z*-axis of the local coordinate system. The values in the matrix specified by `ElementIndices` should be less than or equal to the number of entries in the `ElementSet` property.

Default: `[1 1;1 1]`

`ElementSpacing`

Element spacing

A 1-by-2 vector or a scalar containing the element spacing (in meters) of the array. If `ElementSpacing` is a 1-by-2 vector, it is in the form of `[SpacingBetweenRows,SpacingBetweenColumns]`. See “Spacing Between Columns” on page 1-831 and “Spacing Between Rows” on page 1-832. If `ElementSpacing` is a scalar, both spacings are the same.

Default: `[0.5 0.5]`

`Lattice`

Element lattice

Specify the element lattice as one of `'Rectangular' | 'Triangular'`. When you set the Lattice property to `'Rectangular'`, all elements in the heterogeneous URA are aligned in both row and column directions. When you set the `Lattice` property to `'Triangular'`, the elements in even rows are shifted toward the positive row axis direction by a distance of half the element spacing along the row.

Default: `'Rectangular'`

`ArrayNormal`

Array normal direction

Array normal direction, specified as one of `'x'`, `'y'`, or `'z'`.

URA elements lie in a plane orthogonal to the selected array normal direction. Element boresight directions point along the array normal direction

ArrayNormal Property Value	Element Positions and Boresight Directions
`'x'`	Array elements lie on the *yz*-plane. All element boresight vectors point along the *x*-axis.
`'y'`	Array elements lie on the *zx*-plane. All element boresight vectors point along the *y*-axis.
`'z'`	Array elements lie on the *xy*-plane. All element boresight vectors point along the *z*-axis.

Default: `'x'`

`Taper`

Element tapers

Element tapers, specified as a complex-valued scalar, or a complex-valued 1-by-*MN* row vector, *MN*-by-1 column vector, or *M*-by-*N* matrix. Tapers are applied to each element in the sensor array. Tapers are often referred to as *element weights*. *M* is the number of elements along the *z*-axis, and *N* is the number of elements along *y*-axis. *M* and *N* correspond to the values of `[NumberofRows, NumberOfColumns]` in the `Size` property. If `Taper` is a scalar, the same taper value is applied to all elements. If the value of `Taper` is a vector or matrix, taper values are applied to the corresponding elements. Tapers are used to modify both the amplitude and phase of the received data.

Default: 1

Methods

directivity	Directivity of heterogeneous uniform rectangular array
collectPlaneWave	Simulate received plane waves
getElementNormal	Normal vector to array elements
getElementPosition	Positions of array elements
getNumElements	Number of elements in array
getTaper	Array element tapers
isPolarizationCapable	Polarization capability
pattern	Plot heterogeneous URA direcivity and power pattern
patternAzimuth	Plot heterogeneous URA directivity or pattern versus azimuth
patternElevation	Plot heterogeneous ULA directivity or pattern versus elevation
plotResponse	Plot response pattern of array
step	Output responses of array elements
viewArray	View array geometry

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Azimuth Pattern of 3-by-2 Heterogeneous URA

Construct a 3-by-2 heterogeneous URA with a rectangular lattice, and find the response of each element at 30 degrees azimuth and 0 degrees elevation. Assume the operating frequency is 1 GHz.

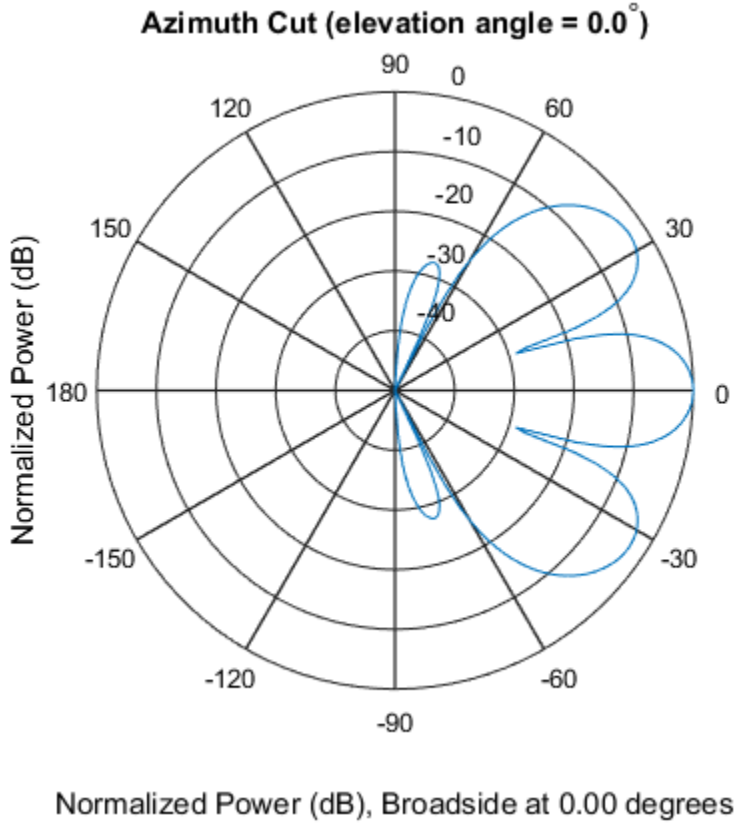
```
antenna1 = phased.CosineAntennaElement('CosinePower',1.5);
antenna2 = phased.CosineAntennaElement('CosinePower',1.8);
array = phased.HeterogeneousURA('ElementSet',{antenna1,antenna2}, ...
    'ElementIndices',[1 1; 2 2; 1 1]);
fc = 1e9;
ang = [30;0];
resp = array(fc,ang)
```

```
resp =

    0.8059
    0.7719
    0.8059
    0.8059
    0.7719
    0.8059
```

Plot the azimuth pattern of the array.

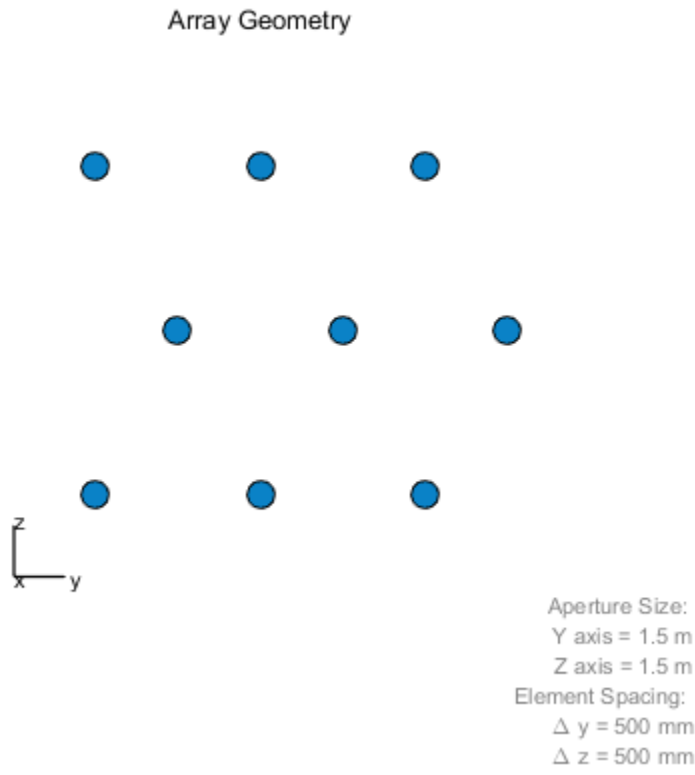
```
c = physconst('LightSpeed');
pattern(array,fc,[-180:180],0,'PropagationSpeed',c, ...
    'CoordinateSystem','polar','Type','powerdb','Normalize',true)
```



Draw Heterogeneous Triangular Lattice Array

Construct a 3-by-3 heterogeneous URA with a triangular lattice. The element spacing is 0.5 meter. Display the array shape.

```
sElement1 = phased.CosineAntennaElement('CosinePower',1.5);
sElement2 = phased.CosineAntennaElement('CosinePower',1.8);
sArray = phased.HeterogeneousURA(...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 1; 2 2 2; 1 1 1],...
    'Lattice','Triangular');
viewArray(sArray);
```



- Phased Array Gallery

Definitions

Spacing Between Columns

The spacing between columns is the distance between adjacent elements in the same row.

Spacing Between Rows

The spacing between rows is the distance along the column axis direction between adjacent rows.

Introduced in R2013a

directivity

System object: phased.HeterogeneousURA
Package: phased

Directivity of heterogeneous uniform rectangular array

Syntax

```
D = directivity(H,FREQ,ANGLE)
D = directivity(H,FREQ,ANGLE,Name,Value)
```

Description

`D = directivity(H,FREQ,ANGLE)` computes the "Directivity (dBi)" on page 1-839 of a heterogeneous uniform rectangular array of antenna or microphone elements, `H`, at frequencies specified by the `FREQ` and in angles of direction specified by the `ANGLE`.

`D = directivity(H,FREQ,ANGLE,Name,Value)` computes the directivity with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`H` — Heterogeneous uniform rectangular array

System object

Uniform rectangular array specified as a phased.HeterogeneousURA System object.

Example: `H = phased.HeterogeneousURA`

`FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-L real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-L real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

`ANGLE` — Angles for computing directivity

1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Angles for computing directivity, specified as a 1-by-*M* real-valued row vector or a 2-by-*M* real-valued matrix, where *M* is the number of angular directions. Angle units are in degrees. If `ANGLE` is a 2-by-*M* matrix, then each column specifies a direction in azimuth and elevation, `[az;el]`. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°.

If `ANGLE` is a 1-by-*M* vector, then each entry represents an azimuth angle, with the elevation angle assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis.

Example: `[45 60; 0 10]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'PropagationSpeed'` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

`'Weights'` — Array weights

1 (default) | *N*-by-1 complex-valued column vector | *N*-by-*L* complex-valued matrix

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *N*-by-1 complex-valued column vector or *N*-by-*L* complex-valued matrix. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *N* is the number of elements in the array. The dimension *L* is the number of frequencies specified by `FREQ`.

Weights Dimension	FREQ Dimension	Purpose
N-by-1 complex-valued column vector	Scalar or 1-by-*L* row vector	Applies a set of weights for the single frequency or for all *L* frequencies.
N-by-*L* complex-valued matrix	1-by-*L* row vector	Applies each of the *L* columns of `'Weights'` for the corresponding frequency in `FREQ`.

Note: Use complex weights to steer the array response toward different directions. You can create weights using the phased.SteeringVector System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as phased.Radiator or phased.Collector. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(N,M)`

Data Types: `double`

Complex Number Support: Yes

Output Arguments

D — Directivity

M-by-*L* matrix

Directivity, returned as an *M*-by-*L* matrix whose columns contain the directivities at the *M* angles specified by ANGLE. Each column corresponds to one of the *L* frequency values specified in FREQ. Directivity units are in dBi.

Examples

Directivity of Heterogeneous Uniform Rectangular Array

Compute the directivity of a 9-element 3-by-3 heterogeneous URA consisting of short-dipole antenna elements. The three elements on the middle row are Y-directed while all the remaining elements are Z-directed.

Set the signal frequency to 1 GHz.

```
c = physconst('LightSpeed');
freq = 1e9;
lambda = c/freq;
```

Create the array of short-dipole antenna elements. The elements have frequency ranges from 0 to 10 GHz.

```
myElement1 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[0 10e9],...
    'AxisDirection','Z');
myElement2 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[0 10e9],...
    'AxisDirection','Y');
myArray = phased.HeterogeneousURA(...
    'ElementSet',{myElement1,myElement2},...
    'ElementIndices',[1 1 1; 2 2 2; 1 1 1]);
```

Create the steering vector to point to 30 degrees azimuth and compute the directivity in the same direction as the steering vector.

```
ang = [30;0];
w = steervec(getElementPosition(myArray)/lambda,ang);
d = directivity(myArray,freq,ang,'PropagationSpeed',c,...
    'Weights',w)

d =

   11.1405
```

Definitions

Directivity (dBi)

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element directivity” and “Array directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular

mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

collectPlaneWave

System object: phased.HeterogeneousURA
Package: phased

Simulate received plane waves

Syntax

```
Y = collectPlaneWave(H,X,ANG)
Y = collectPlaneWave(H,X,ANG,FREQ)
Y = collectPlaneWave(H,X,ANG,FREQ,C)
```

Description

`Y = collectPlaneWave(H,X,ANG)` returns the received signals at the sensor array, `H`, when the input signals indicated by `X` arrive at the array from the directions specified in `ANG`.

`Y = collectPlaneWave(H,X,ANG,FREQ)`, in addition, specifies the incoming signal carrier frequency in `FREQ`.

`Y = collectPlaneWave(H,X,ANG,FREQ,C)`, in addition, specifies the signal propagation speed in `C`.

Input Arguments

`H`

Array object.

`X`

Incoming signals, specified as an M-column matrix. Each column of `X` represents an individual incoming signal.

ANG

Directions from which incoming signals arrive, in degrees. ANG can be either a 2-by-M matrix or a row vector of length M.

If ANG is a 2-by-M matrix, each column specifies the direction of arrival of the corresponding signal in X. Each column of ANG is in the form `[azimuth; elevation]`. The azimuth angle must be between –180° and 180°, inclusive. The elevation angle must be between –90° and 90°, inclusive.

If ANG is a row vector of length M, each entry in ANG specifies the azimuth angle. In this case, the corresponding elevation angle is assumed to be 0°.

FREQ

Carrier frequency of signal in hertz. FREQ must be a scalar.

Default: `3e8`

C

Propagation speed of signal in meters per second.

Default: Speed of light

Output Arguments

Y

Received signals. Y is an N-column matrix, where N is the number of elements in the array H. Each column of Y is the received signal at the corresponding array element, with all incoming signals combined.

Examples

Create Received Signal at Heterogeneous URA

Simulate two received signals at a 2-by-2 element heterogeneous URA with two different cosine antenna patterns. The signals arrive from 10° and 30° azimuth. Both signals have an elevation angle of 0deg; degrees.

```
antenna1 = phased.CosineAntennaElement('CosinePower',1.5);
antenna2 = phased.CosineAntennaElement('CosinePower',1.8);
array = phased.HeterogeneousURA(...
    'ElementSet',{antenna1,antenna2},...
    'ElementIndices',[1 2; 1 2]);
y = collectPlaneWave(array,randn(4,2),[10 30],1e8,physconst('LightSpeed'))
```

```
y =

   0.8433 - 0.1314i   0.8433 - 0.1314i   0.8433 + 0.1314i   0.8433 + 0.1314i
   0.5632 + 0.1721i   0.5632 + 0.1721i   0.5632 - 0.1721i   0.5632 - 0.1721i
  -2.6683 + 0.3175i  -2.6683 + 0.3175i  -2.6683 - 0.3175i  -2.6683 - 0.3175i
   1.1895 - 0.1671i   1.1895 - 0.1671i   1.1895 + 0.1671i   1.1895 + 0.1671i
```

Algorithms

`collectPlaneWave` modulates the input signal with a phase corresponding to the delay caused by the direction of arrival. This method does not account for the response of individual elements in the array.

For further details, see [1].

getElementNormal

System object: phased.HeterogeneousURA
Package: phased

Normal vector to array elements

Syntax

```
normvec = getElementNormal(sURA)
normvec = getElementNormal(sURA,elemidx)
```

Description

`normvec = getElementNormal(sURA)` returns the normal vectors of the array elements of the `phased.URA` System object, `sURA`. The output argument `normvec` is a 2-by-*N* matrix, where *N* is the number of elements in array, `sURA`. Each column of `normvec` defines the normal direction of an element in the local coordinate system in the form `[az;el]`. Units are degrees. The origin of the local coordinate system is defined by the phase center of the array.

`normvec = getElementNormal(sURA,elemidx)` returns only the normal vectors of the elements specified in the element index vector, `elemidx`. This syntax can use any of the input arguments in the previous syntax.

Input Arguments

sURA — Heterogeneous uniform rectangular array

`phased.HeterogeneousURA` System object

Uniform line array, specified as a `phased.HeterogeneousURA` System object.

Example: `sULA = phased.HeterogeneousURA`

elemidx — Element indices

all array elements (default) | integer-valued 1-by-*M* row vector | integer-valued *M*-by-1 column vector

Element indices , specified as a 1-by-*M* or *M*-by-1 vector. Index values lie in the range 1 to *N* where *N* is the number of elements of the array. When `elemidx` is specified, `getElementNormal` returns the normal vectors of the elements contained in `elemidx`.

Example: `[1,5,4]`

Output Arguments

`normvec` — Element normal vectors

2-by-*P* real-valued vector

Element normal vectors, specified as a 2-by-*P* real-valued vector. Each column of `normvec` takes the form `[az,el]`. When `elemidx` is not specified, *P* equals the array dimension. When `elemidx` is specified, *P* equals the length of `elemidx`, *M*. You can determine element indices using the phased.HeterogeneousURA.viewArray method.

Examples

URA Element Normals

Construct three 2-by-2 URA's with element normals along the *x*-, *y*-, and *z*-axes. Obtain the element positions and normal directions.

First, choose the array normal along the *x*-axis.

```
sURA1 = phased.URA('Size',[2,2],'ArrayNormal','x');
pos = getElementPosition(sURA1)
normvec = getElementNormal(sURA1)
```

```
pos =

         0         0         0         0
   -0.2500   -0.2500    0.2500    0.2500
    0.2500   -0.2500    0.2500   -0.2500

normvec =

     0     0     0     0
```

```
     0     0     0     0
```

All elements lie in the *yz*-plane and the element normal vectors point along the *x*-axis *(0°,0°)*.

Next, choose the array normal along the *y*-axis.

```
sURA2 = phased.URA('Size',[2,2],'ArrayNormal','y');
pos = getElementPosition(sURA2)
normvec = getElementNormal(sURA2)
```

```
pos =

   -0.2500   -0.2500    0.2500    0.2500
         0         0         0         0
    0.2500   -0.2500    0.2500   -0.2500

normvec =

    90    90    90    90
     0     0     0     0
```

All elements lie in the *zx*-plane and the element normal vectors point along the *y*-axis *(90°,0°)*.

Finally, set the array normal along the *z*-axis. Obtain the normal vectors of the odd-numbered elements.

```
sURA3 = phased.URA('Size',[2,2],'ArrayNormal','z');
pos = getElementPosition(sURA3)
normvec = getElementNormal(sURA3,[1,3])
```

```
pos =

   -0.2500   -0.2500    0.2500    0.2500
    0.2500   -0.2500    0.2500   -0.2500
         0         0         0         0

normvec =
```

```
     0     0
    90    90
```

All elements lie in the *xy*-plane and the element normal vectors point along the *z*-axis *(0°,90°)*.

Introduced in R2016a

getElementPosition

System object: phased.HeterogeneousURA
Package: phased

Positions of array elements

Syntax

```
POS = getElementPosition(H)
POS = getElementPosition(H,ELEIDX)
```

Description

`POS = getElementPosition(H)` returns the element positions of the HeterogeneousURA System object, `H`. `POS` is a 3-by-N matrix where N is the number of elements in `H`. Each column of `POS` defines the position of an element in the local coordinate system, in meters, using the form `[x; y; z]`.

For details regarding the local coordinate system of the URA or heterogeneous URA, enter `phased.URA.coordinateSystemInfo`.

`POS = getElementPosition(H,ELEIDX)` returns the positions of the elements that are specified in the element index vector, `ELEIDX`. The element indices of a URA run down each column, then to the top of the next column to the right. For example, in a URA with 4 elements in each row and 3 elements in each column, the element in the third row and second column has an index value of 6. This syntax can use any of the input arguments in the previous syntax.

Examples

Element Positions of Heterogeneous URA

Construct a heterogeneous URA with a rectangular lattice, and obtain the element positions.

```
antenna1 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
```

```
    'AxisDirection','Z');
antenna2 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Y');
array = phased.HeterogeneousURA('ElementSet',{antenna1,antenna2}, ...
    'ElementIndices',[1 2; 2 1]);
pos = getElementPosition(array)

pos =

         0         0         0         0
   -0.2500   -0.2500    0.2500    0.2500
    0.2500   -0.2500    0.2500   -0.2500
```

getNumElements

System object: phased.HeterogeneousURA
Package: phased

Number of elements in array

Syntax

```
N = getNumElements(H)
```

Description

`N = getNumElements(H)` returns the number of elements, `N`, in the `HeterogeneousURA` System object `H`.

Examples

Find Number of Elements of Heterogeneous URA

Construct a Heterogeneous URA, and obtain the number of elements.

```
antenna1 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Z');
antenna2 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Y');
array = phased.HeterogeneousURA('ElementSet',{antenna1,antenna2}, ...
    'ElementIndices',[1 2; 2 1]);
N = getNumElements(array)
```

```
N =

     4
```

getTaper

System object: phased.HeterogeneousURA
Package: phased

Array element tapers

Syntax

```
wts = getTaper(h)
```

Description

`wts = getTaper(h)` returns the tapers, `wts`, applied to each element of the phased heterogeneous uniform rectangular array (URA), `h`. Tapers are often referred to as weights.

Input Arguments

h — Uniform rectangular array

`phased.HeterogeneousURA` System object

Uniform rectangular array specified as a phased.HeterogeneousURA System object.

Output Arguments

wts — Array element tapers

N-by-1 complex-valued vector

Array element tapers returned as an *N*-by-1, complex-valued vector. The dimension *N* is the number of elements in the array. The array tapers are returned in the same order as the element indices. The element indices of a URA run down each column, then to the top of the next column to the right.

Examples

Heterogeneous URA Array Element Tapering

Construct a 2-by-5 element heterogeneous URA with a Taylor window taper along each row. Then, show the array with the element taper shading.

```
antenna1 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Z');
antenna2 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Y');
array = phased.HeterogeneousURA('ElementSet',{antenna1,antenna2},...
    'ElementIndices',[1 2 2 2 1 ; 1 2 2 2 1],...
    'Taper',[taylorwin(5)';taylorwin(5)']);
w = getTaper(array)
```

```
w =

    0.5181
```

isPolarizationCapable

System object: phased.HeterogeneousURA
Package: phased

Polarization capability

Syntax

```
flag = isPolarizationCapable(h)
```

Description

`flag = isPolarizationCapable(h)` returns a Boolean value, `flag`, indicating whether the array supports polarization. An array supports polarization if all of its constituent sensor elements support polarization.

Input Arguments

h — Uniform rectangular array

Uniform rectangular array specified as phased.HeterogeneousURA System object.

Output Arguments

flag — Polarization-capability flag

Polarization-capability flag returned as a Boolean value `true` if the array supports polarization or `false` if it does not.

Examples

Short-dipole Antenna Array Polarization

Show that an array of short-dipole antenna element supports polarization.

```
antenna1 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9], ...
    'AxisDirection','Z');
antenna2 = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 1e9],...
    'AxisDirection','Y');
array = phased.HeterogeneousURA('ElementSet',{antenna1,antenna2}, ...
    'ElementIndices',[1 2 2 2 1 ; 1 2 2 2 1]);
isPolarizationCapable(array)

ans =

  logical

   1
```

pattern

System object: phased.HeterogeneousURA
Package: phased

Plot heterogeneous URA direcivity and power pattern

Syntax

```
pattern(sArray,FREQ)
pattern(sArray,FREQ,AZ)
pattern(sArray,FREQ,AZ,EL)
pattern( ___ ,Name,Value)
[PAT,AZ_ANG,EL_ANG] = pattern( ___ )
```

Description

`pattern(sArray,FREQ)` plots the 3-D array directivity pattern (in dBi) for the array specified in `sArray`. The operating frequency is specified in `FREQ`.

`pattern(sArray,FREQ,AZ)` plots the array directivity pattern at the specified azimuth angle.

`pattern(sArray,FREQ,AZ,EL)` plots the array directivity pattern at specified azimuth and elevation angles.

`pattern( ___ ,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`[PAT,AZ_ANG,EL_ANG] = pattern( ___ )` returns the array pattern in `PAT`. The `AZ_ANG` output contains the coordinate values corresponding to the rows of `PAT`. The `EL_ANG` output contains the coordinate values corresponding to the columns of `PAT`. If the `'CoordinateSystem'` parameter is set to `'uv'`, then `AZ_ANG` contains the *U* coordinates of the pattern and `EL_ANG` contains the *V* coordinates of the pattern. Otherwise, they are in angular units in degrees. *UV* units are dimensionless.

Note: This method replaces the `plotResponse` method. See "Convert plotResponse to pattern" on page 1-867 for guidelines on how to use `pattern` in place of `plotResponse`.

Input Arguments

`sArray` — Heterogeneous URA

System object

Heterogeneous conformal array, specified as a phased.HeterogeneousURA System object.

Example: `sArray= phased.HeterogeneousURA;`

`FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `-Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `-Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

`AZ` — Azimuth angles

`[-180:180]` (default) | 1-by-*M* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a 1-by-*M* real-valued row vector where *M* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, this angle is positive.

Example: `[-45:2:45]`

Data Types: `double`

`EL` — Elevation angles

`[-90:90]` (default) | 1-by-*N* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a 1-by-*N* real-valued row vector where *N* is the number of desired elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and *xy*-plane. When measured towards the *z*-axis, this angle is positive.

Example: `[-75:1:70]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'CoordinateSystem'` — Plotting coordinate system

`'polar'` (default) | `'rectangular'` | `'uv'`

Plotting coordinate system of the pattern, specified as the comma-separated pair consisting of `'CoordinateSystem'` and one of `'polar'`, `'rectangular'`, or `'uv'`. When `'CoordinateSystem'` is set to `'polar'` or `'rectangular'`, the `AZ` and `EL` arguments specify the pattern azimuth and elevation, respectively. `AZ` values must lie between –180° and 180°. `EL` values must lie between –90° and 90°. If `'CoordinateSystem'` is set to `'uv'`, `AZ` and `EL` then specify *U* and *V* coordinates, respectively. `AZ` and `EL` must lie between -1 and 1.

Example: `'uv'`

Data Types: `char`

'Type' — Displayed pattern type
'directivity' (default) | 'efield' | 'power' | 'powerdb'

Displayed pattern type, specified as the comma-separated pair consisting of 'Type' and one of

- 'directivity' — directivity pattern measured in dBi.
- 'efield' — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- 'power' — power pattern of the sensor or array defined as the square of the field pattern.
- 'powerdb' — power pattern converted to dB.

Example: 'powerdb'

Data Types: char

'Normalize' — Display normalize pattern
true (default) | false

Display normalized pattern, specified as the comma-separated pair consisting of 'Normalize' and a Boolean. Set this parameter to true to display a normalized pattern. When you set 'Type' to 'directivity', this parameter does not apply. Directivity patterns are already normalized.

Example:

Data Types: logical

'PlotStyle' — Plotting style
'overlay' (default) | 'waterfall'

Plotting style, specified as the comma-separated pair consisting of 'Plotstyle' and either 'overlay' or 'waterfall'. This parameter applies when you specify multiple frequencies in FREQ in 2-D plots. You can draw 2-D plots by setting one of the arguments AZ or EL to a scalar.

Example:

Data Types: char

'Polarization' — Polarized field component
'combined' (default) | 'H' | 'V'

Polarized field component to display, specified as the comma-separated pair consisting of 'Polarization' and `'combined'`, `'H'`, or `'V'`. This parameter applies only when the sensors are polarization-capable and when the `'Type'` parameter is not set to `'directivity'`. This table shows the meaning of the display options

`'Polarization'`	Display
`'combined'`	Combined *H* and *V* polarization components
`'H'`	*H* polarization component
`'V'`	*V* polarization component

Example: `'V'`

Data Types: `char`

`'PropagationSpeed'` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

`'Weights'` — Array weights

1 (default) | *N*-by-1 complex-valued column vector | *N*-by-*L* complex-valued matrix

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *N*-by-1 complex-valued column vector or *N*-by-*L* complex-valued matrix. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *N* is the number of elements in the array. The dimension *L* is the number of frequencies specified by `FREQ`.

Weights Dimension	FREQ Dimension	Purpose
N-by-1 complex-valued column vector	Scalar or 1-by-*L* row vector	Applies a set of weights for the single frequency or for all *L* frequencies.
N-by-*L* complex-valued matrix	1-by-*L* row vector	Applies each of the *L* columns of `'Weights'` for

Weights Dimension	FREQ Dimension	Purpose
		the corresponding frequency in FREQ.

Note: Use complex weights to steer the array response toward different directions. You can create weights using the phased.SteeringVector System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as phased.Radiator or phased.Collector. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(N,M)`

Data Types: `double`
Complex Number Support: Yes

Output Arguments

PAT — Array pattern

M-by-*N* real-valued matrix

Array pattern, returned as an *M*-by-*N* real-valued matrix. The dimensions of PAT correspond to the dimensions of the output arguments AZ_ANG and EL_ANG.

AZ_ANG — Azimuth angles

scalar | 1-by-*M* real-valued row vector

Azimuth angles for displaying directivity or response pattern, returned as a scalar or 1-by-*M* real-valued row vector corresponding to the dimension set in AZ. The rows of PAT correspond to the values in AZ_ANG.

EL_ANG — Elevation angles

scalar | 1-by-*N* real-valued row vector

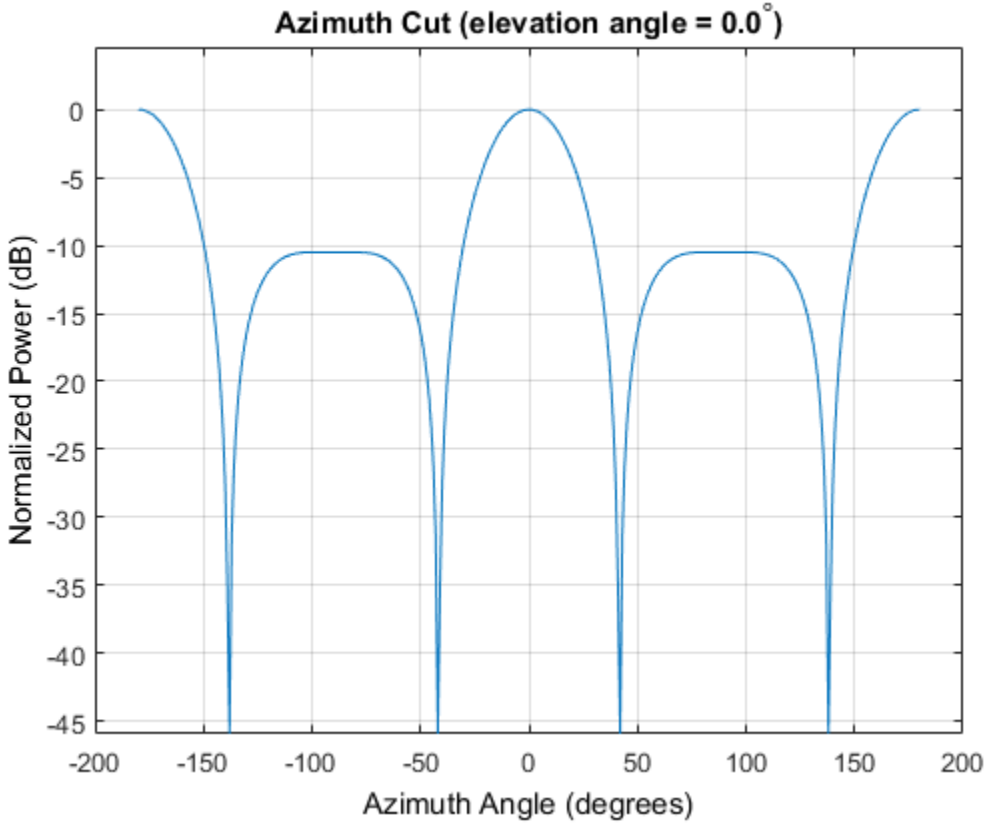
Elevation angles for displaying directivity or response, returned as a scalar or 1-by-*N* real-valued row vector corresponding to the dimension set in EL. The columns of PAT correspond to the values in EL_ANG.

Examples

Azimuth Pattern and Directivity of Heterogeneous URA

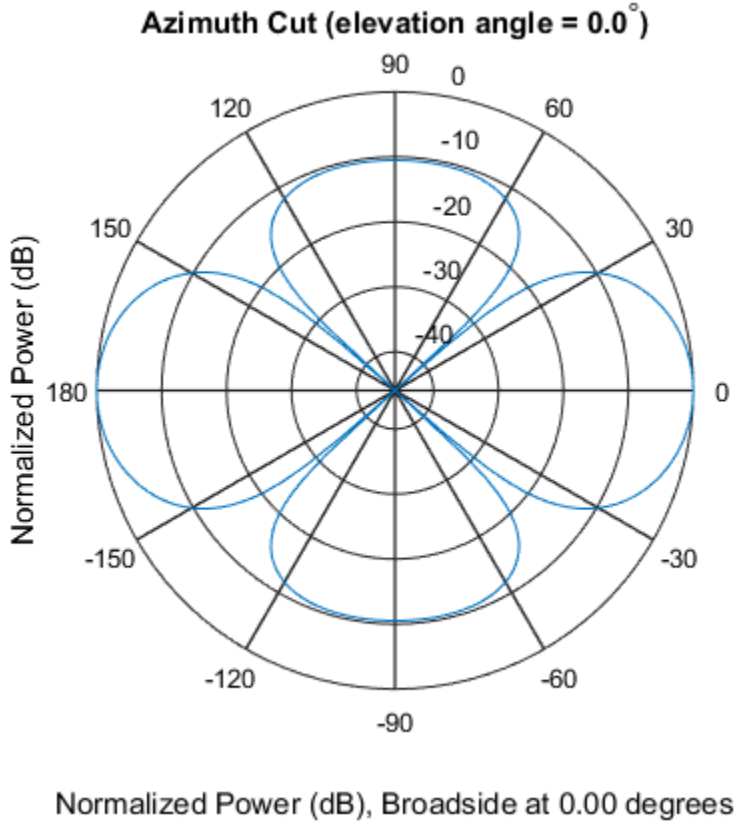
Construct a 3-by-3 heterogeneous URA of short-dipole antenna elements with a rectangular lattice. Then, plot the array's azimuth pattern at 300 MHz.

```
sElement1 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[2e8 5e8],...
    'AxisDirection','Z');
sElement2 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[2e8 5e8],...
    'AxisDirection','Y');
sArray = phased.HeterogeneousURA(...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 1; 2 2 2; 1 1 1]);
fc = 300e6;
c = physconst('LightSpeed');
pattern(sArray,fc,[-180:180],0,...
    'PropagationSpeed',c,...
    'CoordinateSystem','rectangular',...
    'Type','powerdb',...
    'Normalize',true,...
    'Polarization','combined')
```



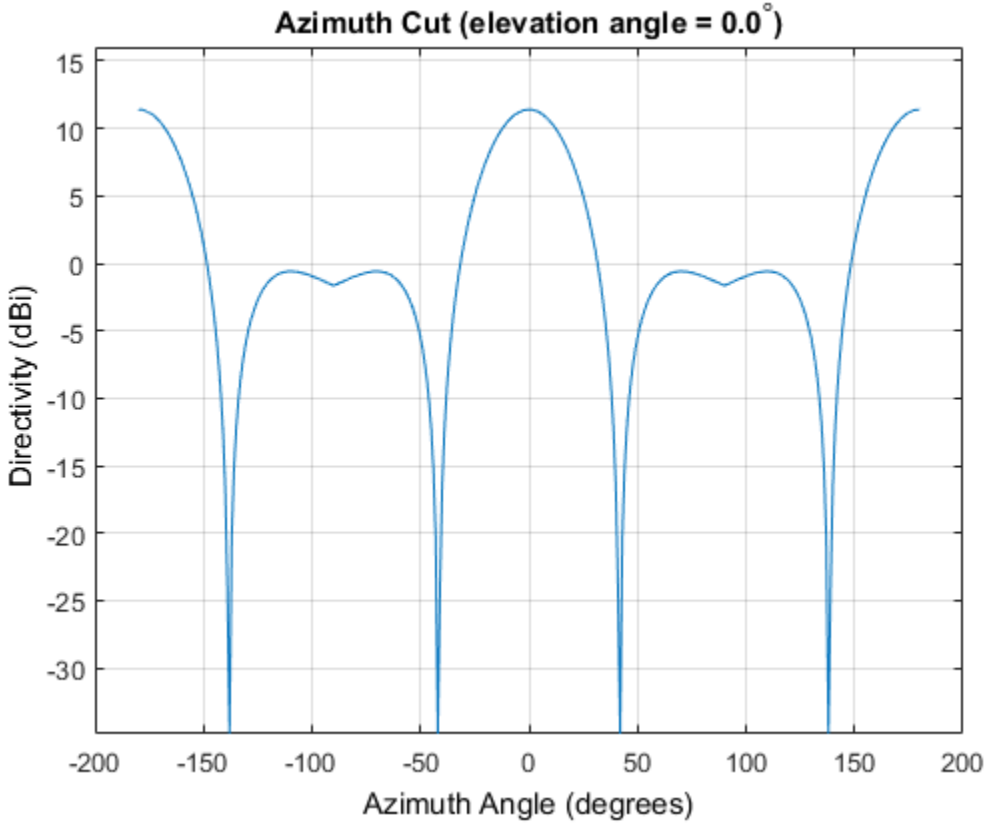
Plot the same result in polar form.

```
pattern(sArray,fc,[-180:180],0,...
    'PropagationSpeed',c,...
    'CoordinateSystem','polar',...
    'Type','powerdb',...
    'Normalize',true,...
    'Polarization','combined')
```



Finally, plot the directivity.

```
pattern(sArray,fc,[-180:180],0,...
    'PropagationSpeed',c,...
    'CoordinateSystem','rectangular',...
    'Type','directivity')
```

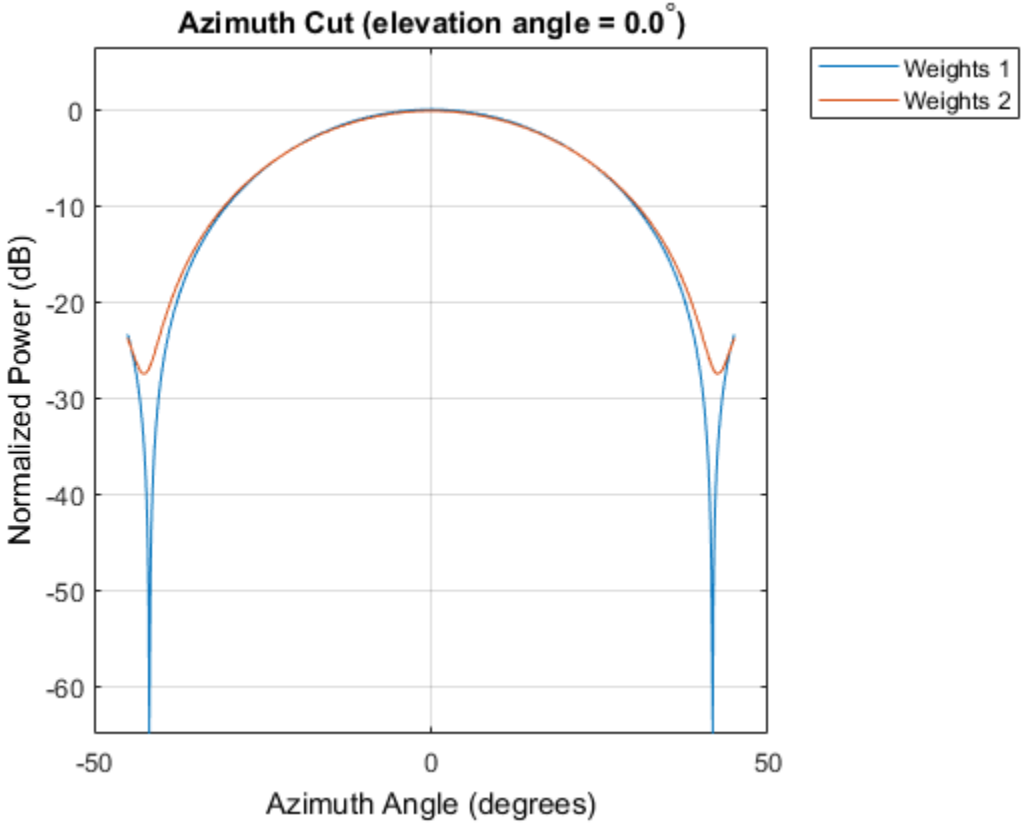


Azimuth Pattern of Heterogeneous URA For Two Sets of Weights

Construct a square 3-by-3 heterogeneous URA composed of 9 short-dipole antenna elements with different orientations. Plot the array azimuth pattern from -45 degrees to 45 degrees in 0.1 degree increments. The `Weights` parameter lets you display the array pattern simultaneously for different sets of weights: in this case a uniform set of weights and a tapered set.

```
sElement1 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[2e8 5e8],...
    'AxisDirection','Z');
sElement2 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[2e8 5e8],...
    'AxisDirection','Y');
```

```
sArray = phased.HeterogeneousURA(...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 1; 2 2 2; 1 1 1]);
fc = [3e8];
c = physconst('LightSpeed');
wts1 = ones(9,1)/9;
wts2 = [.7,.7,.7,.7,1,.7,.7,.7,.7]';
wts2 = wts2/sum(wts2);
pattern(sArray,fc,[-45:0.1:45],0,...
    'PropagationSpeed',c,...
    'CoordinateSystem','rectangular',...
    'Type','powerdb',...
    'Weights',[wts1,wts2],...
    'Polarization','combined')
```



More About

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on "Element directivity" and "Array directivity".

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

Convert plotResponse to pattern

For antenna, microphone, and array System objects, the `pattern` method replaces the `plotResponse` method. In addition, two new simplified methods exist just to draw 2-D azimuth and elevation pattern plots. These methods are `azimuthPattern` and `elevationPattern`.

The following table is a guide for converting your code from using `plotResponse` to `pattern`. Notice that some of the inputs have changed from *input arguments* to *Name-Value* pairs and conversely. The general `pattern` method syntax is

```
pattern(H,FREQ,AZ,EL,'Name1','Value1',...,'NameN','ValueN')
```

plotResponse Inputs	plotResponse Description	pattern Inputs
`H` argument	Antenna, microphone, or array System object.	`H` argument (no change)
`FREQ` argument	Operating frequency.	`FREQ` argument (no change)

plotResponse Inputs	plotResponse Description	pattern Inputs
`V` argument	Propagation speed. This argument is used only for arrays.	`'PropagationSpeed'` name-value pair. This parameter is only used for arrays.

<table>
<tr><th>plotResponse Inputs</th><th>plotResponse Description</th><th>pattern Inputs</th></tr>
<tr>
<td>'Format' and 'RespCut' name-value pairs</td>
<td>These options work together to let you create a plot in angle space (line or polar style) or UV space. They also determine whether the plot is 2-D or 3-D. This table shows you how to create different types of plots using plotResponse.
<table>
<tr><th>Display space</th><th></th></tr>
<tr><td>Angle space (2D)</td><td>Set 'RespCut' to 'Az' or 'El'. Set 'Format' to 'line' or 'polar'.

Set the display axis using either the the 'AzimuthAngl or 'ElevationAn name-value pairs.</td></tr>
<tr><td>Angle space (3D)</td><td>Set 'RespCut' to '3D'. Set 'Format' to 'line' or 'polar'.

Set the display axis using both the</td></tr>
</table>
</td>
<td>'CoordinateSystem' name-value pair used together with the AZ and EL input arguments.

'CoordinateSystem' has the same options as the plotResponse method 'Format'name-value pair, except that 'line' is now named 'rectangular'. The table shows how to create different types of plots using pattern.
<table>
<tr><th>Display space</th><th></th></tr>
<tr><td>Angle space (2D)</td><td>Set 'CoordinateSystem' to 'rectangular' or 'polar'. Specify either AZ or EL as a scalar.</td></tr>
<tr><td>Angle space (3D)</td><td>Set 'CoordinateSystem' to 'rectangular' or 'polar'. Specify both AZ and EL as vectors.</td></tr>
<tr><td>UV space (2D)</td><td>Set 'CoordinateSystem' to 'uv'. Use AZ to specify a U-space vector.</td></tr>

<tr><td>UV space (3D)</td><td>Set 'RespCut' to'3D'. Set 'Format' to 'UV'. Set the display range using both the 'UGrid' and 'VGrid' name-value pairs.</td></tr>
</table></td><td><table>
<tr><th>Display space</th><th></th></tr>
<tr><td></td><td>Use EL to specify a V-space scalar.</td></tr>
<tr><td>UV space (3D)</td><td>Set 'CoordinateSystem' to 'uv'. Use AZ to specify a U-space vector. Use EL to specify a V-space vector.</td></tr>
</table>
If you set CoordinateSystem to 'uv', enter the UV grid values using AZ and EL.</td></tr>
<tr><td>'CutAngle' name-value pair</td><td>Constant angle at to take an azimuth or elevation cut. When producing a 2-D plot and when 'RespCut' is set to 'Az' or 'El', use 'CutAngle' to set the slice across which to view the plot.</td><td>No equivalent name-value pair. To create a cut, specify either AZ or EL as a scalar, not a vector.</td></tr>
</table>

plotResponse Inputs	plotResponse Description	pattern Inputs
`'NormalizeResponse'` name-value pair	Normalizes the plot. When `'Unit'` is set to `'dbi'`, you cannot specify `'NormalizeResponse'`.	`'Normalize'` name-value pair. When `'Type'` is set to `'directivity'`, you cannot specify `'Normalize'`. .
`'OverlayFreq'` name-value pair	Plot multiple frequencies on the same 2-D plot. Available only when `'Format'` is set to `'line'` or `'uv'` and `'RespCut'` is not set to `'3D'`. The value `true` produces an overlay plot and the value `false` produces a waterfall plot.	`'PlotStyle'` name-value pair plots multiple frequencies on the same 2-D plot. The values `'overlay'` and `'waterfall'` correspond to `'OverlayFreq'` values of `true` and `false`. The option `'waterfall'` is allowed only when `'CoordinateSystem'` is set to `'rectangular'` or `'uv'`.
`'Polarization'` name-value pair	Determines how to plot polarized fields. Options are `'None'`, `'Combined'`, `'H'`, or `'V'`.	`'Polarization'` name-value pair determines how to plot polarized fields. The `'None'` option is removed. The options `'Combined'`, `'H'`, or `'V'` are unchanged.

`'Unit'` name-value pair	Determines the plot units. Choose `'db'`, `'mag'`, `'pow'`, or `'dbi'`, where the default is `'db'`.	`'Type'` name-value pair, uses equivalent options with different names
		
		plotResponse pattern
		`'db'` `'powerdb'`
		`'mag'` `'efield'`
		`'pow'` `'power'`
		`'dbi'` `'directivity'`

`'Weights'` name-value pair	Array element tapers (or weights).	`'Weights'` name-value pair (no change).

plotResponse Inputs	plotResponse Description	pattern Inputs
`'AzimuthAngles'` name-value pair	Azimuth angles used to display the antenna or array response.	`AZ` argument
`'ElevationAngles'` name-value pair	Elevation angles used to display the antenna or array response.	`EL` argument
`'UGrid'` name-value pair	Contains *U* coordinates in *UV*-space.	`AZ` argument when `'CoordinateSystem'` name-value pair is set to `'uv'`
`'VGrid'` name-value pair	Contains *V*-coordinates in *UV*-space.	`EL` argument when `'CoordinateSystem'` name-value pair is set to `'uv'`

phased.HeterogeneousURA.patternAzimuth |
phased.HeterogeneousURA.patternElevation

Introduced in R2015a

patternAzimuth

System object: phased.HeterogeneousURA
Package: phased

Plot heterogeneous URA directivity or pattern versus azimuth

Syntax

```
patternAzimuth(sArray,FREQ)
patternAzimuth(sArray,FREQ,EL)
patternAzimuth(sArray,FREQ,EL,Name,Value)
PAT = patternAzimuth( ___ )
```

Description

`patternAzimuth(sArray,FREQ)` plots the 2-D array directivity pattern versus azimuth (in dBi) for the array `sArray` at zero degrees elevation angle. The argument `FREQ` specifies the operating frequency.

`patternAzimuth(sArray,FREQ,EL)`, in addtion, plots the 2-D array directivity pattern versus azimuth (in dBi) for the array `sArray` at the elevation angle specified by `EL`. When `EL` is a vector, multiple overlaid plots are created.

`patternAzimuth(sArray,FREQ,EL,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternAzimuth( ___ )` returns the array pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Azimuth'` parameter and the `EL` input argument.

Input Arguments

`sArray` — Heterogeneous URA

System object

Heterogeneous URA, specified as a phased.HeterogeneousURA System object.

Example: `sArray= phased.HeterogeneousURA;`

FREQ — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `-Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `-Inf`.

Example: `1e8`

Data Types: `double`

EL — Elevation angles

1-by-*N* real-valued row vector

Elevation angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector. The quantity *N* is the number of requested elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and the *xy* plane. When measured toward the *z*-axis, this angle is positive.

Example: `[0,10,20]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Type'` — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

`'PropagationSpeed'` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

`'Weights'` — Array weights

M-by-1 complex-valued column vector

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *M*-by-1 complex-valued column vector. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *M* is the number of elements in the array.

Note: Use complex weights to steer the array response toward different directions. You can create weights using the phased.SteeringVector System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as phased.Radiator or phased.Collector. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(10,1)`

Data Types: `double`
Complex Number Support: Yes

`'Azimuth'` — Azimuth angles

`[-180:180]` (default) | 1-by-*P* real-valued row vector

Azimuth angles, specified as the comma-separated pair consisting of `'Azimuth'` and a 1-by-*P* real-valued row vector. Azimuth angles define where the array pattern is calculated.

Example: `'Azimuth',[-90:2:90]`

Data Types: `double`

Output Arguments

`PAT` — Array directivity or pattern

L-by-*N* real-valued matrix

Array directivity or pattern, returned as an *L*-by-*N* rea-valued matrix. The dimension *L* is the number of azimuth values determined by the `'Azimuth'` name-value pair argument. The dimension *N* is the number of elevation angles, as determined by the `EL` input argument.

Examples

Azimuth Directivity of Heterogeneous URA

Construct a square 4-by-4 heterogeneous URA composed of a mix of crossed-dipole and short-dipole antenna elements with short dipoles in the center. Plot the array azimuth directivity for two different elevation angles. Set the operating frequency to 400 MHz.

```
sElement1 = phased.CrossedDipoleAntennaElement(...
    'FrequencyRange',[200e6 500e6]);
sElement2 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[200e6 500e6],...
    'AxisDirection','Z');
elemindices = ones(4,4);
elemindices(2:3,2:3) = 2;
sArray = phased.HeterogeneousURA(...
    'ElementSet',{sElement1,sElement2},...
```

```
    'ElementIndices',elemindices);
fc = 400e6;
c = physconst('LightSpeed');
patternAzimuth(sArray,fc,[0 30],...
    'PropagationSpeed',c,...
    'Type','directivity')
```

phased.HeterogeneousURA.pattern | phased.HeterogeneousURA.patternElevation

Introduced in R2015a

patternElevation

System object: phased.HeterogeneousURA
Package: phased

Plot heterogeneous ULA directivity or pattern versus elevation

Syntax

```
patternElevation(sArray,FREQ)
patternElevation(sArray,FREQ,AZ)
patternElevation(sArray,FREQ,AZ,Name,Value)
PAT = patternElevation( ___ )
```

Description

`patternElevation(sArray,FREQ)` plots the 2-D array directivity pattern versus elevation (in dBi) for the array `sArray` at zero degrees azimuth angle. When `AZ` is a vector, multiple overlaid plots are created. The argument `FREQ` specifies the operating frequency.

`patternElevation(sArray,FREQ,AZ)`, in addition, plots the 2-D element directivity pattern versus elevation (in dBi) at the azimuth angle specified by `AZ`. When `AZ` is a vector, multiple overlaid plots are created.

`patternElevation(sArray,FREQ,AZ,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternElevation( ___ )` returns the array pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Elevation'` parameter and the `AZ` input argument.

Input Arguments

`sArray` — Heterogeneous URA

System object

Heterogeneous URA array, specified as a phased.HeterogeneousURA System object.

Example: `sArray= phased.HeterogeneousURA;`

`FREQ` — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

`AZ` — Azimuth angles for computing directivity and pattern

1-by-*N* real-valued row vector

Azimuth angles for computing sensor or array directivities and patterns, specified as a 1-by-*M* real-valued row vector where *N* is the number of desired azimuth directions. Angle units are in degrees. The azimuth angle must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `[0,10,20]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'Type' — Displayed pattern type

'directivity' (default) | 'efield' | 'power' | 'powerdb'

Displayed pattern type, specified as the comma-separated pair consisting of 'Type' and one of

- 'directivity' — directivity pattern measured in dBi.
- 'efield' — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- 'power' — power pattern of the sensor or array defined as the square of the field pattern.
- 'powerdb' — power pattern converted to dB.

Example: 'powerdb'

Data Types: char

'PropagationSpeed' — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of 'PropagationSpeed' and a positive scalar in meters per second.

Example: 'PropagationSpeed',physconst('LightSpeed')

Data Types: double

'Weights' — Array weights

M-by-1 complex-valued column vector

Array weights, specified as the comma-separated pair consisting of 'Weights' and an *M*-by-1 complex-valued column vector. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *M* is the number of elements in the array.

Note: Use complex weights to steer the array response toward different directions. You can create weights using the phased.SteeringVector System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as phased.Radiator or phased.Collector. However, for the directivity, pattern, patternAzimuth, and patternElevation methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(10,1)`

Data Types: `double`
Complex Number Support: Yes

`'Elevation'` — Elevation angles

`[-90:90]` (default) | 1-by-*P* real-valued row vector

Elevation angles, specified as the comma-separated pair consisting of `'Elevation'` and a 1-by-*P* real-valued row vector. Elevation angles define where the array pattern is calculated.

Example: `'Elevation',[-90:2:90]`

Data Types: `double`

Output Arguments

`PAT` — Array directivity or pattern

L-by-*N* real-valued matrix

Array directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of elevation angles determined by the `'Elevation'` name-value pair argument. The dimension *N* is the number of azimuth angles determined by the `AZ` argument.

Examples

Elevation Directivity of Heterogeneous URA

Construct a square 4-by-4 heterogeneous URA composed of a mix of crossed-dipole and short-dipole antenna elements with short dipoles in the center. Plot the array elevation directivity for two different azimuth angles. Set the operating frequency to 400 MHz.

```
sElement1 = phased.CrossedDipoleAntennaElement(...
    'FrequencyRange',[200e6 500e6]);
sElement2 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[200e6 500e6],...
    'AxisDirection','Z');
elemindices = ones(4,4);
elemindices(2:3,2:3) = 2;
sArray = phased.HeterogeneousURA(...
```

```
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',elemindices);
fc = 400e6;
c = physconst('LightSpeed');
patternElevation(sArray,fc,[0 75],...
    'PropagationSpeed',c,...
    'Type','directivity')
```

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on "Element directivity" and "Array directivity".

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

Introduced in R2015a

plotResponse

System object: phased.HeterogeneousURA
Package: phased

Plot response pattern of array

Syntax

```
plotResponse(H,FREQ,V)
plotResponse(H,FREQ,V,Name,Value)
hPlot = plotResponse(___)
```

Description

`plotResponse(H,FREQ,V)` plots the array response pattern along the azimuth cut, where the elevation angle is 0. The operating frequency is specified in `FREQ`. The propagation speed is specified in `V`.

`plotResponse(H,FREQ,V,Name,Value)` plots the array response with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = plotResponse(___)` returns handles of the lines or surface in the figure window, using any of the input arguments in the previous syntaxes.

Input Arguments

`H`

Array object

`FREQ`

Operating frequency in Hertz specified as a scalar or 1-by-*K* row vector. Values must lie within the range specified by a property of `H`. That property is named `FrequencyRange` or `FrequencyVector`, depending on the type of element in the array. The element has no response at frequencies outside that range. If you set the `'RespCut'` property of `H` to

'3D', FREQ must be a scalar. When FREQ is a row vector, plotResponse draws multiple frequency responses on the same axes.

V

Propagation speed in meters per second.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

'CutAngle'

Cut angle as a scalar. This argument is applicable only when RespCut is 'Az' or 'El'. If RespCut is 'Az', CutAngle must be between –90 and 90. If RespCut is 'El', CutAngle must be between –180 and 180.

Default: 0

'Format'

Format of the plot, using one of 'Line', 'Polar', or 'UV'. If you set Format to 'UV', FREQ must be a scalar.

Default: 'Line'

'NormalizeResponse'

Set this value to true to normalize the response pattern. Set this value to false to plot the response pattern without normalizing it. This parameter is not applicable when you set the Unit parameter value to 'dbi'.

Default: true

'OverlayFreq'

Set this value to true to overlay pattern cuts in a 2-D line plot. Set this value to false to plot pattern cuts against frequency in a 3-D waterfall plot. If this value is false, FREQ must be a vector with at least two entries.

This parameter applies only when `Format` is not `'Polar'` and RespCut is not `'3D'`.

Default: `true`

`'Polarization'`

Specify the polarization options for plotting the array response pattern. The allowable values are `|'None' | 'Combined' | 'H' | 'V' |` where

- `'None'` specifies plotting a nonpolarized response pattern
- `'Combined'` specifies plotting a combined polarization response pattern
- `'H'` specifies plotting the horizontal polarization response pattern
- `'V'` specifies plotting the vertical polarization response pattern

For arrays that do not support polarization, the only allowed value is `'None'`. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

Default: `'None'`

`'RespCut'`

Cut of the response. Valid values depend on `Format`, as follows:

- If `Format` is `'Line'` or `'Polar'`, the valid values of `RespCut` are `'Az'`, `'El'`, and `'3D'`. The default is `'Az'`.
- If `Format` is `'UV'`, the valid values of `RespCut` are `'U'` and `'3D'`. The default is `'U'`.

If you set `RespCut` to `'3D'`, `FREQ` must be a scalar.

`'Unit'`

The unit of the plot. Valid values are `'db'`, `'mag'`, `'pow'`, or `'dbi'`. This parameter determines the type of plot that is produced.

Unit value	Plot type
`db`	power pattern in dB scale
`mag`	field pattern
`pow`	power pattern

Unit value	Plot type
`dbi`	directivity

Default: `'db'`

`'Weights'`

Weight values applied to the array, specified as a length-*N* column vector or *N*-by-*M* matrix. The dimension *N* is the number of elements in the array. The interpretation of *M* depends upon whether the input argument `FREQ` is a scalar or row vector.

Weights Dimensions	FREQ Dimension	Purpose
N-by-1 column vector	Scalar or 1-by-*M* row vector	Apply one set of weights for the same single frequency or all *M* frequencies.
N-by-*M* matrix	Scalar	Apply all of the *M* different columns in `Weights` for the same single frequency.
	1-by-*M* row vector	Apply each of the *M* different columns in `Weights` for the corresponding frequency in `FREQ`.

`'AzimuthAngles'`

Azimuth angles for plotting array response, specified as a row vector. The `AzimuthAngles` parameter sets the display range and resolution of azimuth angles for visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'Az'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of azimuth angles should lie between –180° and 180° and must be in nondecreasing order. When you set the `RespCut` parameter to `'3D'`, you can set the `AzimuthAngles` and `ElevationAngles` parameters simultaneously.

Default: `[-180:180]`

`'ElevationAngles'`

Elevation angles for plotting array response, specified as a row vector. The `ElevationAngles` parameter sets the display range and resolution of elevation

angles for visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'El'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of elevation angles should lie between –90° and 90° and must be in nondecreasing order. When yous set the `RespCut` parameter to `'3D'`, you can set the `ElevationAngles` and `AzimuthAngles` parameters simultaneously.

Default: `[-90:90]`

`'UGrid'`

U coordinate values for plotting array response, specified as a row vector. The `UGrid` parameter sets the display range and resolution of the *U* coordinates for visualizing the radiation pattern in *U*/*V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'U'` or `'3D'`. The values of `UGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set the `UGrid` and `VGrid` parameters simultaneously.

Default: `[-1:0.01:1]`

`'VGrid'`

V coordinate values for plotting array response, specified as a row vector. The `VGrid` parameter sets the display range and resolution of the *V* coordinates for visualizing the radiation pattern in *U*/*V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'3D'`. The values of `VGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set `VGrid` and `UGrid` parameters simultaneously.

Default: `[-1:0.01:1]`

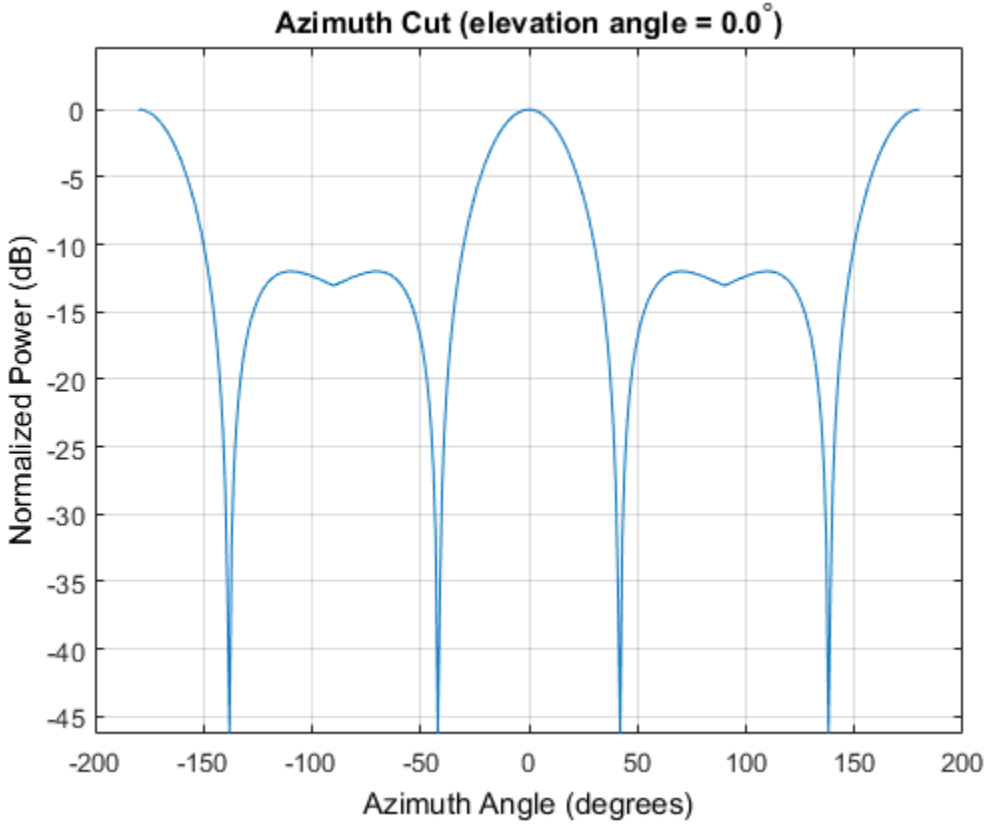
Examples

Azimuth Response and Directivity of Heterogeneous URA

Construct a 3-by-3 heterogeneous URA with a rectangular lattice, then plot the array's azimuth response at 300 MHz.

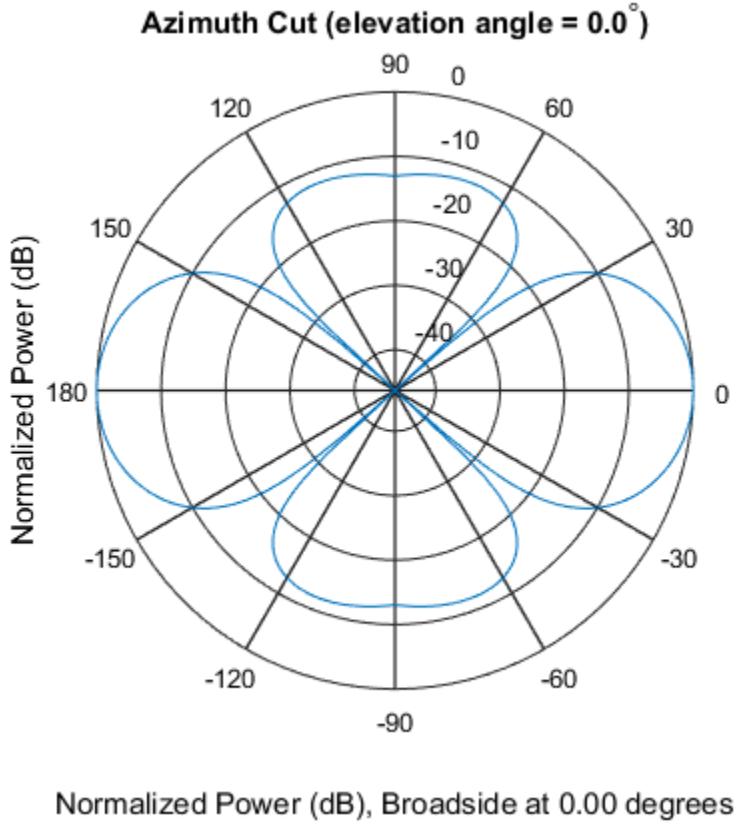
```
sElement1 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[2e8 5e8],...
```

```
    'AxisDirection','Z');
sElement2 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[2e8 5e8],...
    'AxisDirection','Y');
sArray = phased.HeterogeneousURA(...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 1; 2 2 2; 1 1 1]);
fc = [3e8];
c = physconst('LightSpeed');
plotResponse(sArray,fc,c);
```



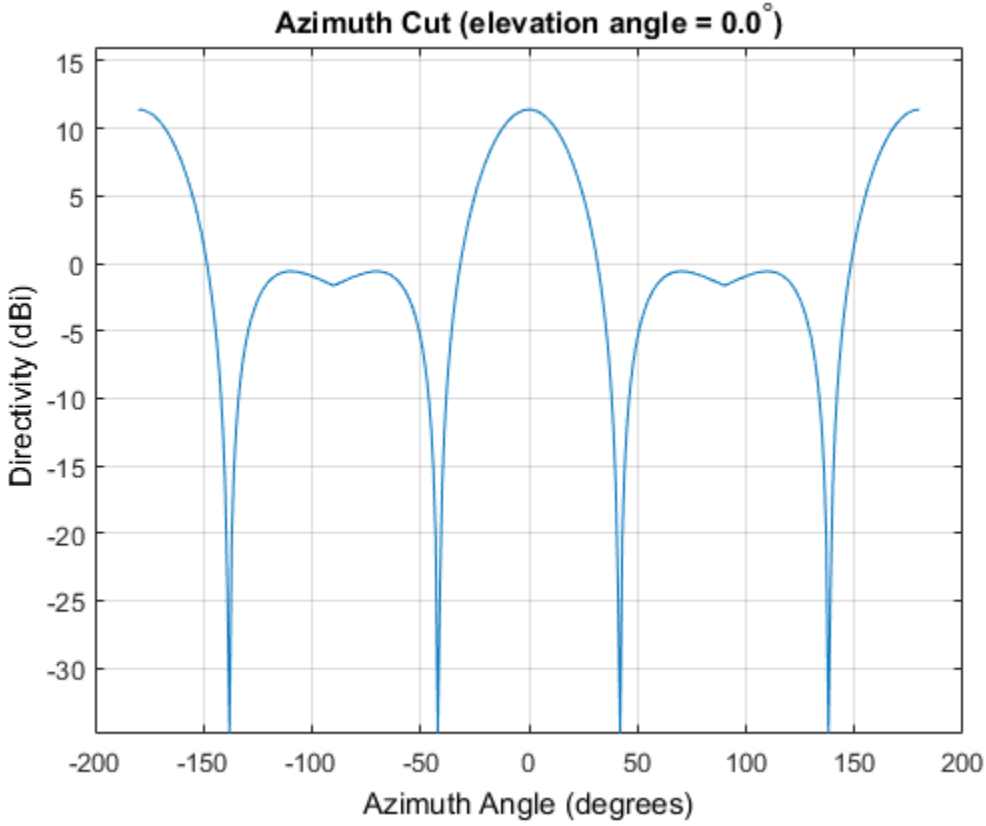
Plot the same result in polar form.

```
plotResponse(sArray,fc,c,'RespCut','Az','Format','Polar');
```



Finally, plot the directivity.

```
plotResponse(sArray,fc,c,'RespCut','Az','Unit','dbi');
```



Azimuth Responses of a Heterogeneous URA For Two Sets of Weights

Construct a square 3-by-3 heterogeneous URA composed of 9 short-dipole antenna elements with different orientations. Using the AzimuthAngles parameter, plot the array's azimuth response in the -45 degrees to 45 degrees in 0.1 degree increments. The `Weights` parameter lets you display the array's response simultaneously for different sets of weights: in this case a uniform set of weights and a tapered set.

```
sElement1 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[2e8 5e8],...
    'AxisDirection','Z');
sElement2 = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[2e8 5e8],...
    'AxisDirection','Y');
```

```
sArray = phased.HeterogeneousURA(...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 1; 2 2 2; 1 1 1]);
fc = [3e8];
c = physconst('LightSpeed');
wts1 = ones(9,1)/9;
wts2 = [.7,.7,.7,.7,1,.7,.7,.7,.7]';
wts2 = wts2/sum(wts2);
plotResponse(sArray,fc,c,'RespCut','Az',...
    'Format','Line',...
    'AzimuthAngles',[-45:0.1:45],...
    'Weights',[wts1,wts2],'Unit','db');
```

`azel2uv` | `uv2azel`

step

System object: phased.HeterogeneousURA
Package: phased

Output responses of array elements

Syntax

```
RESP = step(H,FREQ,ANG)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`RESP = step(H,FREQ,ANG)` returns the array elements' responses `RESP` at operating frequencies specified in `FREQ` and directions specified in `ANG`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`H`

Array object

FREQ

Operating frequencies of array in hertz. `FREQ` is a row vector of length *L*. Typical values are within the range specified by a property of `H.Element`. That property is named `FrequencyRange` or `FrequencyVector`, depending on the type of element in the array. The element has zero response at frequencies outside that range.

ANG

Directions in degrees. `ANG` is either a 2-by-*M* matrix or a row vector of length *M*.

If `ANG` is a 2-by-*M* matrix, each column of the matrix specifies the direction in the form `[azimuth; elevation]`. The azimuth angle must lie between –180° and 180°, inclusive. The elevation angle must lie between –90° and 90°, inclusive.

If `ANG` is a row vector of length *M*, each element specifies the azimuth angle of the direction. In this case, the corresponding elevation angle is assumed to be 0°.

Output Arguments

RESP

Voltage responses of the phased array. The output depends on whether the array supports polarization or not.

- If the array is not capable of supporting polarization, the voltage response, `RESP`, has the dimensions *N*-by-*M*-by-*L*. *N* is the number of elements in the array. The dimension *M* is the number of angles specified in `ANG`. *L* is the number of frequencies specified in `FREQ`. For any element, the columns of `RESP` contain the responses of the array elements for the corresponding direction specified in `ANG`. Each of the *L* pages of `RESP` contains the responses of the array elements for the corresponding frequency specified in `FREQ`.
- If the array is capable of supporting polarization, the voltage response, `RESP`, is a MATLAB `struct` containing two fields, `RESP.H` and `RESP.V`. The field, `RESP.H`, represents the array's horizontal polarization response, while `RESP.V` represents the array's vertical polarization response. Each field has the dimensions *N*-by-*M*-by-*L*. *N* is the number of elements in the array, and *M* is the number of angles specified in `ANG`. *L* is the number of frequencies specified in `FREQ`. Each column of `RESP` contains the responses of the array elements for the corresponding direction specified in `ANG`.

Each of the L pages of RESP contains the responses of the array elements for the corresponding frequency specified in FREQ.

Examples

Response of 2-by-2 Heterogeneous URA of Cosine Antennas

Construct a 2-by-2 rectangular lattice heterogeneous URA of cosine antenna elements. Find the response of each element at 30 degrees azimuth and 0 degrees elevation. Assume the operating frequency is 1 GHz. Then, plot the array directivity.

```
sElement1 = phased.CosineAntennaElement('CosinePower',1.5);
sElement2 = phased.CosineAntennaElement('CosinePower',1.8);
sArray = phased.HeterogeneousURA(...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 2; 2 1]);
fc = 1e9;
c = physconst('LightSpeed');
ang = [30;0];
resp = step(sArray,fc,ang)
```

```
resp =

    0.8059
    0.7719
    0.7719
    0.8059
```

Show the 3-D directivity pattern.

```
pattern(sArray,fc,[-180:180],[-90:90],...
    'PropagationSpeed',c,...
    'CoordinateSystem','rectangular',...
    'Type','directivity')
```

viewArray

System object: phased.HeterogeneousURA
Package: phased

View array geometry

Syntax

```
viewArray(H)
viewArray(H,Name,Value)
hPlot = viewArray( ___ )
```

Description

`viewArray(H)` plots the geometry of the array specified in `H`.

`viewArray(H,Name,Value)` plots the geometry of the array, with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = viewArray( ___ )` returns the handle of the array elements in the figure window. All input arguments described for the previous syntaxes also apply here.

Input Arguments

`H`

Array object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'ShowIndex'`

Vector specifying the element indices to show in the figure. Each number in the vector must be an integer between 1 and the number of elements. You can also specify the value `'All'` to show the indices of all elements of the array or `'None'` to suppress indices.

Default: `'None'`

`'ShowNormals'`

Set this value to `true` to show the normal directions of all elements of the array. Set this value to `false` to plot the elements without showing normal directions.

Default: `false`

`'ShowTaper'`

Set this value to `true` to specify whether to change the element color brightness in proportion to the element taper magnitude. When this value is set to `false`, all elements are drawn with the same color.

Default: `false`

`'Title'`

Character vector specifying the title of the plot.

Default: `'Array Geometry'`

Output Arguments

`hPlot`

Handle of array elements in figure window.

Examples

Geometry, Normal Directions, and Indices of Heterogeneous URA Elements

Display the element positions, normal directions, and indices for all elements of a 4-by-4 heterogeneous URA.

```
sElement1 = phased.CosineAntennaElement('CosinePower',1.5);
```

```
sElement2 = phased.CosineAntennaElement('CosinePower',1.8);
sArray = phased.HeterogeneousURA(...
    'ElementSet',{sElement1,sElement2},...
    'ElementIndices',[1 1 1 1; 1 2 2 1; 1 2 2 1; 1 1 1 1]);
viewArray(sArray,'ShowIndex','all','ShowNormal',true);
```

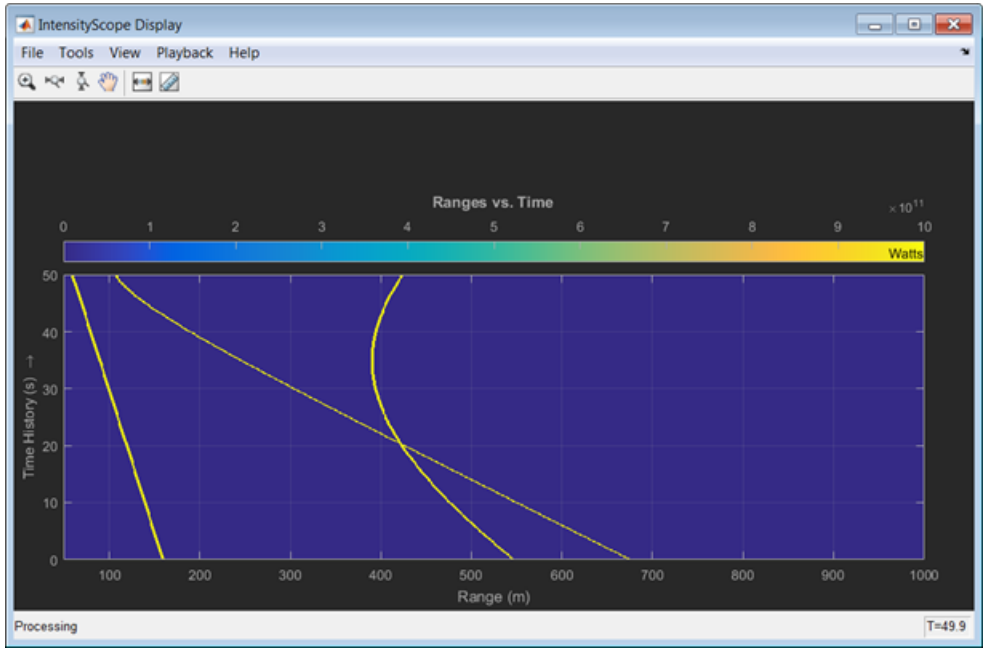
phased.IntensityScope System object

Package: phased

Range-time-intensity (RTI) or Doppler-time-intensity (DTI) display

Description

The `phased.IntensityScope` System object creates an intensity scope for viewing range-time-intensity (RTI) and Doppler-time-intensity (DTI) data. An intensity scope is a scrolling waterfall of intensity values as a function of time. Scan lines appear at the bottom of the display window and scroll off at the top. Each scan line represents signal intensity as a function of a parameter of interest, such as range or speed. You can also use this object to display angle-time-intensity data and spectral data. This figure shows an RTI display.



To create an intensity scope:

1. Define and set up the `phased.IntensityScope` System object. You can set any System object properties at this time or you can leave them at their default values. See "Construction" on page 1-906 .
2. Call the phased.IntensityScope method to add intensity lines to the bottom of the display according to the properties of the `phased.IntensityScope` System object. Some properties are tunable and can be changed at any time. Non-tunable properties cannot be changed after the first call to phased.IntensityScope. Subsequent calls to phased.IntensityScope add more intensity lines.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`sIS = phased.IntensityScope` creates an intensity scope System object, `sIS`, having default property values.

`sIS = phased.IntensityScope(Name,Value)` returns an intensity scope System object, `sIS`, with each specified property `Name` set to a specified `Value`. `Name` must appear inside single quotes (`''`). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Properties

`Name` — Window name

`'Intensity Scope'` (default) | character vector

Intensity scope window name, specified as a character vector. `Name` property and `Title` are different properties. The title appears inside the display window, above the data. The name appears in the title bar of the window.

Example: `'Range Intensity'`

Data Types: `char`

`XResolution` — *X*-axis sample spacing

1 (default) | positive real-valued scalar

X-axis sample spacing, specified as a positive real-valued scalar. This quantity determines the width of each horizontal bin of the scan line. The units depend on the interpretation of the data. For example, if you are creating an RTI display, then setting `XResolution` to `0.5` is interpreted as 0.5 meters.

Example: `0.5`

Data Types: `double`

`XOffset` — *X*-axis offset

`0` (default) | real-valued scalar

X-axis offset, specified as a real-valued scalar. This quantity sets the value of the lowest bin of the scan line. The values of all other bins are equal to this value plus an integer multiple of `Xresolution`. The units depend upon the interpretation of the data. For example, if you are creating an RTI display, then setting `XOffset` to `100.0` is interpreted as 100 meters.

Example: `-0.1`

Data Types: `double`

`Xlabel` — X-axis label

`''` (default) | character vector

X-axis label, specified as a character vector.

Example: `'Range (km)'`

Data Types: `char`

`Title` — Title of display

`''` (default) | character vector

Title of the intensity scope display, specified as a character vector. `Title` property and `Name` are different properties. The title appears inside the display window, above the data. The name appears in the title bar of the window.

Example: `'Range vs Time'`

Data Types: `char`

`TimeResolution` — Time resolution

`.001` (default) | positive real-valued scalar

Time resolution of intensity line(s), specified as a positive real-valued scalar. Units are seconds.

Example: `.0001`

Data Types: `double`

`TimeSpan` — Time span of display window

0.1 (default) | positive real-valued scalar

Time span of intensity display, specified as a positive real-valued scalar. Units are seconds.

Example: `5.0`

Data Types: `double`

`IntensityUnits` — Intensity units label

`'dB'` (default) | character vector

Intensity units label displayed in the color bar, specified as a character vector.

Example: `'Watts'`

Data Types: `char`

`Position` — Location and size of intensity scope window

dependens on display-resolution (default) | 1-by-4 vector of positive values

Location and size of the intensity scope window, specified as a 1-by-4 vector having the form `[left bottom width height]`. Units are in pixels.

- `left` and `bottom` specify the location of the bottom-left corner of the window.
- `width` and `height` specify the width and height of the window.

The default value of this property depends on the resolution of your display. This property is tunable.

Example: `[100 100 500 400]`

Data Types: `double`

Methods

hide	Hide intensity scope window

reset	Reset state of intensity scope System object
show	Show intensity scope window
step	Update intensity scope display

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

RTI Display of Moving Target

Use a `phased.IntensityScope` System object™ to display the echo intensity of a moving target as a function of range and time.

Run the simulation for 5 seconds at 0.1 second steps. In the display, each horizontal scan line shows the intensities of radar echo at each time step.

```
nsteps = 50;
dt = .1;
timespan = nsteps*dt;
```

Simulate a target at a range of 320.0 km and a range rate of 2.0 km/s. Echoes are resolved into range bins of 1 km resolution. The range bins span from 50 to 1000 km.

```
rngres = 1.0;
rngmin = 50.0;
rngmax = 1000.0;
tgtrange = 320.0;
rangerate = 2.0;
rngscan = [rngmin:rngres:rngmax];
```

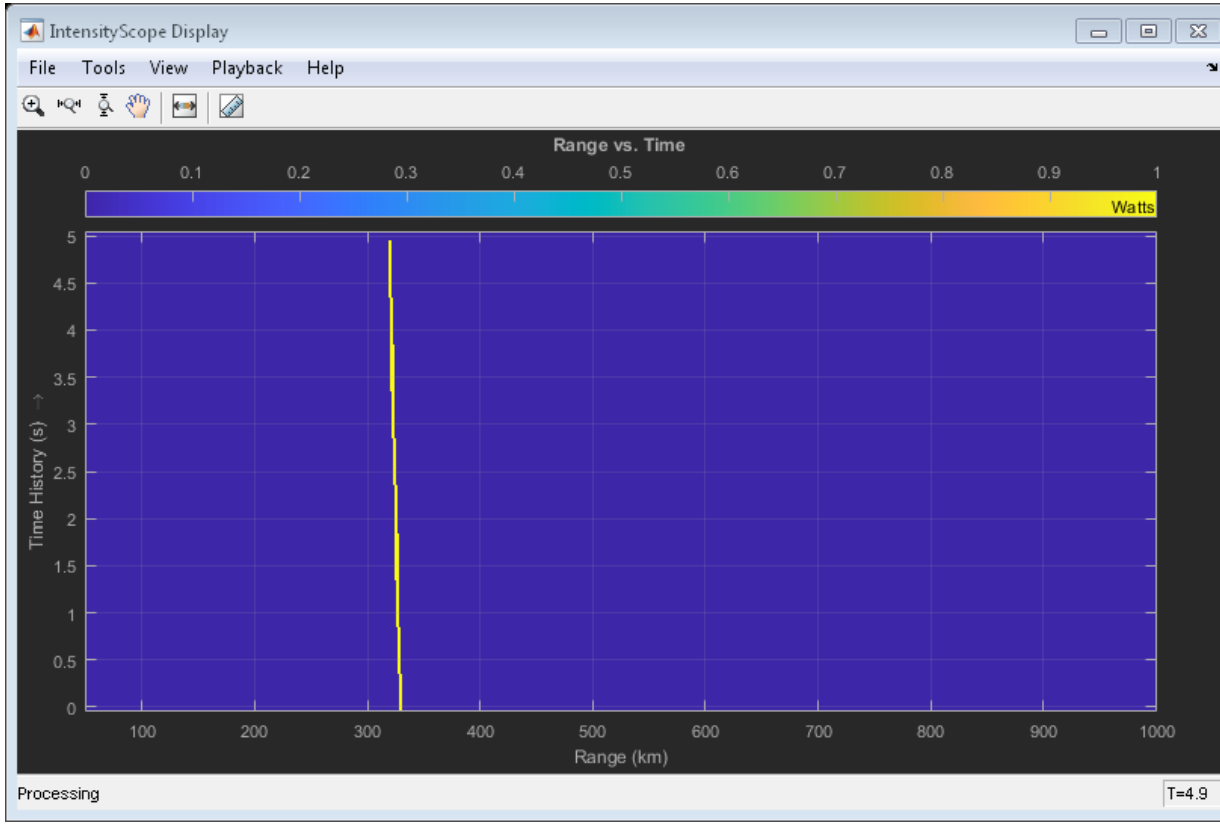
Set up the Intensity Scope using these properties.

- Use the `XResolution` property to set the width of each scan line bin to the range resolution of 1 km.
- Use the `XOffset` property to set the value of the lowest range bin to the minimum range of 50 km.
- Use the `TimeResolution` property to set the value of the scan line time difference to 0.1 s.
- Use the `TimeSpan` property to set the height of the display window to the time duration of the simulation.
- Use the `IntensityUnits` property to set the display units to `Watts`.

```
scope = phased.IntensityScope('Name','IntensityScope Display',...
    'Title','Range vs. Time','XLabel','Range (km)',...
    'XResolution',rngres,'XOffset',rngmin,...
    'TimeResolution',dt,'TimeSpan',timespan, ...
    'IntensityUnits','Watts','Position',[100,100,800,450]);
```

Update the current target bin and create entries for two adjacent range bins. Each call to the `step` method creates a new scan line.

```
for k = 1:nsteps
    bin = floor((tgtrange - rngmin)/rngres) + 1;
    scanline = zeros(size(rngscan));
    scanline(bin+[-1:1]) = 1;
    scope(scanline.');
    tgtrange = tgtrange + dt*rangerate;
    pause(.1);
end
```



RTI Display of Three Moving Targets

Use the `phased.IntensityScope` System object™ to display the intensities of the echoes of three moving targets as functions of range and time.

Create the Radar and Target System Objects

Set up the initial positions and velocities of the three targets. Use the `phased.Platform` System object™ to model radar and target motions. The radar is stationary while the targets undergo constant velocity motion. The simulation runs for 500 steps at 0.1 second increments, giving a total simulation time of 50 seconds.

```
nsteps = 500;
dt = .1;
```

```
timespan = nsteps*dt;
x1 = [60,0,0]';
x2 = [60,-80,40]';
x3 = [300,0,-300]';
v1 = [2,0,0]';
v2 = [10,5,6]';
v3 = [-10,2,-4]';
platform = phased.Platform([0,0,0]',[0,0,0]');
targets = phased.Platform([x1,x2,x3],[v1,v2,v3]);
```

Set Up Range Bins

Each echo is put into a range bin. The range bin resolution is 1 meter and the range is from 50 to 1000 meters.

```
rngres = 1.0;
rngmin = 50.0;
rngmax = 1000.0;
rngscan = [rngmin:rngres:rngmax];
```

Create the Gain Function

Define a range-dependent gain function to enhance the display of targets at larger ranges. The gain function amplifies the returned echo for visualization purposes only.

```
rangegain = @(rng)(1e12*rng^4);
```

Create the Intensity Scope

Set up the Intensity Scope using these properties.

- Use the `XResolution` property to set the width of each scan line bin to the range resolution of 1 km.
- Use the `XOffset` property to set the value of the lowest range bin to the minimum range of 50 km.
- Use the `TimeResolution` property to set the value of the scan line time difference to 0.1 s.
- Use the `TimeSpan` property to set the height of the display window to the time duration of the simulation.
- Use the `IntensityUnits` property to set the display units to `Watts`.

```
scope = phased.IntensityScope('Name','IntensityScope Display',...
```

```
    'Title','Ranges vs. Time','XLabel','Range (m)','XResolution',rngres,...
    'XOffset',rngmin,'TimeResolution',dt,'TimeSpan',timespan, ...
    'IntensityUnits','Watts','Position',[100,100,800,450]);
```

Run Simulation Loop

1. In this loop, move the targets at constant velocity using the `step` method of the `phased.Platform` System object.
2. Compute the target ranges using the `rangeangle` function.
3. Compute the target range bins by quantizing the range values in integer multiples of `rangres`.
4. Fill each target range bin and neighboring bins with a simulated radar intensity value.
5. Add the signal from each target to the scan line.
6. Call the `step` method of the `phased.IntensityScope` System object to display the scan lines.

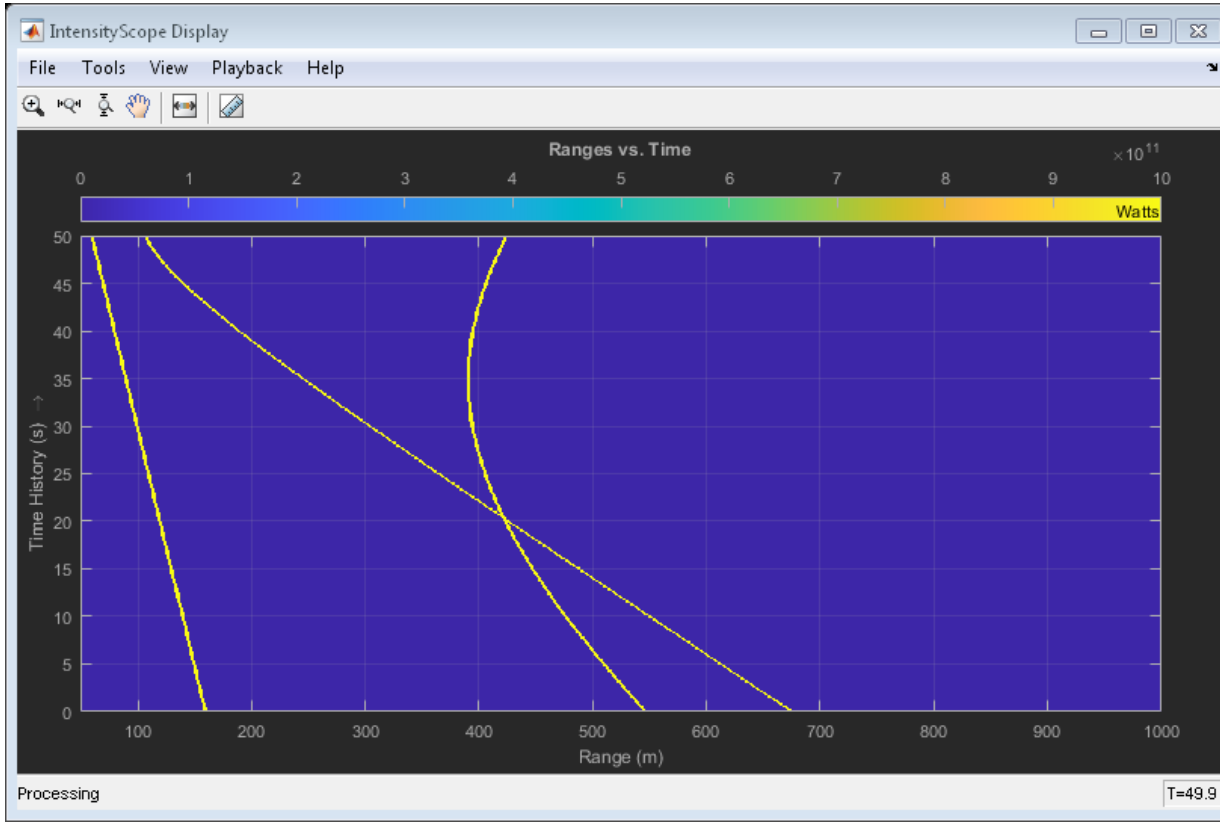
```
for k = 1:nsteps
    xradar = platform(dt);
    xtgts = targets(dt);
    [rngs] = rangeangle(xtgts,xradar);
    scanline = zeros(size(rngscan));

    rngindx = ceil((rngs(1) - rngmin)/rngres);
    scanline(rngindx + [-1:1]) = rangegain(rngs(1))/(rngs(1)^4);

    rngindx = ceil((rngs(2) - rngmin)/rngres);
    scanline(rngindx + [-1:1]) = rangegain(rngs(2))/(rngs(2)^4);

    rngindx = ceil((rngs(3) - rngmin)/rngres);
    scanline(rngindx + [-1:1]) = rangegain(rngs(3))/(rngs(3)^4);

    scope(scanline.');
    pause(.1);
end
```



RTI and DTI Displays in Full Radar Simulation

Use the `phased.IntensityScope` System object™ to display the detection output of a complete radar system simulation. The radar scenario contains a stationary single-element monostatic radar and three moving targets.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Set Radar Operating Parameters

Set the probability of detection, probability of false alarm, maximum range, range resolution, operating frequency, transmitter gain, and target radar cross-section.

```
pd = 0.9;
pfa = 1e-6;
max_range = 5000;
range_res = 50;
fc = 10e9;
tx_gain = 20;
tgt_rcs = 1;
```

Choose the signal propagation speed to be the speed of light, and compute the signal wavelength corresponding to the operating frequency.

```
c = physconst('LightSpeed');
lambda = c/fc;
```

Compute the pulse bandwith from the range resolution. Set the sampling rate, `fs`, to twice the pulse bandwidth. The noise bandwidth is also set to the pulse bandwidth. The radar integrates a number of pulses set by `num_pulse_int`. The duration of each pulse is the inverse of the pulse bandwidth.

```
pulse_bw = c/(2*range_res);
pulse_length = 1/pulse_bw;
fs = 2*pulse_bw;
noise_bw = pulse_bw;
num_pulse_int = 10;
```

Set the pulse repetition frequency to match the maximum range of the radar.

```
prf = c/(2*max_range);
```

Compute Transmit Power

Use the Albersheim equation to compute the SNR required to meet the desired probability of detection and probability of false alarm. Then, use the radar equation to compute the power needed to achieve the required SNR.

```
snr_min = albersheim(pd, pfa, num_pulse_int);
peak_power = radareqpow(lambda,max_range,snr_min,pulse_length,...
    'RCS',tgt_rcs,'Gain',tx_gain);
```

Create System Objects for the Model

Choose a rectangular waveform.

```
waveform = phased.RectangularWaveform('PulseWidth',pulse_length,...
```

```
    'PRF',prf,'SampleRate',fs);
```

Set the receiver amplifier characteristics.

```
amplifier = phased.ReceiverPreamp('Gain',20,'NoiseFigure',0,...
    'SampleRate',fs,'EnableInputPort',true,'SeedSource','Property',...
    'Seed',2007);
transmitter = phased.Transmitter('Gain',tx_gain,'PeakPower',peak_power,...
    'InUseOutputPort',true);
```

Specify the radar antenna as a single isotropic antenna.

```
antenna = phased.IsotropicAntennaElement('FrequencyRange',[5e9 15e9]);
```

Set up a monostatic radar platform.

```
radarplatform = phased.Platform('InitialPosition',[0; 0; 0],...
    'Velocity',[0; 0; 0]);
```

Set up the three target platforms using a single System object.

```
targetplatforms = phased.Platform(...
    'InitialPosition',[2000.66 3532.63 3845.04; 0 0 0; 0 0 0], ...
    'Velocity',[150 -150 0; 0 0 0; 0 0 0]);
```

Create the radiator and collector System objects.

```
radiator = phased.Radiator('Sensor',antenna,'OperatingFrequency',fc);
collector = phased.Collector('Sensor',antenna,'OperatingFrequency',fc);
```

Set up the three target RCS properties.

```
targets = phased.RadarTarget('MeanRCS',[1.6 2.2 1.05],'OperatingFrequency',fc);
```

Create System object to model two-way freespace propagation.

```
channels= phased.FreeSpace('SampleRate',fs,'TwoWayPropagation',true,...
    'OperatingFrequency',fc);
```

Define a matched filter.

```
MFcoef = getMatchedFilter(waveform);
filter = phased.MatchedFilter('Coefficients',MFcoef,'GainOutputPort',true);
```

Create Range and Doppler Bins

Set up the fast-time grid. Fast time is the sampling time of the echoed pulse relative to the pulse transmission time. The range bins are the ranges corresponding to each bin of the fast time grid.

```
fast_time = unigrid(0,1/fs,1/prf,'[)');
range_bins = c*fast_time/2;
```

To compensate for range loss, create a time varying gain System Object™.

```
gain = phased.TimeVaryingGain('RangeLoss',2*fspl(range_bins,lambda),...
    'ReferenceLoss',2*fspl(max_range,lambda));
```

Set up Doppler bins. Doppler bins are determined by the pulse repetition frequency. Create an FFT System object for Doppler processing.

```
DopplerFFTbins = 32;
DopplerRes = prf/DopplerFFTbins;
fft = dsp.FFT('FFTLengthSource','Property',...
    'FFTLength',DopplerFFTbins);
```

Create Data Cube

Set up a reduced data cube. Normally, a data cube has fast-time and slow-time dimensions and the number of sensors. Because data cube has only one sensor, it is two-dimensional.

```
rx_pulses = zeros(numel(fast_time),num_pulse_int);
```

Create IntensityScope System Objects

Create two IntensityScope System objects, one for Doppler-time-intensity and the other for range-time-intensity.

```
dtiscope = phased.IntensityScope('Name','Doppler-Time Display',...
    'XLabel','Velocity (m/sec)', ...
    'XResolution',dop2speed(DopplerRes,c/fc)/2, ...
    'XOffset',dop2speed(-prf/2,c/fc)/2,...
    'TimeResolution',0.05,'TimeSpan',5,'IntensityUnits','dB');
rtiscope = phased.IntensityScope('Name','Range-Time Display',...
    'XLabel','Range (m)', ...
    'XResolution',c/(2*fs), ...
```

```
    'TimeResolution',0.05,'TimeSpan',5,'IntensityUnits','dB');
```

Run the Simulation Loop Over Multiple Radar Transmissions

Transmit 2000 pulses. Coherently process groups of 10 pulses at a time.

For each pulse:

1. Update the radar position and velocity `radarplatform`
2. Update the target positions and velocities `targetplatforms`
3. Create the pulses of a single wave train to be transmitted `transmitter`
4. Compute the ranges and angles of the targets with respect to the radar
5. Radiate the signals to the targets `radiator`
6. Propagate the pulses to the target and back `channels`
7. Reflect the signals off the target `targets`
8. Receive the signal `sCollector`
9. Amplify the received signal `amplifier`
10. Form data cube

For each set of 10 pulses in the data cube:

1. Match filter each row (fast-time dimension) of the data cube.
2. Compute Doppler shifts of each row (slow-time dimension) of the data cube.

```
pri = 1/prf;
nsteps = 200;
for k = 1:nsteps
    for m = 1:num_pulse_int
        [ant_pos,ant_vel] = radarplatform(pri);
        [tgt_pos,tgt_vel] = targetplatforms(pri);
        sig = waveform();
        [s,tx_status] = transmitter(sig);
        [~,tgt_ang] = rangeangle(tgt_pos,ant_pos);
        tsig = radiator(s,tgt_ang);
        tsig = channels(tsig,ant_pos,tgt_pos,ant_vel,tgt_vel);
        rsig = targets(tsig);
        rsig = collector(rsig,tgt_ang);
        rx_pulses(:,m) = amplifier(rsig,~(tx_status>0));
    end
```

```
        rx_pulses = filter(rx_pulses);
        MFdelay = size(MFcoef,1) - 1;
        rx_pulses = buffer(rx_pulses((MFdelay + 1):end), size(rx_pulses,1));
        rx_pulses = gain(rx_pulses);
        range = pulsint(rx_pulses,'noncoherent');
        rtiscope(range);
        dshift = fft(rx_pulses.');
        dshift = fftshift(abs(dshift),1);
        dtiscope(mean(dshift,2));
        radarplatform(.05);
        targetplatforms(.05);
    end
```

All of the targets lie on the x-axis. Two targets are moving along the x-axis and one is stationary. Because the radar is at the origin, you can read the target speed directly from the Doppler-Time Display window. The values agree with the specified velocities of -150, 150, and 0 m/sec.

Topics

"Measure Intensity Levels Using the Intensity Scope "

Introduced in R2016a

hide

System object: phased.IntensityScope
Package: phased

Hide intensity scope window

Syntax

```
hide(sIS)
```

Description

`hide(sIS)` hides the display window of the `phased.IntensityScope` object, `sIS`.

Input Arguments

`sIS` — Intensity scope

`phased.IntensityScope` System object

Intensity scope, specified as a phased.IntensityScope System object.

Example: `phased.IntensityScope`

Examples

Hide and Show Intensity Scope

Create an angle-time-intensity scope. Use the `phased.IntensityScope` System object™ to display simulated intensity as a function of the angular motion of a moving target. After five steps in the processing loop, use the `hide` method to hide the scope. At completion of the loop, use the `show` method to show the scope.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace

`myObject(x)` with `step(myObject,x)`.%% Simulate data for 5 seconds with a time interval of 0.5 seconds between scan lines.

```
nsteps = 10;
dt = 0.5;
timespan = nsteps*dt;
```

Set Up IntensityScope System Object

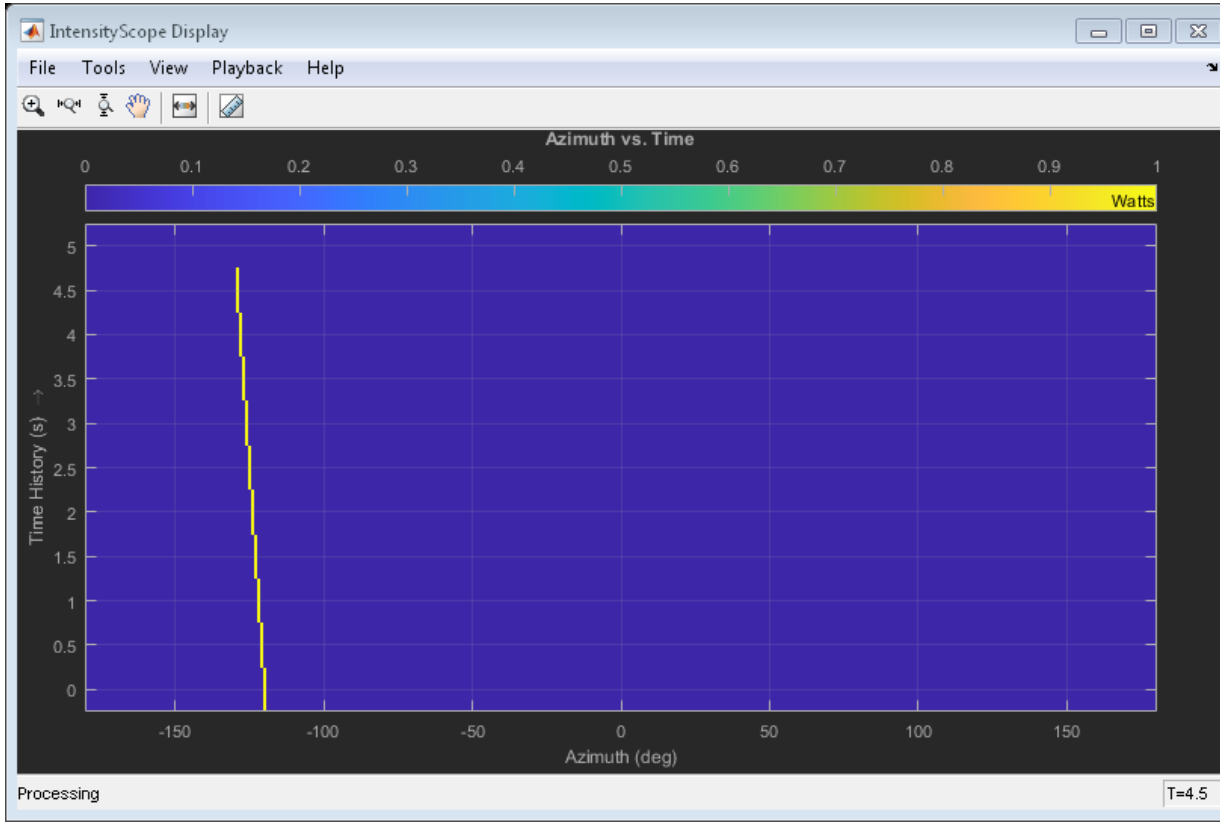
Create an angle-time-intensity scope having azimuth angle bins spanning –180° to 180° with 1° resolution.

```
scanline = zeros(361,1);
angres = 1.0;
angmin = -180.0;
angmax = 180.0;
rtidisplay = phased.IntensityScope( ...
    'Name','IntensityScope Display',...
    'Title','Azimuth vs. Time',...
    'XLabel','Azimuth (deg)', ...
    'XResolution',angres,'XOffset',angmin,...
    'TimeResolution',dt,'TimeSpan',timespan, ...
    'IntensityUnits','Watts',...
    'Position',[100,100,800,450]);
```

Loop Over Scan Updates

Simulate angular motion and fill the bin containing the current angular position of the signal. Hide the scope after the 5th step and show the scope at the end of the simulation.

```
for k = 1:nsteps
    ang = -130.0 + k;
    binindexdx = floor((ang - angmin)/angres) + 1;
    scanline(binindexdx) = 1;
    rtidisplay(scanline);
    scanline(binindexdx) = 0;
    if k == 5
        hide(rtidisplay)
    end
    pause(.1);
end
show(rtidisplay)
```



Introduced in R2016a

reset

System object: phased.IntensityScope
Package: phased

Reset state of intensity scope System object

Syntax

```
reset(sIS)
```

Description

`reset(sIS)` resets the internal state of the `phased.IntensityScope` System object, `sIS`, to its initial value.

Input Arguments

`sIS` — Intensity scope

`phased.IntensityScope` System object

Intensity scope, specified as a phased.IntensityScope System object.

Example: `phased.IntensityScope`

Introduced in R2016a

show

System object: phased.IntensityScope
Package: phased

Show intensity scope window

Syntax

```
show(sIS)
```

Description

`show(sIS)` shows the display window of the `phased.IntensityScope` object, `sIS`.

Input Arguments

`sIS` — Intensity scope

`phased.IntensityScope` System object

Intensity scope, specified as a phased.IntensityScope System object.

Example: `phased.IntensityScope`

Examples

Hide and Show Intensity Scope

Create an angle-time-intensity scope. Use the `phased.IntensityScope` System object™ to display simulated intensity as a function of the angular motion of a moving target. After five steps in the processing loop, use the `hide` method to hide the scope. At completion of the loop, use the `show` method to show the scope.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace

`myObject(x)` with `step(myObject,x)`.%% Simulate data for 5 seconds with a time interval of 0.5 seconds between scan lines.

```
nsteps = 10;
dt = 0.5;
timespan = nsteps*dt;
```

Set Up IntensityScope System Object

Create an angle-time-intensity scope having azimuth angle bins spanning –180° to 180° with 1° resolution.

```
scanline = zeros(361,1);
angres = 1.0;
angmin = -180.0;
angmax = 180.0;
rtidisplay = phased.IntensityScope( ...
    'Name','IntensityScope Display',...
    'Title','Azimuth vs. Time',...
    'XLabel','Azimuth (deg)', ...
    'XResolution',angres,'XOffset',angmin,...
    'TimeResolution',dt,'TimeSpan',timespan, ...
    'IntensityUnits','Watts',...
    'Position',[100,100,800,450]);
```

Loop Over Scan Updates

Simulate angular motion and fill the bin containing the current angular position of the signal. Hide the scope after the 5th step and show the scope at the end of the simulation.

```
for k = 1:nsteps
    ang = -130.0 + k;

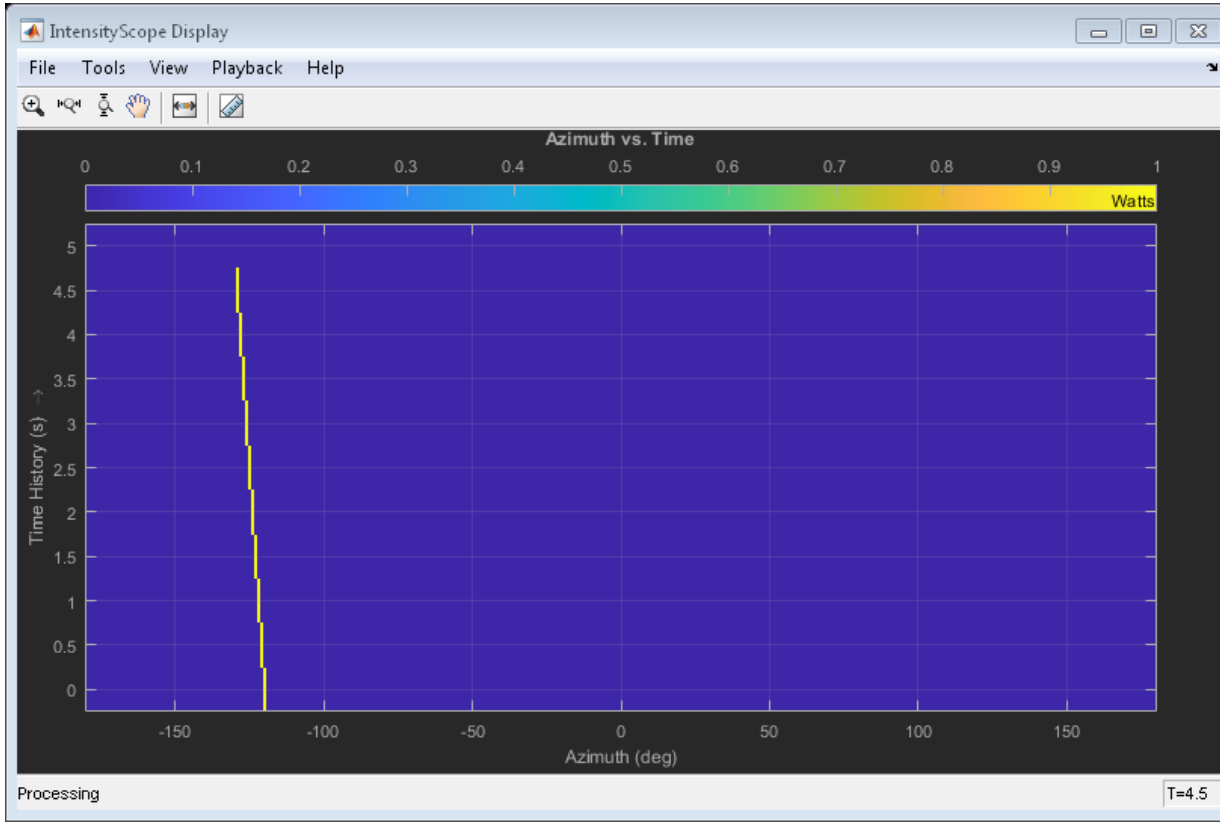
    scanline(binindexdx) = 1;
    rtidisplay(scanline);
    scanline(binindexdx) = 0;
    if k == 5
        hide(rtidisplay)
    end
    pause(.1);
end
show(rtidisplay)
```



Introduced in R2016a

step

System object: phased.IntensityScope
Package: phased

Update intensity scope display

Syntax

```
step(sIS,data)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`step(sIS,data)` updates the intensity scope display with new scan lines from a real signal, `data`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`sIS` — Intensity scope display

`phased.IntensityScope` System object

Intensity scope display, specified as a phased.IntensityScope System object.

Example: `phased.IntensityScope`

`data` — Displayed intensity values

real-valued *N*-by-*M* matrix

Displayed intensity values, specified as a real-valued *N*-by-*M* matrix. The quantity *N* specifies the number of intensity bins in `data`. The quantity *M* specifies the number of intensity vectors in the data. Each column of the matrix creates a display line. Units are arbitrary. Specify the time interval between intensity vectors using the `TimeResolution` property.

Example: `[5.0;5.1;5.0;4.9]`

Data Types: `double`

Examples

RTI Display of Three Moving Targets

Use the `phased.IntensityScope` System object™ to display the intensities of the echoes of three moving targets as functions of range and time.

Create the Radar and Target System Objects

Set up the initial positions and velocities of the three targets. Use the `phased.Platform` System object™ to model radar and target motions. The radar is stationary while the targets undergo constant velocity motion. The simulation runs for 500 steps at 0.1 second increments, giving a total simulation time of 50 seconds.

```
nsteps = 500;
dt = .1;
timespan = nsteps*dt;
x1 = [60,0,0]';
x2 = [60,-80,40]';
x3 = [300,0,-300]';
v1 = [2,0,0]';
v2 = [10,5,6]';
v3 = [-10,2,-4]';
platform = phased.Platform([0,0,0]',[0,0,0]');
targets = phased.Platform([x1,x2,x3],[v1,v2,v3]);
```

Set Up Range Bins

Each echo is put into a range bin. The range bin resolution is 1 meter and the range is from 50 to 1000 meters.

```
rngres = 1.0;
rngmin = 50.0;
rngmax = 1000.0;
rngscan = [rngmin:rngres:rngmax];
```

Create the Gain Function

Define a range-dependent gain function to enhance the display of targets at larger ranges. The gain function amplifies the returned echo for visualization purposes only.

```
rangegain = @(rng)(1e12*rng^4);
```

Create the Intensity Scope

Set up the Intensity Scope using these properties.

- Use the `XResolution` property to set the width of each scan line bin to the range resolution of 1 km.
- Use the `XOffset` property to set the value of the lowest range bin to the minimum range of 50 km.
- Use the `TimeResolution` property to set the value of the scan line time difference to 0.1 s.
- Use the `TimeSpan` property to set the height of the display window to the time duration of the simulation.
- Use the `IntensityUnits` property to set the display units to `Watts`.

```
scope = phased.IntensityScope('Name','IntensityScope Display',...
    'Title','Ranges vs. Time','XLabel','Range (m)','XResolution',rngres,...
    'XOffset',rngmin,'TimeResolution',dt,'TimeSpan',timespan, ...
    'IntensityUnits','Watts','Position',[100,100,800,450]);
```

Run Simulation Loop

1. In this loop, move the targets at constant velocity using the `step` method of the `phased.Platform` System object.
2. Compute the target ranges using the `rangeangle` function.

3. Compute the target range bins by quantizing the range values in integer multiples of `rangres`.
4. Fill each target range bin and neighboring bins with a simulated radar intensity value.
5. Add the signal from each target to the scan line.
6. Call the `step` method of the `phased.IntensityScope` System object to display the scan lines.

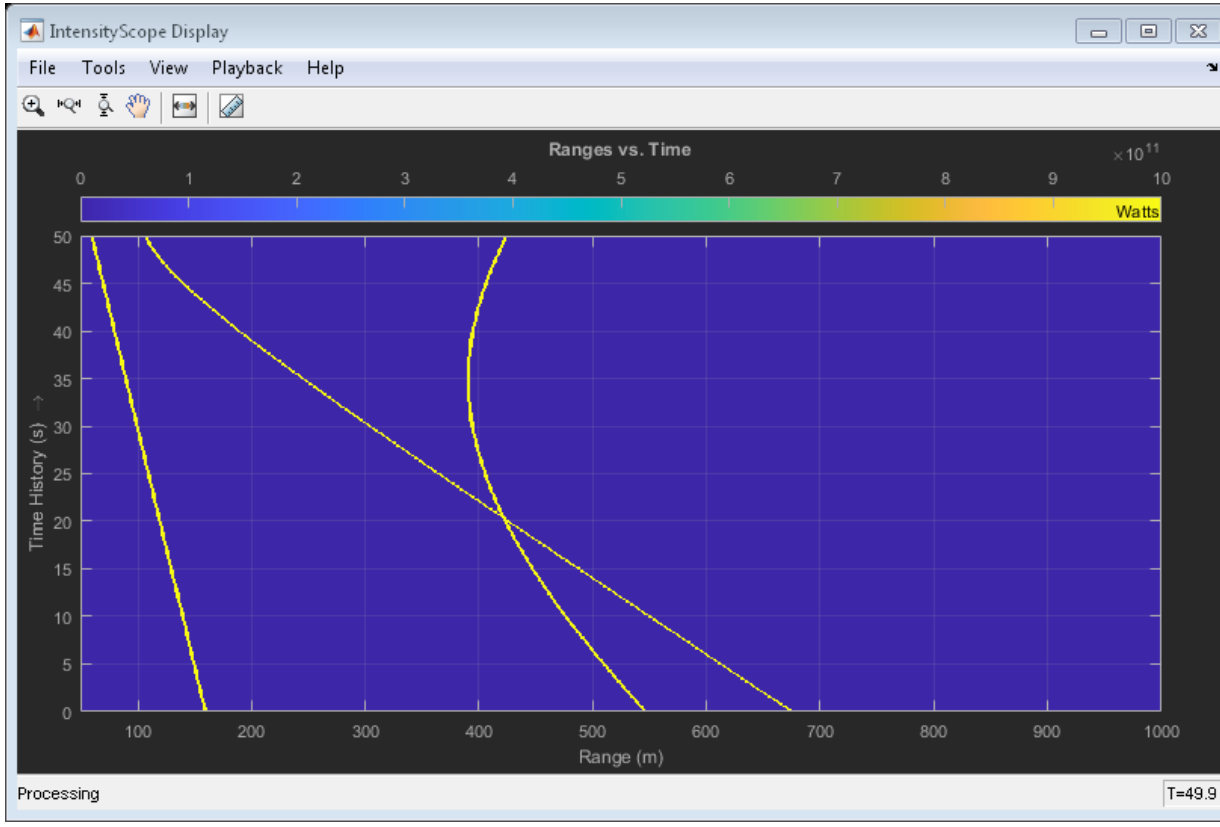
```
for k = 1:nsteps
    xradar = platform(dt);
    xtgts = targets(dt);
    [rngs] = rangeangle(xtgts,xradar);
    scanline = zeros(size(rngscan));

    rngindx = ceil((rngs(1) - rngmin)/rngres);
    scanline(rngindx + [-1:1]) = rangegain(rngs(1))/(rngs(1)^4);

    rngindx = ceil((rngs(2) - rngmin)/rngres);
    scanline(rngindx + [-1:1]) = rangegain(rngs(2))/(rngs(2)^4);

    rngindx = ceil((rngs(3) - rngmin)/rngres);
    scanline(rngindx + [-1:1]) = rangegain(rngs(3))/(rngs(3)^4);

    scope(scanline.');
    pause(.1);
end
```



RTI and DTI Displays in Full Radar Simulation

Use the `phased.IntensityScope` System object™ to display the detection output of a complete radar system simulation. The radar scenario contains a stationary single-element monostatic radar and three moving targets.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Set Radar Operating Parameters

Set the probability of detection, probability of false alarm, maximum range, range resolution, operating frequency, transmitter gain, and target radar cross-section.

```
pd = 0.9;
pfa = 1e-6;
max_range = 5000;
range_res = 50;
fc = 10e9;
tx_gain = 20;
tgt_rcs = 1;
```

Choose the signal propagation speed to be the speed of light, and compute the signal wavelength corresponding to the operating frequency.

```
c = physconst('LightSpeed');
lambda = c/fc;
```

Compute the pulse bandwith from the range resolution. Set the sampling rate, `fs`, to twice the pulse bandwidth. The noise bandwidth is also set to the pulse bandwidth. The radar integrates a number of pulses set by `num_pulse_int`. The duration of each pulse is the inverse of the pulse bandwidth.

```
pulse_bw = c/(2*range_res);
pulse_length = 1/pulse_bw;
fs = 2*pulse_bw;
noise_bw = pulse_bw;
num_pulse_int = 10;
```

Set the pulse repetition frequency to match the maximum range of the radar.

```
prf = c/(2*max_range);
```

Compute Transmit Power

Use the Albersheim equation to compute the SNR required to meet the desired probability of detection and probability of false alarm. Then, use the radar equation to compute the power needed to achieve the required SNR.

```
snr_min = albersheim(pd, pfa, num_pulse_int);
peak_power = radareqpow(lambda,max_range,snr_min,pulse_length,...
    'RCS',tgt_rcs,'Gain',tx_gain);
```

Create System Objects for the Model

Choose a rectangular waveform.

```
waveform = phased.RectangularWaveform('PulseWidth',pulse_length,...
```

```
    'PRF',prf,'SampleRate',fs);
```

Set the receiver amplifier characteristics.

```
amplifier = phased.ReceiverPreamp('Gain',20,'NoiseFigure',0,...
    'SampleRate',fs,'EnableInputPort',true,'SeedSource','Property',...
    'Seed',2007);
transmitter = phased.Transmitter('Gain',tx_gain,'PeakPower',peak_power,...
    'InUseOutputPort',true);
```

Specify the radar antenna as a single isotropic antenna.

```
antenna = phased.IsotropicAntennaElement('FrequencyRange',[5e9 15e9]);
```

Set up a monostatic radar platform.

```
radarplatform = phased.Platform('InitialPosition',[0; 0; 0],...
    'Velocity',[0; 0; 0]);
```

Set up the three target platforms using a single System object.

```
targetplatforms = phased.Platform(...
    'InitialPosition',[2000.66 3532.63 3845.04; 0 0 0; 0 0 0], ...
    'Velocity',[150 -150 0; 0 0 0; 0 0 0]);
```

Create the radiator and collector System objects.

```
radiator = phased.Radiator('Sensor',antenna,'OperatingFrequency',fc);
collector = phased.Collector('Sensor',antenna,'OperatingFrequency',fc);
```

Set up the three target RCS properties.

```
targets = phased.RadarTarget('MeanRCS',[1.6 2.2 1.05],'OperatingFrequency',fc);
```

Create System object to model two-way freespace propagation.

```
channels= phased.FreeSpace('SampleRate',fs,'TwoWayPropagation',true,...
    'OperatingFrequency',fc);
```

Define a matched filter.

```
MFcoef = getMatchedFilter(waveform);
filter = phased.MatchedFilter('Coefficients',MFcoef,'GainOutputPort',true);
```

Create Range and Doppler Bins

Set up the fast-time grid. Fast time is the sampling time of the echoed pulse relative to the pulse transmission time. The range bins are the ranges corresponding to each bin of the fast time grid.

```
fast_time = unigrid(0,1/fs,1/prf,'[)');
range_bins = c*fast_time/2;
```

To compensate for range loss, create a time varying gain System Object™.

```
gain = phased.TimeVaryingGain('RangeLoss',2*fspl(range_bins,lambda),...
    'ReferenceLoss',2*fspl(max_range,lambda));
```

Set up Doppler bins. Doppler bins are determined by the pulse repetition frequency. Create an FFT System object for Doppler processing.

```
DopplerFFTbins = 32;
DopplerRes = prf/DopplerFFTbins;
fft = dsp.FFT('FFTLengthSource','Property',...
    'FFTLength',DopplerFFTbins);
```

Create Data Cube

Set up a reduced data cube. Normally, a data cube has fast-time and slow-time dimensions and the number of sensors. Because data cube has only one sensor, it is two-dimensional.

```
rx_pulses = zeros(numel(fast_time),num_pulse_int);
```

Create IntensityScope System Objects

Create two IntensityScope System objects, one for Doppler-time-intensity and the other for range-time-intensity.

```
dtiscope = phased.IntensityScope('Name','Doppler-Time Display',...
    'XLabel','Velocity (m/sec)', ...
    'XResolution',dop2speed(DopplerRes,c/fc)/2, ...
    'XOffset',dop2speed(-prf/2,c/fc)/2,...
    'TimeResolution',0.05,'TimeSpan',5,'IntensityUnits','dB');
rtiscope = phased.IntensityScope('Name','Range-Time Display',...
    'XLabel','Range (m)', ...
    'XResolution',c/(2*fs), ...
```

```
    'TimeResolution',0.05,'TimeSpan',5,'IntensityUnits','dB');
```

Run the Simulation Loop Over Multiple Radar Transmissions

Transmit 2000 pulses. Coherently process groups of 10 pulses at a time.

For each pulse:

1. Update the radar position and velocity `radarplatform`
2. Update the target positions and velocities `targetplatforms`
3. Create the pulses of a single wave train to be transmitted `transmitter`
4. Compute the ranges and angles of the targets with respect to the radar
5. Radiate the signals to the targets `radiator`
6. Propagate the pulses to the target and back `channels`
7. Reflect the signals off the target `targets`
8. Receive the signal `sCollector`
9. Amplify the received signal `amplifier`
10. Form data cube

For each set of 10 pulses in the data cube:

1. Match filter each row (fast-time dimension) of the data cube.
2. Compute Doppler shifts of each row (slow-time dimension) of the data cube.

```
pri = 1/prf;
nsteps = 200;
for k = 1:nsteps
    for m = 1:num_pulse_int
        [ant_pos,ant_vel] = radarplatform(pri);
        [tgt_pos,tgt_vel] = targetplatforms(pri);
        sig = waveform();
        [s,tx_status] = transmitter(sig);
        [~,tgt_ang] = rangeangle(tgt_pos,ant_pos);
        tsig = radiator(s,tgt_ang);
        tsig = channels(tsig,ant_pos,tgt_pos,ant_vel,tgt_vel);
        rsig = targets(tsig);
        rsig = collector(rsig,tgt_ang);
        rx_pulses(:,m) = amplifier(rsig,~(tx_status>0));
    end
```

```
        rx_pulses = filter(rx_pulses);
        MFdelay = size(MFcoef,1) - 1;
        rx_pulses = buffer(rx_pulses((MFdelay + 1):end), size(rx_pulses,1));
        rx_pulses = gain(rx_pulses);
        range = pulsint(rx_pulses,'noncoherent');
        rtiscope(range);
        dshift = fft(rx_pulses.');
        dshift = fftshift(abs(dshift),1);
        dtiscope(mean(dshift,2));
        radarplatform(.05);
        targetplatforms(.05);
    end
```

All of the targets lie on the x-axis. Two targets are moving along the x-axis and one is stationary. Because the radar is at the origin, you can read the target speed directly from the Doppler-Time Display window. The values agree with the specified velocities of -150, 150, and 0 m/sec.

Intensity Scope Display of Target Angular Motion

Use the `phased.IntensityScope` System object™ to display the angular motions of moving targets as functions of time. Each horizontal line (scan line) shows the strength of radar echoes at different azimuth angles. Azimuth space is divided into azimuth bins and each bin is filled with a simulated value depending upon the position of the targets.

Create Radar and Target System Objects

Set up the initial positions and velocities of the three targets. Use the `phased.Platform` System object™ to model radar and target motions. The radar is stationary while the targets undergo constant velocity motion. The simulation runs for 200 steps at 0.5 second intervals, giving a total simulation time of 100 seconds.

```
nsteps = 200;
dt = 0.5;
timespan = nsteps*dt;
x1 = [60,0,0]';
x2 = [60,-80,40]';
x3 = [300,0,-300]';
x3 = [-300,0,-300]';

v1 = [2,0,0]';
v2 = [10,5,6]';
v3 = [-10,2,-4]';
radarplatform = phased.Platform([0,0,0]',[0,0,0]');
targets = phased.Platform([x1,x2,x3],[v1,v2,v3]);
```

Set Up Azimuth Angle Bins

The signal for each echo is put into an angle bin and two adjacent bins. Bin resolution is 1 degree and the angle span is from -180 to 180 degrees.

```
angres = 1.0;
angmin = -180.0;
angmax = 180.0;
angscan = [angmin:angres:angmax];
na = length(angscan);
```

Range Gain Function

Define a range-dependent gain function to enhance the display of targets at larger ranges. The gain function amplifies the returned echo for visualization purposes only.

```
rangegain = @(rng)(1e12*rng^4);
```

Set Up Scope Viewer

The `XResolution` name-value pair specifies the width of each bin of the scan line. The `XOffset` sets the value of the lowest azimuth angle bin. The `TimeResolution` name-value pair specifies the time difference between scan lines. The `TimeSpan` name-value

pair sets the height of the display window. A scan line is created with each call to the `step` method. Intensity units are amplitude units.

```
scope = phased.IntensityScope( ...
    'Name','IntensityScope Display',...
    'Title','Azimuth vs. Time',...
    'XLabel','Azimuth (deg)', ...
    'XResolution',angres,'XOffset',angmin,...
    'TimeResolution',dt,'TimeSpan',timespan, ...
    'IntensityUnits','Watts',...
    'Position',[100,100,800,450]);
```

Update-Display Loop

1. In this loop, move the targets at constant velocity using the `step` method of the `phased.Platform` System object.
2. Compute the target ranges and azimuth angles using the `rangeangle` function.
3. Compute the azimuth angle bins by quantizing the azimuth angle values in integer multiples of `angres`.
4. Fill each target azimuth bin and neighboring bins with a simulated radar intensity value.
5. Call the `phased.IntensityScope` `step` method to display the scan line.

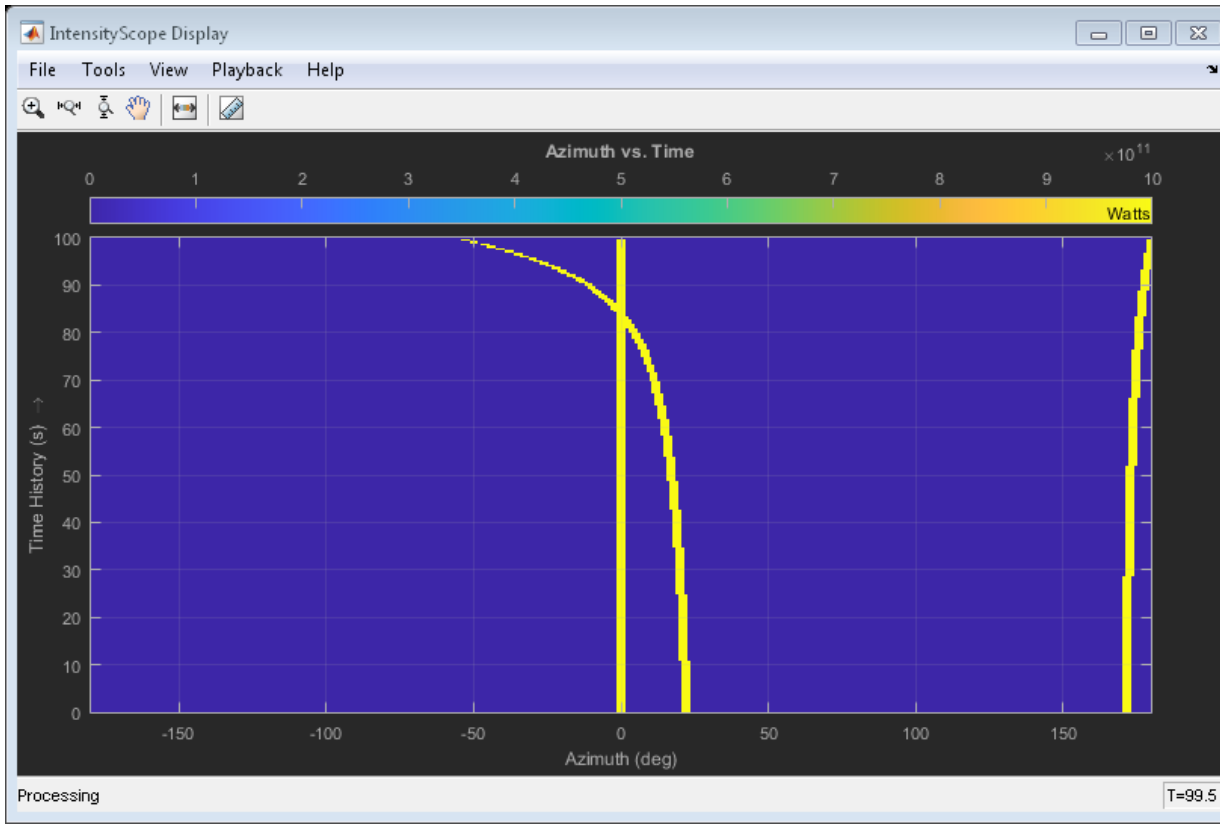
```
for k = 1:nsteps
    xradar = radarplatform(dt);
    xtgts = targets(dt);
    [rngs,angs] = rangeangle(xtgts,xradar);
    scanline = zeros(size(angscan));

    angindx = ceil((angs(1,1) - angmin)/angres) + 1;
    idx = angindx + [-1:1];
    idx(idx>na)=[];
    idx(idx<1)=[];
    scanline(idx) = rangegain(rngs(1))/(rngs(1)^4);

    angindx = ceil((angs(1,2) - angmin)/angres) + 1;
    idx = angindx + [-1:1];
    idx(idx>na)=[];
    idx(idx<1)=[];
    scanline(idx) = rangegain(rngs(2))/(rngs(2)^4);

    angindx = ceil((angs(1,3) - angmin)/angres) + 1;
    idx = angindx + [-1:1];
```

```
    idx(idx>na)=[];
    idx(idx<1)=[];
    scanline(idx) = rangegain(rngs(3))/(rngs(3)^4);
    scope(scanline.');
    pause(.1);
end
```



Introduced in R2016a

phased.IsoSpeedUnderwaterPaths System object

Package: phased

Isospeed multipath sonar channel

Description

The `phased.IsoSpeedUnderwaterPaths` System object creates an underwater acoustic channel to propagate narrowband sound from point to point. The channel has finite constant depth with air-water and water-bottom interfaces. Both interfaces are planar and horizontal. Sound speed is constant throughout the channel. The object generates multiple propagation paths in the channel using the acoustical method of images (see [3]). Because sound speed is constant, all propagation paths are straight lines between the source, boundaries, and receiver. There is always one direct line-of-sight path. For each propagation path, the object outputs range-dependent time delay, gain, Doppler factor, reflection loss, and spreading loss. You can use the channel data as input to the multipath sound propagator, phased.MultipathChannel.

To model an isospeed channel :

1. Define and set up the channel. You can set `phased.IsoSpeedUnderwaterPaths` System object properties at construction time or leave them to their default values. See “Construction” on page 1-944. Some properties that you set at construction time can be changed later. These properties are *tunable*.
2. To create the multipath channel, call the `step` method of `phased.IsoSpeedUnderwaterPaths`. The output of the method depends on the properties of the `phased.IsoSpeedUnderwaterPaths` System object. You can change tunable properties at any time.

Note: Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`channel = phased.IsoSpeedUnderwaterPaths` creates an isospeed multipath underwater channel System object, `channel`.

`channel = phased.IsoSpeedUnderwaterPaths(Name,Value)` creates an isospeed multipath underwater channel System object, `channel`, with each specified property `Name` set to the specified `Value`. You can specify additional name and value pair arguments in any order as (`Name1,Value1`,...,`NameN,ValueN`).

Properties

`ChannelDepth` — Channel depth

`100` (default) | positive scalar

Channel depth, specified as a positive scalar. Units are in meters.

Example: `250.0`

Data Types: `double`

`PropagationSpeed` — Underwater sound propagation speed

`1520.0` (default) | positive scalar

Underwater sound propagation speed, specified as a positive scalar. Units are in meter per second. The default value is a commonly-used underwater sound propagation speed.

Example: `1502.0`

Data Types: `double`

`NumPathsSource` — Source of number of propagation paths

`'Auto'` (default) | `'Property'`

The source of the number of propagation paths, specified as `'Auto'` or `'Property'`. If you set this property to `'Auto'`, the object automatically determines the number of paths based on spreading and reflection losses. If you set this property to `'Property'`, you specify the number of paths using the `NumPaths` property.

When `NumPathsSource` is set to `'Auto'`, only paths having a total loss greater than 20 dB below the direct path loss are returned.

Example: `'Property'`

Data Types: `char`

`NumPaths` — Number of propagation paths

`10` (default) | positive integer

The number of propagation paths, specified as a positive integer between 1 and 51, inclusive.

Example: `11`

Dependencies

To enable this property, set the `NumPathsSource` property to `'Property'`.

Data Types: `double`

`CoherenceTime` — Channel coherence time

`0` (default) | nonnegative scalar

Channel coherence time, specified as a nonnegative scalar. Coherence time is a measure of the temporal stability of the channel. The object keeps a record of cumulative step time. When the cumulative step time exceeds the coherence time, propagation paths are recomputed and the cumulative step time is reset to zero. If you set this quantity to zero, the propagation paths are update at each call to `step`. Units are in seconds.

Example: `5.0`

Data Types: `double`

`BottomLoss` — Bottom reflection loss

`6` (default) | nonnegative scalar

Bottom reflection loss, specified as a nonnegative scalar. This value applies to each bottom reflection of a path. Units are in dB.

Example: `10`

Data Types: `double`

`LossFrequencies` — Absorption loss frequencies

`[1:100]*1000` (default) | positive real-valued vector

Frequencies for which to compute absorption loss, specified as a positive real-valued vector. Units are in Hz.

Example: `[1000:100:3000]`

Data Types: `double`

`TwoWayPropagation` — Enable two-way propagation
`false` (default) | `true`

Enable two-way propagation, specified as a `false` or `true`. Set this property to `true` to perform round-trip propagation between the signal origin and destination specified in `step`. Set this property to `false` to perform only one-way propagation from the origin to the destination.

Example: `true`

Data Types: `logical`

Methods

step	Create propagation paths in an isospeed multipath sound channel
reset	Reset state of System object

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Create One-Way Multipath Underwater Sound Channel

Create a 5-path underwater sound channel and display the propagation path matrix. Assume the source is stationary and the receiver is moving along the *x*-axis towards the source at 20 kph. Assume one-way propagation.

```
speed = -20*1000/3600;
```

```
numpaths = 5;
channelpaths = phased.IsoSpeedUnderwaterPaths('ChannelDepth',200,'BottomLoss',10, ...
    'NumPathsSource','Property','NumPaths',numpaths,'CoherenceTime',5);
tstep = 1;
srcpos = [0;0;-160];
rcvpos = [500;0;-50];
srcvel = [0;0;0];
rcvvel = [speed;0;0];
pathmat = channelpaths(srcpos,rcvpos,srcvel,rcvvel,tstep);
disp(pathmat)
```

```
    0.3356    0.3556    0.4687    0.3507    0.3791
    1.0000   -1.0000   -0.3162    0.3162   -0.3162
   54.1847   54.6850   57.0766   54.5652   55.2388
```

The first row contains the time delay in seconds. The second row contains the bottom reflection loss coefficients, and the third row contains the spreading loss in dB. The reflection loss coefficient for the first path is 1.0 because the direct path has no boundary reflections. The reflection loss coefficient for the second path is -1.0 because the path has only a surface reflection.

Create Two-Way Multipath Underwater Sound Channel

Create a 7-path underwater sound channel and display the propagation path matrix. Assume the source is stationary and the target is moving along the *x*-axis towards the source at 20 kph. Assume two-way propagation.

```
speed = -20*1000/3600;
numpaths = 7;
channelpaths = phased.IsoSpeedUnderwaterPaths('ChannelDepth',200,'BottomLoss',10, ...
    'NumPathsSource','Property','NumPaths',numpaths,'CoherenceTime',5,...
    'TwoWayPropagation',true);
tstep = 1;
srcpos = [0;0;-160];
tgtpos = [500;0;-50];
srcvel = [0;0;0];
tgtvel = [speed;0;0];
[pathmat,dop,aloss,tgtangs,srcangs] = channelpaths(srcpos,tgtpos,srcvel,tgtvel,tstep);
disp(pathmat)
```

```
    0.6712    0.7112    0.9374    1.0354    0.7014    0.7581    1.0152
    1.0000    1.0000    0.1000    0.1000    0.1000    0.1000    0.0100
  108.3693  109.3699  114.1531  115.8772  109.1304  110.4775  115.5355
```

The first row contains the time delay in seconds. The second row contains the bottom reflection loss coefficients, and the third row contains the spreading loss in dB. The reflection loss coefficient for the first path is 1.0 because the direct path has no boundary reflections. The reflection loss coefficient for the second path is -1.0 because the path has only a surface reflection.

Propagate Sound in Channel Having Unknown Number of Paths

Create an underwater sound channel and and plot the combined received signal. Automatically find the number of paths. Assume that the source is stationary and that the receiver is moving along the *x*-axis toward the source at 20 km/h. Assume the default one-way propagation.

```
speed = -20*1000/3600;
channel = phased.IsoSpeedUnderwaterPaths('ChannelDepth',200,'BottomLoss',5, ...
    'NumPathsSource','Auto','CoherenceTime',5);
tstep = 1;
srcpos = [0;0;-160];
rcvpos = [500;0;-50];
srcvel = [0;0;0];
rcvvel = [speed;0;0];
```

Compute the path matrix, Doppler factor, and losses. The propagator outputs 51 paths output but some paths can contain `Nan` values.

```
[pathmat,dop,absloss,rcvangs,srcangs] = channel(srcpos,rcvpos,srcvel,rcvvel,tstep);
```

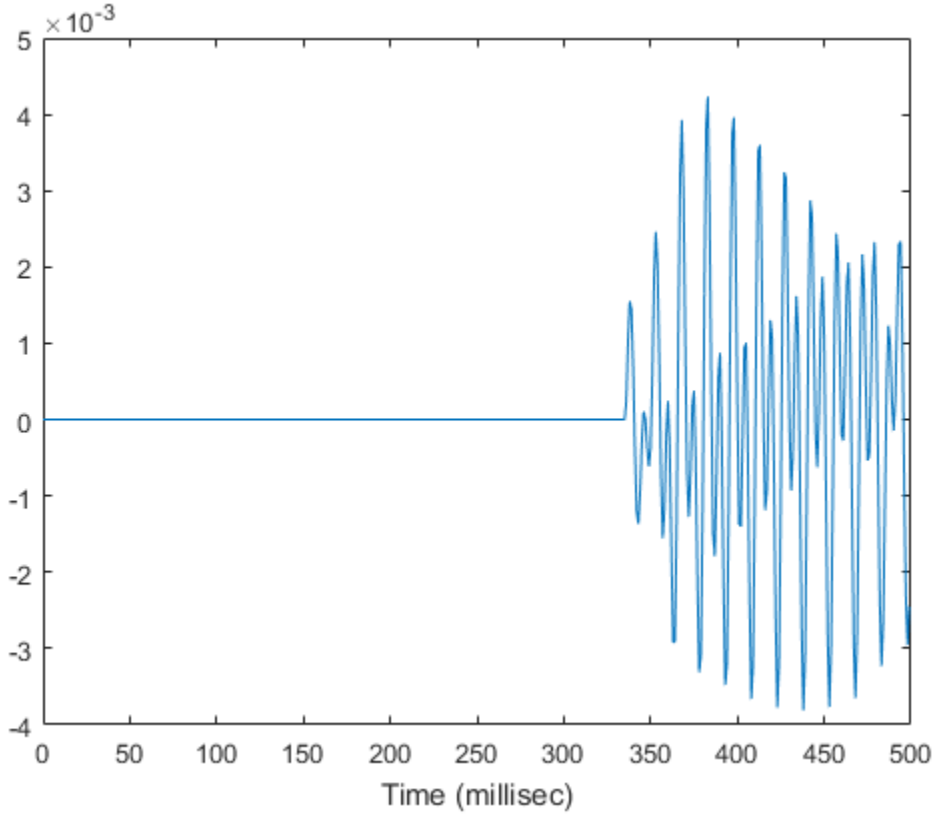
Create of a 100 Hz signal with 500 samples. Assume that all the paths have the same signal. Use a `phased.MultipathChannel` System object to propagate the signals to the receiver. `phased.MultipathChannel` accepts as input all paths produced by `phased.IsoSpeedUnderwaterPaths` but ignores paths that have `NaN` values.

```
fs = 1e3;
nsamp = 500;
propagator = phased.MultipathChannel('OperatingFrequency',10e3,'SampleRate',fs);
t = [0:(nsamp-1)]'/fs;
sig0 = sin(2*pi*100*t);
numpaths = size(pathmat,2);
sig = repmat(sig0,1,numpaths);
propsig = propagator(sig,pathmat,dop,absloss);
```

Plot the real part of the coherent sum of the propagated signals.

```
plot(t*1000,real(sum(propsig,2)))
```

```
xlabel('Time (millisec)')
```



Doppler Stretching of Sonar Signal

Compare the lengths of a propagated signal when the sonar is stationary differs compared to when the sonar is moving. In the second case, the sonar has a radial velocity of 25 m/s moving away from the target. Propagate the signal along a single path.

Define the system parameters: maximum unambiguous range, required range resolution, operating frequency, and propagation speed.

```
maxrange = 5000.0;
rngres = 10.0;
fc = 20.0e3;
```

```
csound = 1520.0;
```

Use a rectangular waveform for the transmitted signal.

```
prf = csound/(2*maxrange);
pulseWidth = 8*rngres/csound;
pulseBW = 1/pulseWidth;
fs = 80*pulseBW;
waveform = phased.RectangularWaveform('PulseWidth',pulseWidth,'PRF',prf, ...
    'SampleRate',fs);
```

Specify the sonar positions.

```
sonarplatform1 = phased.Platform('InitialPosition',[0;0;-60],'Velocity',[0;0;0]);
sonarplatform2 = phased.Platform('InitialPosition',[0;0;-60],'Velocity',[0;-25;0]);
```

Specify the target position.

```
targetplatform = phased.Platform('InitialPosition',[0;500;-60],'Velocity',[0;0;0]);
```

Define the underwater path and propagation channel objects. Assume one-way propagation.

```
paths = phased.IsoSpeedUnderwaterPaths('ChannelDepth',100, ...
    'CoherenceTime',0,'NumPathsSource','Property','NumPaths',1, ...
    'PropagationSpeed',csound);
propagator = phased.MultipathChannel('SampleRate',fs,'OperatingFrequency',fc);
```

Transmit a rectangular waveform.

```
wav = waveform();
nsamp = size(wav,1);
rxpulses = zeros(nsamp,2);
t = (0:nsamp-1)/fs;
```

Transmit and receive at the stationary sonar.

```
[pathmat,dop,aloss,tgtang,srcang] = paths(sonarplatform1.InitialPosition, ...
    targetplatform.InitialPosition,sonarplatform1.InitialVelocity, ...
    targetplatform.InitialVelocity,1/prf);
rxpulses(:,1) = propagator(wav,pathmat,dop,aloss);
```

Transmit and receive at the moving sonar.

```
[pathmat,dop,aloss,tgtang,srcang] = paths(sonarplatform2.InitialPosition, ...
    targetplatform.InitialPosition,sonarplatform2.Velocity, ...
    targetplatform.Velocity,1/prf);
```

```
rxpulses(:,2) = propagator(wav,pathmat,dop,aloss);
```

Plot the received pulses.

```
plot(abs(rxpulses))
xlim([490 650])
ylim([0 1.65e-3])
legend('Stationary sonar','Moving sonar')
xlabel('Received Sample Time (sec)')
ylabel('Integrated Received Pulses')
```

The signal received at the moving sonar has increased in duration compared to the stationary sonar.

step

System object: phased.IsoSpeedUnderwaterPaths
Package: phased

Create propagation paths in an isospeed multipath sound channel

Syntax

```
pathmat = step(channel,srcpos,destpos,srcvel,destvel,T)
[pathmat,dop,aloss,destang,srcang] = step(channel,srcpos,destpos,
srcvel,destvel,T)
```

Description

Note: Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`pathmat = step(channel,srcpos,destpos,srcvel,destvel,T)` returns the propagation paths matrix, `pathmat`, for a multipath underwater acoustic channel. The matrix describes one or two-way propagation from the signal source position, `srcpos`, to the signal destination position, `destpos`. The velocity of the signal source is specified in `srcvel` and the velocity of the signal destination is specified in `destvel`. `T` is the step time interval.

When you use this method for one-way propagation, `srcpos` refers to the origin of the signal and `destpos` to the receiver. One-way propagation modeling is useful for passive sonar and underwater communications.

When you use this method for two-way propagation, `destpos` now refers to the reflecting target, not the sonar receiver. A two-way path consists of a one-way path from source to target and then along an identical one-way path from target to receiver (which is collocated with the source). Two-way propagation modeling is useful for active sonar systems.

`[pathmat,dop,aloss,destang,srcang] = step(channel,srcpos,destpos, srcvel,destvel,T)` also returns the Doppler factor, `dop`, the frequency dependent absorption loss, `aloss`, the receiver arrival angles, `destang`, and the `srcang` transmitting angles.

When you use this method for two-way propagation, `destang` now refers to the reflecting target, not the sonar receiver.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Note: Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Input Arguments

`channel` — Isospeed underwater channel path

`phased.IsoSpeedUnderwaterPaths` System object

Isospeed underwater channel paths, specified as a `phased.IsoSpeedUnderwaterPaths` System object.

Example: `phased.IsoSpeedUnderwaterPaths`

`srcpos` — Source of sonar signals

real-valued 3-by-1 column vector

Source of the sonar signal, specified as a real-valued 3-by-1 column vector. Position units are meters.

Example: `[1000;100;500]`

Data Types: `double`

`destpos` — Destination of signal

real-valued 3-by-1 column vector

Destination position of the signal, specified as a real-valued 3-by-1 column vector. Position units are in meters.

Example: `[0;0;0]`

Data Types: `double`

`srcvel` — Velocity of signal source

real-valued 3-by-1 column vector

Velocity of signal source, specified as a real-valued 3-by-1 column vector. Velocity units are in meters per second.

Example: `[10;0;5]`

Data Types: `double`

`destvel` — Velocity of signal destination

real-valued 3-by-1 column vector

Velocity of signal destination, specified as a real-valued 3-by-1 column vector. Velocity units are in meters per second.

Example: `[0;0;0]`

Data Types: `double`

`T` — Elapsed time of current step

positive scalar

Elapsed time of current step, specified as a positive scalar. Time units are in seconds.

Example: `0.1`

Data Types: `double`

Output Arguments

`pathmat` — Propagation paths matrix

real-valued 3-by-N matrix

Propagation paths matrix, returned as a real-valued 3-by-*N* matrix. *N* is the number of paths in the channel. Each column represents a path. When you set `NumPathsSource` to `'Auto'`, *N* is 51. In this case, any columns filled with `NaN` do not correspond to found paths. The matrix rows represent:

Row	Data
1	Propagation delays for each path. Units are in seconds.
2	Total reflection coefficient for each path. Units are dimensionless
3	Spreading loss for each path. Units are in dB.

Except for the direct path, paths consists of alternating surface and bottom reflections. The losses for multiple reflections are multiplied. Bottom loss per reflection is specified by the `BottomLoss` property. The loss at the surface is *–1* indicating no loss, but only a 180° phase change. This is because the air-water interface surface is a pressure-release surface.

Data Types: `double`

`dop` — Doppler factor

real-valued *N*-by-1 row vector

Doppler factor, returned as a real-valued *N*-by-1 row vector where *N* is the number of paths. The Doppler factor multiplies the transmitted frequency to produce the Doppler-shifted received frequency for each path. The Doppler shift is defined as the difference between the transmitted frequency and the received frequency. The Doppler factor also defines the time compression or expansion of a signal. Units are dimensionless.

Data Types: `double`

`aloss` — Frequency-dependent absorption loss

real-valued *K*-by-*(N+1)* matrix

Frequency-dependent absorption loss, returned as a real-valued *K*-by-*(N+1)* matrix. *K* is the number of frequencies specified in the `LossFrequencies` property. *N* is the number of paths returned. The first column of `aloss` contains the absorption loss frequencies in Hz. You specify the frequencies using the `LossFrequencies` property. The remaining columns contain the absorption losses for each frequency. There is one column for each path. Units are in dB.

Data Types: `double`

`destang` — Angles of paths at destination

real-valued 2-by-*N* matrix

Angles of paths at destination, returned as a real-valued 2-by-*N* matrix. Each column contains the direction of the received path with respect to the destination position as azimuth and elevation, `[az;el]`. Units are in degrees.

Data Types: `double`

`srcang` — Angles of paths from source

real-valued 2-by-*N* matrix

Angles of paths from source, returned as a real-valued 2-by-*N* matrix. Each column contains the direction of the transmitted path with respect to the source position as azimuth and elevation, `[az;el]`. Units are in degrees.

Data Types: `double`

Examples

Create One-Way Multipath Underwater Sound Channel

Create a 5-path underwater sound channel and display the propagation path matrix. Assume the source is stationary and the receiver is moving along the *x*-axis towards the source at 20 kph. Assume one-way propagation.

```
speed = -20*1000/3600;
numpaths = 5;
channelpaths = phased.IsoSpeedUnderwaterPaths('ChannelDepth',200,'BottomLoss',10, ...
    'NumPathsSource','Property','NumPaths',numpaths,'CoherenceTime',5);
tstep = 1;
srcpos = [0;0;-160];
rcvpos = [500;0;-50];
srcvel = [0;0;0];
rcvvel = [speed;0;0];
pathmat = channelpaths(srcpos,rcvpos,srcvel,rcvvel,tstep);
disp(pathmat)
```

```
    0.3356    0.3556    0.4687    0.3507    0.3791
    1.0000   -1.0000   -0.3162    0.3162   -0.3162
   54.1847   54.6850   57.0766   54.5652   55.2388
```

The first row contains the time delay in seconds. The second row contains the bottom reflection loss coefficients, and the third row contains the spreading loss in dB. The reflection loss coefficient for the first path is 1.0 because the direct path has no boundary reflections. The reflection loss coefficient for the second path is -1.0 because the path has only a surface reflection.

Create Two-Way Multipath Underwater Sound Channel

Create a 7-path underwater sound channel and display the propagation path matrix. Assume the source is stationary and the target is moving along the *x*-axis towards the source at 20 kph. Assume two-way propagation.

```
speed = -20*1000/3600;
numpaths = 7;
channelpaths = phased.IsoSpeedUnderwaterPaths('ChannelDepth',200,'BottomLoss',10, ...
    'NumPathsSource','Property','NumPaths',numpaths,'CoherenceTime',5,...
    'TwoWayPropagation',true);
tstep = 1;
srcpos = [0;0;-160];
tgtpos = [500;0;-50];
srcvel = [0;0;0];
tgtvel = [speed;0;0];
[pathmat,dop,aloss,tgtangs,srcangs] = channelpaths(srcpos,tgtpos,srcvel,tgtvel,tstep);
disp(pathmat)
```

```
    0.6712    0.7112    0.9374    1.0354    0.7014    0.7581    1.0152
    1.0000    1.0000    0.1000    0.1000    0.1000    0.1000    0.0100
  108.3693  109.3699  114.1531  115.8772  109.1304  110.4775  115.5355
```

The first row contains the time delay in seconds. The second row contains the bottom reflection loss coefficients, and the third row contains the spreading loss in dB. The reflection loss coefficient for the first path is 1.0 because the direct path has no boundary reflections. The reflection loss coefficient for the second path is -1.0 because the path has only a surface reflection.

Automatically Find the Number of Paths

Create an underwater sound channel and and display the propagation paths which are found automatically. Assume the source is stationary and the receiver is moving along the *x*-axis towards the source at 20 kph. Assume two-way propagation.

```
speed = -20*1000/3600;
channelpaths = phased.IsoSpeedUnderwaterPaths('ChannelDepth',200,'BottomLoss',5, ...
```

```
    'NumPathsSource','Auto','CoherenceTime',5,'TwoWayPropagation',true);
tstep = 1;
srcpos = [0;0;-160];
tgtpos = [500;0;-50];
srcvel = [0;0;0];
tgtpos = [speed;0;0];
[pathmat,dop,aloss,rcvangs,srcangs] = channelpaths(srcpos,tgtpos,srcvel,tgtpos,tstep);
```

Display the first 7 columns of `pathmat`. Some columns are filled with |NaN|s.

```
disp(pathmat(:,1:7))
```

```
    0.2107    0.2107       NaN       NaN       NaN       NaN       NaN
    1.0000    1.0000       NaN       NaN       NaN       NaN       NaN
   88.1753   88.1753       NaN       NaN       NaN       NaN       NaN
```

Select the column indices of the valid paths from the entire matrix.

```
idx = find(~isnan(pathmat(1,:)))
```

```
idx =

     1     2    27    28
```

Display the valid paths information.

```
validpaths = pathmat(:,idx)
```

```
validpaths =

    0.2107    0.2107    0.3159    0.3159
    1.0000    1.0000    0.3162    0.3162
   88.1753   88.1753   95.2131   95.2131
```

The first row contains the time delays in seconds. The second row contains the bottom reflected loss coefficients, and the third row contains the spreading losses.

Introduced in R2017a

reset

System object: phased.IsoSpeedUnderwaterPaths
Package: phased

Reset state of System object

Syntax

```
reset(channel)
```

Description

`reset(channel)` resets the internal state of the `phased.IsoSpeedUnderwaterPaths` object, `channel`. This method resets the coherence time clock.

Input Arguments

`channel` — Isospeed underwater channel path

`phased.IsoSpeedUnderwaterPaths` System object

Isospeed underwater channel paths, specified as a `phased.IsoSpeedUnderwaterPaths` System object.

Example: `phased.IsoSpeedUnderwaterPaths`

Introduced in R2017a

phased.IsotropicAntennaElement System object

Package: phased

Isotropic antenna element

Description

The `IsotropicAntennaElement` object creates an antenna element with an isotropic response pattern. This antenna object does not support polarization.

To compute the response of the antenna element for specified directions:

1. Define and set up your isotropic antenna element. See "Construction" on page 1-961.
2. Call step to compute the antenna response according to the properties of `phased.IsotropicAntennaElement`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.IsotropicAntennaElement` creates an isotropic antenna system object, `H`. The object models an antenna element whose response is 1 in all directions.

`H = phased.IsotropicAntennaElement(Name,Value)` creates an isotropic antenna object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`FrequencyRange`

Operating frequency range

Specify the antenna element operating frequency range (in Hz) as a 1-by-2 row vector in the form of `[LowerBound HigherBound]`. The antenna element has zero response outside the specified frequency range.

Default: `[0 1e20]`

`BackBaffled`

Baffle the back of antenna element

Set this property to `true` to baffle the back of the antenna element. In this case, the antenna responses to all azimuth angles beyond +/– 90 degrees from the broadside (0 degrees azimuth and elevation) are 0.

When the value of this property is `false`, the back of the antenna element is not baffled.

Default: `false`

Methods

directivity	Directivity of isotropic antenna element
isPolarizationCapable	Polarization capability
pattern	Plot isotropic antenna element directivity and patterns
patternAzimuth	Plot isotropic antenna element directivity or pattern versus azimuth
patternElevation	Plot isotropic antenna element directivity or pattern versus elevation
plotResponse	Plot response pattern of antenna
step	Output response of antenna element

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Plot Isotropic Antenna Element Response

Create an isotropic antenna operating over a frequency range from 800 MHz to 1.2 GHz. The operating frequency is 1 GHz. Find the response of the antenna at boresight. Then, plot the polar-pattern elevation response of the antenna.

```
antenna = phased.IsotropicAntennaElement('FrequencyRange',[800e6 1.2e9]);
fc = 1e9;
```

Obtain the response at boresight.

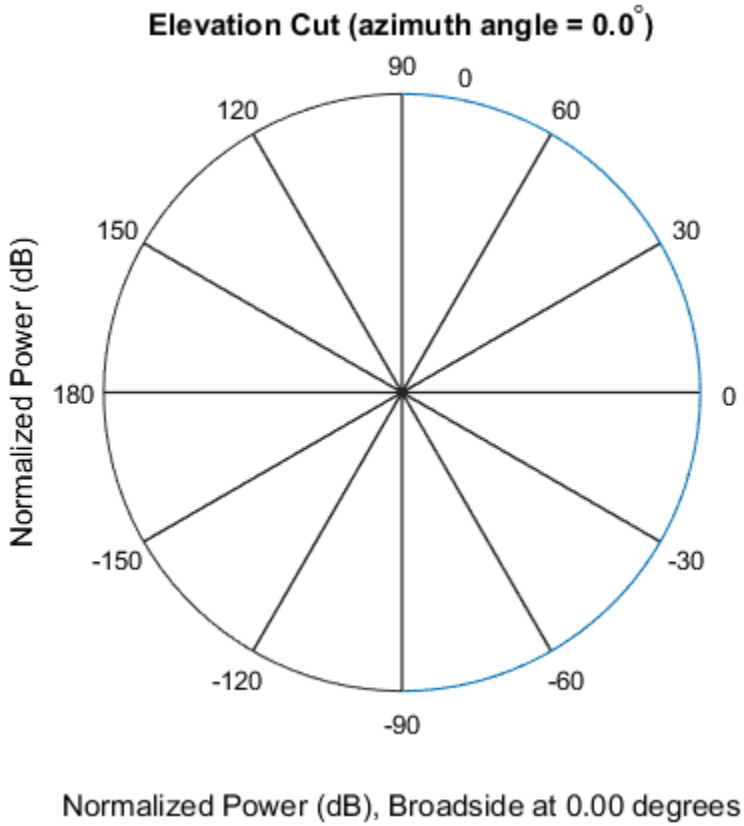
```
resp = antenna(fc,[0;0])
```

```
resp =

     1
```

Plot the response pattern.

```
pattern(antenna,fc,0,[-90:90],'CoordinateSystem','polar','Type','powerdb', ...
    'Normalize',true)
```



Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- `pattern`, `patternAzimuth`, `patternElevation`, and `plotResponse` methods are not supported.

- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Introduced in R2012a

directivity

System object: phased.IsotropicAntennaElement
Package: phased

Directivity of isotropic antenna element

Syntax

```
D = directivity(H,FREQ,ANGLE)
```

Description

`D = directivity(H,FREQ,ANGLE)` returns the "Directivity (dBi)" on page 1-969 of an isotropic antenna element, `H`, at frequencies specified by `FREQ` and in direction angles specified by `ANGLE`.

Input Arguments

`H` — Isotropic antenna element

System object

Isotropic antenna element specified as a phased.IsotropicAntennaElement System object.

Example: `H = phased.IsotropicAntennaElement;`

`FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the

directivity is returned as `-Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.

- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `-Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

`ANGLE` — Angles for computing directivity

1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Angles for computing directivity, specified as a 1-by-*M* real-valued row vector or a 2-by-*M* real-valued matrix, where *M* is the number of angular directions. Angle units are in degrees. If `ANGLE` is a 2-by-*M* matrix, then each column specifies a direction in azimuth and elevation, `[az;el]`. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°.

If `ANGLE` is a 1-by-*M* vector, then each entry represents an azimuth angle, with the elevation angle assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis.

Example: `[45 60; 0 10]`

Data Types: `double`

Output Arguments

`D` — Directivity

M-by-*L* matrix

Directivity, returned as an *M*-by-*L* matrix whose columns contain the directivities at the *M* angles specified by `ANGLE`. Each column corresponds to one of the *L* frequency values specified in `FREQ`. Directivity units are in dBi.

Examples

Directivity of Isotropic Antenna Element

Compute the directivity of an isotropic antenna element in different directions.

Create an isotropic antenna element system object.

```
myAnt = phased.IsotropicAntennaElement();
```

First, select the angles of interest to be constant elevation angle at zero degrees. The seven azimuth angles are centered around boresight (zero degrees azimuth and zero degrees elevation). Set the frequency to 1 GHz.

```
ang = [-30,-20,-10,0,10,20,30; 0,0,0,0,0,0,0];
freq = 1e9;
```

Compute the directivity along the constant elevation cut.

```
d = directivity(myAnt,freq,ang)
```

```
d =

     0
     0
     0
     0
     0
     0
     0
```

Next choose the desired angles of interest to be at constant azimuth angle at zero degrees. All elevation angles are centered around boresight. The five elevation angles range from -20 to +20 degrees. Set the desired frequency to 1 GHz.

```
ang = [0,0,0,0,0; -20,-10,0,10,20];
freq = 1e9;
```

Compute the directivity along the constant azimuth cut.

```
d = directivity(myAnt,freq,ang)
```

```
d =

     0
     0
     0
     0
     0
```

For an isotropic antenna, the directivity is independent of direction.

Definitions

Directivity (dBi)

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element directivity” and “Array directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular

mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

phased.IsotropicAntennaElement.plotResponse

isPolarizationCapable

System object: phased.IsotropicAntennaElement
Package: phased

Polarization capability

Syntax

```
flag = isPolarizationCapable(h)
```

Description

`flag = isPolarizationCapable(h)` returns a Boolean value, `flag`, indicating whether the phased.IsotropicAntennaElement System object supports polarization. An antenna element supports polarization if it can create or respond to polarized fields. This object does not support polarization.

Input Arguments

h — Isotropic antenna element

Isotropic antenna element specified as a phased.IsotropicAntennaElement System object.

Output Arguments

`flag` — Polarization-capability flag

Polarization-capability returned as a Boolean value `true` if the antenna element supports polarization or `false` if it does not. Since the phased.IsotropicAntennaElement object does not support polarization, `flag` is always returned as `false`.

Examples

Isotropic Antenna Does Not Support Polarization

Create an isotropic antenna element using the `phased.IsotropicAntennaElement` System object™ and show that it does not support polarization.

```
antenna = phased.IsotropicAntennaElement('FrequencyRange',[1.0,10]*1e9);
isPolarizationCapable(antenna)
```

```
ans =

  logical

   0
```

The returned value `0` shows that the antenna element does not support polarization.

pattern

System object: phased.IsotropicAntennaElement
Package: phased

Plot isotropic antenna element directivity and patterns

Syntax

```
pattern(sElem,FREQ)
pattern(sElem,FREQ,AZ)
pattern(sElem,FREQ,AZ,EL)
pattern( ___ ,Name,Value)
[PAT,AZ_ANG,EL_ANG] = pattern( ___ )
```

Description

`pattern(sElem,FREQ)` plots the 3-D array directivity pattern (in dBi) for the element specified in `sElem`. The operating frequency is specified in `FREQ`.

`pattern(sElem,FREQ,AZ)` plots the element directivity pattern at the specified azimuth angle.

`pattern(sElem,FREQ,AZ,EL)` plots the element directivity pattern at specified azimuth and elevation angles.

`pattern( ___ ,Name,Value)` plots the element pattern with additional options specified by one or more `Name,Value` pair arguments.

`[PAT,AZ_ANG,EL_ANG] = pattern( ___ )` returns the element pattern in `PAT`. The `AZ_ANG` output contains the coordinate values corresponding to the rows of `PAT`. The `EL_ANG` output contains the coordinate values corresponding to the columns of `PAT`. If the `'CoordinateSystem'` parameter is set to `'uv'`, then `AZ_ANG` contains the *U* coordinates of the pattern and `EL_ANG` contains the *V* coordinates of the pattern. Otherwise, they are in angular units in degrees. *UV* units are dimensionless.

Note: This method replaces the `plotResponse` method. See "Convert plotResponse to pattern" on page 1-983 for guidelines on how to use `pattern` in place of `plotResponse`.

Input Arguments

`sElem` — Isotropic antenna element

System object

Isotropic antenna element, specified as a phased.IsotropicAntennaElement System object.

Example: `sElem = phased.IsotropicAntennaElement;`

`FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `-Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `-Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

`AZ` — Azimuth angles

`[-180:180]` (default) | 1-by-*M* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a 1-by-*M* real-valued row vector where *M* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, this angle is positive.

Example: `[-45:2:45]`

Data Types: `double`

`EL` — Elevation angles

`[-90:90]` (default) | 1-by-*N* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a 1-by-*N* real-valued row vector where *N* is the number of desired elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and *xy*-plane. When measured towards the *z*-axis, this angle is positive.

Example: `[-75:1:70]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'CoordinateSystem'` — Plotting coordinate system

`'polar'` (default) | `'rectangular'` | `'uv'`

Plotting coordinate system of the pattern, specified as the comma-separated pair consisting of `'CoordinateSystem'` and one of `'polar'`, `'rectangular'`, or `'uv'`. When `'CoordinateSystem'` is set to `'polar'` or `'rectangular'`, the `AZ` and `EL` arguments specify the pattern azimuth and elevation, respectively. `AZ` values must lie between –180° and 180°. `EL` values must lie between –90° and 90°. If `'CoordinateSystem'` is set to `'uv'`, `AZ` and `EL` then specify *U* and *V* coordinates, respectively. `AZ` and `EL` must lie between -1 and 1.

Example: `'uv'`

Data Types: `char`

'Type' — Displayed pattern type

'directivity' (default) | 'efield' | 'power' | 'powerdb'

Displayed pattern type, specified as the comma-separated pair consisting of 'Type' and one of

- 'directivity' — directivity pattern measured in dBi.
- 'efield' — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- 'power' — power pattern of the sensor or array defined as the square of the field pattern.
- 'powerdb' — power pattern converted to dB.

Example: 'powerdb'

Data Types: char

'Normalize' — Display normalize pattern

true (default) | false

Display normalized pattern, specified as the comma-separated pair consisting of 'Normalize' and a Boolean. Set this parameter to true to display a normalized pattern. When you set 'Type' to 'directivity', this parameter does not apply. Directivity patterns are already normalized.

Example:

Data Types: logical

'PlotStyle' — Plotting style

'overlay' (default) | 'waterfall'

Plotting style, specified as the comma-separated pair consisting of 'Plotstyle' and either 'overlay' or 'waterfall'. This parameter applies when you specify multiple frequencies in FREQ in 2-D plots. You can draw 2-D plots by setting one of the arguments AZ or EL to a scalar.

Example:

Data Types: char

Output Arguments

PAT — Element pattern

M-by-*N* real-valued matrix

Element pattern, returned as an *M*-by-*N* real-valued matrix. The dimensions of PAT correspond to the dimensions of the output arguments AZ_ANG and EL_ANG.

AZ_ANG — Azimuth angles

scalar | 1-by-*M* real-valued row vector

Azimuth angles for displaying directivity or response pattern, returned as a scalar or 1-by-*M* real-valued row vector corresponding to the dimension set in AZ. The rows of PAT correspond to the values in AZ_ANG.

EL_ANG — Elevation angles

scalar | 1-by-*N* real-valued row vector

Elevation angles for displaying directivity or response, returned as a scalar or 1-by-*N* real-valued row vector corresponding to the dimension set in EL. The columns of PAT correspond to the values in EL_ANG.

Examples

Plot Pattern and Directivity of Isotropic Antenna

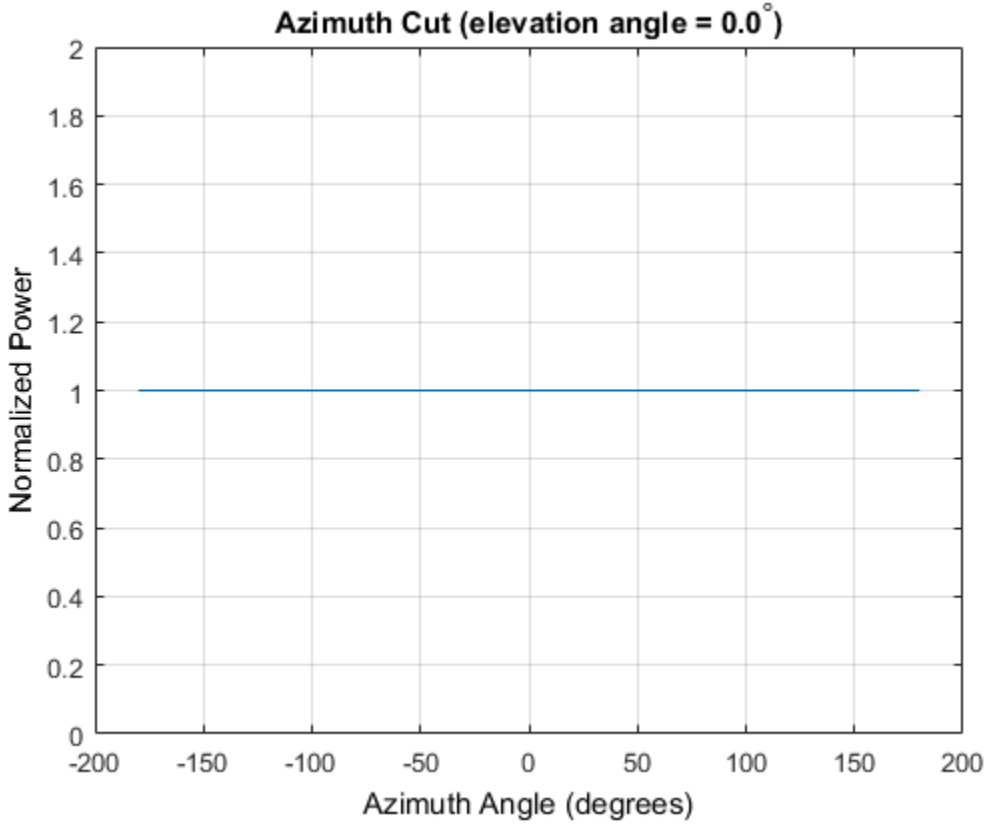
Create an isotropic antenna element. The, plot the power pattern and the directivity.

First, create the antenna.

```
sIso = phased.IsotropicAntennaElement;
```

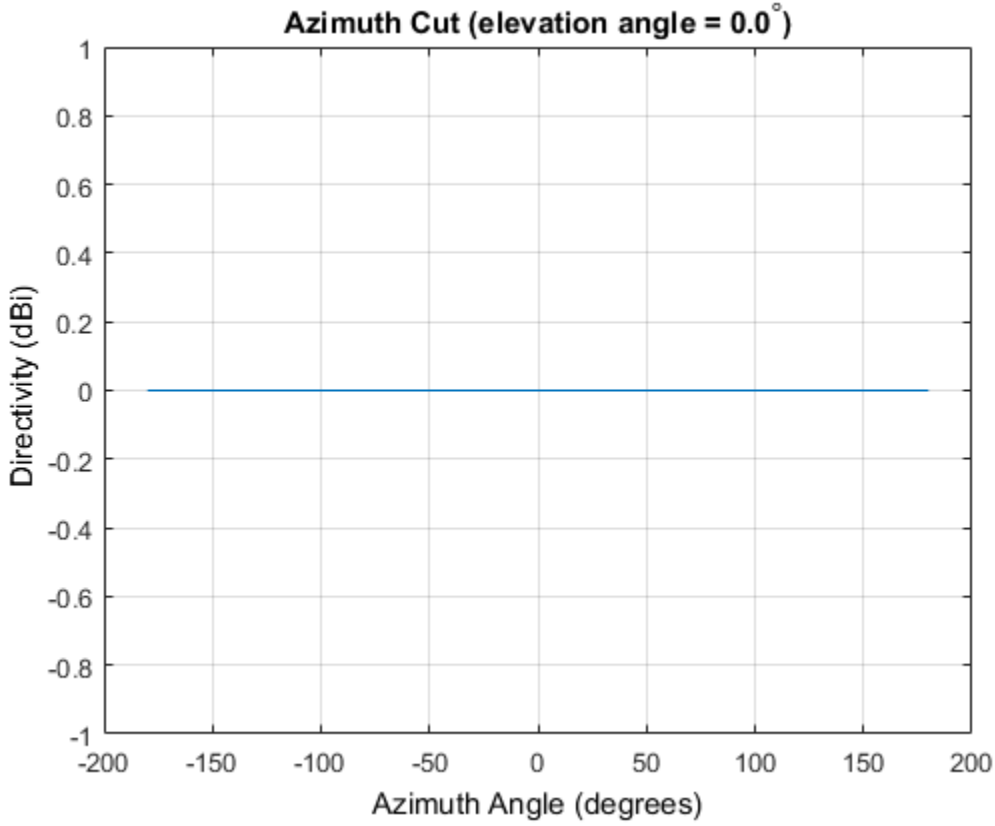
Draw an azimuth cut of the power pattern at 0 degrees elevation. Assume the operating frequency is 1 GHz.

```
fc = 1e9;
pattern(sIso,fc,[-180:180],0,...
    'Type','power',...
    'CoordinateSystem','rectangular')
```



Draw the same azimuth cut of the antenna directivity.

```
pattern(sIso,fc,[-180:180],0,...
    'Type','directivity',...
    'CoordinateSystem','rectangular')
```



Elevation-Cut of Isotropic Antenna Pattern

Construct an isotropic antenna operating in the frequency range from 800 MHz to 1.2 GHz. Compute the response at boresight at 1 GHz. Display the power pattern of the antenna at 1 GHz.

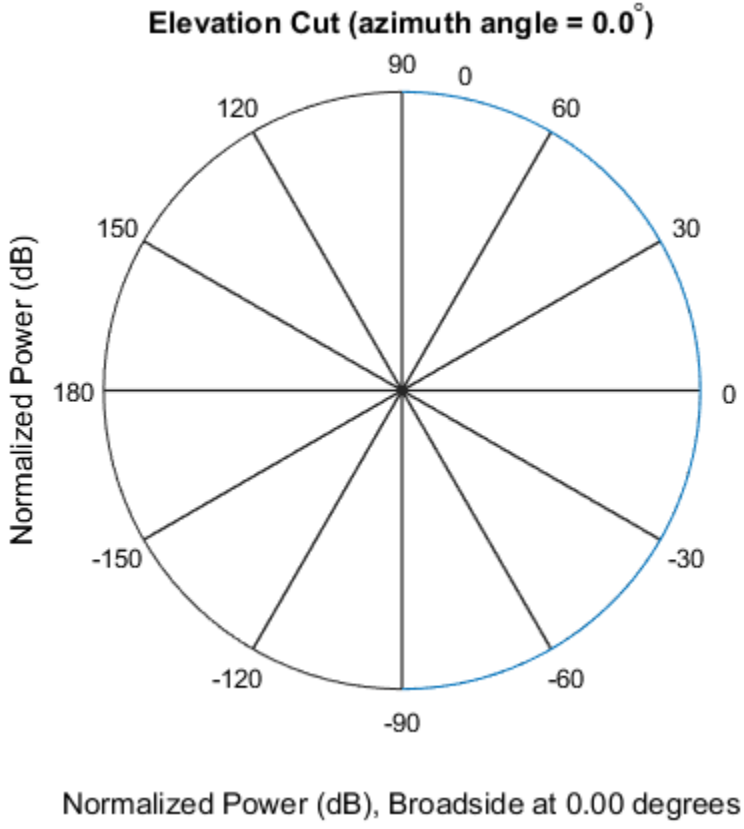
```
sIso = phased.IsotropicAntennaElement(...
    'FrequencyRange',[800e6 1.2e9]);
fc = 1e9;
resp = step(sIso,fc,[0;0])
```

```
resp =
```

```
1
```

Plot the elevation power pattern of the antenna in polar coordinates.

```
pattern(sIso,fc,0,[-90:90],...
    'Type','powerdb',...
    'CoordinateSystem','polar')
```



3-D Isotropic Antenna Pattern

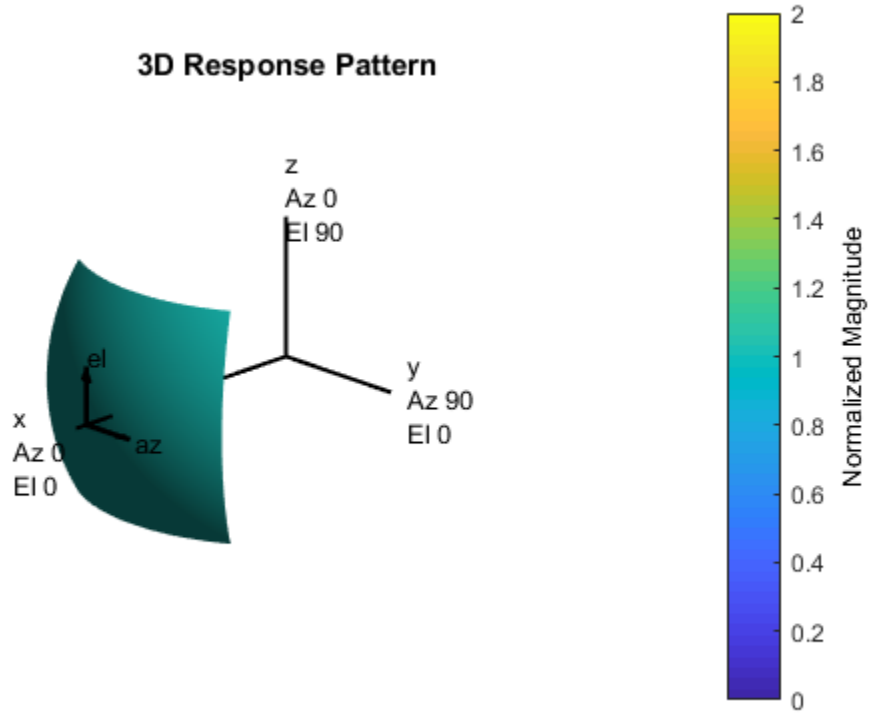
Construct an isotropic antenna operating over a frequency range from 800 MHz to 1.2 GHz. Then plot the 3-D antenna field pattern.

Construct the antenna element.

```
sIso = phased.IsotropicAntennaElement(...
    'FrequencyRange',[800e6 1.2e9]);
```

Plot the 3-D magnitude pattern of the antenna at 1 GHz from -30 to 30 degrees in both azimuth and elevation in 0.1 degree increments.

```
fc = 1e9;
pattern(sIso,fc,[-30:0.1:30],[-30:0.1:30],...
    'Type','efield',...
    'CoordinateSystem','polar')
```



More About

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on "Element directivity" and "Array directivity".

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

Convert plotResponse to pattern

For antenna, microphone, and array System objects, the `pattern` method replaces the `plotResponse` method. In addition, two new simplified methods exist just to draw 2-D azimuth and elevation pattern plots. These methods are `azimuthPattern` and `elevationPattern`.

The following table is a guide for converting your code from using `plotResponse` to `pattern`. Notice that some of the inputs have changed from *input arguments* to *Name-Value* pairs and conversely. The general `pattern` method syntax is

```
pattern(H,FREQ,AZ,EL,'Name1','Value1',...,'NameN','ValueN')
```

plotResponse Inputs	plotResponse Description	pattern Inputs
`H` argument	Antenna, microphone, or array System object.	`H` argument (no change)
`FREQ` argument	Operating frequency.	`FREQ` argument (no change)

plotResponse Inputs	plotResponse Description	pattern Inputs
`V` argument	Propagation speed. This argument is used only for arrays.	`'PropagationSpeed'` name-value pair. This parameter is only used for arrays.

<table>
<tr><th>plotResponse Inputs</th><th>plotResponse Description</th><th>pattern Inputs</th></tr>
<tr>
<td>'Format' and 'RespCut' name-value pairs</td>
<td>These options work together to let you create a plot in angle space (line or polar style) or UV space. They also determine whether the plot is 2-D or 3-D. This table shows you how to create different types of plots using plotResponse.
<table>
<tr><th>Display space</th><th></th></tr>

To create a cut, specify either AZ or EL as a scalar, not a vector.</td></tr>
</table>

plotResponse Inputs	plotResponse Description	pattern Inputs
`'NormalizeResponse'` name-value pair	Normalizes the plot. When `'Unit'` is set to `'dbi'`, you cannot specify `'NormalizeResponse'`.	`'Normalize'` name-value pair. When `'Type'` is set to `'directivity'`, you cannot specify `'Normalize'`. .
`'OverlayFreq'` name-value pair	Plot multiple frequencies on the same 2-D plot. Available only when `'Format'` is set to `'line'` or `'uv'` and `'RespCut'` is not set to `'3D'`. The value `true` produces an overlay plot and the value `false` produces a waterfall plot.	`'PlotStyle'` name-value pair plots multiple frequencies on the same 2-D plot. The values `'overlay'` and `'waterfall'` correspond to `'OverlayFreq'` values of `true` and `false`. The option `'waterfall'` is allowed only when `'CoordinateSystem'` is set to `'rectangular'` or `'uv'`.
`'Polarization'` name-value pair	Determines how to plot polarized fields. Options are `'None'`, `'Combined'`, `'H'`, or `'V'`.	`'Polarization'` name-value pair determines how to plot polarized fields. The `'None'` option is removed. The options `'Combined'`, `'H'`, or `'V'` are unchanged.

`'Unit'` name-value pair	Determines the plot units. Choose `'db'`, `'mag'`, `'pow'`, or `'dbi'`, where the default is `'db'`.	`'Type'` name-value pair, uses equivalent options with different names
		
		plotResponse pattern
		`'db'` `'powerdb'`
		`'mag'` `'efield'`
		`'pow'` `'power'`
		`'dbi'` `'directivity'`

`'Weights'` name-value pair	Array element tapers (or weights).	`'Weights'` name-value pair (no change).

plotResponse Inputs	plotResponse Description	pattern Inputs
`'AzimuthAngles'` name-value pair	Azimuth angles used to display the antenna or array response.	`AZ` argument
`'ElevationAngles'` name-value pair	Elevation angles used to display the antenna or array response.	`EL` argument
`'UGrid'` name-value pair	Contains *U* coordinates in *UV*-space.	`AZ` argument when `'CoordinateSystem'` name-value pair is set to `'uv'`
`'VGrid'` name-value pair	Contains *V*-coordinates in *UV*-space.	`EL` argument when `'CoordinateSystem'` name-value pair is set to `'uv'`

phased.IsotropicAntennaElement.patternAzimuth | phased.IsotropicAntennaElement.patternElevation

Introduced in R2015a

patternAzimuth

System object: phased.IsotropicAntennaElement
Package: phased

Plot isotropic antenna element directivity or pattern versus azimuth

Syntax

```
patternAzimuth(sElem,FREQ)
patternAzimuth(sElem,FREQ,EL)
patternAzimuth(sElem,FREQ,EL,Name,Value)
PAT = patternAzimuth( ___ )
```

Description

`patternAzimuth(sElem,FREQ)` plots the 2-D element directivity pattern versus azimuth (in dBi) for the element `sElem` at zero degrees elevation angle. The argument `FREQ` specifies the operating frequency.

`patternAzimuth(sElem,FREQ,EL)`, in addition, plots the 2-D element directivity pattern versus azimuth (in dBi) at the elevation angle specified by `EL`. When `EL` is a vector, multiple overlaid plots are created.

`patternAzimuth(sElem,FREQ,EL,Name,Value)` plots the element pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternAzimuth( ___ )` returns the element pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Azimuth'` parameter and the `EL` input argument.

Input Arguments

`sElem` — Isotropic antenna element

System object

Isotropic antenna element, specified as a phased.IsotropicAntennaElement System object.

Example: `sElem = phased.IsotropicAntennaElement;`

`FREQ` — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

`EL` — Elevation angles

1-by-*N* real-valued row vector

Elevation angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector. The quantity *N* is the number of requested elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and the *xy* plane. When measured toward the *z*-axis, this angle is positive.

Example: `[0,10,20]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Type'` — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

`'Azimuth'` — Azimuth angles

`[-180:180]` (default) | 1-by-*P* real-valued row vector

Azimuth angles, specified as the comma-separated pair consisting of `'Azimuth'` and a 1-by-*P* real-valued row vector. Azimuth angles define where the array pattern is calculated.

Example: `'Azimuth',[-90:2:90]`

Data Types: `double`

Output Arguments

`PAT` — Element directivity or pattern

L-by-*N* real-valued matrix

Element directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of azimuth values determined by the `'Azimuth'` name-value pair argument. The dimension *N* is the number of elevation angles, as determined by the `EL` input argument.

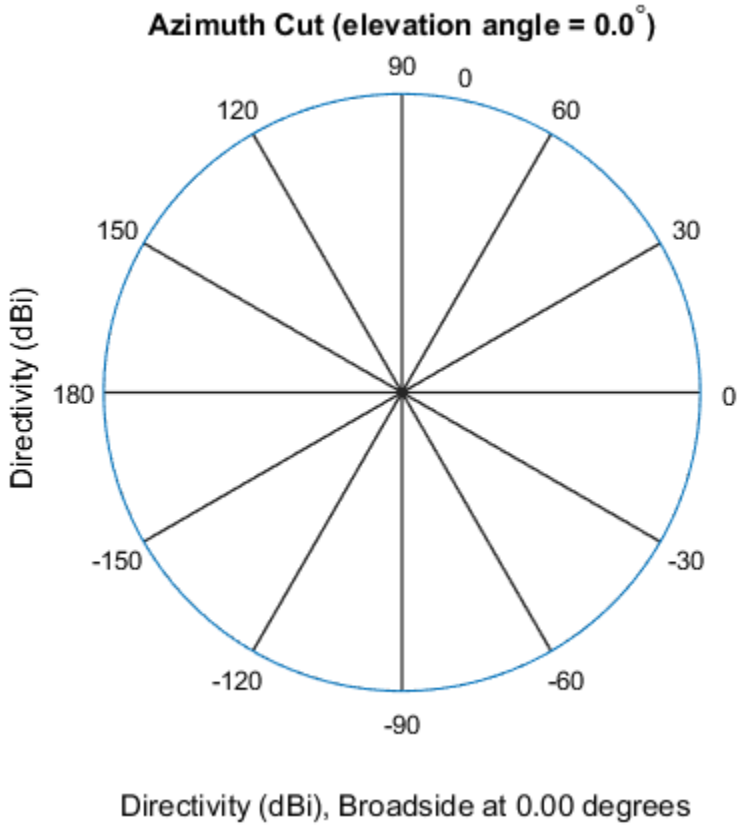
Examples

Restricted Azimuth Directivity Pattern of Isotropic Antenna Element

Plot an azimuth cut of the directivity of an isotropic antenna element at 0 and then at 30 degrees elevation. Assume the operating frequency is 500 MHz.

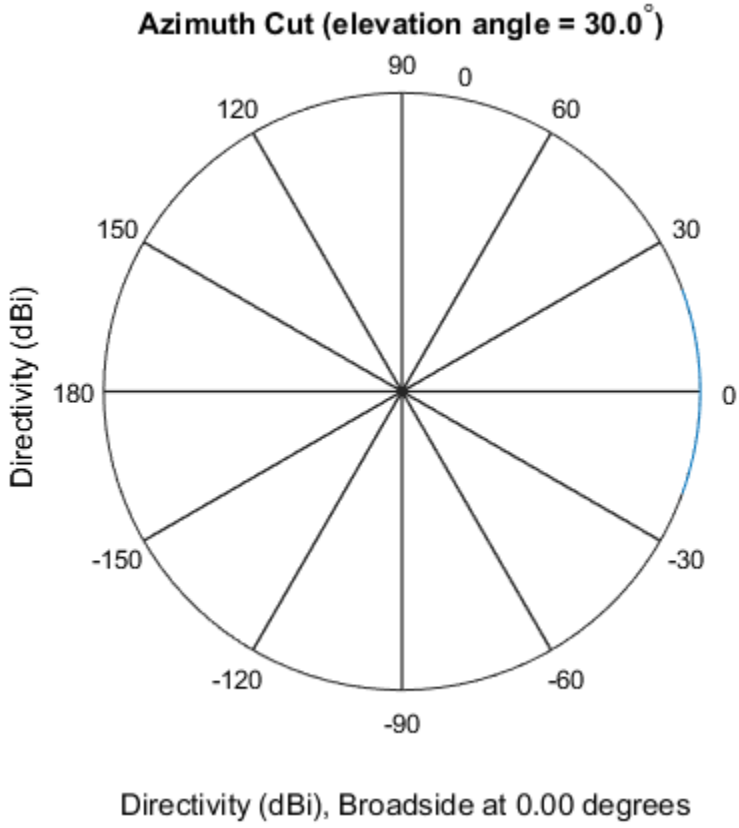
Create the antenna element.

```
fc = 500e6;
sIso = phased.IsotropicAntennaElement('FrequencyRange',[100,900]*1e6);
patternAzimuth(sIso,fc,0)
```



Plot a reduced range of azimuth angles using the `Azimuth` parameter.

```
patternAzimuth(sIso,fc,30,'Azimuth',[-20:20])
```



Definitions

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on "Element directivity" and "Array directivity".

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

phased.IsotropicAntennaElement.pattern |
phased.IsotropicAntennaElement.patternElevation

Introduced in R2015a

patternElevation

System object: phased.IsotropicAntennaElement
Package: phased

Plot isotropic antenna element directivity or pattern versus elevation

Syntax

```
patternElevation(sElem,FREQ)
patternElevation(sElem,FREQ,AZ)
patternElevation(sElem,FREQ,AZ,Name,Value)
PAT = patternElevation( ___ )
```

Description

`patternElevation(sElem,FREQ)` plots the 2-D element directivity pattern versus elevation (in dBi) for the element `sElem` at zero degrees azimuth angle. The argument `FREQ` specifies the operating frequency.

`patternElevation(sElem,FREQ,AZ)`, in addition, plots the 2-D element directivity pattern versus elevation (in dBi) at the azimuth angle specified by `AZ`. When `AZ` is a vector, multiple overlaid plots are created.

`patternElevation(sElem,FREQ,AZ,Name,Value)` plots the element pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternElevation( ___ )` returns the element pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Elevation'` parameter and the `AZ` input argument.

Input Arguments

`sElem` — Isotropic antenna element

System object

Isotropic antenna element, specified as a phased.IsotropicAntennaElement System object.

Example: `sElem = phased.IsotropicAntennaElement;`

`FREQ` — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

`AZ` — Azimuth angles for computing directivity and pattern

1-by-*N* real-valued row vector

Azimuth angles for computing sensor or array directivities and patterns, specified as a 1-by-*M* real-valued row vector where *N* is the number of desired azimuth directions. Angle units are in degrees. The azimuth angle must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `[0,10,20]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Type'` — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

`'Elevation'` — Elevation angles

`[-90:90]` (default) | 1-by-*P* real-valued row vector

Elevation angles, specified as the comma-separated pair consisting of `'Elevation'` and a 1-by-*P* real-valued row vector. Elevation angles define where the array pattern is calculated.

Example: `'Elevation',[-90:2:90]`

Data Types: `double`

Output Arguments

`PAT` — Element directivity or pattern

L-by-*N* real-valued matrix

Element directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of elevation angles determined by the `'Elevation'` name-value pair argument. The dimension *N* is the number of azimuth angles determined by the `AZ` argument.

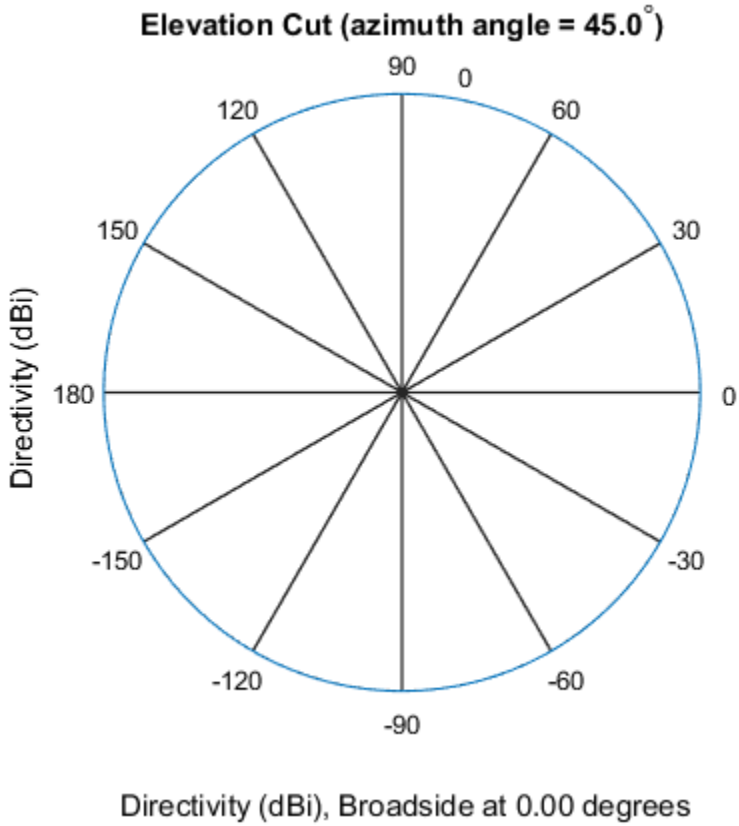
Examples

Restricted Elevation Directivity Pattern of Isotropic Antenna Element

Plot an elevation cut of directivity of an isotropic antenna element at 45 degrees azimuth. Assume the operating frequency is 500 MHz.

Create the antenna element.

```
fc = 500e6;
sIso = phased.IsotropicAntennaElement('FrequencyRange',[100,900]*1e6);
patternElevation(sIso,fc,45)
```



Plot a reduced range of elevation angles using the `Elevation` parameter.

```
patternElevation(sIso,fc,45,'Elevation',[-20:20])
```

phased.IsotropicAntennaElement.pattern |
phased.IsotropicAntennaElement.patternAzimuth

Introduced in R2015a

plotResponse

System object: phased.IsotropicAntennaElement
Package: phased

Plot response pattern of antenna

Syntax

```
plotResponse(H,FREQ)
plotResponse(H,FREQ,Name,Value)
hPlot = plotResponse( ___ )
```

Description

`plotResponse(H,FREQ)` plots the element response pattern along the azimuth cut, where the elevation angle is 0. The operating frequency is specified in `FREQ`.

`plotResponse(H,FREQ,Name,Value)` plots the element response with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = plotResponse( ___ )` returns handles of the lines or surface in the figure window, using any of the input arguments in the previous syntaxes.

Input Arguments

`H`

Element System object

`FREQ`

Operating frequency in Hertz specified as a scalar or 1–by-*K* row vector. `FREQ` must lie within the range specified by the `FrequencyVector` property of `H`. If you set the `'RespCut'` property of `H` to `'3D'`, `FREQ` must be a scalar. When `FREQ` is a row vector, `plotResponse` draws multiple frequency responses on the same axes.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'CutAngle'`

Cut angle specified as a scalar. This argument is applicable only when `RespCut` is `'Az'` or `'El'`. If `RespCut` is `'Az'`, `CutAngle` must be between –90 and 90. If `RespCut` is `'El'`, `CutAngle` must be between –180 and 180.

Default: `0`

`'Format'`

Format of the plot, using one of `'Line'`, `'Polar'`, or `'UV'`. If you set `Format` to `'UV'`, `FREQ` must be a scalar.

Default: `'Line'`

`'NormalizeResponse'`

Set this value to `true` to normalize the response pattern. Set this value to `false` to plot the response pattern without normalizing it. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

Default: `true`

`'OverlayFreq'`

Set this value to `true` to overlay pattern cuts in a 2-D line plot. Set this value to `false` to plot pattern cuts against frequency in a 3-D waterfall plot. If this value is `false`, `FREQ` must be a vector with at least two entries.

This parameter applies only when `Format` is not `'Polar'` and RespCut is not `'3D'`.

Default: `true`

`'Polarization'`

Specify the polarization options for plotting the antenna response pattern. The allowable values are `|'None' | 'Combined' | 'H' | 'V' |` where

- `'None'` specifies plotting a nonpolarized response pattern
- `'Combined'` specifies plotting a combined polarization response pattern
- `'H'` specifies plotting the horizontal polarization response pattern
- `'V'` specifies plotting the vertical polarization response pattern

For antennas that do not support polarization, the only allowed value is `'None'`. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

Default: `'None'`

`'RespCut'`

Cut of the response. Valid values depend on `Format`, as follows:

- If `Format` is `'Line'` or `'Polar'`, the valid values of `RespCut` are `'Az'`, `'El'`, and `'3D'`. The default is `'Az'`.
- If `Format` is `'UV'`, the valid values of `RespCut` are `'U'` and `'3D'`. The default is `'U'`.

If you set `RespCut` to `'3D'`, `FREQ` must be a scalar.

`'Unit'`

The unit of the plot. Valid values are `'db'`, `'mag'`, `'pow'`, or `'dbi'`. This parameter determines the type of plot that is produced.

Unit value	Plot type
`db`	power pattern in dB scale
`mag`	field pattern
`pow`	power pattern
`dbi`	directivity

Default: `'db'`

`'AzimuthAngles'`

Azimuth angles for plotting element response, specified as a row vector. The `AzimuthAngles` parameter sets the display range and resolution of azimuth angles for

visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'Az'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of azimuth angles should lie between –180° and 180° and must be in nondecreasing order. When you set the `RespCut` parameter to `'3D'`, you can set the `AzimuthAngles` and `ElevationAngles` parameters simultaneously.

Default: `[-180:180]`

`'ElevationAngles'`

Elevation angles for plotting element response, specified as a row vector. The `ElevationAngles` parameter sets the display range and resolution of elevation angles for visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'El'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of elevation angles should lie between –90° and 90° and must be in nondecreasing order. When you set the `RespCut` parameter to `'3D'`, you can set the `ElevationAngles` and `AzimuthAngles` parameters simultaneously.

Default: `[-90:90]`

`'UGrid'`

U coordinate values for plotting element response, specified as a row vector. The `UGrid` parameter sets the display range and resolution of the *U* coordinates for visualizing the radiation pattern in *U*/*V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'U'` or `'3D'`. The values of `UGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set the `UGrid` and `VGrid` parameters simultaneously.

Default: `[-1:0.01:1]`

`'VGrid'`

V coordinate values for plotting element response, specified as a row vector. The `VGrid` parameter sets the display range and resolution of the *V* coordinates for visualizing the radiation pattern in *U*/*V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'3D'`. The values of `VGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set the `VGrid` and `UGrid` parameters simultaneously.

Default: `[-1:0.01:1]`

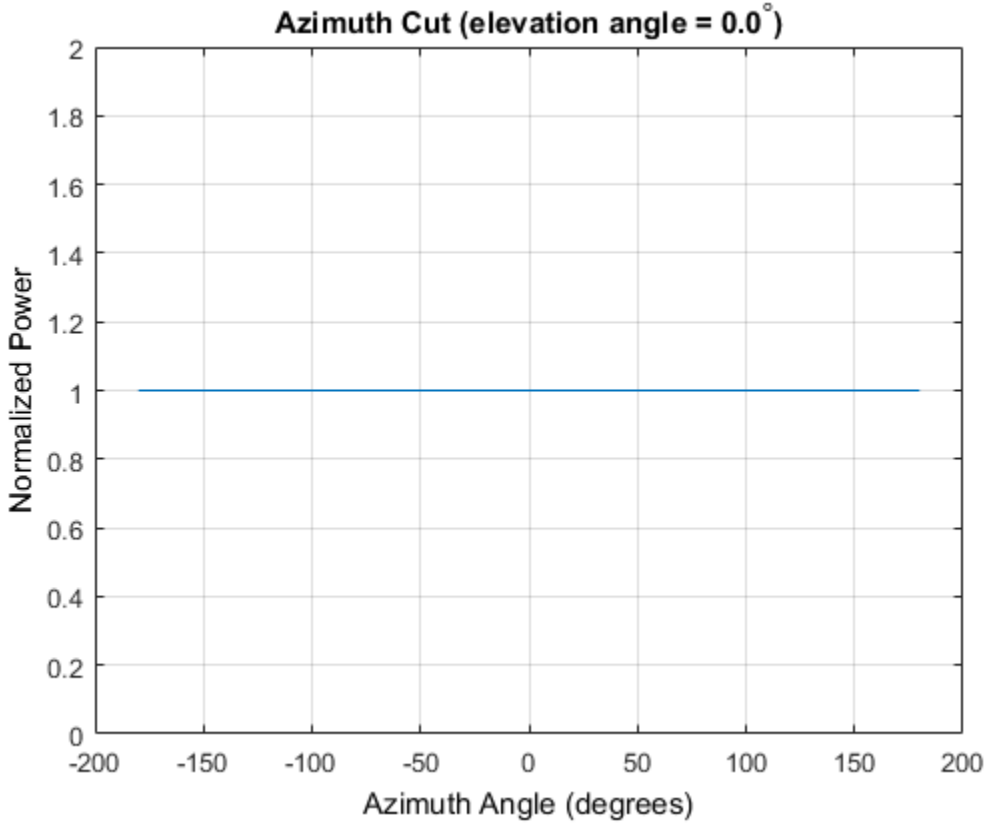
Examples

Plot Response and Directivity of Isotropic Antenna

This example shows how to plot the response and the directivity of an isotropic antenna element.

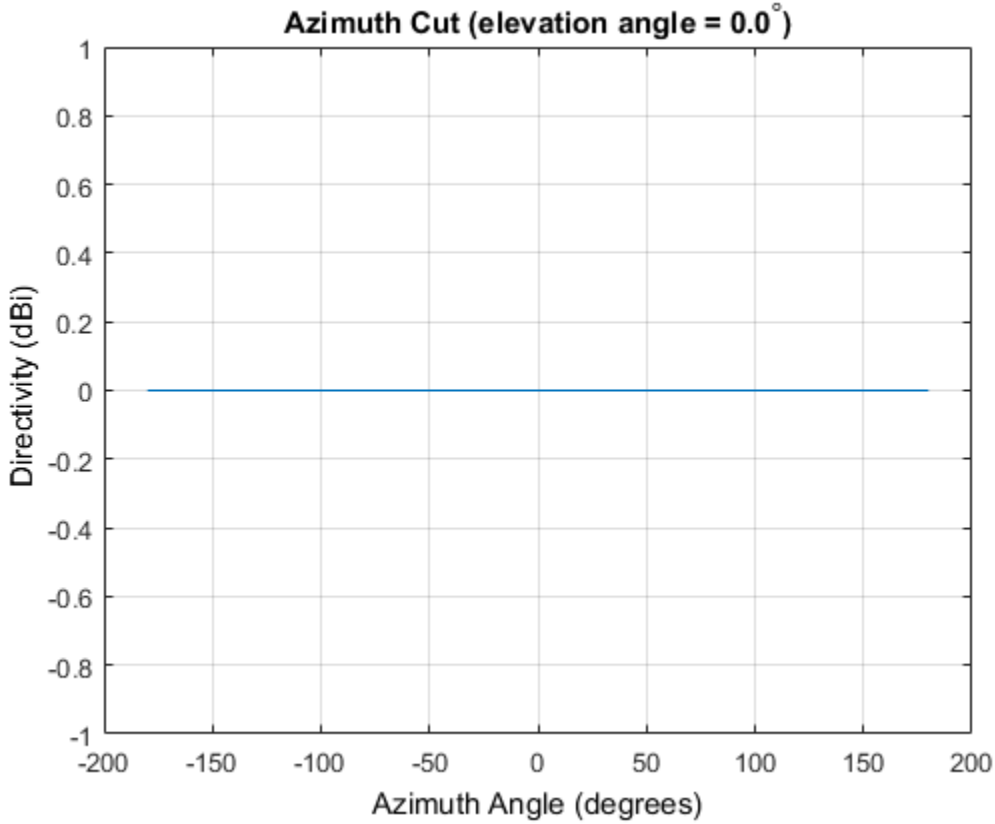
Draw a line plot of an azimuth cut of the response of an isotropic antenna along 0 degrees elevation. Assume the operating frequency is 1 GHz.

```
sIso = phased.IsotropicAntennaElement;
plotResponse(sIso,1e9,'Unit','pow');
```



Draw an azimuth cut of the antenna directivity.

```
plotResponse(sIso,1e9,'Unit','dbi');
```



Plot Elevation-Cut of Isotropic Antenna Response

Construct an isotropic antenna operating in the frequency range from 800 MHz to 1.2 GHz. Find the response of the antenna at boresight at 1 GHz.

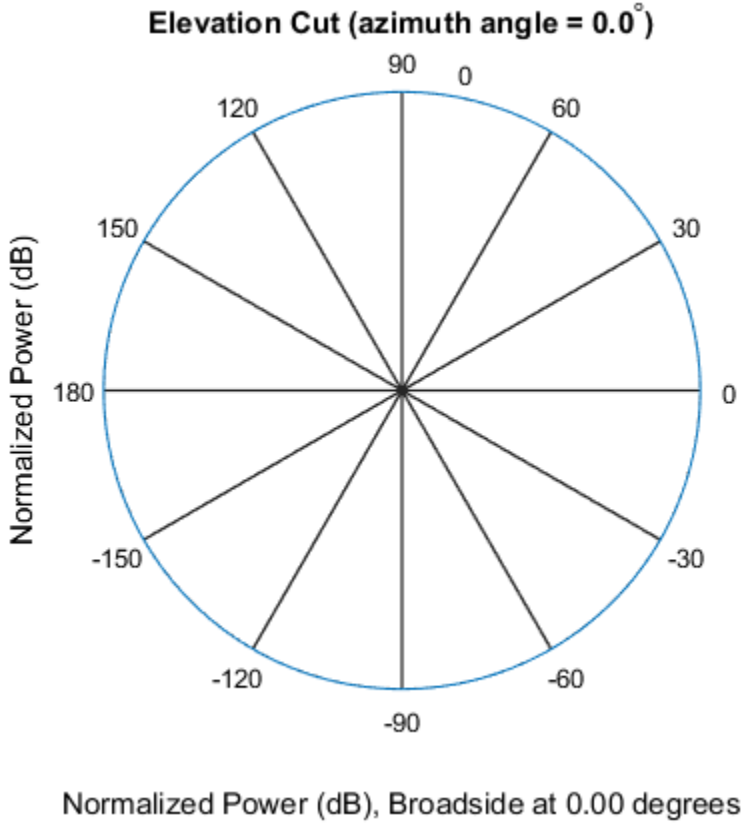
```
sIso = phased.IsotropicAntennaElement(...
    'FrequencyRange',[800e6 1.2e9]);
fc = 1e9;
resp = step(sIso,fc,[0;0])
```

```
resp =

     1
```

Plot the polar-form of the elevation response of the antenna.

```
plotResponse(sIso,fc,'RespCut','El','Format','Polar');
```



Plot 3-D Response

This example shows how to construct an isotropic antenna operating over a frequency range from 800 MHz to 1.2 GHz and how to plot its response.

Construct the antenna element.

```
sIso = phased.IsotropicAntennaElement(...
    'FrequencyRange',[0.8e9 1.2e9]);
```

Plot the 3-D response of the antenna at 1 GHz from -30 to 30 degrees in both azimuth and elevation at 0.1 degree increments.

```
fc = 1e9;
plotResponse(sIso,fc,'RespCut','3D','Format','Polar',...
    'Unit','mag','AzimuthAngles',[-30:.1:30],...
    'ElevationAngles',[-30:.1:30]);
```

`azel2uv` | `uv2azel`

step

System object: phased.IsotropicAntennaElement
Package: phased

Output response of antenna element

Syntax

```
RESP = step(H,FREQ,ANG)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`RESP = step(H,FREQ,ANG)` returns the antenna's voltage response `RESP` at operating frequencies specified in `FREQ` and directions specified in `ANG`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`H`

Antenna element object.

FREQ

Operating frequencies of antenna in hertz. FREQ is a row vector of length L.

ANG

Directions in degrees. ANG can be either a 2-by-M matrix or a row vector of length M.

If ANG is a 2-by-M matrix, each column of the matrix specifies the direction in the form [azimuth; elevation]. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

If ANG is a row vector of length M, each element specifies a direction's azimuth angle. In this case, the corresponding elevation angle is assumed to be 0.

Output Arguments

RESP

Voltage response of antenna element specified as an *M*-by-*L*, complex-valued matrix. In this matrix, *M* represents the number of angles specified in ANG while *L* represents the number of frequencies specified in FREQ.

Examples

Plot Isotropic Antenna Element Response

Create an isotropic antenna operating over a frequency range from 800 MHz to 1.2 GHz. The operating frequency is 1 GHz. Find the response of the antenna at boresight. Then, plot the polar-pattern elevation response of the antenna.

```
antenna = phased.IsotropicAntennaElement('FrequencyRange',[800e6 1.2e9]);
fc = 1e9;
```

Obtain the response at boresight.

```
resp = antenna(fc,[0;0])
```

```
resp =
```

```
1
```

Plot the response pattern.

```
pattern(antenna,fc,0,[-90:90],'CoordinateSystem','polar','Type','powerdb', ...
    'Normalize',true)
```

`phitheta2azel` | `uv2azel`

phased.IsotropicHydrophone System object

Package: phased

Isotropic hydrophone

Description

The `phased.IsotropicHydrophone` System object creates an isotropic hydrophone for sonar applications. An isotropic hydrophone has the same response in all signal directions. The response is the output voltage of the hydrophone per unit sound pressure. The response for a hydrophone is also call its sensitivity. You can specify the response using the `VoltageSensitivity` property.

To compute the response of a hydrophone for specified directions:

1. Define and set up an isotropic hydrophone System object. See "Construction" on page 1-1013.
2. Call step to compute the response according to the properties of `phased.IsotropicHydrophone`.

Note: Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`hydrophone = phased.IsotropicHydrophone` creates a isotropic hydrophone System object, `hydrophone`.

`hydrophone = phased.IsotropicHydrophone(Name,Value)` creates an isotropic hydrophone System object, with each specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as (`Name1,Value1,...,NameN,ValueN`).

Properties

`FrequencyRange` — Operating frequency range of hydrophone

`[0 200e3]` (default) | real-valued 1-by-2 vector

Operating frequency range of hydrophone, specified as a real-valued 1-by-2 row vector of the form `[LowerBound HigherBound]`. This property defines the frequency range over which the hydrophone has a response. The hydrophone element has zero response outside this frequency range. Units are in Hz.

Example: `[0 1000]`

Data Types: `double`

`VoltageSensitivity` — Voltage sensitivity of hydrophone

`-120` (default) | scalar | real-valued 1-by-*K* row vector

Voltage sensitivity of hydrophone, specified as a scalar or real-valued 1-by-*K* row vector. When you specify the voltage sensitivity as a scalar, that value applies to the entire frequency range specified by `FrequencyRange`. When you specify the voltage sensitivity as a vector, the frequency range is divided into K-1 equal intervals. The sensitivity values are assigned to the interval end points. The `step` method interpolates the voltage sensitivity for any frequency inside the frequency range. Units are in dB//1V/µPa. See "Hydrophone Sensitivity" on page 1-1018 for more details.

Example: `10`

Data Types: `double`

`BackBaffled` — Backbaffle hydrophone element

`false` (default) | `true`

Backbaffle hydrophone element, specified as `false` or `true`. Set this property to `true` to backbaffle the hydrophone. When the hydrophone is backbaffled, the hydrophone response for all azimuth angles beyond ±90° from broadside are zero. Broadside is defined as 0° azimuth and 0° elevation.

When the value of this property is `false`, the hydrophone is not backbaffled.

Methods

directivity	Directivity of isotropic hydrophone

isPolarizationCapable	Polarization capability
pattern	Plot isotropic hydrophone directivity and patterns
patternAzimuth	Plot isotropic hydrophone directivity and response patterns versus azimuth
patternElevation	Plot isotropic hydrophone directivity and response patterns versus elevation
step	Voltage sensitivity of isotropic hydrophone

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Single Frequency Response and Pattern of Isotropic Hydrophone

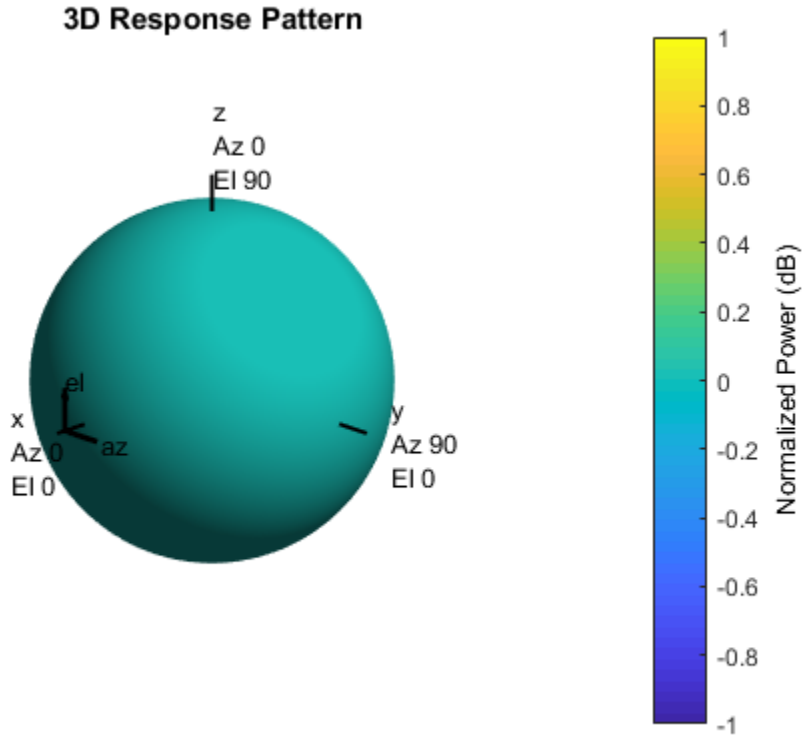
Examine the response and patterns of an isotropic hydrophone operating between 1 kHz and 10 kHz.

Set up the hydophone parameters. Obtain the voltage sensitivity at five different elevation angles: -30°, -15°, 0°, 15° and 30°. All elevation angles are at 0&deg. The sensitivities are computed at the signal frequency of 2 kHz.

```
hydrophone = phased.IsotropicHydrophone('FrequencyRange',[1 10]*1e3);
fc = 2e3;
resp = hydrophone(fc,[0 0 0 0 0;-30 -15 0 15 30]);
```

Draw a 3-D plot of the voltage sensitivity.

```
pattern(hydrophone,fc,[-180:180],[-90:90],'CoordinateSystem','polar', ...
    'Type','powerdb')
```



Response and Pattern of Isotropic Hydrophone at Multiple Frequencies

Examine the response and patterns of an isotropic hydrophone at three different frequencies. The hydrophone operates between 1 kHz and 10 kHz. Specify the voltage sensitivity as a vector.

Set up the hydrophone parameters and obtain the voltage sensitivity at 45° azimuth and 30° elevation. Compute the sensitivities at the signal frequencies of 2, 5, and 7 kHz.

```
hydrophone = phased.IsotropicHydrophone('FrequencyRange',[1 10]*1e3, ...
    'VoltageSensitivity',[-100 -90 -100]);
fc = [2e3 5e3 7e3];
resp = hydrophone(fc,[45;30])
```

```
resp =

   14.8051   29.2202   24.4152
```

Draw a 2-D plot of the voltage sensitivity as a function of azimuth.

```
pattern(hydrophone,fc,[-180:180],0,'CoordinateSystem','rectangular',...
    'Type','power')
```

Hydrophone Sensitivity

Hydrophone sensitivity measures the response of a hydrophone to input sound pressure.

Hydrophone voltage sensitivity is the open circuit voltage (OCV) at the output of a hydrophone for a given input sound intensity. Another term for hydrophone sensitivity is open circuit receiving response (OCRR). Specifically, OCRR is the voltage generated by a hydrophone per μPa of sound intensity. OCRR is generally a function of frequency. If the sound intensity level (SIL) is expressed in dB//μPa and the output voltage is expressed in dB//1V, then OCRR is expressed in dB//1V/μPa. The output voltage of a hydrophone is related to the input sound level by
VdB = SIL + OCRR.
Consider a hydrophone that has OCRR = –160 dB//1V/μPa at 10 kHz. Assume that the SIL at the hydrophone due to a nearby ship is 120 dB//μPa. Then, the output voltage of the hydrophone is
VdB = SIL + OCRR = 120 dB + (–160) dB = –40 dB//1V.

In linear units,
$V = 10^{VdB/10} = 100\ \mu V$.

directivity

System object: phased.IsotropicHydrophone
Package: phased

Directivity of isotropic hydrophone

Syntax

```
D = directivity(hydrophone,FREQ,ANGLE)
```

Description

`D = directivity(hydrophone,FREQ,ANGLE)` returns the "Directivity" on page 1-349 of the isotropic hydrophone, `hydrophone`, at frequencies specified by `FREQ` and in direction angles specified by `ANGLE`.

Input Arguments

`hydrophone` — Isotropic hydrophone

`phased.IsotropicHydrophone` System object

Isotropic hydrophone, specified as a `phased.IsotropicHydrophone` System object.

Example: `phased.IsotropicHydrophone`

`FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the

directivity is returned as `-Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.

- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `-Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

`ANGLE` — Angles for computing directivity

1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Angles for computing directivity, specified as a 1-by-*M* real-valued row vector or a 2-by-*M* real-valued matrix, where *M* is the number of angular directions. Angle units are in degrees. If `ANGLE` is a 2-by-*M* matrix, then each column specifies a direction in azimuth and elevation, `[az;el]`. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°.

If `ANGLE` is a 1-by-*M* vector, then each entry represents an azimuth angle, with the elevation angle assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis.

Example: `[45 60; 0 10]`

Data Types: `double`

Output Arguments

`D` — Directivity

M-by-*L* matrix

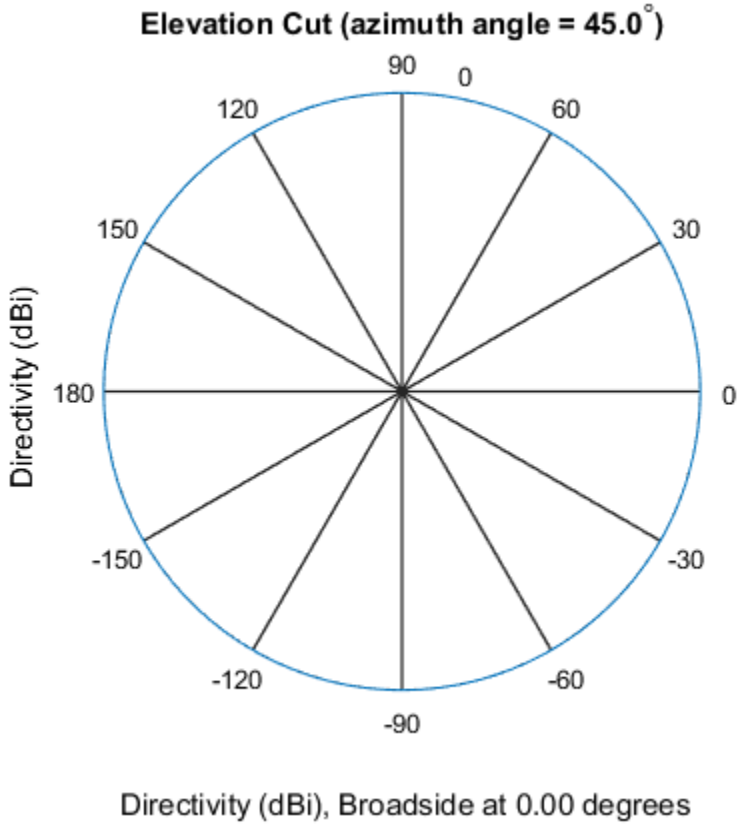
Directivity, returned as an *M*-by-*L* matrix whose columns contain the directivities at the *M* angles specified by `ANGLE`. Each column corresponds to one of the *L* frequency values specified in `FREQ`. Directivity units are in dBi.

Examples

Directivity of Isotropic Hydrophone

Compute the directivity of an isotropic hydrophone in different directions. Assume the signal frequency is 3 kHz. First, set up the hydrophone parameters.

```
fc = 3e3;
hydrophone = phased.IsotropicHydrophone('FrequencyRange',[1,10]*1e3, ...
    'VoltageSensitivity',[-100,-90,-100]);
patternElevation(hydrophone,fc,45)
```



First, select the angles of interest to be constant elevation angle at zero degrees. The five azimuth angles are centered around boresight (zero degrees azimuth and zero degrees elevation).

```
ang = [-20,-10,0,10,20; 0,0,0,0,0];
```

Compute the directivity along the constant elevation cut.

```
d = directivity(hydrophone,fc,ang)
```

```
d =

     0
     0
     0
     0
     0
```

The directivity of an isotropic hydrophone is zero in every direction.

Definitions

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission.

When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element directivity” and “Array directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

Introduced in R2017a

isPolarizationCapable

System object: phased.IsotropicHydrophone
Package: phased

Polarization capability

Syntax

```
flag = isPolarizationCapable(hydrophone)
```

Description

`flag = isPolarizationCapable(hydrophone)` returns a Boolean value, `flag`, indicating whether the `phased.IsotropicHydrophone` supports polarization. An element supports polarization if it can create or respond to polarized fields. This hydrophone does not support polarization.

Input Arguments

`hydrophone` — Isotropic hydrophone

`phased.IsotropicHydrophone` System object

Isotropic hydrophone, specified as a `phased.IsotropicHydrophone` System object.

Example: `phased.IsotropicHydrophone`

Output Arguments

`flag` — Polarization-capability flag

`true` | `false`

Polarization-capability returned as a Boolean value `true` if the hydrophone supports polarization or `false` if it does not. Because the `phased.IsotropicHydrophone` object does not support polarization, `flag` is always returned as `false`.

Introduced in R2017a

pattern

System object: phased.IsotropicHydrophone
Package: phased

Plot isotropic hydrophone directivity and patterns

Syntax

```
pattern(hydrophone,FREQ)
pattern(hydrophone,FREQ,AZ)
pattern(hydrophone,FREQ,AZ,EL)
pattern( ___ ,Name,Value)
[PAT,AZ_ANG,EL_ANG] = pattern( ___ )
```

Description

`pattern(hydrophone,FREQ)` plots the 3D directivity pattern (in dBi) for the hydrophone, `hydrophone`. The operating frequency is specified in `FREQ`.

`pattern(hydrophone,FREQ,AZ)` plots the directivity pattern at the specified azimuth angle.

`pattern(hydrophone,FREQ,AZ,EL)` plots the directivity pattern at specified azimuth and elevation angles.

`pattern( ___ ,Name,Value)` plots the directivity pattern with additional options specified by one or more `Name,Value` pair arguments.

`[PAT,AZ_ANG,EL_ANG] = pattern( ___ )` returns the array pattern in `PAT`. The `AZ_ANG` output contains the coordinate values corresponding to the rows of `PAT`. The `EL_ANG` output contains the coordinate values corresponding to the columns of `PAT`. If the `'CoordinateSystem'` parameter is set to `'uv'`, then `AZ_ANG` contains the *U* coordinates of the pattern and `EL_ANG` contains the *V* coordinates of the pattern. Otherwise, they are in angular units in degrees. *UV* units are dimensionless.

Input Arguments

`hydrophone` — Isotropic hydrophone

`phased.IsotropicHydrophone` System object

Isotropic hydrophone, specified as a `phased.IsotropicHydrophone` System object.

Example: `phased.IsotropicHydrophone`

`FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `-Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `-Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

`AZ` — Azimuth angles

`[-180:180]` (default) | 1-by-*M* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a 1-by-*M* real-valued row vector where *M* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, this angle is positive.

Example: `[-45:2:45]`

Data Types: `double`

`EL` — Elevation angles

`[-90:90]` (default) | 1-by-*N* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a 1-by-*N* real-valued row vector where *N* is the number of desired elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and *xy*-plane. When measured towards the *z*-axis, this angle is positive.

Example: `[-75:1:70]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'CoordinateSystem'` — Plotting coordinate system

`'polar'` (default) | `'rectangular'` | `'uv'`

Plotting coordinate system of the pattern, specified as the comma-separated pair consisting of `'CoordinateSystem'` and one of `'polar'`, `'rectangular'`, or `'uv'`. When `'CoordinateSystem'` is set to `'polar'` or `'rectangular'`, the `AZ` and `EL` arguments specify the pattern azimuth and elevation, respectively. `AZ` values must lie between –180° and 180°. `EL` values must lie between –90° and 90°. If `'CoordinateSystem'` is set to `'uv'`, `AZ` and `EL` then specify *U* and *V* coordinates, respectively. `AZ` and `EL` must lie between -1 and 1.

Example: `'uv'`

Data Types: `char`

`'Type'` — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

`'Normalize'` — Display normalize pattern

`true` (default) | `false`

Display normalized pattern, specified as the comma-separated pair consisting of `'Normalize'` and a Boolean. Set this parameter to `true` to display a normalized pattern. When you set `'Type'` to `'directivity'`, this parameter does not apply. Directivity patterns are already normalized.

Example:

Data Types: `logical`

`'PlotStyle'` — Plotting style

`'overlay'` (default) | `'waterfall'`

Plotting style, specified as the comma-separated pair consisting of `'Plotstyle'` and either `'overlay'` or `'waterfall'`. This parameter applies when you specify multiple frequencies in `FREQ` in 2-D plots. You can draw 2-D plots by setting one of the arguments `AZ` or `EL` to a scalar.

Example:

Data Types: `char`

`'Polarization'` — Polarized field component

`'combined'` (default) | `'H'` | `'V'`

Polarized field component to display, specified as the comma-separated pair consisting of 'Polarization' and `'combined'`, `'H'`, or `'V'`. This parameter applies only when the sensors are polarization-capable and when the `'Type'` parameter is not set to `'directivity'`. This table shows the meaning of the display options

'Polarization'	Display
'combined'	Combined *H* and *V* polarization components
'H'	*H* polarization component
'V'	*V* polarization component

Example: 'V'

Data Types: char

Output Arguments

PAT — Element pattern

M-by-*N* real-valued matrix

Element pattern, returned as an *M*-by-*N* real-valued matrix. The dimensions of PAT correspond to the dimensions of the output arguments AZ_ANG and EL_ANG.

AZ_ANG — Azimuth angles

scalar | 1-by-*M* real-valued row vector

Azimuth angles for displaying directivity or response pattern, returned as a scalar or 1-by-*M* real-valued row vector corresponding to the dimension set in AZ. The rows of PAT correspond to the values in AZ_ANG.

EL_ANG — Elevation angles

scalar | 1-by-*N* real-valued row vector

Elevation angles for displaying directivity or response, returned as a scalar or 1-by-*N* real-valued row vector corresponding to the dimension set in EL. The columns of PAT correspond to the values in EL_ANG.

Examples

Single Frequency Response and Pattern of Isotropic Hydrophone

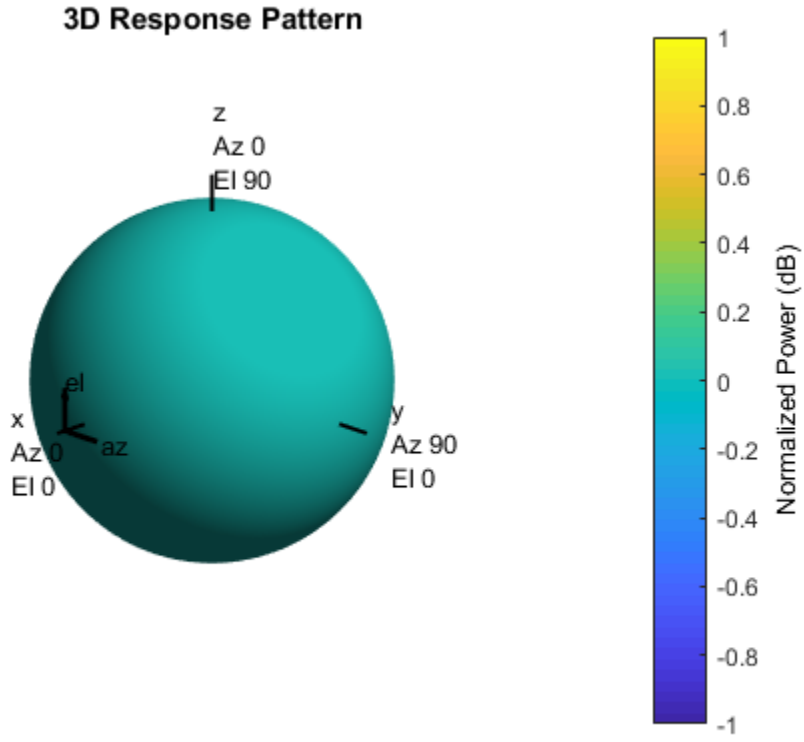
Examine the response and patterns of an isotropic hydrophone operating between 1 kHz and 10 kHz.

Set up the hydophone parameters. Obtain the voltage sensitivity at five different elevation angles: -30°, -15°, 0°, 15° and 30°. All elevation angles are at 0&deg. The sensitivities are computed at the signal frequency of 2 kHz.

```
hydrophone = phased.IsotropicHydrophone('FrequencyRange',[1 10]*1e3);
fc = 2e3;
resp = hydrophone(fc,[0 0 0 0 0;-30 -15 0 15 30]);
```

Draw a 3-D plot of the voltage sensitivity.

```
pattern(hydrophone,fc,[-180:180],[-90:90],'CoordinateSystem','polar', ...
    'Type','powerdb')
```



Response and Pattern of Isotropic Hydrophone at Multiple Frequencies

Examine the response and patterns of an isotropic hydrophone at three different frequencies. The hydrophone operates between 1 kHz and 10 kHz. Specify the voltage sensitivity as a vector.

Set up the hydrophone parameters and obtain the voltage sensitivity at 45° azimuth and 30° elevation. Compute the sensitivities at the signal frequencies of 2, 5, and 7 kHz.

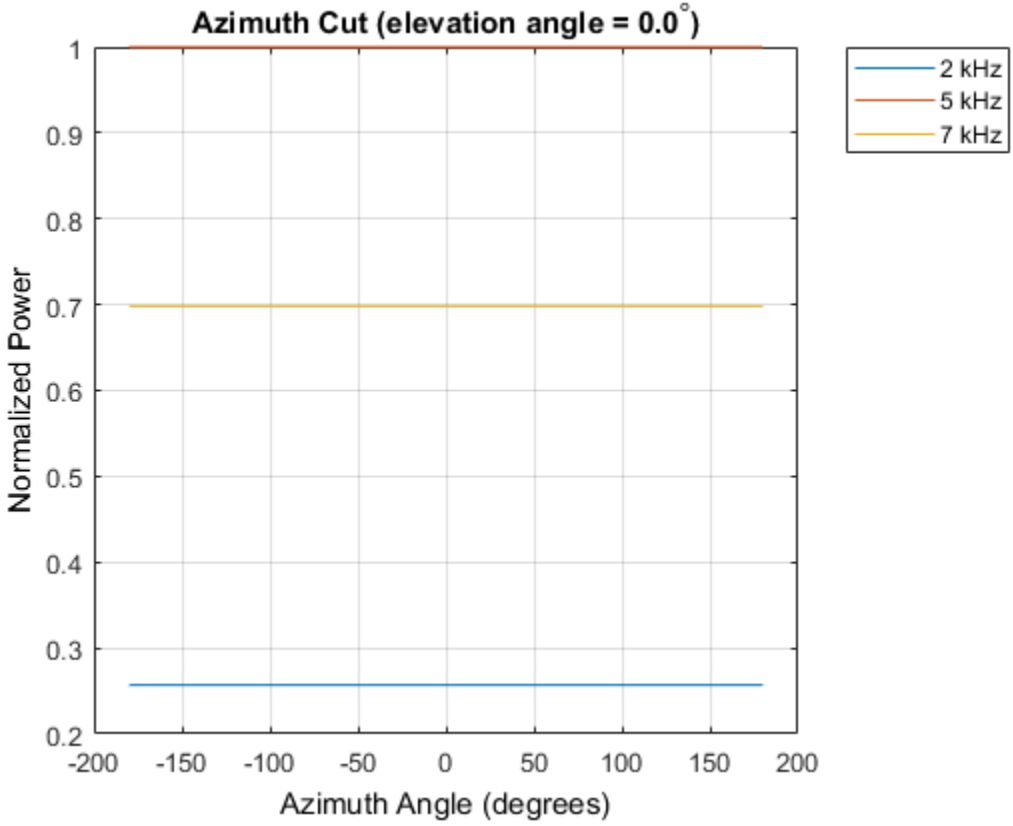
```
hydrophone = phased.IsotropicHydrophone('FrequencyRange',[1 10]*1e3, ...
    'VoltageSensitivity',[-100 -90 -100]);
fc = [2e3 5e3 7e3];
resp = hydrophone(fc,[45;30])
```

```
resp =

   14.8051   29.2202   24.4152
```

Draw a 2-D plot of the voltage sensitivity as a function of azimuth.

```
pattern(hydrophone,fc,[-180:180],0,'CoordinateSystem','rectangular',...
    'Type','power')
```



More About

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on "Element directivity" and "Array directivity".

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

patternAzimuth

System object: phased.IsotropicHydrophone
Package: phased

Plot isotropic hydrophone directivity and response patterns versus azimuth

Syntax

```
patternAzimuth(hydrophone,FREQ)
patternAzimuth(hydrophone,FREQ,EL)
patternAzimuth(hydrophone,FREQ,EL,Name,Value)
PAT = patternAzimuth( ___ )
```

Description

`patternAzimuth(hydrophone,FREQ)` plots the 2-D element directivity pattern versus azimuth (in dBi) for the element `hydrophone` at zero degrees elevation angle. The argument `FREQ` specifies the operating frequency.

`patternAzimuth(hydrophone,FREQ,EL)`, in addition, plots the 2-D element directivity pattern versus azimuth (in dBi) at the elevation angle specified by `EL`. When `EL` is a vector, multiple overlaid plots are created.

`patternAzimuth(hydrophone,FREQ,EL,Name,Value)` plots the element pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternAzimuth( ___ )` returns the element pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Azimuth'` parameter and the `EL` input argument.

Input Arguments

`hydrophone` — Isotropic hydrophone

`phased.IsotropicHydrophone` System object

Isotropic hydrophone, specified as a `phased.IsotropicHydrophone` System object.

Example: `phased.IsotropicHydrophone`

`FREQ` — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

`EL` — Elevation angles

1-by-*N* real-valued row vector

Elevation angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector. The quantity *N* is the number of requested elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and the *xy* plane. When measured toward the *z*-axis, this angle is positive.

Example: `[0,10,20]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Type'` — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

`'Azimuth'` — Azimuth angles

`[-180:180]` (default) | 1-by-*P* real-valued row vector

Azimuth angles, specified as the comma-separated pair consisting of `'Azimuth'` and a 1-by-*P* real-valued row vector. Azimuth angles define where the array pattern is calculated.

Example: `'Azimuth',[-90:2:90]`

Data Types: `double`

Output Arguments

`PAT` — Element directivity or pattern

L-by-*N* real-valued matrix

Element directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of azimuth values determined by the `'Azimuth'` name-value pair argument. The dimension *N* is the number of elevation angles, as determined by the `EL` input argument.

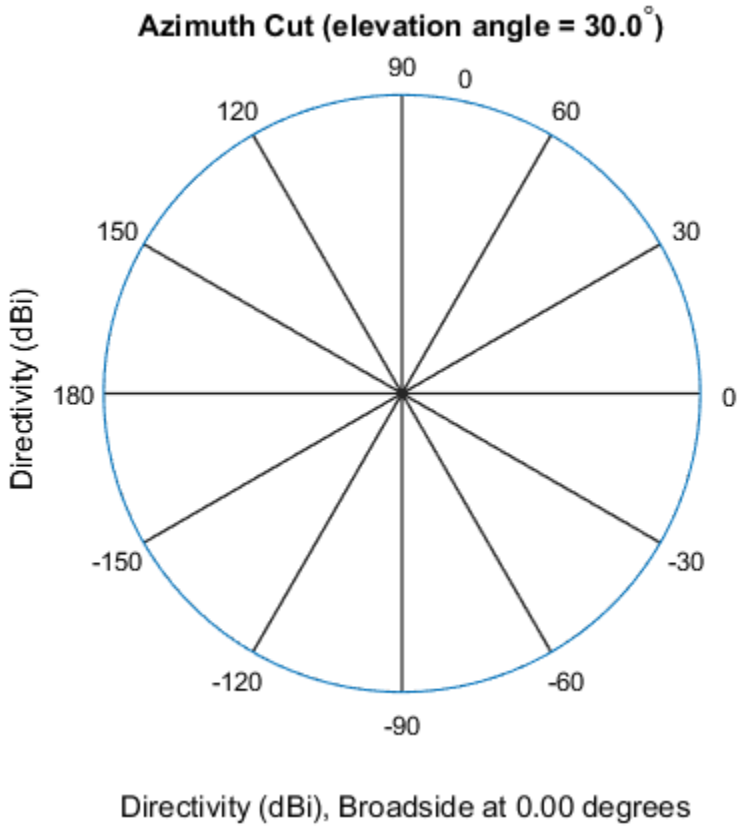
Examples

Azimuth Pattern of Isotropic Hydrophone

Examine the azimuth pattern of an isotropic hydrophone at 30° elevation. The frequency range is between 1 kHz and 10 kHz. Specify the voltage sensitivity as a vector.

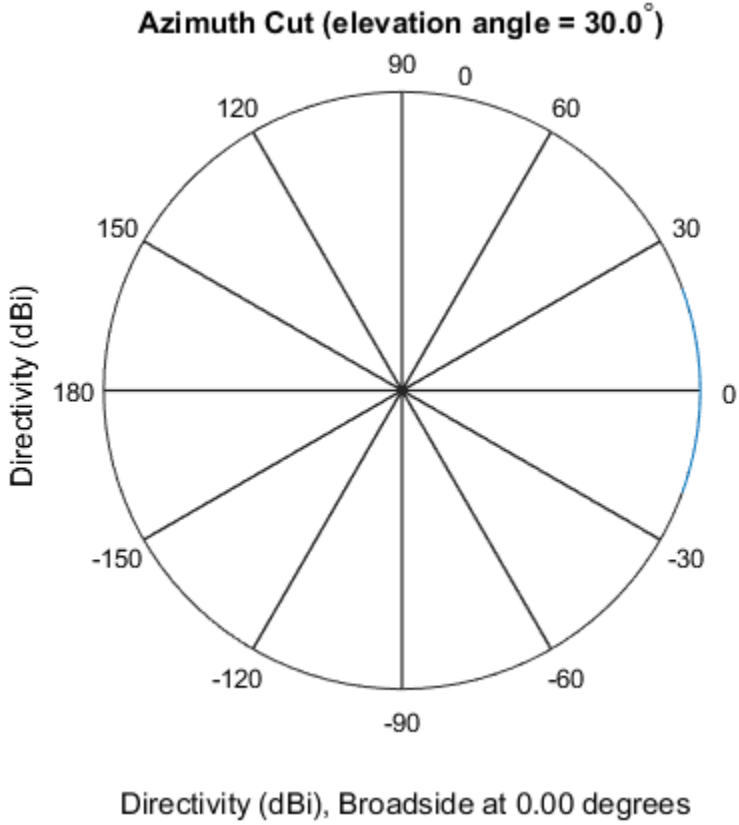
First, set up the hydrophone parameters.

```
fc = 3e3;
hydrophone = phased.IsotropicHydrophone('FrequencyRange',[1,10]*1e3, ...
    'VoltageSensitivity',[-100,-90,-100]);
patternAzimuth(hydrophone,fc,30)
```



Plot a smaller range of azimuth angles using the `Azimuth` parameter.

```
patternAzimuth(hydrophone,fc,30,'Azimuth',[-20:20])
```



Definitions

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant

intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element directivity” and “Array directivity”.

patternElevation

System object: phased.IsotropicHydrophone
Package: phased

Plot isotropic hydrophone directivity and response patterns versus elevation

Syntax

```
patternElevation(hydrophone,FREQ)
patternElevation(hydrophone,FREQ,AZ)
patternElevation(hydrophone,FREQ,AZ,Name,Value)
PAT = patternElevation( ___ )
```

Description

`patternElevation(hydrophone,FREQ)` plots the 2-D element directivity pattern versus elevation (in dBi) for the element `hydrophone` at zero degrees azimuth angle. The argument `FREQ` specifies the operating frequency.

`patternElevation(hydrophone,FREQ,AZ)`, in addition, plots the 2-D element directivity pattern versus elevation (in dBi) at the azimuth angle specified by `AZ`. When `AZ` is a vector, multiple overlaid plots are created.

`patternElevation(hydrophone,FREQ,AZ,Name,Value)` plots the element pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternElevation( ___ )` returns the element pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Elevation'` parameter and the `AZ` input argument.

Input Arguments

`hydrophone` — Isotropic hydrophone

`phased.IsotropicHydrophone` System object

Isotropic hydrophone, specified as a `phased.IsotropicHydrophone` System object.

Example: `phased.IsotropicHydrophone`

`FREQ` — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

`AZ` — Azimuth angles for computing directivity and pattern

1-by-*N* real-valued row vector

Azimuth angles for computing sensor or array directivities and patterns, specified as a 1-by-*M* real-valued row vector where *N* is the number of desired azimuth directions. Angle units are in degrees. The azimuth angle must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `[0,10,20]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Type'` — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

`'Elevation'` — Elevation angles

`[-90:90]` (default) | 1-by-*P* real-valued row vector

Elevation angles, specified as the comma-separated pair consisting of `'Elevation'` and a 1-by-*P* real-valued row vector. Elevation angles define where the array pattern is calculated.

Example: `'Elevation',[-90:2:90]`

Data Types: `double`

Output Arguments

`PAT` — Element directivity or pattern

L-by-*N* real-valued matrix

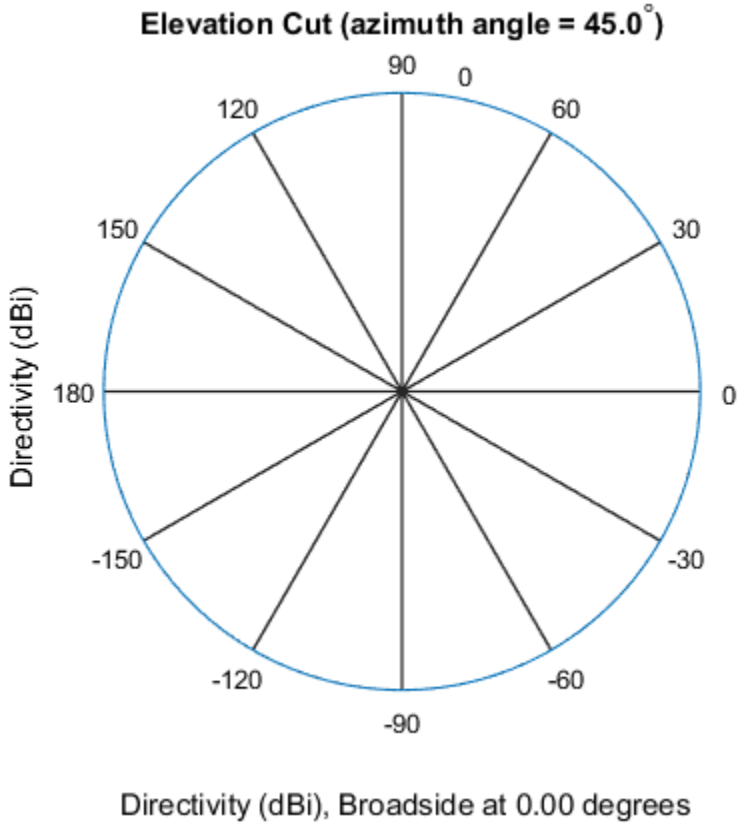
Element directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of elevation angles determined by the `'Elevation'` name-value pair argument. The dimension *N* is the number of azimuth angles determined by the `AZ` argument.

Examples

Elevation Pattern of Isotropic Hydrophone

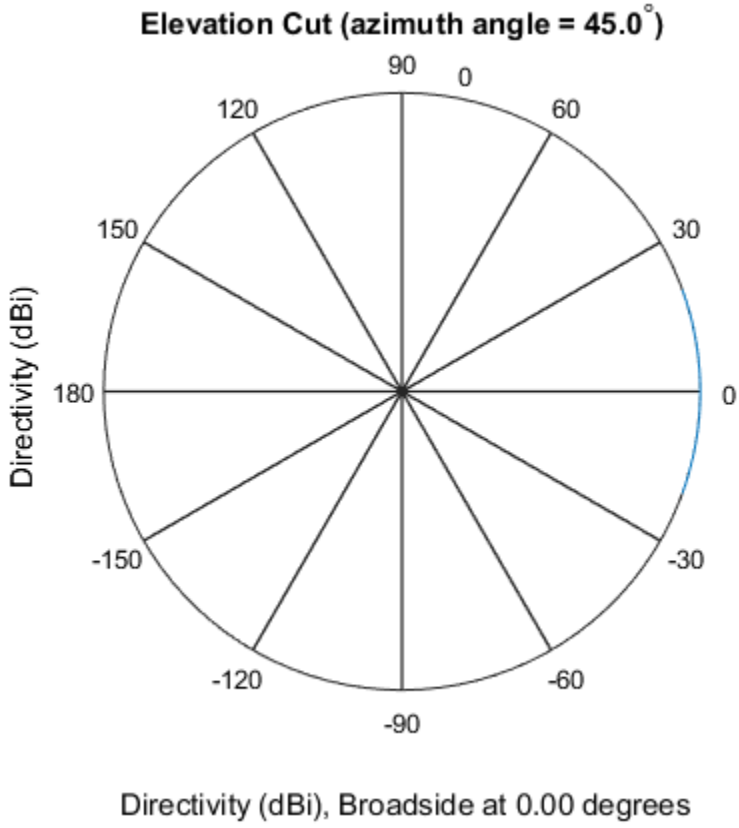
Plot an elevation cut of directivity of an isotropic hydrophone at 45° azimuth. Assume the signal frequency is 3 kHz. First, set up the hydrophone parameters.

```
fc = 3e3;
hydrophone = phased.IsotropicHydrophone('FrequencyRange',[1,10]*1e3, ...
    'VoltageSensitivity',[-100,-90,-100]);
patternElevation(hydrophone,fc,45)
```



Plot a smaller range of elevation angles using the `Elevation` parameter.

```
patternElevation(hydrophone,fc,45,'Elevation',[-20:20])
```



Definitions

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on "Element directivity" and "Array directivity".

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

Introduced in R2017a

step

System object: phased.IsotropicHydrophone
Package: phased

Voltage sensitivity of isotropic hydrophone

Syntax

```
resp = step(hydrophone,freq,ang)
```

Description

Note: Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`resp = step(hydrophone,freq,ang)` returns the voltage sensitivity for the hydrophone at the specified operating frequencies and in the specified directions of arriving signals.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`hydrophone` — Isotropic hydrophone

`phased.IsotropicHydrophone` System object

Isotropic hydrophone, specified as a `phased.IsotropicHydrophone` System object.

Example: `phased.IsotropicHydrophone`

`freq` — Voltage sensitivity frequencies

positive real scalar | real-valued 1-by-*L* vector of positive values

Voltage sensitivity frequencies of hydrophone, specified as a positive real scalar or a real-valued 1-by-*L* vector of positive values. Units are in Hz.

Data Types: `double`

`ang` — Direction of arriving signals

real-valued 1-by-*M* row vector | real-valued 2-by-*M* matrix

Direction of arriving signals, specified as a real-valued 1-by-*M* row vector or 2-by-*M* matrix. When `ang` is a 2-by-*M* matrix, each column of the matrix specifies the direction in the form `[azimuth;elevation]`. The azimuth angle must lie between –180° and 180°, inclusive. The elevation angle must lie between –90° and 90°, inclusive.

When `ang` is a 1-by-*M* row vector, each element specifies the azimuth angle of the arriving signal. In this case, the corresponding elevation angle is assumed to be zero.

Data Types: `double`

Output Arguments

`resp` — Voltage sensitivity of hydrophone

Voltage sensitivity of hydrophone, returned as a real-valued *M*-by-*L* matrix. *M* represents the number of angles specified in `ang`, and *L* represents the number of frequencies specified in `freq`. Units are in V/Pa.

Examples

Single Frequency Response and Pattern of Isotropic Hydrophone

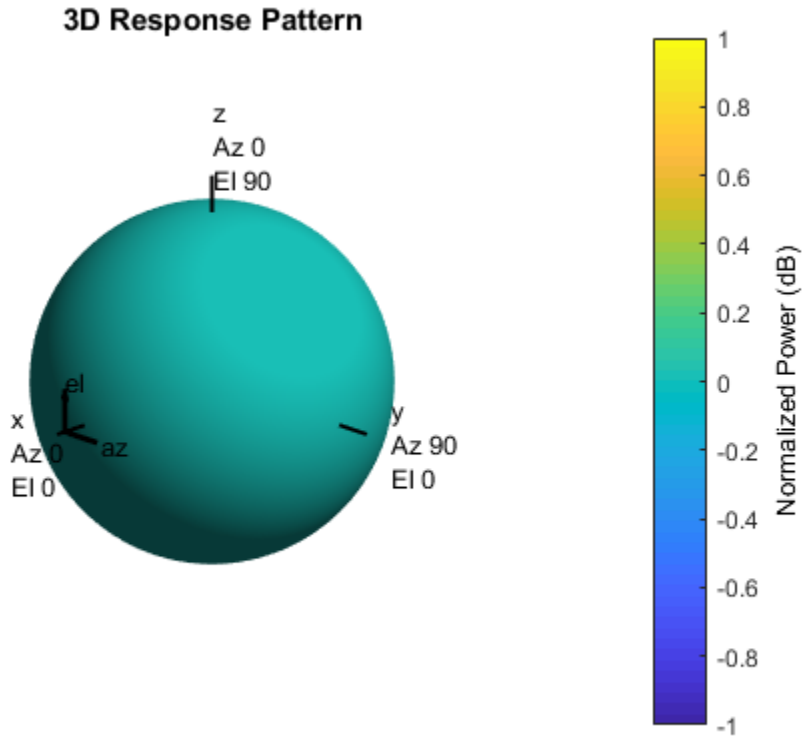
Examine the response and patterns of an isotropic hydrophone operating between 1 kHz and 10 kHz.

Set up the hydophone parameters. Obtain the voltage sensitivity at five different elevation angles: -30°, -15°, 0°, 15° and 30°. All elevation angles are at 0&deg. The sensitivities are computed at the signal frequency of 2 kHz.

```
hydrophone = phased.IsotropicHydrophone('FrequencyRange',[1 10]*1e3);
fc = 2e3;
resp = hydrophone(fc,[0 0 0 0 0;-30 -15 0 15 30]);
```

Draw a 3-D plot of the voltage sensitivity.

```
pattern(hydrophone,fc,[-180:180],[-90:90],'CoordinateSystem','polar', ...
    'Type','powerdb')
```



Response and Pattern of Isotropic Hydrophone at Multiple Frequencies

Examine the response and patterns of an isotropic hydrophone at three different frequencies. The hydrophone operates between 1 kHz and 10 kHz. Specify the voltage sensitivity as a vector.

Set up the hydrophone parameters and obtain the voltage sensitivity at 45° azimuth and 30° elevation. Compute the sensitivities at the signal frequencies of 2, 5, and 7 kHz.

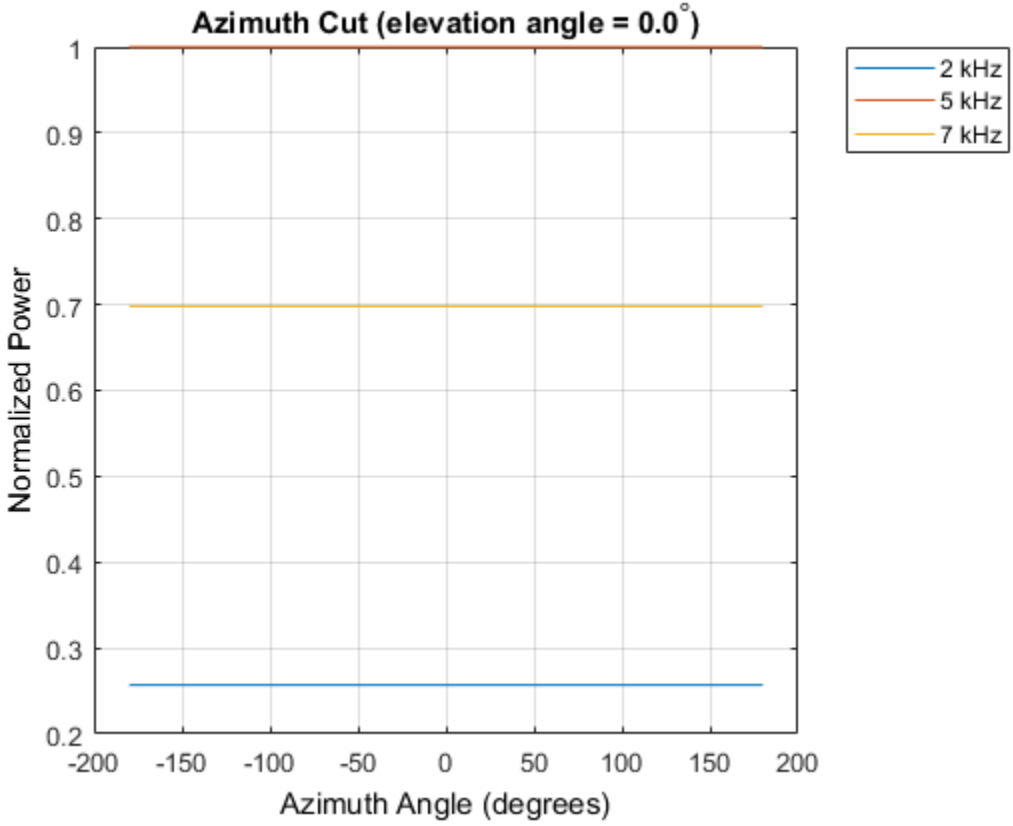
```
hydrophone = phased.IsotropicHydrophone('FrequencyRange',[1 10]*1e3, ...
    'VoltageSensitivity',[-100 -90 -100]);
fc = [2e3 5e3 7e3];
resp = hydrophone(fc,[45;30])
```

```
resp =

   14.8051   29.2202   24.4152
```

Draw a 2-D plot of the voltage sensitivity as a function of azimuth.

```
pattern(hydrophone,fc,[-180:180],0,'CoordinateSystem','rectangular',...
    'Type','power')
```



Algorithms

The total sensitivity of a hydrophone is a combination of its frequency sensitivity and spatial sensitivity. `phased.IsotropicHydrophone` calculates both sensitivities using nearest neighbor interpolation, and then multiplies the sensitivities to form the total sensitivity.

phased.IsotropicProjector System object

Package: phased

Isotropic projector

Description

The `phased.IsotropicProjector` System object creates an isotropic sound projector for sonar applications. An isotropic projector has the same response in all directions. The response is the radiated sound intensity per unit input voltage to the projector. You can adjust the response using the `VoltageResponse` property.

To compute the response of a projector for specified directions:

1. Define and set up an isotropic projector System object. See "Construction" on page 1-1055.
2. Call step to compute the response according to the properties of `phased.IsotropicProjector`.

Note: Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`projector = phased.IsotropicProjector` creates an isotropic projector System object, `projector`.

`projector = phased.IsotropicProjector(Name,Value)` creates an isotropic projector System object, `projector`, with each specified property `Name` set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1,Value1,...,NameN,ValueN`).

Properties

`FrequencyRange` — Operating frequency range of projector

`[0 200e3]` (default) | real-valued 1-by-2 vector

Operating frequency range of projector, specified as a 1-by-2 row vector in the form of `[LowerBound HigherBound]`. The projector defines the nonzero response range over which the hydrophone has a response. The projector has zero response outside this frequency range. Units are Hz.

Example: `[0 1000]`

Data Types: `double`

`VoltageResponse` — Voltage response of projector

`120` (default) | scalar | real-valued 1-by-*K* row vector

Voltage response of projector, specified as a scalar or real-valued 1-by-*K* row vector. When you specify voltage response as a scalar, that value applies to the entire frequency range specified by `FrequencyRange`. When you specify the voltage sensitivity as a vector, the frequency range is divided into K-1 equal intervals. The response values are assigned to the interval end points. Then, the `step` method interpolates the voltage response for any frequency inside the frequency range. Units are in dB ref: 1 µPa/V. See “Projector Voltage Response” on page 1-1060 for more details.

Example: `10`

Data Types: `double`

`BackBaffled` — Backbaffle response of projector

`false` (default) | `true`

Backbaffle response of projector, specified as `false` or `true`. Set this property to `true` to backbaffle the projector response. When the projector is backbaffled, the projector response for all azimuth angles beyond ±90° from broadside are zero. Broadside is defined as 0° azimuth and 0° elevation.

When the value of this property is `false`, the projector is not backbaffled.

Methods

directivity	Directivity of isotropic projector

isPolarizationCapable	Polarization capability
pattern	Plot isotropic projector directivity and patterns
patternAzimuth	Plot isotropic projector directivity and response patterns versus azimuth
patternElevation	Plot isotropic projector directivity and response patterns versus elevation
step	Voltage response of isotropic projector

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Response and Pattern of Isotropic Projector at Single Frequency

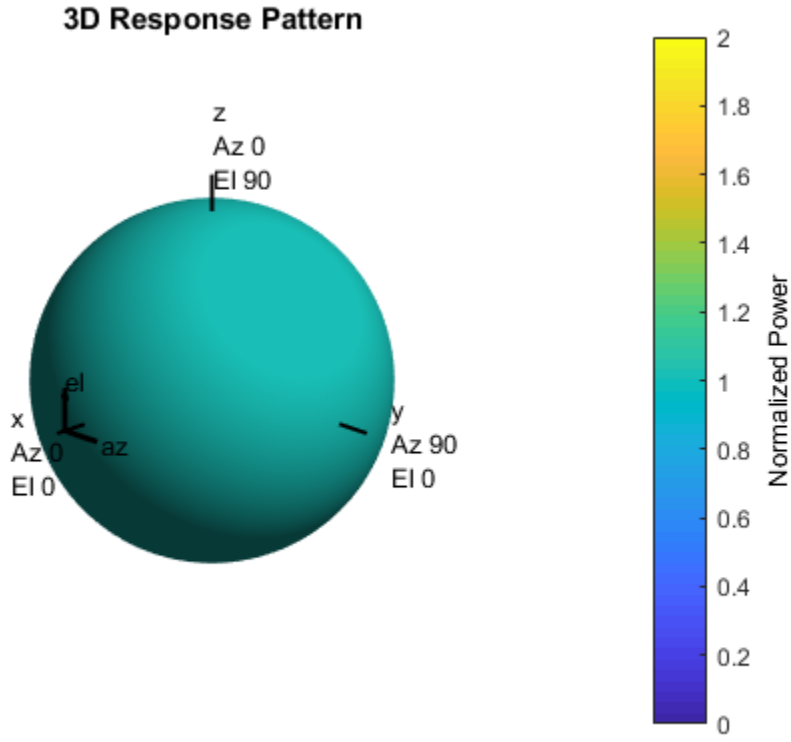
Examine the response and patterns of an isotropic projector operating between 1 kHz and 10 kHz.

Set the projector parameters and obtain the voltage response at five different elevation angles: -30°, -15°, 0°, 15° and 30&deg. All elevation angles at 0° azimuth angle. The voltage response is computed at 2 kHz.

```
projector = phased.IsotropicProjector('FrequencyRange',[1,10]*1e3);
fc = 2e3;
resp = projector(fc,[0,0,0,0,0;-30,-15,0,15,30]);
```

Draw a 3-D plot of the voltage response.

```
pattern(projector,fc,[-180:180],[-90:90],'CoordinateSystem','polar', ...
    'Type','power')
```



Response and Pattern of Isotropic Projector at Multiple Frequencies

Examine the response and patterns of an isotropic projector at three different frequencies. The projector operates between 1 kHz and 10 kHz. Specify the voltage response as a vector.

Set up the projector parameters, and obtain the voltage response at 45° azimuth and 30° elevation. Compute the responses at signal frequencies of 2, 5, and 7 kHz.

```
projector = phased.IsotropicProjector('FrequencyRange',[1 10]*1e3, ...
    'VoltageResponse',[90 95 100 95 90]);
fc = [2e3 5e3 7e3];
resp = projector(fc,[45;30]);
resp
```

```
resp =

    0.0426    0.0903    0.0708
```

Next, draw a 2-D plot of the voltage response as a function of azimuth

```
pattern(projector,fc,[-180:180],0,'CoordinateSystem','rectangular', ...
    'Type','power')
```

Definitions

Projector Voltage Response

The voltage response of a projector relates the transmitted sound intensity to the input voltage.

For a sound projector, the transmitting voltage response (TVR) is the sound intensity in μPa per volt, when measured at one meter from the projector. TVR is generally a function of frequency. If the sound intensity level (SIL) is expressed in dB//μPa and the output voltage (VdB) is expressed in dB//1V, then TVR is expressed in dB//μPa/1V. The output sound pressure level of a hydrophone is related to the input voltage level by
SIL = TVR + VdB.
Consider a projector that has TVR = 160 dB//μPa/1V at 10 kHz. If the projector input voltage is 200 V, then the VdB is 23 dB and the sound intensity level (SIL) at one meter is
SIL = TVR + VdB = 160 + 23 = 173 dB//μPa.

directivity

System object: phased.IsotropicProjector
Package: phased

Directivity of isotropic projector

Syntax

```
D = directivity(projector,FREQ,ANGLE)
```

Description

`D = directivity(projector,FREQ,ANGLE)` returns the "Directivity" on page 1-349 of the isotropic projector, `projector`, at frequencies specified by `FREQ` and in direction angles specified by `ANGLE`.

Input Arguments

`projector` — Isotropic projector

`phased.IsotropicProjector` System object

Isotropic projector, specified as a `phased.IsotropicProjector` System object.

Example: `phased.IsotropicProjector`

`FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the

directivity is returned as `-Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.

- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `-Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

`ANGLE` — Angles for computing directivity

1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Angles for computing directivity, specified as a 1-by-*M* real-valued row vector or a 2-by-*M* real-valued matrix, where *M* is the number of angular directions. Angle units are in degrees. If `ANGLE` is a 2-by-*M* matrix, then each column specifies a direction in azimuth and elevation, `[az;el]`. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°.

If `ANGLE` is a 1-by-*M* vector, then each entry represents an azimuth angle, with the elevation angle assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis.

Example: `[45 60; 0 10]`

Data Types: `double`

Output Arguments

`D` — Directivity

M-by-*L* matrix

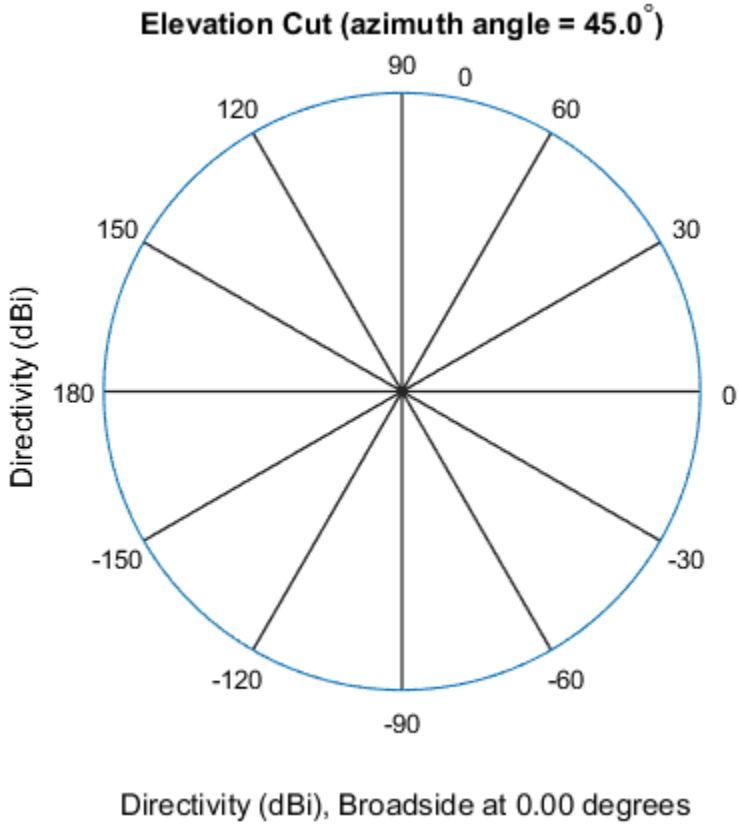
Directivity, returned as an *M*-by-*L* matrix whose columns contain the directivities at the *M* angles specified by `ANGLE`. Each column corresponds to one of the *L* frequency values specified in `FREQ`. Directivity units are in dBi.

Examples

Directivity of Isotropic Projector

Compute the directivity of an isotropic projector in different directions. Assume the signal frequency is 3 kHz. First, set the projector parameters.

```
fc = 3e3;
projector = phased.IsotropicProjector('FrequencyRange',[1,10]*1e3, ...
    'VoltageResponse',[100,110,120,110,100]);
patternElevation(projector,fc,45)
```



Select the angles of interest to be constant elevation angle at zero degrees. The five azimuth angles are centered around boresight (zero degrees azimuth and zero degrees elevation).

```
ang = [-20,-10,0,10,20; 0,0,0,0,0];
```

Compute the directivity along the constant elevation cut.

```
d = directivity(projector,fc,ang)
```

```
d =

     0
     0
     0
     0
     0
```

The directivity of an isotropic projector is zero in every direction.

Definitions

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission.

When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element directivity” and “Array directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

Introduced in R2017a

isPolarizationCapable

System object: phased.IsotropicProjector
Package: phased

Polarization capability

Syntax

```
flag = isPolarizationCapable(projector)
```

Description

`flag = isPolarizationCapable(projector)` returns a Boolean value, `flag`, indicating whether the `phased.IsotropicProjector` supports polarization. An element supports polarization if it can create or respond to polarized fields. This projector does not support polarization.

Input Arguments

`projector` — Isotropic projector

`phased.IsotropicProjector` System object

Isotropic projector, specified as a `phased.IsotropicProjector` System object.

Example: `phased.IsotropicProjector`

Output Arguments

`flag` — Polarization-capability flag

`true` | `false`

Polarization-capability returned as a Boolean value `true` if the projector supports polarization or `false` if it does not. Because the `phased.IsotropicProjector` object does not support polarization, `flag` is always returned as `false`.

Introduced in R2017a

pattern

System object: phased.IsotropicProjector
Package: phased

Plot isotropic projector directivity and patterns

Syntax

```
pattern(projector,FREQ)
pattern(projector,FREQ,AZ)
pattern(projector,FREQ,AZ,EL)
pattern( ___ ,Name,Value)
[PAT,AZ_ANG,EL_ANG] = pattern( ___ )
```

Description

`pattern(projector,FREQ)` plots the 3D directivity pattern (in dBi) for the projector specified in `projector`. The operating frequency is specified in `FREQ`.

`pattern(projector,FREQ,AZ)` plots the projector directivity pattern at the specified azimuth angle.

`pattern(projector,FREQ,AZ,EL)` plots the projector directivity pattern at specified azimuth and elevation angles.

`pattern( ___ ,Name,Value)` plots the projector pattern with additional options specified by one or more `Name,Value` pair arguments.

`[PAT,AZ_ANG,EL_ANG] = pattern( ___ )` returns the projector pattern in `PAT`. The `AZ_ANG` output contains the coordinate values corresponding to the rows of `PAT`. The `EL_ANG` output contains the coordinate values corresponding to the columns of `PAT`. If the `'CoordinateSystem'` parameter is set to `'uv'`, then `AZ_ANG` contains the *U* coordinates of the pattern and `EL_ANG` contains the *V* coordinates of the pattern. Otherwise, they are in angular units in degrees. *UV* units are dimensionless.

Input Arguments

FREQ — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `-Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `-Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

AZ — Azimuth angles

`[-180:180]` (default) | 1-by-*M* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a 1-by-*M* real-valued row vector where *M* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, this angle is positive.

Example: `[-45:2:45]`

Data Types: `double`

EL — Elevation angles

`[-90:90]` (default) | 1-by-*N* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a 1-by-*N* real-valued row vector where *N* is the number of desired elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and *xy*-plane. When measured towards the *z*-axis, this angle is positive.

Example: `[-75:1:70]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'CoordinateSystem'` — Plotting coordinate system

`'polar'` (default) | `'rectangular'` | `'uv'`

Plotting coordinate system of the pattern, specified as the comma-separated pair consisting of `'CoordinateSystem'` and one of `'polar'`, `'rectangular'`, or `'uv'`. When `'CoordinateSystem'` is set to `'polar'` or `'rectangular'`, the `AZ` and `EL` arguments specify the pattern azimuth and elevation, respectively. `AZ` values must lie between –180° and 180°. `EL` values must lie between –90° and 90°. If `'CoordinateSystem'` is set to `'uv'`, `AZ` and `EL` then specify *U* and *V* coordinates, respectively. `AZ` and `EL` must lie between -1 and 1.

Example: `'uv'`

Data Types: `char`

`'Type'` — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: 'powerdb'

Data Types: char

'Normalize' — Display normalize pattern

true (default) | false

Display normalized pattern, specified as the comma-separated pair consisting of 'Normalize' and a Boolean. Set this parameter to true to display a normalized pattern. When you set 'Type' to 'directivity', this parameter does not apply. Directivity patterns are already normalized.

Example:

Data Types: logical

'PlotStyle' — Plotting style

'overlay' (default) | 'waterfall'

Plotting style, specified as the comma-separated pair consisting of 'Plotstyle' and either 'overlay' or 'waterfall'. This parameter applies when you specify multiple frequencies in FREQ in 2-D plots. You can draw 2-D plots by setting one of the arguments AZ or EL to a scalar.

Example:

Data Types: char

'Polarization' — Polarized field component

'combined' (default) | 'H' | 'V'

Polarized field component to display, specified as the comma-separated pair consisting of 'Polarization' and 'combined', 'H', or 'V'. This parameter applies only when the sensors are polarization-capable and when the 'Type' parameter is not set to 'directivity'. This table shows the meaning of the display options

'Polarization'	Display
'combined'	Combined *H* and *V* polarization components
'H'	*H* polarization component
'V'	*V* polarization component

Example: `'V'`

Data Types: `char`

Output Arguments

`PAT` — Element pattern

M-by-*N* real-valued matrix

Element pattern, returned as an *M*-by-*N* real-valued matrix. The dimensions of `PAT` correspond to the dimensions of the output arguments `AZ_ANG` and `EL_ANG`.

`AZ_ANG` — Azimuth angles

scalar | 1-by-*M* real-valued row vector

Azimuth angles for displaying directivity or response pattern, returned as a scalar or 1-by-*M* real-valued row vector corresponding to the dimension set in `AZ`. The rows of `PAT` correspond to the values in `AZ_ANG`.

`EL_ANG` — Elevation angles

scalar | 1-by-*N* real-valued row vector

Elevation angles for displaying directivity or response, returned as a scalar or 1-by-*N* real-valued row vector corresponding to the dimension set in `EL`. The columns of `PAT` correspond to the values in `EL_ANG`.

Examples

Response and Pattern of Isotropic Projector at Single Frequency

Examine the response and patterns of an isotropic projector operating between 1 kHz and 10 kHz.

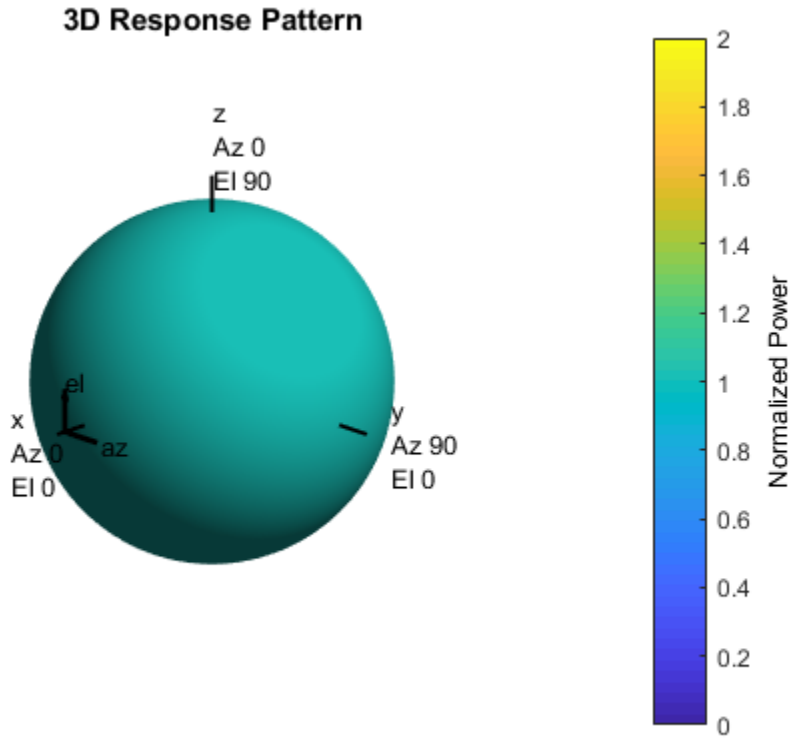
Set the projector parameters and obtain the voltage response at five different elevation angles: -30°, -15°, 0°, 15° and 30&deg. All elevation angles at 0° azimuth angle. The voltage response is computed at 2 kHz.

```
projector = phased.IsotropicProjector('FrequencyRange',[1,10]*1e3);
```

```
fc = 2e3;
resp = projector(fc,[0,0,0,0,0;-30,-15,0,15,30]);
```

Draw a 3-D plot of the voltage response.

```
pattern(projector,fc,[-180:180],[-90:90],'CoordinateSystem','polar', ...
    'Type','power')
```



Response and Pattern of Isotropic Projector at Multiple Frequencies

Examine the response and patterns of an isotropic projector at three different frequencies. The projector operates between 1 kHz and 10 kHz. Specify the voltage response as a vector.

Set up the projector parameters, and obtain the voltage response at 45° azimuth and 30° elevation. Compute the responses at signal frequencies of 2, 5, and 7 kHz.

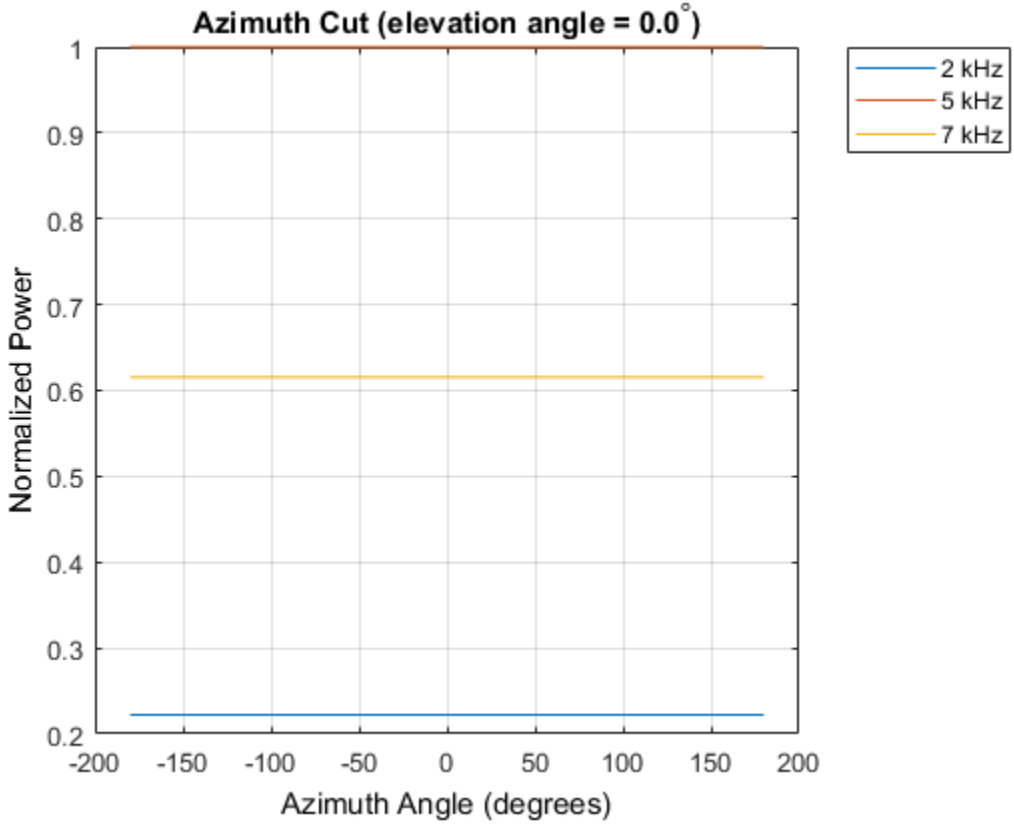
```
projector = phased.IsotropicProjector('FrequencyRange',[1 10]*1e3, ...
    'VoltageResponse',[90 95 100 95 90]);
fc = [2e3 5e3 7e3];
resp = projector(fc,[45;30]);
resp
```

```
resp =

    0.0426    0.0903    0.0708
```

Next, draw a 2-D plot of the voltage response as a function of azimuth

```
pattern(projector,fc,[-180:180],0,'CoordinateSystem','rectangular', ...
    'Type','power')
```



More About

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on "Element directivity" and "Array directivity".

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

phased.IsotropicProjector.directivity | phased.IsotropicProjector.patternAzimuth | phased.IsotropicProjector.patternElevation

Introduced in R2017a

patternAzimuth

System object: phased.IsotropicProjector
Package: phased

Plot isotropic projector directivity and response patterns versus azimuth

Syntax

```
patternAzimuth(projector,FREQ)
patternAzimuth(projector,FREQ,EL)
patternAzimuth(projector,FREQ,EL,Name,Value)
PAT = patternAzimuth( ___ )
```

Description

`patternAzimuth(projector,FREQ)` plots the 2-D element directivity pattern versus azimuth (in dBi) for the projector, `projector,` at zero-degrees elevation angle. The argument `FREQ` specifies the operating frequency.

`patternAzimuth(projector,FREQ,EL)`, in addition, plots the 2-D element directivity pattern versus azimuth (in dBi) at the elevation angle specified by `EL`. When `EL` is a vector, multiple overlaid plots are created.

`patternAzimuth(projector,FREQ,EL,Name,Value)` plots the element pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternAzimuth( ___ )` returns the element pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Azimuth'` parameter and the `EL` input argument.

Input Arguments

`projector` — Isotropic projector

`phased.IsotropicProjector` System object

Isotropic projector, specified as a `phased.IsotropicProjector` System object.

Example: `phased.IsotropicProjector`

`FREQ` — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

`EL` — Elevation angles

1-by-*N* real-valued row vector

Elevation angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector. The quantity *N* is the number of requested elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and the *xy* plane. When measured toward the *z*-axis, this angle is positive.

Example: `[0,10,20]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'Type' — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

'Azimuth' — Azimuth angles

`[-180:180]` (default) | 1-by-*P* real-valued row vector

Azimuth angles, specified as the comma-separated pair consisting of `'Azimuth'` and a 1-by-*P* real-valued row vector. Azimuth angles define where the array pattern is calculated.

Example: `'Azimuth',[-90:2:90]`

Data Types: `double`

Output Arguments

PAT — Element directivity or pattern

L-by-*N* real-valued matrix

Element directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of azimuth values determined by the `'Azimuth'` name-value pair argument. The dimension *N* is the number of elevation angles, as determined by the `EL` input argument.

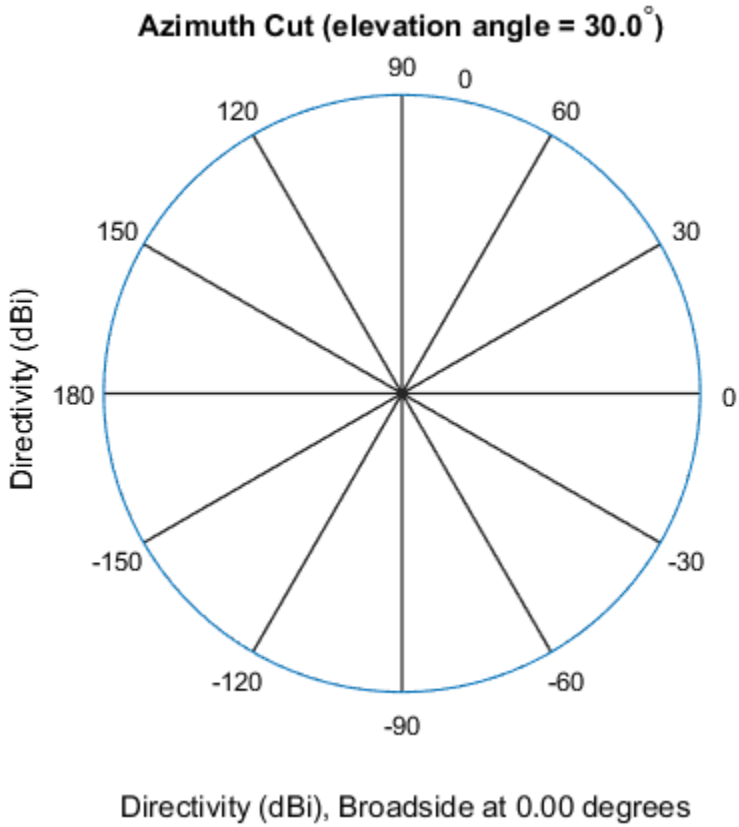
Examples

Azimuth Pattern of Isotropic Projector

Examine the azimuth pattern of an isotropic projector at 30° elevation. The frequency range is between 1 kHz and 10 kHz. Specify the voltage response as a scalar.

Set the projector parameters.

```
fc = 3e3;
projector = phased.IsotropicProjector('FrequencyRange',[1,10]*1e3, ...
    'VoltageResponse',-115);
patternAzimuth(projector,fc,30)
```



Plot a smaller range of azimuth angles using the `Azimuth` parameter.

```
patternAzimuth(projector,fc,30,'Azimuth',[-20:20])
```

Introduced in R2017a

patternElevation

System object: phased.IsotropicProjector
Package: phased

Plot isotropic projector directivity and response patterns versus elevation

Syntax

```
patternElevation(projector,FREQ)
patternElevation(projector,FREQ,AZ)
patternElevation(projector,FREQ,AZ,Name,Value)
PAT = patternElevation( ___ )
```

Description

`patternElevation(projector,FREQ)` plots the 2D element directivity pattern versus elevation (in dBi) for the projector, `projector`, at zero-degrees azimuth angle. The argument `FREQ` specifies the operating frequency.

`patternElevation(projector,FREQ,AZ)`, in addition, plots the 2D element directivity pattern versus elevation (in dBi) at the azimuth angle specified by `AZ`. When `AZ` is a vector, multiple overlaid plots are created.

`patternElevation(projector,FREQ,AZ,Name,Value)` plots the element pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternElevation( ___ )` returns the element pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Elevation'` parameter and the `AZ` input argument.

Input Arguments

`projector` — Isotropic projector

`phased.IsotropicProjector` System object

Isotropic projector, specified as a `phased.IsotropicProjector` System object.

Example: `phased.IsotropicProjector`

`FREQ` — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

`AZ` — Azimuth angles for computing directivity and pattern

1-by-*N* real-valued row vector

Azimuth angles for computing sensor or array directivities and patterns, specified as a 1-by-*M* real-valued row vector where *N* is the number of desired azimuth directions. Angle units are in degrees. The azimuth angle must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `[0,10,20]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Type'` — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

`'Elevation'` — Elevation angles

`[-90:90]` (default) | 1-by-*P* real-valued row vector

Elevation angles, specified as the comma-separated pair consisting of `'Elevation'` and a 1-by-*P* real-valued row vector. Elevation angles define where the array pattern is calculated.

Example: `'Elevation',[-90:2:90]`

Data Types: `double`

Output Arguments

`PAT` — Element directivity or pattern

L-by-*N* real-valued matrix

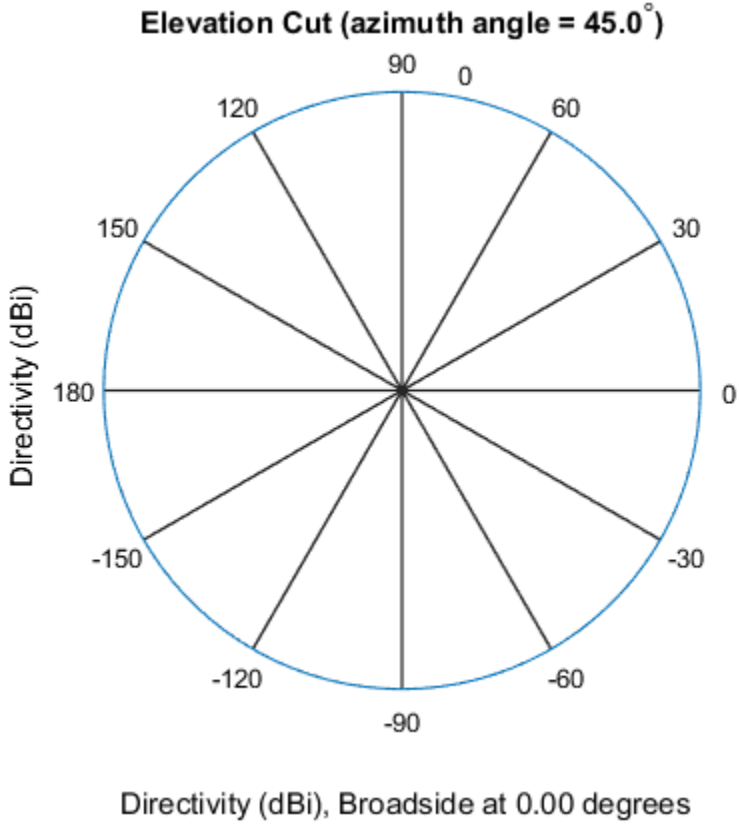
Element directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of elevation angles determined by the `'Elevation'` name-value pair argument. The dimension *N* is the number of azimuth angles determined by the `AZ` argument.

Examples

Elevation Pattern of Isotropic Projector

Plot an elevation cut of the directivity of an isotropic projector at 45° azimuth. Assume the signal frequency is 3 kHz. Set up the projector parameters.

```
fc = 3e3;
projector = phased.IsotropicProjector('FrequencyRange',[1,10]*1e3, ...
    'VoltageResponse',70);
patternElevation(projector,fc,45)
```



Plot a smaller range of elevation angles using the `Elevation` parameter.

```
patternElevation(projector,fc,45,'Elevation',[-20:20])
```

Introduced in R2017a

step

System object: phased.IsotropicProjector
Package: phased

Voltage response of isotropic projector

Syntax

```
resp = step(projector,freq,ang)
```

Description

Note: Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`resp = step(projector,freq,ang)` returns the voltage response for the projector at the specified operating frequencies and in the specified directions of arriving signals.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`projector` — Isotropic projector

`phased.IsotropicProjector` System object

Isotropic projector, specified as a `phased.IsotropicProjector` System object.

Example: `phased.IsotropicProjector`

`freq` — Voltage response frequencies

positive real scalar | real-valued 1-by-*L* vector of positive values

Voltage response frequencies of projector, specified as a positive real scalar or a real-valued 1-by-*L* vector of positive values. Units are in Hz.

Data Types: `double`

`ang` — Direction of arriving signals

real-valued 1-by-*M* row vector | real-valued 2-by-*M* matrix

Direction of arriving signals, specified as a real-valued 1-by-*M* row vector or 2-by-*M* matrix. When `ang` is a 2-by-*M* matrix, each column of the matrix specifies the direction in the form `[azimuth;elevation]`. The azimuth angle must lie between –180° and 180°, inclusive. The elevation angle must lie between –90° and 90°, inclusive.

When `ang` is a 1-by-*M* row vector, each element specifies the azimuth angle of the arriving signal. In this case, the corresponding elevation angle is assumed to be zero.

Data Types: `double`

Output Arguments

`resp` — Voltage response of projector

real-valued *M*-by-*L* matrix

Voltage response of projector, returned as a real-valued *M*-by-*L* matrix. *M* represents the number of angles specified in `ang`, and *L* represents the number of frequencies specified in `freq`. Units are in V/Pa.

Examples

Response and Pattern of Isotropic Projector at Single Frequency

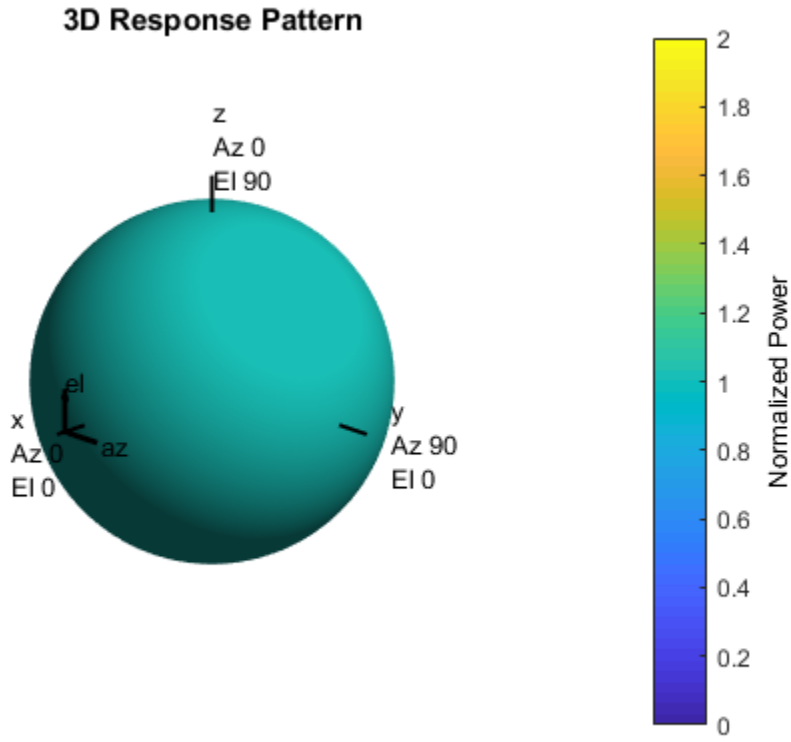
Examine the response and patterns of an isotropic projector operating between 1 kHz and 10 kHz.

Set the projector parameters and obtain the voltage response at five different elevation angles: -30°, -15°, 0°, 15° and 30&deg. All elevation angles at 0° azimuth angle. The voltage response is computed at 2 kHz.

```
projector = phased.IsotropicProjector('FrequencyRange',[1,10]*1e3);
fc = 2e3;
resp = projector(fc,[0,0,0,0,0;-30,-15,0,15,30]);
```

Draw a 3-D plot of the voltage response.

```
pattern(projector,fc,[-180:180],[-90:90],'CoordinateSystem','polar', ...
    'Type','power')
```



Response and Pattern of Isotropic Projector at Multiple Frequencies

Examine the response and patterns of an isotropic projector at three different frequencies. The projector operates between 1 kHz and 10 kHz. Specify the voltage response as a vector.

Set up the projector parameters, and obtain the voltage response at 45° azimuth and 30° elevation. Compute the responses at signal frequencies of 2, 5, and 7 kHz.

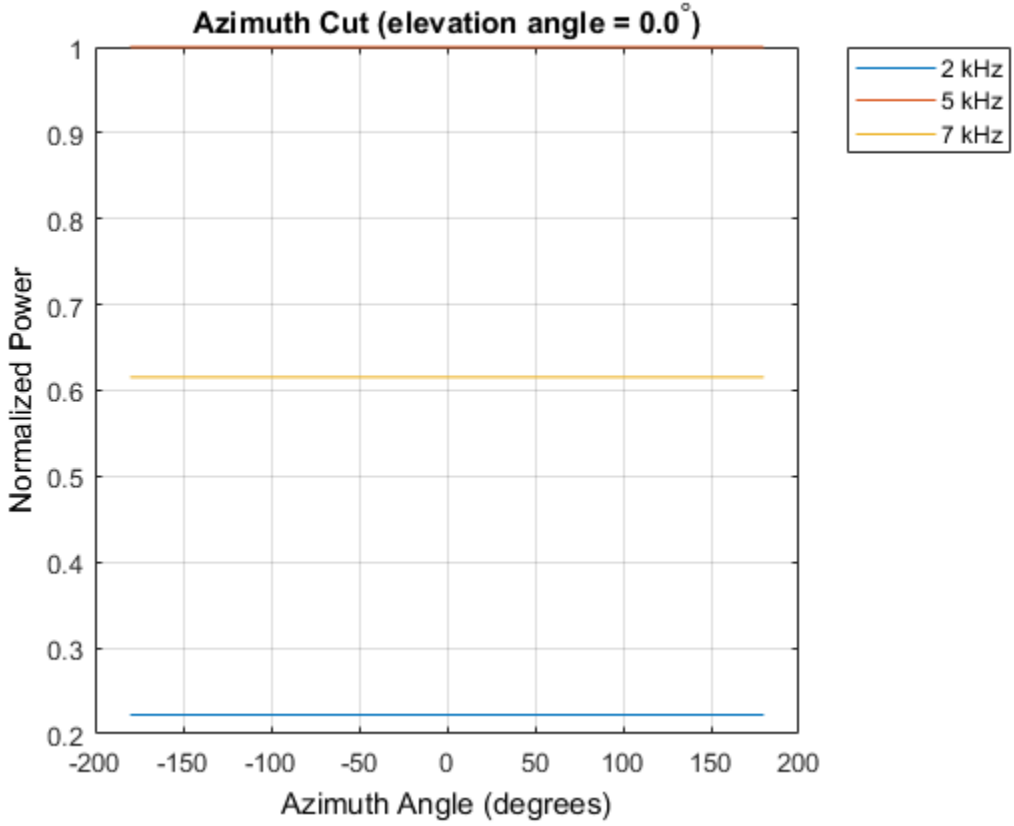
```
projector = phased.IsotropicProjector('FrequencyRange',[1 10]*1e3, ...
    'VoltageResponse',[90 95 100 95 90]);
fc = [2e3 5e3 7e3];
resp = projector(fc,[45;30]);
resp
```

```
resp =

    0.0426    0.0903    0.0708
```

Next, draw a 2-D plot of the voltage response as a function of azimuth

```
pattern(projector,fc,[-180:180],0,'CoordinateSystem','rectangular', ...
    'Type','power')
```



Algorithms

The total response of a projector is a combination of its frequency response and spatial response. `phased.IsotropicProjector` calculates both responses using nearest neighbor interpolation, and then multiplies the responses to form the total response.

`phitheta2azel` | `uv2azel`

phased.LCMVBeamformer System object

Package: phased

Narrowband LCMV beamformer

Description

The `LCMVBeamformer` object implements a linear constraint minimum variance beamformer.

To compute the beamformed signal:

1. Define and set up your LCMV beamformer. See "Construction" on page 1-1095.
2. Call step to perform the beamforming operation according to the properties of `phased.LCMVBeamformer`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.LCMVBeamformer` creates a linear constraint minimum variance (LCMV) beamformer System object, `H`. The object performs narrowband LCMV beamforming on the received signal.

`H = phased.LCMVBeamformer(Name,Value)` creates an LCMV beamformer object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`Constraint`

Constraint matrix

Specify the constraint matrix used for LCMV beamforming as an *N*-by-*K* matrix. Each column of the matrix is a constraint and *N* is the number of elements in the sensor array. The number of constraints, *K*, must be less than or equal to the number of sensors, $N,K \leq N$.

Default: `[1; 1]`

`DesiredResponse`

Desired response vector

Specify the desired response used for LCMV beamforming as a column vector of length K, where K is the number of constraints in the `Constraint` property. Each element in the vector defines the desired response of the constraint specified in the corresponding column of the `Constraint` property.

Default: 1, which corresponds to a distortionless response

`DiagonalLoadingFactor`

Diagonal loading factor

Specify the diagonal loading factor as a positive scalar. Diagonal loading is a technique used to achieve robust beamforming performance, especially when the sample support is small. This property is tunable.

Default: 0

`TrainingInputPort`

Add input to specify training data

To specify additional training data, set this property to `true` and use the corresponding input argument when you invoke step. To use the input signal as the training data, set this property to `false`.

Default: `false`

`WeightsOutputPort`

Output beamforming weights

To obtain the weights used in the beamformer, set this property to `true` and use the corresponding output argument when invoking step. If you do not want to obtain the weights, set this property to `false`.

Default: `false`

Methods

step	Perform LCMV beamforming

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

LCMV Beamformer with One Constraint

Apply an LCMV beamformer to a 5-element ULA of isotropic sensor elements, preserving the signal from a desired direction. The operating frequency is 300 MHz.

Simulate a low-frequency sinusoid signal in gaussian noise.

```
f = 50;
```

```
t = (0:.001:.3)';
x = sin(2*pi*f*t);
c = physconst('LightSpeed');
fc = 300e6;
lambda = c/fc;
incidentAngle = [45;0];
sIso = phased.IsotropicAntennaElement('FrequencyRange',[20 20e8]);
sULA = phased.ULA('NumElements',5,'ElementSpacing',lambda/2,...
    'Element',sIso);
x = collectPlaneWave(sULA,x,incidentAngle,fc,c);
noise = 0.2*(randn(size(x)) + 1j*randn(size(x)));
rx = x + noise;
```

Beamform the array.

```
sSV = phased.SteeringVector('SensorArray',sULA,...
    'PropagationSpeed',c);
sLCMV = phased.LCMVBeamformer;
sLCMV.Constraint = step(sSV,fc,incidentAngle);
sLCMV.DesiredResponse = 1;
y = step(sLCMV,rx);
```

Plot the original and beamformed signals.

```
plot(t,real(rx(:,3)),'r:',t,real(y),t,real(x(:,3)),'g')
xlabel('Time (sec)'); ylabel('Amplitude')
legend('Signal at Sensor 3','Beamformed Signal','Noise Free Signal')
```

Package: phased

Perform LCMV beamforming

Syntax

```
Y = step(H,X)
Y = step(H,X,XT)
[Y,W] = step( ___ )
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` performs LCMV beamforming on the input, `X`, and returns the beamformed output in `Y`. `X` is an M-by-N matrix where N is the number of elements of the sensor array. `Y` is a column vector of length M.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

`Y = step(H,X,XT)` uses `XT` as the training samples to calculate the beamforming weights. This syntax is available when you set the `TrainingInputPort` property to `true`. `XT` is a P-by-N matrix, where N is the number of elements of the sensor array. P must be greater than N.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

`[Y,W] = step( ___ )` returns the beamforming weights `W`. This syntax is available when you set the `WeightsOutputPort` property to `true`. `W` is a column vector of length N, where N is the number of elements in the sensor array.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

phased.LinearFMWaveform System object

Package: phased

Linear FM pulse waveform

Description

The `LinearFMWaveform` object creates a linear FM pulse waveform.

To obtain waveform samples:

1. Define and set up your linear FM waveform. See "Construction" on page 1-1104.
2. Call step to generate the linear FM waveform samples according to the properties of `phased.LinearFMWaveform`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations. When the only argument to the `step` method is the System object itself, replace `y = step(obj)` by `y = obj()`.

Construction

`H = phased.LinearFMWaveform` creates a linear FM pulse waveform System object, `H`. The object generates samples of a linear FM pulse waveform.

`H = phased.LinearFMWaveform(Name,Value)` creates a linear FM pulse waveform object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`SampleRate`

Sample rate

Signal sample rate, specified as a positive scalar. Units are Hertz. The ratio of sample rate to pulse repetition frequency *(PRF)* must be a positive integer — each pulse must contain an integer number of samples.

Default: `1e6`

`DurationSpecification`

Method to set pulse duration

Method to set pulse duration (pulse width), specified as `'Pulse width'` or `'Duty cycle'`. This property determines how you set the pulse duration. When you set this property to `'Pulse width'`, then you set the pulse duration directly using the `PulseWidth` property. When you set this property to `'Duty cycle'`, you set the pulse duration from the values of the `PRF` and `DutyCycle` properties. The pulse width is equal to the duty cycle divided by the *PRF*.

Default: `'Pulse width'`

`PulseWidth`

Pulse width

Specify the length of each pulse (in seconds) as a positive scalar. The value must satisfy `PulseWidth <= 1./PRF`.

Default: `50e-6`

`DutyCycle`

Waveform duty cycle

Waveform duty cycle, specified as a scalar from 0 through 1, inclusive. This property applies when you set the `DurationSpecification` property to `'Duty cycle'`. The pulse width is the value of the `DutyCycle` property divided by the value of the `PRF` property.

Default: `0.5`

PRF

Pulse repetition frequency

Pulse repetition frequency, *PRF*, specified as a scalar or a row vector. Units are in Hz. The pulse repetition interval *PRI* is the inverse of the *PRF*. The value of the `PRF` property must satisfy these constraints:

- The product of *PRF* and *PulseWidth* must be less than or equal to one. This is equivalent to the requirement that the pulse width is less than a pulse repetition interval. For the phase-coded waveform, the pulse width is the product of the chip width and number of chips.
- The ratio of sample rate to PRF must be an integer. This is equivalent to requiring that the number of samples in one pulse repetition interval be an integer.

You can select the value of *PRF* by using property settings or input arguments.

- When `PRFSelectionInputPort` is `false`, you set the *PRF* using properties
  - implement a constant *PRF* by specifying `PRF` as a positive real-valued scalar.
  - implement a staggered *PRF* by specifying `PRF` as a row vector with positive real-valued entries. Then, each call to the `step` method uses successive elements of this vector for the *PRF*. If the last element of the vector is reached, the process continues cyclically with the first element of the vector.
- When `PRFSelectionInputPort` is `true`, you can implement a selectable *PRF* by specifying `PRF` as a row vector with positive real-valued entries. But this time, when you execute the `step` method, select a *PRF* by passing an index into the *PRF* vector as an argument.

In all cases, when you use a varying *PRF* and choose the `OutputFormat` property as `'Pulses'`, the number of samples per pulse can vary as well. When you choose `'Samples'` the number of samples per pulse is fixed.

Default: `10e3`

PRFSelectionInputPort

Enable PRF selection input

Enable the PRF selection input, specified as `true` or `false`. When you set this property to `false`, the step method uses the values set in the `PRF` property in order. When you set this property to `true`, you can pass an additional argument into the `step` method to select any value from the PRF vector.

Default: `false`

`SweepBandwidth`

FM sweep bandwidth

Specify the bandwidth of the linear FM sweeping (in hertz) as a positive scalar. The default value corresponds to 100 kHz.

Default: `1e5`

`SweepDirection`

FM sweep direction

Specify the direction of the linear FM sweep as one of `'Up'` or `'Down'`.

Default: `'Up'`

`SweepInterval`

Location of FM sweep interval

If you set this property value to `'Positive'`, the waveform sweeps in the interval between *0* and *B*, where *B* is the `SweepBandwidth` property value. If you set this property value to `'Symmetric'`, the waveform sweeps in the interval between *–B/2* and *B/2*.

Default: `'Positive'`

`Envelope`

Envelope function

Specify the envelope function as one of `'Rectangular'` or `'Gaussian'`.

Default: `'Rectangular'`

`OutputFormat`

Output signal format

Specify the format of the output signal as `'Pulses'` or `'Samples'`. When you set the `OutputFormat` property to `'Pulses'`, the output of the `step` method takes the form of multiple pulses specified by the value of the `NumPulses` property. The number of samples per pulse can vary if you change the pulse repetition frequency during the simulation.

When you set the `OutputFormat` property to `'Samples'`, the output of the `step` method is in the form of multiple samples. In this case, the number of output signal samples is the value of the `NumSamples` property and is fixed.

Default: `'Pulses'`

`NumSamples`

Number of samples in output

Specify the number of samples in the output of the `step` method as a positive integer. This property applies only when you set the `OutputFormat` property to `'Samples'`.

Default: `100`

`NumPulses`

Number of pulses in output

Specify the number of pulses in the output of the `step` method as a positive integer. This property applies only when you set the `OutputFormat` property to `'Pulses'`.

Default: `1`

Methods

bandwidth	Bandwidth of linear FM waveform
getMatchedFilter	Matched filter coefficients for waveform

getStretchProcessor	Create stretch processor for waveform
plot	Plot linear FM pulse waveform
reset	Reset states of the linear FM waveform object
step	Samples of linear FM pulse waveform

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

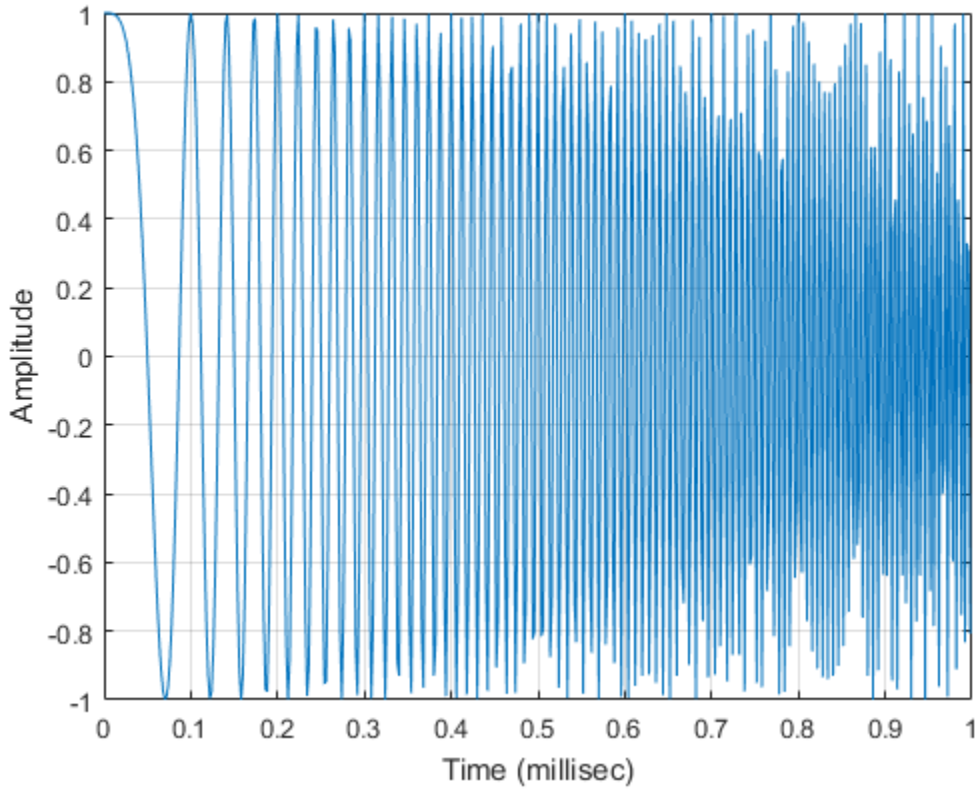
Plot LFM Waveform and Spectrum

Create and plot an upsweep linear FM pulse waveform. The sample rate is 500 kHz, the sweep bandwidth is 200 kHz and the pulse width is 1 millisecond (equal to the pulse repetition interval).

```
fs = 500e3;
sLFM = phased.LinearFMWaveform('SampleRate',fs,...
    'SweepBandwidth',200e3,...
    'PulseWidth',1e-3,'PRF',1e3);
```

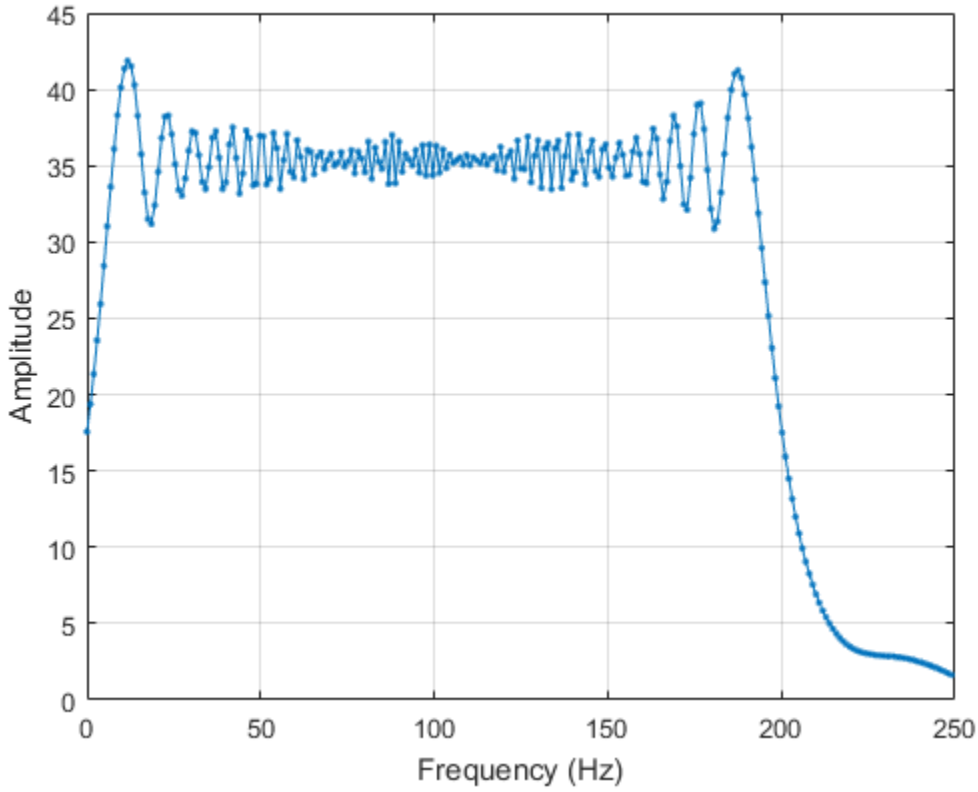
Obtain and then plot the real part of the LFM waveform.

```
lfmwav = step(sLFM);
nsamp = size(lfmwav,1);
t = [0:(nsamp-1)]/fs;
plot(t*1000,real(lfmwav))
xlabel('Time (millisec)')
ylabel('Amplitude')
grid
```



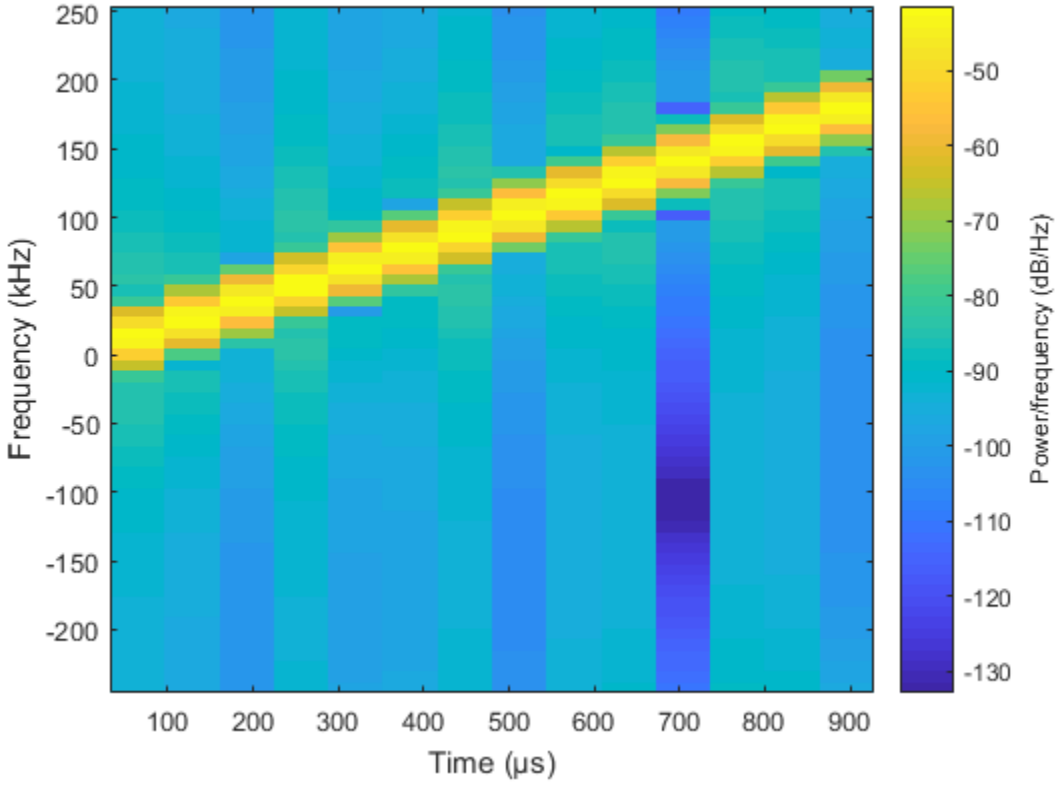
Plot the Fourier transform of the complex signal.

```
nfft = 2^nextpow2(nsamp);
Z = fft(lfmwav,nfft);
fr = [0:(nfft/2-1)]/nfft*fs;
plot(fr/1000,abs(Z(1:nfft/2)),'.-')
xlabel('Frequency (Hz)')
ylabel('Amplitude')
grid
```



Plot a spectrogram of the function with window size of 64 samples and 50% overlap.

```
nfft1 = 64;
nov = floor(0.5*nfft1);
spectrogram(lfmwav,hamming(nfft1),nov,nfft1,fs,'centered','yaxis')
```



This plot shows the increasing frequency of the signal.

Waveform Analysis Using the Ambiguity Function

Introduced in R2012a

bandwidth

System object: phased.LinearFMWaveform
Package: phased

Bandwidth of linear FM waveform

Syntax

```
BW = bandwidth(H)
```

Description

`BW = bandwidth(H)` returns the bandwidth (in hertz) of the pulses for the linear FM pulse waveform `H`. The bandwidth equals the value of the `SweepBandwidth` property.

Input Arguments

H

Linear FM pulse waveform object.

Output Arguments

BW

Bandwidth of the pulses, in hertz.

Examples

Compute Linear FM Bandwidth

Determine the bandwidth of a linear FM pulse waveform. The default value for an LFM waveform is 100 kHz.

```
waveform = phased.LinearFMWaveform;
bw = bandwidth(waveform)
```

```
bw =

       100000
```

getMatchedFilter

System object: phased.LinearFMWaveform
Package: phased

Matched filter coefficients for waveform

Syntax

```
Coeff = getMatchedFilter(H)
```

Description

`Coeff = getMatchedFilter(H)` returns the matched filter coefficients for the linear FM waveform object `H`. `Coeff` is a column vector.

Examples

Matched Filter Coefficients of Linear FM Waveform

Get the matched filter coefficients for a linear FM pulse.

```
waveform = phased.LinearFMWaveform('PulseWidth',5e-05,...
    'SweepBandwidth',1e5,'OutputFormat','Pulses');
coeff = getMatchedFilter(waveform);
stem(real(coeff))
title('Matched filter coefficients, real part')

getStretchProcessor

System object: phased.LinearFMWaveform
Package: phased

Create stretch processor for waveform

Syntax

```
HS = getStretchProcessor(H)
HS = getStretchProcessor(H,refrng)
HS = getStretchProcessor(H,refrng,rngspan)
HS = getStretchProcessor(H,refrng,rngspan,v)
```

Description

`HS = getStretchProcessor(H)` returns the stretch processor for the waveform, `H`. `HS` is set up so the reference range corresponds to 1/4 of the maximum unambiguous range of a pulse. The range span corresponds to 1/10 of the distance traveled by the wave within the pulse width. The propagation speed is the speed of light.

`HS = getStretchProcessor(H,refrng)` specifies the reference range.

`HS = getStretchProcessor(H,refrng,rngspan)` specifies the range span. The reference interval is centered at `refrng`.

`HS = getStretchProcessor(H,refrng,rngspan,v)` specifies the propagation speed.

Input Arguments

`H`

Linear FM pulse waveform object.

`refrng`

Reference range, in meters, as a positive scalar.

Default: 1/4 of the maximum unambiguous range of a pulse

`rngspan`

Length of the interval of ranges of interest, in meters, as a positive scalar. The center of the interval is the range value specified in the `refrng` argument.

Default: 1/10 of the distance traveled by the wave within the pulse width

`v`

Propagation speed, in meters per second, as a positive scalar.

Default: Speed of light

Output Arguments

`HS`

Stretch processor as a phased.StretchProcessor System object.

Examples

Detect a Target Using Stretch Processing

Use stretch processing to locate a target at a range of 4950 m.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Simulate the signal.

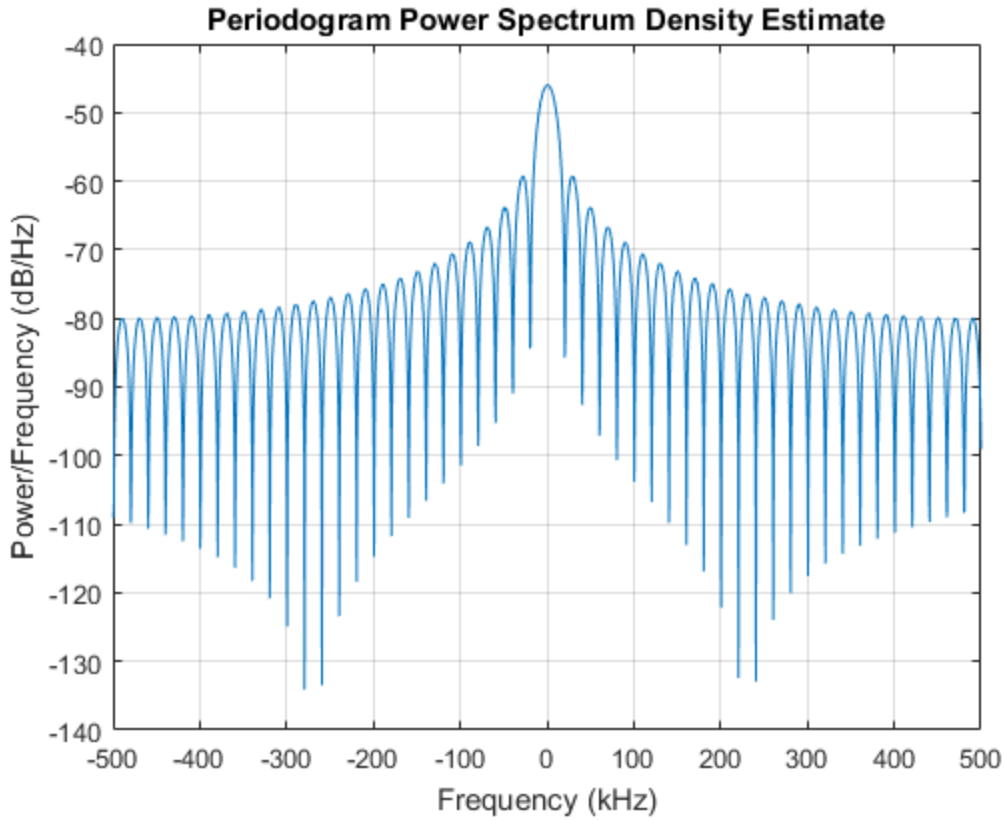
```
waveform = phased.LinearFMWaveform;
x = waveform();
c = physconst('LightSpeed');
rng = 4950.0;
num_samples = round(rng/(c/(2*waveform.SampleRate)));
x = circshift(x,num_samples);
```

Perform stretch processing.

```
stretchproc = getStretchProcessor(waveform,5000,200,c);
y = stretchproc(x);
```

Plot the spectrum of the resulting signal.

```
[Pxx,F] = periodogram(y,[],2048,stretchproc.SampleRate,'centered');
plot(F/1000,10*log10(Pxx))
grid
xlabel('Frequency (kHz)')
ylabel('Power/Frequency (dB/Hz)')
title('Periodogram Power Spectrum Density Estimate')
```



Detect the range.

```
[~,rngidx] = findpeaks(pow2db(Pxx/max(Pxx)),'MinPeakHeight',-5);
```

```
rngfreq = F(rngidx);
rng = stretchfreq2rng(rngfreq,stretchproc.SweepSlope,stretchproc.ReferenceRange,c)
```

```
rng =

   4.9634e+03
```

plot

System object: phased.LinearFMWaveform
Package: phased

Plot linear FM pulse waveform

Syntax

```
plot(Hwav)
plot(Hwav,Name,Value)
plot(Hwav,Name,Value,LineSpec)
h = plot( ___ )
```

Description

`plot(Hwav)` plots the real part of the waveform specified by `Hwav`.

`plot(Hwav,Name,Value)` plots the waveform with additional options specified by one or more `Name,Value` pair arguments.

`plot(Hwav,Name,Value,LineSpec)` specifies the same line color, line style, or marker options as are available in the MATLAB `plot` function.

`h = plot( ___ )` returns the line handle in the figure.

Input Arguments

`Hwav`

Waveform object. This variable must be a scalar that represents a single waveform object.

`LineSpec`

Character vector to specifies the same line color, style, or marker options as are available in the MATLAB `plot` function. If you specify a `PlotType` value of `'complex'`, then `LineSpec` applies to both the real and imaginary subplots.

Default: `'b'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'PlotType'`

Specifies whether the function plots the real part, imaginary part, or both parts of the waveform. Valid values are `'real'`, `'imag'`, and `'complex'`.

Default: `'real'`

`'PulseIdx'`

Index of the pulse to plot. This value must be a scalar.

Default: `1`

Output Arguments

`h`

Handle to the line or lines in the figure. For a `PlotType` value of `'complex'`, `h` is a column vector. The first and second elements of this vector are the handles to the lines in the real and imaginary subplots, respectively.

Examples

Plot Linear FM Pulse

Create and plot an upsweep linear FM pulse waveform.

```
waveform = phased.LinearFMWaveform('SweepBandwidth',1e5,'PulseWidth',1e-4);
plot(waveform);
```

reset

System object: phased.LinearFMWaveform
Package: phased

Reset states of the linear FM waveform object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `LinearFMWaveform` object, `H`. Afterward, if the `PRF` property is a vector, the next call to `step` uses the first PRF value in the vector.

step

System object: phased.LinearFMWaveform
Package: phased

Samples of linear FM pulse waveform

Syntax

```
Y = step(sLFM)
Y = step(sLFM,prfidx)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations. When the only argument to the `step` method is the System object itself, replace `y = step(obj)` by `y = obj()`.

`Y = step(sLFM)` returns samples of the linear FM pulse in a column vector `Y`.

`Y = step(sLFM,prfidx)`, uses the `prfidx` index to select the PRF from the predefined vector of values specified by in the `PRF` property. This syntax applies when you set the `PRFSelectionInputPort` property to `true`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Examples

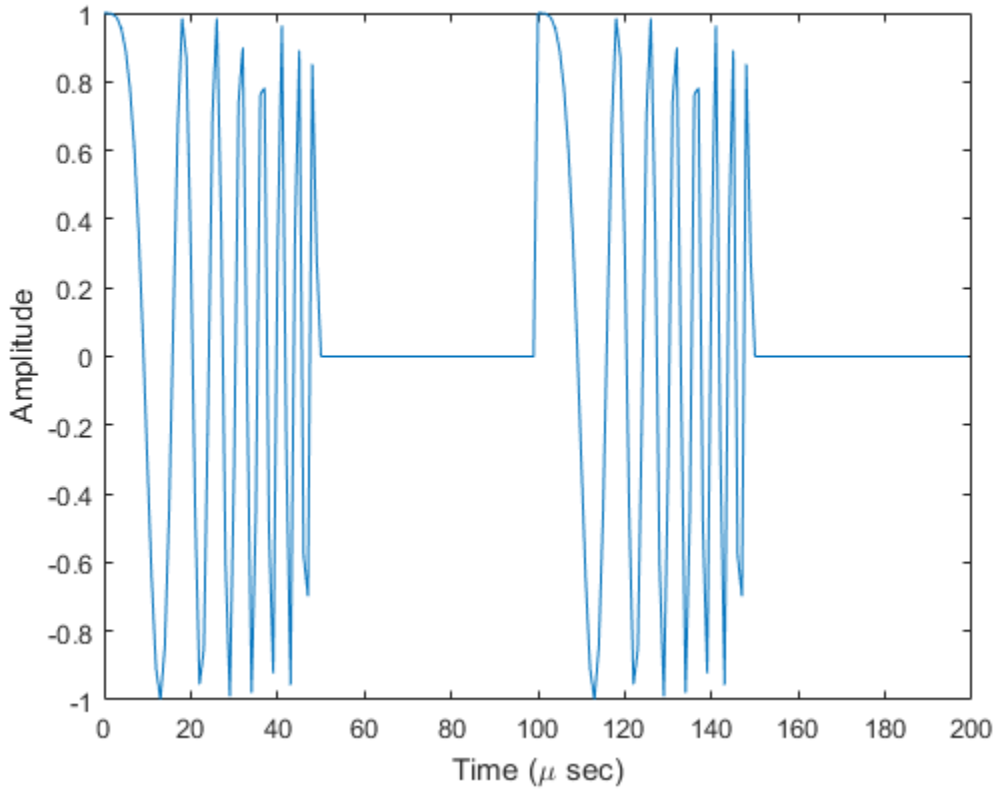
Create Linear FM Pulses

Construct a linear FM waveform having a sweep bandwidth of 300 kHz, a sample rate of 1 MHz, a pulse width of 50 microseconds, and a pulse repetition frequency of 10 kHz. Generate two pulses.

```
sLFM = phased.LinearFMWaveform('SweepBandwidth',3e5,...
    'OutputFormat','Pulses','SampleRate',1e6,...
    'PulseWidth',50e-6,'PRF',10e3,'NumPulses',2);
```

Obtain and plot the linear FM waveform.

```
wav = step(sLFM);
numpulses = size(wav,1);
t = [0:(numpulses-1)]/sLFM.SampleRate;
plot(t*1e6,real(wav))
xlabel('Time (\mu sec)')
ylabel('Amplitude')
```



Create Linear FM Pulses with Variable PRF

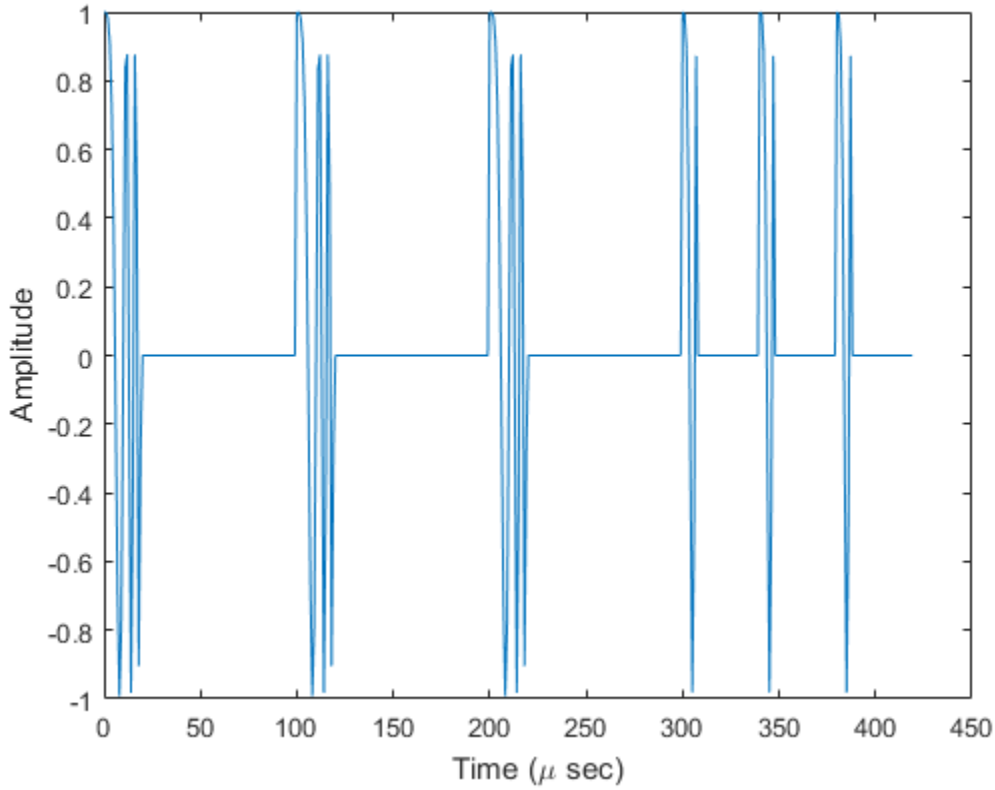
Construct six linear FM waveform pulses having a sweep bandwidth of 300 kHz, a sample rate of 1 MHz, a pulse width of 50 microseconds, and a duty cycle of 20%. Vary the pulse repetition frequency.

Set the sample rate and PRF. The ratio of sample rate to PRF must be an integer.

```
fs = 1e6;
PRF = [10000,25000];
sLFM = phased.LinearFMWaveform('SweepBandwidth',3e5,...
    'OutputFormat','Pulses','SampleRate',fs,...
    'DurationSpecification','Duty Cycle','DutyCycle',.2,...
    'PRF',PRF,'NumPulses',1,'PRFSelectionInputPort',true);
```

Obtain and plot the linear FM waveforms. For the first three calls to the step method, set the PRF to 10kHz using the PRF index. For the next three calls, set the PRF to 25 kHz.

```
wav = [];
for n = 1:6
    idx = floor((n-1)/3)+1;
    wav1 = step(sLFM,idx);
    wav = [wav;wav1];
end
nsamps = size(wav,1);
t = [0:(nsamps-1)]/sLFM.SampleRate;
plot(t*1e6,real(wav))
xlabel('Time (\mu sec)')
ylabel('Amplitude')
```



phased.LOSChannel System object

Package: phased

Narrowband LOS propagation channel

Description

The `phased.LOSChannel` models the propagation of narrowband electromagnetic signals through a line-of-sight (LOS) channel from a source to a destination. In an LOS channel, propagation paths are straight lines from point to point. The propagation model in the LOS channel includes free-space attenuation in addition to attenuation due to atmospheric gases, rain, fog, and clouds. You can use `phased.LOSChannel` to model the propagation of signals between multiple points simultaneously.

While the System object works for all frequencies, the attenuation models for atmospheric gases and rain are valid for electromagnetic signals in the frequency range 1–1000 GHz only. The attenuation model for fog and clouds is valid for 10–1000 GHz. Outside these frequency ranges, the System object uses the nearest valid value.

The `phased.LOSChannel` System object applies range-dependent time delays to the signals, as well as gains or losses. When either the source or destination is moving, the System object applies Doppler shifts.

Like the phased.FreeSpace System object, the `phased.LOSChannel` System object supports two-way propagation.

To compute the propagation delay for specified source and receiver points:

1. Define and set up your LOS channel using the “Construction” on page 1-1131 procedure. You can set the System object properties during construction or leave them at their default values. Some properties are tunable and can be changed at any time.
2. Call the phased.LOSChannel.step method to compute the propagated signal using the properties of the `phased.LOSChannel` System object.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were

a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`sLOS = phased.LOSChannel` creates an LOS attenuating propagation channel System object, `sLOS`.

`sLOS = phased.LOSChannel(Name,Value)` creates a System object, `sLOS`, with each specified property `Name` set to the specified `Value`. You can specify additional name and value pair arguments in any order as (`Name1,Value1,...,NameN,ValueN`).

Properties

`PropagationSpeed` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. Units are in m/s. The default value of the speed of light is the value returned by `physconst('LightSpeed')`.

Example: `3e8`

Data Types: `double`

`OperatingFrequency` — Signal carrier frequency

`300e6` (default) | positive real-valued scalar

Signal carrier frequency, specified as a positive real-valued scalar. Units are in Hz.

Example: `1e9`

Data Types: `double`

`SpecifyAtmosphere` — Enable atmospheric attenuation model

`false` (default) | `true`

Option to enable the atmospheric attenuation model, specified as a `false` or `true`. Set this property to `true` to add signal attenuation caused by atmospheric gases, rain, fog, or clouds. Set this property to `false` to ignore atmospheric effects in propagation.

Setting `SpecifyAtmosphere` to `true`, enables the `Temperature`, `DryAirPressure`, `WaterVapourDensity`, `LiquidWaterDensity`, and `RainRate` properties.

Data Types: `logical`

`Temperature` — Ambient temperature

`15` (default) | real-valued scalar

Ambient temperature, specified as a real-valued scalar. Units are in degrees Celsius.

Example: `20.0`

Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

`DryAirPressure` — Atmospheric dry air pressure

`101.325e3` (default) | positive real-valued scalar

Atmospheric dry air pressure, specified as a positive real-valued scalar. Units are in pascals (Pa). The default value of this property corresponds to one standard atmosphere.

Example: `101.0e3`

Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

`WaterVapourDensity` — Atmospheric water vapor density

`7.5` (default) | positive real-valued scalar

Atmospheric water vapor density, specified as a positive real-valued scalar. Units are in g/m^3.

Example: `7.4`

Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

`LiquidWaterDensity` — Liquid water density

`0.0` (default) | nonnegative real-valued scalar

Liquid water density of fog or clouds, specified as a nonnegative real-valued scalar. Units are in g/m^3. Typical values for liquid water density are 0.05 for medium fog and 0.5 for thick fog.

Example: `0.1`

Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

`RainRate` — Rainfall rate

`0.0` (default) | nonnegative scalar

Rainfall rate, specified as a nonnegative scalar. Units are in mm/hr.

Example: `10.0`

Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

`TwoWayPropagation` — Enable two-way propagation

`false` (default) | `true`

Enable two-way propagation, specified as a `false` or `true`. Set this property to `true` to perform round-trip propagation between the signal origin and destination specified in

`step`. Set this property to `false` to perform only one-way propagation from the origin to the destination.

Example: `true`

Data Types: `logical`

`SampleRate` — Sample rate of signal

`1e6` (default) | positive scalar

Sample rate of signal, specified as a positive scalar. Units are in Hz. The System object uses this quantity to calculate the propagation delay in units of samples.

Example: `1e6`

Data Types: `double`

`MaximumDistanceSource` — Source of maximum one-way propagation distance

`'Auto'` (default) | `'Property'`

Source of maximum one-way propagation distance, specified as `'Auto'` or `'Property'`. The maximum one-way propagation distance is used to allocate sufficient memory for signal delay computation. When you set this property to `'Auto'`, the System object automatically allocates memory. When you set this property to `'Property'`, you specify the maximum one-way propagation distance using the value of the `MaximumDistance` property.

Data Types: `char`

`MaximumDistance` — Maximum one-way propagation distance

`10000` (default) | positive real-valued scalar

Maximum one-way propagation distance, specified as a positive real-valued scalar. Units are in meters. Any signal that propagates more than the maximum one-way distance is ignored. The maximum distance must be greater than or equal to the largest position-to-position distance.

Example: `5000`

Dependencies

To enable this property, set the `MaximumDistanceSource` property to `'Property'`.

Data Types: `double`

Methods

reset	Reset states of System object
step	Propagate signal in LOS channel

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Propagate Polarized Wave in LOS Channel

Propagate a polarized electromagnetic wave radiating from a short-dipole antenna element. The dipole is rotated 30° around the *y*-axis. Set the orientation of the local axis to coincide with the dipole. Assume the dipole radiates at 30.0 GHz. Propagate the signal toward a target approximately 10 km away.

Create the short-dipole antenna element and radiator System objects. Set the `EnablePolarization` property to `true` to generate polarized waves.

```
freq = 30.0e9;
c = physconst('LightSpeed');
antenna = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6 40e9],...
    'AxisDirection','Z');
radiator = phased.Radiator('Sensor',antenna,...
    'PropagationSpeed',c,...
    'OperatingFrequency',freq,...
    'EnablePolarization',true,...
    'WeightsInputPort',false);
```

Create a signal to radiate. The signal envelope consists of several cycles of a 4 kHz sinusoid with amplitude set to unity. Set the sampling frequency to 1 MHz.

```
fsig = 4.0e3;
fs = 1.0e6;
```

```
t = [1:1000]/fs;
signal = sin(2*pi*fsig*t');
laxes = roty(30)*eye(3,3);
```

Use a `phased.FreeSpace` System object to propagate the field from the origin to the destination in free space.

```
fschannel = phased.FreeSpace('PropagationSpeed',c,...
    'OperatingFrequency',freq,...
    'TwoWayPropagation',false,...
    'SampleRate',fs);
```

Use a `phased.LOSChannel` System object to propagate the field from the origin to the destination in the LOS channel. Attenuation is due to atmospheric gases and fog.

```
loschannel = phased.LOSChannel('PropagationSpeed',c,...
    'OperatingFrequency',freq,...
    'TwoWayPropagation',false,...
    'SampleRate',fs,'SpecifyAtmosphere',true,'LiquidWaterDensity',0.5);
```

Set the signal origin, signal origin velocity, signal destination, and signal destination velocity.

```
source_pos = [0;0;0];
target_pos = [10000;200;0];
source_vel = [0;0;0];
target_vel = [0;0;0];
[~,radiatingAngles] = rangeangle(target_pos,source_pos,laxes);
```

Radiate the signal towards the target. The radiated signal is a `struct` containing the polarized field.

```
rad_sig = radiator(signal,radiatingAngles,laxes);
```

Propagate the signals to the target in free space.

```
prop_sig = fschannel(rad_sig,source_pos,target_pos,...
    source_vel,target_vel);
```

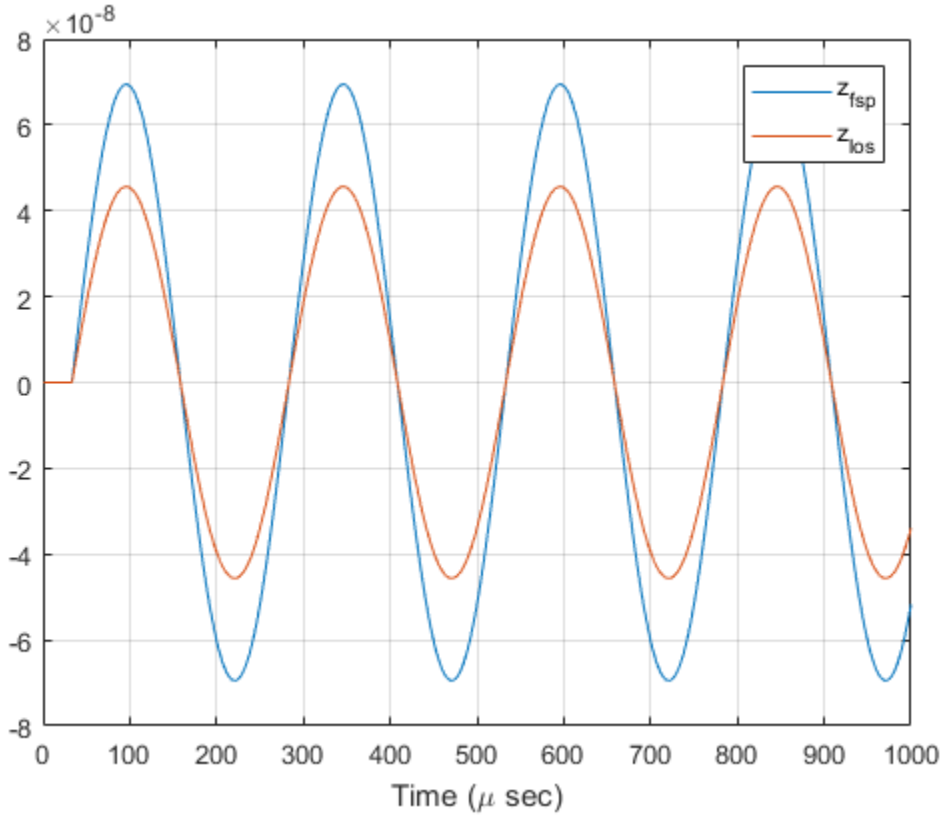
Propagate the signals to the target in the LOS channel.

```
prop_att_sig = loschannel(rad_sig,source_pos,target_pos,...
    source_vel,target_vel);
```

Plot the z-components of both the free-space and LOS-channel-propagated signals.

```
plot(1e6*t,real(prop_sig.Z),1e6*t,real(prop_att_sig.Z))
```

```
grid
xlabel('Time (\mu sec)')
legend('z_{fsp}','z_{los}')
```



The LOS channel signal is attenuated as compared to the free-space signal.

Definitions

Path Attenuation or Loss

Attenuation or path loss in the LOS channel consists of four components. $L = L_{fsp}L_gL_cL_r$, where

- L_{fsp} is the free space path attenuation
- L_g is the atmospheric path attenuation
- L_c is the fog and cloud path attenuation
- L_r is the rain path attenuation

Each path attenuation is in magnitude units, not in dB.

Free-space Time Delay and Path Loss

When the origin and destination are stationary relative to each other, you can write the output signal of a free-space channel as $Y(t) = x(t-\tau)/L_{fsp}$. The quantity τ is the signal delay and L_{fsp} is the free-space path loss. The delay τ is given by R/c, where R is the propagation distance and c is the propagation speed. The free-space path loss is given by

$$L_{fsp} = \frac{(4\pi R)^2}{\lambda^2},$$

where λ is the signal wavelength.

This formula assumes that the target is in the far field of the transmitting element or array. In the near field, the free-space path loss formula is not valid and can result in a loss smaller than one, equivalent to a signal gain. Therefore, the loss is set to unity for range values, $R \le \lambda/4\pi$.

When the origin and destination have relative motion, the processing also introduces a Doppler frequency shift. The frequency shift is v/λ for one-way propagation and $2v/\lambda$ for two-way propagation. The quantity v is the relative speed of the destination with respect to the origin.

For more details on free-space channel propagation, see [5].

Atmospheric Gas Attenuation Model

This model calculates the attenuation of signals that propagate through atmospheric gases.

Electromagnetic signals attenuate when they propagate through the atmosphere. This effect is due primarily to the absorption resonance lines of oxygen and water vapor, with smaller contributions coming from nitrogen gas. The model also includes

a continuous absorption spectrum below 10 GHz. Phased Array System Toolbox uses the ITU model *Recommendation ITU-R P.676-10: Attenuation by atmospheric gases*. The model computes the specific attenuation (attenuation per kilometer) as a function of temperature, pressure, water vapor density, and signal frequency. The atmospheric gas model is valid for frequencies from 1–1000 GHz and applies to polarized and nonpolarized fields.

The formula for specific attenuation at each frequency is

$$\gamma = \gamma_o(f) + \gamma_w(f) = 0.1820 f N''(f).$$

The quantity $N''()$ is the imaginary part of the complex atmospheric refractivity. It consists of a spectral line component and a continuous component:

$$N''(f) = \sum_i S_i F_i + N''_D(f)$$

The spectral component consists of a sum of discrete spectrum terms composed of a localized frequency bandwidth function, $F(f)_i$, multiplied by a spectral line strength, S_i. For atmospheric oxygen, each spectral line strength is

$$S_i = a_1 \times 10^{-7} \left(\frac{300}{T}\right)^3 \exp\left[a_2 (1 - \left(\frac{300}{T}\right)\right] P.$$

For atmospheric water vapor, each spectral line strength is

$$S_i = b_1 \times 10^{-1} \left(\frac{300}{T}\right)^{3.5} \exp\left[b_2 (1 - \left(\frac{300}{T}\right)\right] W.$$

P is the atmospheric pressure, W is the water vapor density, and T is the ambient temperature.

For each oxygen line, S_i depends on constants a_1 and a_2. Similarly, each water vapor line has constants b_1 and b_2. The ITU documentation cited at the end of this section contains tabulations of these constants.

The localized frequency bandwidth functions $F_i(f)$ are complicated functions of frequency described in the ITU references cited below. The functions depend on empirical model parameters that are also tabulated in the reference.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length, R. Then, the total attenuation is $L_g = R(\gamma_o + \gamma_w)$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

Fog and Cloud Attenuation Model

This model calculates the attenuation of signals that propagate through fog or clouds.

Fog and cloud attenuation are the same atmospheric phenomenon. Phased Array System Toolbox uses the ITU model, *Recommendation ITU-R P.840-6: Attenuation due to clouds and fog*. The model computes the specific attenuation (attenuation per kilometer), of a signal as a function of liquid water density, signal frequency, and temperature. The model applies to polarized and nonpolarized fields. The formula for specific attenuation at each frequency is

$$\gamma_c = K_l(f)M,$$

where M is the liquid water density in gm/m^3. The quantity $K_l(f)$ is the specific attenuation coefficient and depends on frequency. The cloud and fog attenuation model is valid for frequencies 10–1000 GHz. Units for the specific attenuation coefficient are (dB/km)/(g/m^3).

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length R. Total attenuation is $L_c = R\gamma_c$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply narrowband attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

Rainfall Attenuation Model

This model calculates the attenuation of signals that propagate through regions of rainfall.

Electromagnetic signals are attenuate when propagating through a region of rainfall. Rainfall attenuation is computed according to the ITU rainfall model *Recommendation*

ITU-R P.838-3: Specific attenuation model for rain for use in prediction methods. The model computes the specific attenuation (attenuation per kilometer) of a signal as a function of rainfall rate, signal frequency, polarization, and path elevation angle. To compute the attenuation, this model uses

$$\gamma_r = kr^{\alpha},$$

where r is the rain rate in mm/hr. The parameter k and exponent α depend on the frequency, the polarization state, and the elevation angle of the signal path. The specific attenuation model is valid for frequencies from 1–1000 GHz.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by a propagation distance, R. Then, total attenuation is $L_r = R\gamma_r$. Instead of using geometric range as the propagation distance, the toolbox uses a modified range. The modified range is the geometric range multiplied by a range factor

$$\frac{1}{1+\frac{R}{R_0}}$$

where

$$R_0 = 35e^{-0.015r}$$

is the effective path length in kilometers (see Seybold, J. *Introduction to RF Propagation*.) When there is no rain, the effective path length is 35 km. When the rain rate is, for example, 10 mm/hr, the effective path length is 30.1 km. At short range, the propagation distance is approximately the geometric range. For longer ranges, the propagation distance asymptotically approaches the effective path length.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

System Objects

phased.FreeSpace | phased.RadarTarget | phased.BackscatterRadarTarget | phased.TwoRayChannel | phased.WidebandFreeSpace | phased.WidebandLOSChannel

Introduced in R2016a

reset

System object: phased.LOSChannel
Package: phased

Reset states of System object

Syntax

```
reset(sLOS)
```

Description

`reset(sLOS)` resets the internal state of the `phased.LOSChannel` System object, `sLOS`. If `SeedSource` is a property of this System object and has the value `'Property'`, then this method resets the random number generator state.

Input Arguments

`sLOS` — LOS channel

`phased.LOSChannel` System object

LOS channel, specified as a phased.LOSChannel System object.

Example: `phased.LOSChannel`

Introduced in R2016a

step

System object: phased.LOSChannel
Package: phased

Propagate signal in LOS channel

Syntax

```
prop_sig = step(sLOS,sig,origin_pos,dest_pos,origin_vel,dest_vel)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`prop_sig = step(sLOS,sig,origin_pos,dest_pos,origin_vel,dest_vel)` returns the resulting signal, `prop_sig`, when a narrowband signal, `sig`, propagates through a line-of-sight (LOS) channel from a source located at the `origin_pos` position to a destination at the `dest_pos` position. Only one of the `origin_pos` or `dest_pos` arguments can specify multiple positions. The other must contain a single position. The velocity of the signal origin is specified in `origin_vel` and the velocity of the signal destination is specified in `dest_vel`. The dimensions of `origin_vel` and `dest_vel` must match the dimensions of `origin_pos` and `dest_pos`, respectively.

Electromagnetic fields propagating through an LOS channel can be polarized or nonpolarized. For nonpolarized fields, the propagating signal field, `sig`, is a vector or matrix. For polarized fields, `sig` is an array of structures. The structure elements represent an electric field vector in Cartesian form.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications,

such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`sLOS` — LOS channel

`phased.LOSChannel` System object

LOS channel, specified as a phased.LOSChannel System object.

Example: `phased.LOSChannel`

`sig` — Narrowband signal

M-by-*N* complex-valued matrix | 1-by-*N* `struct` array containing complex-valued fields

Narrowband signal, specified as a matrix or `struct` array, depending on whether is signal or polarized or nonpolarized. The quantity *M* is the number of samples in the signal, and *N* is the number of LOS channels. Each channel corresponds to a source-destination pair.

- Narrowband nonpolarized scalar signal. Specify `sig` as an *M*-by-*N* complex-valued matrix. Each column contains one signal propagated along the line-of-sight path.

  The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

- Narrowband polarized signal. Specify `sig` as a 1-by-*N* `struct` array containing complex-valued fields. Each `struct` represents a polarized signal propagated along the line-of-sight path. Each `struct` element contains three *M*-by-1 complex-valued column vectors, `sig.X`, `sig.Y`, and `sig.Z`. These vectors represent the *x*, *y*, and *z* Cartesian components of the polarized signal.

  The size of the first dimension of the matrix fields within the `struct` can vary to simulate a changing signal length such as a pulse waveform with variable pulse repetition frequency.

Example: `[1,1;j,1;0.5,0]`

Data Types: `double`

Complex Number Support: Yes

`origin_pos` — Signal origins

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Origin of signals, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. The quantity *N* is the number of LOS channels. If `origin_pos` is a column vector, it takes the form `[x;y;z]`. If `origin_pos` is a matrix, each column specifies a different signal origin and has the form `[x;y;z]`. Units are in meters.

You cannot specify both `origin_pos` and `dest_pos` as matrices. At least one must be a 3-by-1 column vector.

Example: `[1000;100;500]`

Data Types: `double`

`dest_pos` — Signal destinations

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Destination position of the signal or signals, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. The quantity *N* is the number of LOS channels propagating from or to *N* signal origins. If `dest_pos` is a 3-by-1 column vector, it takes the form `[x;y;z]`. If `dest_pos` is a matrix, each column specifies a different signal destination and takes the form `[x;y;z]` Position units are in meters.

You cannot specify both `origin_pos` and `dest_pos` as matrices. At least one must be a 3-by-1 column vector.

Example: `[0;0;0]`

Data Types: `double`

`origin_vel` — Velocities of signal origins

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Velocity of signal origin, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. The dimensions of `origin_vel` must match the dimensions of `origin_pos`. If `origin_vel` is a column vector, it takes the form `[Vx;Vy;Vz]`. If `origin_vel` is a 3-by-*N* matrix, each column specifies a different origin velocity and has the form `[Vx;Vy;Vz]`. Velocity units are in meters per second.

Example: `[10;0;5]`

Data Types: `double`

`dest_vel` — Velocities of signal destinations

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Velocity of signal destinations, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. The dimensions of `dest_vel` must match the dimensions of `dest_pos`. If `dest_vel` is a column vector, it takes the form `[Vx;Vy;Vz]`. If `dest_vel` is a 3-by-*N* matrix, each column specifies a different destination velocity and has the form `[Vx;Vy;Vz]` Velocity units are in meters per second.

Example: `[0;0;0]`

Data Types: `double`

Output Arguments

`prop_sig` — Narrowband propagated signal

M-by-*N* complex-valued matrix | 1-by-*N* `struct` array containing complex-valued fields

Narrowband signal, returned as a matrix or `struct` array, depending on whether signal is polarized or nonpolarized. The quantity *M* is the number of samples in the signal and *N* is the number of narrowband LOS channels. Each channel corresponds to a source-destination pair.

- Narrowband nonpolarized scalar signal. `prop_sig` is an *M*-by-*N* complex-valued matrix.
- Narrowband polarized scalar signal. `prop_sig` is a 1-by-*N* `struct` array containing complex-valued fields. Each `struct` element contains three *M*-by-1 complex-valued column vectors, `sig.X`, `sig.Y`, and `sig.Z`. These vectors represent the *x*, *y*, and *z* Cartesian components of the polarized signal.

The `prop_sig` output contains signal samples arriving at the signal destination within the current time frame. The current time frame is the time frame of the input signals to `step`. Whenever it takes longer than the current time frame for the signal to propagate from the origin to the destination, the output might not contain all contributions from the input of the current time frame. The remaining output appears in the next call to `step`.

Examples

Propagate Signal in LOS Channel

Propagate a sinusoidal signal in a line of sight (LOS) channel from a radar at *(1000,0,0)* meters to a target at *(10000,4000,500)* meters in medium fog specified by the liquid water density of 0.05 g/m^3. Assume that the radar and the target are stationary. The signal carrier frequency is 10 GHz. The signal frequency is 500 Hz and the sample rate is 8.0 kHz.

Set up the transmitted signal.

```
fs = 8.0e3;
dt = 1/fs;
fsig = 500.0;
fc = 10.0e9;
t = [0:dt:.01];
sig = sin(2*pi*fsig*t);
```

Set the liquid water density and specify the LOS channel System object™.

```
lwd = 0.05;
sLOS = phased.LOSChannel('SampleRate',fs,'SpecifyAtmosphere',true,...
    'LiquidWaterDensity',lwd,'OperatingFrequency',fc);
```

Set the origin and destination of the signal.

```
xradar = [1000,0,0].';
vradar = [0,0,0].';
xtgt = [10000,4000,500].';
vtgt = [0,0,0].';
```

Propagate the signal from origin to destination and plot the result.

```
prog_sig = step(sLOS,sig.',xradar,xtgt,vradar,vtgt);
plot(t*1000,real(prog_sig))
grid
xlabel('Time (milliseconds)')
ylabel('Amplitude')
```

Introduced in R2016a

phased.MatchedFilter System object

Package: phased

Matched filter

Description

The `MatchedFilter` object implements matched filtering of an input signal.

To compute the matched filtered signal:

1. Define and set up your matched filter. See "Construction" on page 1-1151.
2. Call step to perform the matched filtering according to the properties of `phased.MatchedFilter`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.MatchedFilter` creates a matched filter System object, `H`. The object performs matched filtering on the input data.

`H = phased.MatchedFilter(Name,Value)` creates a matched filter object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`CoefficientsSource`

Source of matched filter coefficients

Specify whether the matched filter coefficients come from the `Coefficients` property of this object or from an input argument in step. Values of this property are:

`'Property'`	The `Coefficients` property of this object specifies the coefficients.
`'Input port'`	An input argument in each invocation of `step` specifies the coefficients.

Default: `'Property'`

`Coefficients`

Matched filter coefficients

Specify the matched filter coefficients as a column vector. This property applies when you set the `CoefficientsSource` property to `'Property'`. This property is tunable.

Default: `[1;1]`

`SpectrumWindow`

Window for spectrum weighting

Specify the window used for spectrum weighting using one of `'None'`, `'Hamming'`, `'Chebyshev'`, `'Hann'`, `'Kaiser'`, `'Taylor'`, or `'Custom'`. Spectrum weighting is often used with linear FM waveform to reduce the sidelobes in the time domain. The object computes the window length internally, to match the FFT length.

Default: `'None'`

`CustomSpectrumWindow`

User-defined window for spectrum weighting

Specify the user-defined window for spectrum weighting using a function handle or a cell array. This property applies when you set the `SpectrumWindow` property to `'Custom'`.

If `CustomSpectrumWindow` is a function handle, the specified function takes the window length as the input and generates appropriate window coefficients.

If `CustomSpectrumWindow` is a cell array, then the first cell must be a function handle. The specified function takes the window length as the first input argument, with other

additional input arguments if necessary, and generates appropriate window coefficients. The remaining entries in the cell array are the additional input arguments to the function, if any.

Default: `@hamming`

`SpectrumRange`

Spectrum window coverage region

Specify the spectrum region on which the spectrum window is applied as a 1-by-2 vector in the form of `[StartFrequency EndFrequency]` (in hertz). This property applies when you set the `SpectrumWindow` property to a value other than `'None'`.

Note that both `StartFrequency` and `EndFrequency` are measured in baseband. That is, they are within `[-Fs/2 Fs/2]`, where `Fs` is the sample rate that you specify in the `SampleRate` property. `StartFrequency` cannot be larger than `EndFrequency`.

Default: `[0 1e5]`

`SampleRate`

Coefficient sample rate

Specify the matched filter coefficients sample rate (in hertz) as a positive scalar. This property applies when you set the `SpectrumWindow` property to a value other than `'None'`.

Default: `1e6`

`SidelobeAttenuation`

Window sidelobe attenuation level

Specify the sidelobe attenuation level (in decibels) of a Chebyshev or Taylor window as a positive scalar. This property applies when you set the `SpectrumWindow` property to `'Chebyshev'` or `'Taylor'`.

Default: `30`

`Beta`

Kaiser window parameter

Specify the parameter that affects the Kaiser window sidelobe attenuation as a nonnegative scalar. Please refer to `kaiser` for more details. This property applies when you set the `SpectrumWindow` property to `'Kaiser'`.

Default: `0.5`

`Nbar`

Number of nearly constant sidelobes in Taylor window

Specify the number of nearly constant level sidelobes adjacent to the mainlobe in a Taylor window as a positive integer. This property applies when you set the `SpectrumWindow` property to `'Taylor'`.

Default: `4`

`GainOutputPort`

Output gain

To obtain the matched filter gain, set this property to `true` and use the corresponding output argument when invoking step. If you do not want to obtain the matched filter gain, set this property to `false`.

Default: `false`

Methods

step	Perform matched filtering

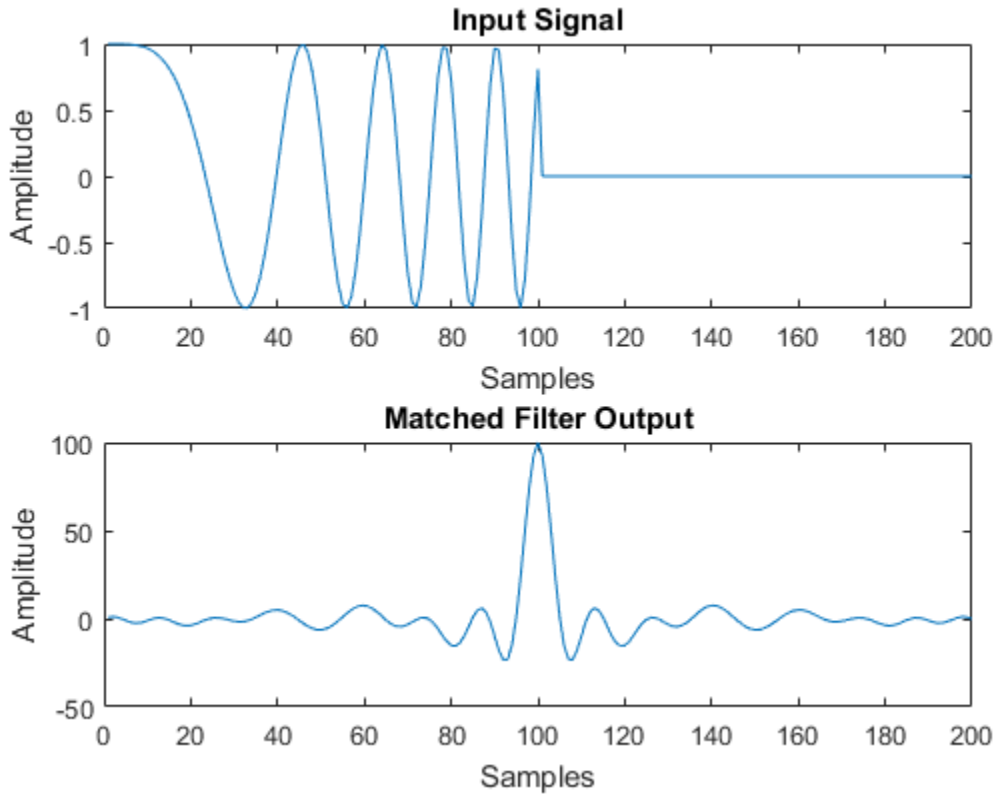
Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Matched Filter for Linear FM Waveform

Construct a matched filter for a linear FM waveform.

```
waveform = phased.LinearFMWaveform('PulseWidth',1e-4,'PRF',5e3);
x = waveform();
filter = phased.MatchedFilter( ...
    'Coefficients',getMatchedFilter(waveform));
y = filter(x);
subplot(2,1,1),plot(real(x))
xlabel('Samples')
ylabel('Amplitude')
title('Input Signal')
subplot(2,1,2),plot(real(y))
xlabel('Samples')
ylabel('Amplitude')
title('Matched Filter Output')
```

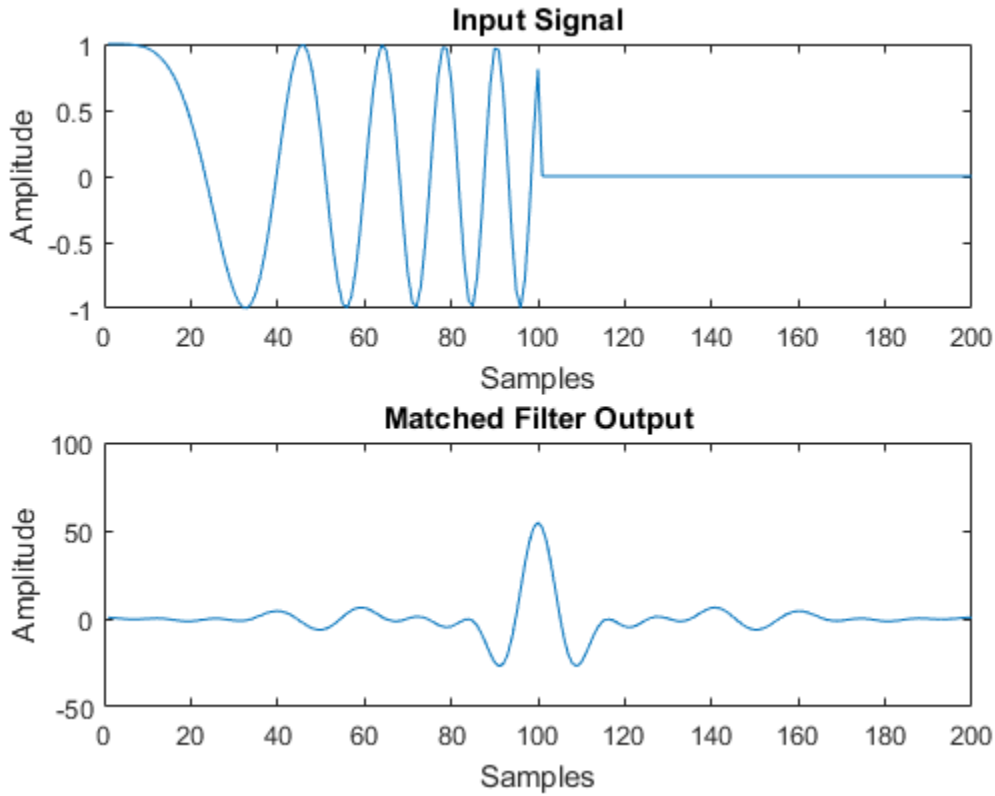


Matched Filter Using Hamming Window

Apply a matched filter, using a Hamming window to do spectrum weighting.

```
waveform = phased.LinearFMWaveform('PulseWidth',1e-4,'PRF',5e3);
x = waveform();
filter = phased.MatchedFilter( ...
    'Coefficients',getMatchedFilter(waveform), ...
 'SpectrumWindow','Hamming');
y = filter(x);
subplot(2,1,1)
plot(real(x))
xlabel('Samples')
ylabel('Amplitude')
```

```
title('Input Signal')
subplot(2,1,2)
plot(real(y))
xlabel('Samples')
ylabel('Amplitude')
title('Matched Filter Output')
```

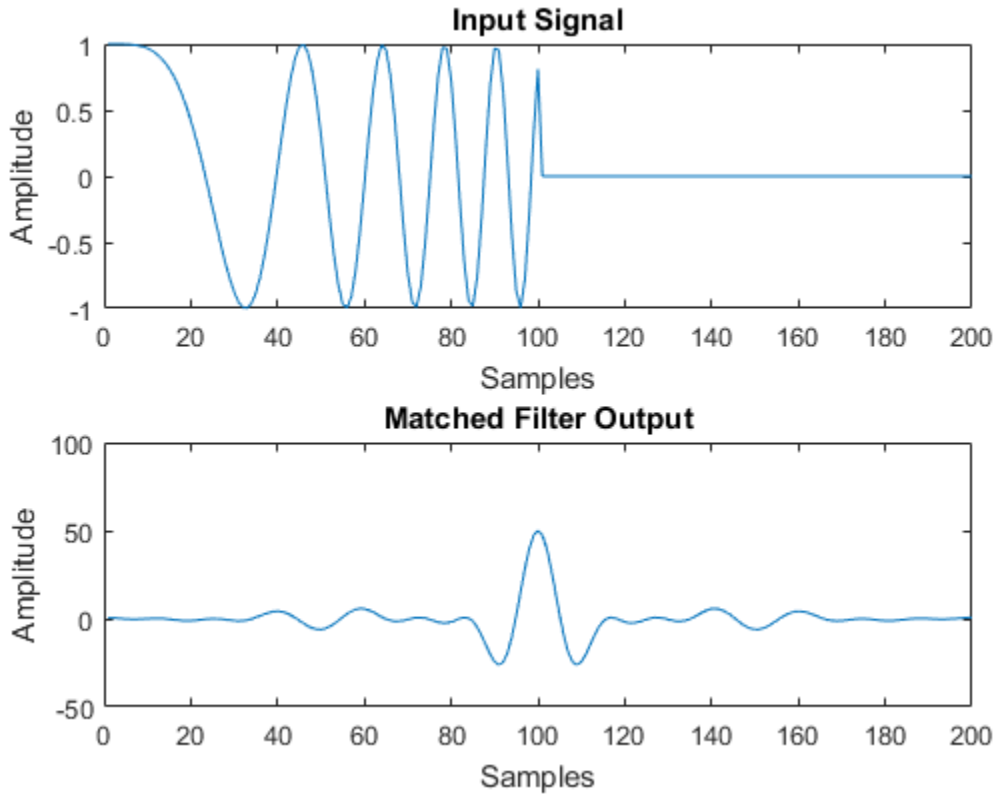


Matched Filter with Custom Window

Apply a matched filter, using a custom Gaussian window for spectrum weighting.

```
waveform = phased.LinearFMWaveform('PulseWidth',1e-4,'PRF',5e3);
x = waveform();
filter = phased.MatchedFilter( ...
    'Coefficients',getMatchedFilter(waveform), ...
```

```
 'SpectrumWindow','Custom', ...
 'CustomSpectrumWindow',{@gausswin,2.5});
y = filter(x);
subplot(2,1,1)
plot(real(x))
xlabel('Samples')
ylabel('Amplitude')
title('Input Signal')
subplot(2,1,2)
plot(real(y))
xlabel('Samples')
ylabel('Amplitude')
title('Matched Filter Output')
```



Algorithms

The filtering operation uses the overlap-add method.

Spectrum weighting produces a transfer function

$$H'(F) = w(F)H(F)$$

where $w(F)$ is the window and $H(F)$ is the original transfer function.

For further details on matched filter theory, see [1]or [2].

Introduced in R2012a

step

System object: phased.MatchedFilter
Package: phased

Perform matched filtering

Syntax

```
Y = step(H,X)
Y = step(H,X,COEFF)
[Y,GAIN] = step( ___ )
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` applies the matched filtering to the input `X` and returns the filtered result in `Y`. The filter is applied along the first dimension. `Y` and `X` have the same dimensions. The initial transient is removed from the filtered result.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

`Y = step(H,X,COEFF)` uses the input `COEFF` as the matched filter coefficients. This syntax is available when you set the `CoefficientsSource` property to `'Input port'`.

`[Y,GAIN] = step( ___ )` returns additional output `GAIN` as the gain (in decibels) of the matched filter. This syntax is available when you set the `GainOutputPort` property to `true`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications,

such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Examples

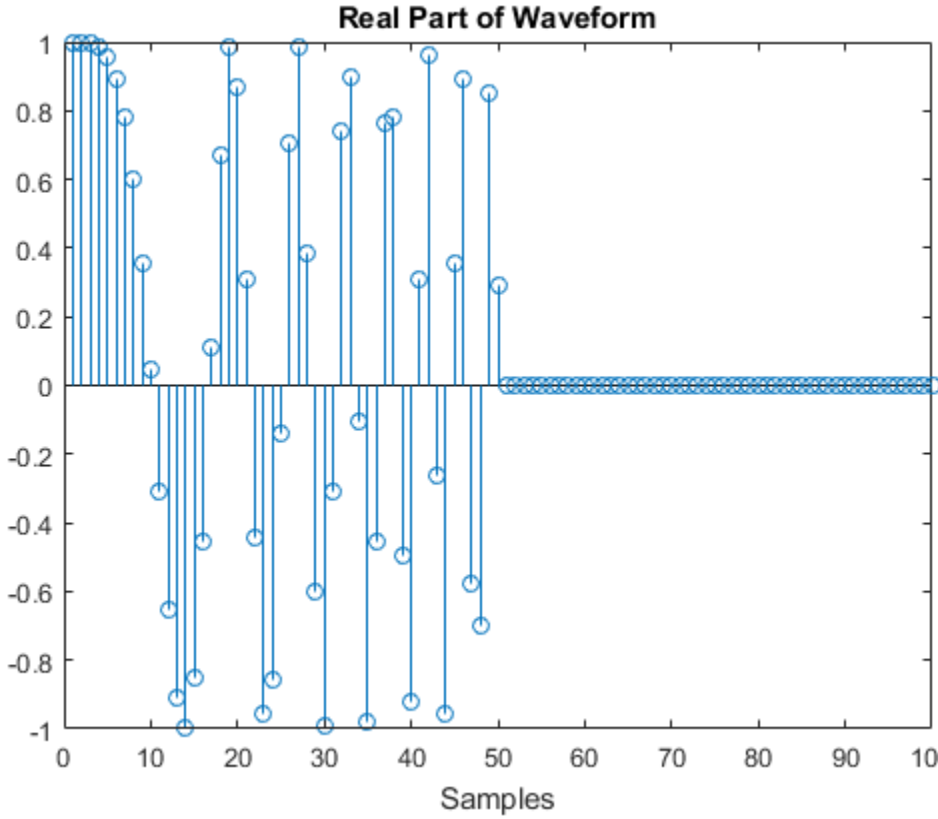
Match Filter Linear FM Waveform

Construct a linear FM waveform with a sweep bandwidth of 300 kHz and a pulse width of 50 µs. Obtain the matched filter coefficients using the `getMatchedFilter` method. Then, use the `step` to match-filter the waveform.

```
waveform = phased.LinearFMWaveform('SweepBandwidth',3e5,...
    'OutputFormat','Pulses','SampleRate',1e6,...
    'PulseWidth',50e-6,'PRF',1e4);
wav = waveform();
```

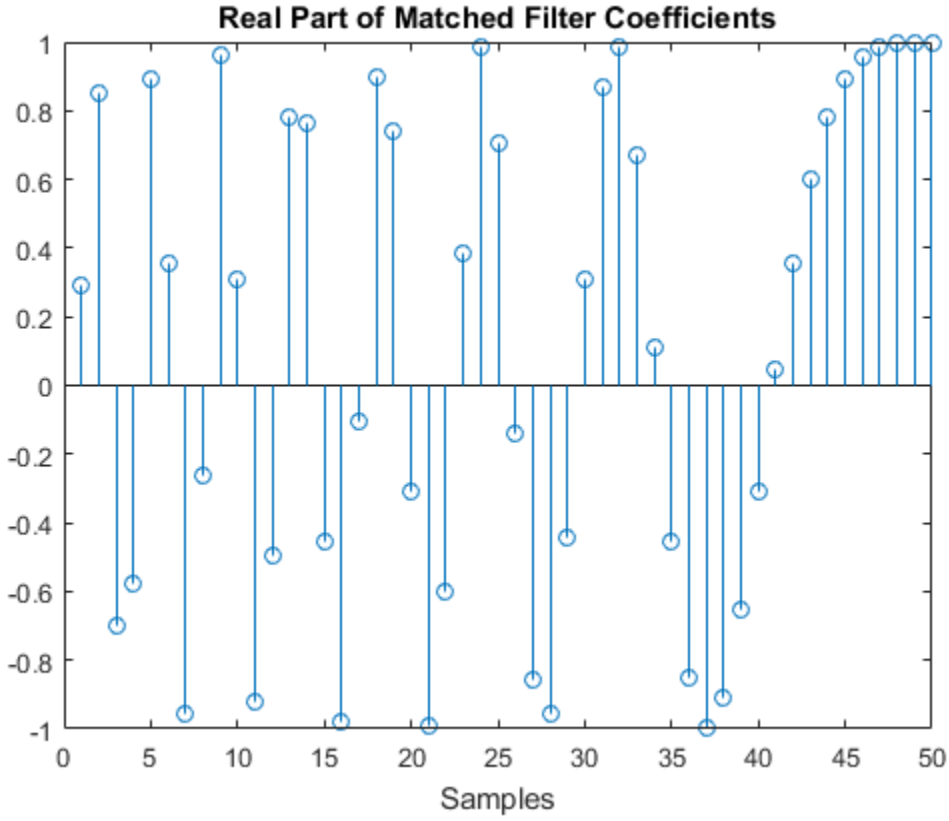
Plot the entire waveform. The length of the waveform is the pulse repetition interval (100 samples).

```
stem(real(wav))
xlabel('Samples')
title('Real Part of Waveform')
```



Obtain the matched filter coefficients for the linear FM waveform. The length of the matched filter coefficiens is the length of the pulse.

```
mfcoeffs = getMatchedFilter(waveform);
stem(real(mfcoeffs))
xlabel('Samples')
title('Real Part of Matched Filter Coefficients')
```



Use `phased.MatchedFilter` `step` method to obtain the matched filter output.

```
filter = phased.MatchedFilter('Coefficients',mfcoeffs);
mfoutput = filter(wav);
stem(real(mfoutput))
xlabel('Samples')
title('Real Part of Matched Filter Output')

phased.MFSKWaveform System object

Package: phased

MFSK waveform

Description

The multiple frequency shift keying (MFSK) waveform is used in automotive radar to improve simultaneous range and Doppler estimation of multiple targets. The `MFSKWaveform` System object creates the baseband representation of an MFSK waveform. An MFSK waveform consists of two interleaved sequences of increasing frequencies, as described in "Algorithms" on page 1-1170.

To obtain waveform samples:

1. Define and set up the MFSK waveform. See "Construction" on page 1-1166.
2. Call step to generate the MFSK waveform samples according to the properties of `phased.MFSKWaveform`. The behavior of `step` is specific to each object in the toolbox. The output of the step method is controlled by the `OutputFormat` property, which has no effect on the properties of the waveform.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations. When the only argument to the `step` method is the System object itself, replace `y = step(obj)` by `y = obj()`.

Construction

`sMFSK = phased.MFSKWaveform` creates an MFSK waveform System object, `sMFSK`.

`sMFSK = phased.MFSKWaveform(Name,Value)` creates an MFSK waveform object, `sMFSK`, with additional properties specified by one or more `Name-Value pair` arguments. `Name` must appear inside single quotes (`' '`). You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

Properties

`SampleRate` — Sample rate

1e6 (default) | positive scalar

Sample rate of the signal, specified as a positive scalar. Units are hertz.

Example: 96e6

Data Types: `double`

`SweepBandwidth` — MFSK sweep bandwidth

1e5 (default) | positive scalar

MFSK sweep bandwidth, specified as a positive scalar. Units are in hertz. The sweep bandwidth is the difference between the highest and lowest frequencies of either sequence.

Example: 9e7

Data Types: `double`

`StepTime` — Duration of frequency step

1e-4 (default) | positive scalar

Time duration of each frequency step, specified as a positive scalar in seconds.

Example: 0.2e-3

Data Types: `double`

`StepsPerSweep` — Total number of frequency steps

64 (default) | even positive integer

Total number of frequency steps in a sweep, specified as an even positive integer.

Example: 16

Data Types: `double`

`FrequencyOffset` — Chirp offset frequency

1000 (default) | real scalar

Chirp offset frequency, specified as a real scalar. Units are in hertz. The offset determines the frequency translation between the two sequences.

Example: 500

Data Types: `double`

`OutputFormat` — Output signal grouping

`'Steps'` (default) | `'Sweeps'` | `'Samples'`

Output signal grouping, specified as one of `'Steps'`, `'Sweeps'`, or `'Samples'`. This property has no effect on the waveform but determines the output form of the `step` method.

- `'Steps'` — The output consists of all samples contained in an integer number of frequency steps, `NumSteps`.
- `'Samples'` — The output consists of an integer number of samples, `NumSamples`.
- `'Sweeps'` — The output consists of all samples contained in an integer number of sweeps, `NumSweeps`.

Example: `'Samples'`

Data Types: `char`

`NumSamples` — Number of samples in output

1 (default) | positive integer

Number of samples in output, specified as a positive integer. This property applies only when you set `OutputFormat` to `'Samples'`.

Example: 200

Data Types: `double`

`NumSteps` — Number of frequency steps in output

1 (default) | positive integer

Number of frequency steps in output, specified as a positive integer. This property applies only when you set `OutputFormat` to `'Steps'`.

Example: 10

Data Types: `double`

`NumSweeps` — Number of sweeps in output

1 (default) | positive integer

Number of sweeps in output, specified as a positive integer. This property applies only when you set `OutputFormat` to `'Sweeps'`.

Example: 5

Data Types: `double`

Methods

plot	Plot continuous MFSK waveform
reset	Reset states of the MFSK waveform object
step	Samples of continuous MFSK waveform

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Plot MFSK Waveform

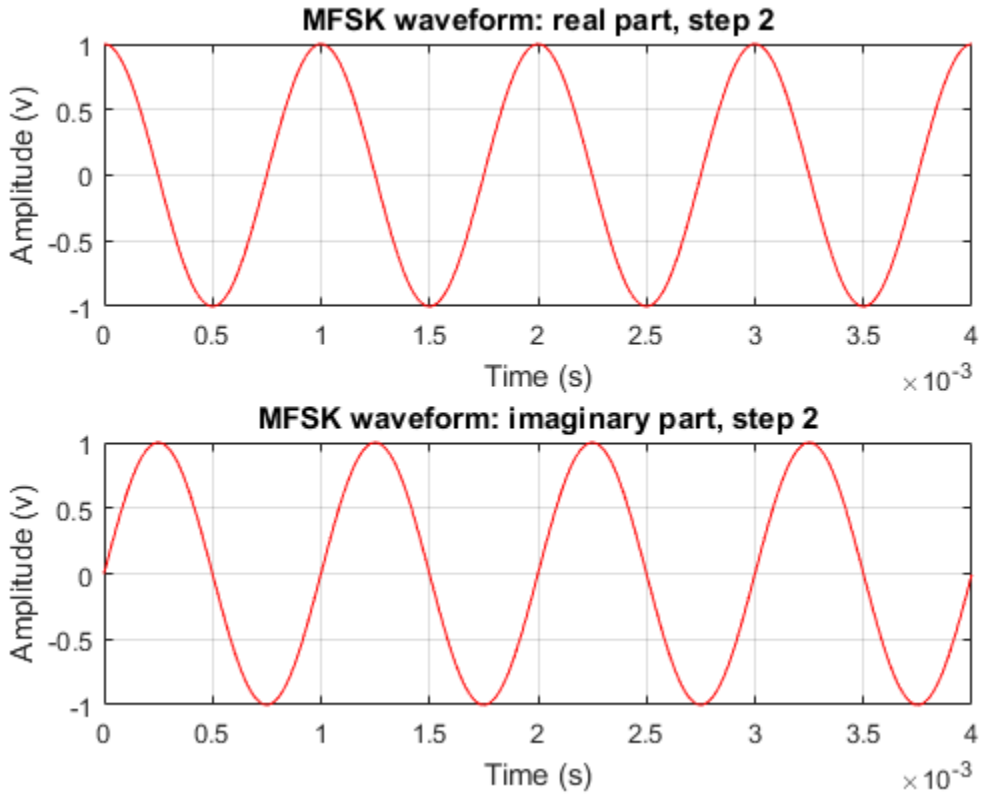
Construct an MFSK waveform with a sample rate of 1 MHz and a sweep bandwidth of 0.1 MHz. Assume 52 steps with a step time of 4 milliseconds. Set the frequency offset to 1 kHz. There are 4000 samples per step.

```
fs = 1e6;
fsweep = 1e5;
tstep = 4e-3;
numsteps = 52;
foffset = 1000;
noutputsteps = 4;
sMFSK = phased.MFSKWaveform('SampleRate',fs,...
    'SweepBandwidth',fsweep,...
    'StepTime',tstep,...
    'StepsPerSweep',numsteps,...
    'FrequencyOffset',foffset,...
    'OutputFormat','Steps',...
```

```
    'NumSteps',noutputsteps);
```

Plot the real and imaginary components of the second step of the waveform using the `plot` method. Set the plot color to red.

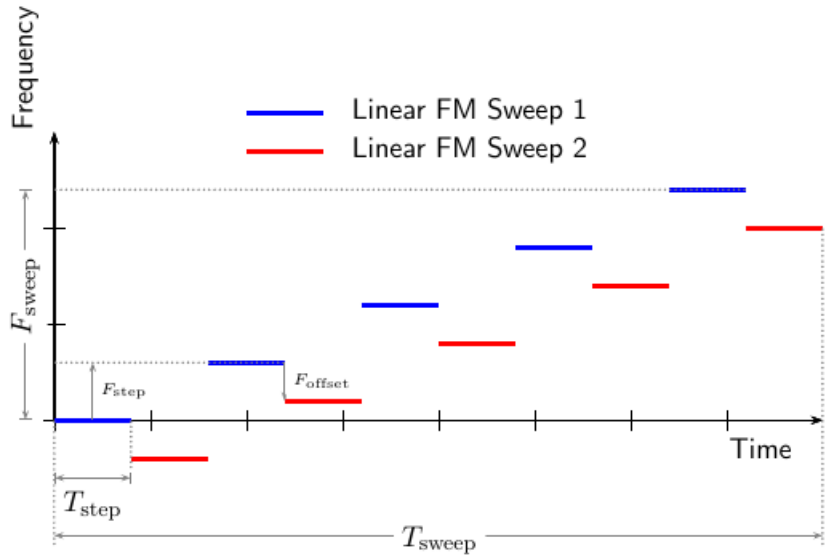
```
plot(sMFSK,'PlotType','complex','StepIdx',2,'r')
```



- "Simultaneous Range and Speed Estimation Using MFSK Waveform"

Algorithms

An MFSK waveform consists of two interleaved stepped-frequency sequences, as shown in this time-frequency diagram.



Each sequence is a set of continuous waveform (CW) signals increasing in frequency. The offset, F_{offset}, between the two sequences is constant and can be positive or negative. A complete waveform consists of an even number of steps, N, of equal duration, T_{step}. Then, each sequence consists of $N/2$ steps. The sweep frequency, F_{sweep}, is the difference between the lowest and highest frequency of either sequence. F_{sweep} is always positive, indicating increasing frequency. The frequency difference between successive steps of each sequence is given by
$F_{step} = F_{sweep}/(N/2–1)$.
The lowest frequency of the first sequence is always 0 hertz and corresponds to the carrier frequency of the bandpass signal. The lowest frequency of the second sequence can be positive or negative and is equal to F_{offset}. Negative frequencies correspond to bandpass frequencies that are lower than the carrier frequency. The duration of the waveform is given by $T_{sweep} = N * T_{step}$. The System object properties corresponding to the signal parameters are

Signal Parameter	Property
F_{sweep}	`'SweepBandwidth'`

Signal Parameter	Property
T_{step}	`'StepTime'`
N	`'StepsPerSweep'`
F_{offset}	`'FrequencyOffset'`

plot

System object: phased.MFSKWaveform
Package: phased

Plot continuous MFSK waveform

Syntax

```
plot(sMFSK)
plot(sMFSK,Name,Value)
plot(sMFSK,Name,Value,LineSpec)
h = plot( ___ )
```

Description

`plot(sMFSK)` plots the real part of the waveform specified by `sMFSK`.

`plot(sMFSK,Name,Value)` plots the waveform with additional options specified by one or more `Name,Value` pair arguments.

`plot(sMFSK,Name,Value,LineSpec)` specifies the same line color, line style, or marker options that are available in the MATLAB `plot` function.

`h = plot( ___ )` returns the line handle in the figure.

Input Arguments

`sMFSK` — MFSK waveform

MFSK waveform System object

MFSK waveform, specified as a phased.MFSKWaveform System object.

Example: `sMFSK = phased.MFSKWaveform;`

`LineSpec` — Plot style

`'b'` (default) | character vector

Plot style, specified as a character vector. You can specify the same line color, style, or marker options that are available in the MATLAB `plot` function. If you specify a `PlotType` value of `'complex'`, then `LineSpec` applies to both the real and imaginary subplots.

Example: `'k.'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'PlotType'` — Waveform component to plot

`'real'` (default) | `'imag'` | `'complex'`

Waveform component to plot, specified as the comma-separated pair consisting of `'PlotType'` and one of the following:

- `'real'` — Plots the real part of the waveform
- `'imag'` — Plots the imaginary part of the waveform
- `'complex'` — Plots both parts of the waveform

Example: `'PlotType','complex'`

`'StepIdx'` — Index of step

1 (default) | positive integer

Index of the step to plot, specified as the comma-separated pair consisting of `'StepIdx'` and a positive integer. If you specify a `'StepIdx'` value greater than `'StepsPerSweep'`, the frequency corresponds to the `mod('StepIdx','StepsPerSweep') value`.

Output Arguments

`h` — Plot handle

double

Plot handle(s) to the line or lines in the figure, returned as a double. When `PlotType` is set to `'complex'`, `h` is a 2-by-1 column vector. The first and second elements of this vector are the handles to the lines in the real and imaginary subplots, respectively.

Examples

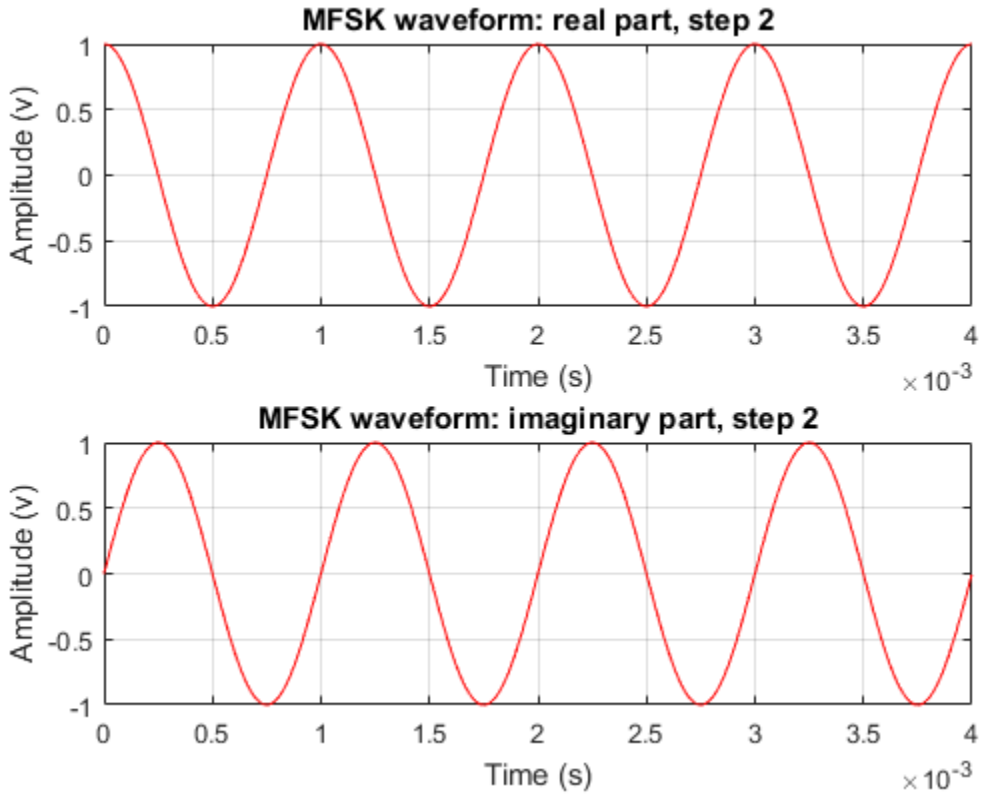
Plot MFSK Waveform

Construct an MFSK waveform with a sample rate of 1 MHz and a sweep bandwidth of 0.1 MHz. Assume 52 steps with a step time of 4 milliseconds. Set the frequency offset to 1 kHz. There are 4000 samples per step.

```
fs = 1e6;
fsweep = 1e5;
tstep = 4e-3;
numsteps = 52;
foffset = 1000;
noutputsteps = 4;
sMFSK = phased.MFSKWaveform('SampleRate',fs,...
    'SweepBandwidth',fsweep,...
    'StepTime',tstep,...
    'StepsPerSweep',numsteps,...
    'FrequencyOffset',foffset,...
    'OutputFormat','Steps',...
    'NumSteps',noutputsteps);
```

Plot the real and imaginary components of the second step of the waveform using the `plot` method. Set the plot color to red.

```
plot(sMFSK,'PlotType','complex','StepIdx',2,'r')
```



Introduced in R2015a

reset

System object: phased.MFSKWaveform
Package: phased

Reset states of the MFSK waveform object

Syntax

```
reset(sMFSK)
```

Description

`reset(sMFSK)` resets the internal states of the `phased.MFSKWaveform` object, `sMFSK`, to their initial values.

Input Arguments

sMFSK — MFSK waveform

System object

MFSK waveform, specified as a phased.MFSKWaveform System object.

Example: `sMFSK= phased.MFSKWaveform;`

Introduced in R2015a

step

System object: phased.MFSKWaveform
Package: phased

Samples of continuous MFSK waveform

Syntax

```
Y = step(sMFSK)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations. When the only argument to the `step` method is the System object itself, replace `y = step(obj)` by `y = obj()`.

`Y = step(sMFSK)` returns samples of the MFSK waveform in a *N*-by-1 complex valued column vector, `Y`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`sMFSK` — MFSK waveform

System object

MFSK waveform, specified as a phased.MFSKWaveform System object.

Example: `sMFSK= phased.MFSKWaveform;`

Output Arguments

Y — Output samples

N-by-1 complex valued vector

Output samples of MFSK waveform, returned as an *N*-by-1 complex valued vector. When the `step` method reaches the end of the waveform, the output samples wrap around from the start of the waveform, yielding a periodic waveform.

Examples

Construct MFSK Step Output

Construct an MFSK waveform with a sample rate of 1 MHz and a sweep bandwidth of 0.1 MHz. Assume 52 steps, with a step time of 4 milliseconds. Set the frequency offset to 1 kHz. There are 4000 samples per step.

```
fs = 1e6;
fsweep = 1e5;
tstep = 40e-4;
numsteps = 52;
foffset = 1000;
noutputsteps = 4;
sMFSK = phased.MFSKWaveform('SampleRate',fs,...
    'SweepBandwidth',fsweep,...
    'StepTime',tstep,...
    'StepsPerSweep',numsteps,...
    'FrequencyOffset',foffset,...
    'OutputFormat','Steps',...
    'NumSteps',noutputsteps);
```

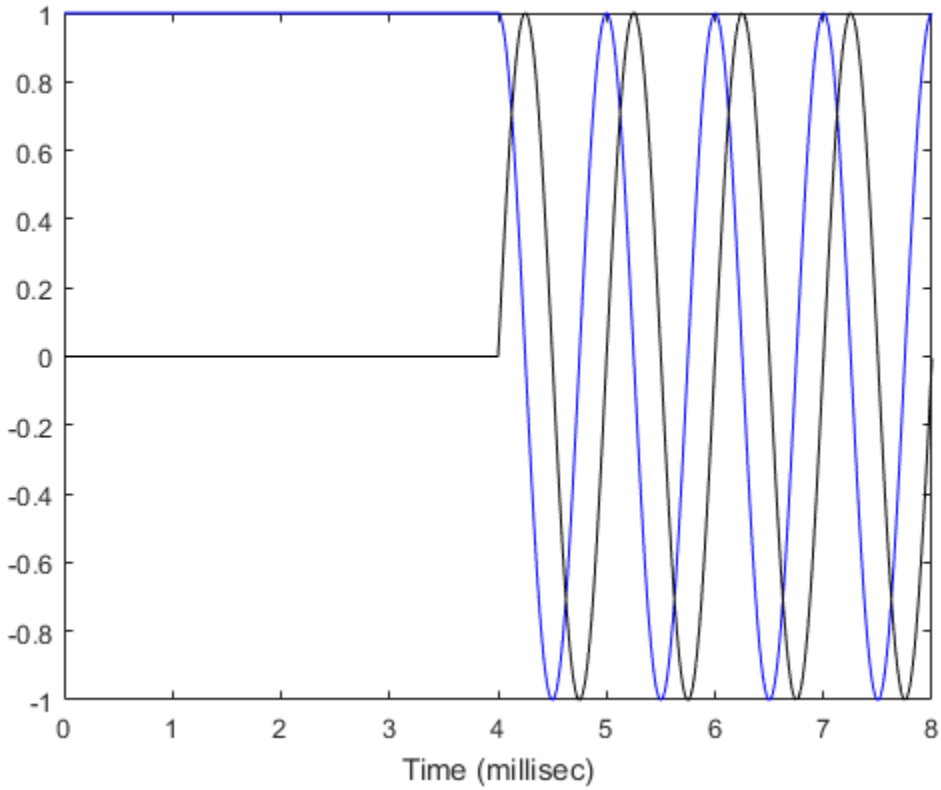
Call the step method to retrieve the samples for the four steps.

```
z = step(sMFSK);
```

Plot the real and imaginary parts of the first two steps.

```
samplesperstep = fs*tstep;
disp(samplesperstep)
idx = [1:2*samplesperstep]';
time = idx/fs*1000;
plot(time,real(z(idx)),'b',time,imag(z(idx)),'k');
xlabel('Time (millisec)')
```

```
        4000
```



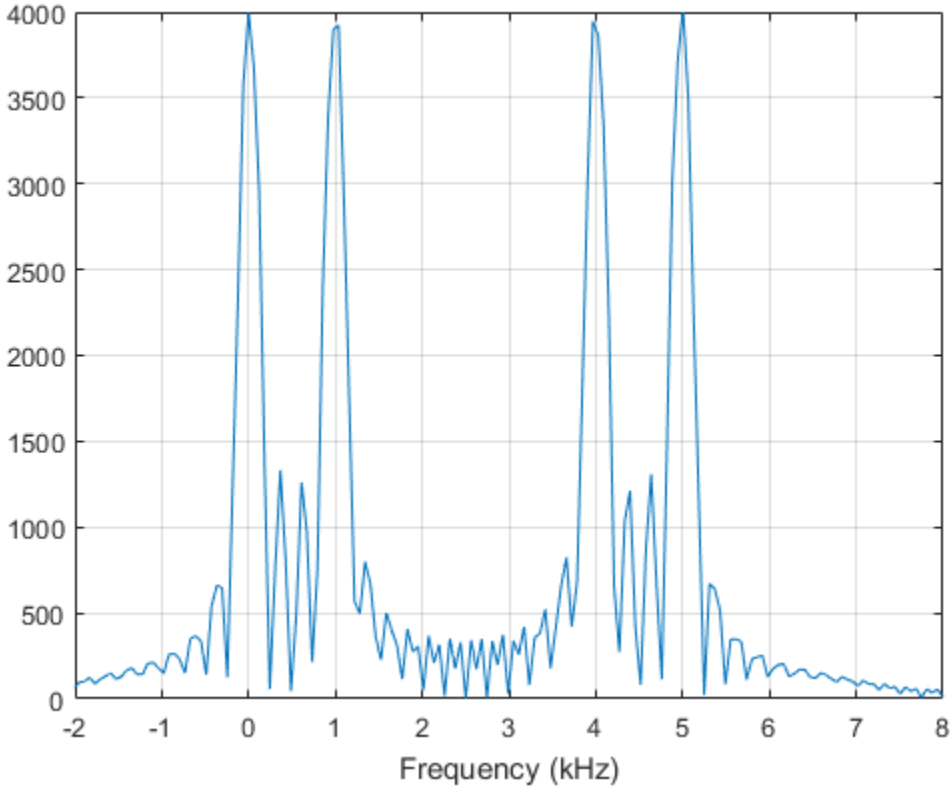
Compute the FFT of all the data.

```
n = size(z,1);
nfft = 2^ceil(log2(n));
```

```
Y = fftshift(fft(z,nfft));
```

Plot the magnitudes of the spectrum.

```
fmax = fs/2;
ft = [-nfft/2:nfft/2-1]*fmax/(nfft/2);
figure(2);
hp = plot(ft/1000,abs(Y));
axis([-2,8,-1,4000]);
xlabel('Frequency (kHz)')
grid
```



The plot shows two pairs of peaks. The first pair lies at 0 Hz and 1000 Hz. The second pair lies at 4000 Hz and 5000 Hz. The frequency offset is 1000 Hz.

Compute the frequency increase to the second pair off peaks.

```
fdelta = fsweep/(numsteps/2-1);
disp(fdelta)
```

```
        4000
```

The increase agrees with the location of the second pair of peaks in the FFT spectrum.

MFSK Samples per Sweep

Construct an MFSK waveform with a sample rate of 1 MHz and a sweep bandwidth of 0.1 MHz. Assume 52 steps with a step time of 400 microseconds. Set the frequency offset to 1 kHz. Find the number of samples returned when the `OutputFormat` property is set to return the samples for one sweep.

```
fs = 1e6;
fsweep = 1e5;
tstep = 40e-4;
numsteps = 52;
foffset = 1000;
noutputsweeps = 1;
sMFSK = phased.MFSKWaveform('SampleRate',fs,...
    'SweepBandwidth',fsweep,...
    'StepTime',tstep,...
    'StepsPerSweep',numsteps,...
    'FrequencyOffset',foffset,...
    'OutputFormat','Sweeps',...
    'NumSweeps',noutputsweeps);
```

Call the `step` method to retrieve the samples for the four steps.

```
z = step(sMFSK);
```

Count the number of samples in a sweep.

```
samplespersweep = fs*tstep*numsteps;
disp(samplespersweep)
```

```
      208000
```

Verify that this value agrees with the number of samples returned by the `step` method.

```
disp(size(z))
```

208000 1

Introduced in R2015a

phased.MVDRBeamformer System object

Package: phased

Narrowband MVDR (Capon) beamformer

Description

The `MVDRBeamformer` object implements a minimum variance distortionless response beamformer. This is also referred to as a Capon beamformer.

To compute the beamformed signal:

1. Define and set up your MVDR beamformer. See "Construction" on page 1-1185.
2. Call step to perform the beamforming operation according to the properties of `phased.MVDRBeamformer`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.MVDRBeamformer` creates a minimum variance distortionless response (MVDR) beamformer System object, `H`. The object performs MVDR beamforming on the received signal.

`H = phased.MVDRBeamformer(Name,Value)` creates an MVDR beamformer object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`SensorArray`

Sensor array

Sensor array specified as an array System object belonging to the `phased` package. A sensor array can contain subarrays.

Default: phased.ULA with default property values

`PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

Default: Speed of light

`OperatingFrequency`

System operating frequency

Specify the operating frequency of the beamformer in hertz as a positive scalar. The default value corresponds to 300 MHz.

Default: `3e8`

`DiagonalLoadingFactor`

Diagonal loading factor

Specify the diagonal loading factor as a positive scalar. Diagonal loading is a technique used to achieve robust beamforming performance, especially when the sample support is small. This property is tunable.

Default: `0`

`TrainingInputPort`

Add input to specify training data

To specify additional training data, set this property to `true` and use the corresponding input argument when you invoke step. To use the input signal as the training data, set this property to `false`.

Default: `false`

`DirectionSource`

Source of beamforming direction

Specify whether the beamforming direction for the beamformer comes from the `Direction` property of this object or from an input argument in step. Values of this property are:

`'Property'`	The `Direction` property of this object specifies the beamforming direction.
`'Input port'`	An input argument in each invocation of `step` specifies the beamforming direction.

Default: `'Property'`

`Direction`

Beamforming directions

Specify the beamforming directions of the beamformer as a two-row matrix. Each column of the matrix has the form [AzimuthAngle; ElevationAngle] (in degrees). Each azimuth angle must be between –180 and 180 degrees, and each elevation angle must be between –90 and 90 degrees. This property applies when you set the `DirectionSource` property to `'Property'`.

Default: `[0; 0]`

`NumPhaseShifterBits`

Number of phase shifter quantization bits

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

Default: `0`

`WeightsOutputPort`

Output beamforming weights

To obtain the weights used in the beamformer, set this property to `true` and use the corresponding output argument when invoking step. If you do not want to obtain the weights, set this property to `false`.

Default: `false`

Methods

step	Perform MVDR beamforming

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

MVDR Beamforming

Apply an MVDR beamformer to a 5-element ULA. The incident angle of the signal is 45 degrees in azimuth and 0 degree in elevation. The signal frequency is .01 hertz. The carrier frequency is 300 MHz.

```
t = [0:.1:200]';
fr = .01;
xm = sin(2*pi*fr*t);
c = physconst('LightSpeed');
fc = 300e6;
rng('default');
incidentAngle = [45;0];
array = phased.ULA('NumElements',5,'ElementSpacing',0.5);
x = collectPlaneWave(array,xm,incidentAngle,fc,c);
noise = 0.1*(randn(size(x)) + 1j*randn(size(x)));
```

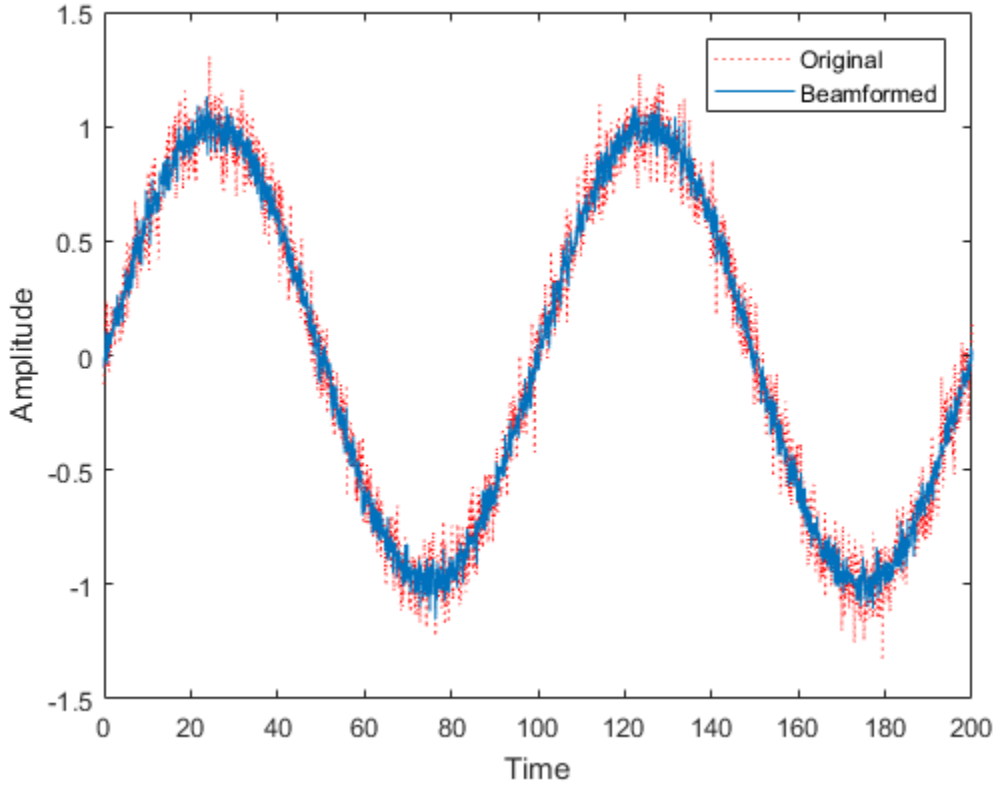
```
rx = x + noise;
```

Compute the beamforming weights

```
beamformer = phased.MVDRBeamformer('SensorArray',array,...
    'PropagationSpeed',c,'OperatingFrequency',fc,...
    'Direction',incidentAngle,'WeightsOutputPort',true);
[y,w] = beamformer(rx);
```

Plot the signals

```
plot(t,real(rx(:,3)),'r:',t,real(y))
xlabel('Time')
ylabel('Amplitude')
legend('Original','Beamformed')
```



Plot the array response pattern using the MVDR weights

```
pattern(array,fc,[-180:180],0,'PropagationSpeed',c,...
    'Weights',w,'CoordinateSystem','rectangular',...
    'Type','powerdb');
```

Introduced in R2012a

step

System object: phased.MVDRBeamformer
Package: phased

Perform MVDR beamforming

Syntax

```
Y = step(H,X)
Y = step(H,X,XT)
Y = step(H,X,ANG)
Y = step(H,X,XT,ANG)
[Y,W] = step( ___ )
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` performs MVDR beamforming on the input, `X`, and returns the beamformed output in `Y`. This syntax uses `X` as the training samples to calculate the beamforming weights.

`Y = step(H,X,XT)` uses `XT` as the training samples to calculate the beamforming weights. This syntax is available when you set the `TrainingInputPort` property to `true`.

`Y = step(H,X,ANG)` uses `ANG` as the beamforming direction. This syntax is available when you set the `DirectionSource` property to `'Input port'`.

`Y = step(H,X,XT,ANG)` combines all input arguments. This syntax is available when you set the `TrainingInputPort` property to `true` and set the `DirectionSource` property to `'Input port'`.

`[Y,W] = step( ___ )` returns the beamforming weights, `W`. This syntax is available when you set the `WeightsOutputPort` property to `true`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`H`

Beamformer object.

`X`

Input signal, specified as an *M*-by-*N* matrix. If the sensor array contains subarrays, *N* is the number of subarrays; otherwise, *N* is the number of elements. If you set the `TrainingInputPort` to `false`, *M* must be larger than *N*; otherwise, *M* can be any positive integer.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

`XT`

Training samples, specified as a *P*-by-*N* matrix. If the sensor array contains subarrays, *N* is the number of subarrays; otherwise, *N* is the number of elements. *P* must be larger than *N*.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

`ANG`

Beamforming directions, specified as a two-row matrix. Each column has the form [AzimuthAngle; ElevationAngle], in degrees. Each azimuth angle must be between –180 and 180 degrees, and each elevation angle must be between –90 and 90 degrees.

Output Arguments

Y

Beamformed output. Y is an M-by-L matrix, where M is the number of rows of X and L is the number of beamforming directions.

W

Beamforming weights. W is an N-by-L matrix, where L is the number of beamforming directions. If the sensor array contains subarrays, N is the number of subarrays; otherwise, N is the number of elements.

Examples

MVDR Beamforming

Apply an MVDR beamformer to a 5-element ULA. The incident angle of the signal is 45 degrees in azimuth and 0 degree in elevation. The signal frequency is .01 hertz. The carrier frequency is 300 MHz.

phased.MVDREstimator System object

Package: phased

MVDR (Capon) spatial spectrum estimator for ULA

Description

The `MVDREstimator` object computes a minimum variance distortionless response (MVDR) spatial spectrum estimate for a uniform linear array. This DOA estimator is also referred to as a Capon DOA estimator.

To estimate the spatial spectrum:

1. Define and set up your MVDR spatial spectrum estimator. See "Construction" on page 1-1197.
2. Call step to estimate the spatial spectrum according to the properties of `phased.MVDREstimator`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.MVDREstimator` creates an MVDR spatial spectrum estimator System object, `H`. The object estimates the incoming signal's spatial spectrum using a narrowband MVDR beamformer for a uniform linear array (ULA).

`H = phased.MVDREstimator(Name,Value)` creates object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`SensorArray`

Handle to sensor array

Specify the sensor array as a handle. The sensor array must be a `phased.ULA` object.

Default: phased.ULA with default property values

`PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

Default: Speed of light

`OperatingFrequency`

System operating frequency

Specify the operating frequency of the system in hertz as a positive scalar. The default value corresponds to 300 MHz.

Default: `3e8`

`NumPhaseShifterBits`

Number of phase shifter quantization bits

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

Default: `0`

`ForwardBackwardAveraging`

Perform forward-backward averaging

Set this property to `true` to use forward-backward averaging to estimate the covariance matrix for sensor arrays with conjugate symmetric array manifold.

Default: `false`

`SpatialSmoothing`

Spatial smoothing

Specify the number of averaging used by spatial smoothing to estimate the covariance matrix as a nonnegative integer. Each additional smoothing handles one extra coherent source, but reduces the effective number of element by 1. The maximum value of this property is M–2, where M is the number of sensors.

Default: `0`, indicating no spatial smoothing

`ScanAngles`

Scan angles

Specify the scan angles (in degrees) as a real vector. The angles are broadside angles and must be between –90 and 90, inclusive. You must specify the angles in ascending order.

Default: `-90:90`

`DOAOutputPort`

Enable DOA output

To obtain the signal's direction of arrival (DOA), set this property to `true` and use the corresponding output argument when invoking step. If you do not want to obtain the DOA, set this property to `false`.

Default: `false`

`NumSignals`

Number of signals

Specify the number of signals for DOA estimation as a positive scalar integer. This property applies when you set the `DOAOutputPort` property to true.

Default: 1

Methods

plotSpectrum	Plot spatial spectrum
reset	Reset states of MVDR spatial spectrum estimator object
step	Perform spatial spectrum estimation

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Estimate DOA of Two Signals Using MVDR

First, estimate the DOAs of two signals received by a standard 10-element ULA with element spacing of 1 meter. The antenna operating frequency is 150 MHz. The actual direction of the first signal is 10° in azimuth and 20° in elevation. The direction of the second signal is 60° in azimuth and −5° in elevation. Then, plot the MVDR spatial spectrum.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Create the signals with added noise. Then, create the ULA System object™.

```
fs = 8000;
```

```
t = (0:1/fs:1).';
x1 = cos(2*pi*t*300);
x2 = cos(2*pi*t*400);
array = phased.ULA('NumElements',10,'ElementSpacing',1);
array.Element.FrequencyRange = [100e6 300e6];
fc = 150.0e6;
x = collectPlaneWave(array,[x1 x2],[10 20;60 -5]',fc);
noise = 0.1*(randn(size(x)) + 1i*randn(size(x)));
```

Construct MVDR estimator System object.

```
estimator = phased.MVDREstimator('SensorArray',array,...
    'OperatingFrequency',fc,'DOAOutputPort',true,'NumSignals',2);
```

Estimate the DOAs.

```
[y,doas] = estimator(x + noise);
doas = broadside2az(sort(doas),[20 -5])
```

```
doas =

    9.5829   60.3813
```

Plot the spectrum.

```
plotSpectrum(estimator)
```

plotSpectrum

System object: phased.MVDREstimator
Package: phased

Plot spatial spectrum

Syntax

```
plotSpectrum(H)
plotSpectrum(H,Name,Value)
h = plotSpectrum( ___ )
```

Description

`plotSpectrum(H)` plots the spatial spectrum resulting from the last call of the `step` method.

`plotSpectrum(H,Name,Value)` plots the spatial spectrum with additional options specified by one or more `Name,Value` pair arguments.

`h = plotSpectrum( ___ )` returns the line handle in the figure.

Input Arguments

`H`

Spatial spectrum estimator object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'NormalizeResponse'`

Set this value to `true` to plot the normalized spectrum. Setting this value to `false` plots the spectrum without normalization.

Default: `false`

`'Title'`

Character vector to use as figure title.

Default: `''`

`'Unit'`

Plot units, specified as `'db'`, `'mag'`, or `'pow'`.

Default: `'db'`

Reset states of MVDR spatial spectrum estimator object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `MVDREstimator` object, `H`.

step

System object: phased.MVDREstimator
Package: phased

Perform spatial spectrum estimation

Syntax

```
Y = step(H,X)
[Y,ANG] = step(H,X)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` estimates the spatial spectrum from `X` using the estimator `H`. `X` is a matrix whose columns correspond to channels. `Y` is a column vector representing the magnitude of the estimated spatial spectrum.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

`[Y,ANG] = step(H,X)` returns additional output `ANG` as the signal's direction of arrival (DOA) when the `DOAOutputPort` property is true. `ANG` is a row vector of the estimated broadside angles (in degrees).

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To

change nontunable properties or inputs, you must first call the `release` method to unlock the object.

phased.MVDREstimator2D System object

Package: phased

2-D MVDR (Capon) spatial spectrum estimator

Description

The `MVDREstimator2D` object computes a 2-D minimum variance distortionless response (MVDR) spatial spectrum estimate. This DOA estimator is also referred to as a Capon estimator.

To estimate the spatial spectrum:

1. Define and set up your 2-D MVDR spatial spectrum estimator. See "Construction" on page 1-1212.
2. Call step to estimate the spatial spectrum according to the properties of `phased.MVDREstimator2D`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.MVDREstimator2D` creates a 2-D MVDR spatial spectrum estimator System object, `H`. The object estimates the signal's spatial spectrum using a narrowband MVDR beamformer.

`H = phased.MVDREstimator2D(Name,Value)` creates object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`SensorArray`

Handle to sensor array

Specify the sensor array as a handle. The sensor array must be an array object in the `phased` package. The array cannot contain subarrays.

Default: phased.ULA with default property values

`PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

Default: Speed of light

`OperatingFrequency`

System operating frequency

Specify the operating frequency of the system in hertz as a positive scalar. The default value corresponds to 300 MHz.

Default: `3e8`

`NumPhaseShifterBits`

Number of phase shifter quantization bits

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

Default: `0`

`ForwardBackwardAveraging`

Perform forward-backward averaging

Set this property to `true` to use forward-backward averaging to estimate the covariance matrix for sensor arrays with conjugate symmetric array manifold.

Default: `false`

`AzimuthScanAngles`

Azimuth scan angles (degrees)

Specify the azimuth scan angles (in degrees) as a real vector. The angles must be between –180 and 180, inclusive. You must specify the angles in ascending order.

Default: `-90:90`

`ElevationScanAngles`

Elevation scan angles

Specify the elevation scan angles (in degrees) as a real vector or scalar. The angles must be between –90 and 90, inclusive. You must specify the angles in ascending order.

Default: `0`

`DOAOutputPort`

Enable DOA output

To obtain the signal's direction of arrival (DOA), set this property to `true` and use the corresponding output argument when invoking step. If you do not want to obtain the DOA, set this property to `false`.

Default: `false`

`NumSignals`

Number of signals

Specify the number of signals for DOA estimation as a positive scalar integer. This property applies when you set the `DOAOutputPort` property to `true`.

Default: `1`

Methods

plotSpectrum	Plot spatial spectrum

reset	Reset states of 2-D MVDR spatial spectrum estimator object
step	Perform spatial spectrum estimation

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Estimate DOA of Two Signals Arriving at URA

Estimate the DOAs of two signals received by a 50-element URA with a rectangular lattice. The antenna operating frequency is 150 MHz. The actual direction of the first signal is −37° in azimuth and 0° in elevation. The direction of the second signal is 17° in azimuth and 20° degrees in elevation. Then, plot the spatial spectrum.

Create the arriving signals.

```
fs = 8000;
t = (0:1/fs:1).';
x1 = cos(2*pi*t*300);
x2 = cos(2*pi*t*400);
array = phased.URA('Size',[5 10],'ElementSpacing',[1 0.6]);
array.Element.FrequencyRange = [100e6 300e6];
fc = 150e6;
x = collectPlaneWave(array,[x1 x2],[-37 0;17 20]',fc);
```

Add noise.

```
noise = 0.1*(randn(size(x))+1i*randn(size(x)));
```

Create the MVDR DOA estimator and estimate the DOAs.

```
estimator = phased.MVDREstimator2D('SensorArray',array,...
    'OperatingFrequency',fc,...
```

```
    'DOAOutputPort',true,'NumSignals',2,...
    'AzimuthScanAngles',-50:50,...
    'ElevationScanAngles',-30:30);
[~,doas] = estimator(x + noise);
```

Plot the spectrum.

```
plotSpectrum(estimator)
```

plotSpectrum

System object: phased.MVDREstimator2D
Package: phased

Plot spatial spectrum

Syntax

```
plotSpectrum(H)
plotSpectrum(H,Name,Value)
h = plotSpectrum( ___ )
```

Description

`plotSpectrum(H)` plots the spatial spectrum resulting from the last call of the `step` method.

`plotSpectrum(H,Name,Value)` plots the spatial spectrum with additional options specified by one or more `Name,Value` pair arguments.

`h = plotSpectrum( ___ )` returns the line handle in the figure.

Input Arguments

`H`

Spatial spectrum estimator object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'NormalizeResponse'`

Set this value to `true` to plot the normalized spectrum. Setting this value to `false` plots the spectrum without normalization.

Default: `false`

`'Title'`

Character vector to use as figure title.

Default: `''`

`'Unit'`

Plot units, specified as `'db'`, `'mag'`, or `'pow'`.

Default: `'db'`

Examples

Estimate DOA Using 2D MVDR

Estimate the DOAs of two signals received by a 50-element URA with a rectangular lattice. The antenna operating frequency is 150 MHz. The actual direction of the first signal is −37° in azimuth and 0° in elevation. The direction of the second signal is 17° in azimuth and 20° in elevation.

Create signals sampled at 8 kHz.

```
fc = 150e6;
fs = 8000;
t = (0:1/fs:1).';
x1 = cos(2*pi*t*300);
x2 = cos(2*pi*t*400);
array = phased.URA('Size',[5 10],'ElementSpacing',[1 0.6]);
array.Element.FrequencyRange = [100e6 300e6];
x = collectPlaneWave(array,[x1 x2],[-37 0;17 20]',fc);

Package: phased

Reset states of 2-D MVDR spatial spectrum estimator object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `MVDREstimator2D` object, `H`.

step

System object: phased.MVDREstimator2D
Package: phased

Perform spatial spectrum estimation

Syntax

```
Y = step(H,X)
[Y,ANG] = step(H,X)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` estimates the spatial spectrum from `X` using the estimator `H`. `X` is a matrix whose columns correspond to channels. `Y` is a matrix representing the magnitude of the estimated 2-D spatial spectrum. The row dimension of `Y` is equal to the number of angles in the `ElevationScanAngles` and the column dimension of `Y` is equal to the number of angles in the `AzimuthScanAngles` property.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

`[Y,ANG] = step(H,X)` returns additional output `ANG` as the signal's direction of arrival (DOA) when the `DOAOutputPort` property is `true`. `ANG` is a two-row matrix where the first row represents estimated azimuth and the second row represents estimated elevation (in degrees).

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications,

such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Examples

Estimate DOA Using 2D MVDR

Estimate the DOAs of two signals received by a 50-element URA with a rectangular lattice. The antenna operating frequency is 150 MHz. The actual direction of the first signal is −37° in azimuth and 0° in elevation. The direction of the second signal is 17° in azimuth and 20° in elevation.

Create signals sampled at 8 kHz.

```
fc = 150e6;
fs = 8000;
t = (0:1/fs:1).';

`azel2phitheta` | `azel2uv`

phased.MultipathChannel System object

Package: phased

Propagate signals in multipath channel

Description

The `phased.MultipathChannel` System object propagates a signal through a multipath channel. To run the object, you must provide characteristics for each path: time delay, gain, Doppler factor, reflection loss, and spreading loss.

For sonar applications, you can use the phased.IsoSpeedUnderwaterPaths System object to generate channel path characteristics. You can also supply these characteristics independently.

To model signal propagation through a multipath channel:

1. Define and set up the propagator. You can set `phased.MultipathChannel` properties at construction time or leave them to their default values. See "Construction" on page 1-1226. Some properties that you set at construction time can be changed later. These properties are *tunable*.
2. To compute the propagated signal, call the step method of `phased.MultipathChannel`. The output of the `step` method depends on the properties of the `phased.MultipathChannel` System object. You can change tunable properties at any time.

Note: Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`propagator = phased.MultipathChannel` creates a signal propagator System object for a multipath underwater channel.

`propagator = phased.MultipathChannel(Name,Value)` creates a signal propagator System object with each specified property `Name` set to the specified

`Value`. You can specify additional name and value pair arguments in any order as (`Name1,Value1,...,NameN,ValueN`).

Properties

`OperatingFrequency` — Signal carrier frequency

`20e3` (default) | positive real-valued scalar

Signal carrier frequency, specified as a positive real-valued scalar. Units are in Hz.

Example: `10000`

Data Types: `double`

`SampleRate` — Signal sample rate

`1e3` (default) | positive real-valued scalar

Signal sample rate, specified as a positive real-valued scalar. Units are in Hz. The System object uses this quantity to calculate the propagation delay in units of samples.

Example: `3e3`

Data Types: `double`

`MaximumDelaySource` — Source of maximum delay

`'Auto'` (default) | `'Property'`

Source of the maximum delay value, specified as `'Auto'` or `'Property'`. When you set this property to `'Auto'`, the channel automatically allocates enough memory to simulate the propagation delay. When you set this property to `'Property'`, you can specify the maximum delay by using the `MaximumDelay` property. Signals arriving after the maximum delay are ignored.

`MaximumDelay` — Maximum signal delay

`1` (default) | positive scalar

Maximum signal delay, specified as a positive scalar. Delays greater than this value are ignored. Units are in seconds.

Dependencies

To enable this property, set the `MaximumDelaySource` property to `'Property'`.

Data Types: `double`

Methods

step	Propagate signal through multipath sound channel
reset	Reset state of System object

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

One-Way Signal Propagation in Multipath Underwater Sound Channel

Create a five-path underwater sound channel and compute the propagation path matrix, the Doppler factor, and the absorption loss. Assume that the source is stationary and the receiver is moving along the *x*-axis toward the source at 20 km/h. Assume the default one-way propagation.

Create the channel and specify the source and receiver locations and velocities.

```
numpaths = 5;
channel = phased.IsoSpeedUnderwaterPaths('ChannelDepth',200,'BottomLoss',10, ...
    'NumPathsSource','Property','NumPaths',numpaths);
tstep = 1;
srcpos = [0;0;-160];
rcvpos = [100;0;-50];
speed = -20*1000/3600;
srcvel = [0;0;0];
```

```
rcvvel = [speed;0;0];
```

Compute the path matrix, Doppler factor, and losses.

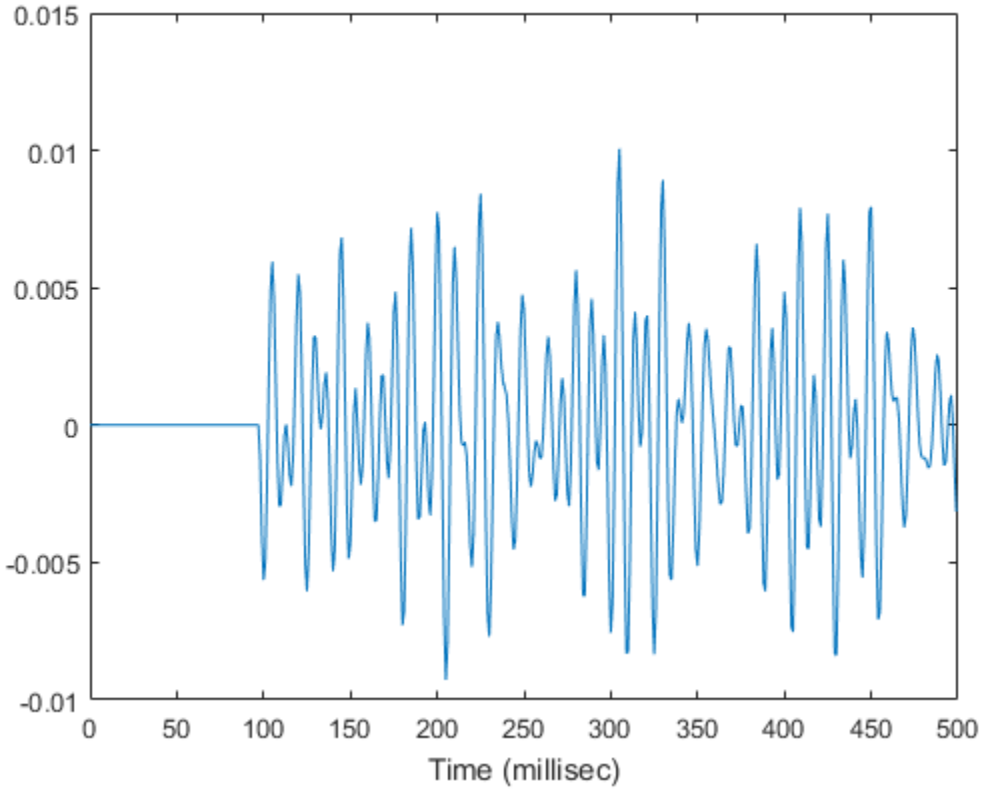
```
[pathmat,dop,absloss] = channel(srcpos,rcvpos,srcvel,rcvvel,tstep);
```

Create 500 samples of a 100 Hz signal. Assume all the paths have the same signal. Propagate the signals to the receiver.

```
fs = 1e3;
nsamp = 500;
propagator = phased.MultipathChannel('OperatingFrequency',10e3,'SampleRate',fs);
t = [0:(nsamp-1)]'/fs;
sig0 = sin(2*pi*100*t);
sig = repmat(sig0,1,numpaths);
propsig = propagator(sig,pathmat,dop,absloss);
```

Plot the real part of the coherent sum of the propagated signals.

```
plot(t*1000,real(sum(propsig,2)))
xlabel('Time (millisec)')
```



Two-Way Signal Propagation in Multipath Underwater Sound Channel

Create a seven-path underwater sound channel and display the propagation path matrix. Assume that the source is stationary and that the receiver is moving along the *x*-axis toward the source at 20 km/h. Assume two-way propagation.

```
speed = -20*1000/3600;
numpaths = 7;
csound = 1515.0;
channel = phased.IsoSpeedUnderwaterPaths('ChannelDepth',200, ...
    'PropagationSpeed',csound,'BottomLoss',10,'NumPathsSource','Property', ...
    'NumPaths',numpaths,'TwoWayPropagation',true);
tstep = 1;
srcpos = [0;0;-160];
```

```
tgtpos = [500;0;-50];
srcvel = [0;0;0];
tgtvel = [speed;0;0];
```

Obtain the path matrix, Doppler factor, loss, and target reflection and transmit angles.

```
[pathmat,dop,aloss,tgtangs,srcangs] = channel(srcpos,tgtpos,srcvel,tgtvel,tstep);
```

Create a 100 Hz signal with 500 samples. Assume that all the paths have the same signal but with different amplitudes. Then, propagate the signals to the target and back. You can use the angle information to calculate any angular dependence of the source and target responses. Each channel can have a different amplitude. This example uses a simple cosine model.

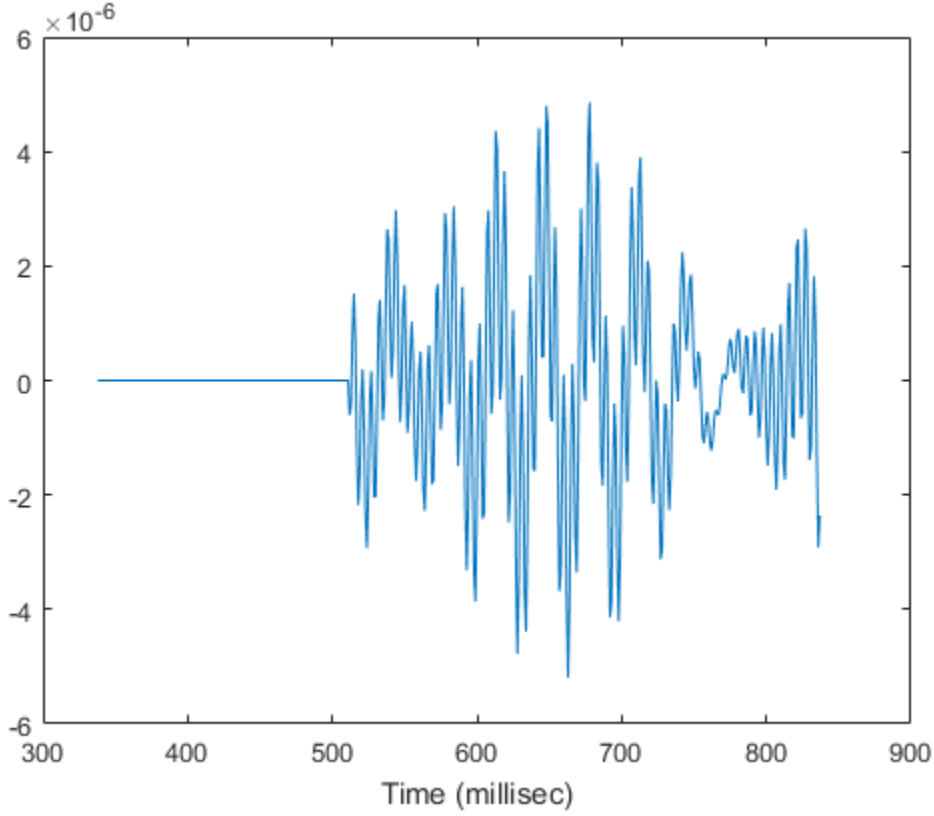
```
fs = 1e3;
nsamp = 500;
propagator = phased.MultipathChannel('OperatingFrequency',10e3,'SampleRate',fs);
t = [0:(nsamp-1)]'/fs;
ampsrc = cosd(srcangs(2,:));
amptgt = cosd(tgtangs(2,:));
sig0 = sin(2*pi*100*t);
sig = repmat(sig0,1,numpaths);
amptotal = ampsrc.^2.*amptgt;
sig = bsxfun(@times,amptotal,sig);
```

Because of the finite propagation delay, the first call to the propagator does not return the signal. Call `propagator` twice to obtain the returned signal.

```
propsig = propagator(sig,pathmat,dop,aloss);
propsig = propagator(sig,pathmat,dop,aloss);
```

Plot the real part of the coherent sum of the propagated signals. Compute the round trip time.

```
rng = rangeangle(srcpos,tgtpos);
tr = rng/csound;
plot((t+tr)*1000,real(sum(propsig,2)))
xlabel('Time (millisec)')
```



Propagate Sound in Channel Having Unknown Number of Paths

Create an underwater sound channel and and plot the combined received signal. Automatically find the number of paths. Assume that the source is stationary and that the receiver is moving along the *x*-axis toward the source at 20 km/h. Assume the default one-way propagation.

```
speed = -20*1000/3600;
channel = phased.IsoSpeedUnderwaterPaths('ChannelDepth',200,'BottomLoss',5, ...
    'NumPathsSource','Auto','CoherenceTime',5);
tstep = 1;
srcpos = [0;0;-160];
rcvpos = [500;0;-50];
srcvel = [0;0;0];
```

```
rcvvel = [speed;0;0];
```

Compute the path matrix, Doppler factor, and losses. The propagator outputs 51 paths output but some paths can contain `Nan` values.

```
[pathmat,dop,absloss,rcvangs,srcangs] = channel(srcpos,rcvpos,srcvel,rcvvel,tstep);
```

Create of a 100 Hz signal with 500 samples. Assume that all the paths have the same signal. Use a `phased.MultipathChannel` System object to propagate the signals to the receiver. `phased.MultipathChannel` accepts as input all paths produced by `phased.IsoSpeedUnderwaterPaths` but ignores paths that have `NaN` values.

```
fs = 1e3;
nsamp = 500;
propagator = phased.MultipathChannel('OperatingFrequency',10e3,'SampleRate',fs);
t = [0:(nsamp-1)]'/fs;
sig0 = sin(2*pi*100*t);
numpaths = size(pathmat,2);
sig = repmat(sig0,1,numpaths);
propsig = propagator(sig,pathmat,dop,absloss);
```

Plot the real part of the coherent sum of the propagated signals.

```
plot(t*1000,real(sum(propsig,2)))
xlabel('Time (millisec)')
```

Doppler Stretching of Sonar Signal

Compare the lengths of a propagated signal when the sonar is stationary differs compared to when the sonar is moving. In the second case, the sonar has a radial velocity of 25 m/s moving away from the target. Propagate the signal along a single path.

Define the system parameters: maximum unambiguous range, required range resolution, operating frequency, and propagation speed.

```
maxrange = 5000.0;
rngres = 10.0;
fc = 20.0e3;
csound = 1520.0;
```

Use a rectangular waveform for the transmitted signal.

```
prf = csound/(2*maxrange);
pulseWidth = 8*rngres/csound;
pulseBW = 1/pulseWidth;
fs = 80*pulseBW;
waveform = phased.RectangularWaveform('PulseWidth',pulseWidth,'PRF',prf, ...
    'SampleRate',fs);
```

Specify the sonar positions.

```
sonarplatform1 = phased.Platform('InitialPosition',[0;0;-60],'Velocity',[0;0;0]);
sonarplatform2 = phased.Platform('InitialPosition',[0;0;-60],'Velocity',[0;-25;0]);
```

Specify the target position.

```
targetplatform = phased.Platform('InitialPosition',[0;500;-60],'Velocity',[0;0;0]);
```

Define the underwater path and propagation channel objects. Assume one-way propagation.

```
paths = phased.IsoSpeedUnderwaterPaths('ChannelDepth',100, ...
    'CoherenceTime',0,'NumPathsSource','Property','NumPaths',1, ...
    'PropagationSpeed',csound);
propagator = phased.MultipathChannel('SampleRate',fs,'OperatingFrequency',fc);
```

Transmit a rectangular waveform.

```
wav = waveform();
nsamp = size(wav,1);
rxpulses = zeros(nsamp,2);
t = (0:nsamp-1)/fs;
```

Transmit and receive at the stationary sonar.

```
[pathmat,dop,aloss,tgtang,srcang] = paths(sonarplatform1.InitialPosition, ...
    targetplatform.InitialPosition,sonarplatform1.InitialVelocity, ...
    targetplatform.InitialVelocity,1/prf);
rxpulses(:,1) = propagator(wav,pathmat,dop,aloss);
```

Transmit and receive at the moving sonar.

```
[pathmat,dop,aloss,tgtang,srcang] = paths(sonarplatform2.InitialPosition, ...
    targetplatform.InitialPosition,sonarplatform2.Velocity, ...
    targetplatform.Velocity,1/prf);
rxpulses(:,2) = propagator(wav,pathmat,dop,aloss);
```

Plot the received pulses.

```
plot(abs(rxpulses))
xlim([490 650])
ylim([0 1.65e-3])
legend('Stationary sonar','Moving sonar')
xlabel('Received Sample Time (sec)')
ylabel('Integrated Received Pulses')
```

The signal received at the moving sonar has increased in duration compared to the stationary sonar.

step

System object: phased.MultipathChannel
Package: phased

Propagate signal through multipath sound channel

Syntax

```
propsig = step(propagator,sig,pathmat,dop,aloss)
```

Description

Note: Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`propsig = step(propagator,sig,pathmat,dop,aloss)` returns a signal, `propsig`, propagated through a multipath channel. `sig` is the input signal to the channel. The `pathmat` matrix contains the path time delay, the total reflection coefficient, and the spreading loss. `dop` specifies the Doppler factor and `aloss` specifies the frequency-dependent absorption loss. The matrix can describe one-way or two-way propagation from the signal source position to the signal destination position.

- When you use this method for one-way propagation, the source refers to the origin of the signal and the destination refers to the receiver. You can use one-way propagation modeling to model passive sonar and underwater communications.
- When you use this method for two-way propagation, the destination refers to the reflecting target, not the sonar receiver. A two-way path consists of a two identical one-way paths from source to target and back to receiver (collocated with the source). You can use two-way propagation to model active sonar systems.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a

nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Note: Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Input Arguments

`propagator` — Multipath channel propagator

`phased.MultipathChannel` System object

Multipath channel propagator, specified as a `phased.MultipathChannel` System object.

Example: `phased.MultipathChannel`

`sig` — Channel input signal

complex-valued *M*-by-*N* matrix

Channel input signal, specified as a complex-valued *M*-by-*N* matrix. *M* is the number of samples in the signal and *N* is the number of paths.

Data Types: `double`
Complex Number Support: Yes

`pathmat` — Propagation paths matrix

real-valued 3-by-*N* matrix

Propagation paths matrix, specified as a real-valued 3-by-*N* matrix. *N* is the number of paths in the channel. Each column represents a path. The matrix rows represent:

Row	Data
1	Propagation delays for each path. Units are in seconds.
2	Total reflection coefficient for each path. Units are dimensionless
3	Spreading loss for each path. Units are in dB.

Except for the direct path, paths consist of alternating surface and bottom reflections. The losses for multiple reflections at the boundaries are multiplied. When you use

phased.IsoSpeedUnderwaterPaths to create a path matrix, some of the columns can contain `NaN` values. `phased.MultipathChannel` ignores these paths.

Data Types: `double`

`dop` — Doppler factor

real-valued *N*-by-1 row vector

Doppler factor, specified as a real-valued *N*-by-1 row vector where *N* is the number of paths. The Doppler factor multiplies the transmitted frequency to produce the Doppler-shifted frequency for each path. The factor also defines the time contraction or dilation of a signal. Units are dimensionless.

Data Types: `double`

`aloss` — Frequency-dependent absorption loss

real-valued *K*-by-*N*+1 matrix

Frequency-dependent absorption loss, specified as a real-valued *K*-by-*N*+1 matrix. *K* is the number of frequencies and *N* is the number of paths. The first column of `aloss` contains the absorption-loss frequencies in Hz. The remaining columns contain the absorption losses for the corresponding frequency. Units are in dB.

Data Types: `double`

Output Arguments

`propsig` — Channel output signal

complex-valued *M*-by-*N* matrix

Channel output signal, returned as a complex-valued *M*-by-*N* matrix. *M* is the number of samples in the signal and *N* is the number of paths. The output is the signal propagated through the channel. `propsig` has the same dimensions as the input signal, `sig`.

Examples

One-Way Signal Propagation in Multipath Underwater Sound Channel

Create a five-path underwater sound channel and compute the propagation path matrix, the Doppler factor, and the absorption loss. Assume that the source is stationary and the

receiver is moving along the *x*-axis toward the source at 20 km/h. Assume the default one-way propagation.

Create the channel and specify the source and receiver locations and velocities.

```
numpaths = 5;
channel = phased.IsoSpeedUnderwaterPaths('ChannelDepth',200,'BottomLoss',10, ...
    'NumPathsSource','Property','NumPaths',numpaths);
tstep = 1;
srcpos = [0;0;-160];
rcvpos = [100;0;-50];
speed = -20*1000/3600;
srcvel = [0;0;0];
rcvvel = [speed;0;0];
```

Compute the path matrix, Doppler factor, and losses.

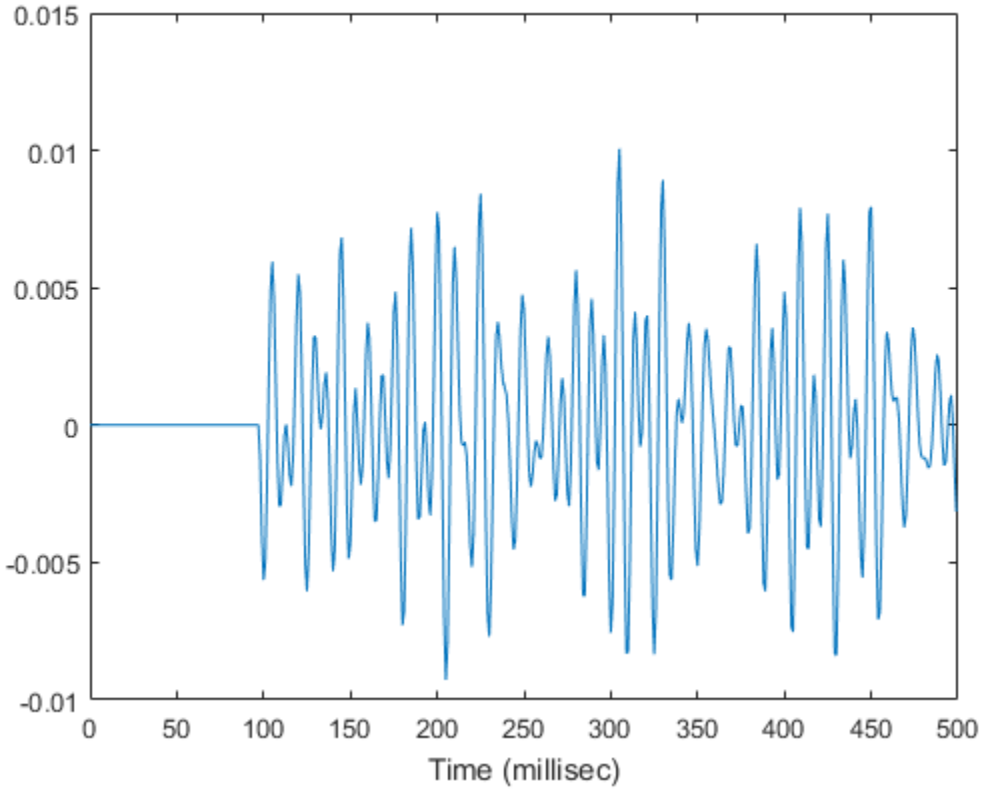
```
[pathmat,dop,absloss] = channel(srcpos,rcvpos,srcvel,rcvvel,tstep);
```

Create 500 samples of a 100 Hz signal. Assume all the paths have the same signal. Propagate the signals to the receiver.

```
fs = 1e3;
nsamp = 500;
propagator = phased.MultipathChannel('OperatingFrequency',10e3,'SampleRate',fs);
t = [0:(nsamp-1)]'/fs;
sig0 = sin(2*pi*100*t);
sig = repmat(sig0,1,numpaths);
propsig = propagator(sig,pathmat,dop,absloss);
```

Plot the real part of the coherent sum of the propagated signals.

```
plot(t*1000,real(sum(propsig,2)))
xlabel('Time (millisec)')
```



Two-Way Signal Propagation in Multipath Underwater Sound Channel

Create a seven-path underwater sound channel and display the propagation path matrix. Assume that the source is stationary and that the receiver is moving along the *x*-axis toward the source at 20 km/h. Assume two-way propagation.

```
speed = -20*1000/3600;
numpaths = 7;
csound = 1515.0;
channel = phased.IsoSpeedUnderwaterPaths('ChannelDepth',200, ...
    'PropagationSpeed',csound,'BottomLoss',10,'NumPathsSource','Property', ...
    'NumPaths',numpaths,'TwoWayPropagation',true);
tstep = 1;
srcpos = [0;0;-160];
```

```
tgtpos = [500;0;-50];
srcvel = [0;0;0];
tgtvel = [speed;0;0];
```

Obtain the path matrix, Doppler factor, loss, and target reflection and transmit angles.

```
[pathmat,dop,aloss,tgtangs,srcangs] = channel(srcpos,tgtpos,srcvel,tgtvel,tstep);
```

Create a 100 Hz signal with 500 samples. Assume that all the paths have the same signal but with different amplitudes. Then, propagate the signals to the target and back. You can use the angle information to calculate any angular dependence of the source and target responses. Each channel can have a different amplitude. This example uses a simple cosine model.

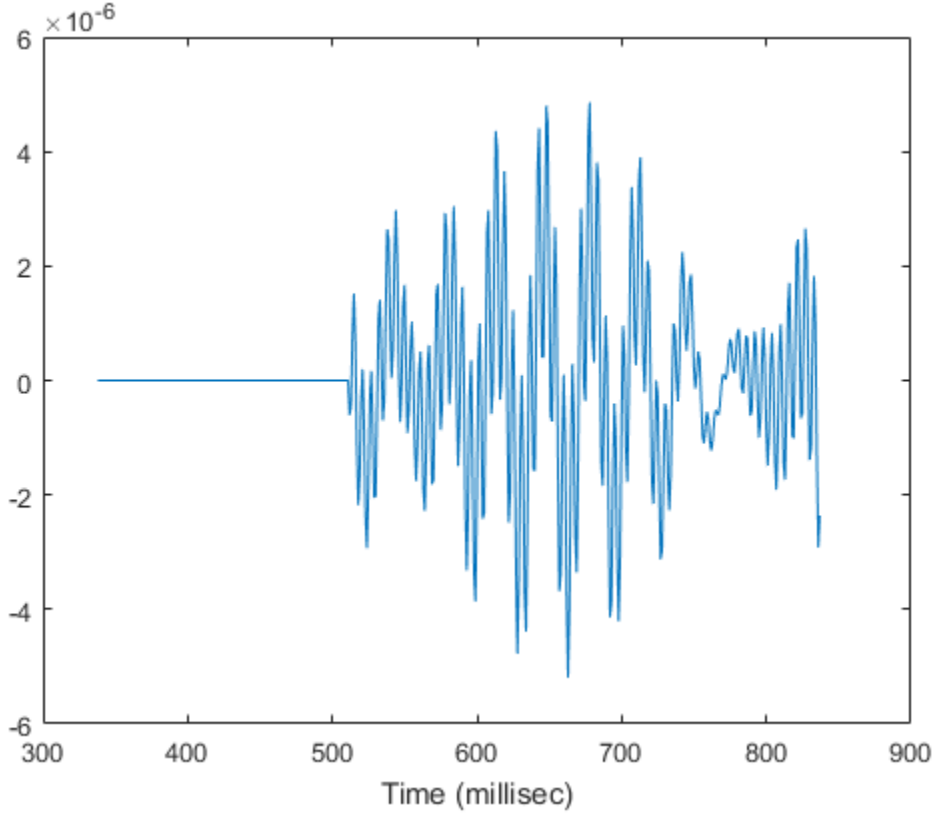
```
fs = 1e3;
nsamp = 500;
propagator = phased.MultipathChannel('OperatingFrequency',10e3,'SampleRate',fs);
t = [0:(nsamp-1)]'/fs;
ampsrc = cosd(srcangs(2,:));
amptgt = cosd(tgtangs(2,:));
sig0 = sin(2*pi*100*t);
sig = repmat(sig0,1,numpaths);
amptotal = ampsrc.^2.*amptgt;
sig = bsxfun(@times,amptotal,sig);
```

Because of the finite propagation delay, the first call to the propagator does not return the signal. Call `propagator` twice to obtain the returned signal.

```
propsig = propagator(sig,pathmat,dop,aloss);
propsig = propagator(sig,pathmat,dop,aloss);
```

Plot the real part of the coherent sum of the propagated signals. Compute the round trip time.

```
rng = rangeangle(srcpos,tgtpos);
tr = rng/csound;
plot((t+tr)*1000,real(sum(propsig,2)))
xlabel('Time (millisec)')
```



Propagate Sound in Channel Having Unknown Number of Paths

Create an underwater sound channel and and plot the combined received signal. Automatically find the number of paths. Assume that the source is stationary and that the receiver is moving along the *x*-axis toward the source at 20 km/h. Assume the default one-way propagation.

```
speed = -20*1000/3600;
channel = phased.IsoSpeedUnderwaterPaths('ChannelDepth',200,'BottomLoss',5, ...
    'NumPathsSource','Auto','CoherenceTime',5);
tstep = 1;
srcpos = [0;0;-160];
rcvpos = [500;0;-50];
srcvel = [0;0;0];
```

```
rcvvel = [speed;0;0];
```

Compute the path matrix, Doppler factor, and losses. The propagator outputs 51 paths output but some paths can contain `Nan` values.

```
[pathmat,dop,absloss,rcvangs,srcangs] = channel(srcpos,rcvpos,srcvel,rcvvel,tstep);
```

Create of a 100 Hz signal with 500 samples. Assume that all the paths have the same signal. Use a `phased.MultipathChannel` System object to propagate the signals to the receiver. `phased.MultipathChannel` accepts as input all paths produced by `phased.IsoSpeedUnderwaterPaths` but ignores paths that have `NaN` values.

```
fs = 1e3;
nsamp = 500;
propagator = phased.MultipathChannel('OperatingFrequency',10e3,'SampleRate',fs);
t = [0:(nsamp-1)]'/fs;
sig0 = sin(2*pi*100*t);
numpaths = size(pathmat,2);
sig = repmat(sig0,1,numpaths);
propsig = propagator(sig,pathmat,dop,absloss);
```

Plot the real part of the coherent sum of the propagated signals.

```
plot(t*1000,real(sum(propsig,2)))
xlabel('Time (millisec)')
```

Introduced in R2017a

reset

System object: phased.MultipathChannel
Package: phased

Reset state of System object

Syntax

```
reset(propagator)
```

Description

`reset(propagator)` resets the internal state of the `phased.MultipathChannel` object, `propagator`.

Input Arguments

`propagator` — Multipath channel

`phased.MultipathChannel` System object

Multipath channel, specified as a `phased.MultipathChannel` System object.

Example: `phased.MultipathChannel`

Introduced in R2017a

phased.MUSICEstimator System object

Package: phased

Estimate direction of arrival using narrowband MUSIC algorithm for ULA

Description

The `phased.MUSICEstimator` System object implements the narrowband multiple signal classification (*MUSIC*) algorithm for uniform linear arrays (ULA). MUSIC is a high-resolution direction-finding algorithm capable of resolving closely-spaced signal sources. The algorithm is based on eigenspace decomposition of the sensor spatial covariance matrix.

To estimate directions of arrival (*DOA*):

1. Define and set up a `phased.MUSICEstimator` System object. See "Construction" on page 1-1248.
2. Call the step method to estimate the DOAs according to the properties of `phased.MUSICEstimator`.

Note: Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`estimator = phased.MUSICEstimator` creates a MUSIC DOA estimator System object, `estimator`.

`estimator = phased.MUSICEstimator(Name,Value)` creates a System object, `estimator`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`SensorArray` — ULA sensor array

`phased.ULA` System object (default)

ULA sensor array, specified as a phased.ULA System object. If you do not specify any name-value pair properties for the ULA sensor array, the default properties of the array are used.

`PropagationSpeed` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. Units are in m/s. The default value of the speed of light is the value returned by `physconst('LightSpeed')`.

Example: `3e8`

Data Types: `double`

`OperatingFrequency` — Signal carrier frequency

`300e6` (default) | positive real-valued scalar

Signal carrier frequency, specified as a positive real-valued scalar. Units are in Hz.

Example: `1e9`

Data Types: `double`

`ForwardBackwardAveraging` — Enable forward-backward averaging

`false` (default) | `true`

Enable forward-backward averaging, specified as `false` or `true`. Set this property to `true` to use forward-backward averaging to estimate the covariance matrix for sensor arrays with a conjugate symmetric array manifold.

Data Types: `logical`

`ScanAngles` — Scan angles

`[-90:90]` (default) | real-valued *K*-length vector

Scan angles, specified as a real-valued vector. Units are in degrees. Scan angles are broadside angles between the search direction and the ULA array axis. The angles lie between –90° and 90°, inclusive. Specify the angles in increasing value.

Example: `[-20:20]`

Data Types: `double`

`DOAOutputPort` — Enable directions of arrival output

`false` (default) | `true`

Option to enable directions-of-arrival (DOA) output, specified as `false` or `true`. To obtain the DOAs of signals, set this property to `true`. The DOAs are returned in the second output argument of the `step` method.

Data Types: `logical`

`NumSignalsSource` — Source of number of signals

`'Auto'` (default) | `'Property'`

Source of the number of arriving signals, specified as `'Auto'` or `'Property'`.

- `'Auto'` — The System object estimates the number of arriving signals using the method specified in the `NumSignalsMethod` property.
- `'Property'` — Specify the number of arriving signals using the `NumSignals` property.

Data Types: `char`

`NumSignalsMethod` — Method used to estimate number of arriving signals

`'AIC'` (default) | `'MDL'`

Method used to estimate the number of arriving signals, specified as `'AIC'` or `'MDL'`.

- `'AIC'` — Akaike Information Criterion
- `'MDL'` — Minimum Description Length criterion

Dependencies

To enable this property, set `NumSignalsSource` to `'Auto'`.

Data Types: `char`

`NumSignals` — Number of arriving signals

1 (default) | positive integer

Number of arriving signals, specified as a positive integer.

Example: 3

Dependencies

To enable this property, set `NumSignalsSource` to `'Property'`.

Data Types: `double`

`SpatialSmoothing` — Enable spatial smoothing

0 (default) | nonnegative integer

Option to enable spatial smoothing, specified as a nonnegative integer. Use spatial smoothing to compute the arrival directions of coherent signals. A value of zero specifies no spatial smoothing. A positive value represents the number of subarrays used to compute the smoothed (averaged) source covariance matrix. Each increment in this value lets you handle one additional coherent source, but reduces the effective number of array elements by one. The length of the smoothing aperture, L, depends on the array length, M, and the averaging number, K, by $L = M - K + 1$. The maximum value of K is $M - 2$.

Example: 5

Data Types: `double`

Methods

plotSpectrum	Plot MUSIC spectrum
reset	Reset states of System object
step	Estimate direction of arrival using MUSIC

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object

Common to All System Objects	
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Plot MUSIC Spectrum of Two Signals Arriving at ULA

Estimate the DOAs of two signals received by a standard 10-element ULA having an element spacing of 1 meter. Then plot the MUSIC spectrum.

Note: You can replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Create the ULA array. The antenna operating frequency is 150 MHz.

```
fc = 150.0e6;
array = phased.ULA('NumElements',10,'ElementSpacing',1.0);
```

Create the arriving signals at the ULA. The true direction of arrival of the first signal is 10° in azimuth and 20° in elevation. The direction of the second signal is 60° in azimuth and -5° in elevation.

```
fs = 8000.0;
t = (0:1/fs:1).';
sig1 = cos(2*pi*t*300.0);
sig2 = cos(2*pi*t*400.0);
sig = collectPlaneWave(array,[sig1 sig2],[10 20; 60 -5]',fc);
noise = 0.1*(randn(size(sig)) + 1i*randn(size(sig)));
```

Estimate the DOAs.

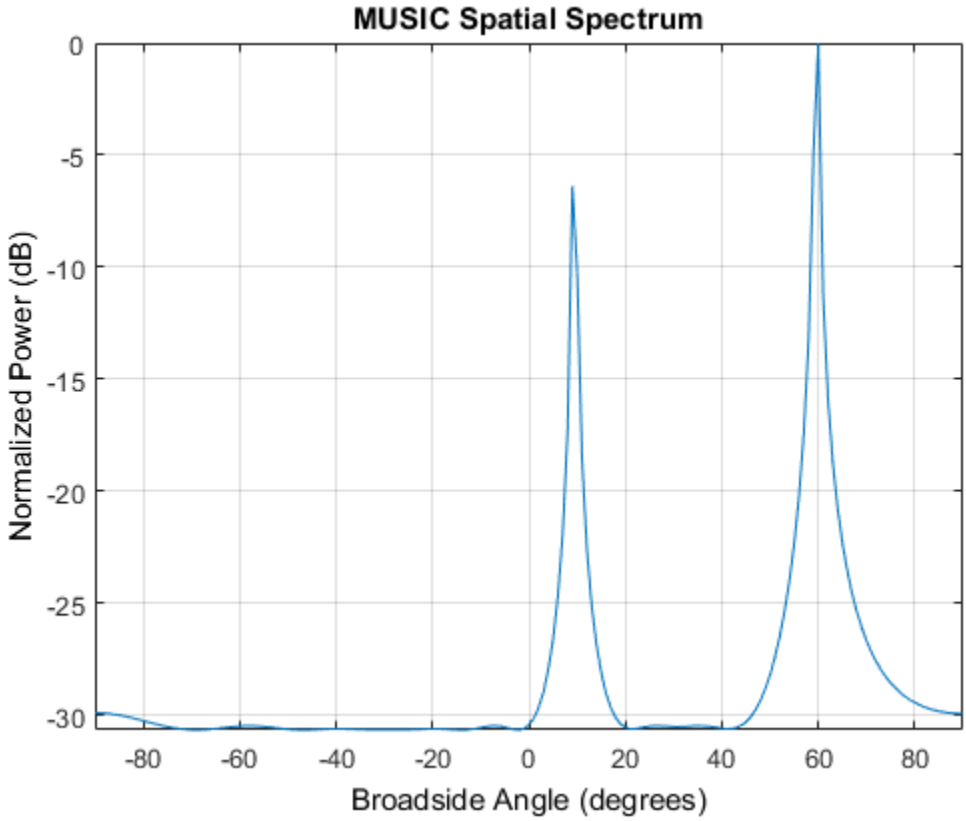
```
estimator = phased.MUSICEstimator('SensorArray',array,...
    'OperatingFrequency',fc,...
    'DOAOutputPort',true,'NumSignalsSource','Property',...
    'NumSignals',2);
[y,doas] = estimator(sig + noise);
doas = broadside2az(sort(doas),[20 -5])
```

```
doas =

    9.5829   60.3813
```

Plot the MUSIC spectrum.

```
plotSpectrum(estimator,'NormalizeResponse',true)
```



Compute DOA of Two Nearby Signals Using MUSIC

First, estimate the DOAs of two signals received by a standard 10-element ULA having an element spacing of one-half wavelength.Then, plot the spatial spectrum.

Note: You can replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

The antenna operating frequency is 150 MHz. The arrival directions of the two signals are separated by 2°. The direction of the first signal is 30° azimuth and 0° elevation. The direction of the second signal is 32° azimuth and 0° elevation. Estimate the number of signals using the Minimum Description Length (MDL) criterion.

Create the signals arriving at the ULA.

```
fs = 8000;
t = (0:1/fs:1).';
f1 = 300.0;
f2 = 600.0;
sig1 = cos(2*pi*t*f1);
sig2 = cos(2*pi*t*f2);
fc = 150.0e6;
c = physconst('LightSpeed');
lam = c/fc;
array = phased.ULA('NumElements',10,'ElementSpacing',0.5*lam);
sig = collectPlaneWave(array,[sig1 sig2],[30 0; 32 0]',fc);
noise = 0.1*(randn(size(sig)) + 1i*randn(size(sig)));
```

Estimate the DOAs.

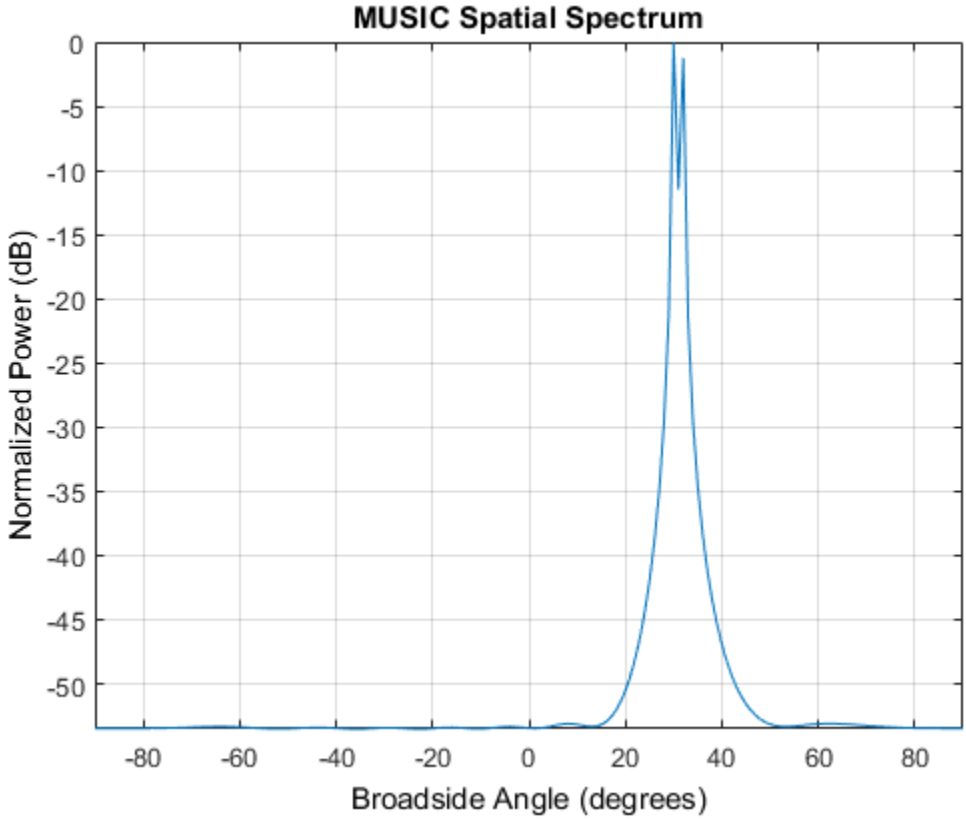
```
estimator = phased.MUSICEstimator('SensorArray',array,...
    'OperatingFrequency',fc,'DOAOutputPort',true,...
    'NumSignalsSource','Auto','NumSignalsMethod','MDL');
[y,doas] = estimator(sig + noise);
doas = broadside2az(sort(doas),[0 0])
```

```
doas =

   30.0000   32.0000
```

Plot the MUSIC spectrum.

```
plotSpectrum(estimator,'NormalizeResponse',true)
```



- "High Resolution Direction of Arrival Estimation"
- "Direction of Arrival Estimation with Beamscan, MVDR, and MUSIC"

Algorithms

MUSIC is a high-resolution direction-finding algorithm that estimates directions of arrival (DOA) of signals at an array from the covariance matrix of array sensor data. MUSIC belongs to the subspace-decomposition family of direction-finding algorithms. Unlike conventional beamforming, MUSIC can resolve closely spaced signal sources.

Based on eigenspace decomposition of the sensor covariance matrix, MUSIC divides the observation space into orthogonal signal and noise subspaces. Eigenvectors

corresponding to the largest eigenvalues span the signal subspace. Eigenvectors corresponding to the smaller eigenvalues span the noise subspace. Because arrival (or steering) vectors lie in the signal subspace, they are orthogonal to the noise subspace. For ULAs, arrival vectors are functions of the broadside direction angles of the sources. The algorithm searches a grid of arrival angles to find the arrival vectors that have zero or small projections into the noise subspace. These angles are the directions of the sources.

MUSIC requires that the number of source signals is known. If the number of specified sources does not match the actual number of sources, the algorithm degrades. Generally, you must provide an estimate of the number of sources or use one of the built-in source number estimation methods. For a description of the methods used to estimate the number of sources, see the `aictest` or `mdltest` functions.

In place of the true sensor covariance matrix, the algorithm computes the sample covariance matrix from the sensor data. MUSIC applies to noncoherent signals but can be extended to coherent signals using *spatial smoothing* and/or *forward-backward averaging* techniques. For a high-level description of the algorithm, see "MUSIC Super-Resolution DOA Estimation".

plotSpectrum

System object: phased.MUSICEstimator
Package: phased

Plot MUSIC spectrum

Syntax

```
plotSpectrum(estimator)
output_args = method(estimator,Name,Value)
lh = plotSpectrum( ___ )
```

Description

`plotSpectrum(estimator)` plots the MUSIC spectrum computed by the most recent `step` method execution for the `phased.MUSICEstimator` System object, `estimator`.

`output_args = method(estimator,Name,Value)` plots the MUSIC spatial spectrum with additional options specified by one or more `Name,Value` pair arguments.

`lh = plotSpectrum( ___ )` returns the line handle to the figure.

Input Arguments

`estimator` — MUSIC estimator

`phased.MUSICEstimator` System object.

MUSIC estimator, specified as a phased.MUSICEstimator System object

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Unit'` — Units used for plotting

`'db'` (default) | `'mag'` | `'pow'`

Units used for plotting, specified as the comma-separated pair consisting of `'Unit'` and `'db'`, `'mag'`, or `'pow'`.

Data Types: `char`

`'NormalizeResponse'` — Plot normalized spectrum

`false` (default) | `true`

Plot a normalized spectrum, specified as the comma-separated pair consisting of `'NormalizedResponse'` and `false` or `true`. Normalization sets the magnitude of the largest spectrum value to one.

Data Types: `char`

`'Title'` — Title of plot

`'MUSIC Spatial Spectrum'` (default) | character vector

Title of plot, specified as a comma-separated pair consisting of `'Title'` and a character vector.

Example: `true`

Data Types: `char`

Output Arguments

`lh` — Line handle of plot

line handle

Line handle of plot.

Examples

Plot MUSIC Spectrum of Two Signals Arriving at ULA

Estimate the DOAs of two signals received by a standard 10-element ULA having an element spacing of 1 meter. Then plot the MUSIC spectrum.

Note: You can replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Create the ULA array. The antenna operating frequency is 150 MHz.

```
fc = 150.0e6;
array = phased.ULA('NumElements',10,'ElementSpacing',1.0);
```

Create the arriving signals at the ULA. The true direction of arrival of the first signal is 10° in azimuth and 20° in elevation. The direction of the second signal is 60° in azimuth and -5° in elevation.

```
fs = 8000.0;
t = (0:1/fs:1).';
sig1 = cos(2*pi*t*300.0);
sig2 = cos(2*pi*t*400.0);
sig = collectPlaneWave(array,[sig1 sig2],[10 20; 60 -5]',fc);
noise = 0.1*(randn(size(sig)) + 1i*randn(size(sig)));
```

Estimate the DOAs.

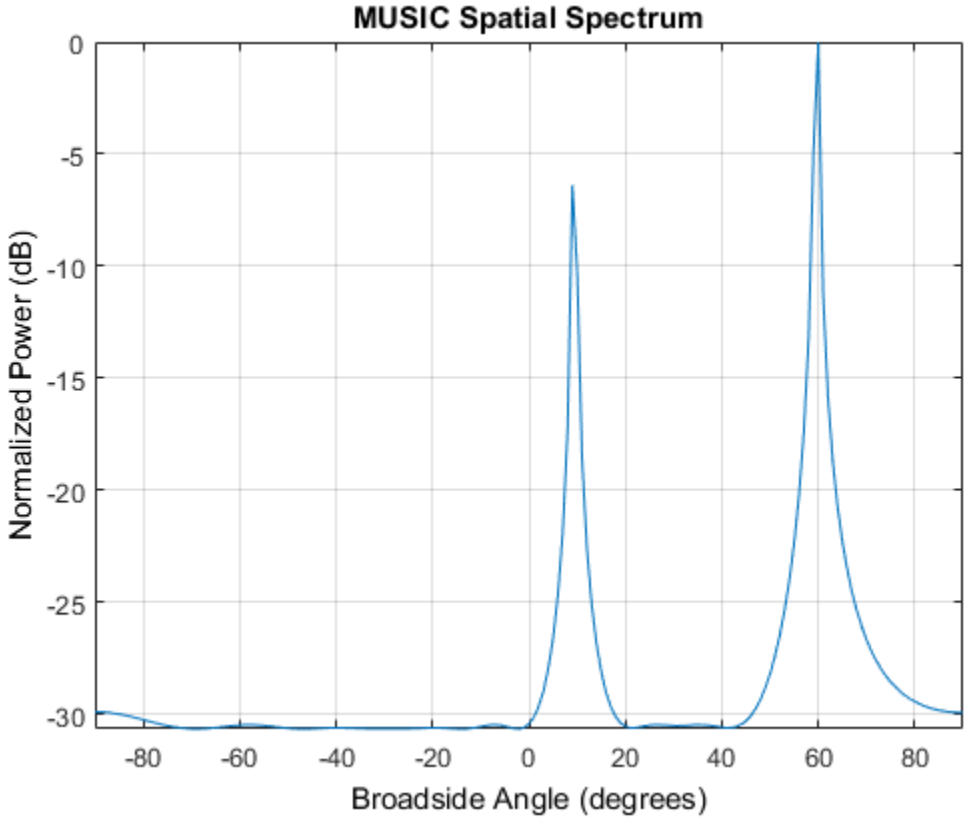
```
estimator = phased.MUSICEstimator('SensorArray',array,...
    'OperatingFrequency',fc,...
    'DOAOutputPort',true,'NumSignalsSource','Property',...
    'NumSignals',2);
[y,doas] = estimator(sig + noise);
doas = broadside2az(sort(doas),[20 -5])
```

```
doas =

    9.5829   60.3813
```

Plot the MUSIC spectrum.

```
plotSpectrum(estimator,'NormalizeResponse',true)
```



Introduced in R2016b

reset

System object: phased.MUSICEstimator
Package: phased

Reset states of System object

Syntax

```
reset(estimator)
```

Description

`reset(estimator)` resets the internal state of the `phased.MUSICEstimator` System object, `estimator`.

Input Arguments

`estimator` — MUSIC estimator

`phased.MUSICEstimator` System object

MUSIC estimator, specified as a phased.MUSICEstimator System object.

Introduced in R2016b

step

System object: phased.MUSICEstimator
Package: phased

Estimate direction of arrival using MUSIC

Syntax

```
spectrum = step(estimator,sig)
[spectrum,doa] = step(estimator,sig)
```

Description

Note: Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`spectrum = step(estimator,sig)` returns the MUSIC spectrum for a signal specified by `sig`.

`[spectrum,doa] = step(estimator,sig)` also returns the signal broadside directions of arrival, `doa`. To use this syntax, set the `DOAOutputPort` property to `true`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`estimator` — MUSIC estimator

`phased.MUSICEstimator` System object

MUSIC estimator, specified as a phased.MUSICEstimator System object.

Example: `phased.MUSICEstimator`

`sig` — Received signal

M-by-*N* complex-valued matrix

Received signal, specified as an *M*-by-*N* complex-valued matrix. The quantity *M* is the number of sample values (snapshots) contained in the signal, and *N* is the number of sensor elements in the array.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Example: `[[0;1;2;3;4;3;2;1;0],[1;2;3;4;3;2;1;0;0]]`

Data Types: `double`
Complex Number Support: Yes

Output Arguments

`spectrum` — MUSIC spatial spectrum

nonnegative, real-valued *K*-length column vector

MUSIC spatial spectrum, returned as a non-negative, real-valued *K*-length column vector representing the magnitude of the estimated MUSIC spatial spectrum. Each entry corresponds to an angle specified by the `ScanAngles` property.

`doa` — Directions of arrival

real-valued *L*-length row vector

Directions of arrival of the signals, returned as a real-valued *L*-length row vector. The direction of arrival angle is the angle between the source direction and the array axis or broadside angle. Angle units are in degrees. *L* is the number of signals specified by the `NumSignals` property or computed using the method specified by the `NumSignalsMethod` property.

Dependencies

To enable this output argument, set the `DOAOutputPort` property to `true`.

Examples

Plot MUSIC Spectrum of Two Signals Arriving at ULA

Estimate the DOAs of two signals received by a standard 10-element ULA having an element spacing of 1 meter. Then plot the MUSIC spectrum.

Note: You can replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Create the ULA array. The antenna operating frequency is 150 MHz.

```
fc = 150.0e6;
array = phased.ULA('NumElements',10,'ElementSpacing',1.0);
```

Create the arriving signals at the ULA. The true direction of arrival of the first signal is 10° in azimuth and 20° in elevation. The direction of the second signal is 60° in azimuth and -5° in elevation.

```
fs = 8000.0;
t = (0:1/fs:1).';
sig1 = cos(2*pi*t*300.0);
sig2 = cos(2*pi*t*400.0);
sig = collectPlaneWave(array,[sig1 sig2],[10 20; 60 -5]',fc);
noise = 0.1*(randn(size(sig)) + 1i*randn(size(sig)));
```

Estimate the DOAs.

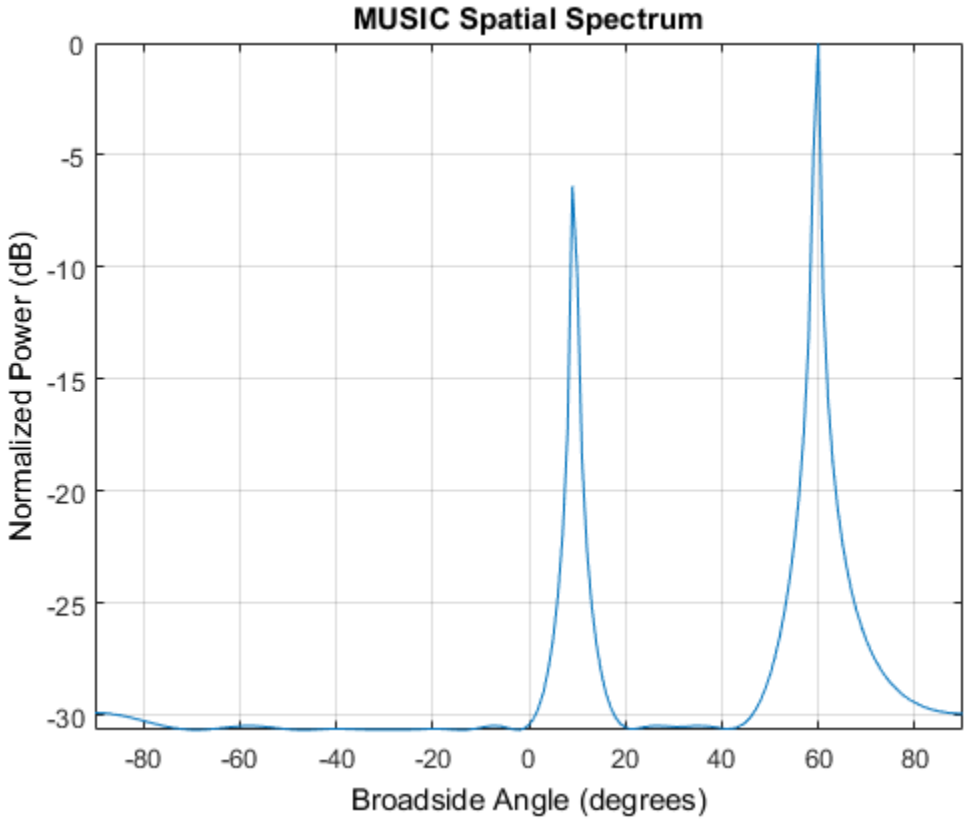
```
estimator = phased.MUSICEstimator('SensorArray',array,...
    'OperatingFrequency',fc,...
    'DOAOutputPort',true,'NumSignalsSource','Property',...
    'NumSignals',2);
[y,doas] = estimator(sig + noise);
doas = broadside2az(sort(doas),[20 -5])
```

```
doas =

    9.5829   60.3813
```

Plot the MUSIC spectrum.

```
plotSpectrum(estimator,'NormalizeResponse',true)
```



Compute DOA of Two Nearby Signals Using MUSIC

First, estimate the DOAs of two signals received by a standard 10-element ULA having an element spacing of one-half wavelength.Then, plot the spatial spectrum.

Note: You can replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

The antenna operating frequency is 150 MHz. The arrival directions of the two signals are separated by 2°. The direction of the first signal is 30° azimuth and 0° elevation. The direction of the second signal is 32° azimuth and 0° elevation. Estimate the number of signals using the Minimum Description Length (MDL) criterion.

Create the signals arriving at the ULA.

```
fs = 8000;
t = (0:1/fs:1).';
f1 = 300.0;
f2 = 600.0;
sig1 = cos(2*pi*t*f1);
sig2 = cos(2*pi*t*f2);
fc = 150.0e6;
c = physconst('LightSpeed');
lam = c/fc;
array = phased.ULA('NumElements',10,'ElementSpacing',0.5*lam);
sig = collectPlaneWave(array,[sig1 sig2],[30 0; 32 0]',fc);
noise = 0.1*(randn(size(sig)) + 1i*randn(size(sig)));
```

Estimate the DOAs.

```
estimator = phased.MUSICEstimator('SensorArray',array,...
    'OperatingFrequency',fc,'DOAOutputPort',true,...
    'NumSignalsSource','Auto','NumSignalsMethod','MDL');
[y,doas] = estimator(sig + noise);
doas = broadside2az(sort(doas),[0 0])
```

```
doas =

   30.0000   32.0000
```

Plot the MUSIC spectrum.

```
plotSpectrum(estimator,'NormalizeResponse',true)
```

phased.MUSICEstimator2D System object

Package: phased

Estimate 2D direction of arrival using narrowband MUSIC algorithm

Description

The `phased.MUSICEstimator2D` System object implements the narrowband multiple signal classification (*MUSIC*) algorithm for 2-D planar or 3-D arrays such as a uniform rectangular array (URA). MUSIC is a high-resolution direction-finding algorithm capable of resolving closely-spaced signal sources. The algorithm is based on the eigenspace decomposition of the sensor covariance matrix.

To estimate directions of arrival (DOA):

1. Define and set up a `phased.MUSICEstimator2D` System object. See "Construction" on page 1-1269.
2. Call the step method to estimate the DOAs according to the properties of `phased.MUSICEstimator2D`.

Note: Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`estimator = phased.MUSICEstimator2D` creates a MUSIC DOA estimator System object, `estimator`.

`estimator = phased.MUSICEstimator2D(Name,Value)` creates a System object, `estimator`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`SensorArray` — Sensor array

Phased Array System Toolbox array System object

Sensor array, specified as a Phased Array System Toolbox array System object.

Example: `phased.URA`

`PropagationSpeed` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. Units are in m/s. The default value of the speed of light is the value returned by `physconst('LightSpeed')`.

Example: `3e8`

Data Types: `double`

`OperatingFrequency` — Signal carrier frequency

`300e6` (default) | positive real-valued scalar

Signal carrier frequency, specified as a positive real-valued scalar. Units are in Hz.

Example: `1e9`

Data Types: `double`

`ForwardBackwardAveraging` — Enable forward-backward averaging

`false` (default) | `true`

Enable forward-backward averaging, specified as `false` or `true`. Set this property to `true` to use forward-backward averaging to estimate the covariance matrix for sensor arrays with a conjugate symmetric array manifold.

Data Types: `logical`

`AzimuthScanAngles` — Azimuth scan angles

`[-90:90]` (default) | real-valued scalar | real-valued row vector

Azimuth scan angles, specified as a real-valued scalar or real-valued row vector. Angle units are in degrees. The angle values must lie between –180° and 180°, inclusive, and be in ascending order.

Example: `[-30:20]`

Data Types: `double`

`ElevationScanAngles` — Elevation scan angles

`0` (default) | real-valued scalar | real-valued row vector

Elevation scan angles, specified as a real-valued scalar or real-valued row vector. Angle units are in degrees. The angle values must lie between –90° and 90°, inclusive, and be in ascending order.

Example: `[-70:75]`

Data Types: `double`

`DOAOutputPort` — Enable directions of arrival output

`false` (default) | `true`

Option to enable directions-of-arrival (DOA) output, specified as `false` or `true`. To obtain the DOAs of signals, set this property to `true`. The DOAs are returned in the second output argument of the `step` method.

Data Types: `logical`

`NumSignalsSource` — Source of number of signals

`'Auto'` (default) | `'Property'`

Source of the number of arriving signals, specified as `'Auto'` or `'Property'`.

- `'Auto'` — The System object estimates the number of arriving signals using the method specified in the `NumSignalsMethod` property.
- `'Property'` — Specify the number of arriving signals using the `NumSignals` property.

Data Types: `char`

`NumSignalsMethod` — Method used to estimate number of arriving signals

`'AIC'` (default) | `'MDL'`

Method used to estimate the number of arriving signals, specified as `'AIC'` or `'MDL'`.

- `'AIC'` — Akaike Information Criterion
- `'MDL'` — Minimum Description Length criterion

Dependencies

To enable this property, set `NumSignalsSource` to `'Auto'`.

Data Types: `char`

`NumSignals` — Number of arriving signals

1 (default) | positive integer

Number of arriving signals, specified as a positive integer.

Example: 3

Dependencies

To enable this property, set `NumSignalsSource` to `'Property'`.

Data Types: `double`

Methods

plotSpectrum	Plot 2-D MUSIC spectrum
reset	Reset states of System object
step	Estimate direction of arrival using 2-D MUSIC

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Estimate DOAs of Two Signals

Assume that two sinusoidal waves of frequencies 450 Hz and 600 Hz strike a URA from two different directions. Signals arrive from -37° azimuth, 0° elevation and 17° azimuth, 20° elevation. Use 2-D MUSIC to estimate the directions of arrival of the two signals. The array operating frequency is 150 MHz and the signal sampling frequency is 8 kHz.

```
f1 = 450.0;
f2 = 600.0;
doa1 = [-37;0];
doa2 = [17;20];
fc = 150e6;
c = physconst('LightSpeed');
lam = c/fc;
fs = 8000;
```

Create the URA with default isotropic elements. Set the frequency response range of the elements.

```
array = phased.URA('Size',[11 11],'ElementSpacing',[lam/2 lam/2]);
array.Element.FrequencyRange = [50.0e6 500.0e6];
```

Create the two signals and add random noise.

```
t = (0:1/fs:1).';
x1 = cos(2*pi*t*f1);
x2 = cos(2*pi*t*f2);
x = collectPlaneWave(array,[x1 x2],[doa1,doa2],fc);
noise = 0.1*(randn(size(x))+1i*randn(size(x)));
```

Create and execute the 2-D MUSIC estimator to find the directions of arrival.

```
estimator = phased.MUSICEstimator2D('SensorArray',array,...
    'OperatingFrequency',fc,...
    'NumSignalsSource','Property',...
    'DOAOutputPort',true,'NumSignals',2,...
    'AzimuthScanAngles',-50:.5:50,...
    'ElevationScanAngles',-30:.5:30);
[~,doas] = estimator(x + noise)

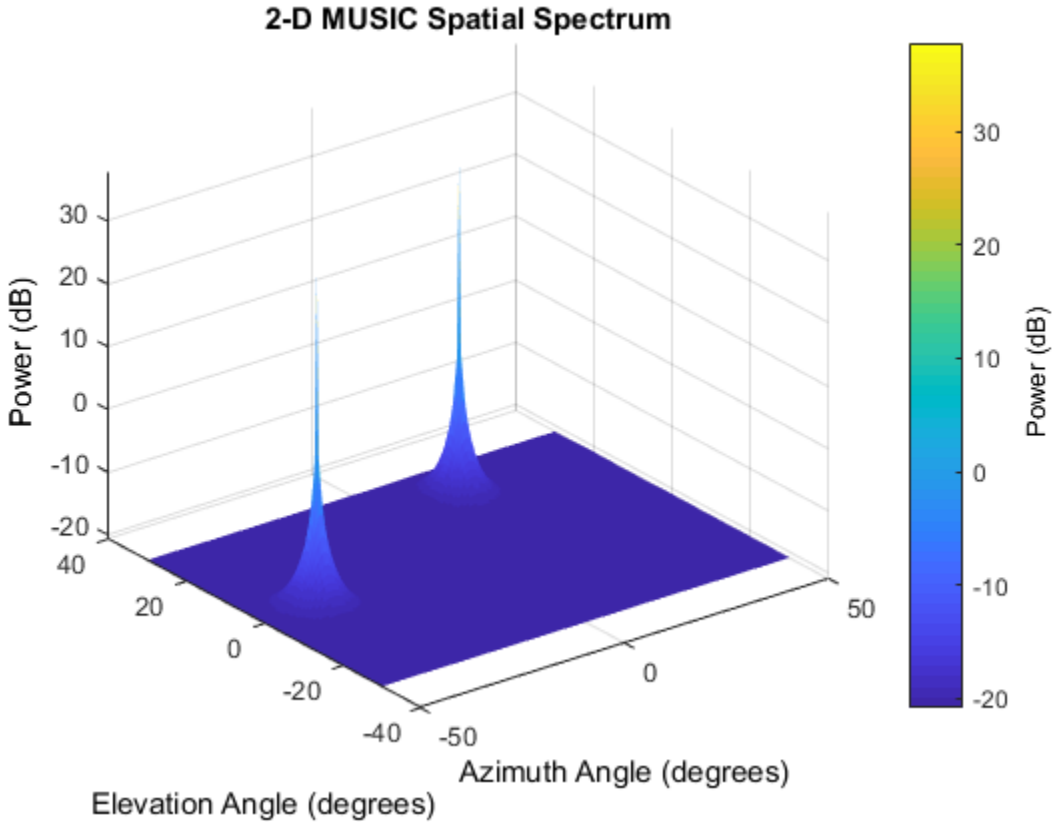
doas =
```

```
   -37    17
     0    20
```

The estimated DOAs exactly match the true DOAs.

Plot the 2-D spatial spectrum

```
plotSpectrum(estimator);
```



Estimate DOAs of Two Signals at Disk Array

Assume that two sinusoidal waves of frequencies 1.6 kHz and 1.8 kHz strike a disk array from two different directions. The spacing between elements of the disk is 1/2

wavelength. Signals arrive from -31° azimuth, -11° elevation and 35° azimuth, 55° elevation. Use 2-D MUSIC to estimate the directions of arrival of the two signals. The array operating frequency is 300 MHz and the signal sampling frequency is 8 kHz.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
f1 = 1.6e3;
f2 = 1.8e3;
doa1 = [-31;-11];
doa2 = [35;55];
fc = 300e6;
c = physconst('LightSpeed');
lam = c/fc;
fs = 8.0e3;
```

Create a conformal array with default isotropic elements. First, create a URA to get the element positions.

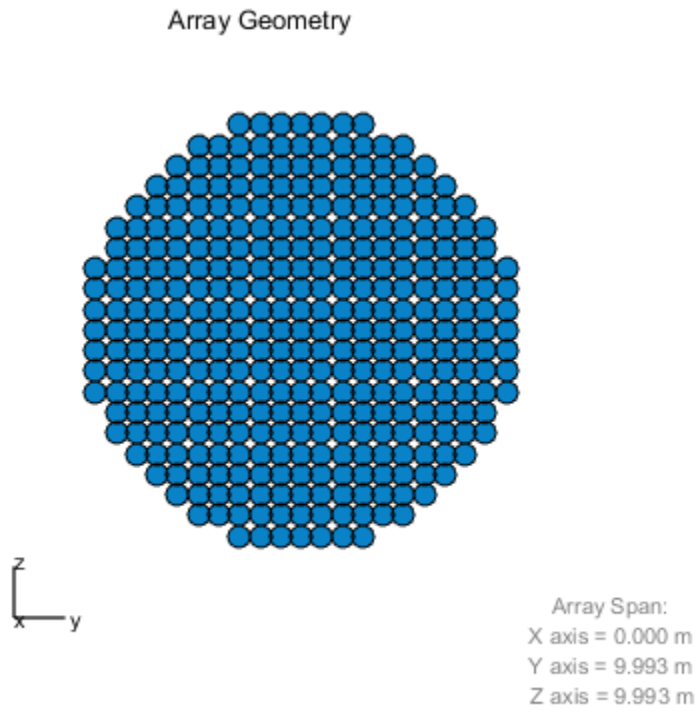
```
uraarray = phased.URA('Size',[21 21],'ElementSpacing',[lam/2 lam/2]);
pos = getElementPosition(uraarray);
```

Extract a subset of these to form an inscribed disk.

```
radius = 10.5*lam/2;
pos(:,sum(pos.^2) > radius^2) = [];
```

Then, create the conformal array using these positions.

```
confarray = phased.ConformalArray('ElementPosition',pos);
viewArray(confarray)
```



Set the frequency response range of the elements.

```
confarray.Element.FrequencyRange = [50.0e6 600.0e6];
```

Create the two signals and add random noise.

```
t = (0:1/fs:1.5).';
x1 = cos(2*pi*t*f1);
x2 = cos(2*pi*t*f2);
x = collectPlaneWave(confarray,[x1 x2],[doa1,doa2],fc);
noise = 0.1*(randn(size(x)) + 1i*randn(size(x)));
```

Create and execute the 2-D MUSIC estimator to find the directions of arrival.

```
estimator = phased.MUSICEstimator2D('SensorArray',confarray,...
```

```
    'OperatingFrequency',fc,...
    'NumSignalsSource','Property',...
    'DOAOutputPort',true,'NumSignals',2,...
    'AzimuthScanAngles',-60:.1:60,...
    'ElevationScanAngles',-60:.1:60);
[~,doas] = estimator(x + noise)

doas =

    35   -31
    55   -11
```

The estimated DOAs exactly match the true DOAs.

Plot the 2-D spatial spectrum

```
plotSpectrum(estimator);
```

MUSIC Algorithm

MUSIC stands for *MUltiple SIgnal Classification*. MUSIC is a high-resolution direction-finding algorithm that estimates directions of arrival (DOA) of signals at an array from the covariance matrix of array sensor data. MUSIC belongs to the subspace-decomposition family of direction-finding algorithms. Unlike conventional beamforming, *MUSIC* can resolve closely-spaced signal sources.

Based on eigenspace decomposition of the sensor covariance matrix, MUSIC divides the observation space into orthogonal signal and noise subspaces. Eigenvectors corresponding to the largest eigenvalues span the signal subspace. Eigenvectors corresponding to the smaller eigenvalues span the noise subspace. Because arrival (or steering) vectors lie in the signal subspace, they are orthogonal to the noise subspace. The arrival vectors depend on the direction of arrival of a signals. For a 2-D or 3-D array. the directions are determined by the azimuth and elevation of the sources. By searching over a grid of arrival angles, the algorithm finds those arrival vectors whose projection into the noise subspace is zero or at least very small.

MUSIC requires that the number of source signals is known. The algorithm degrades if the number of specified sources does not match the actual number of sources. Generally, you must provide an estimate of the number of sources or use one of the built-in source number estimation methods. For a description of the methods used to estimate the number of sources, see the `aictest` or `mdltest` functions.

In place of the true sensor covariance matrix, the algorithm computes the sample covariance matrix from the sensor data. MUSIC applies to noncoherent signals but can be extended to coherent signals using *forward-backward averaging* techniques. For a high-level description of the algorithm, see "MUSIC Super-Resolution DOA Estimation".

plotSpectrum

System object: phased.MUSICEstimator2D
Package: phased

Plot 2-D MUSIC spectrum

Syntax

```
plotSpectrum(estimator)
output_args = method(estimator,Name,Value)
lh = plotSpectrum( ___ )
```

Description

`plotSpectrum(estimator)` plots the 2-D MUSIC spatial spectrum computed by the most recent `step` method execution for the `phased.MUSICEstimator2D`, `estimator`.

`output_args = method(estimator,Name,Value)` plots the 2-D MUSIC spatial spectrum with additional options specified by one or more `Name,Value` pair arguments.

`lh = plotSpectrum( ___ )` returns the line handle to the figure.

Input Arguments

`estimator` — 2-D MUSIC estimator

`phased.MUSICEstimator2D` System object

2-D MUSIC estimator, specified as a phased.MUSICEstimator2D System object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Unit'` — Units used for plotting

`'db'` (default) | `'mag'` | `'pow'`

Units used for plotting, specified as the comma-separated pair consisting of `'Unit'` and `'db'`, `'mag'`, or `'pow'`.

Example:

Data Types: `char`

`'NormalizeResponse'` — Plot normalized spectrum

`false` (default) | `true`

Plot a normalized spectrum, specified as the comma-separated pair consisting of `'NormalizedResponse'` and `false` or `true`. Normalization sets the magnitude of the largest spectrum value to one.

Example: `true`

Data Types: `char`

`'Title'` — Title of plot

`'2D MUSIC Spatial Spectrum'` (default) | character vector

Title of plot, specified as a comma-separated pair consisting of `'Title'` and a character vector.

Example: `true`

Data Types: `char`

Output Arguments

`lh` — Line handle of plot

line handle

Line handle of plot.

step

System object: phased.MUSICEstimator2D
Package: phased

Estimate direction of arrival using 2-D MUSIC

Syntax

```
spectrum = step(estimator,sig)
[spectrum,doa] = step(estimator,sig)
```

Description

Note: Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`spectrum = step(estimator,sig)` returns the 2-D MUSIC spectrum of a signal specified in `sig`.

`[spectrum,doa] = step(estimator,sig)` also returns the signal directions of arrival angles, `doa`. To use this syntax, set the `DOAOutputPort` property to `true`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`estimator` — 2-D MUSIC estimator

`phased.MUSICEstimator2D` System object

2-D MUSIC estimator, specified as a phased.MUSICEstimator2D System object.

`sig` — Received signal

M-by-*N* complex-valued matrix

Received signal, specified as an *M*-by-*N* complex-valued matrix. The quantity *M* is the number of sample values (snapshots) contained in the signal and *N* is the number of sensor elements in the array.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Example: `[[0;1;2;3;4;3;2;1;0],[1;2;3;4;3;2;1;0;0]]`

Data Types: `double`
Complex Number Support: Yes

Output Arguments

`spectrum` — 2-D MUSIC spatial spectrum

nonnegative, real-valued *K*-length column vector

2-D MUSIC spatial spectrum, returned as a nonnegative, real-valued *K*-length column vector representing the magnitude of the estimated MUSIC spatial spectrum. Each entry corresponds to an angle specified by the `AzimuthScanAngles` and `ElevationScanAngles` properties.

`doa` — Directions of arrival

real-valued 2-by-*L* matrix

Directions of arrival of the signals, returned as a real-valued 2-by-*L* matrix. The direction of arrival angle is defined by the azimuth and elevation angles of the source with respect to the array local coordinate system. The first row of the matrix contains the azimuth angles and the second row contains the elevation angles. Angle units are in degrees. *L* is

the number of signals specified by the `NumSignals` property or derived using the method specified by the `NumSignalsMethod` property.

Dependencies

To enable this output argument, set the `DOAOutputPort` property to `true`.

Examples

Estimate DOAs of Two Signals

Assume that two sinusoidal waves of frequencies 450 Hz and 600 Hz strike a URA from two different directions. Signals arrive from -37° azimuth, 0° elevation and 17° azimuth, 20° elevation. Use 2-D MUSIC to estimate the directions of arrival of the two signals. The array operating frequency is 150 MHz and the signal sampling frequency is 8 kHz.

```
f1 = 450.0;
f2 = 600.0;
doa1 = [-37;0];
doa2 = [17;20];
fc = 150e6;
c = physconst('LightSpeed');
lam = c/fc;
fs = 8000;
```

Create the URA with default isotropic elements. Set the frequency response range of the elements.

```
array = phased.URA('Size',[11 11],'ElementSpacing',[lam/2 lam/2]);
array.Element.FrequencyRange = [50.0e6 500.0e6];
```

Create the two signals and add random noise.

```
t = (0:1/fs:1).';
x1 = cos(2*pi*t*f1);
x2 = cos(2*pi*t*f2);
x = collectPlaneWave(array,[x1 x2],[doa1,doa2],fc);
noise = 0.1*(randn(size(x))+1i*randn(size(x)));
```

Create and execute the 2-D MUSIC estimator to find the directions of arrival.

```
estimator = phased.MUSICEstimator2D('SensorArray',array,...
    'OperatingFrequency',fc,...
    'NumSignalsSource','Property',...
    'DOAOutputPort',true,'NumSignals',2,...
    'AzimuthScanAngles',-50:.5:50,...
    'ElevationScanAngles',-30:.5:30);
[~,doas] = estimator(x + noise)
```

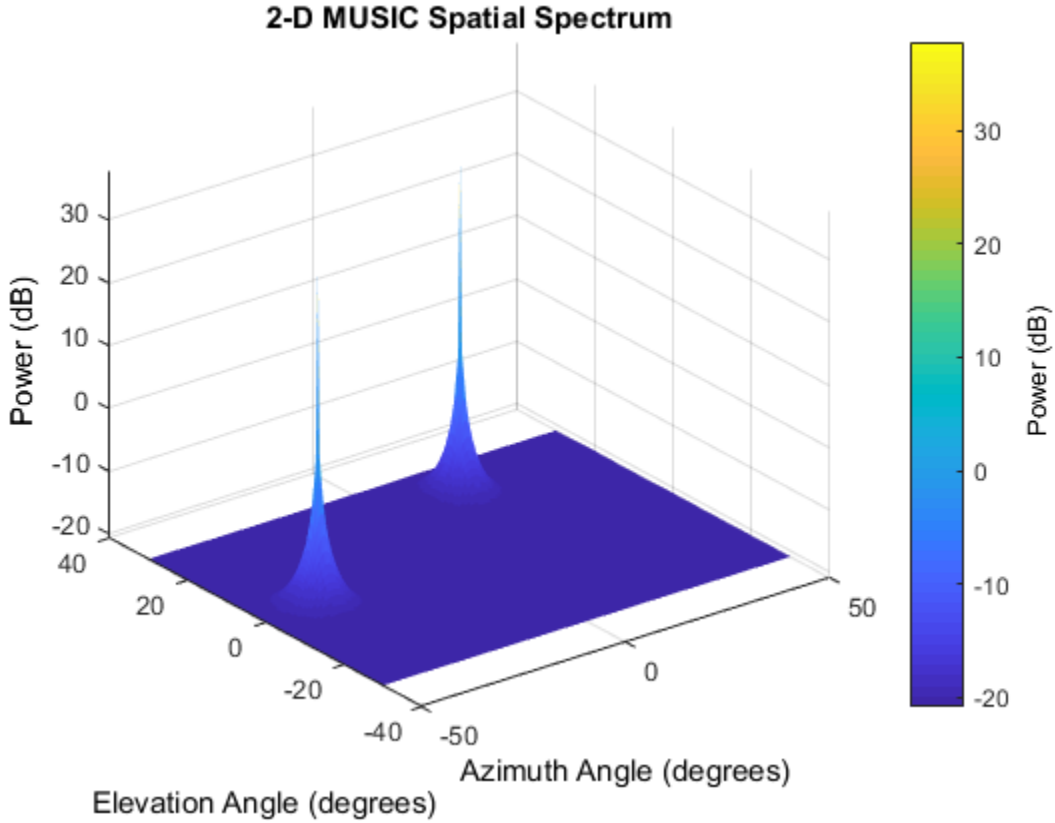
```
doas =

   -37    17
     0    20
```

The estimated DOAs exactly match the true DOAs.

Plot the 2-D spatial spectrum

```
plotSpectrum(estimator);
```



Estimate DOAs of Two Signals at Disk Array

Assume that two sinusoidal waves of frequencies 1.6 kHz and 1.8 kHz strike a disk array from two different directions. The spacing between elements of the disk is 1/2 wavelength. Signals arrive from -31° azimuth, -11° elevation and 35° azimuth, 55° elevation. Use 2-D MUSIC to estimate the directions of arrival of the two signals. The array operating frequency is 300 MHz and the signal sampling frequency is 8 kHz.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
f1 = 1.6e3;
```

```
f2 = 1.8e3;
doa1 = [-31;-11];
doa2 = [35;55];
fc = 300e6;
c = physconst('LightSpeed');
lam = c/fc;
fs = 8.0e3;
```

Create a conformal array with default isotropic elements. First, create a URA to get the element positions.

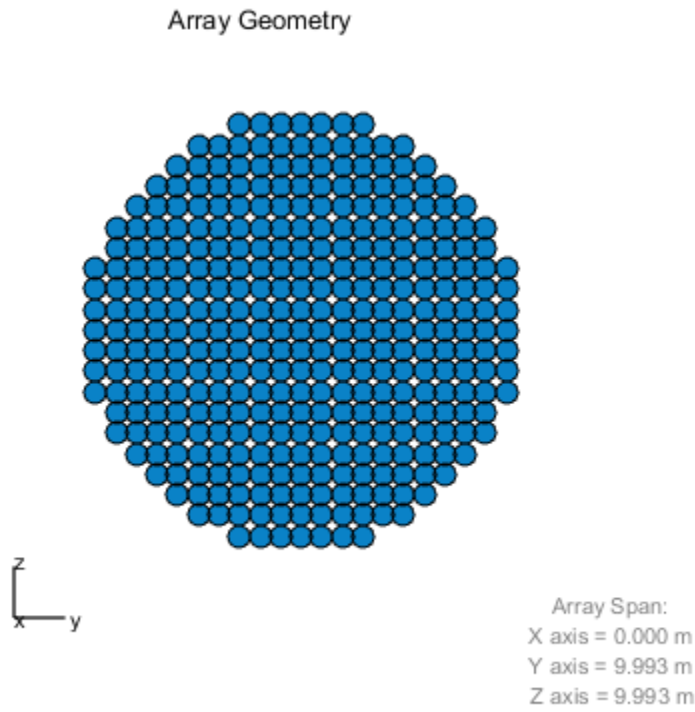
```
uraarray = phased.URA('Size',[21 21],'ElementSpacing',[lam/2 lam/2]);
pos = getElementPosition(uraarray);
```

Extract a subset of these to form an inscribed disk.

```
radius = 10.5*lam/2;
pos(:,sum(pos.^2) > radius^2) = [];
```

Then, create the conformal array using these positions.

```
confarray = phased.ConformalArray('ElementPosition',pos);
viewArray(confarray)
```



Set the frequency response range of the elements.

```
confarray.Element.FrequencyRange = [50.0e6 600.0e6];
```

Create the two signals and add random noise.

```
t = (0:1/fs:1.5).';
x1 = cos(2*pi*t*f1);
x2 = cos(2*pi*t*f2);
x = collectPlaneWave(confarray,[x1 x2],[doa1,doa2],fc);
noise = 0.1*(randn(size(x)) + 1i*randn(size(x)));
```

Create and execute the 2-D MUSIC estimator to find the directions of arrival.

```
estimator = phased.MUSICEstimator2D('SensorArray',confarray,...
```

```
    'OperatingFrequency',fc,...
    'NumSignalsSource','Property',...
    'DOAOutputPort',true,'NumSignals',2,...
    'AzimuthScanAngles',-60:.1:60,...
    'ElevationScanAngles',-60:.1:60);
[~,doas] = estimator(x + noise)

doas =

    35   -31
    55   -11
```

The estimated DOAs exactly match the true DOAs.

Plot the 2-D spatial spectrum

```
plotSpectrum(estimator);
```

System Objects
phased.MUSICEstimator.step | phased.RootMUSICEstimator.step

Introduced in R2016b

phased.OmnidirectionalMicrophoneElement System object

Package: phased

Omnidirectional microphone

Description

The `OmnidirectionalMicrophoneElement` object models an omnidirectional microphone with an equal response in all directions.

To compute the response of the microphone element for specified directions:

1. Define and set up your omnidirectional microphone element. See "Construction" on page 1-1295.
2. Call step to estimate the microphone response according to the properties of `phased.OmnidirectionalMicrophoneElement`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.OmnidirectionalMicrophoneElement` creates an omnidirectional microphone system object, `H`, that models an omnidirectional microphone element whose response is 1 in all directions.

`H = phased.OmnidirectionalMicrophoneElement(Name,Value)` creates an omnidirectional microphone object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`FrequencyRange`

Operating frequency range

Specify the operating frequency range (in Hz) of the microphone element as a 1x2 row vector in the form of `[LowerBound HigherBound]`. The microphone element has no response outside the specified frequency range.

Default: `[0 1e20]`

`BackBaffled`

Baffle the back of microphone element

Set this property to `true` to baffle the back of the microphone element. In this case, the microphone responses to all azimuth angles beyond +/– 90 degrees from the broadside (0 degree azimuth and elevation) are 0.

When the value of this property is `false`, the back of the microphone element is not baffled.

Default: `false`

Methods

directivity	Directivity of omnidirectional microphone element
isPolarizationCapable	Polarization capability
pattern	Plot omnidirectional microphone element directivity and patterns
patternAzimuth	Plot omnidirectional microphone element directivity or pattern versus azimuth
patternElevation	Plot omnidirectional microphone element directivity or pattern versus elevation

plotResponse	Plot response pattern of microphone
step	Output response of microphone

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

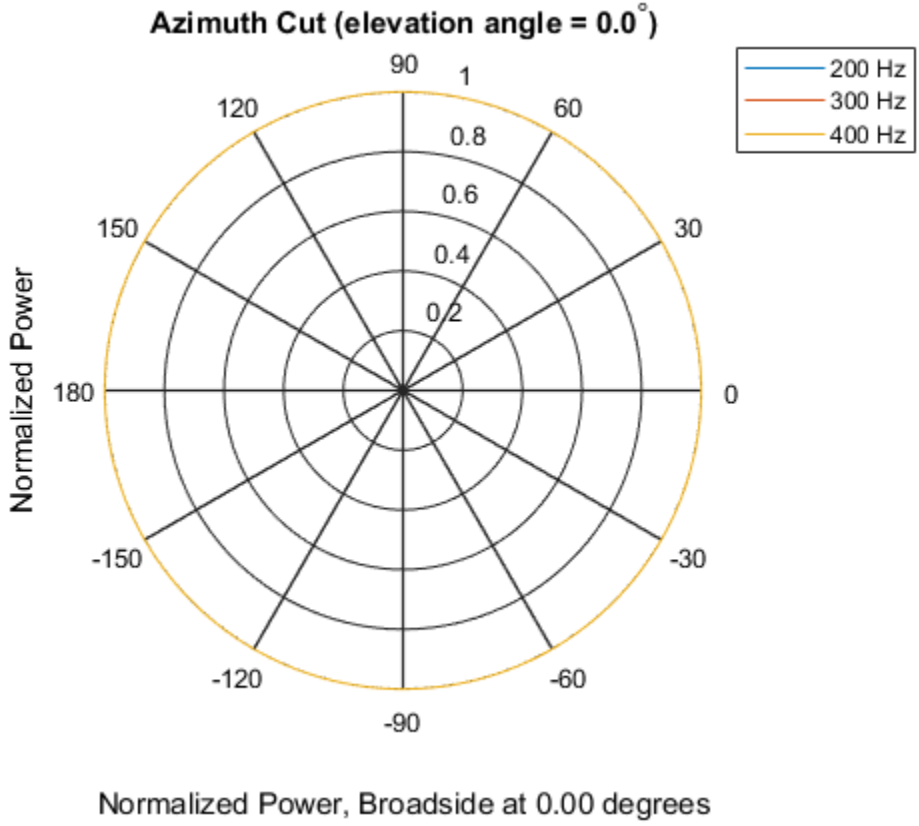
Display Omni-Directional Microphone Pattern

Create an omnidirectional microphone. Find the microphone response at 200, 300, and 400 Hz for the incident angle 0° azimuth and 0° elevation. Then, plot the azimuth response of the microphone at three frequencies.

```
microphone = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[20 2e3]);
fc = [200 300 400];
ang = [0;0];
resp = microphone(fc,ang);
```

Plot the response pattern. Response patterns for all three frequencies are the same.

```
pattern(microphone,fc,[-180:180],0,'CoordinateSystem','polar','Type','power');
```



Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- `pattern`, `patternAzimuth`, `patternElevation`, and `plotResponse` methods are not supported.

- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Introduced in R2012a

directivity

System object: phased.OmnidirectionalMicrophoneElement
Package: phased

Directivity of omnidirectional microphone element

Syntax

```
D = directivity(H,FREQ,ANGLE)
```

Description

`D = directivity(H,FREQ,ANGLE)` returns the "Directivity (dBi)" on page 1-1303 of an omnidirectional microphone element, `H`, at frequencies specified by `FREQ` and in direction angles specified by `ANGLE`.

Input Arguments

`H` — Omnidirectional Microphone Element

System object

Omnidirectional microphone element specified as a phased.OmnidirectionalMicrophoneElement System object.

Example: `H = phased.OmnidirectionalMicrophoneElement`

`FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the

directivity is returned as `-Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.

- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `-Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

`ANGLE` — Angles for computing directivity

1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Angles for computing directivity, specified as a 1-by-*M* real-valued row vector or a 2-by-*M* real-valued matrix, where *M* is the number of angular directions. Angle units are in degrees. If `ANGLE` is a 2-by-*M* matrix, then each column specifies a direction in azimuth and elevation, `[az;el]`. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°.

If `ANGLE` is a 1-by-*M* vector, then each entry represents an azimuth angle, with the elevation angle assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis.

Example: `[45 60; 0 10]`

Data Types: `double`

Output Arguments

`D` — Directivity

M-by-*L* matrix

Directivity, returned as an *M*-by-*L* matrix whose columns contain the directivities at the *M* angles specified by `ANGLE`. Each column corresponds to one of the *L* frequency values specified in `FREQ`. Directivity units are in dBi.

Examples

Directivity of Omnidirectional Microphone Element

Compute the directivity of an omnidirectional microphone element for several different directions.

Create the omnidirectional microphone element system object.

```
myMic = phased.OmnidirectionalMicrophoneElement();
```

Select the angles of interest at constant elevation angle set equal to zero degrees. Select seven azimuth angles centered at boresight (zero degrees azimuth and zero degrees elevation). Finally, set the desired frequency to 1 kHz.

```
ang = [-30,-20,-10,0,10,20,30; 0,0,0,0,0,0,0];
freq = 1000;
```

Compute the directivity along the constant elevation cut.

```
d = directivity(myMic,freq,ang)
```

```
d =

     0
     0
     0
     0
     0
     0
     0
```

Next select the angles of interest to be at constant azimuth angle at zero degrees. All elevation angles are centered around boresight. The five elevation angles range from -20 to +20 degrees. Set the desired frequency to 1 GHz.

```
ang = [0,0,0,0,0; -20,-10,0,10,20];
freq = 1000;
```

Compute the directivity along the constant azimuth cut.

```
d = directivity(myMic,freq,ang)
```

```
d =

     0
     0
     0
     0
     0
```

For an omnidirectional microphone, the directivity is independent of direction.

Definitions

Directivity (dBi)

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\mathrm{rad}}(\theta,\varphi)}{P_{\mathrm{total}}}$$

where $U_{\mathrm{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element directivity” and “Array directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For

Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

phased.OmnidirectionalMicrophoneElement.plotResponse

isPolarizationCapable

System object: phased.OmnidirectionalMicrophoneElement
Package: phased

Polarization capability

Syntax

```
flag = isPolarizationCapable(microphone)
```

Description

`flag = isPolarizationCapable(microphone)` returns a Boolean value, `flag`, indicating whether the phased.OmnidirectionalMicrophoneElement supports polarization. An element supports polarization if it can create or respond to polarized fields. This microphone element, as all microphone elements, does not support polarization.

Input Arguments

`microphone` — Omni-directional microphone element

Omni-directional microphone element specified as a phased.OmnidirectionalMicrophoneElement System object

Output Arguments

`flag` — Polarization-capability flag

Polarization-capability returned as a Boolean value `true` if the microphone element supports polarization or `false` if it does not. Because the phased.OmnidirectionalMicrophoneElement object does not support polarization, `flag` is always returned as `false`.

Examples

Omnidirectional Microphone Element Does Not Support Polarization

Determine whether a `phased.OmnidirectionalMicrophoneElement` microphone element supports polarization.

```
microphone = phased.OmnidirectionalMicrophoneElement;
isPolarizationCapable(microphone)
```

```
ans =

  logical

   0
```

The returned value `0` shows that the omnidirectional microphone element does not support polarization.

pattern

System object: phased.OmnidirectionalMicrophoneElement
Package: phased

Plot omnidirectional microphone element directivity and patterns

Syntax

```
pattern(sElem,FREQ)
pattern(sElem,FREQ,AZ)
pattern(sElem,FREQ,AZ,EL)
pattern( ___ ,Name,Value)
[PAT,AZ_ANG,EL_ANG] = pattern( ___ )
```

Description

`pattern(sElem,FREQ)` plots the 3-D array directivity pattern (in dBi) for the element specified in `sElem`. The operating frequency is specified in `FREQ`.

`pattern(sElem,FREQ,AZ)` plots the element directivity pattern at the specified azimuth angle.

`pattern(sElem,FREQ,AZ,EL)` plots the element directivity pattern at specified azimuth and elevation angles.

`pattern( ___ ,Name,Value)` plots the element pattern with additional options specified by one or more `Name,Value` pair arguments.

`[PAT,AZ_ANG,EL_ANG] = pattern( ___ )` returns the element pattern in `PAT`. The `AZ_ANG` output contains the coordinate values corresponding to the rows of `PAT`. The `EL_ANG` output contains the coordinate values corresponding to the columns of `PAT`. If the `'CoordinateSystem'` parameter is set to `'uv'`, then `AZ_ANG` contains the *U* coordinates of the pattern and `EL_ANG` contains the *V* coordinates of the pattern. Otherwise, they are in angular units in degrees. *UV* units are dimensionless.

Note: This method replaces the `plotResponse` method. See "Convert plotResponse to pattern" on page 1-1316 for guidelines on how to use `pattern` in place of `plotResponse`.

Input Arguments

`sElem` — Omnidirectional microphone element

System object

Omnidirectional microphone element, specified as a phased.OmnidirectionalMicrophoneElement System object.

Example: `sElem = phased.OmnidirectionalMicrophoneElement;`

`FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `-Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `-Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

`AZ` — Azimuth angles

`[-180:180]` (default) | 1-by-*M* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a 1-by-*M* real-valued row vector where *M* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, this angle is positive.

Example: `[-45:2:45]`

Data Types: `double`

`EL` — Elevation angles

`[-90:90]` (default) | 1-by-*N* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a 1-by-*N* real-valued row vector where *N* is the number of desired elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and *xy*-plane. When measured towards the *z*-axis, this angle is positive.

Example: `[-75:1:70]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'CoordinateSystem'` — Plotting coordinate system

`'polar'` (default) | `'rectangular'` | `'uv'`

Plotting coordinate system of the pattern, specified as the comma-separated pair consisting of `'CoordinateSystem'` and one of `'polar'`, `'rectangular'`, or `'uv'`. When `'CoordinateSystem'` is set to `'polar'` or `'rectangular'`, the `AZ` and `EL` arguments specify the pattern azimuth and elevation, respectively. `AZ` values must lie between –180° and 180°. `EL` values must lie between –90° and 90°. If `'CoordinateSystem'` is set to `'uv'`, `AZ` and `EL` then specify *U* and *V* coordinates, respectively. `AZ` and `EL` must lie between -1 and 1.

Example: `'uv'`

Data Types: `char`

'Type' — Displayed pattern type

'directivity' (default) | 'efield' | 'power' | 'powerdb'

Displayed pattern type, specified as the comma-separated pair consisting of 'Type' and one of

- 'directivity' — directivity pattern measured in dBi.
- 'efield' — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- 'power' — power pattern of the sensor or array defined as the square of the field pattern.
- 'powerdb' — power pattern converted to dB.

Example: 'powerdb'

Data Types: char

'Normalize' — Display normalize pattern

true (default) | false

Display normalized pattern, specified as the comma-separated pair consisting of 'Normalize' and a Boolean. Set this parameter to true to display a normalized pattern. When you set 'Type' to 'directivity', this parameter does not apply. Directivity patterns are already normalized.

Example:

Data Types: logical

'PlotStyle' — Plotting style

'overlay' (default) | 'waterfall'

Plotting style, specified as the comma-separated pair consisting of 'Plotstyle' and either 'overlay' or 'waterfall'. This parameter applies when you specify multiple frequencies in FREQ in 2-D plots. You can draw 2-D plots by setting one of the arguments AZ or EL to a scalar.

Example:

Data Types: char

Output Arguments

PAT — Element pattern

M-by-*N* real-valued matrix

Element pattern, returned as an *M*-by-*N* real-valued matrix. The dimensions of PAT correspond to the dimensions of the output arguments AZ_ANG and EL_ANG.

AZ_ANG — Azimuth angles

scalar | 1-by-*M* real-valued row vector

Azimuth angles for displaying directivity or response pattern, returned as a scalar or 1-by-*M* real-valued row vector corresponding to the dimension set in AZ. The rows of PAT correspond to the values in AZ_ANG.

EL_ANG — Elevation angles

scalar | 1-by-*N* real-valued row vector

Elevation angles for displaying directivity or response, returned as a scalar or 1-by-*N* real-valued row vector corresponding to the dimension set in EL. The columns of PAT correspond to the values in EL_ANG.

Examples

Magnitude and Directivity Patterns of Omnidirectional Microphone

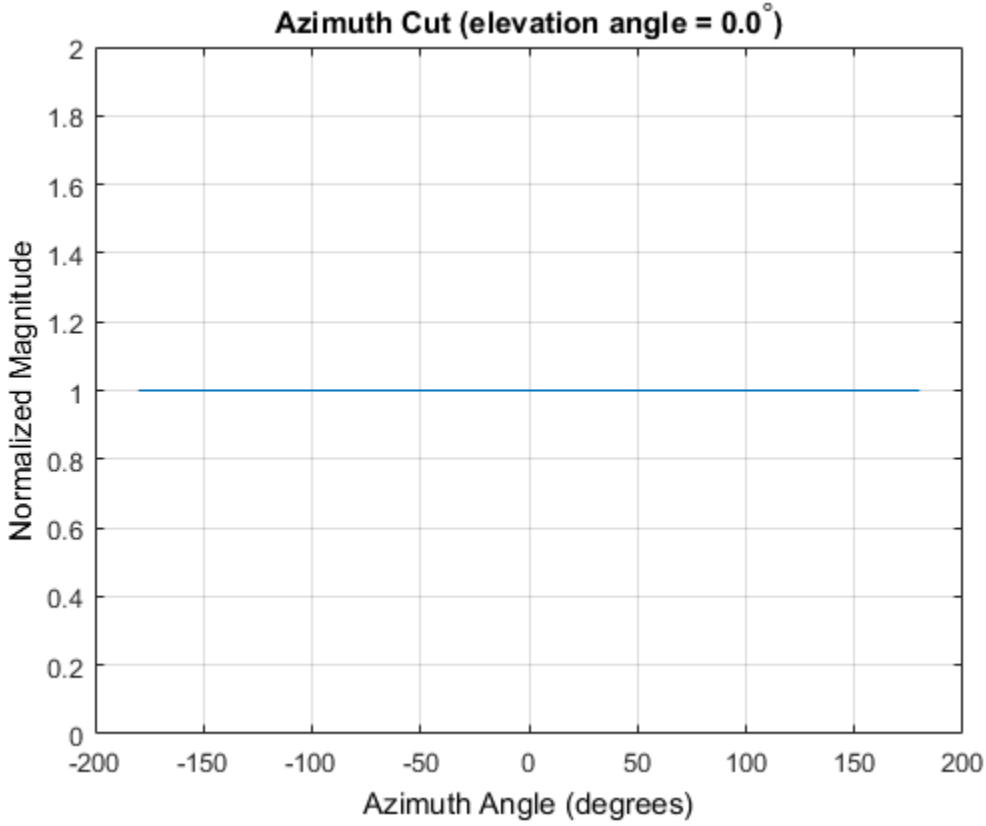
Construct an omnidirectional microphone and plot the magnitude and directivity patterns. The microphone operating frequency spans the range 20 to 20000 Hz.

Construct the omnidirectional microphone.

```
sOmni = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[20 20e3]);
```

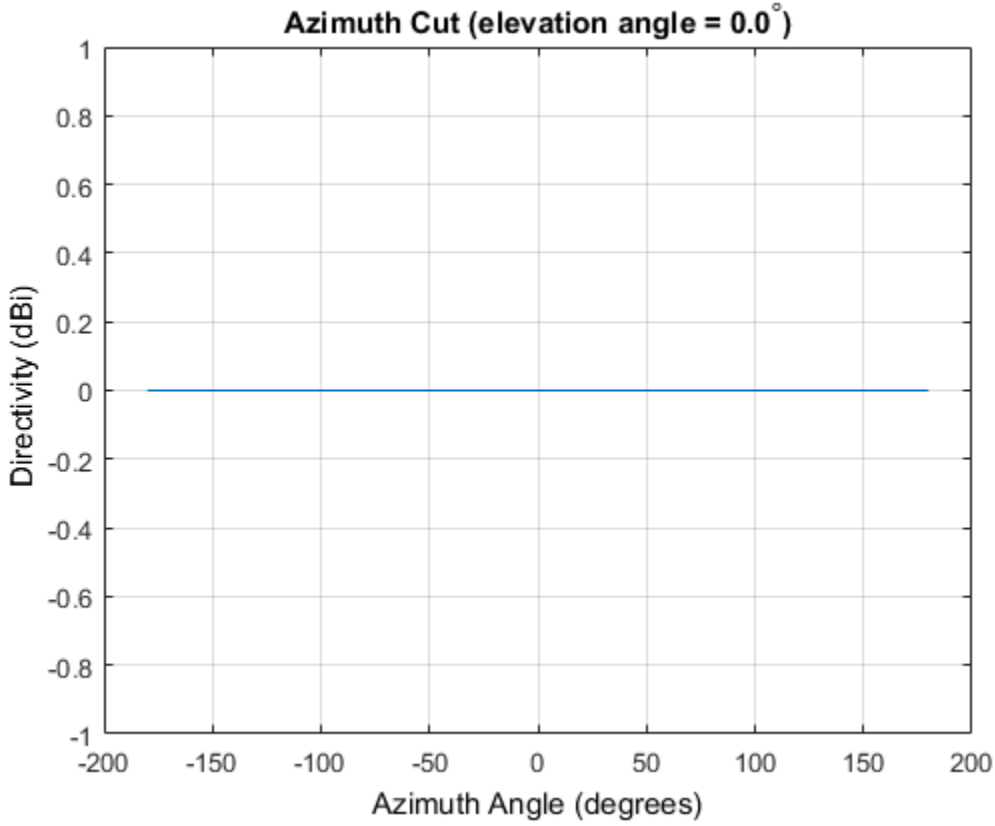
Plot the microphone magnitude pattern at 200 Hz.

```
fc = 200;
pattern(sOmni,fc,[-180:180],0,...
    'CoordinateSystem','rectangular',...
    'Type','efield')
```



Plot the microphone directivity.

```
pattern(sOmni,fc,[-180:180],0,...
    'CoordinateSystem','rectangular',...
    'Type','directivity')
```



The directivity is 0 dbi as expected for an omnidimensional element.

3-D Magnitude Pattern of Omnidirectional Microphone

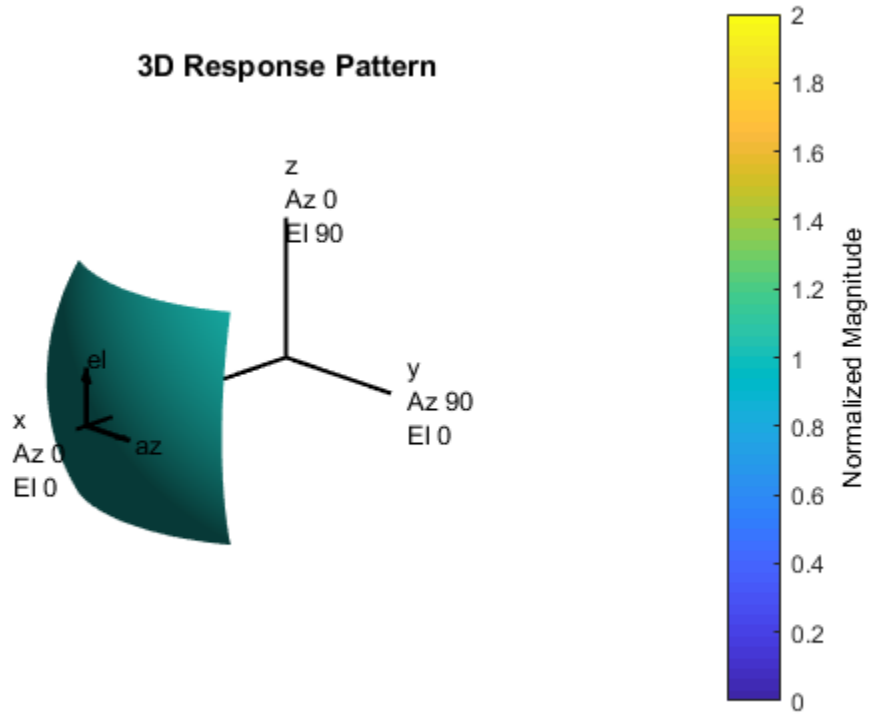
Construct an omnidirection microphone with response in the frequency range 20-20000 Hz. Then, plot the 3-D magnitude pattern over a range of angles.

Construct the microphone element.

```
sOmin = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[20 20e3]);
```

Plot the 3-D pattern at 500 Hz between -30 to 30 degrees in both azimuth and elevation in 0.1 degree increments.

```
fc = 500;
pattern(sOmin,fc,[-30:0.1:30],[-30:0.1:30],...
    'CoordinateSystem','polar',...
    'Type','efield')
```

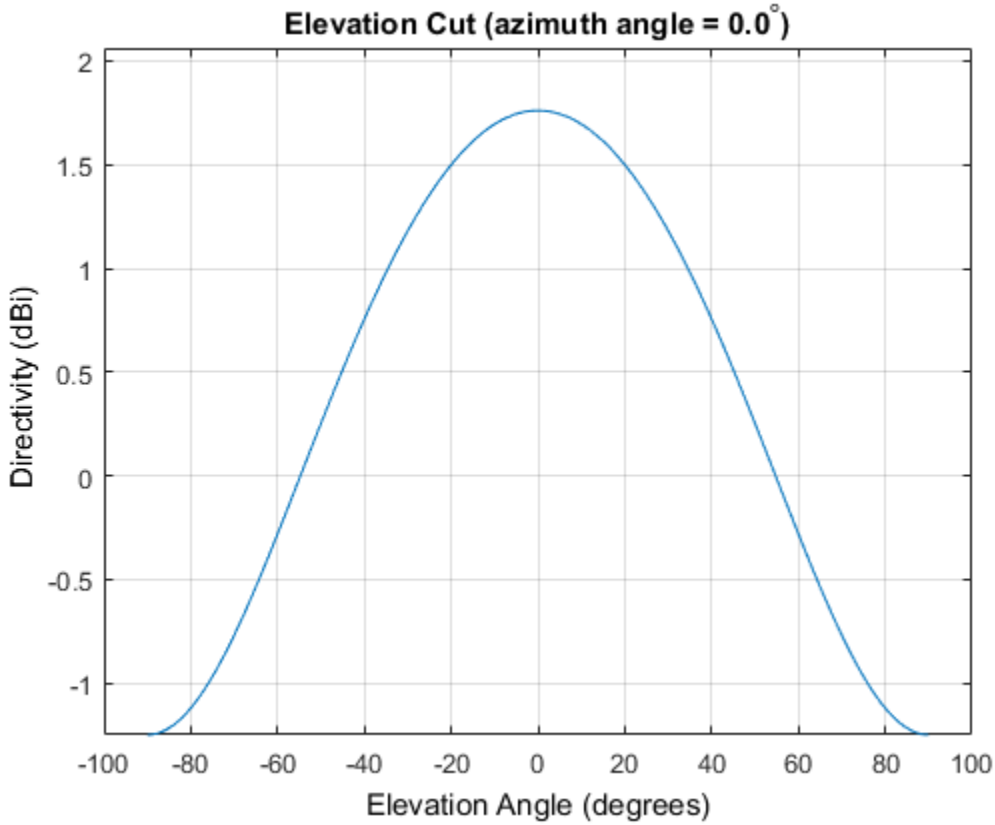


Directivity of Crossed-Dipole Antenna

Create a crossed-dipole antenna. Assume the antenna works between 1 and 2 GHz and its operating frequency is 1.5 GHz. Then, plot an elevation cut of its directivity.

```
sCD = phased.CrossedDipoleAntennaElement('FrequencyRange',[1e9 2e9]);
fc = 1.5e9;
pattern(sCD,fc,0,[-90:90],...
    'Type','directivity',...
```

```
'CoordinateSystem','rectangular')
```



The directivity is maximum at 0 degrees elevation and attains a value of approximately 1.75 dB.

More About

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant

intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on "Element directivity" and "Array directivity".

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

Convert plotResponse to pattern

For antenna, microphone, and array System objects, the `pattern` method replaces the `plotResponse` method. In addition, two new simplified methods exist just to draw 2-D azimuth and elevation pattern plots. These methods are `azimuthPattern` and `elevationPattern`.

The following table is a guide for converting your code from using `plotResponse` to `pattern`. Notice that some of the inputs have changed from *input arguments* to *Name-Value* pairs and conversely. The general `pattern` method syntax is

```
pattern(H,FREQ,AZ,EL,'Name1','Value1',...,'NameN','ValueN')
```

plotResponse Inputs	plotResponse Description	pattern Inputs
`H` argument	Antenna, microphone, or array System object.	`H` argument (no change)

plotResponse Inputs	plotResponse Description	pattern Inputs
`FREQ` argument	Operating frequency.	`FREQ` argument (no change)
`V` argument	Propagation speed. This argument is used only for arrays.	`'PropagationSpeed'` name-value pair. This parameter is only used for arrays.

<table>
<tr><th>plotResponse Inputs</th><th>plotResponse Description</th><th>pattern Inputs</th></tr>
<tr>
<td>'Format' and 'RespCut' name-value pairs</td>
<td>These options work together to let you create a plot in angle space (line or polar style) or UV space. They also determine whether the plot is 2-D or 3-D. This table shows you how to create different types of plots using plotResponse.

When producing a 2-D plot and when 'RespCut' is set to 'Az' or 'El', use 'CutAngle' to set the slice across which to view the plot.</td><td>No equivalent name-value pair. To create a cut, specify either AZ or EL as a scalar, not a vector.</td></tr>
</table>

plotResponse Inputs	plotResponse Description	pattern Inputs
`'NormalizeResponse'` name-value pair	Normalizes the plot. When `'Unit'` is set to `'dbi'`, you cannot specify `'NormalizeResponse'`.	`'Normalize'` name-value pair. When `'Type'` is set to `'directivity'`, you cannot specify `'Normalize'`. .
`'OverlayFreq'` name-value pair	Plot multiple frequencies on the same 2-D plot. Available only when `'Format'` is set to `'line'` or `'uv'` and `'RespCut'` is not set to `'3D'`. The value `true` produces an overlay plot and the value `false` produces a waterfall plot.	`'PlotStyle'` name-value pair plots multiple frequencies on the same 2-D plot. The values `'overlay'` and `'waterfall'` correspond to `'OverlayFreq'` values of `true` and `false`. The option `'waterfall'` is allowed only when `'CoordinateSystem'` is set to `'rectangular'` or `'uv'`.
`'Polarization'` name-value pair	Determines how to plot polarized fields. Options are `'None'`, `'Combined'`, `'H'`, or `'V'`.	`'Polarization'` name-value pair determines how to plot polarized fields. The `'None'` option is removed. The options `'Combined'`, `'H'`, or `'V'` are unchanged.

`'Unit'` name-value pair	Determines the plot units. Choose `'db'`, `'mag'`, `'pow'`, or `'dbi'`, where the default is `'db'`.	`'Type'` name-value pair, uses equivalent options with different names
		
		plotResponse pattern
		`'db'` `'powerdb'`
		`'mag'` `'efield'`
		`'pow'` `'power'`
		`'dbi'` `'directivity'`

`'Weights'` name-value pair	Array element tapers (or weights).	`'Weights'` name-value pair (no change).

plotResponse Inputs	plotResponse Description	pattern Inputs
`'AzimuthAngles'` name-value pair	Azimuth angles used to display the antenna or array response.	`AZ` argument
`'ElevationAngles'` name-value pair	Elevation angles used to display the antenna or array response.	`EL` argument
`'UGrid'` name-value pair	Contains *U* coordinates in *UV*-space.	`AZ` argument when `'CoordinateSystem'` name-value pair is set to `'uv'`
`'VGrid'` name-value pair	Contains *V*-coordinates in *UV*-space.	`EL` argument when `'CoordinateSystem'` name-value pair is set to `'uv'`

phased.OmnidirectionalMicrophoneElement.patternAzimuth |
phased.OmnidirectionalMicrophoneElement.patternElevation

Introduced in R2015a

patternAzimuth

System object: phased.OmnidirectionalMicrophoneElement
Package: phased

Plot omnidirectional microphone element directivity or pattern versus azimuth

Syntax

```
patternAzimuth(sElem,FREQ)
patternAzimuth(sElem,FREQ,EL)
patternAzimuth(sElem,FREQ,EL,Name,Value)
PAT = patternAzimuth( ___ )
```

Description

`patternAzimuth(sElem,FREQ)` plots the 2-D element directivity pattern versus azimuth (in dBi) for the element `sElem` at zero degrees elevation angle. The argument `FREQ` specifies the operating frequency.

`patternAzimuth(sElem,FREQ,EL)`, in addition, plots the 2-D element directivity pattern versus azimuth (in dBi) at the elevation angle specified by `EL`. When `EL` is a vector, multiple overlaid plots are created.

`patternAzimuth(sElem,FREQ,EL,Name,Value)` plots the element pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternAzimuth( ___ )` returns the element pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Azimuth'` parameter and the `EL` input argument.

Input Arguments

`sElem` — Omnidirectional microphone element

System object

Omnidirectional microphone element, specified as a phased.OmnidirectionalMicrophoneElement System object.

Example: `sElem = phased.OmnidirectionalMicrophoneElement;`

`FREQ` — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

`EL` — Elevation angles

1-by-*N* real-valued row vector

Elevation angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector. The quantity *N* is the number of requested elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and the *xy* plane. When measured toward the *z*-axis, this angle is positive.

Example: `[0,10,20]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'Type' — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

'Azimuth' — Azimuth angles

`[-180:180]` (default) | 1-by-*P* real-valued row vector

Azimuth angles, specified as the comma-separated pair consisting of `'Azimuth'` and a 1-by-*P* real-valued row vector. Azimuth angles define where the array pattern is calculated.

Example: `'Azimuth',[-90:2:90]`

Data Types: `double`

Output Arguments

PAT — Element directivity or pattern

L-by-*N* real-valued matrix

Element directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of azimuth values determined by the `'Azimuth'` name-value pair argument. The dimension *N* is the number of elevation angles, as determined by the `EL` input argument.

Examples

Azimuth Pattern of Omnidirectional Microphone Element

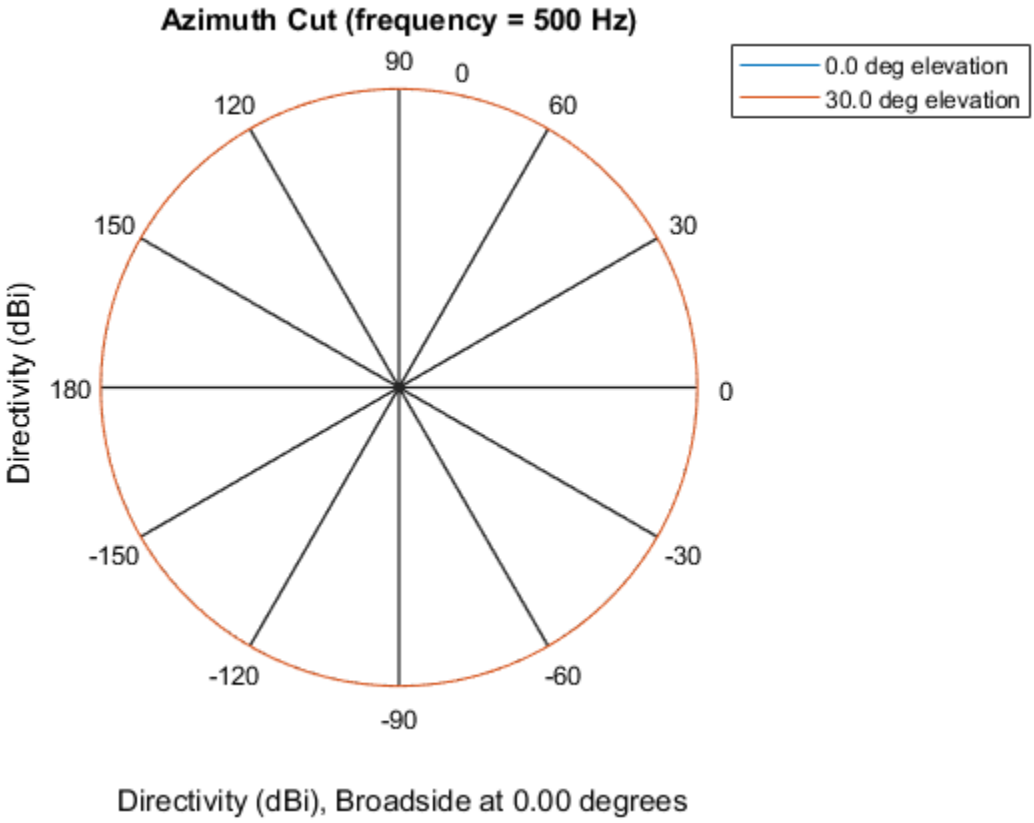
Create an omnidirectional microphone element. Plot an azimuth cut of the directivity at 0 and 30 degrees elevation. Assume an operating frequency of 500 Hz.

Create the microphone element.

```
sOmni = phased.OmnidirectionalMicrophoneElement('FrequencyRange',[100,900]);
fc = 500;
```

Plot the azimuth pattern.

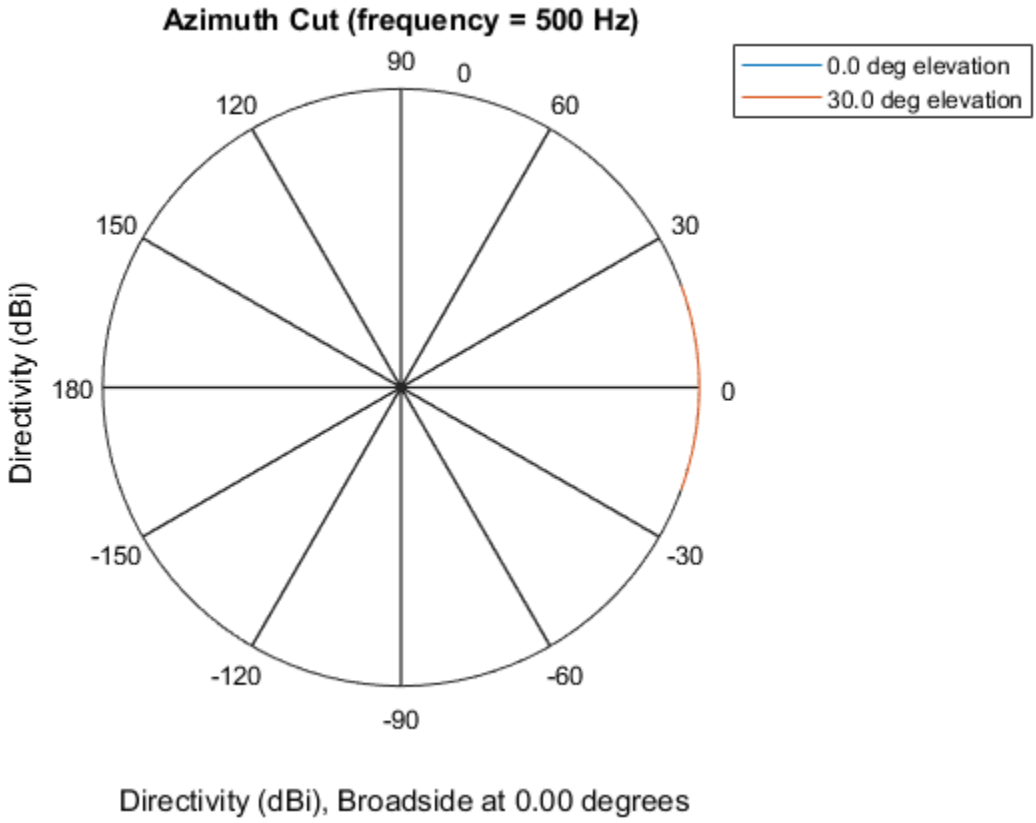
```
patternAzimuth(sOmni,fc,[0 30])
```



Because of the omnidirectionality of the microphone, the two patterns coincide.

Plot a reduced range of azimuth angles using the `Azimuth` parameter.

```
patternAzimuth(sOmni,fc,[0 30],'Azimuth',[-20:20])
```



Definitions

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on "Element directivity" and "Array directivity".

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

phased.OmnidirectionalMicrophoneElement.pattern |
phased.OmnidirectionalMicrophoneElement.patternElevation

Introduced in R2015a

patternElevation

System object: phased.OmnidirectionalMicrophoneElement
Package: phased

Plot omnidirectional microphone element directivity or pattern versus elevation

Syntax

```
patternElevation(sElem,FREQ)
patternElevation(sElem,FREQ,AZ)
patternElevation(sElem,FREQ,AZ,Name,Value)
PAT = patternElevation( ___ )
```

Description

`patternElevation(sElem,FREQ)` plots the 2-D element directivity pattern versus elevation (in dBi) for the element `sElem` at zero degrees azimuth angle. The argument `FREQ` specifies the operating frequency.

`patternElevation(sElem,FREQ,AZ)`, in addition, plots the 2-D element directivity pattern versus elevation (in dBi) at the azimuth angle specified by `AZ`. When `AZ` is a vector, multiple overlaid plots are created.

`patternElevation(sElem,FREQ,AZ,Name,Value)` plots the element pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternElevation( ___ )` returns the element pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Elevation'` parameter and the `AZ` input argument.

Input Arguments

`sElem` — Omnidirectional microphone element

System object

Omnidirectional microphone element, specified as a phased.OmnidirectionalMicrophoneElement System object.

Example: `sElem = phased.OmnidirectionalMicrophoneElement;`

FREQ — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

AZ — Azimuth angles for computing directivity and pattern

1-by-*N* real-valued row vector

Azimuth angles for computing sensor or array directivities and patterns, specified as a 1-by-*M* real-valued row vector where *N* is the number of desired azimuth directions. Angle units are in degrees. The azimuth angle must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `[0,10,20]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Type'` — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

`'Elevation'` — Elevation angles

`[-90:90]` (default) | 1-by-*P* real-valued row vector

Elevation angles, specified as the comma-separated pair consisting of `'Elevation'` and a 1-by-*P* real-valued row vector. Elevation angles define where the array pattern is calculated.

Example: `'Elevation',[-90:2:90]`

Data Types: `double`

Output Arguments

`PAT` — Element directivity or pattern

L-by-*N* real-valued matrix

Element directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of elevation angles determined by the `'Elevation'` name-value pair argument. The dimension *N* is the number of azimuth angles determined by the `AZ` argument.

Examples

Elevation Pattern of Omnidirectional Microphone Element

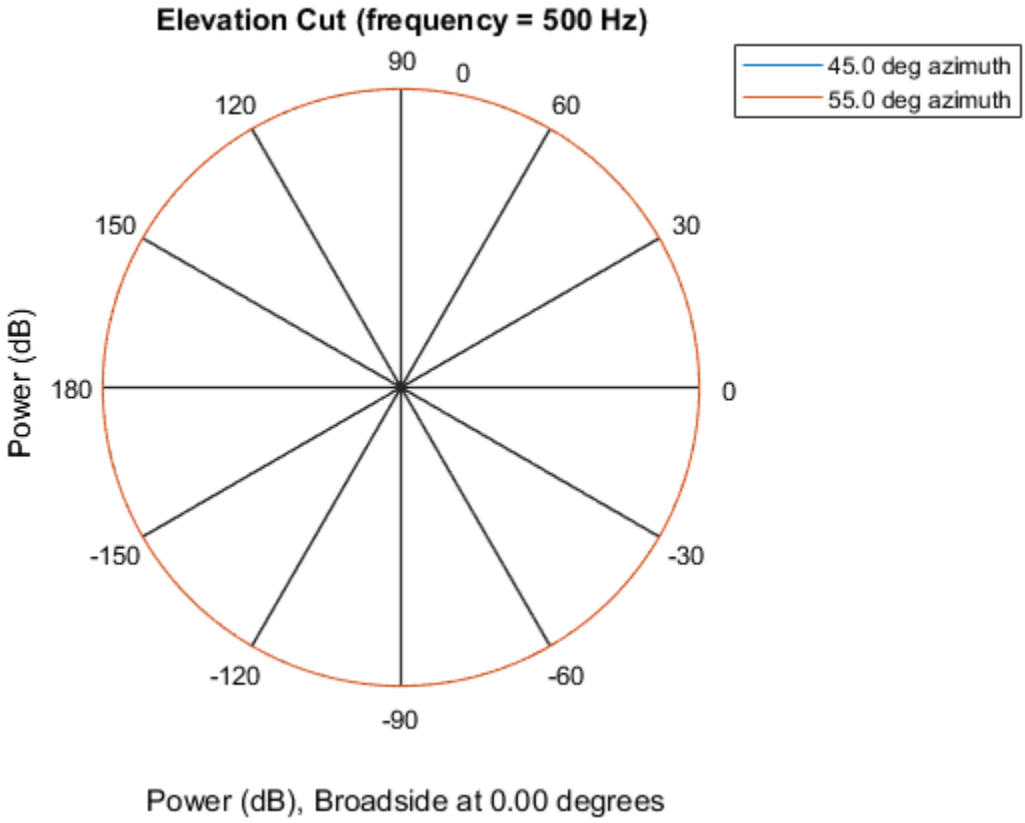
Contstruct an omnidirectional microphone element. Plot an elevation cut of the power 45 and 55 degrees azimuth. Assume the operating frequency is 500 Hz.

Create the microphone element.

```
fc = 500;
sOmni = phased.OmnidirectionalMicrophoneElement('FrequencyRange',[100,900]);
```

Display the power pattern.

```
patternElevation(sOmni,fc,[45 55],'Type','powerdb')
```



Because of the omnidirectionality, the two plots coincide.

Plot a reduced range of elevation angles using the `Elevation` parameter.

```
patternElevation(sOmni,fc,[45 55],...
    'Elevation',[-20:20],...
    'Type','powerdb')
```

phased.OmnidirectionalMicrophoneElement.pattern |
phased.OmnidirectionalMicrophoneElement.patternAzimuth

Introduced in R2015a

plotResponse

System object: phased.OmnidirectionalMicrophoneElement
Package: phased

Plot response pattern of microphone

Syntax

```
plotResponse(H,FREQ)
plotResponse(H,FREQ,Name,Value)
hPlot = plotResponse( ___ )
```

Description

`plotResponse(H,FREQ)` plots the element response pattern along the azimuth cut, where the elevation angle is 0. The operating frequency is specified in `FREQ`.

`plotResponse(H,FREQ,Name,Value)` plots the element response with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = plotResponse( ___ )` returns handles of the lines or surface in the figure window, using any of the input arguments in the previous syntaxes.

Input Arguments

`H`

Element System object

`FREQ`

Operating frequency in Hertz specified as a scalar or 1–by-*K* row vector. `FREQ` must lie within the range specified by the `FrequencyVector` property of `H`. If you set the `'RespCut'` property of `H` to `'3D'`, `FREQ` must be a scalar. When `FREQ` is a row vector, `plotResponse` draws multiple frequency responses on the same axes.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'CutAngle'`

Cut angle specified as a scalar. This argument is applicable only when `RespCut` is `'Az'` or `'El'`. If `RespCut` is `'Az'`, `CutAngle` must be between –90 and 90. If `RespCut` is `'El'`, `CutAngle` must be between –180 and 180.

Default: `0`

`'Format'`

Format of the plot, using one of `'Line'`, `'Polar'`, or `'UV'`. If you set `Format` to `'UV'`, `FREQ` must be a scalar.

Default: `'Line'`

`'NormalizeResponse'`

Set this value to `true` to normalize the response pattern. Set this value to `false` to plot the response pattern without normalizing it. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

Default: `true`

`'OverlayFreq'`

Set this value to `true` to overlay pattern cuts in a 2-D line plot. Set this value to `false` to plot pattern cuts against frequency in a 3-D waterfall plot. If this value is `false`, `FREQ` must be a vector with at least two entries.

This parameter applies only when `Format` is not `'Polar'` and RespCut is not `'3D'`.

Default: `true`

`'Polarization'`

Specify the polarization options for plotting the antenna response pattern. The allowable values are `|'None' | 'Combined' | 'H' | 'V' |` where

- `'None'` specifies plotting a nonpolarized response pattern
- `'Combined'` specifies plotting a combined polarization response pattern
- `'H'` specifies plotting the horizontal polarization response pattern
- `'V'` specifies plotting the vertical polarization response pattern

For antennas that do not support polarization, the only allowed value is `'None'`. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

Default: `'None'`

`'RespCut'`

Cut of the response. Valid values depend on `Format`, as follows:

- If `Format` is `'Line'` or `'Polar'`, the valid values of `RespCut` are `'Az'`, `'El'`, and `'3D'`. The default is `'Az'`.
- If `Format` is `'UV'`, the valid values of `RespCut` are `'U'` and `'3D'`. The default is `'U'`.

If you set `RespCut` to `'3D'`, `FREQ` must be a scalar.

`'Unit'`

The unit of the plot. Valid values are `'db'`, `'mag'`, `'pow'`, or `'dbi'`. This parameter determines the type of plot that is produced.

Unit value	Plot type
`db`	power pattern in dB scale
`mag`	field pattern
`pow`	power pattern
`dbi`	directivity

Default: `'db'`

`'AzimuthAngles'`

Azimuth angles for plotting element response, specified as a row vector. The `AzimuthAngles` parameter sets the display range and resolution of azimuth angles for

visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'Az'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of azimuth angles should lie between –180° and 180° and must be in nondecreasing order. When you set the `RespCut` parameter to `'3D'`, you can set the `AzimuthAngles` and `ElevationAngles` parameters simultaneously.

Default: `[-180:180]`

`'ElevationAngles'`

Elevation angles for plotting element response, specified as a row vector. The `ElevationAngles` parameter sets the display range and resolution of elevation angles for visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'El'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of elevation angles should lie between –90° and 90° and must be in nondecreasing order. When you set the `RespCut` parameter to `'3D'`, you can set the `ElevationAngles` and `AzimuthAngles` parameters simultaneously.

Default: `[-90:90]`

`'UGrid'`

U coordinate values for plotting element response, specified as a row vector. The `UGrid` parameter sets the display range and resolution of the *U* coordinates for visualizing the radiation pattern in *U*/*V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'U'` or `'3D'`. The values of `UGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set the `UGrid` and `VGrid` parameters simultaneously.

Default: `[-1:0.01:1]`

`'VGrid'`

V coordinate values for plotting element response, specified as a row vector. The `VGrid` parameter sets the display range and resolution of the *V* coordinates for visualizing the radiation pattern in *U*/*V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'3D'`. The values of `VGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set the `VGrid` and `UGrid` parameters simultaneously.

Default: `[-1:0.01:1]`

Examples

Plot Response and Directivity of Omnidirectional Microphone

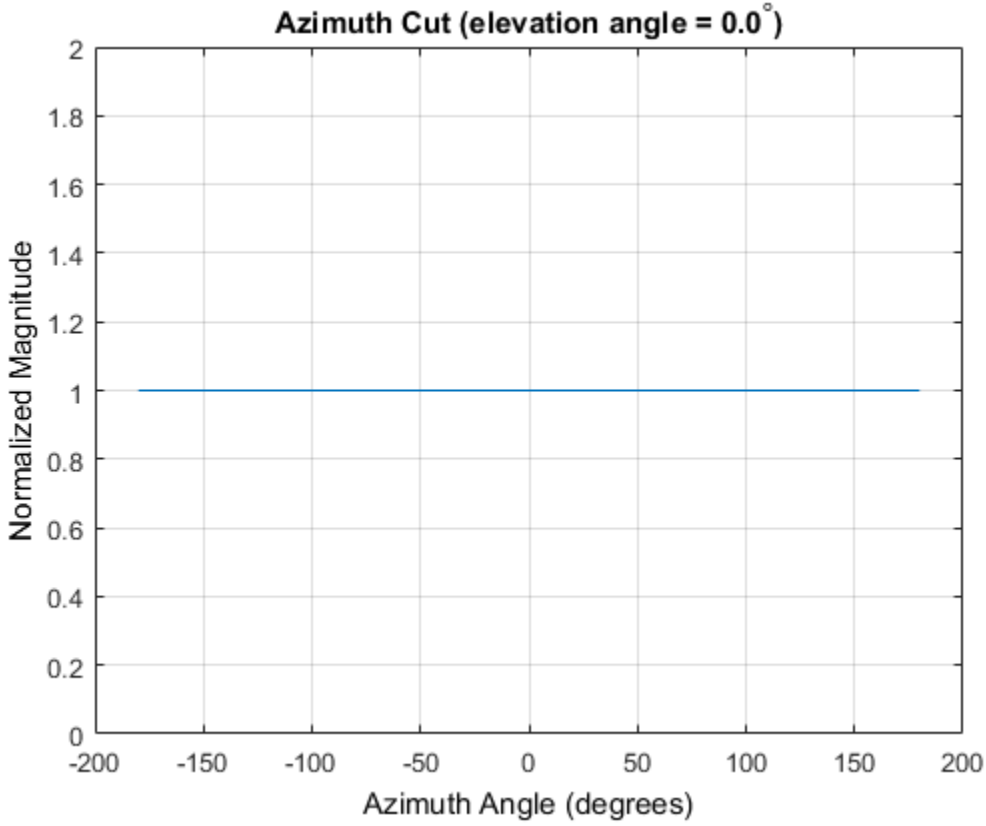
This example shows how to construct an omnidirectional microphone and how to plot its response and directivity. The microphone operating frequency spans the range 20 to 20000 Hz.

Construct the omnidirectional microphone.

```
sOmni = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[20 20e3]);
```

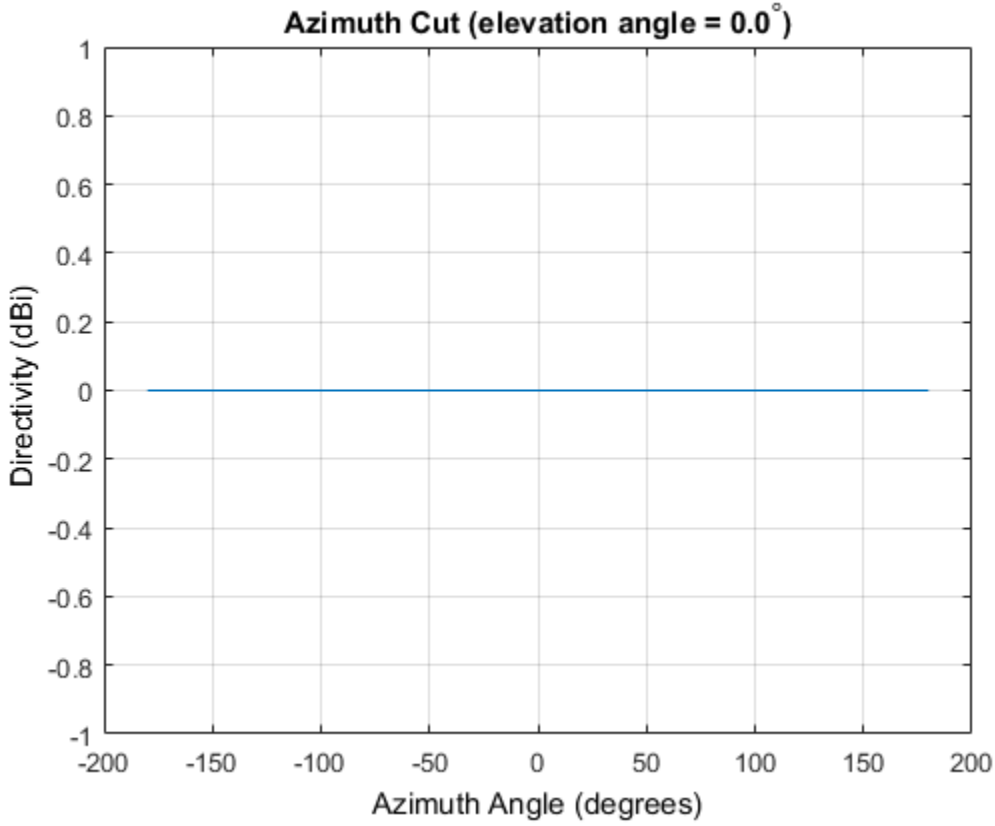
Plot the microphone response at 200 Hz.

```
fc = 200;
plotResponse(sOmni,fc,'Unit','mag');
```



Plot the microphone directivity.

```
plotResponse(sOmni,fc,'Unit','dbi');
```



Plot 3-D Response of Omnidirectional Microphone

This example shows how to construct an omnidirection microphone with response in the frequency range 20 - 20000 Hz and how to plot its 3-D response over a range of angles.

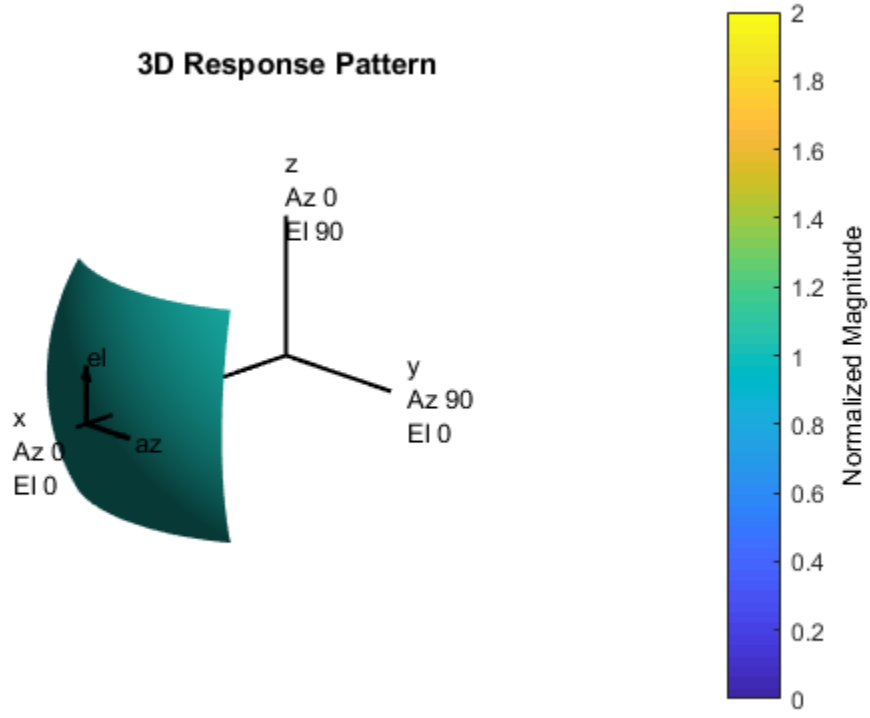
Construct the microphone element.

```
sOmin = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[20 20e3]);
```

Plot the 3-D response at 500 Hz. Show the response between -30 to 30 degrees in both azimuth and elevation in 0.1 degree increments.

```
plotResponse(sOmin,500,'Format','Polar',...
```

```
'RespCut','3D','Unit','mag',...
'AzimuthAngles',[-30:0.1:30],...
'ElevationAngles',[-30:0.1:30]);
```



See Also

azel2uv | uv2azel

step

System object: phased.OmnidirectionalMicrophoneElement
Package: phased

Output response of microphone

Syntax

```
RESP = step(H,FREQ,ANG)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`RESP = step(H,FREQ,ANG)` returns the microphone's magnitude response, `RESP`, at frequencies specified in `FREQ` and directions specified in `ANG`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`H`

Microphone object.

FREQ

Frequencies in hertz. FREQ is a row vector of length L.

ANG

Directions in degrees. ANG can be either a 2-by-M matrix or a row vector of length M.

If ANG is a 2-by-M matrix, each column of the matrix specifies the direction in the form [azimuth; elevation]. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

If ANG is a row vector of length M, each element specifies a direction's azimuth angle. In this case, the corresponding elevation angle is assumed to be 0.

Output Arguments

RESP

Response of microphone. RESP is an M-by-L matrix that contains the responses of the microphone element at the M angles specified in ANG and the L frequencies specified in FREQ.

Examples

Display Omni-Directional Microphone Pattern

Create an omnidirectional microphone. Find the microphone response at 200, 300, and 400 Hz for the incident angle 0° azimuth and 0° elevation. Then, plot the azimuth response of the microphone at three frequencies.

```
microphone = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[20 2e3]);
fc = [200 300 400];
ang = [0;0];
resp = microphone(fc,ang);
```

Plot the response pattern. Response patterns for all three frequencies are the same.

```
pattern(microphone,fc,[-180:180],0,'CoordinateSystem','polar','Type','power');
```

phased.PartitionedArray System object

Package: phased

Phased array partitioned into subarrays

Description

The `PartitionedArray` object represents a phased array that is partitioned into one or more subarrays.

To obtain the response of the subarrays in a partitioned array:

1. Define and set up your partitioned array. See "Construction" on page 1-1347.
2. Call step to compute the response of the subarrays according to the properties of `phased.PartitionedArray`. The behavior of `step` is specific to each object in the toolbox.

You can also specify a `PartitionedArray` object as the value of the `SensorArray` or `Sensor` property of objects that perform beamforming, steering, and other operations.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.PartitionedArray` creates a partitioned array System object, `H`. This object represents an array that is partitioned into subarrays.

`H = phased.PartitionedArray(Name,Value)` creates a partitioned array object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

Array

Array aperture

Specify a phased array as a `phased.ULA`, `phased.URA`, or `phased.ConformalArray` object.

Default: `phased.ULA('NumElements',4)`

SubarraySelection

Subarray definition matrix

Specify the subarray selection as an *M*-by-*N* matrix. *M* is the number of subarrays and *N* is the total number of elements in the array. Each row of the matrix indicates which elements belong to the corresponding subarray. Each entry in the matrix is 1 or 0, where 1 indicates that the element appears in the subarray and 0 indicates the opposite. Each row must contain at least one 1.

The phase center of each subarray is at the subarray geometric center. The `SubarraySelection` and `Array` properties determine the geometric center.

Default: `[1 1 0 0; 0 0 1 1]`

SubarraySteering

Subarray steering method

Specify the method of steering the subarray as one of `'None' | 'Phase' | 'Time'`.

Default: `'None'`

PhaseShifterFrequency

Subarray phase shifter frequency

Specify the operating frequency of phase shifters that perform subarray steering. The property value is a positive scalar in hertz. This property applies when you set the `SubarraySteering` property to `'Phase'`.

Default: 300e6

`NumPhaseShifterBits`

Number of phase shifter quantization bits

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

Default: 0

Methods

directivity	Directivity of partitioned array
collectPlaneWave	Simulate received plane waves
getElementPosition	Positions of array elements
getNumElements	Number of elements in array
getNumSubarrays	Number of subarrays in array
getSubarrayPosition	Positions of subarrays in array
isPolarizationCapable	Polarization capability
pattern	Plot partitioned array directivity, field, and power patterns
patternAzimuth	Plot partitioned array directivity or pattern versus azimuth
patternElevation	Plot partitioned array directivity or pattern versus elevation
plotResponse	Plot response pattern of array
step	Output responses of subarrays
viewArray	View array geometry

Common to All System Objects	
`clone`	Create System object with same property values

Common to All System Objects	
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Azimuth Response of Partitioned ULA

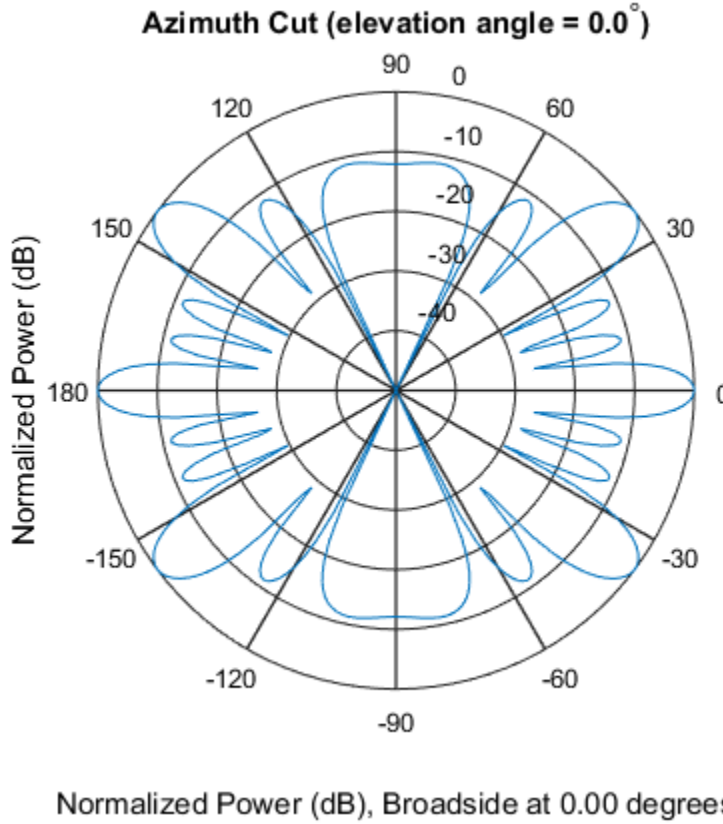
Plot the azimuth response of a 4-element ULA partitioned into two 2-element ULA's. The element spacing is one-half wavelength.

Create the ULA, and partition it into two 2-element ULA's.

```
sULA = phased.ULA('NumElements',4,'ElementSpacing',0.5);
sPA = phased.PartitionedArray('Array',sULA,...
    'SubarraySelection',[1 1 0 0;0 0 1 1]);
```

Plot the azimuth response of the array. Assume the operating frequency is 1 GHz and the propagation speed is the speed of light.

```
fc = 1e9;
pattern(sPA,fc,[-180:180],0,'Type','powerdb',...
    'CoordinateSystem','polar',...
    'Normalize',true)
```



Response of Subarrays of Partitioned ULA

Create a 4-element ULA. Then partition the ULA into two 2-element ULAs. Then, calculate the response at boresight of a 4-element ULA partitioned into two 2-element ULAs.

```
sULA = phased.ULA('NumElements',4,'ElementSpacing',0.5);
sPA = phased.PartitionedArray('Array',sULA,...
   'SubarraySelection',[1 1 0 0;0 0 1 1]);
```

Calculate the response at 1 GHz. The signal propagation speed is the speed of light.

```
fc = 1e9;
resp = step(sPA,fc,[0;0],physconst('LightSpeed'))
```

```
resp =

     2
     2
```

Introduced in R2012a

directivity

System object: phased.PartitionedArray
Package: phased

Directivity of partitioned array

Syntax

```
D = directivity(H,FREQ,ANGLE)
D = directivity(H,FREQ,ANGLE,Name,Value)
```

Description

`D = directivity(H,FREQ,ANGLE)` returns the "Directivity" on page 1-1358 of a partitioned array of antenna or microphone elements, `H`, at frequencies specified by `FREQ` and in angles of direction specified by `ANGLE`.

`D = directivity(H,FREQ,ANGLE,Name,Value)` returns the directivity with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`H` — Partitioned array

System object

Partitioned array, specified as a phased.PartitionedArray System object.

Example: `H = phased.PartitionedArray;`

`FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector`

property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.

- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

`ANGLE` — Angles for computing directivity

1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Angles for computing directivity, specified as a 1-by-*M* real-valued row vector or a 2-by-*M* real-valued matrix, where *M* is the number of angular directions. Angle units are in degrees. If `ANGLE` is a 2-by-*M* matrix, then each column specifies a direction in azimuth and elevation, `[az;el]`. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°.

If `ANGLE` is a 1-by-*M* vector, then each entry represents an azimuth angle, with the elevation angle assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis.

Example: `[45 60; 0 10]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'PropagationSpeed'` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

`'Weights'` — Subarray weights

1 (default) | *N*-by-1 complex-valued column vector | *N*-by-*L* complex-valued matrix

Subarray weights, specified as the comma-separated pair consisting of `'Weights'` and an *N*-by-1 complex-valued column vector or *N*-by-*M* complex-valued matrix. The dimension *N* is the number of subarrays in the array. The dimension *L* is the number of frequencies specified by the `FREQ` argument.

`Weights` dimension	`FREQ` dimension	Purpose
N-by-1 complex-valued column vector	Scalar or 1-by-*L* row vector	Applies a set of weights for the single frequency or for all *L* frequencies.
N-by-*L* complex-valued matrix	1-by-*L* row vector	Applies each of the *L* columns of `'Weights'` for the corresponding frequency in the `FREQ` argument.

Example: `'Weights',ones(N,M)`

Data Types: `double`

`'SteerAngle'` — Subarray steering angle

`[0;0]` (default) | scalar | 2-element column vector

Subarray steering angle, specified as the comma-separated pair consisting of `'SteerAngle'` and a scalar or a 2-by-1 column vector.

If `'SteerAngle'` is a 2-by-1 column vector, it has the form `[azimuth; elevation]`. The azimuth angle must be between –180° and 180°, inclusive. The elevation angle must be between –90° and 90°, inclusive.

If `'SteerAngle'` is a scalar, it specifies the azimuth angle only. In this case, the elevation angle is assumed to be 0.

This option applies only when the `'SubarraySteering'` property of the System object is set to `'Phase'` or `'Time'`.

Example: `'SteerAngle',[20;30]`

Data Types: `double`

Output Arguments

`D` — Directivity

M-by-*L* matrix

Directivity, returned as an *M*-by-*L* matrix whose columns contain the directivities at the *M* angles specified by `ANGLE`. Each column corresponds to one of the *L* frequency values specified in `FREQ`. Directivity units are in dBi.

Examples

Directivity of Partitioned Array

Compute the directivity of a partitioned array formed from a single 20-element ULA with elements spaced one-quarter wavelength apart. The subarrays are then phase-steered towards 30 degrees azimuth. The directivities are computed at azimuth angles from 0 to 60 degrees.

```
c = physconst('LightSpeed');
fc = 3e8;
lambda = c/fc;
angsteer = [30;0];
ang = [0:10:60;0,0,0,0,0,0,0];
```

Create a partitioned ULA array using the `SubarraySelection` property.

```
myArray = phased.PartitionedArray('Array',...
    phased.ULA(20,lambda/4),'SubarraySelection',...
    [ones(1,10) zeros(1,10);zeros(1,10) ones(1,10)],...
    'SubarraySteering','Phase','PhaseShifterFrequency',fc);
```

Create the steering vector and compute the directivity.

```
myStv = phased.SteeringVector('SensorArray',myArray,...
    'PropagationSpeed',c);
d = directivity(myArray,fc,ang,'PropagationSpeed',c,'Weights',...
    step(myStv,fc,angsteer),'SteerAngle',angsteer)
```

```
d =

   -7.5778
   -4.7676
   -2.0211
   10.0996
    0.9714
   -3.5575
  -10.8439
```

Definitions

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element directivity” and “Array directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For

Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

collectPlaneWave

System object: phased.PartitionedArray
Package: phased

Simulate received plane waves

Syntax

```
Y = collectPlaneWave(H,X,ANG)
Y = collectPlaneWave(H,X,ANG,FREQ)
Y = collectPlaneWave(H,X,ANG,FREQ,C)
```

Description

`Y = collectPlaneWave(H,X,ANG)` returns the received signals at the sensor array, `H`, when the input signals indicated by `X` arrive at the array from the directions specified in `ANG`.

`Y = collectPlaneWave(H,X,ANG,FREQ)`, in addition, specifies the incoming signal carrier frequency in `FREQ`.

`Y = collectPlaneWave(H,X,ANG,FREQ,C)`, in addition, specifies the signal propagation speed in `C`.

Input Arguments

`H`

Array object.

`X`

Incoming signals, specified as an M-column matrix. Each column of `X` represents an individual incoming signal.

ANG

Directions from which incoming signals arrive, in degrees. ANG can be either a 2-by-M matrix or a row vector of length M.

If ANG is a 2-by-M matrix, each column specifies the direction of arrival of the corresponding signal in X. Each column of ANG is in the form `[azimuth; elevation]`. The azimuth angle must be between –180° and 180°, inclusive. The elevation angle must be between –90° and 90°, inclusive.

If ANG is a row vector of length M, each entry in ANG specifies the azimuth angle. In this case, the corresponding elevation angle is assumed to be 0°.

FREQ

Carrier frequency of signal in hertz. FREQ must be a scalar.

Default: `3e8`

C

Propagation speed of signal in meters per second.

Default: Speed of light

Output Arguments

Y

Received signals. Y is an N-column matrix, where N is the number of subarrays in the array H. Each column of Y is the received signal at the corresponding subarray, with all incoming signals combined.

Examples

Plane Waves Received at Array Containing Subarrays

Simulate the received signal at a 16-element ULA partitioned into four 4-element ULAs.

Create a 16-element ULA, and partition it into 4-element ULAs.

```
ula = phased.ULA('NumElements',16);
array = phased.PartitionedArray('Array',ula,...
   'SubarraySelection',....
   [1 1 1 1 0 0 0 0 0 0 0 0 0 0 0 0;...
    0 0 0 0 1 1 1 1 0 0 0 0 0 0 0 0;...
    0 0 0 0 0 0 0 0 1 1 1 1 0 0 0 0;...
    0 0 0 0 0 0 0 0 0 0 0 0 1 1 1 1]);
```

Simulate received signals from 10° and 30° azimuth. Both signals have an elevation angle of 0°. Assume the propagation speed is the speed of light and the carrier frequency of the signal is 100 MHz.

```
sig = collectPlaneWave(array,randn(4,2),[10 30],1.0e8,physconst('LightSpeed'))
```

```
sig =

  -0.0710 - 0.4765i   0.6616 - 0.4676i   0.6616 + 0.4676i  -0.0710 + 0.4765i
   2.1529 - 1.6304i   1.0607 + 0.4802i   1.0607 - 0.4802i   2.1529 + 1.6304i
  -0.6074 + 2.0037i  -2.3274 + 1.1797i  -2.3274 - 1.1797i  -0.6074 - 2.0037i
   0.0547 - 0.7644i   0.9768 - 0.6037i   0.9768 + 0.6037i   0.0547 + 0.7644i
```

Algorithms

`collectPlaneWave` modulates the input signal with a phase corresponding to the delay caused by the direction of arrival. This method does not account for the response of individual elements in the array and only models the array factor among subarrays. Therefore, the result does not depend on whether the subarray is steered.

getElementPosition

System object: phased.PartitionedArray
Package: phased

Positions of array elements

Syntax

```
POS = getElementPosition(H)
```

Description

`POS = getElementPosition(H)` returns the element positions in the array `H`.

Input Arguments

`H`

Partitioned array object.

Output Arguments

`POS`

Element positions in array. `POS` is a 3-by-N matrix, where N is the number of elements in `H`. Each column of `POS` defines the position of an element in the local coordinate system, in meters, using the form [x; y; z].

Examples

Element Positions in Partitioned Array

Obtain the positions of the six elements in a partitioned array.

```
array = phased.PartitionedArray('Array',phased.URA('Size',[2 3]),...
    'SubarraySelection',[1 0 1 0 1 0; 0 1 0 1 0 1]);
pos = getElementPosition(array)
```

```
pos =

         0         0         0         0         0         0
   -0.5000   -0.5000         0         0    0.5000    0.5000
    0.2500   -0.2500    0.2500   -0.2500    0.2500   -0.2500
```

getSubarrayPosition

getNumElements

System object: phased.PartitionedArray
Package: phased

Number of elements in array

Syntax

```
N = getNumElements(H)
```

Description

`N = getNumElements(H)` returns the number of elements in the array object `H`.

Input Arguments

`H`

Partitioned array object.

Examples

Number of Elements in Partitioned Array

Obtain the number of elements in an array that is partitioned into subarrays.

```
array = phased.PartitionedArray('Array',phased.URA('Size',[2 3]),...
   'SubarraySelection',[1 0 1 0 1 0; 0 1 0 1 0 1]);
N = getNumElements(array)
```

```
N =

     6
```

getNumSubarrays

getNumSubarrays

System object: phased.PartitionedArray
Package: phased

Number of subarrays in array

Syntax

```
N = getNumSubarrays(H)
```

Description

`N = getNumSubarrays(H)` returns the number of subarrays in the array object `H`. This number matches the number of rows in the `SubarraySelection` property of `H`.

Input Arguments

`H`

Partitioned array object.

Examples

Number of Subarrays in Partitioned Array

Obtain the number of subarrays in a partitioned array.

```
array = phased.PartitionedArray('Array',...
   phased.ULA('NumElements',5),...
   'SubarraySelection',[1 1 1 0 0; 0 0 1 1 1]);
N = getNumSubarrays(array)
```

```
N =

getNumElements

getSubarrayPosition

System object: phased.PartitionedArray
Package: phased

Positions of subarrays in array

Syntax

```
POS = getSubarrayPosition(H)
```

Description

`POS = getSubarrayPosition(H)` returns the subarray positions in the array `H`.

Input Arguments

H

Partitioned array object.

Output Arguments

POS

Subarrays positions in array. `POS` is a 3-by-N matrix, where N is the number of subarrays in `H`. Each column of `POS` defines the position of a subarray in the local coordinate system, in meters, using the form [x; y; z].

Examples

Subarray Positions in Partitioned Array

Obtain the positions of the two subarrays in a partitioned array.

```
array = phased.PartitionedArray('Array',phased.URA('Size',[2 3]),...
    'SubarraySelection',[1 0 1 0 1 0; 0 1 0 1 0 1]);
pos = getSubarrayPosition(array)

getElementPosition

isPolarizationCapable

System object: phased.PartitionedArray
Package: phased

Polarization capability

Syntax

```
flag = isPolarizationCapable(h)
```

Description

`flag = isPolarizationCapable(h)` returns a Boolean value, `flag`, indicating whether the array supports polarization. An array supports polarization if all its constituent sensor elements support polarization.

Input Arguments

h — Partitioned array

Partitioned array specified as a phased.PartitionedArray System object.

Output Arguments

flag — Polarization-capability flag

Polarization-capability flag returned as a Boolean value. This value is `true`, if the array supports polarization or `false`, if it does not.

Examples

Partitioned Array of Short-Dipole Antenna Elements Supports Polarization

Determine whether a partitioned array of `phased.ShortDipoleAntennaElements` supports polarization.

```
antenna = phased.ShortDipoleAntennaElement('FrequencyRange',[1e9 10e9]);
ulaarray = phased.ULA(4,'Element',antenna);
partitionedarray = phased.PartitionedArray('Array',ulaarray,...
     'SubarraySelection',[1 1 0 0; 0 0 1 1]);
isPolarizationCapable(partitionedarray)

ans =

  logical

   1
```

The returned value `1` shows that this array supports polarization.

pattern

System object: phased.PartitionedArray
Package: phased

Plot partitioned array directivity, field, and power patterns

Syntax

```
pattern(sArray,FREQ)
pattern(sArray,FREQ,AZ)
pattern(sArray,FREQ,AZ,EL)
pattern( ___ ,Name,Value)
[PAT,AZ_ANG,EL_ANG] = pattern( ___ )
```

Description

`pattern(sArray,FREQ)` plots the 3-D array directivity pattern (in dBi) for the array specified in `sArray`. The operating frequency is specified in `FREQ`.

`pattern(sArray,FREQ,AZ)` plots the array directivity pattern at the specified azimuth angle.

`pattern(sArray,FREQ,AZ,EL)` plots the array directivity pattern at specified azimuth and elevation angles.

`pattern( ___ ,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`[PAT,AZ_ANG,EL_ANG] = pattern( ___ )` returns the array pattern in `PAT`. The `AZ_ANG` output contains the coordinate values corresponding to the rows of `PAT`. The `EL_ANG` output contains the coordinate values corresponding to the columns of `PAT`. If the `'CoordinateSystem'` parameter is set to `'uv'`, then `AZ_ANG` contains the *U* coordinates of the pattern and `EL_ANG` contains the *V* coordinates of the pattern. Otherwise, they are in angular units in degrees. *UV* units are dimensionless.

Note: This method replaces the `plotResponse` method. See "Convert plotResponse to pattern" on page 1-1384 for guidelines on how to use `pattern` in place of `plotResponse`.

Input Arguments

`sArray` — Partitioned array

System object

Partitioned array, specified as a phased.PartitionedArray System object.

Example: `sArray= phased.PartitionedArray;`

`FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `-Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `-Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

`AZ` — Azimuth angles

`[-180:180]` (default) | 1-by-*M* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a 1-by-*M* real-valued row vector where *M* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, this angle is positive.

Example: `[-45:2:45]`

Data Types: `double`

`EL` — Elevation angles

`[-90:90]` (default) | 1-by-*N* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a 1-by-*N* real-valued row vector where *N* is the number of desired elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and *xy*-plane. When measured towards the *z*-axis, this angle is positive.

Example: `[-75:1:70]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'CoordinateSystem'` — Plotting coordinate system

`'polar'` (default) | `'rectangular'` | `'uv'`

Plotting coordinate system of the pattern, specified as the comma-separated pair consisting of `'CoordinateSystem'` and one of `'polar'`, `'rectangular'`, or `'uv'`. When `'CoordinateSystem'` is set to `'polar'` or `'rectangular'`, the `AZ` and `EL` arguments specify the pattern azimuth and elevation, respectively. `AZ` values must lie between –180° and 180°. `EL` values must lie between –90° and 90°. If `'CoordinateSystem'` is set to `'uv'`, `AZ` and `EL` then specify *U* and *V* coordinates, respectively. `AZ` and `EL` must lie between -1 and 1.

Example: `'uv'`

Data Types: `char`

'Type' — Displayed pattern type

'directivity' (default) | 'efield' | 'power' | 'powerdb'

Displayed pattern type, specified as the comma-separated pair consisting of 'Type' and one of

- 'directivity' — directivity pattern measured in dBi.
- 'efield' — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- 'power' — power pattern of the sensor or array defined as the square of the field pattern.
- 'powerdb' — power pattern converted to dB.

Example: 'powerdb'

Data Types: char

'Normalize' — Display normalize pattern

true (default) | false

Display normalized pattern, specified as the comma-separated pair consisting of 'Normalize' and a Boolean. Set this parameter to true to display a normalized pattern. When you set 'Type' to 'directivity', this parameter does not apply. Directivity patterns are already normalized.

Example:

Data Types: logical

'PlotStyle' — Plotting style

'overlay' (default) | 'waterfall'

Plotting style, specified as the comma-separated pair consisting of 'Plotstyle' and either 'overlay' or 'waterfall'. This parameter applies when you specify multiple frequencies in FREQ in 2-D plots. You can draw 2-D plots by setting one of the arguments AZ or EL to a scalar.

Example:

Data Types: char

'Polarization' — Polarized field component

'combined' (default) | 'H' | 'V'

Polarized field component to display, specified as the comma-separated pair consisting of 'Polarization' and `'combined'`, `'H'`, or `'V'`. This parameter applies only when the sensors are polarization-capable and when the `'Type'` parameter is not set to `'directivity'`. This table shows the meaning of the display options

`'Polarization'`	Display
`'combined'`	Combined *H* and *V* polarization components
`'H'`	*H* polarization component
`'V'`	*V* polarization component

Example: `'V'`

Data Types: `char`

`'PropagationSpeed'` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

`'Weights'` — Subarray weights

1 (default) | *N*-by-1 complex-valued column vector | *N*-by-*L* complex-valued matrix

Subarray weights, specified as the comma-separated pair consisting of `'Weights'` and an *N*-by-1 complex-valued column vector or *N*-by-*M* complex-valued matrix. The dimension *N* is the number of subarrays in the array. The dimension *L* is the number of frequencies specified by the `FREQ` argument.

`Weights` dimension	`FREQ` dimension	Purpose
N-by-1 complex-valued column vector	Scalar or 1-by-*L* row vector	Applies a set of weights for the single frequency or for all *L* frequencies.
N-by-*L* complex-valued matrix	1-by-*L* row vector	Applies each of the *L* columns of `'Weights'` for the corresponding frequency in the `FREQ` argument.

Example: `'Weights',ones(N,M)`

Data Types: `double`

`'SteerAngle'` — Subarray steering angle

`[0;0]` (default) | scalar | 2-element column vector

Subarray steering angle, specified as the comma-separated pair consisting of `'SteerAngle'` and a scalar or a 2-by-1 column vector.

If `'SteerAngle'` is a 2-by-1 column vector, it has the form `[azimuth; elevation]`. The azimuth angle must be between –180° and 180°, inclusive. The elevation angle must be between –90° and 90°, inclusive.

If `'SteerAngle'` is a scalar, it specifies the azimuth angle only. In this case, the elevation angle is assumed to be 0.

This option applies only when the `'SubarraySteering'` property of the System object is set to `'Phase'` or `'Time'`.

Example: `'SteerAngle',[20;30]`

Data Types: `double`

Output Arguments

`PAT` — Array pattern

M-by-*N* real-valued matrix

Array pattern, returned as an *M*-by-*N* real-valued matrix. The dimensions of `PAT` correspond to the dimensions of the output arguments `AZ_ANG` and `EL_ANG`.

`AZ_ANG` — Azimuth angles

scalar | 1-by-*M* real-valued row vector

Azimuth angles for displaying directivity or response pattern, returned as a scalar or 1-by-*M* real-valued row vector corresponding to the dimension set in `AZ`. The rows of `PAT` correspond to the values in `AZ_ANG`.

`EL_ANG` — Elevation angles

scalar | 1-by-*N* real-valued row vector

Elevation angles for displaying directivity or response, returned as a scalar or 1-by-*N* real-valued row vector corresponding to the dimension set in `EL`. The columns of `PAT` correspond to the values in `EL_ANG`.

Examples

Azimuth Response of Partitioned ULA

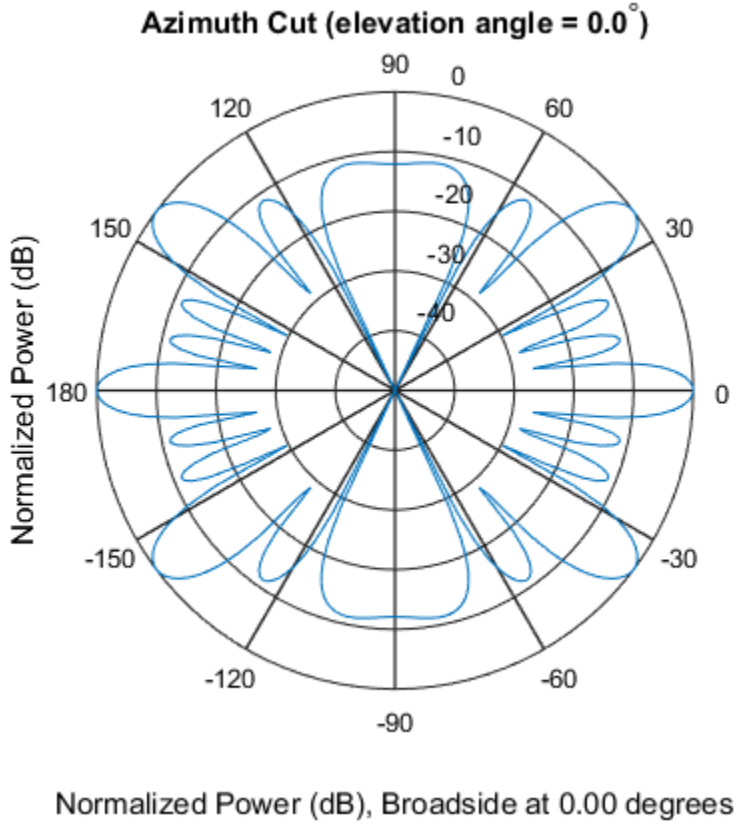
Plot the azimuth response of a 4-element ULA partitioned into two 2-element ULA's. The element spacing is one-half wavelength.

Create the ULA, and partition it into two 2-element ULA's.

```
sULA = phased.ULA('NumElements',4,'ElementSpacing',0.5);
sPA = phased.PartitionedArray('Array',sULA,...
    'SubarraySelection',[1 1 0 0;0 0 1 1]);
```

Plot the azimuth response of the array. Assume the operating frequency is 1 GHz and the propagation speed is the speed of light.

```
fc = 1e9;
pattern(sPA,fc,[-180:180],0,'Type','powerdb',...
    'CoordinateSystem','polar',...
    'Normalize',true)
```



Plot Pattern and Directivity of Partitioned URA Over Restricted Range of Angles

Convert a 2-by-6 URA of isotropic antenna elements into a 1-by-3 partitioned array so that each subarray of the partitioned array is a 2-by-2 URA. Assume that the frequency response of the elements lies between 1 and 6 GHz. The elements are spaced one-half wavelength apart corresponding to the highest frequency of the element response. Plot an azimuth cut from -50 to 50 degrees for different two sets of weights. For partitioned arrays, weights are applied to the subarrays instead of the elements.

Create partitioned array

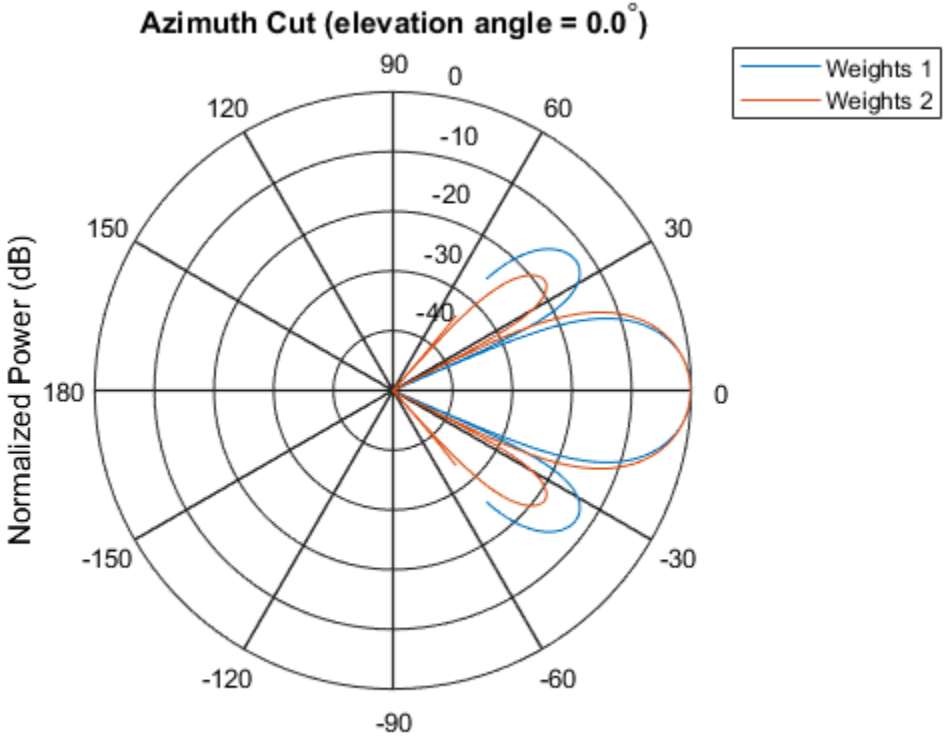
```
fmin = 1e9;
fmax = 6e9;
c = physconst('LightSpeed');
```

```
lam = c/fmax;
sIso = phased.IsotropicAntennaElement(...
    'FrequencyRange',[fmin,fmax],...
    'BackBaffled',false);
sURA = phased.URA('Element',sIso,'Size',[2,6],...
    'ElementSpacing',[lam/2,lam/2]);
subarraymap = [[1,1,1,1,0,0,0,0,0,0,0,0];...
    [0,0,0,0,1,1,1,1,0,0,0,0];...
    [0,0,0,0,0,0,0,0,1,1,1,1]];
sPA = phased.PartitionedArray('Array',sURA,...
    'SubarraySelection',subarraymap);
```

Plot power pattern

Plot the response of the array at 5 GHz over the restricted range of azimuth angles.

```
fc = 5e9;
wts = [[1,1,1]',[.862,1.23,.862]'];
pattern(sPA,fc,[-50:0.1:50],0,...
    'Type','powerdb',...
    'CoordinateSystem','polar',...
    'Weights',wts)
```

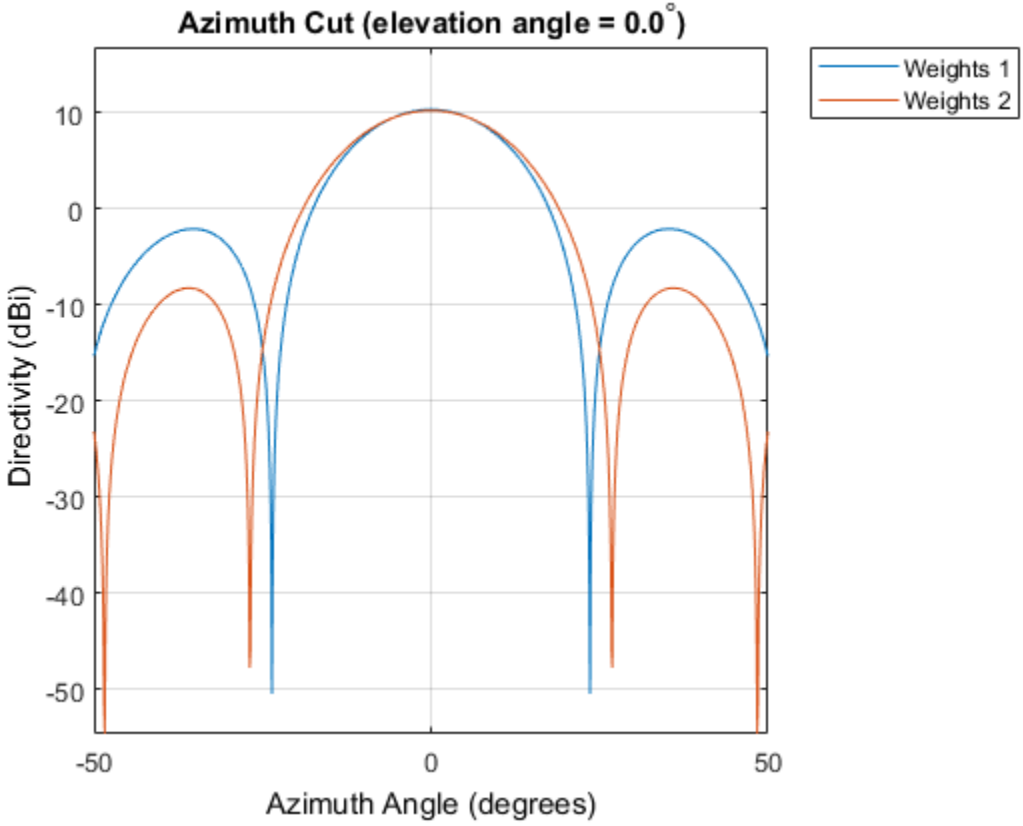


The plot of the response shows the broadening of the main lobe and the reduction of the strength of the sidelobes caused by the weight tapering.

Plot directivity

Plot an azimuth cut of the directivity of the array at 5 GHz over the restricted range of azimuth angles for the two different sets of weights.

```
fc = 5e9;
wts = [[1,1,1]',[.862,1.23,.862]'];
pattern(sPA,fc,[-50:0.1:50],0,...
    'Type','directivity',...
    'CoordinateSystem','rectangular',...
    'Weights',wts)
```



More About

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on "Element directivity" and "Array directivity".

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

Convert plotResponse to pattern

For antenna, microphone, and array System objects, the `pattern` method replaces the `plotResponse` method. In addition, two new simplified methods exist just to draw 2-D azimuth and elevation pattern plots. These methods are `azimuthPattern` and `elevationPattern`.

The following table is a guide for converting your code from using `plotResponse` to `pattern`. Notice that some of the inputs have changed from *input arguments* to *Name-Value* pairs and conversely. The general `pattern` method syntax is

```
pattern(H,FREQ,AZ,EL,'Name1','Value1',...,'NameN','ValueN')
```

plotResponse Inputs	plotResponse Description	pattern Inputs
`H` argument	Antenna, microphone, or array System object.	`H` argument (no change)
`FREQ` argument	Operating frequency.	`FREQ` argument (no change)

plotResponse Inputs	plotResponse Description	pattern Inputs
`V` argument	Propagation speed. This argument is used only for arrays.	`'PropagationSpeed'` name-value pair. This parameter is only used for arrays.

<table>
<tr><th>plotResponse Inputs</th><th>plotResponse Description</th><th>pattern Inputs</th></tr>
<tr>
<td>'Format' and 'RespCut' name-value pairs</td>
<td>These options work together to let you create a plot in angle space (line or polar style) or UV space. They also determine whether the plot is 2-D or 3-D. This table shows you how to create different types of plots using plotResponse.
<table>
<tr><th>Display space</th><th></th></tr>
<tr><td>Angle space (2D)</td><td>Set 'RespCut' to 'Az' or 'El'. Set 'Format' to 'line' or 'polar'.

Set the display axis using either the the 'AzimuthAngl or 'ElevationAn name-value pairs.</td></tr>
<tr><td>Angle space (3D)</td><td>Set 'RespCut' to '3D'. Set 'Format' to 'line' or 'polar'.

Set the display axis using both the</td></tr>
</table>
</td>
<td>'CoordinateSystem' name-value pair used together with the AZ and EL input arguments.

'CoordinateSystem' has the same options as the plotResponse method 'Format'name-value pair, except that 'line' is now named 'rectangular'. The table shows how to create different types of plots using pattern.
<table>
<tr><th>Display space</th><th></th></tr>
<tr><td>Angle space (2D)</td><td>Set 'CoordinateSystem' to 'rectangular' or 'polar'. Specify either AZ or EL as a scalar.</td></tr>
<tr><td>Angle space (3D)</td><td>Set 'CoordinateSystem' to 'rectangular' or 'polar'. Specify both AZ and EL as vectors.</td></tr>
<tr><td>UV space (2D)</td><td>Set 'CoordinateSystem' to 'uv'. Use AZ to specify a U-space vector.</td></tr>
</table>
</td>

<tr><td>UV space (3D)</td><td>Set 'RespCut' to'3D'. Set 'Format' to 'UV'. Set the display range using both the 'UGrid' and 'VGrid' name-value pairs.</td></tr>
</table></td><td><table>
<tr><th>Display space</th><th></th></tr>
<tr><td></td><td>Use EL to specify a V-space scalar.</td></tr>
<tr><td>UV space (3D)</td><td>Set 'Coordinate System' to 'uv'. Use AZ to specify a U-space vector. Use EL to specify a V-space vector.</td></tr>
</table>
If you set CoordinateSystem to 'uv', enter the UV grid values using AZ and EL.</td></tr>
<tr><td>'CutAngle' name-value pair</td><td>Constant angle at to take an azimuth or elevation cut. When producing a 2-D plot and when 'RespCut' is set to 'Az' or 'El', use 'CutAngle' to set the slice across which to view the plot.</td><td>No equivalent name-value pair. To create a cut, specify either AZ or EL as a scalar, not a vector.</td></tr>
</table>

plotResponse Inputs	plotResponse Description	pattern Inputs
`'NormalizeResponse'` name-value pair	Normalizes the plot. When `'Unit'` is set to `'dbi'`, you cannot specify `'NormalizeResponse'`.	`'Normalize'` name-value pair. When `'Type'` is set to `'directivity'`, you cannot specify `'Normalize'`. .
`'OverlayFreq'` name-value pair	Plot multiple frequencies on the same 2-D plot. Available only when `'Format'` is set to `'line'` or `'uv'` and `'RespCut'` is not set to `'3D'`. The value `true` produces an overlay plot and the value `false` produces a waterfall plot.	`'PlotStyle'` name-value pair plots multiple frequencies on the same 2-D plot. The values `'overlay'` and `'waterfall'` correspond to `'OverlayFreq'` values of `true` and `false`. The option `'waterfall'` is allowed only when `'CoordinateSystem'` is set to `'rectangular'` or `'uv'`.
`'Polarization'` name-value pair	Determines how to plot polarized fields. Options are `'None'`, `'Combined'`, `'H'`, or `'V'`.	`'Polarization'` name-value pair determines how to plot polarized fields. The `'None'` option is removed. The options `'Combined'`, `'H'`, or `'V'` are unchanged.

`'Unit'` name-value pair	Determines the plot units. Choose `'db'`, `'mag'`, `'pow'`, or `'dbi'`, where the default is `'db'`.	`'Type'` name-value pair, uses equivalent options with different names
		
		plotResponse pattern
		`'db'` `'powerdb'`
		`'mag'` `'efield'`
		`'pow'` `'power'`
		`'dbi'` `'directivity'`

`'Weights'` name-value pair	Array element tapers (or weights).	`'Weights'` name-value pair (no change).

plotResponse Inputs	plotResponse Description	pattern Inputs
`'AzimuthAngles'` name-value pair	Azimuth angles used to display the antenna or array response.	`AZ` argument
`'ElevationAngles'` name-value pair	Elevation angles used to display the antenna or array response.	`EL` argument
`'UGrid'` name-value pair	Contains *U* coordinates in *UV*-space.	`AZ` argument when `'CoordinateSystem'` name-value pair is set to `'uv'`
`'VGrid'` name-value pair	Contains *V*-coordinates in *UV*-space.	`EL` argument when `'CoordinateSystem'` name-value pair is set to `'uv'`

phased.PartitionedArray.patternAzimuth | phased.PartitionedArray.patternElevation

Introduced in R2015a

patternAzimuth

System object: phased.PartitionedArray
Package: phased

Plot partitioned array directivity or pattern versus azimuth

Syntax

```
patternAzimuth(sArray,FREQ)
patternAzimuth(sArray,FREQ,EL)
patternAzimuth(sArray,FREQ,EL,Name,Value)
PAT = patternAzimuth( ___ )
```

Description

`patternAzimuth(sArray,FREQ)` plots the 2-D array directivity pattern versus azimuth (in dBi) for the array `sArray` at zero degrees elevation angle. The argument `FREQ` specifies the operating frequency.

`patternAzimuth(sArray,FREQ,EL)`, in addtion, plots the 2-D array directivity pattern versus azimuth (in dBi) for the array `sArray` at the elevation angle specified by `EL`. When `EL` is a vector, multiple overlaid plots are created.

`patternAzimuth(sArray,FREQ,EL,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternAzimuth( ___ )` returns the array pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Azimuth'` parameter and the `EL` input argument.

Input Arguments

`sArray` — Partitioned array

System object

Partitioned array, specified as a phased.PartitionedArray System object.

Example: `sArray= phased.PartitionedArray;`

`FREQ` — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

`EL` — Elevation angles

1-by-*N* real-valued row vector

Elevation angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector. The quantity *N* is the number of requested elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and the *xy* plane. When measured toward the *z*-axis, this angle is positive.

Example: `[0,10,20]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'Type' — Displayed pattern type

'directivity' (default) | 'efield' | 'power' | 'powerdb'

Displayed pattern type, specified as the comma-separated pair consisting of 'Type' and one of

- 'directivity' — directivity pattern measured in dBi.
- 'efield' — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- 'power' — power pattern of the sensor or array defined as the square of the field pattern.
- 'powerdb' — power pattern converted to dB.

Example: 'powerdb'

Data Types: char

'PropagationSpeed' — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of 'PropagationSpeed' and a positive scalar in meters per second.

Example: 'PropagationSpeed',physconst('LightSpeed')

Data Types: double

'Weights' — Subarray weights

M-by-1 complex-valued column vector

Subarray weights, specified as the comma-separated pair consisting of 'Weights' and an *M*-by-1 complex-valued column vector. Subarray weights are applied to the subarrays of the array to produce array steering, tapering, or both. The dimension *M* is the number of subarrays in the array.

Example: 'Weights',ones(10,1)

Data Types: double
Complex Number Support: Yes

'SteerAngle' — Subarray steering angle

[0;0] (default) | scalar | 2-element column vector

Subarray steering angle, specified as the comma-separated pair consisting of `'SteerAngle'` and a scalar or a 2-by-1 column vector.

If `'SteerAngle'` is a 2-by-1 column vector, it has the form `[azimuth; elevation]`. The azimuth angle must be between –180° and 180°, inclusive. The elevation angle must be between –90° and 90°, inclusive.

If `'SteerAngle'` is a scalar, it specifies the azimuth angle only. In this case, the elevation angle is assumed to be 0.

This option applies only when the `'SubarraySteering'` property of the System object is set to `'Phase'` or `'Time'`.

Example: `'SteerAngle',[20;30]`

Data Types: `double`

`'Azimuth'` — Azimuth angles

`[-180:180]` (default) | 1-by-*P* real-valued row vector

Azimuth angles, specified as the comma-separated pair consisting of `'Azimuth'` and a 1-by-*P* real-valued row vector. Azimuth angles define where the array pattern is calculated.

Example: `'Azimuth',[-90:2:90]`

Data Types: `double`

Output Arguments

`PAT` — Array directivity or pattern

L-by-*N* real-valued matrix

Array directivity or pattern, returned as an *L*-by-*N* rea-valued matrix. The dimension *L* is the number of azimuth values determined by the `'Azimuth'` name-value pair argument. The dimension *N* is the number of elevation angles, as determined by the `EL` input argument.

Examples

Plot Azimuth Directivity of Partitioned URA

Convert a 2-by-6 URA of isotropic antenna elements into a 1-by-3 partitioned array so that each subarray of the partitioned array is a 2-by-2 URA. Assume that the frequency response of the elements lies between 1 and 6 GHz. The elements are spaced one-half wavelength apart corresponding to the highest frequency of the element response. Plot the azimuth directivity. For partitioned arrays, weights are applied to the subarrays instead of the elements.

Create partitioned array

```
fmin = 1e9;
fmax = 6e9;
c = physconst('LightSpeed');
lam = c/fmax;
sIso = phased.IsotropicAntennaElement(...
    'FrequencyRange',[fmin,fmax],...
    'BackBaffled',false);
sURA = phased.URA('Element',sIso,'Size',[2,6],...
    'ElementSpacing',[lam/2,lam/2]);
subarraymap = [[1,1,1,1,0,0,0,0,0,0,0,0];...
    [0,0,0,0,1,1,1,1,0,0,0,0];...
    [0,0,0,0,0,0,0,0,1,1,1,1]];
sPA = phased.PartitionedArray('Array',sURA,...
    'SubarraySelection',subarraymap);
```

Plot azimuth directivity pattern

Plot the response of the array at 5 GHz

```
fc = 5e9;
wts = [0.862,1.23,0.862]';
patternAzimuth(sPA,fc,0,...
    'Type','directivity',...
    'PropagationSpeed',physconst('LightSpeed'),...
    'Weights',wts)
```

phased.PartitionedArray.pattern | phased.PartitionedArray.patternElevation

Introduced in R2015a

patternElevation

System object: phased.PartitionedArray
Package: phased

Plot partitioned array directivity or pattern versus elevation

Syntax

```
patternElevation(sArray,FREQ)
patternElevation(sArray,FREQ,AZ)
patternElevation(sArray,FREQ,AZ,Name,Value)
PAT = patternElevation( ___ )
```

Description

`patternElevation(sArray,FREQ)` plots the 2-D array directivity pattern versus elevation (in dBi) for the array `sArray` at zero degrees azimuth angle. When `AZ` is a vector, multiple overlaid plots are created. The argument `FREQ` specifies the operating frequency.

`patternElevation(sArray,FREQ,AZ)`, in addition, plots the 2-D element directivity pattern versus elevation (in dBi) at the azimuth angle specified by `AZ`. When `AZ` is a vector, multiple overlaid plots are created.

`patternElevation(sArray,FREQ,AZ,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternElevation( ___ )` returns the array pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Elevation'` parameter and the `AZ` input argument.

Input Arguments

`sArray` — Partitioned array

System object

Partitioned array, specified as a phased.PartitionedArray System object.

Example: `sArray= phased.PartitionedArray;`

FREQ — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

AZ — Azimuth angles for computing directivity and pattern

1-by-*N* real-valued row vector

Azimuth angles for computing sensor or array directivities and patterns, specified as a 1-by-*M* real-valued row vector where *N* is the number of desired azimuth directions. Angle units are in degrees. The azimuth angle must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `[0,10,20]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Type'` — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

`'PropagationSpeed'` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

`'Weights'` — Subarray weights

M-by-1 complex-valued column vector

Subarray weights, specified as the comma-separated pair consisting of `'Weights'` and an *M*-by-1 complex-valued column vector. Subarray weights are applied to the subarrays of the array to produce array steering, tapering, or both. The dimension *M* is the number of subarrays in the array.

Example: `'Weights',ones(10,1)`

Data Types: `double`
Complex Number Support: Yes

`'SteerAngle'` — Subarray steering angle

`[0;0]` (default) | scalar | 2-element column vector

Subarray steering angle, specified as the comma-separated pair consisting of `'SteerAngle'` and a scalar or a 2-by-1 column vector.

If `'SteerAngle'` is a 2-by-1 column vector, it has the form `[azimuth; elevation]`. The azimuth angle must be between –180° and 180°, inclusive. The elevation angle must be between –90° and 90°, inclusive.

If `'SteerAngle'` is a scalar, it specifies the azimuth angle only. In this case, the elevation angle is assumed to be 0.

This option applies only when the `'SubarraySteering'` property of the System object is set to `'Phase'` or `'Time'`.

Example: `'SteerAngle',[20;30]`

Data Types: `double`

`'Elevation'` — Elevation angles

`[-90:90]` (default) | 1-by-*P* real-valued row vector

Elevation angles, specified as the comma-separated pair consisting of `'Elevation'` and a 1-by-*P* real-valued row vector. Elevation angles define where the array pattern is calculated.

Example: `'Elevation',[-90:2:90]`

Data Types: `double`

Output Arguments

`PAT` — Array directivity or pattern

L-by-*N* real-valued matrix

Array directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of elevation angles determined by the `'Elevation'` name-value pair argument. The dimension *N* is the number of azimuth angles determined by the `AZ` argument.

Examples

Plot Elevation Directivity of Partitioned URA

Convert a 2-by-6 URA of isotropic antenna elements into a 1-by-3 partitioned array so that each subarray of the partitioned array is a 2-by-2 URA. Assume that the frequency response of the elements lies between 1 and 6 GHz. The elements are spaced one-half wavelength apart corresponding to the highest frequency of the element response. Plot the directivity for elevation angles from -45 to 45 degrees. For partitioned arrays, weights are applied to the subarrays instead of the elements.

Create partitioned array

```
fmin = 1e9;
fmax = 6e9;
c = physconst('LightSpeed');
lam = c/fmax;
sIso = phased.IsotropicAntennaElement(...
    'FrequencyRange',[fmin,fmax],...
    'BackBaffled',false);
sURA = phased.URA('Element',sIso,'Size',[2,6],...
    'ElementSpacing',[lam/2,lam/2]);
subarraymap = [[1,1,1,1,0,0,0,0,0,0,0,0];...
    [0,0,0,0,1,1,1,1,0,0,0,0];...
    [0,0,0,0,0,0,0,0,1,1,1,1]];
sPA = phased.PartitionedArray('Array',sURA,...
    'SubarraySelection',subarraymap);
```

Plot elevation directivity pattern

Plot the response of the array at 5 GHz

```
fc = 5e9;
wts = [0.862,1.23,0.862]';
azimangle = 0;
patternElevation(sPA,fc,azimangle,...
    'Type','directivity',...
    'PropagationSpeed',physconst('LightSpeed'),...
    'Elevation',[-45:45],...
    'Weights',wts)
```

plotResponse

System object: phased.PartitionedArray
Package: phased

Plot response pattern of array

Syntax

```
plotResponse(H,FREQ,V)
plotResponse(H,FREQ,V,Name,Value)
hPlot = plotResponse( ___ )
```

Description

`plotResponse(H,FREQ,V)` plots the array response pattern along the azimuth cut, where the elevation angle is 0. The operating frequency is specified in `FREQ`. The propagation speed is specified in `V`.

`plotResponse(H,FREQ,V,Name,Value)` plots the array response with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = plotResponse( ___ )` returns handles of the lines or surface in the figure window, using any of the input arguments in the previous syntaxes.

Input Arguments

`H`

Array object.

`FREQ`

Operating frequency in hertz. Typical values are within the range specified by a property of `H.Array.Element`. That property is named `FrequencyRange` or `FrequencyVector`, depending on the type of element in the array. The element has zero response at

frequencies outside that range. If `FREQ` is a nonscalar row vector, the plot shows multiple frequency responses on the same axes.

`V`

Propagation speed in meters per second.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'CutAngle'`

Cut angle specified as a scalar. This argument is applicable only when `RespCut` is `'Az'` or `'El'`. If `RespCut` is `'Az'`, `CutAngle` must be between –90 and 90. If `RespCut` is `'El'`, `CutAngle` must be between –180 and 180.

Default: `0`

`'Format'`

Format of the plot, using one of `'Line'`, `'Polar'`, or `'UV'`. If you set `Format` to `'UV'`, `FREQ` must be a scalar.

Default: `'Line'`

`'NormalizeResponse'`

Set this value to `true` to normalize the response pattern. Set this value to `false` to plot the response pattern without normalizing it. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

Default: `true`

`'OverlayFreq'`

Set this value to `true` to overlay pattern cuts in a 2-D line plot. Set this value to `false` to plot pattern cuts against frequency in a 3-D waterfall plot. If this value is `false`, then `FREQ` must be a vector with at least two entries.

This parameter applies only when `Format` is not `'Polar'` and `RespCut` is not `'3D'`.

Default: `true`

`'Polarization'`

Specify the polarization options for plotting the array response pattern. The allowable values are `|'None' | 'Combined' | 'H' | 'V' |` where:

- `'None'` specifies plotting a nonpolarized response pattern
- `'Combined'` specifies plotting a combined polarization response pattern
- `'H'` specifies plotting the horizontal polarization response pattern
- `'V'` specifies plotting the vertical polarization response pattern

For arrays that do not support polarization, the only allowed value is `'None'`. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

Default: `'None'`

`'RespCut'`

Cut of the response. Valid values depend on `Format`, as follows:

- If `Format` is `'Line'` or `'Polar'`, the valid values of `RespCut` are `'Az'`, `'El'`, and `'3D'`. The default is `'Az'`.
- If `Format` is `'UV'`, the valid values of `RespCut` are `'U'` and `'3D'`. The default is `'U'`.

If you set `RespCut` to `'3D'`, `FREQ` must be a scalar.

`'SteerAng'`

Subarray steering angle. `SteerAng` can be either a 2-element column vector or a scalar.

If `SteerAng` is a 2-element column vector, it has the form [azimuth; elevation]. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

If `SteerAng` is a scalar, it specifies the azimuth angle. In this case, the elevation angle is assumed to be 0.

This option is applicable only if the `SubarraySteering` property of `H` is `'Phase'` or `'Time'`.

Default: `[0;0]`

`'Unit'`

The unit of the plot. Valid values are `'db'`, `'mag'`, `'pow'`, or `'dbi'`. This parameter determines the type of plot that is produced.

Unit value	Plot type
`db`	power pattern in dB scale
`mag`	field pattern
`pow`	power pattern
`dbi`	directivity

Default: `'db'`

`'Weights'`

Weight values applied to the array, specified as a length-*N* column vector or *N*-by-*M* matrix. The dimension *N* is the number of subarrays in the array. The interpretation of *M* depends upon whether the input argument `FREQ` is a scalar or row vector.

Weights Dimension	FREQ Dimension	Purpose
N-by-1 column vector	Scalar or 1-by-*M* row vector	Apply one set of weights for the same single frequency or all *M* frequencies.
N-by-*M* matrix	Scalar	Apply all of the *M* different columns in `Weights` for the same single frequency.
	1-by-*M* row vector	Apply each of the *M* different columns in `Weights` for the corresponding frequency in `FREQ`.

`'AzimuthAngles'`

Azimuth angles for plotting subarray response, specified as a row vector. The `AzimuthAngles` parameter sets the display range and resolution of azimuth angles for

visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'Az'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of azimuth angles should lie between –180° and 180° and must be in nondecreasing order. When you set the `RespCut` parameter to `'3D'`, you can set the `AzimuthAngles` and `ElevationAngles` parameters simultaneously.

Default: `[-180:180]`

`'ElevationAngles'`

Elevation angles for plotting subarray response, specified as a row vector. The `ElevationAngles` parameter sets the display range and resolution of elevation angles for visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'El'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of elevation angles should lie between –90° and 90° and must be in nondecreasing order. When you set the `RespCut` parameter to `'3D'`, you can set the `ElevationAngles` and `AzimuthAngles` parameters simultaneously.

Default: `[-90:90]`

`'UGrid'`

U coordinate values for plotting subarray response, specified as a row vector. The `UGrid` parameter sets the display range and resolution of the *U* coordinates for visualizing the radiation pattern in *U*/*V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'U'` or `'3D'`. The values of `UGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set the `UGrid` and `VGrid` parameters simultaneously.

Default: `[-1:0.01:1]`

`'VGrid'`

V coordinate values for plotting subarray response, specified as a row vector. The `VGrid` parameter sets the display range and resolution of the *V* coordinates for visualizing the radiation pattern in *U*/*V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'3D'`. The values of `VGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set the `VGrid` and `UGrid` parameters simultaneously.

Default: `[-1:0.01:1]`

Examples

Azimuth Response of Partitioned ULA

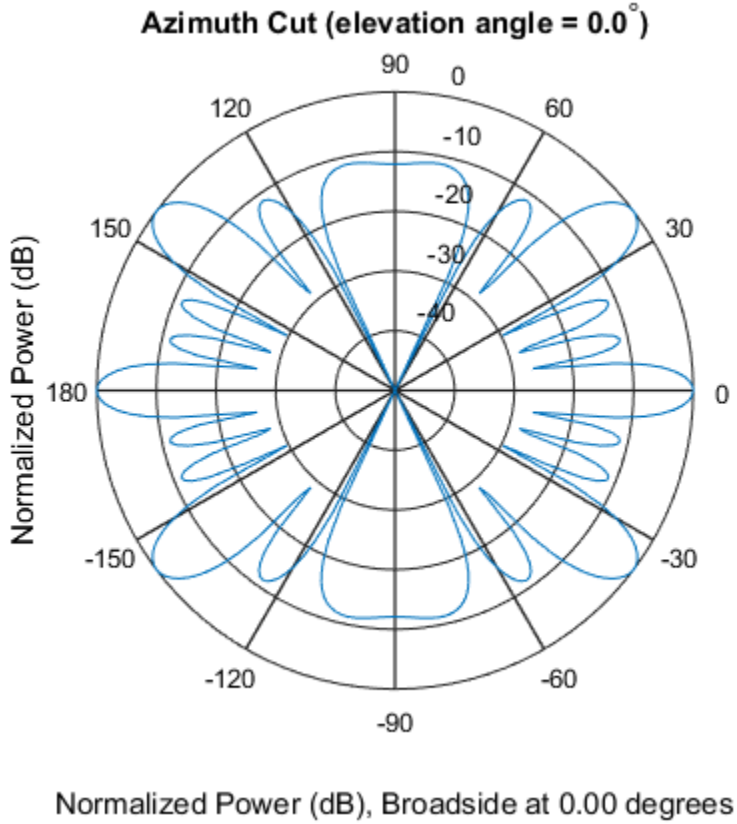
Plot the azimuth response of a 4-element ULA partitioned into two 2-element ULA's. The element spacing is one-half wavelength.

Create the ULA, and partition it into two 2-element ULA's.

```
sULA = phased.ULA('NumElements',4,'ElementSpacing',0.5);
sPA = phased.PartitionedArray('Array',sULA,...
    'SubarraySelection',[1 1 0 0;0 0 1 1]);
```

Plot the azimuth response of the array. Assume the operating frequency is 1 GHz and the propagation speed is the speed of light.

```
fc = 1e9;
pattern(sPA,fc,[-180:180],0,'Type','powerdb',...
    'CoordinateSystem','polar',...
    'Normalize',true)
```



Plot Response and Directivity of Partitioned URA Over Restricted Range of Angles

Convert a 2-by-6 URA of isotropic antenna elements into a 1-by-3 partitioned array so that each subarray of the partitioned array is a 2-by-2 URA. Assume that the frequency response of the elements lies between 1 and 6 GHz. The elements are spaced one-half wavelength apart corresponding to the highest frequency of the element response. Plot an azimuth cut from -50 to 50 degrees for different two sets of weights. For partitioned arrays, weights are applied to the subarrays instead of the elements.

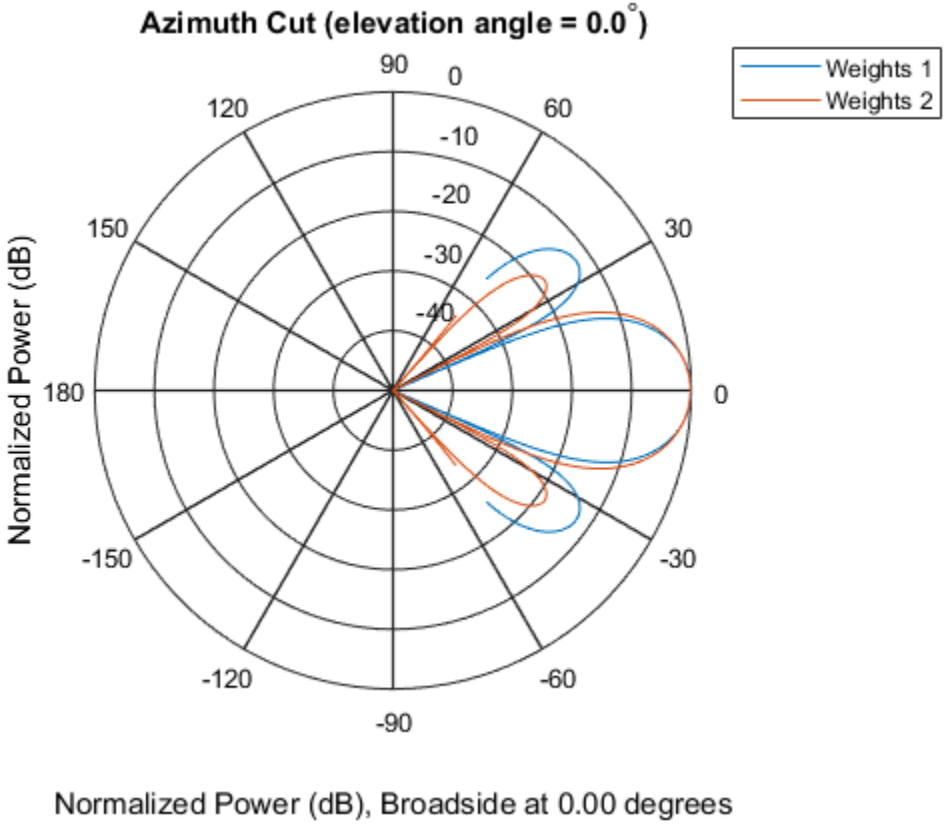
Set up the partitioned array.

```
fmin = 1e9;
fmax = 6e9;
```

```
c = physconst('LightSpeed');
lam = c/fmax;
s_iso = phased.IsotropicAntennaElement(...
    'FrequencyRange',[fmin,fmax],...
    'BackBaffled',false);
s_ura = phased.URA('Element',s_iso,'Size',[2,6],...
    'ElementSpacing',[lam/2,lam/2]);
subarraymap = [[1,1,1,1,0,0,0,0,0,0,0,0];...
    [0,0,0,0,1,1,1,1,0,0,0,0];...
    [0,0,0,0,0,0,0,0,1,1,1,1]];
s_pa = phased.PartitionedArray('Array',s_ura,...
    'SubarraySelection',subarraymap);
```

Plot the response of the array at 5 GHz over the restricted range of azimuth angles.

```
fc = 5e9;
wts = [[1,1,1]',[.862,1.23,.862]'];
plotResponse(s_pa,fc,c,'RespCut','Az',...
    'AzimuthAngles',[-50:0.1:50],...
    'Unit','db','Format','Polar',...
    'Weights',wts);
```



The plot of the response shows the broadening of the main lobe and the reduction of the strength of the sidelobes caused by the weight tapering.

Next, plot an azimuth cut of the directivity of the array at 5 GHz over the restricted range of azimuth angles for the two different sets of weights.

```
fc = 5e9;
wts = [[1,1,1]',[.862,1.23,.862]'];
plotResponse(s_pa,fc,c,'RespCut','Az',...
    'AzimuthAngles',[-50:0.1:50],...
    'Unit','dbi',...
    'Weights',wts);
```

step

System object: phased.PartitionedArray
Package: phased

Output responses of subarrays

Syntax

```
RESP = step(H,FREQ,ANG,V)
RESP = step(H,FREQ,ANG,V,STEERANGLE)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`RESP = step(H,FREQ,ANG,V)` returns the responses `RESP` of the subarrays in the array, at operating frequencies specified in `FREQ` and directions specified in `ANG`. The phase center of each subarray is at its geometric center. `V` is the propagation speed. The elements within each subarray are connected to the subarray phase center using an equal-path feed.

`RESP = step(H,FREQ,ANG,V,STEERANGLE)` uses `STEERANGLE` as the subarray's steering direction. This syntax is available when you set the `SubarraySteering` property to either `'Phase'` or `'Time'`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

H

Partitioned array object.

FREQ

Operating frequencies of array in hertz. `FREQ` is a row vector of length L. Typical values are within the range specified by a property of `H.Array.Element`. That property is named `FrequencyRange` or `FrequencyVector`, depending on the type of element in the array. The element has zero response at frequencies outside that range.

ANG

Directions in degrees. `ANG` can be either a 2-by-M matrix or a row vector of length M.

If `ANG` is a 2-by-M matrix, each column of the matrix specifies the direction in the form [azimuth; elevation]. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

If `ANG` is a row vector of length M, each element specifies a direction's azimuth angle. In this case, the corresponding elevation angle is assumed to be 0.

V

Propagation speed in meters per second. This value must be a scalar.

STEERANGLE

Subarray steering direction. `STEERANGLE` can be either a 2-element column vector or a scalar.

If `STEERANGLE` is a 2-element column vector, it has the form `[azimuth; elevation]`. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

If `STEERANGLE` is a scalar, it specifies the direction's azimuth angle. In this case, the elevation angle is assumed to be 0.

Output Arguments

RESP

Voltage responses of the subarrays of a phased array. The output depends on whether the array supports polarization or not.

- If the array is not capable of supporting polarization, the voltage response, `RESP`, has the dimensions *N*-by-*M*-by-*L*. The size *N* represents the number of subarrays in the phased array, *M* represents the number of angles specified in `ANG`, and *L* represents the number of frequencies specified in `FREQ`. For a particular subarray, each column of `RESP` contains the responses of the subarray for the corresponding direction specified in `ANG`. Each of the *L* pages of `RESP` contains the responses of the subarrays for the corresponding frequency specified in `FREQ`.
- If the array is capable of supporting polarization, the voltage response, `RESP`, is a MATLAB `struct` containing two fields, `RESP.H` and `RESP.V`. The field `RESP.H` represents the array's horizontal polarization response while `RESP.V` represents the array's vertical polarization response. Each field has the dimensions *N*-by-*M*-by-*L*. The size *N* represents the number of subarrays in the phased array, *M* represents the number of angles specified in `ANG`, and *L* represents the number of frequencies specified in `FREQ`. For a particular subarray, each column of `RESP` contains the responses of the subarray for the corresponding direction specified in `ANG`. Each of the *L* pages of `RESP` contains the responses of the subarrays for the corresponding frequency specified in `FREQ`.

Examples

Response of Subarrays in Partitioned ULA

Calculate the response at boresight of a 4-element ULA partitioned into two 2-element ULAs.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Set up the partitioned array.

```
hula = phased.ULA('NumElements',4,'ElementSpacing',0.5);
```

```
partitionedarray = phased.PartitionedArray('Array',hula,...
   'SubarraySelection',[1 1 0 0;0 0 1 1]);
```

Calculate the response of the subarrays at boresight. Assume the operating frequency is 1 GHz and the propagation speed is the speed of light.

```
resp = partitionedarray(1.0e9,[0;0],physconst('Lightspeed'))
```

```
resp =

     2
     2
```

viewArray

System object: phased.PartitionedArray
Package: phased

View array geometry

Syntax

```
viewArray(H)
viewArray(H,Name,Value)
hPlot = viewArray( ___ )
```

Description

`viewArray(H)` plots the geometry of the array specified in `H`.

`viewArray(H,Name,Value)` plots the geometry of the array, with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = viewArray( ___ )` returns the handles of the array elements in the figure window. All input arguments described for the previous syntaxes also apply here.

Input Arguments

`H`

Array object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'ShowIndex'`

Vector specifying the element indices to show in the figure. Each number in the vector must be an integer between 1 and the number of elements. You can also specify the value `'All'` to show indices of all elements of the array or `'None'` to suppress indices.

Default: `'None'`

`'ShowNormals'`

Set this value to `true` to show the normal directions of all elements of the array. Set this value to `false` to plot the elements without showing normal directions.

Default: `false`

`'ShowTaper'`

Set this value to `true` to specify whether to change the element color brightness in proportion to the element taper magnitude. When this value is set to `false`, all elements are drawn with the same color. The default value is `false`.

Default: `false`

`'ShowSubarray'`

Vector specifying the indices of subarrays to highlight in the figure. Each number in the vector must be an integer between 1 and the number of subarrays. You can also specify the value `'All'` to highlight all subarrays of the array or `'None'` to suppress the subarray highlighting. The highlighting uses different colors for different subarrays, and white for elements that occur in multiple subarrays.

Default: `'All'`

`'Title'`

Character vector specifying the title of the plot.

Default: `'Array Geometry'`

Output Arguments

`hPlot`

Handles of array elements in figure window.

Examples

Highlight Overlapped Subarrays

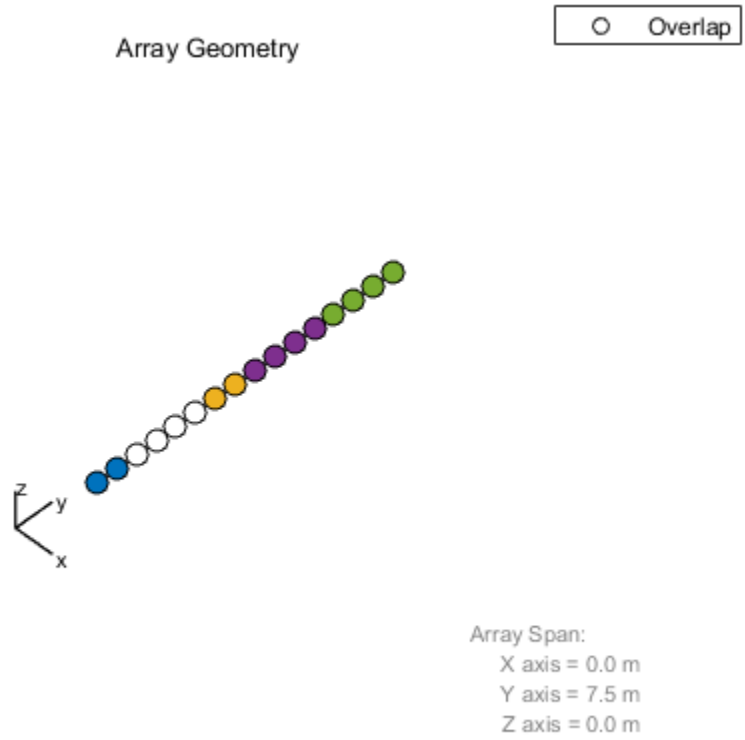
Display the geometry of a uniform linear array having overlapped subarrays.

Create a 16-element ULA that has five 4-element subarrays. Some elements occur in more than one subarray.

```
h = phased.ULA(16);
ha = phased.PartitionedArray('Array',h,...
    'SubarraySelection',...
    [1 1 1 1 0 0 0 0 0 0 0 0 0 0 0 0;...
    0 0 1 1 1 1 0 0 0 0 0 0 0 0 0 0;...
    0 0 0 0 1 1 1 1 0 0 0 0 0 0 0 0;...
    0 0 0 0 0 0 0 0 1 1 1 1 0 0 0 0;...
    0 0 0 0 0 0 0 0 0 0 0 0 1 1 1 1]);
```

Display the geometry of the array, highlighting all subarrays.

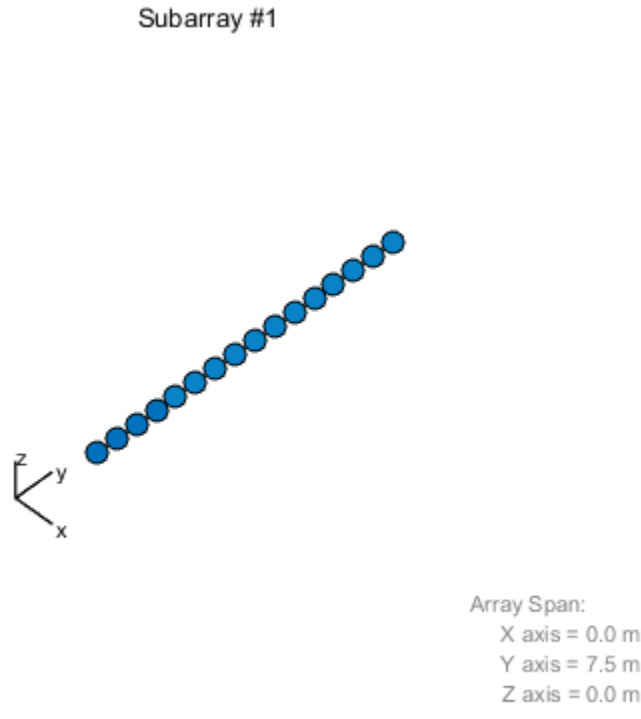
```
viewArray(ha);
```



Each color other than white represents a different subarray. White represents elements that occur in multiple subarrays.

Examine the overlapped subarrays by creating separate figures that highlight the first, second, and third subarrays. In each figure, dark blue represents the highlighted elements.

```
for idx = 1:3
    figure;
    viewArray(ha,'ShowSubarray',idx,...
        'Title',['Subarray #' num2str(idx)]);
end
```



Subarray #1
z
y

phased.PhaseCodedWaveform System object

Package: phased

Phase-coded pulse waveform

Description

The `PhaseCodedWaveform` object creates a phase-coded pulse waveform.

To obtain waveform samples:

1. Define and set up your phase-coded pulse waveform. See "Construction" on page 1-1425.
2. Call step to generate the phase-coded pulse waveform samples according to the properties of `phased.PhaseCodedWaveform`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations. When the only argument to the `step` method is the System object itself, replace `y = step(obj)` by `y = obj()`.

Construction

`H = phased.PhaseCodedWaveform` creates a phase-coded pulse waveform System object, `H`. The object generates samples of a phase-coded pulse.

`H = phased.PhaseCodedWaveform(Name,Value)` creates a phase-coded pulse waveform object, `H`, with additional options specified by one or more `Name,Value` pair arguments. `Name` is a property name, and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

Properties

SampleRate

Sample rate

Specify the sample rate in hertz as a positive scalar. The default value of this property corresponds to 1 MHz. The value of this property must satisfy these constraints:

- `(SampleRate./PRF)` is a scalar or vector that contains only integers — the number of samples in a pulse must be an integer.
- `(SampleRate*ChipWidth)` is an integer value — the number of samples in a chip must be an integer.

Default: `1e6`

Code

Phase code type

Specify the phase code type used in phase modulation. Valid values are:

- `'Barker'`
- `'Frank'`
- `'P1'`
- `'P2'`
- `'P3'`
- `'P4'`
- `'Px'`
- `'Zadoff-Chu'`

Default: `'Frank'`

ChipWidth

Time duration of each chip

Specify the time duration of each chip in a phase-coded waveform as a positive scalar. Units are seconds. For this waveform, the pulse duration is equal to the product of the chip width and number of chips.

The value of this property must satisfy these constraints:

- `ChipWidth` is less than or equal to `(1./(NumChips*PRF))` — the total time duration of all chips cannot exceed the duration of the pulse.
- `(SampleRate*ChipWidth)` is an integer value — the number of samples in a chip must be an integer.

Default: `1e-5`

`NumChips`

Number of chips

Specify the number of chips per pulse in a phase-coded waveform as a positive integer. The value of this property must be less than or equal to `(1./(ChipWidth*PRF))` — the total time duration of all chips cannot exceed the pulse repetition interval.

The table shows additional constraints on the number of chips for different code types.

If the `Code` property is ...	Then the `NumChips` property must be...
`'Frank'`, `'P1'`, or `'Px'`	A perfect square
`'P2'`	An even number that is a perfect square
`'Barker'`	2, 3, 4, 5, 7, 11, or 13

Default: `4`

`SequenceIndex`

Zadoff-Chu sequence index

Specify the sequence index used in Zadoff-Chu code as a positive integer. This property applies only when you set the `Code` property to `'Zadoff-Chu'`. The value of `SequenceIndex` must be relatively prime to the value of the `NumChips` property.

Default: `1`

`PRF`

Pulse repetition frequency

Pulse repetition frequency, *PRF*, specified as a scalar or a row vector. Units are in Hz. The pulse repetition interval *PRI* is the inverse of the *PRF*. The value of the `PRF` property must satisfy these constraints:

- The product of *PRF* and *PulseWidth* must be less than or equal to one. This is equivalent to the requirement that the pulse width is less than a pulse repetition interval. For the phase-coded waveform, the pulse width is the product of the chip width and number of chips.
- The ratio of sample rate to PRF must be an integer. This is equivalent to requiring that the number of samples in one pulse repetition interval be an integer.

You can select the value of *PRF* by using property settings or input arguments.

- When `PRFSelectionInputPort` is `false`, you set the *PRF* using properties
  - implement a constant *PRF* by specifying `PRF` as a positive real-valued scalar.
  - implement a staggered *PRF* by specifying `PRF` as a row vector with positive real-valued entries. Then, each call to the `step` method uses successive elements of this vector for the *PRF*. If the last element of the vector is reached, the process continues cyclically with the first element of the vector.
- When `PRFSelectionInputPort` is `true`, you can implement a selectable *PRF* by specifying `PRF` as a row vector with positive real-valued entries. But this time, when you execute the `step` method, select a *PRF* by passing an index into the *PRF* vector as an argument.

In all cases, when you use a varying *PRF* and choose the `OutputFormat` property as `'Pulses'`, the number of samples per pulse can vary as well. When you choose `'Samples'` the number of samples per pulse is fixed.

Default: `10e3`

`PRFSelectionInputPort`

Enable PRF selection input

Enable the PRF selection input, specified as `true` or `false`. When you set this property to `false`, the step method uses the values set in the `PRF` property in order. When you set this property to `true`, you can pass an additional argument into the `step` method to select any value from the PRF vector.

Default: `false`

`OutputFormat`

Output signal format

Specify the format of the output signal as `'Pulses'` or `'Samples'`. When you set the `OutputFormat` property to `'Pulses'`, the output of the `step` method takes the form of multiple pulses specified by the value of the `NumPulses` property. The number of samples per pulse can vary if you change the pulse repetition frequency during the simulation.

When you set the `OutputFormat` property to `'Samples'`, the output of the `step` method is in the form of multiple samples. In this case, the number of output signal samples is the value of the `NumSamples` property and is fixed.

Default: `'Pulses'`

`NumSamples`

Number of samples in output

Specify the number of samples in the output of the `step` method as a positive integer. This property applies only when you set the `OutputFormat` property to `'Samples'`.

Default: `100`

`NumPulses`

Number of pulses in output

Specify the number of pulses in the output of the `step` method as a positive integer. This property applies only when you set the `OutputFormat` property to `'Pulses'`.

Default: `1`

Methods

bandwidth	Bandwidth of phase-coded waveform
getMatchedFilter	Matched filter coefficients for waveform
plot	Plot phase-coded pulse waveform
reset	Reset states of phase-coded waveform object
step	Samples of phase-coded waveform

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

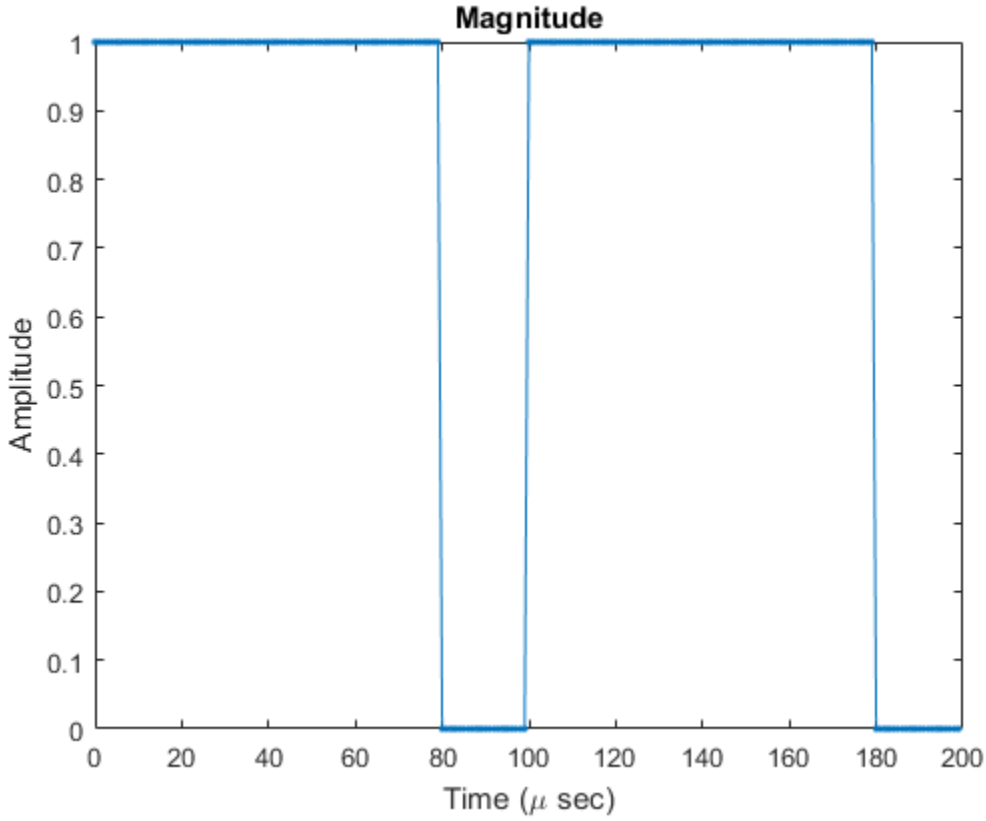
Plot Phase-Coded Waveform and Spectrum

Create and plot a two-pulse phase-coded waveform that uses the Zadoff-Chu code.

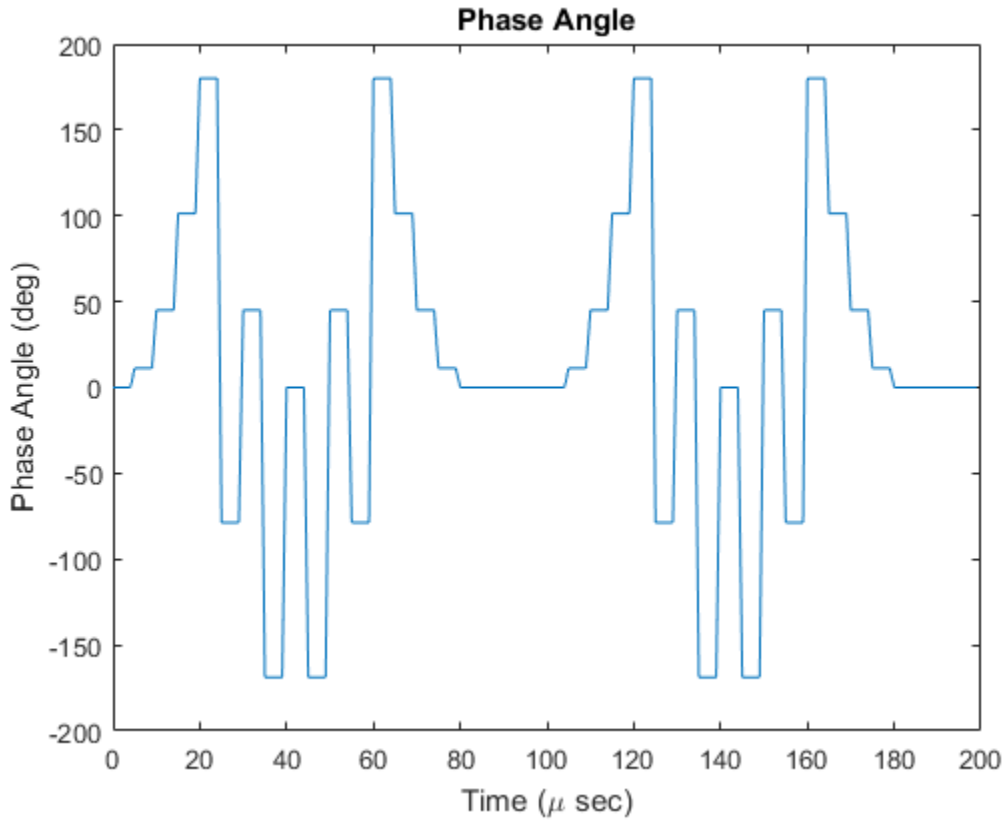
```
sPCW = phased.PhaseCodedWaveform('Code','Zadoff-Chu',...
    'ChipWidth',5e-6,'NumChips',16,...
    'OutputFormat','Pulses','NumPulses',2);
fs = sPCW.SampleRate;
```

Generate signal samples and plot the magnitude and phase of the waveforms.

```
wav = step(sPCW);
nsamp = size(wav,1);
t = [0:(nsamp-1)]/fs;
plot(t*1e6,abs(wav),'.-')
title('Magnitude')
xlabel('Time (\mu sec)')
ylabel('Amplitude')
```

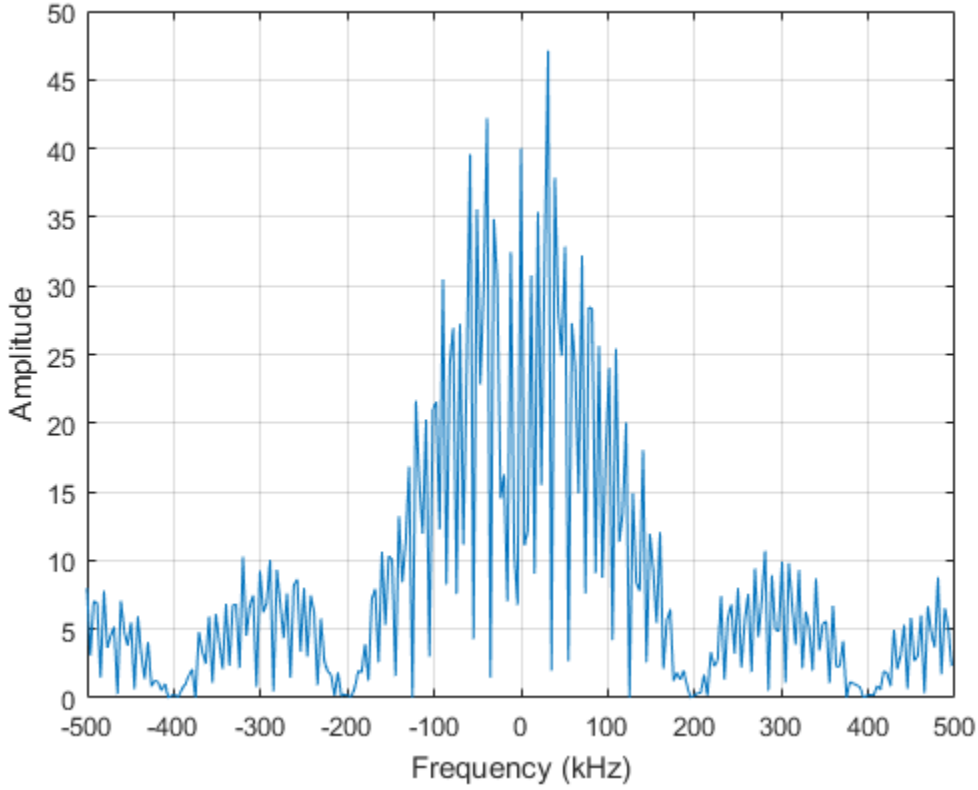


```
plot(t*1e6,180/pi*angle(wav))
title('Phase Angle')
xlabel('Time (\mu sec)')
ylabel('Phase Angle (deg)')
```



Plot the spectrum.

```
nsamp = size(wav,1);
nfft = 2^nextpow2(nsamp);
Z = fft(wav,nfft);
fr = [0:(nfft-1)]/nfft*fs;
fr = fr - fs/2;
plot(fr/1000,abs(fftshift(Z)))
xlabel('Frequency (kHz)')
ylabel('Amplitude')
grid
```



- Waveform Analysis Using the Ambiguity Function

Algorithms

A 2-chip Barker code can use [1 –1] or [1 1] as the sequence of amplitudes. This software implements [1 –1].

A 4-chip Barker code can use [1 1 –1 1] or [1 1 1 –1] as the sequence of amplitudes. This software implements [1 1 –1 1].

A Zadoff-Chu code can use a clockwise or counterclockwise sequence of phases. This software implements the latter, such as $\pi \cdot f(k) \cdot \texttt{SequenceIndex}/\texttt{NumChips}$ instead of

$-\pi \cdot f(k) \cdot$ `SequenceIndex/NumChips` . In these expressions, k is the index of the chip and $f(k)$ is a function of k.

For further details, see [1].

Topics

Waveform Analysis Using the Ambiguity Function
"Phase-Coded Waveforms"

Introduced in R2012a

bandwidth

System object: phased.PhaseCodedWaveform
Package: phased

Bandwidth of phase-coded waveform

Syntax

```
bw = bandwidth(waveform)
```

Description

`bw = bandwidth(waveform)` returns the bandwidth (in hertz) of the pulses for the phase-coded pulse waveform, `waveform`. The bandwidth value is the reciprocal of the chip width.

Input Arguments

`waveform`

Phase-coded waveform object.

Output Arguments

`bw`

Bandwidth of the pulses, in hertz.

Examples

Phase-Coded Waveform Bandwidth

Determine the bandwidth of a Frank phased-coded waveform.

```
waveform = phased.PhaseCodedWaveform;
bw = bandwidth(waveform)

bw =

   1.0000e+05
```

getMatchedFilter

System object: phased.PhaseCodedWaveform
Package: phased

Matched filter coefficients for waveform

Syntax

```
Coeff = getMatchedFilter(H)
```

Description

`Coeff = getMatchedFilter(H)` returns the matched filter coefficients for the phase-coded waveform object, `H`. `Coeff` is a column vector.

Input Arguments

`H`

Phase-coded waveform object.

Output Arguments

`Coeff`

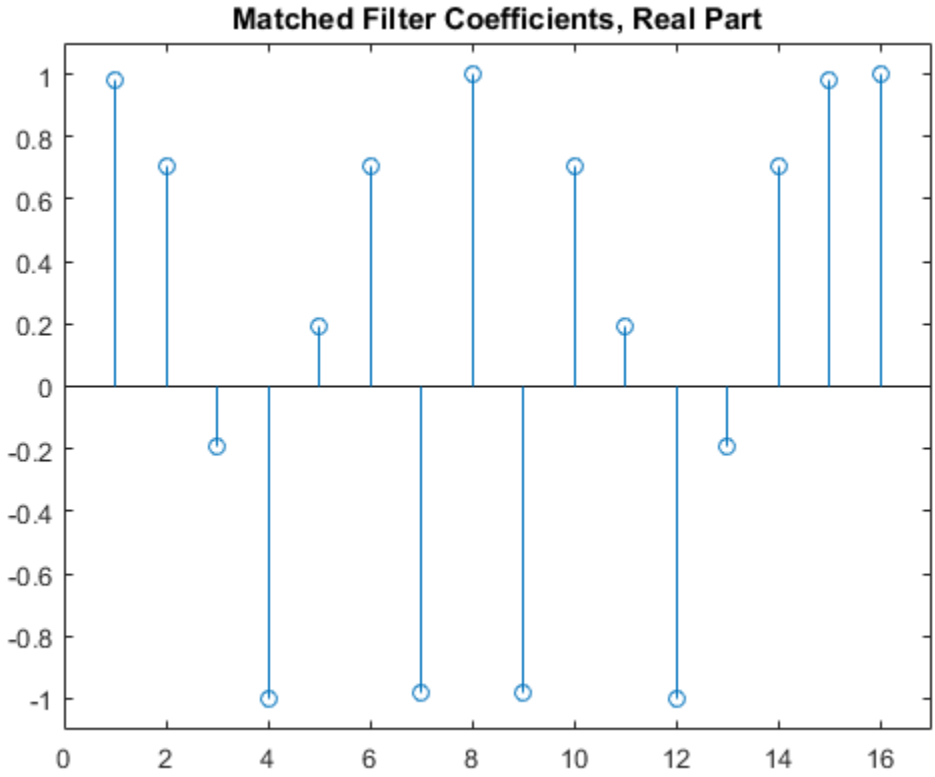
Column vector containing coefficients of the matched filter for `H`.

Examples

Matched-Filter Coefficients for Pulse-Coded Waveform

Obtain the matched filter coefficients for a phase-coded pulse waveform that uses the Zadoff-Chu code.

```
waveform = phased.PhaseCodedWaveform('Code','Zadoff-Chu','ChipWidth',1e-6, ...
    'NumChips',16,'OutputFormat','Pulses','NumPulses',2);
coeff = getMatchedFilter(waveform);
stem(real(coeff))
title('Matched Filter Coefficients, Real Part')
axis([0 17 -1.1 1.1])
```



plot

System object: phased.PhaseCodedWaveform
Package: phased

Plot phase-coded pulse waveform

Syntax

```
plot(Hwav)
plot(Hwav,Name,Value)
plot(Hwav,Name,Value,LineSpec)
h = plot( ___ )
```

Description

`plot(Hwav)` plots the real part of the waveform specified by `Hwav`.

`plot(Hwav,Name,Value)` plots the waveform with additional options specified by one or more `Name,Value` pair arguments.

`plot(Hwav,Name,Value,LineSpec)` specifies the same line color, line style, or marker options as are available in the MATLAB `plot` function.

`h = plot( ___ )` returns the line handle in the figure.

Input Arguments

`Hwav`

Waveform object. This variable must be a scalar that represents a single waveform object.

`LineSpec`

Character vector to specifies the same line color, style, or marker options as are available in the MATLAB `plot` function. If you specify a `PlotType` value of `'complex'`, then `LineSpec` applies to both the real and imaginary subplots.

Default: `'b'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'PlotType'`

Specifies whether the function plots the real part, imaginary part, or both parts of the waveform. Valid values are `'real'`, `'imag'`, and `'complex'`.

Default: `'real'`

`'PulseIdx'`

Index of the pulse to plot. This value must be a scalar.

Default: 1

Output Arguments

`h`

Handle to the line or lines in the figure. For a `PlotType` value of `'complex'`, `h` is a column vector. The first and second elements of this vector are the handles to the lines in the real and imaginary subplots, respectively.

Examples

Plot Pulse-Coded Waveform

Create and plot a phase-coded pulse waveform that uses the Zadoff-Chu code.

```
waveform = phased.PhaseCodedWaveform('Code','Zadoff-Chu','ChipWidth',1e-6, ...
    'NumChips',16,'OutputFormat','Pulses','NumPulses',2);
plot(waveform)

reset

System object: phased.PhaseCodedWaveform
Package: phased

Reset states of phase-coded waveform object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `PhaseCodedWaveform` object, `H`. Afterward, the next call to `step` restarts the phase sequence from the beginning. Also, if the `PRF` property is a vector, the next call to `step` uses the first PRF value in the vector.

step

System object: phased.PhaseCodedWaveform
Package: phased

Samples of phase-coded waveform

Syntax

```
Y = step(sPCW)
Y = step(sPCW,prfidx)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations. When the only argument to the `step` method is the System object itself, replace `y = step(obj)` by `y = obj()`.

`Y = step(sPCW)` returns samples of the phase-coded pulse in a column vector, `Y`.

`Y = step(sPCW,prfidx)`, uses the `prfidx` index to select the PRF from the predefined vector of values specified by in the `PRF` property. This syntax applies when you set the `PRFSelectionInputPort` property to `true`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

sPCW

Phase-coded waveform object.

Output Arguments

Y

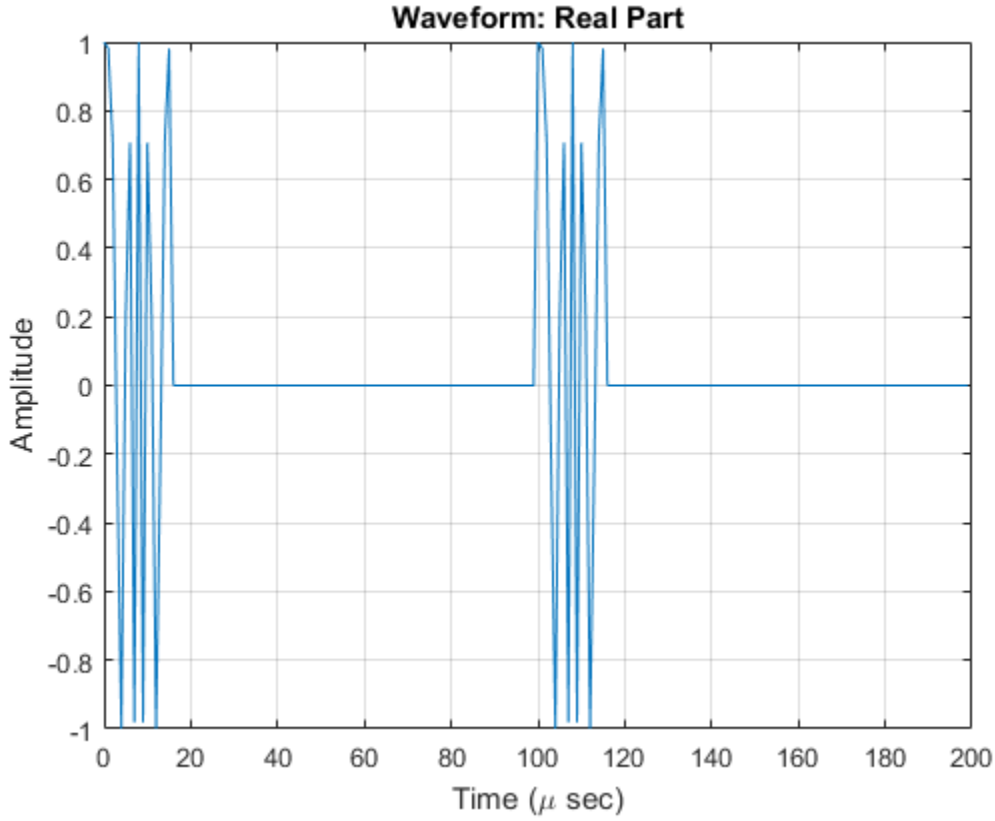
Column vector containing the waveform samples.

Examples

Create Pulse Coded Waveform

Generate samples of two pulses of a phase-coded pulse waveform that uses the Zadoff-Chu code.

```
sPCW = phased.PhaseCodedWaveform('Code','Zadoff-Chu',...
    'ChipWidth',1e-6,'NumChips',16,...
    'OutputFormat','Pulses','NumPulses',2);
wav = step(sPCW);
fs = sPCW.SampleRate;
nsamps = size(wav,1);
t = [0:(nsamps-1)]/fs;
plot(t*1e6,real(wav))
title('Waveform: Real Part')
xlabel('Time (\mu sec)')
ylabel('Amplitude')
grid
```



Create Phase-Coded Waveform with Variable PRF

Create and plot two-pulse phase-coded waveforms that uses the Zadoff-Chu code. Set the sample rate to 1 MHz, a chip width of 5 microseconds, 16 chips per pulse. Vary the pulse repetition frequency.

```
fs = 1e6;
PRF = [5000,10000];
waveform = phased.PhaseCodedWaveform('SampleRate',fs,...
    'Code','Zadoff-Chu','PRFSelectionInputPort',true,...
    'ChipWidth',5e-6,'NumChips',16,'PRF',PRF,...
    'OutputFormat','Pulses','NumPulses',2);
```

Obtain and plot the phsed-coded waveforms. For the first call to the `step` method, set the PRF to 10kHz using the PRF index. For the next call, set the PRF to 25 kHz. For the final call, set the PRF to 10kHz.

```
wav = [];
wav1 = waveform(1);
wav = [wav; wav1];
wav1 = waveform(2);
wav = [wav; wav1];
wav1 = waveform(1);
wav = [wav; wav1];
nsamps = size(wav,1);
t = [0:(nsamps-1)]/fs;
plot(t*1e6,real(wav))
xlabel('Time (\mu sec)')
ylabel('Amplitude')
```

phased.PhaseShiftBeamformer System object

Package: phased

Narrowband phase shift beamformer

Description

The `PhaseShiftBeamformer` object implements a phase shift beamformer.

To compute the beamformed signal:

1. Define and set up your phase shift beamformer. See "Construction" on page 1-1448.
2. Call step to perform the beamforming operation according to the properties of `phased.PhaseShiftBeamformer`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.PhaseShiftBeamformer` creates a conventional phase shift beamformer System object, `H`. The object performs phase shift beamforming on the received signal.

`H = phased.PhaseShiftBeamformer(Name,Value)` creates a phase shift beamformer object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`SensorArray`

Sensor array

Sensor array specified as an array System object belonging to the `phased` package. A sensor array can contain subarrays.

Default: phased.ULA with default property values

`PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

Default: Speed of light

`OperatingFrequency`

System operating frequency

Specify the operating frequency of the beamformer in hertz as a scalar. The default value of this property corresponds to 300 MHz.

Default: `3e8`

`DirectionSource`

Source of beamforming direction

Specify whether the beamforming direction for the beamformer comes from the `Direction` property of this object or from an input argument in step. Values of this property are:

`'Property'`	The `Direction` property of this object specifies the beamforming direction.
`'Input port'`	An input argument in each invocation of `step` specifies the beamforming direction.

Default: `'Property'`

`Direction`

Beamforming directions

Specify the beamforming directions of the beamformer as a two-row matrix. Each column of the matrix has the form [AzimuthAngle; ElevationAngle] (in degrees). Each azimuth

angle must be between –180 and 180 degrees, and each elevation angle must be between –90 and 90 degrees. This property applies when you set the `DirectionSource` property to `'Property'`.

Default: `[0; 0]`

`NumPhaseShifterBits`

Number of phase shifter quantization bits

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

Default: `0`

`WeightsNormalization`

Approach for normalizing beamformer weights

If you set this property value to `'Distortionless'`, the gain in the beamforming direction is 0 dB. If you set this property value to `'Preserve power'`, the norm of the weights is unity.

Default: `'Distortionless'`

`WeightsOutputPort`

Output beamforming weights

To obtain the weights used in the beamformer, set this property to `true` and use the corresponding output argument when invoking step. If you do not want to obtain the weights, set this property to `false`.

Default: `false`

Methods

step	Perform phase shift beamforming

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Phase-Shift ULA Beamformer

Apply phase-shift beamforming to a sinewave signal received by a 5-element ULA. The beamforming direction is 45° azimuth and 0° elevation. Assume the array operates at 300 MHz.

Simulate the signal.

```
t = (0:1000)';
fsignal = 0.01;
x = sin(2*pi*fsignal*t);
c = physconst('Lightspeed');
fc = 300e6;
incidentAngle = [45;0];
array = phased.ULA('NumElements',5);
x = collectPlaneWave(array,x,incidentAngle,fc,c);
noise = 0.1*(randn(size(x)) + 1j*randn(size(x)));
rx = x + noise;
```

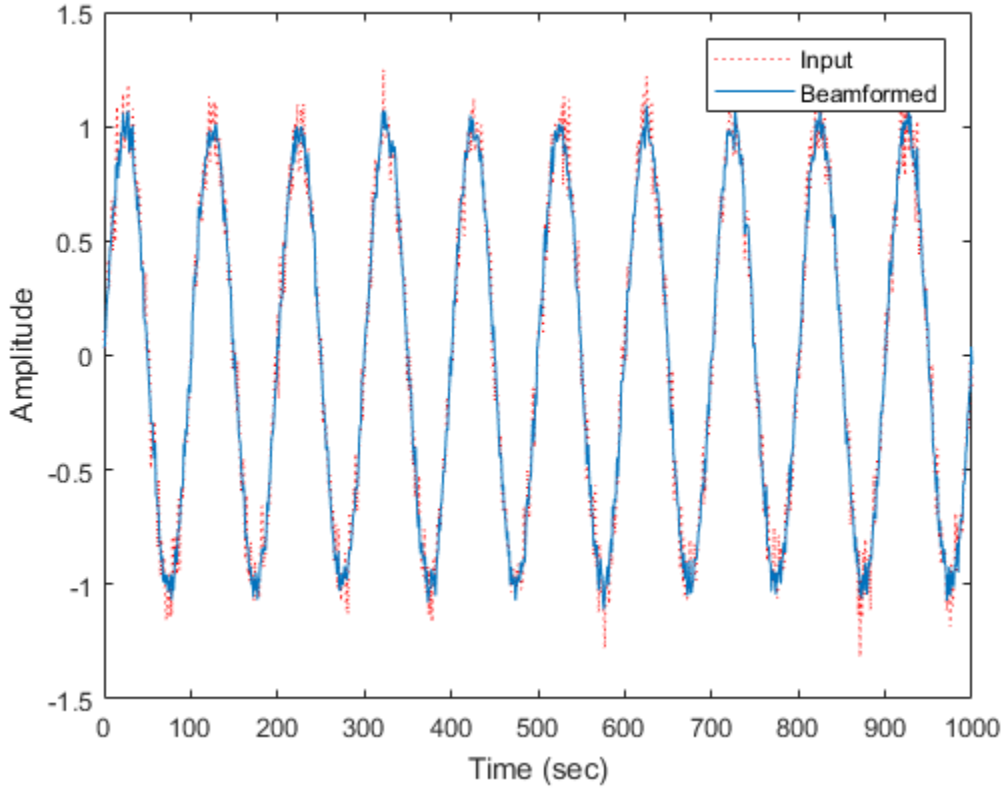
Set up a phase-shift beamformer and then perform the beamforming step on the input data.

```
beamformer = phased.PhaseShiftBeamformer('SensorArray',array,...
    'OperatingFrequency',fc,'PropagationSpeed',c,...
    'Direction',incidentAngle,'WeightsOutputPort',true);
[y,w] = beamformer(rx);
```

Plot the beamformed data with the middle sensor input data.

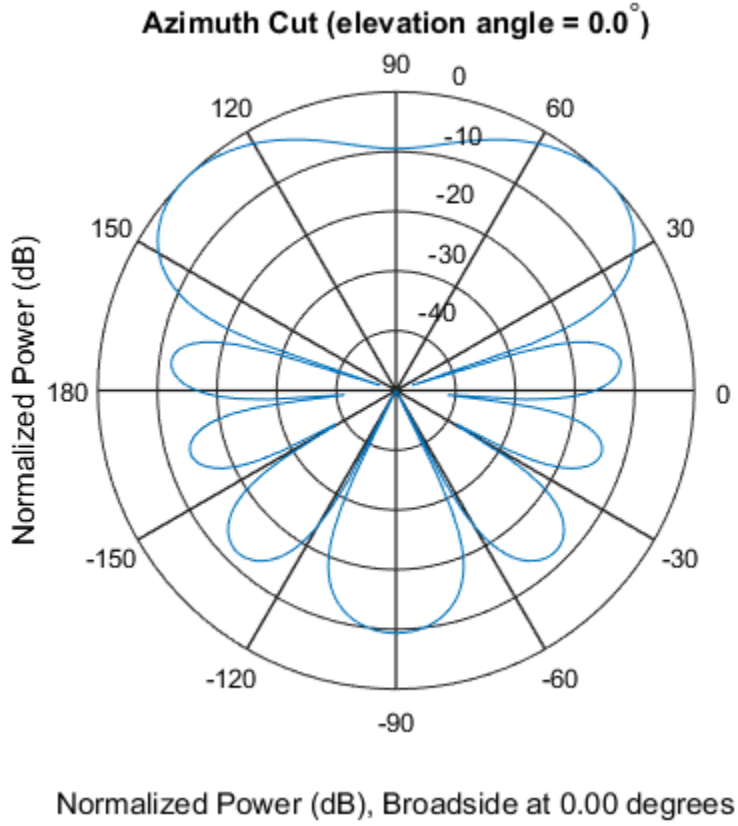
```
plot(t,real(rx(:,3)),'r:',t,real(y))
```

```
xlabel('Time (sec)')
ylabel('Amplitude')
legend('Input','Beamformed')
```



Plot the response pattern.

```
pattern(array,fc,[-180:180],0,'PropagationSpeed',c,'Type',...
    'powerdb','CoordinateSystem','polar','Weights',w)
```



Algorithms

The phase shift beamformer uses the conventional delay-and-sum beamforming algorithm. The beamformer assumes the signal is narrowband, so a phase shift can approximate the required delay. The beamformer preserves the incoming signal power.

For further details, see [1].

Introduced in R2012a

step

System object: phased.PhaseShiftBeamformer
Package: phased

Perform phase shift beamforming

Syntax

```
Y = step(H,X)
Y = step(H,X,ANG)
[Y,W] = step( ___ )
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` performs phase shift beamforming on the input, `X`, and returns the beamformed output in `Y`.

`Y = step(H,X,ANG)` uses `ANG` as the beamforming direction. This syntax is available when you set the `DirectionSource` property to `'Input port'`.

`[Y,W] = step( ___ )` returns the beamforming weights, `W`. This syntax is available when you set the `WeightsOutputPort` property to `true`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

H

Beamformer object.

X

Input signal, specified as an *M*-by-*N* matrix. If the sensor array contains subarrays, *N* is the number of subarrays; otherwise, *N* is the number of elements.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

ANG

Beamforming directions, specified as a two-row matrix. Each column has the form [AzimuthAngle; ElevationAngle], in degrees. Each azimuth angle must be between –180 and 180 degrees, and each elevation angle must be between –90 and 90 degrees.

Output Arguments

Y

Beamformed output. `Y` is an *M*-by-*L* matrix, where *M* is the number of rows of `X` and *L* is the number of beamforming directions.

W

Beamforming weights. `W` is an *N*-by-*L* matrix, where *L* is the number of beamforming directions. If the sensor array contains subarrays, *N* is the number of subarrays; otherwise, *N* is the number of elements.

Examples

Phase-Shift Beamformer Using ULA

Apply phase-shift beamforming to the signal received by a 5-element ULA. The beamforming direction is 45° azimuth and 0° elevation.

Create the signal.

```
t = (0:1000)';
x = sin(2*pi*0.01*t);
c = physconst('LightSpeed');
fc = 3e8;
incidentAngle = [45;0];
array = phased.ULA('NumElements',5);
x = collectPlaneWave(array,x,incidentAngle,fc,c);
noise = 0.1*(randn(size(x)) + 1j*randn(size(x)));
rx = x + noise;
```

Construct the phase-shift beamformer.

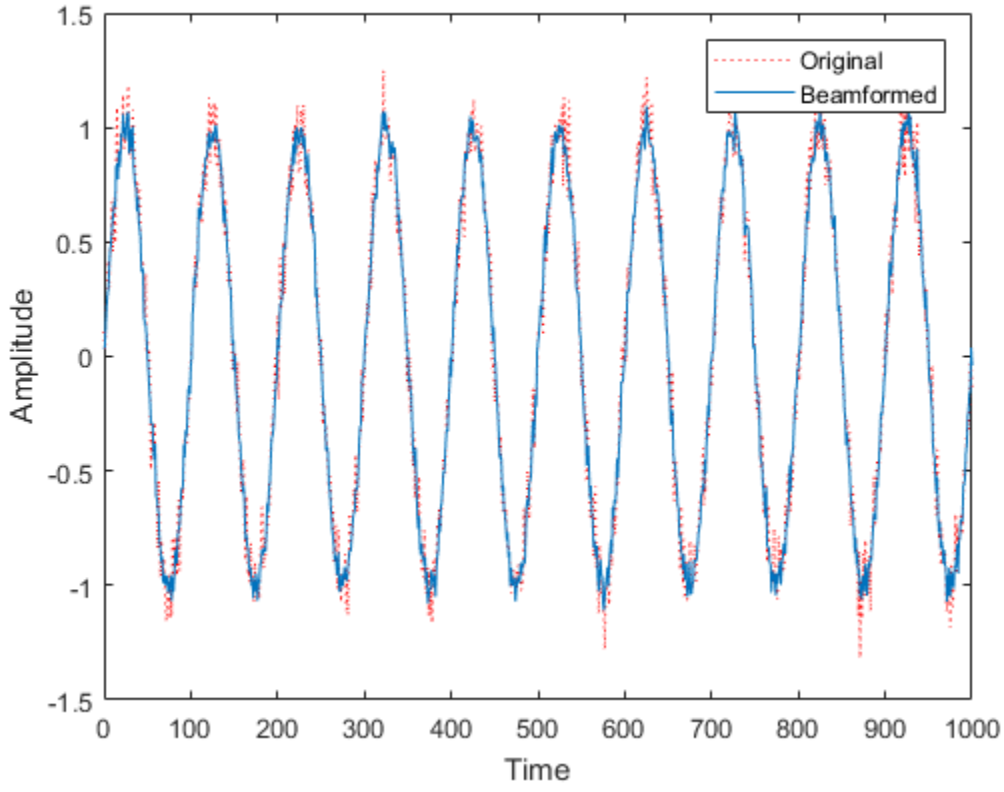
```
beamformer = phased.PhaseShiftBeamformer('SensorArray',array,...
    'OperatingFrequency',fc,'PropagationSpeed',c,...
    'Direction',incidentAngle,'WeightsOutputPort',true);
```

Obtain the beamformed signal and beamformer weights.

```
[y,w] = beamformer(rx);
```

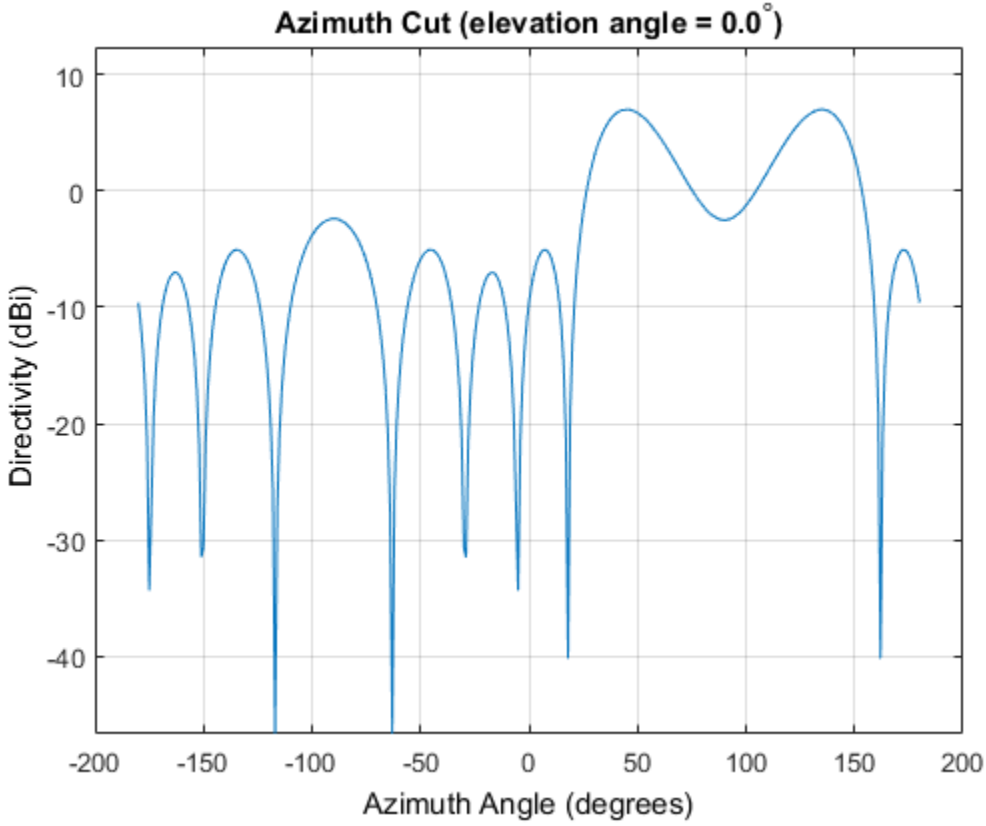
Plot the original signal at the middle element and the beamformed signal.

```
plot(t,real(rx(:,3)),'r:',t,real(y))
xlabel('Time')
ylabel('Amplitude')
legend('Original','Beamformed')
```



Plot the array response pattern when applying the weights.

```
pattern(array,fc,[-180:180],0,'PropagationSpeed',c,'CoordinateSystem','rectangular','We
```



Algorithms

The phase shift beamformer uses the conventional delay-and-sum beamforming algorithm. The beamformer assumes the signal is narrowband, so a phase shift can approximate the required delay. The beamformer preserves the incoming signal power.

For further details, see [1].

phased.Platform System object

Package: phased

Model platform motion

Description

The `phased.Platform` System object models the translational motion of one or more platforms in space. A platform can be a target such as a vehicle or airplane, or a sonar or radar transmitter and receiver. The model assumes that the platform undergoes translational motion at constant velocity or constant acceleration during each simulation step. Positions and velocities are always defined in the global coordinate system.

To model a moving platform:

1. Define and set up your platform using the "Construction" on page 1-1461 procedure.
2. Repeatedly call the step method to move the platform along a path determined by the `phased.Platform` properties.

   The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`sPlat = phased.Platform` creates a platform System object, `sPlat`. The object models a stationary platform with position at the origin and velocity set to zero.

`sPlat = phased.Platform(Name,Value)` creates an object, `sPlat`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

`sPlat = phased.Platform(pos,vel,Name,Value)` creates a platform object, `sPlat`, with `InitialPosition` set to `pos` and `Velocity` set to `vel`. Other specified property

Names are set to specified Values. The `pos` and `vel` arguments are value-only. Value-only arguments do not require a specified Name but are interpreted according to their argument positions. To specify any value-only argument, specify all preceding value-only arguments.

The motion model is either constant velocity or constant acceleration. You can choose one of two motion models using the `MotionModel` property.

MotionModel Property	Usage
`Velocity`	If you set the `VelocitySource` property to `'Property'`, the platform moves with constant velocity determined by the `Velocity` property. You can specify the `InitialPosition` property or leave it to its default value. You can change the tunable `Velocity` property at any simulation step. When you set the `VelocitySource` property to `'Input port'`, you can input instantaneous velocity as an argument to the `step` method. Specify the initial position using the `InitialPosition` property or leave it as a default value.
`Acceleration`	When you set the `AccelerationSource` property to `'Property'`, the platform moves with constant acceleration determined by the `Acceleration` property. You can specify the `InitialPosition` and `InitialVelocity` properties or leave them to their defaults. You can change the tunable `Acceleration` property at any simulation step. When you set the `AccelerationSource` property to `'Input port'`, you can input instantaneous acceleration as an argument to the `step` method. Specify the `InitialPosition` and

MotionModel Property	Usage
	`InitialVelocity` properties or leave them as their defaults.

Properties

`MotionModel`

Object motion model

Object motion model, specified as one of `'Velocity'` or `'Acceleration'`. When you set this property to `'Velocity'`, the object follows a constant velocity trajectory during each simulation step. When you set this property to `'Acceleration'`, the object follows a constant acceleration trajectory during each simulation step.

Default: `'Velocity'`

`InitialPosition`

Initial position of platform

Initial position of platform, specified as a real-valued 3-by-1 column vector in the form of `[x;y;z]` or a real-valued 3-by-*N* matrix where *N* is the number of platforms. Each column takes the form `[x;y;z]`. Position units are meters.

Default: `[0;0;0]`

`InitialVelocity`

Initial velocity of platform

Initial velocity of platform, specified as a real-valued 3-by-1 column vector in the form of `[vx;vy;vz]` or a real-valued 3-by-*N* matrix where *N* is the number of platforms. Each column taking the form `[vx;vy;vz]`. Velocity units are meters per second.

This property only applies when you set the `MotionModel` property to `'Velocity'` and the `VelocitySource` to `'Input port'`, or when you set the `MotionModel` property to `'Acceleration'`.

Default: `[0;0;0]`

`VelocitySource`

Source of velocity data

Source of velocity data, specified as one of `'Property'` or `'Input port'`. When you set the value of this property to `'Property'`, use `Velocity` property to set the velocity. When you set this property to `'Input port'`, use an input argument of the step method to set the velocity.

This property applies when you set the `MotionModel` property to `'Velocity'`.

Default: `'Property'`

`Velocity`

Current velocity of platform

Specify the current velocity of the platform as a 3-by-1 real-valued column vector in the form of `[vx;vy;vz]` or a 3-by-*N* real-valued matrix for multiple platforms. Each column taking the form `[vx;vy;vz]`. Velocity units are meters/sec. The dimension *N* is the number of platforms.

This property applies when you set the `MotionModel` property to `'Velocity'` and the `VelocitySource` to `'Property'`. This property is tunable.

Default: `[0;0;0]`

`AccelerationSource`

Source of acceleration data

Source of acceleration data, specified as one of `'Property'` or `'Input port'`. When you set the value of this property to `'Property'`, specify the acceleration using the `Acceleration` property. When you set this property to `'Input port'`, use an input argument of the step method to set the acceleration.

This property applies when you set the `MotionModel` property to `'Acceleration'`.

Default: `'Property'`

`Acceleration`

Acceleration of platform

Specify the current acceleration of the platform as a real-valued 3-by-1 column vector in the form `[ax;ay;az]` or a real-valued 3-by-*N* matrix with each column taking the form `[ax;ay;az]`. The dimension *N* is the number of platforms. Acceleration units are meters/sec/sec.

This property applies when you set the `MotionModel` property to `'Acceleration'` and `AccelerationSource` to `'Property'`. This property is tunable.

Default: `[0;0;0]`

`InitialOrientationAxes`

Initial orientation axes of platform

Initial orientation axes of platform, specified as a 3-by-3 real-valued orthonormal matrix for a single platform or as a 3-by-3-by-*N* real-valued matrix for multiple platforms. The dimension *N* is the number of platforms. When the orientation matrix is 3-by-3, the three columns represent the axes of the local coordinate system *(xyz)*. When the orientation matrix is 3-by-3-by-*N*, for each *page* index, the resulting 3-by-3 matrix represents the axes of a local coordinate system.

Default: `[1 0 0;0 1 0;0 0 1]`

`OrientationAxesOutputPort`

Output orientation axes

To obtain the instantaneous orientation axes of the platform, set this property to `true` and use the corresponding output argument when invoking step. If you do not want to obtain the orientation axes of the platform, set this property to `false`.

Default: `false`

Methods

reset	Reset platform to initial position

step	Output current position, velocity, and orientation axes of platform

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Simulate motion of a platform

Create a platform at the origin having a velocity of (100,100,0) meters per second. Simulate the motion of the platform for two time steps, assuming the time elapsed for each step is one second. The position of the platform is updated after each step.

```
sPlat = phased.Platform([0; 0; 0],[100; 100; 0]);
T = 1;
```

At the first call to step, the position is at its initial value.

```
[pos,v] = step(sPlat,T);
pos
```

```
pos =

     0
     0
     0
```

At the second call to step, the position changes.

```
[pos,v] = step(sPlat,T);
pos
```

```
pos =

   100
   100
     0
```

Model Motion of Circling Airplane

Start with an airplane moving at 150 kmh in a circle of radius 10 km and descending at the same time at a rate of 20 m/sec. Compute the motion of the airplane from its instantaneous acceleration as an argument to the `step` method. Set the initial orientation of the platform to the identity, coinciding with the global coordinate system.

Set up the scenario

Specify the initial position and velocity of the airplane. The airplane has a ground range of 10 km and an altitude of 20 km.

```
range = 10000;
alt = 20000;
initPos = [cosd(60)*range;sind(60)*range;alt];
originPos = [1000,1000,0]';
originVel = [0,0,0]';
vs = 150.0;
phi = atan2d(initPos(2)-originPos(2),initPos(1)-originPos(1));
phi1 = phi + 90;
vx = vs*cosd(phi1);
vy = vs*sind(phi1);
initVel = [vx,vy,-20]';
platform = phased.Platform('MotionModel','Acceleration',...
    'AccelerationSource','Input port','InitialPosition',initPos,...
    'InitialVelocity',initVel,'OrientationAxesOutputPort',true,...
    'InitialOrientationAxes',eye(3));
relPos = initPos - originPos;
relVel = initVel - originVel;
rel2Pos = [relPos(1),relPos(2),0]';
rel2Vel = [relVel(1),relVel(2),0]';
r = sqrt(rel2Pos'*rel2Pos);
accelmag = vs^2/r;
unitvec = rel2Pos/r;
accel = -accelmag*unitvec;
T = 0.5;
```

```
N = 1000;
```

Compute the trajectory

Specify the acceleration of an object moving in a circle in the *x*-*y* plane. The acceleration is v^2/r towards the orign

```
posmat = zeros(3,N);
r1 = zeros(N);
v = zeros(N);
for n = 1:N
    [pos,vel,oax] = platform(T,accel);
    posmat(:,n) = pos;
    vel2 = vel(1)^2 + vel(2)^2;
    v(n) = sqrt(vel2);
    relPos = pos - originPos;
    rel2Pos = [relPos(1),relPos(2),0]';
    r = sqrt(rel2Pos'*rel2Pos);
    r1(n) = r;
    accelmag = vel2/r;
    accelmag = vs^2/r;
    unitvec = rel2Pos/r;
    accel = -accelmag*unitvec;
end
```

- “Motion Modeling in Phased Array Systems”

Definitions

Platform Orientation

A platform has an associated local coordinate system. The coordinate system is defined by three orthonormal axis vectors. The direction and magnitude of the velocity vector can change with each call to the method. When the platform undergoes curvilinear

motion, the orientation of the local coordinate system axes rotates with the motion of the platform. The change of direction of the velocity vector defines a rotation matrix. The same rotation matrix is then used to rotate the local coordinate system as well. When the velocity vector maintains a constant direction, the rotation matrix is the identity matrix. The initial orientation of the local coordinate system is specified using the `InitalOrientationAxes` property. When you specify multiple platforms, each platform rotates independently.

Topics

"Motion Modeling in Phased Array Systems"

Introduced in R2012a

reset

System object: phased.Platform
Package: phased

Reset platform to initial position

Syntax

```
reset(H)
```

Description

`reset(H)` resets the initial position of the `Platform` object, `H`.

step

System object: phased.Platform
Package: phased

Output current position, velocity, and orientation axes of platform

Syntax

```
[Pos,Vel] = step(sPlat,T)
[Pos,Vel] = step(sPlat,T,V)
[Pos,Vel] = step(sPlat,T,A)
[Pos,Vel,Laxes] = step(___)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[Pos,Vel] = step(sPlat,T)` returns the current position, `Pos`, and velocity, `Vel`, of the platform. The method then updates the position and velocity. When the `MotionModel` property is set to `'Velocity'` and the `VelocitySource` property is set to `'Property'`, the position is updated using the equation *Pos* = *Pos* + *Vel***T* where *T* specifies the elapsed time (in seconds) for the current step. When the `MotionModel` property is set to `'Acceleration'` and the `AccelerationSource` property is set to `'Property'`, the position and velocity are updated using the equations *Pos* = *Pos* + *Vel***T* + *1/2Acl***T*^*2* and *Vel* = *Vel* + *Acl***T* where *T* specifies the elapsed time (in seconds) for the current step.

`[Pos,Vel] = step(sPlat,T,V)` returns the current position, `Pos`, and the current velocity, `Vel`, of the platform. The method then updates the position and velocity using the equation *Pos* = *Pos* + *Vel***T* where *T* specifies the elapsed time (in seconds) for the current step. This syntax applies when you set the `MotionModel` property to `'Velocity'` and the `VelocitySource` property to `'Input port'`.

`[Pos,Vel] = step(sPlat,T,A)` returns the current position, `Pos`, and the current velocity, `Vel`, of the platform. The method then updates the position and velocity using the equations *Pos* = *Pos* + *Vel*T* + *1/2Acl*T^2* and *Vel* = *Vel* + *Acl*T* where *T* specifies the elapsed time (in seconds) for the current step. This syntax applies when you set the `MotionModel` property to `'Acceleration'` and the `AccelerationSource` property to `'Input port'`.

`[Pos,Vel,Laxes] = step( ___ )` returns the additional output `Laxes` as the platform's orientation axes when you set the `OrientationAxesOutputPort` property to `true`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`sPlat`

Platform

Platform, specified as a `phased.Platform` System object.

`T`

Step time

Step time, specified as a real-valued scalar. Units are seconds

`V`

Platform velocity

Platform velocity, specified as a real-valued 3-by-*N* matrix where *N* is the number of platforms to model. This argument applies when you set the `MotionModel` property to

`'Velocity'` and the `VelocitySource` property to `'Input port'`. Units are meters per second.

`A`

Platform acceleration

Platform acceleration, specified as a real-valued 3-by-*N* matrix where *N* is the number of platforms to model. This argument applies when you set the `MotionModel` property to `'Acceleration'` and the `AccelerationSource` property to `'Input port'`. Units are meters per second-squared.

Output Arguments

`Pos`

Current platform position

Current position of platform, specified as a real-valued 3-by-1 column vector in the form of `[x;y;z]` or a real-valued 3-by-*N* matrix where *N* is the number of platforms to model. Each column takes the form `[x;y;z]`. Units are meters.

`Vel`

Current platform velocity

Current velocity of platform, specify as a real-valued 3-by-1 column vector in the form of `[vx;vy;vz]` or a real-valued 3-by-*N* matrix where *N* is the number of platforms to model. Each column taking the form `[vx;vy;vz]`. Velocity units are meters per second.

`Laxes`

Current platform orientation axes

Current platform orientation axes, returned as real-valued 3-by-3-by-*N* matrix where *N* is the number of platforms to model. Each 3-by-3 submatrix is an orthonormal matrix. This output is enabled when you set the `OrientationAxesOutputPort` property to `true`. The current platform axes rotate around the normal vector to the path of the platform.

Examples

Simulate motion of two platforms

Create two moving platforms. The first platform, starting at the origin, has a velocity of (100,100,0) meters per second. The second starts at (1000,0,0) meters and has a velocity of (0,200,0) meters per second. Next, specify different local coordinate axes for each platform defined by rotation matrices. Setting the `OrientationAxesOutputPort` property to `true` lets you retrieve the local coordinate axes at each step.

Set up the plaform object.

```
pos0 = [[0;0;0],[1000;0;0]];
vel0 = [[100;100;0],[0;200;0]];
R1 = rotx(30);
R2 = roty(45);
laxes(:,:,1) = R1;
laxes(:,:,2) = R2;
sPlat = phased.Platform(pos0,vel0,...
    'OrientationAxesOutputPort',true,...
    'InitialOrientationAxes',laxes);
```

Simulate the motion of the platform for two time steps, assuming the time elapsed for each step is one second. The position of the platform is updated after each step.

```
T = 1;
```

At the first step, the position and velocity equal the initial values.

```
[pos,v,lax] = step(sPlat,T);
pos
lax
```

```
pos =

           0        1000
           0           0
           0           0

lax(:,:,1) =
```

```
    1.0000         0         0
         0    0.8660   -0.5000
         0    0.5000    0.8660

lax(:,:,2) =

    0.7071         0    0.7071
         0    1.0000         0
   -0.7071         0    0.7071
```

At the second step, the position is updated.

```
[pos,v,lax] = step(sPlat,T);
pos
lax
```

```
pos =

         100        1000
         100         200
           0           0

lax(:,:,1) =

    1.0000         0         0
         0    0.8660   -0.5000
         0    0.5000    0.8660

lax(:,:,2) =

    0.7071         0    0.7071
         0    1.0000         0
   -0.7071         0    0.7071
```

Free-fall accelerating platform

Find the trajectory of a platform which has starts with some initial upward velocity but accelerates downward with a constant acceleration of gravity, -9.8 m/sec/sec. Call the step method every two seconds.

Construct System™ object.

```
sPlat = phased.Platform('MotionModel','Acceleration','InitialPosition',[2000,100,3000]
    'InitialVelocity',[300,150,20]','AccelerationSource','Property','Acceleration',[0,0
T = 2;
N = 100;
```

Call the step method for 100 time samples.

```
posmat = zeros(3,N);
for n = 1:N
    [pos,vel] = step(sPlat,T);
    posmat(:,n) = pos;
end
```

Plot the trejectory.

```
plot3(posmat(1,:),posmat(2,:),posmat(3,:),'b.')

phased.RadarTarget System object

Package: phased

Radar target

Description

The `RadarTarget` System object models how a signal is reflected from a radar target. The quantity that determines the response of a target to an incoming signals is called the radar target cross-section (RCS). While all electromagnetic radar signals are polarized, you can sometimes ignore polarization and process them as if they were scalar signals. To ignore polarization, you should specify the `EnablePolarization` property as `false`. To utilize polarization, you must specify the `EnablePolarization` property as `true`. For non-polarized processing, the radar cross section is encapsulated in a single scalar quantity called the `MeanRCS`. For polarized processing, the radar cross-section is more generally expressed by a 2-by-2 scattering matrix in the `ScatteringMatrix` property. For both polarization processing types, there are several Swerling models available to be used to generate random fluctuations in the RCS. These models are chosen using the `Model` property. The random fluctuations are controlled by the `SeedSource` and `Seed` properties.

The properties that you can use to model the radar cross-section or scattering matrix depend upon the polarization type.

`EnablePolarization`	Use these properties
`false`	• `MeanRCSSource` • `MeanRCS`
`true`	• `ScatteringMatrixSource` • `ScatteringMatrix` • `Mode`

To compute the signal reflected from a radar target:

1. Define and set up your radar target. See “Construction” on page 1-1480.
2. Call step to compute the reflected signal according to the properties of `phased.RadarTarget`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.RadarTarget` creates a radar target System object, `H`, that computes the reflected signal from a target.

`H = phased.RadarTarget(Name,Value)` creates a radar target object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`EnablePolarization`

Allow polarized signals

Set this property to `true` to allow the target to simulate the reflection of polarized radiation. Set this property to `false` to ignore polarization.

Default: `false`

`Mode`

Target scattering mode

Target scattering mode specified as one of `'Monostatic'` or `'Bistatic'`. If you set this property to `'Monostatic'`, the signal's reflection direction is the opposite to its incoming direction. If you set this property to `'Bistatic'`, the signal's reflection direction differs from its incoming direction. This property applies when you set the `EnablePolarization` property to `true`.

Default: `'Monostatic'`

`ScatteringMatrixSource`

Source of target mean scattering matrix

Source of target mean scattering matrix specified as one of `'Property'` or `'Input port'`. If you set the `ScatteringMatrixSource` property to `'Property'`, the target's mean scattering matrix is determined by the value of the `ScatteringMatrix` property. If you set this property to `'Input port'`, the mean scattering matrix is determined by an input argument of the step method. This property applies only when you set the `EnablePolarization` property to `true`. When the `EnablePolarization` property is set to `false`, use the `MeanRCSSource` property instead, together with the `MeanRCS` property, if needed.

Default: `'Property'`

`ScatteringMatrix`

Mean radar scattering matrix

Mean radar scattering matrix specified as a complex–valued 2-by-2 matrix. This matrix represents the mean value of the target's radar cross-section (in square meters). The matrix has the form `[s_hh s_hv;s_vh s_vv]`. In this matrix, the component `s_hv` specifies the complex scattering response when the input signal is vertically polarized and the reflected signal is horizontally polarized. The other components are defined similarly. This property applies when you set the `ScatteringMatrixSource` property to `'Property'` and the `EnablePolarization` property to `true`. When the `EnablePolarization` property is set to `false`, use the `MeanRCS` property instead, together with the `MeanRCSSource` property. This property is tunable.

Default: `[1 0;0 1]`

`MeanRCSSource`

Source of mean radar cross section

Specify whether the target's mean RCS value(s) comes from the `MeanRCS` property of this object or from an input argument in step. Values of this property are:

`'Property'`	The `MeanRCS` property of this object specifies the mean RCS value(s).
`'Input port'`	An input argument in each invocation of `step` specifies the mean RCS value.

When `EnablePolarization` property is set to `true`, use the `ScatteringMatrixSource` property together with `ScatteringMatrix`.

Default: `'Property'`

`MeanRCS`

Mean radar cross section

Specify the mean value of the target's radar cross section (in square meters) as a nonnegative scalar or as a 1-by-*M* nonnegative row vector. Using a vector allows you to process multiple targets simultaneous. The quantity *M*is the number of targets. This property is used when `MeanRCSSource` is set to `'Property'`. This property is tunable.

When `EnablePolarization` property is set to `true`, use the `ScatteringMatrix` property together with the `ScatteringMatrixSource`.

Default: `1`

`Model`

Target statistical model

Specify the statistical model of the target as one of `'Nonfluctuating'`, `'Swerling1'`, `'Swerling2'`, `'Swerling3'`, or `'Swerling4'`. If you set this property to a value other than `'Nonfluctuating'`, you must use the `UPDATERCS` input argument when invoking step. You can set the mean value of the radar cross-section model by specifying `MeanRCS` or use its default va;ue.

Default: `'Nonfluctuating'`

`PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

Default: Speed of light

`OperatingFrequency`

Signal carrier frequency

Specify the carrier frequency of the signal you are reflecting from the target, as a scalar in hertz.

Default: `3e8`

SeedSource

Source of seed for random number generator

Specify how the object generates random numbers. Values of this property are:

`'Auto'`	The default MATLAB random number generator produces the random numbers. Use `'Auto'` if you are using this object with Parallel Computing Toolbox software.
`'Property'`	The object uses its own private random number generator to produce random numbers. The `Seed` property of this object specifies the seed of the random number generator. Use `'Property'` if you want repeatable results and are not using this object with Parallel Computing Toolbox software.

The random numbers are used to model random RCS values. This property applies when the `Model` property is `'Swerling1'`, `'Swerling2'`, `'Swerling3'`, or `'Swerling4'`.

Default: `'Auto'`

Seed

Seed for random number generator

Specify the seed for the random number generator as a scalar integer between 0 and $2^{32}-1$. This property applies when you set the `SeedSource` property to `'Property'`.

Default: `0`

Methods

reset	Reset states of radar target object
step	Reflect incoming signal

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object

Common to All System Objects	
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Compute the Reflected Signal from a Non-fluctuating Radar Target

Create a simple signal and compute the value of the reflected signal from a target having a radar cross section of $10m^2$. Set the radar cross section using the `MeanRCS` property. Set the radar operating frequency to 600 MHz.

```
x = ones(10,1);
sRadarTarget = phased.RadarTarget('Model','Nonfluctuating',...
        'MeanRCS',10,...
        'OperatingFrequency',600e6);
y = step(sRadarTarget,x);
disp(y(1:3))
```

```
   22.4355
   22.4355
   22.4355
```

This value agrees with the formula $y = \sqrt{G}x$ where

$$G = 4\pi\sigma/\lambda^2$$

Algorithms

For a narrowband nonpolarized signal, the reflected signal, *Y*, is

$$Y = \sqrt{G} \cdot X,$$

where:

- *X* is the incoming signal.

- G is the target gain factor, a dimensionless quantity given by

$$G = \frac{4\pi\sigma}{\lambda^2}.$$

  - σ is the mean radar cross-section (RCS) of the target.
  - λ is the wavelength of the incoming signal.

The incident signal on the target is scaled by the square root of the gain factor.

For narrowband polarized waves, the single scalar signal, X, is replaced by a vector signal, (E_H, E_V), with horizontal and vertical components. The scattering matrix, S, replaces the scalar cross-section, σ. Through the scattering matrix, the incident horizontal and vertical polarized signals are converted into the reflected horizontal and vertical polarized signals.

$$\begin{bmatrix} E_H^{(scat)} \\ E_V^{(scat)} \end{bmatrix} = \sqrt{\frac{4\pi}{\lambda^2}} \begin{bmatrix} S_{HH} & S_{VH} \\ S_{HV} & S_{VV} \end{bmatrix} \begin{bmatrix} E_H^{(inc)} \\ E_V^{(inc)} \end{bmatrix} = \sqrt{\frac{4\pi}{\lambda^2}} [S] \begin{bmatrix} E_H^{(inc)} \\ E_V^{(inc)} \end{bmatrix}$$

For further details, see Mott, [1] or Richards, [2] .

reset

System object: phased.RadarTarget
Package: phased

Reset states of radar target object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `RadarTarget` object, `H`. This method resets the random number generator state if the `SeedSource` property is applicable and has the value `'Property'`.

step

System object: phased.RadarTarget
Package: phased

Reflect incoming signal

Syntax

```
Y = step(H,X)
Y = step(H,X,MEANRCS)
Y = step(H,X,UPDATERCS)
Y = step(H,X,MEANRCS,UPDATERCS)

Y = step(H,X,ANGLE_IN,LAXES)
Y = step(H,X,ANGLE_IN,ANGLE_OUT,LAXES)
Y = step(H,X,ANGLE_IN,LAXES,SMAT)
Y = step(H,X,ANGLE_IN,LAXES,UPDATESMAT)
Y = step(H,X,ANGLE_IN,ANGLE_OUT,LAXES,SMAT,UPDATESMAT)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` returns the reflected signal `Y` due to the incident signal `X`. The argument `X` is a complex-valued *N*-by-*1* column vector or *N*-by-*M* matrix. The value *M* is the number of signals. Each signal corresponds to a different target. The value *N* is the number of samples in each signal. Use this syntax when you set the `Model` property of `H` to `'Nonfluctuating'`. In this case, the value of the `MeanRCS` property is used as the *Radar cross-section* (RCS) value. This syntax applies only when the `EnablePolarization` property is set to `false`. If you specify *M* incident signals, you can specify the radar cross-section as a scalar or as a 1-by-*M* vector. For a scalar, the same value will be applied to all signals.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

`Y = step(H,X,MEANRCS)` uses `MEANRCS` as the mean RCS value. This syntax is available when you set the `MeanRCSSource` property to `'Input port'` and set `Model` to `'Nonfluctuating'`. The value of `MEANRCS` must be a nonnegative scalar or 1-by-*M* row vector for multiple targets. This syntax applies only when the `EnablePolarization` property is set to `false`.

`Y = step(H,X,UPDATERCS)` uses `UPDATERCS` as the indicator of whether to update the RCS value. This syntax is available when you set the `Model` property to `'Swerling1'`, `'Swerling2'`, `'Swerling3'`, or `'Swerling4'`. If `UPDATERCS` is `true`, a new RCS value is generated. If `UPDATERCS` is `false`, the previous RCS value is used. This syntax applies only when the `EnablePolarization` property is set to `false`. In this case, the value of the `MeanRCS` property is used as the radar cross-section (RCS) value.

`Y = step(H,X,MEANRCS,UPDATERCS)` lets you can combine optional input arguments when their enabling properties are set. In this syntax, `MeanRCSSource` is set to `'Input port'` and `Model` is set to one of the `Swerling` models. This syntax applies only when the `EnablePolarization` property is set to `false`. For this syntax, changes in `MEANRCS` will be ignored after the first call to the `step` method.

`Y = step(H,X,ANGLE_IN,LAXES)` returns the reflected signal `Y` from an incident signal `X`. This syntax applies only when the `EnablePolarization` property is set to `true`. The input argument, `ANGLE_IN`, specifies the direction of the incident signal with respect to the target's local coordinate system. The input argument, `LAXES`, specifies the direction of the local coordinate axes with respect to the global coordinate system. This syntax requires that you set the `Model` property to `'Nonfluctuating'` and the `Mode` property to `'Monostatic'`. In this case, the value of the `ScatteringMatrix` property is used as the scattering matrix value.

`X` is a 1-by-*M* row array of MATLAB `struct` type, each member of the array representing a different signal. The `struct` contains three fields, `X.X`, `X.Y`, and `X.Z`. Each field corresponds to the *x*, *y*, and *z* components of the polarized input signal. Polarization components are measured with respect to the global coordinate system. Each field is a column vector representing a sequence of values for each incoming signal. The `X.X`, `X.Y`, and `Y.Z` fields must all have the same dimension. The argument, `ANGLE_IN`, is a 2-by-*M* matrix representing the signals' incoming directions with respect to the target's local coordinate system. Each column of `ANGLE_IN` specifies the incident direction of the corresponding signal in the form `[AzimuthAngle; ElevationAngle]`. Angle units are in degrees. The number of columns in `ANGLE_IN` must equal the number of signals

in the X array. The argument, LAXES, is a 3-by-3 matrix. The columns are unit vectors specifying the local coordinate system's orthonormal *x*, *y*, and *z* axes, respectively, with respect to the global coordinate system. Each column is written in [x;y;z] form.

Y is a row array of struct type having the same size as X. Each struct contains the three reflected polarized fields, Y.X, Y.Y, and Y.Z. Each field corresponds to the *x*, *y*, and *z* component of the signal. Polarization components are measured with respect to the global coordinate system. Each field is a column vector representing one reflected signal.

The size of the first dimension of the matrix fields within the struct can vary to simulate a changing signal length such as a pulse waveform with variable pulse repetition frequency.

Y = step(H,X,ANGLE_IN,ANGLE_OUT,LAXES), in addition, specifies the reflection angle, ANGLE_OUT, of the reflected signal when you set the Mode property to 'Bistatic'. This syntax applies only when the EnablePolarization property is set to true. ANGLE_OUT is a 2-row matrix representing the reflected direction of each signal. Each column of ANGLE_OUT specifies the reflected direction of the signal in the form [AzimuthAngle; ElevationAngle]. Angle units are in degrees. The number of columns in ANGLE_OUT must equal the number of members in the X array. The number of columns in ANGLE_OUT must equal the number of elements in the X array.

Y = step(H,X,ANGLE_IN,LAXES,SMAT) specifies SMAT as the scattering matrix. This syntax applies only when the EnablePolarization property is set to true. The input argument SMAT is a 2-by-2 matrix. You must set the ScatteringMatrixSource property 'Input port' to use SMAT.

Y = step(H,X,ANGLE_IN,LAXES,UPDATESMAT) specifies UPDATESMAT to indicate whether to update the scattering matrix when you set the Model property to 'Swerling1', 'Swerling2'', 'Swerling3', or 'Swerling4'. This syntax applies only when the EnablePolarization property is set to true. If UPDATESMAT is set to true, a scattering matrix value is generated. If UPDATESMAT is false, the previous scattering matrix value is used.

Y = step(H,X,ANGLE_IN,ANGLE_OUT,LAXES,SMAT,UPDATESMAT). You can combine optional input arguments when their enabling properties are set. Optional inputs must be listed in the same order as the order of their enabling properties.

Note: The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications,

such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Examples

Compute Reflected Signals from Two Non-fluctuating Radar Targets

Create two sinusoidal signals and compute the value of the reflected signals from targets having radar cross section of $5m^2$ and $10m^2$, respectively. Set the radar cross sections in the `step` method by choosing `Input port` for the value of the `MeanRCSSource` property. Set the radar operating frequency to 600 MHz.

```
sRadarTarget = phased.RadarTarget('Model','Nonfluctuating',...
        'MeanRCSSource','Input port',...
        'OperatingFrequency',600e6);
t = linspace(0,1,1000);
x = [cos(2*pi*250*t)',10*sin(2*pi*250*t)'];
y = step(sRadarTarget,x,[5,10]);
disp(y(1:3,1:2))

Algorithms

For a narrowband nonpolarized signal, the reflected signal, *Y*, is

$$Y = \sqrt{G} \cdot X,$$

where:

- X is the incoming signal.
- G is the target gain factor, a dimensionless quantity given by

$$G = \frac{4\pi\sigma}{\lambda^2}.$$

  - σ is the mean radar cross-section (RCS) of the target.
  - λ is the wavelength of the incoming signal.

The incident signal on the target is scaled by the square root of the gain factor.

For narrowband polarized waves, the single scalar signal, X, is replaced by a vector signal, (E_H, E_V), with horizontal and vertical components. The scattering matrix, S, replaces the scalar cross-section, σ. Through the scattering matrix, the incident horizontal and vertical polarized signals are converted into the reflected horizontal and vertical polarized signals.

$$\begin{bmatrix} E_H^{(scat)} \\ E_V^{(scat)} \end{bmatrix} = \sqrt{\frac{4\pi}{\lambda^2}} \begin{bmatrix} S_{HH} & S_{VH} \\ S_{HV} & S_{VV} \end{bmatrix} \begin{bmatrix} E_H^{(inc)} \\ E_V^{(inc)} \end{bmatrix} = \sqrt{\frac{4\pi}{\lambda^2}} [S] \begin{bmatrix} E_H^{(inc)} \\ E_V^{(inc)} \end{bmatrix}$$

For further details, see Mott [1] or Richards[2].

phased.Radiator System object

Package: phased

Narrowband signal radiator

Description

The `phased.Radiator` object implements a narrowband signal radiator. For any antenna element, microphone element, or array, the radiator creates the outgoing signal that is to be propagated to the far field using the phased.FreeSpace or phased.TwoRayChannel System objects. The output of `phased.Radiator` represents the field at a reference distance from the element or center of the array. The signal can represent a polarized or nonpolarized field depending upon whether the element or array supports polarization and the value of the `EnablePolarization` property. For arrays, you can create a superposed field of all array elements signals or a separate field for each element depending upon the value of the `CombineRadiatedSignals` property.

To compute the radiated signal from the sensor(s):

1. Define and set up your radiator. See "Construction" on page 1-1494.
2. Call step to compute the radiated signal according to the properties of `phased.Radiator`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.Radiator` creates a narrowband signal radiator System object, `H`. The object returns radiated narrowband signals for given directions using a sensor array or a single element.

`H = phased.Radiator(Name,Value)` creates a radiator object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`Sensor`

Sensor element or sensor array

Sensor element or sensor array specified as a System object in the Phased Array System Toolbox. A sensor array can contain subarrays.

Antenna Toolbox antenna

Default: phased.ULA with default property values

`PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

Default: Speed of light

`OperatingFrequency`

System operating frequency

Specify the operating frequency of the system in hertz as a positive scalar. The default value corresponds to 300 MHz.

Default: `3e8`

`CombineRadiatedSignals`

Combine radiated signals

Set this property to `true` to combine radiated signals from all radiating elements. Set this property to `false` to obtain the radiated signal for each radiating element. If the `Sensor` property is an array that contains subarrays, the `CombineRadiatedSignals` property must be `true`.

Default: `true`

`EnablePolarization`

Enable Polarization

Set this property to `true` to simulate the radiation of polarized waves. Set this property to `false` to ignore polarization. This property applies when the sensor specified in the `Sensor` property is capable of simulating polarization.

Default: `false`

`WeightsInputPort`

Enable weights input

To specify weights, set this property to `true` and then use the corresponding input argument when you invoke step. If you do not want to specify weights, set this property to `false`.

Default: `false`

Methods

step Radiate signals

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Radiate Signal From Isotropic Antenna

Radiate the signal from a single isotropic antenna.

```
antenna = phased.IsotropicAntennaElement;
radiator = phased.Radiator('Sensor',antenna,'OperatingFrequency',300e6);
sig = [1;1];
```

```
radiatingAngles = [30 10]';
y = step(radiator,sig,radiatingAngles);
```

Radiate a far field signal with a 5-element array in two directions.

```
array = phased.ULA('NumElements',5);
radiator = phased.Radiator('Sensor',array,'OperatingFrequency',300e6);
sig = [1;1];
radiatingAngles = [30 10; 20 0]';
y = step(radiator,sig,radiatingAngles);
```

Radiate signal from a 3-element antenna array. Each antenna radiates a separate signal in a separate direction.

```
array = phased.ULA('NumElements',3);
radiator = phased.Radiator('Sensor',array,'OperatingFrequency',1e9,...
    'CombineRadiatedSignals',false);
sig = [1 2 3; 1 2 3];
radiatingAngles = [10 0; 20 5; 45 2]';
y = step(radiator,sig,radiatingAngles)
```

```
y =

     1     2     3
     1     2     3
```

step

System object: phased.Radiator
Package: phased

Radiate signals

Syntax

```
Y = step(H,X,ANG)
Y = step(H,X,ANG,LAXES)
Y = step(H,X,ANG,WEIGHTS)
Y = step(H,X,ANG,STEERANGLE)
Y = step(H,X,ANG,LAXES,WEIGHTS,STEERANGLE)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X,ANG)` radiates signal `X` in the direction `ANG`. `Y` is the radiated signal. The radiating process depends on the `CombineRadiatedSignals` property of `H`, as follows:

- If `CombineRadiatedSignals` has the value `true`, each radiating element or subarray radiates `X` in all the directions in `ANG`. `Y` combines the outputs of all radiating elements or subarrays. If the `Sensor` property of `H` contains subarrays, the radiating process distributes the power equally among the elements of each subarray.
- If `CombineRadiatedSignals` has the value `false`, each radiating element radiates `X` in only one direction in `ANG`. Each column of `Y` contains the output of the corresponding element. The `false` option is available when the `Sensor` property of `H` does not contain subarrays.

`Y = step(H,X,ANG,LAXES)` uses `LAXES` as the local coordinate system axes directions. This syntax is available when you set the `EnablePolarization` property to `true`.

`Y = step(H,X,ANG,WEIGHTS)` uses `WEIGHTS` as the weight vector. This syntax is available when you set the `WeightsInputPort` property to `true`.

`Y = step(H,X,ANG,STEERANGLE)` uses `STEERANGLE` as the subarray steering angle. This syntax is available when you configure `H` so that `H.Sensor` is an array that contains subarrays and `H.Sensor.SubarraySteering` is either `'Phase'` or `'Time'`.

`Y = step(H,X,ANG,LAXES,WEIGHTS,STEERANGLE)` combines all input arguments. This syntax is available when you configure `H` so that `H.EnablePolarization` is `true`, `H.WeightsInputPort` is `true`, `H.Sensor` is an array that contains subarrays, and `H.Sensor.SubarraySteering` is either `'Phase'` or `'Time'`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`H`

Radiator object.

`X`

Signals to radiate. `X` can be either a vector or a matrix.

If `X` is a vector, that vector is radiated through all radiating elements or subarrays. The computation does not divide the signal's power among elements or subarrays, but rather treats the `X` vector the same as a matrix in which each column equals this vector.

If `X` is a matrix, the number of columns of `X` must equal the number of subarrays if `H.Sensor` is an array that contains subarrays, or the number of radiating elements otherwise. Each column of `X` is radiated by the corresponding element or subarray.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

ANG

Radiating directions of signals. `ANG` is a two-row matrix. Each column specifies a radiating direction in the form `[AzimuthAngle;ElevationAngle]`, in degrees.

LAXES

Local coordinate system. `LAXES` is a 3-by-3 matrix whose columns specify the local coordinate system's orthonormal *x*, *y*, and *z* axes, respectively. Each axis is specified in terms of `[x;y;z]` with respect to the global coordinate system. This argument is only used when the `EnablePolarization` property is set to `true`.

WEIGHTS

Vector of weights. `WEIGHTS` is a column vector whose length equals the number of radiating elements or subarrays.

STEERANGLE

Subarray steering angle, specified as a length-2 column vector. The vector has the form [azimuth; elevation], in degrees. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90° and 90°, inclusive.

Output Arguments

Y

Radiated signals

- If the `EnablePolarization` property value is set to `false`, the output argument `Y` is a matrix. The number of columns of the matrix equals the number of radiating signals. Each column of `Y` contains a separate radiating signal. The number of radiating signals depends upon the `CombineRadiatedSignals` property of `H`.
- If the `EnablePolarization` property value is set to `true`, `Y` is a row vector of elements of MATLAB `struct` type. The length of the `struct` vector equals the number of radiating signals. Each `struct` contains a separate radiating signal. The number of radiating signals depends upon the `CombineRadiatedSignals` property of `H`. Each `struct` contains three column-vector fields, `X`, `Y`, and `Z`. These fields represent the *x*, *y*, and *z* components of the polarized wave vector signal in the global coordinate system.

Examples

Radiation from 5-Element ULA

Combine the radiation from five isotropic antenna elements.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Set up a uniform line array of five isotropic antennas. Then, construct the radiator object.

```
ula = phased.ULA('NumElements',5);
```

Construct the radiator object.

```
radiator = phased.Radiator('Sensor',ula,...
    'OperatingFrequency',300e6,'CombineRadiatedSignals',true);
```

Create a simple signal to radiate.

```
x = [1;1];
```

Specify the radiating direction in azimuth and elevation.

```
radiatingAngle = [30; 10];
```

Radiate the signal.

```
y = radiator(x,radiatingAngle)
```

```
y =

  -0.9523 - 0.0000i
  -0.9523 - 0.0000i
```

Radiation from 5-Element ULA of Polarized Antennas

Combine the radiation from five short-dipole antenna elements.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Set up a uniform line array of five short-dipole antennas with polarization enabled. Then, construct the radiator object.

```
antenna = phased.ShortDipoleAntennaElement;
ula = phased.ULA('Element',antenna,'NumElements',5);
radiator = phased.Radiator('Sensor',ula,'OperatingFrequency',300e6,...
    'CombineRadiatedSignals',true,'EnablePolarization',true);
```

Rotate the local coordinate system by 10° around the x-axis. Demonstrate that the output represents a polarized field.

Spcify a simple signal to radiate and specify the radiating direction in azimuth and elevation

```
x = [1;1];
radiatingAngle = [30 30; 0 20];
y = radiator(x,radiatingAngle,rotx(10))
```

```
y =

  1×2 struct array with fields:

    X
    Y
    Z
```

phased.RangeDopplerResponse System object

Package: phased

Range-Doppler response

Description

The `phased.RangeDopplerResponse` System object calculates the filtered response to fast-time and slow-time data. or equivalently, range data, using either a matched filter or an FFT.

The input to the Doppler response object is a data cube. The organization of the data cube follows the Phased Array System Toolbox convention. The first dimension of the cube represents the fast-time samples or ranges of the received signals. The second dimension represents multiple channels such as sensors or beams. The third dimension, slow time, represent pulses. If the data contains only one channel or pulse, the data cube can contain fewer than three dimensions. Range processing operates along the first dimension of the cube. Doppler processing operates along the last dimension.

The output of the object is also a data cube with the same number of dimensions as the input. The first dimension contains range-processed data but its length can differ from the first dimension of the input. The last dimension contains Doppler processed data. Its length can differ from the last dimension of the input.

To compute the range-Doppler response:

1. Define and set up your `phased.RangeDopplerResponse` System object. See "Construction" on page 1-1505.
2. Call step to compute the range-Doppler response of the input signal according to the properties of `phased.RangeDopplerResponse`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.RangeDopplerResponse` creates a range-Doppler response System object, `H`. The object calculates the range-Doppler response of the input data.

`H = phased.RangeDopplerResponse(Name,Value)` creates a range-Doppler response object, `H`, with additional options specified by one or more `Name,Value` pair arguments. `Name` is a property name, and `Value` is the corresponding value. `Name` must appear inside single quotes (`''`). You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

Properties

`RangeMethod`

Range processing method

Specify the method of range processing as `'Matched filter'` or `'FFT'`.

`'Matched filter'`	Algorithm applies a matched filter to the incoming signal. This approach is common with pulsed signals, where the matched filter is the time reverse of the transmitted signal.
`'FFT'`	Algorithm performs range processing by applying an FFT to the input signal. This approach is commonly used with FMCW and linear FM pulsed signals.

Default: `'Matched filter'`

`PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

Default: Speed of light

`SampleRate`

Sample rate

Specify the sample rate, in hertz, as a positive scalar. The default value corresponds to 1 MHz.

Default: `1e6`

`SweepSlope`

FM sweep slope

Specify the slope of the linear FM sweeping, in hertz per second, as a scalar. The `x` data you provide to `step` or `plotResponse` must correspond to sweeps having this slope.

To enable this property, set the `RangeMethod` property to `'FFT'`.

Default: `1e9`

`DechirpInput`

Option to dechirp input signal

Set this property to `true` to have the range-Doppler response object dechirp the input signal. Set this property to `false` to indicate that the input signal is already dechirped and no dechirp operation is necessary.

To enable this property, set the `RangeMethod` property to `'FFT'`.

Default: `false`

`DecimationFactor`

Decimation factor for dechirped signal

Specify the decimation factor for the dechirped signal as a positive integer. When processing FMCW signals, you can often decimate the dechirped signal to reduce the requirements on the analog-to-digital converter.

To enable this property, set the `RangeMethod` property to `'FFT'` and the `DechirpInput` property to `true`. The default value indicates no decimation.

Default: `1`

`RangeFFTLengthSource`

Source of FFT length used in range processing

Specify how the object determines the FFT length used in range processing. Values of this property are:

`'Auto'`	The FFT length equals the number of rows of the input signal.
`'Property'`	The `RangeFFTLength` property of this object specifies the FFT length.

To enable this property, set the `RangeMethod` property to `'FFT'`.

Default: `'Auto'`

`RangeFFTLength`

FFT length in range processing

Specify the FFT length in the range domain as a positive integer.

To enable this property, set the `RangeMethod` property to `'FFT'` and the `RangeFFTLengthSource` property to `'Property'`.

Default: `1024`

`RangeWindow`

Window for range weighting

Specify the window used for range processing using one of `'None'`, `'Hamming'`, `'Chebyshev'`, `'Hann'`, `'Kaiser'`, `'Taylor'`, or `'Custom'`. If you set this property to `'Taylor'`, the generated Taylor window has four nearly constant sidelobes adjacent to the mainlobe.

To enable this property, set the `RangeMethod` property to `'FFT'`.

Default: `'None'`

`RangeSidelobeAttenuation`

Sidelobe attenuation level for range processing

Specify the sidelobe attenuation level of a Kaiser, Chebyshev, or Taylor window in range processing as a positive scalar, in decibels.

To enable this property, set the `RangeMethod` property to `'FFT'` and the `RangeWindow` property to `'Kaiser'`, `'Chebyshev'`, or `'Taylor'`.

Default: 30

`CustomRangeWindow`

User-defined window for range processing

Specify the user-defined window for range processing using a function handle or a cell array.

To enable this property, set the `RangeMethod` property to `'FFT'` and the `RangeWindow` property to `'Custom'`.

If `CustomRangeWindow` is a function handle, the specified function takes the window length as the input and generates appropriate window coefficients.

If `CustomRangeWindow` is a cell array, then the first cell must be a function handle. The specified function takes the window length as the first input argument, with other additional input arguments, if necessary. The function then generates appropriate window coefficients. The remaining entries in the cell array are the additional input arguments to the function, if any.

Default: `@hamming`

`PRFSource`

Source of pulse repetition frequency

Source of pulse repetition frequency, specified as

- `'Auto'` — You assume that the pulse repetition frequency (prf) is the inverse of the duration of the input signal to the step method. Then the prf equals the sample rate of the signal divided by the number of rows in the input signal.
- `'Property'`— specify the pulse repetition frequency using the `PRF` property.
- `'Input port'`— specify the PRF using an input argument of the step method.

Use the `'Property'` or `'Input port'` option when the pulse repetition frequency cannot be determined by the signal duration, as is the case with range-gated data.

Default: `'Auto'`

`PRF`

Pulse repetition frequency of input signal

Pulse repetition frequency of the input signal, specified as a positive scalar. `PRF` must be less than or equal to the sample rate divided by the number of rows of the input signal to the step method. When the signal length is variable, use the maximum possible number of rows of the input signal instead.

To enable this property, set the `PRFSource` property to `'Property'`.

Default: `10e3`

`DopplerFFTLengthSource`

Source of FFT length in Doppler processing

Specify how the object determines the FFT length in Doppler processing. Values of this property are:

`'Auto'`	The FFT length is equal to the number of rows of the input signal.
`'Property'`	The `DopplerFFTLength` property of this object specifies the FFT length.

To enable this property, set the `RangeMethod` property to `'FFT'`.

Default: `'Auto'`

`DopplerFFTLength`

FFT length for Doppler processing

FFT length for Doppler processing, specified as a positive integer.

To enable this property, set the `RangeMethod` property to `'FFT'` and the `DopplerFFTLengthSource` property to `'Property'`.

Default: `1024`

`DopplerWindow`

Window for Doppler weighting

Specify the window used for Doppler processing using one of `'None'`, `'Hamming'`, `'Chebyshev'`, `'Hann'`, `'Kaiser'`, `'Taylor'`, or `'Custom'`. If you set this property to

'Taylor', the generated Taylor window has four nearly constant sidelobes adjacent to the mainlobe.

To enable this property, set the RangeMethod property to 'FFT'.

Default: 'None'

DopplerSidelobeAttenuation

Sidelobe attenuation level for Doppler processing

Specify the sidelobe attenuation level of a Kaiser, Chebyshev, or Taylor window in Doppler processing as a positive scalar, in decibels.

To enable this property, set the RangeMethod property to 'FFT' and the DopplerWindow property to 'Kaiser', 'Chebyshev', or 'Taylor'.

Default: 30

CustomDopplerWindow

User-defined window for Doppler processing

Specify the user-defined window for Doppler processing using a function handle or a cell array..

If CustomDopplerWindow is a function handle, the specified function takes the window length as the input and generates appropriate window coefficients.

If CustomDopplerWindow is a cell array, then the first cell must be a function handle. The specified function takes the window length as the first input argument, with other additional input arguments, if necessary. The function then generates appropriate window coefficients. The remaining entries in the cell array are the additional input arguments to the function, if any.

To enable this property, set the RangeMethod property to 'FFT' and the DopplerWindow property to 'Custom'

Default: @hamming

DopplerOutput

Doppler domain output

Specify the Doppler domain output as `'Frequency'` or `'Speed'`. The Doppler domain output is the `DOP_GRID` argument of `step`.

`'Frequency'`	`DOP_GRID` is the Doppler shift, in hertz.
`'Speed'`	`DOP_GRID` is the radial speed corresponding to the Doppler shift, in meters per second.

Default: `'Frequency'`

`OperatingFrequency`

Signal carrier frequency

Specify the carrier frequency, in hertz, as a scalar. The default value of this property corresponds to 300 MHz.

To enable this property, set the `DopplerOutput` property to `'Speed'`

Default: `3e8`

`MaximumNumInputSamplesSource`

Source of maximum number of samples

The source of the maximum number of samples of the input signal, specified as `'Auto'` or `'Property'`. When you set this property to `'Auto'`, the object automatically allocates enough memory to buffer the input signal. When you set this property to `'Property'`, you specify the maximum number of samples in the input signal using the `MaximumNumInputSamples` property. Any input signal longer than that value is truncated.

To enable this property, set the `RangeMethod` property to `'Matched Filter'`.

Default: `'Auto'`

`MaximumNumInputSamples`

Maximum number of input signal samples

Maximum number of samples in the input signal, specified as a positive integer. This property limits the size of the input signal. Any input signal longer than this value is truncated. The input signal is the first argument to the `step` method. The number of samples is the number of rows in the input.

To enable this property, set the `RangeMethod` property to `'Matched filter'` and `MaximumNumInputSamplesSource` property to `'Property'`.

Default: 100

Methods

plotResponse	Plot range-Doppler response
step	Calculate range-Doppler response

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Range-Doppler Response Using Matched Filter

Compute the range-doppler response of a pulsed radar signal using a matched filter.

Load data for a pulsed radar signal. The signal includes three target returns. Two targets are approximately 2000 m away, while the third is approximately 3500 m away. In addition, two of the targets are stationary relative to the radar. The third is moving away from the radar at about 100 m/s.

```
load RangeDopplerExampleData;
```

Create a range-Doppler response object.

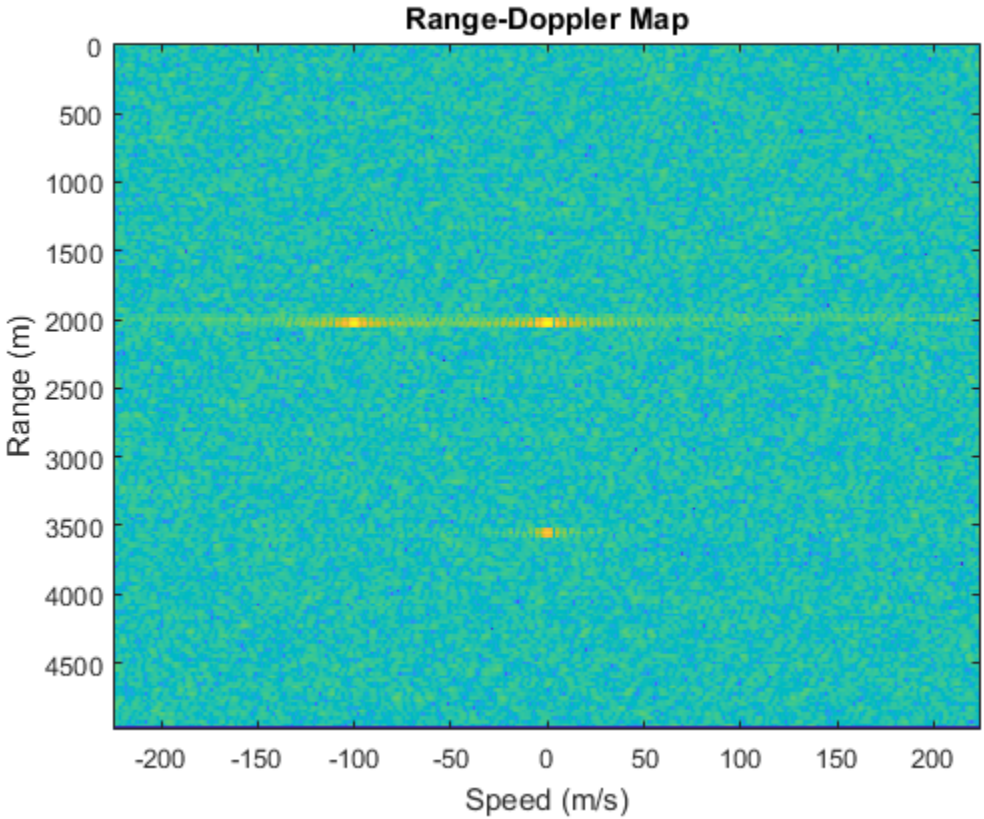
```
response = phased.RangeDopplerResponse('DopplerFFTLengthSource','Property', ...
   'DopplerFFTLength',RangeDopplerEx_MF_NFFTDOP, ...
   'SampleRate',RangeDopplerEx_MF_Fs,'DopplerOutput','Speed', ...
   'OperatingFrequency',RangeDopplerEx_MF_Fc);
```

Calculate the range-Doppler response.

```
[resp,rng_grid,dop_grid] = response(RangeDopplerEx_MF_X, ...
    RangeDopplerEx_MF_Coeff);
```

Plot the range-Doppler response.

```
imagesc(dop_grid,rng_grid,mag2db(abs(resp)));
xlabel('Speed (m/s)');
ylabel('Range (m)');
title('Range-Doppler Map');
```



Range-Doppler Response of FMCW Signal

Compute the range-Doppler response of an FMCW signal using an FFT.

Load data for an FMCW signal that has not been dechirped. The signal contains the return from a target about 2200 m away. The signal has a normalized Doppler frequency of approximately -0.36 relative to the radar.

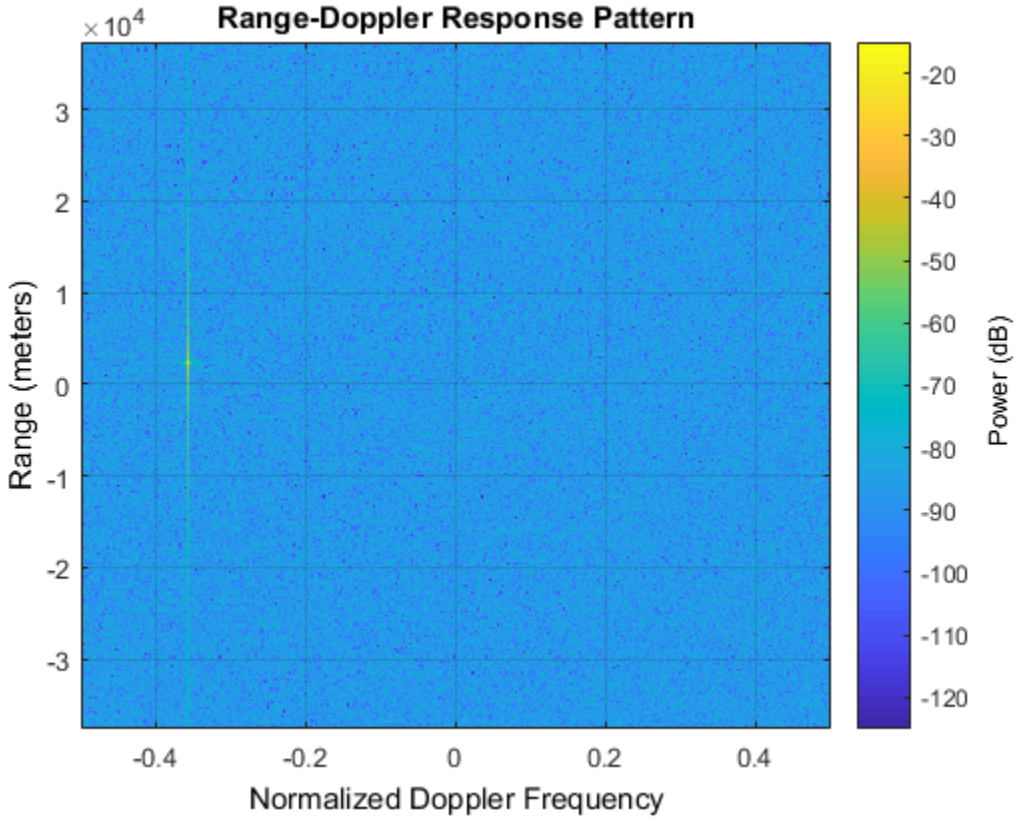
```
load RangeDopplerExampleData;
```

Create a range-Doppler response object.

```
hrdresp = phased.RangeDopplerResponse(...
   'RangeMethod','FFT',...
   'PropagationSpeed',RangeDopplerEx_Dechirp_PropSpeed,...
   'SampleRate',RangeDopplerEx_Dechirp_Fs,...
   'DechirpInput',true,...
   'SweepSlope',RangeDopplerEx_Dechirp_SweepSlope);
```

Plot the range-Doppler response.

```
plotResponse(hrdresp,...
   RangeDopplerEx_Dechirp_X,RangeDopplerEx_Dechirp_Xref,...
   'Unit','db','NormalizeDoppler',true)
```



Estimate Doppler and Range with Specified PRF

Estimate the Doppler and range responses for three targets. Two targets are approximately 2000 m away, while the third is approximately 3500 m away. In addition, two of the targets are stationary relative to the radar. The third is moving away from the radar at about 100 m/s. Specify the pulse repetition frequency.

Load data for a pulsed radar signal.

```
load RangeDopplerExampleData;
```

Create a range-Doppler response object. Set the PRF to 25 kHz.

```
response = phased.RangeDopplerResponse('DopplerFFTLengthSource','Property', ...
```

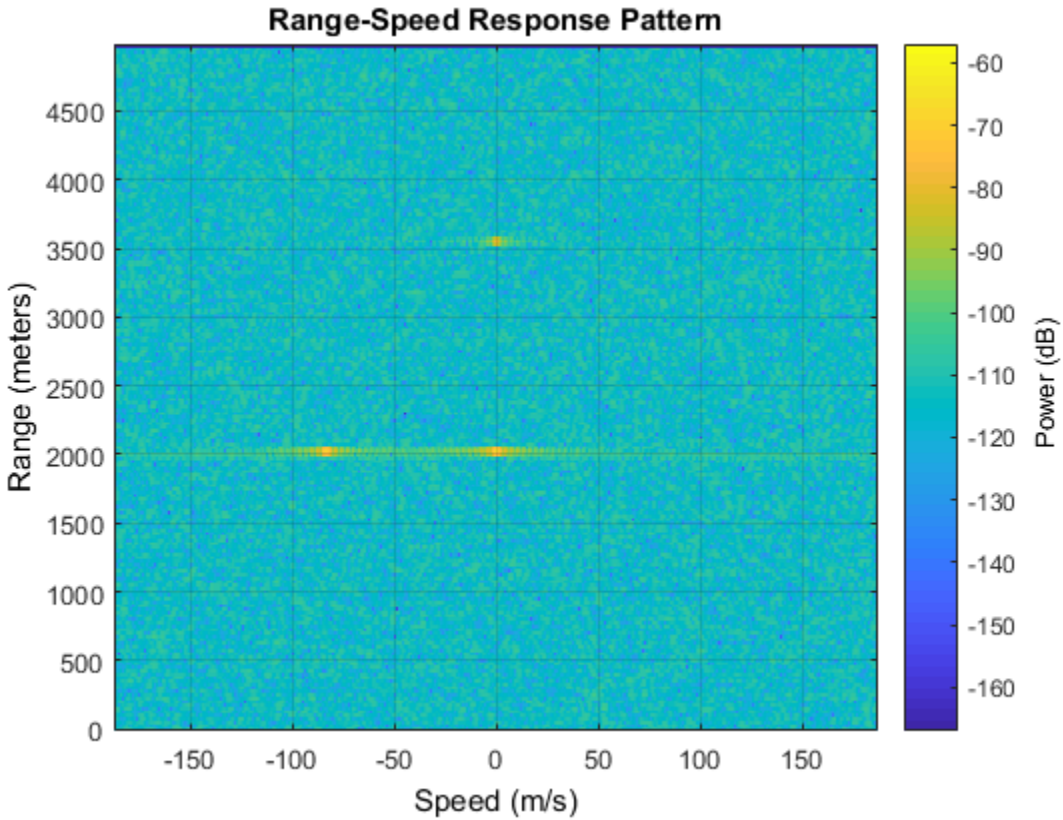
```
    'DopplerFFTLength',RangeDopplerEx_MF_NFFTDOP,'SampleRate', ...
    RangeDopplerEx_MF_Fs,'DopplerOutput','Speed','OperatingFrequency', ...
    RangeDopplerEx_MF_Fc,'PRFSource','Property','PRF',25.0e3);
```

Calculate the range-Doppler response.

```
[resp,rng_grid,dop_grid] = response(RangeDopplerEx_MF_X, ...
    RangeDopplerEx_MF_Coeff);
```

Plot the range-Doppler response.

```
plotResponse(response,RangeDopplerEx_MF_X,RangeDopplerEx_MF_Coeff,'Unit','db')
```



- Automotive Adaptive Cruise Control Using FMCW Technology

Algorithms

The `phased.RangeDopplerResponse` object generates a response as follows:

1. Processes the input signal in the fast-time dimension using either a matched filter or dechirp/FFT operation.
2. Processes the input signal in the pulse dimension using an FFT.

The decimation algorithm uses a 30th order FIR filter generated by `fir1(30,1/R)`, where `R` is the value of the `DecimationFactor` property.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `CustomRangeWindow` and `CustomDopplerWindow` properties are not supported.
- The `plotResponse` method is not supported.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

plotResponse

System object: phased.RangeDopplerResponse
Package: phased

Plot range-Doppler response

Syntax

```
plotResponse(H,x)
plotResponse(H,x,xref)
plotResponse(H,x,coeff)
plotResponse( ___ ,Name,Value)
hPlot = plotResponse( ___ )
```

Description

`plotResponse(H,x)` plots the range-Doppler response of the input signal, `x`, in decibels. This syntax is available when you set the `RangeMethod` property to `'FFT'` and the `DechirpInput` property to `false`.

`plotResponse(H,x,xref)` plots the range-Doppler response after performing a dechirp operation on `x` using the reference signal, `xref`. This syntax is available when you set the `RangeMethod` property to `'FFT'` and the `DechirpInput` property to `true`.

`plotResponse(H,x,coeff)` plots the range-Doppler response after performing a matched filter operation on `x` using the matched filter coefficients in `coeff`. This syntax is available when you set the `RangeMethod` property to `'Matched filter'`.

`plotResponse( ___ ,Name,Value)` plots the angle-Doppler response with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = plotResponse( ___ )` returns the handle of the image in the figure window, using any of the input arguments in the previous syntaxes.

Input Arguments

`H`

Range-Doppler response object.

`x`

Input data. Specific requirements depend on the syntax:

- In the syntax `plotResponse(H,x)`, each column of the matrix `x` represents a dechirped signal from one frequency sweep. The function assumes all sweeps in `x` are consecutive.
- In the syntax `plotResponse(H,x,xref)`, each column of the matrix `x` represents a signal from one frequency sweep. The function assumes all sweeps in `x` are consecutive and have not been dechirped yet.
- In the syntax `plotResponse(H,x,coeff)`, each column of the matrix `x` represents a signal from one pulse. The function assumes all pulses in `x` are consecutive.

In the case of an FMCW waveform with a triangle sweep, the sweeps alternate between positive and negative slopes. However, `phased.RangeDopplerResponse` is designed to process consecutive sweeps of the same slope. To apply `phased.RangeDopplerResponse` for a triangle-sweep system, use one of the following approaches:

- Specify a positive `SweepSlope` property value, with `x` corresponding to upsweeps only. In the plot, change the tick mark labels on the horizontal axis to reflect that the Doppler or speed values are half of what the plot shows by default.
- Specify a negative `SweepSlope` property value, with `x` corresponding to downsweeps only. In the plot, change the tick mark labels on the horizontal axis to reflect that the Doppler or speed values are half of what the plot shows by default.

`xref`

Reference signal, specified as a column vector having the same number of rows as `x`.

`coeff`

Matched filter coefficients, specified as a column vector.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'NormalizeDoppler'`

Set this value to `true` to normalize the Doppler frequency. Set this value to `false` to plot the range-Doppler response without normalizing the Doppler frequency. This parameter applies when you set the `DopplerOutput` property of `H` to `'Frequency'`.

Default: `false`

`'Unit'`

The unit of the plot. Valid values are `'db'`, `'mag'`, and `'pow'`.

Default: `'db'`

Examples

Range-Doppler Response of FMCW Signal

Compute the range-Doppler response of an FMCW signal using an FFT.

Load data for an FMCW signal that has not been dechirped. The signal contains the return from a target about 2200 m away. The signal has a normalized Doppler frequency of approximately -0.36 relative to the radar.

```
load RangeDopplerExampleData;
```

Create a range-Doppler response object.

```
hrdresp = phased.RangeDopplerResponse(...
   'RangeMethod','FFT',...
   'PropagationSpeed',RangeDopplerEx_Dechirp_PropSpeed,...
   'SampleRate',RangeDopplerEx_Dechirp_Fs,...
   'DechirpInput',true,...
   'SweepSlope',RangeDopplerEx_Dechirp_SweepSlope);
```

Plot the range-Doppler response.

```
plotResponse(hrdresp,...
   RangeDopplerEx_Dechirp_X,RangeDopplerEx_Dechirp_Xref,...
   'Unit','db','NormalizeDoppler',true)
```

step

System object: phased.RangeDopplerResponse
Package: phased

Calculate range-Doppler response

Syntax

```
[resp,rnggrid,dopgrid] = step(H,x)
[resp,rnggrid,dopgrid] = step(H,x,xref)
[resp,rnggrid,dopgrid] = step(H,x,coeff)
[resp,rnggrid,dopgrid] = step(H,___,prf)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[resp,rnggrid,dopgrid] = step(H,x)` calculates the range-Doppler response of the input signal, `x`. `resp` is the complex range-Doppler response. `rnggrid` and `dopgrid` provide the range samples and Doppler samples, respectively, at which the range-Doppler response is evaluated. This syntax is available when you set the `RangeMethod` property to `'FFT'` and the `DechirpInput` property to `false`. This syntax is most commonly used with FMCW signals.

`[resp,rnggrid,dopgrid] = step(H,x,xref)` uses `xref` as the reference signal to dechirp `x`. This syntax is available when you set the `RangeMethod` property to `'FFT'` and the `DechirpInput` property to `true`. This syntax is most commonly used with FMCW signals, where the reference signal is typically the transmitted signal.

`[resp,rnggrid,dopgrid] = step(H,x,coeff)` uses `coeff` as the matched filter coefficients. This syntax is available when you set the `RangeMethod` property to

`'Matched filter'`. This syntax is most commonly used with pulsed signals, where the matched filter is the time reverse of the transmitted signal.

`[resp,rnggrid,dopgrid] = step(H, ___ ,prf)` uses `prf` as the pulse repetition frequency. These syntaxes are available when you set the `PRFSource` property to `'Input port'`. This syntax is most commonly used with pulsed signals, where the matched filter is the time reverse of the transmitted signal.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`H`

Range-Doppler response System object

`x`

Input data, specified as a complex-valued *K*-by-*L* matrix or *K*-by-*N*-by-*L* array where

- *K* denotes the number of fast-time samples.
- *N* denotes the number of channels such as beams or sensors. When *N* is one, only a single data channel is present.
- *L* denotes the number of pulses for matched-filter processing and the number of sweeps for FFT processing.

Specific requirements depend on the syntax:

- In the syntax `step(H,x)`, each column of `x` represents a dechirped signal from one frequency sweep. The function assumes all sweeps in `x` are consecutive.
- In the syntax `step(H,x,xref)`, each column of `x` represents a signal from one frequency sweep. The function assumes all sweeps in `x` are consecutive and are not dechirped.

- In the syntax `step(H,x,coeff)`, each column of the matrix `x` represents a signal from one pulse. The function assumes all pulses in `x` are consecutive.

  The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

In the case of an FMCW waveform with a triangle sweep, the sweeps alternate between positive and negative slopes. However, `phased.RangeDopplerResponse` is designed to process consecutive sweeps of the same slope. To apply `phased.RangeDopplerResponse` for a triangle-sweep system, use one of the following approaches:

- Specify a positive `SweepSlope` property value, with `x` corresponding to upsweeps only. After obtaining the Doppler or speed values, divide them by 2.
- Specify a negative `SweepSlope` property value, with `x` corresponding to downsweeps only. After obtaining the Doppler or speed values, divide them by 2.

`xref`

Reference signal, specified as a column vector having the same number of rows as `x`.

`coeff`

Matched filter coefficients, specified as a column vector.

`prf`

Pulse repetition frequency, specified as a positive scalar. `prf` must be less than or equal to the sample rate specified in the `SampleRate` property divided by the length of the first dimension of the input signal, `x`.

To enable this argument, set the `PRFSource` property to `'Input port'`.

Output Arguments

`resp`

Range-Doppler response of `x`, returned as a complex-valued *M*-by-*P* matrix or a *M*-by-*N*-by-*P* array. The values of *P* and *M* depend on the syntax. *N* has the same value as for the input argument, `x`.

Syntax	Values of *M* and *P*
`step(H,x)`	If you set the `RangeFFTLength` property to `'Auto'`, $M = K$, the length of the first dimension of `x`. Otherwise, M equals the value of the `RangeFFTLength` property. If you set the `DopplerFFTLength` property to `'Auto'`, $P = L$, the length of the last dimension of `x`. Otherwise, P equals the value of the `DopplerFFTLength` property.
`step(H,x,xref)`	M is the quotient of the length of the first dimension of `x` divided by the value of the `DecimationFactor` property. If you set the `DopplerFFTLength` property to `'Auto'`, $P = L$, the length of the last dimension of `x`. Otherwise, P equals the value of the `DopplerFFTLength` property.
`step(H,x,coeff)`	M is the number of rows of `x`. If you set the `DopplerFFTLength` property to `'Auto'`, $P = L$, the length of the last dimension of `x`. Otherwise, P equals the value of the `DopplerFFTLength` property.

`rnggrid`

Range samples at which the range-Doppler response is evaluated. `rnggrid` is a column vector of length M.

`dopgrid`

Doppler samples or speed samples at which the range-Doppler response is evaluated. `dopgrid` is a column vector of length P. Whether `dopgrid` contains Doppler or speed samples depends on the `DopplerOutput` property of `H`.

Examples

Range-Doppler Response Using Matched Filter

Compute the range-doppler response of a pulsed radar signal using a matched filter.

Load data for a pulsed radar signal. The signal includes three target returns. Two targets are approximately 2000 m away, while the third is approximately 3500 m away. In addition, two of the targets are stationary relative to the radar. The third is moving away from the radar at about 100 m/s.

```
load RangeDopplerExampleData;
```

Create a range-Doppler response object.

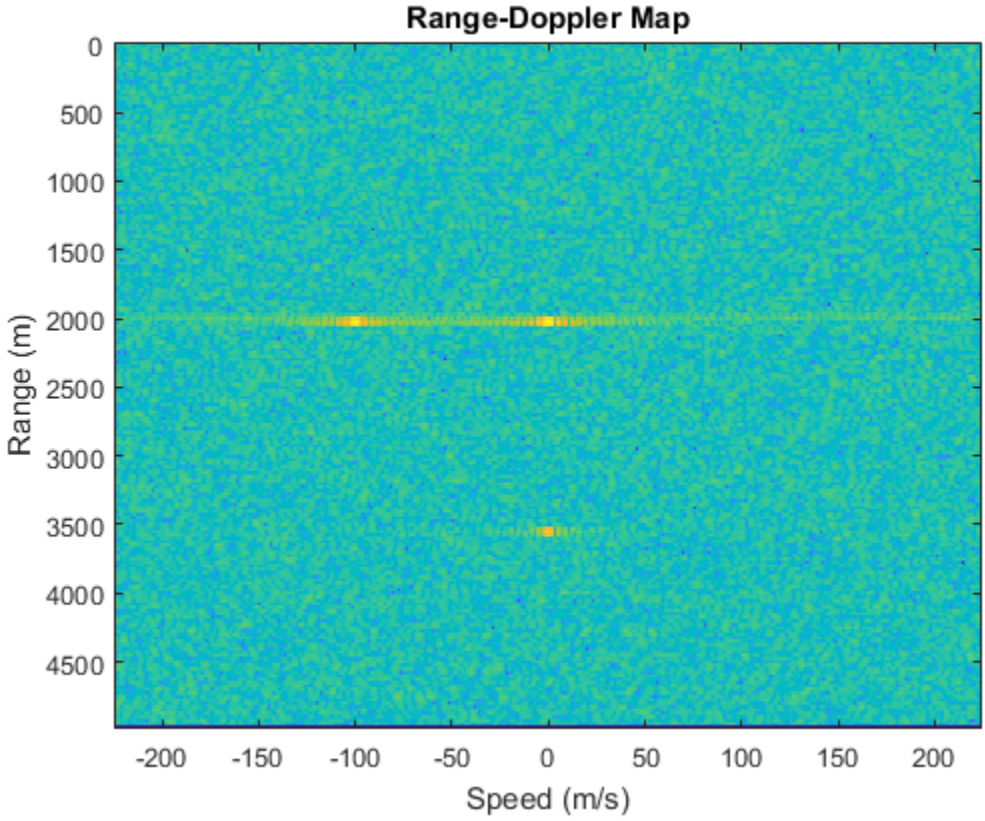
```
response = phased.RangeDopplerResponse('DopplerFFTLengthSource','Property', ...
   'DopplerFFTLength',RangeDopplerEx_MF_NFFTDOP, ...
   'SampleRate',RangeDopplerEx_MF_Fs,'DopplerOutput','Speed', ...
   'OperatingFrequency',RangeDopplerEx_MF_Fc);
```

Calculate the range-Doppler response.

```
[resp,rng_grid,dop_grid] = response(RangeDopplerEx_MF_X, ...
    RangeDopplerEx_MF_Coeff);
```

Plot the range-Doppler response.

```
imagesc(dop_grid,rng_grid,mag2db(abs(resp)));
xlabel('Speed (m/s)');
ylabel('Range (m)');
title('Range-Doppler Map');
```



Estimate Doppler and Range from Range-Doppler Response

Estimate the Doppler and range values of a single target from the range-Doppler response.

Load data for an FMCW signal that has not yet been dechirped. The signal contains the return from one target.

```
load RangeDopplerExampleData;
```

Create a range-Doppler response object.

```
hrdresp = phased.RangeDopplerResponse(...
   'RangeMethod','FFT',...
```

```
    'PropagationSpeed',RangeDopplerEx_Dechirp_PropSpeed,...
    'SampleRate',RangeDopplerEx_Dechirp_Fs,...
    'DechirpInput',true,...
    'SweepSlope',RangeDopplerEx_Dechirp_SweepSlope);
```

Obtain the range-Doppler response data.

```
[resp,rng_grid,dop_grid] = step(hrdresp,...
   RangeDopplerEx_Dechirp_X,RangeDopplerEx_Dechirp_Xref);
```

Estimate the range and Doppler by finding the location of the maximum response.

```
[x_temp,idx_temp] = max(abs(resp));
[~,dop_idx] = max(x_temp);
rng_idx = idx_temp(dop_idx);
dop_est = dop_grid(dop_idx)
rng_est = rng_grid(rng_idx)
```

```
dop_est =

 -712.8906

rng_est =

        2250
```

The target is approximately 2250 meters away, and is moving fast enough to cause a Doppler shift of approximately -713 Hz.

phased.RangeEstimator System object

Package: phased

Range estimation

Description

The `phased.RangeEstimator` System object estimates the ranges of targets. Input to the estimator consists of a range-response or range-Doppler response data cube, and detection locations from a detector. When information about clusters of detections is available, the ranges are computed using cluster information. Clustering associates multiple detections into one extended detection.

To compute the detections for a range-response or range-Doppler cube:

1. Define and set up a range estimator using the "Construction" on page 1-1531 procedure that follows.
2. Call the step method to compute the range, using the properties you specify for the `phased.RangeEstimator` System object.

Note: Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`estimator = phased.RangeEstimator` creates a range estimator System object, `estimator`.

`estimator = phased.RangeEstimator(Name,Value)` creates a System object, `estimator`, with each specified property `Name` set to the specified `Value`. You can specify additional name and value pair arguments in any order as (`Name1,Value1,...,NameN,ValueN`).

Properties

`NumEstimatesSource` — Source of number of range estimates to report

`'Auto'` (default) | `'Property'`

Source of the number of range estimates to report, specified as `'Auto'` or `'Property'`.

If you set this property to `'Auto'`, the number of reported estimates is determined from the number of columns in the `detidx` input to the `step` method. If cluster IDs are provided, the number of estimates is determined from the number of unique cluster IDs in the `clusterids` input to the `step` method.

If you set this property to `'Property'`, the number of reported estimates is obtained from the value of the `NumEstimates` property.

Data Types: `char`

`NumEstimates` — Maximum number of estimates

`1` (default) | positive integer

The maximum number of range estimates to report, specified as a positive integer. The number of requested estimates can be greater than the number of columns in the `detidx` argument or the number of unique IDs in the `clusterids` argument of the `step` method. In that case, the remainder is filled with `NaN`.

Dependencies

To enable this property, set the `NumEstimatesSource` property to `'Property'`.

Data Types: `double`

`ClusterInputPort` — Accept cluster IDs as input

`false` (default) | `true`

Option to accept cluster IDs as an input argument to the `step` method, specified as `false` or `true`. Setting this property to `true` enables the `clusterids` input argument.

Data Types: `logical`

`VarianceOutputPort` — Output variance for range estimates

`false` (default) | `true`

Option to enable output of range estimate variances, specified as `false` or `true`. Range variances are returned by the `rngvar` output argument of the `step` method.

Data Types: `logical`

`RMSResolution` — Root-mean-square range resolution

`1.0` (default) | positive scalar

Root-mean-square range resolution of the detection, specified as a positive scalar. The value of the `RMSResolution` must have the same units as the `rangegrid` input argument of the `step` method.

Dependencies

To enable this property, set the value of the `VarianceOutputPort` property to `true`.

Data Types: `double`

`NoisePowerSource` — Source of noise power values

`'Property'` (default) | `'Input port'`

Source of noise power values, specified as `'Property'` or `'Input port'`. Noise power is used to compute range estimation variance and SNR. If you set this property to `'Property'`, the value of the `NoisePower` property represents the noise power at the detection locations. If you set this property to `'Input port'`, you can specify noise power using the `noisepower` input argument, of the `step` method.

Data Types: `char`

`NoisePower` — Noise power

`1.0` (default) | positive scalar

Constant noise power value over the range-response or range-Doppler response data cube, specified as a positive real scalar. Noise power units are linear. The same noise power value is applied to all detections.

Dependencies

To enable this property, set the value of the `VarianceOutputPort` property to `true` and set `NoisePowerSource` to `'Property'`.

Data Types: `double`

Methods

step	Estimate target range

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Estimate Range and Speed of Three Targets

To estimate the range and speed of three targets, create a range-Doppler map using the `phased.RangeDopplerResponse` System object™. Then use the `phased.RangeEstimator` and `phased.DopplerEstimator` System objects to estimate range and speed. The transmitter and receiver are collocated isotropic antenna elements forming a monostatic radar system.

The transmitted signal is a linear FM waveform with a pulse repetition interval (PRI) of 7.0 μs and a duty cycle of 2%. The operating frequency is 77 GHz and the sample rate is 150 MHz.

```
fs = 150e6;
c = physconst('LightSpeed');
fc = 77.0e9;
pri = 7e-6;
prf = 1/pri;
```

Set up the scenario parameters. The transmitter and receiver are stationary and located at the origin. The targets are 500, 530, and 750 meters from the radar along the *x*-axis.

The targets move along the *x*-axis at speeds of –60, 20, and 40 m/s. All three targets have a nonfluctuating radar cross-section (RCS) of 10 dB. Create the target and radar platforms.

```
Numtgts = 3;
tgtpos = zeros(Numtgts);
tgtpos(1,:) = [500 530 750];
tgtvel = zeros(3,Numtgts);
tgtvel(1,:) = [-60 20 40];
tgtrcs = db2pow(10)*[1 1 1];
tgtmotion = phased.Platform(tgtpos,tgtvel);
target = phased.RadarTarget('PropagationSpeed',c,'OperatingFrequency',fc, ...
    'MeanRCS',tgtrcs);
radarpos = [0;0;0];
radarvel = [0;0;0];
radarmotion = phased.Platform(radarpos,radarvel);
```

Create the transmitter and receiver antennas.

```
txantenna = phased.IsotropicAntennaElement;
rxantenna = clone(txantenna);
```

Set up the transmitter-end signal processing. Create an upsweep linear FM signal with a bandwidth of one half the sample rate. Find the length of the PRI in samples and then estimate the rms bandwidth and range resolution.

```
bw = fs/2;
waveform = phased.LinearFMWaveform('SampleRate',fs, ...
    'PRF',prf,'OutputFormat','Pulses','NumPulses',1,'SweepBandwidth',fs/2, ...
    'DurationSpecification','Duty cycle','DutyCycle',0.02);
sig = waveform();
Nr = length(sig);
bwrms = bandwidth(waveform)/sqrt(12);
rngrms = c/bwrms;
```

Set up the transmitter and radiator System object properties. The peak output power is 10 W and the transmitter gain is 36 dB.

```
peakpower = 10;
txgain = 36.0;
txgain = 36.0;
transmitter = phased.Transmitter( ...
    'PeakPower',peakpower, ...
    'Gain',txgain, ...
```

```
    'InUseOutputPort',true);
radiator = phased.Radiator( ...
    'Sensor',txantenna,...
    'PropagationSpeed',c,...
    'OperatingFrequency',fc);
```

Set up the free-space channel in two-way propagation mode.

```
channel = phased.FreeSpace( ...
    'SampleRate',fs, ...
    'PropagationSpeed',c, ...
    'OperatingFrequency',fc, ...
    'TwoWayPropagation',true);
```

Set up the receiver-end processing. Set the receiver gain and noise figure.

```
collector = phased.Collector( ...
    'Sensor',rxantenna, ...
    'PropagationSpeed',c, ...
    'OperatingFrequency',fc);
rxgain = 42.0;
noisefig = 1;
receiver = phased.ReceiverPreamp( ...
    'SampleRate',fs, ...
    'Gain',rxgain, ...
    'NoiseFigure',noisefig);
```

Loop over the pulses to create a data cube of 128 pulses. For each step of the loop, move the target and propagate the signal. Then put the received signal into the data cube. The data cube contains the received signal per pulse. Ordinarily, a data cube has three dimensions where the last dimension corresponds to antennas or beams. Because only one sensor is used, the cube has only two dimensions.

The processing steps are:

1. Move the radar and targets.
2. Transmit a waveform.
3. Propagate the waveform signal to the target.
4. Reflect the signal from the target.
5. Propagate the waveform back to the radar. Two-way propagation enables enables you to combine the return propagation with the outbound propagation.

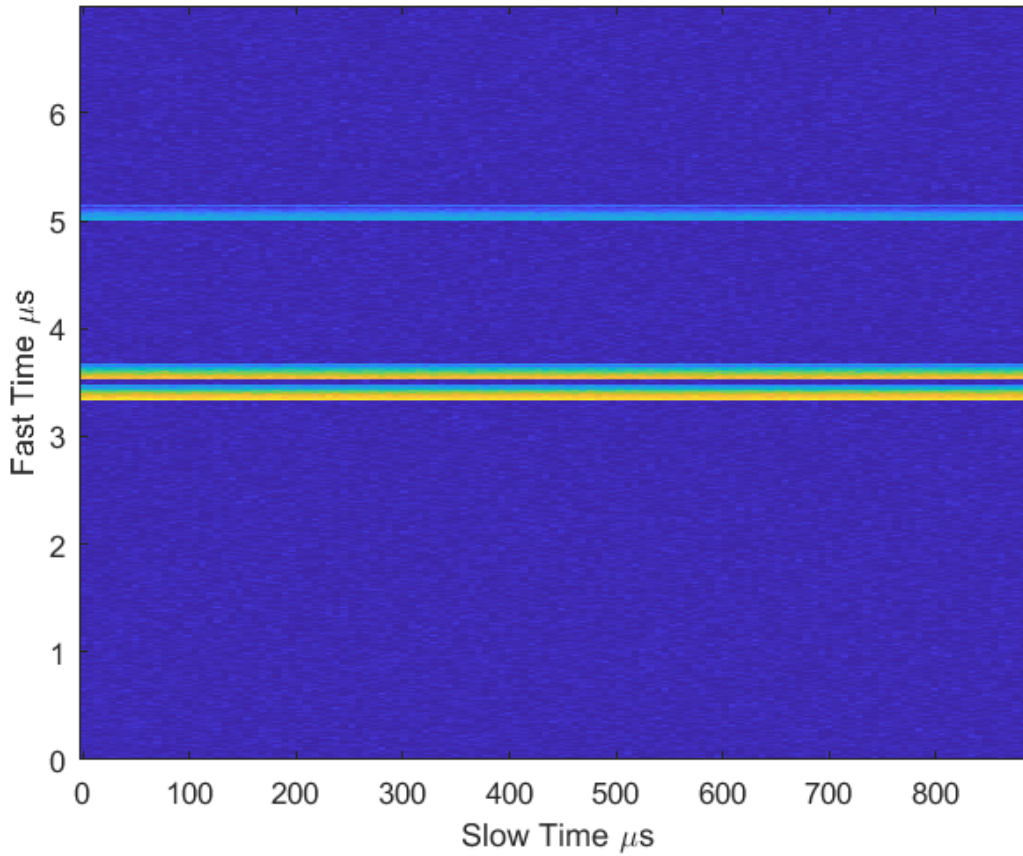
6 Receive the signal at the radar.

7 Load the signal into the data cube.

```
Np = 128;
dt = pri;
cube = zeros(Nr,Np);
for n = 1:Np
    [sensorpos,sensorvel] = radarmotion(dt);
    [tgtpos,tgtvel] = tgtmotion(dt);
    [tgtrng,tgtang] = rangeangle(tgtpos,sensorpos);
    sig = waveform();
    [txsig,txstatus] = transmitter(sig);
    txsig = radiator(txsig,tgtang);
    txsig = channel(txsig,sensorpos,tgtpos,sensorvel,tgtvel);
    tgtsig = target(txsig);
    rxcol = collector(tgtsig,tgtang);
    rxsig = receiver(rxcol);
    cube(:,n) = rxsig;
end
```

Display the data cube containing signals per pulse.

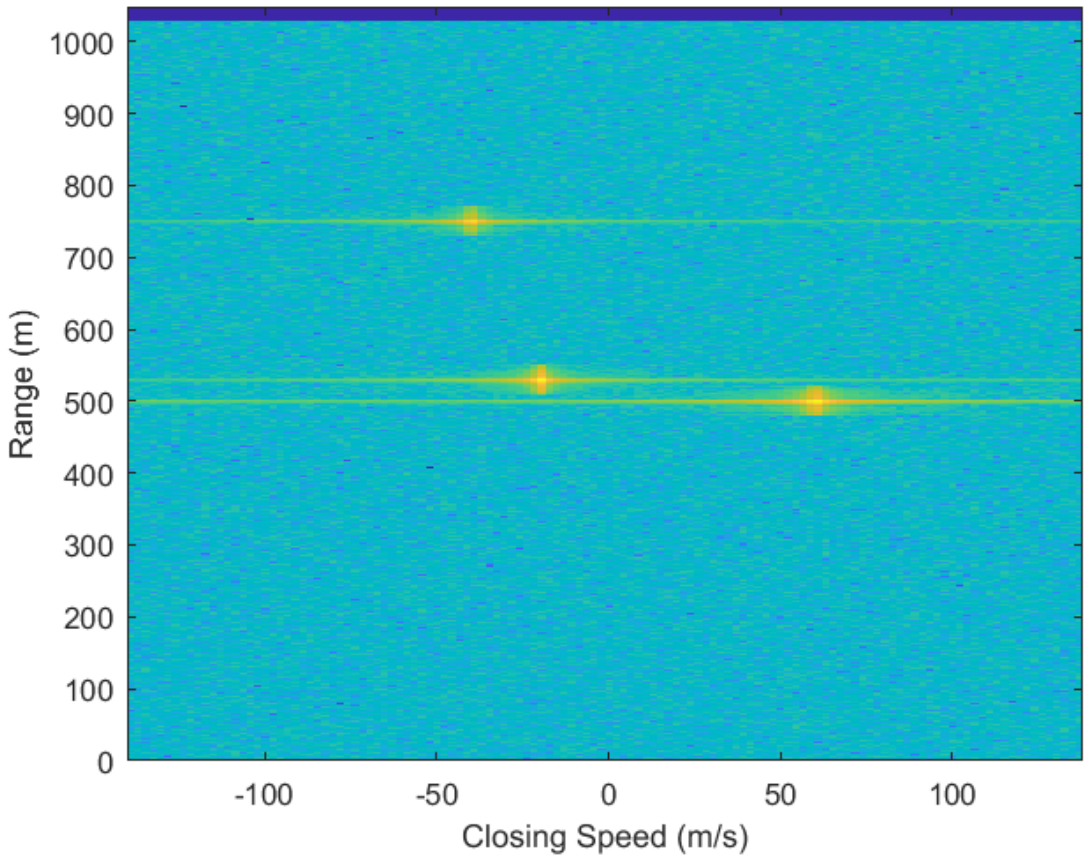
```
imagesc([0:(Np-1)]*pri*1e6,[0:(Nr-1)]/fs*1e6,abs(cube))
xlabel('Slow Time {\mu}s')
ylabel('Fast Time {\mu}s')
axis xy
```



Create and display the range-Doppler image for 128 Doppler bins. The image shows range vertically and speed horizontally. Use the linear FM waveform for match filtering. The image is here is the range-Doppler map.

```
ndop = 128;
rangedopresp = phased.RangeDopplerResponse('SampleRate',fs, ...
    'PropagationSpeed',c,'DopplerFFTLengthSource','Property', ...
    'DopplerFFTLength',ndop,'DopplerOutput','Speed', ...
    'OperatingFrequency',fc);
matchingcoeff = getMatchedFilter(waveform);
[rngdopresp,rnggrid,dopgrid] = rangedopresp(cube,matchingcoeff);
```

```
imagesc(dopgrid,rnggrid,10*log10(abs(rngdopresp)))
xlabel('Closing Speed (m/s)')
ylabel('Range (m)')
axis xy
```



Because the targets lie along the positive *x*-axis, positive velocity in the global coordinate system corresponds to negative closing speed. Negative velocity in the global coordinate system corresponds to positive closing speed.

Estimate the noise power after matched filtering. Create a constant noise background image for simulation purposes.

```
mfgain = matchingcoeff'*matchingcoeff;
dopgain = Np;
noisebw = fs;
noisepower = noisepow(noisebw,receiver.NoiseFigure,receiver.ReferenceTemperature);
noisepowerprc = mfgain*dopgain*noisepower;
noise = noisepowerprc*ones(size(rngdopresp));
```

Create the range and Doppler estimator objects.

```
rangeestimator = phased.RangeEstimator('NumEstimatesSource','Auto', ...
    'VarianceOutputPort',true,'NoisePowerSource','Input port', ...
    'RMSResolution',rngrms);
dopestimator = phased.DopplerEstimator('VarianceOutputPort',true, ...
    'NoisePowerSource','Input port','NumPulses',Np);
```

Locate the target indices in the range-Doppler image. Instead of using a CFAR detector, for simplicity, use the known locations and speeds of the targets to obtain the corresponding index in the range-Doppler image.

```
detidx = NaN(2,Numtgts);
tgtrng = rangeangle(tgtpos,radarpos);
tgtspd = radialspeed(tgtpos,tgtvel,radarpos,radarvel);
tgtdop = 2*speed2dop(tgtspd,c/fc);
for m = 1:numel(tgtrng)
    [~,iMin] = min(abs(rnggrid-tgtrng(m)));
    detidx(1,m) = iMin;
    [~,iMin] = min(abs(dopgrid-tgtspd(m)));
    detidx(2,m) = iMin;
end
```

Find the noise power at the detection locations.

```
ind = sub2ind(size(noise),detidx(1,:),detidx(2,:));
```

Estimate the range and range variance at the detection locations. The estimated ranges agree with the postulated ranges.

```
[rngest,rngvar] = rangeestimator(rngdopresp,rnggrid,detidx,noise(ind))
```

```
rngest =

  499.7911
  529.8380
```

```
  750.0983

rngvar =

   1.0e-04 *

    0.0273
    0.0276
    0.2094
```

Estimate the speed and speed variance at the detection locations. The estimated speeds agree with the predicted speeds.

```
[spdest,spdvar] = dopestimator(rngdopresp,dopgrid,detidx,noise(ind))
```

```
spdest =

   60.5241
  -19.6167
  -39.5838

spdvar =

   1.0e-05 *

    0.0806
    0.0816
    0.6188
```

Definitions

Date Cube

One input to the range estimator is a response data cube. To create a response data cube, use the phased.RangeDopplerResponse or phased.RangeResponse System objects. The first dimension of the cube represents the range. Only the first dimension is used to

estimate range. All other dimensions are ignored. To interpret the detection location, you must pass in the `rnggrid` vector corresponding to the range values along this dimension. See “Radar Data Cube Concept”.

Algorithms

The `phased.RangeEstimator` System object estimates the range of a detection by following these steps:

1. Input a range-processed response data cube obtained from either the phased.RangeResponse or phased.RangeDopplerResponse System object. The first dimension of the cube represents the fast-time or equivalent range of the returned signal samples. Only this dimension is used to estimate detection range. All others are ignored.
2. Input a matrix of detection indices that specify the location of detections in the data cube. Each column denotes a separate detection. The row entries designate indices into the data cube. You can obtain detection indices as an output of the phased.CFARDetector or phased.CFARDetector2D detectors. To return these indices, set the `OutputFormat` property of either CFAR detector to `'Detection index'`.
3. Optionally input a row vector of cluster IDs. This vector is equal in length to the number of detections. Each element of this vector assigns an ID to a corresponding detection. To form clusters of detections, the same ID can be assigned to more than one detection. To enable this option, set the `ClusterInputPort` property to `true`.
4. When `ClusterInputPort` is `false`, the object computes the range for each detection. The algorithm finds the response values at the detection location and at two adjacent indices in the cube along the range dimension. Then, the algorithm fits a quadratic curve to the magnitudes of the range response at these three locations and finds the location of the peak. When detections occur at the first or last sample in the range dimension, the range response is estimated from a two-point centroid. The estimation is at the location of the detection index and at the sample adjacent to the detection index.

   When `ClusterInputPort` is `true`, the object computes range for each cluster. The algorithm finds the indices of the largest response value in the cluster and fits a quadratic formula to that detection in the same way as for individual detections.
5. Convert the fractional index values of the fitted peak locations to range. To convert the indices, choose appropriate units for the `rnggrid` input argument

of the `step` method. You can use values for `rnggrid` obtained from either the phased.RangeResponse or phased.RangeDopplerResponse System objects.

The object computes the estimated range variance using the Ziv-Zakai bound.

step

System object: phased.RangeEstimator
Package: phased

Estimate target range

Syntax

```
rngest = step(estimator,resp,rnggrid,detidx)
[rngest,rngvar] = step(estimator,resp,rnggrid,detidx,noisepower)
[rngest,rngvar] = step(estimator,resp,rnggrid,detidx,clusterids)
[rngest,rngvar] = step(estimator,resp,rnggrid,detidx,noisepower,
clusterids)
```

Description

Note: Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`rngest = step(estimator,resp,rnggrid,detidx)` estimates ranges from detections derived from the range response data cube, `resp`. Range estimates are computed for each detection position reported in `detidx`. The `rnggrid` argument sets the units for the range dimension of the response data cube.

`[rngest,rngvar] = step(estimator,resp,rnggrid,detidx,noisepower)` also specifies the noise power. This syntax applies when you set the `VarianceOutputPort` property to `true` and the `NoisePowerSource` property to `'Input port'`.

`[rngest,rngvar] = step(estimator,resp,rnggrid,detidx,clusterids)` also specifies the cluster IDs for the detections. This syntax applies when you set the `ClusterInputPort` to `true`.

You can combine optional input and output arguments when their enabling properties are set. Optional inputs and outputs must be listed in the same order as the order of

the enabling properties. For example, `[rngest,rngvar] = step(estimator,resp, rnggrid,detidx,noisepower,clusterids)`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`estimator` — Range estimator

`phased.RangeEstimator` System object

Range estimator, specified as a `phased.RangeEstimator` System object.

Example: `phased.RangeEstimator`

`resp` — Range-processed response data cube

complex-valued *M*-by-1 column vector | complex-valued *M*-by-*N* matrix | complex-valued *M*-by-*N*-by-*P* matrix

Range-processed response data cube, specified as a complex-valued *M*-by-1 column vector, a complex-valued *M*-by-*N* matrix, or a complex-valued *M*-by-*N*-by-*P* array. *M* is the number of fast-time or range samples. *N* is the number of spatial elements, such as sensor elements or beams, *P* is the number of Doppler bins or pulses, depending on whether the data cube has been Doppler processed.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Data Types: `double`

`rnggrid` — Range values along range dimension

real-valued *M*-by-1 column vector

Range values along range dimension of the `resp` argument, specified as a real-valued *M*-by-1 column vector. `rnggrid` defines the range values corresponding to the fast-time or range dimension. Range values must be monotonically increasing and equally spaced. Units are in meters.

Example: `[0.1,0.2,0.3]`

Data Types: `double`

`detidx` — Detection indices

real-valued N_d-by-Q matrix

Detection indices, specified as a real-valued N_d-by-Q matrix. Q is the number of detections and N_d is the number of dimensions of the response data cube, `resp`. Each column of `detidx` contains the N_d indices of the detection in the response data cube.

To generate detection indices, you can use the phased.CFARDetector object or phased.CFARDetector2D object.

Data Types: `double`

`noisepower` — Noise power at detection locations

positive scalar | real-valued 1-by-Q row vector of positive values

Noise power at detection locations, specified as a positive scalar or real-valued 1-by-Q row vector where Q is the number of detections specified in `detidx`.

Dependencies

To enable this input argument, set the value of the `NoisePowerSource` property to `'Input port'`.

Data Types: `double`

`clusterids` — Cluster IDs

real-valued 1-by-Q row vector of positive values

Cluster IDs, specified as a real-valued 1-by-Q row vector, where Q is the number of detections specified in `detidx`. Each element of `clusterids` corresponds to a column in `detidx`. Detections with the same cluster ID are in the same cluster.

Dependencies

To enable this input argument, set the value of the `ClusterInputPort` property to `true`.

Data Types: `double`

Output Arguments

`rngest` — Range estimates

real-valued *K*-by-1 column vector

Range estimates, returned as a real-valued *K*-by-1 column vector.

- When `ClusterInputPort` is `false`, Doppler estimates are computed for each detection location in the `detidx` argument. Then *K* equals the column dimension, *Q*, of `detidx`.
- When `ClusterInputPort` is `true`, Doppler estimates are computed for each cluster ID in the `clusterids` argument. Then *K* equals the number of unique cluster IDs, *Q*.

Data Types: `double`

`rngvar` — Range estimation variance

positive, real-valued *K*-by-1 column vector

Range estimation variance, returned as a positive, real-valued *K*-by-1 column vector, where *K* is the dimension of `rngest`. Each element of `rngvar` corresponds to an element of `rngest`. The estimator variance is computed using the Ziv-Zakai bound.

Data Types: `double`

Examples

Estimate Range and Speed of Three Targets

To estimate the range and speed of three targets, create a range-Doppler map using the `phased.RangeDopplerResponse` System object™. Then use the `phased.RangeEstimator` and `phased.DopplerEstimator` System objects to estimate range and speed. The transmitter and receiver are collocated isotropic antenna elements forming a monostatic radar system.

The transmitted signal is a linear FM waveform with a pulse repetition interval (PRI) of 7.0 µs and a duty cycle of 2%. The operating frequency is 77 GHz and the sample rate is 150 MHz.

```
fs = 150e6;
c = physconst('LightSpeed');
fc = 77.0e9;
```

```
pri = 7e-6;
prf = 1/pri;
```

Set up the scenario parameters. The transmitter and receiver are stationary and located at the origin. The targets are 500, 530, and 750 meters from the radar along the *x*-axis. The targets move along the *x*-axis at speeds of –60, 20, and 40 m/s. All three targets have a nonfluctuating radar cross-section (RCS) of 10 dB. Create the target and radar platforms.

```
Numtgts = 3;
tgtpos = zeros(Numtgts);
tgtpos(1,:) = [500 530 750];
tgtvel = zeros(3,Numtgts);
tgtvel(1,:) = [-60 20 40];
tgtrcs = db2pow(10)*[1 1 1];
tgtmotion = phased.Platform(tgtpos,tgtvel);
target = phased.RadarTarget('PropagationSpeed',c,'OperatingFrequency',fc, ...
    'MeanRCS',tgtrcs);
radarpos = [0;0;0];
radarvel = [0;0;0];
radarmotion = phased.Platform(radarpos,radarvel);
```

Create the transmitter and receiver antennas.

```
txantenna = phased.IsotropicAntennaElement;
rxantenna = clone(txantenna);
```

Set up the transmitter-end signal processing. Create an upsweep linear FM signal with a bandwidth of one half the sample rate. Find the length of the PRI in samples and then estimate the rms bandwidth and range resolution.

```
bw = fs/2;
waveform = phased.LinearFMWaveform('SampleRate',fs, ...
    'PRF',prf,'OutputFormat','Pulses','NumPulses',1,'SweepBandwidth',fs/2, ...
    'DurationSpecification','Duty cycle','DutyCycle',0.02);
sig = waveform();
Nr = length(sig);
bwrms = bandwidth(waveform)/sqrt(12);
rngrms = c/bwrms;
```

Set up the transmitter and radiator System object properties. The peak output power is 10 W and the transmitter gain is 36 dB.

```
peakpower = 10;
txgain = 36.0;
```

```
txgain = 36.0;
transmitter = phased.Transmitter( ...
    'PeakPower',peakpower, ...
    'Gain',txgain, ...
    'InUseOutputPort',true);
radiator = phased.Radiator( ...
    'Sensor',txantenna,...
    'PropagationSpeed',c,...
    'OperatingFrequency',fc);
```

Set up the free-space channel in two-way propagation mode.

```
channel = phased.FreeSpace( ...
    'SampleRate',fs, ...
    'PropagationSpeed',c, ...
    'OperatingFrequency',fc, ...
    'TwoWayPropagation',true);
```

Set up the receiver-end processing. Set the receiver gain and noise figure.

```
collector = phased.Collector( ...
    'Sensor',rxantenna, ...
    'PropagationSpeed',c, ...
    'OperatingFrequency',fc);
rxgain = 42.0;
noisefig = 1;
receiver = phased.ReceiverPreamp( ...
    'SampleRate',fs, ...
    'Gain',rxgain, ...
    'NoiseFigure',noisefig);
```

Loop over the pulses to create a data cube of 128 pulses. For each step of the loop, move the target and propagate the signal. Then put the received signal into the data cube. The data cube contains the received signal per pulse. Ordinarily, a data cube has three dimensions where the last dimension corresponds to antennas or beams. Because only one sensor is used, the cube has only two dimensions.

The processing steps are:

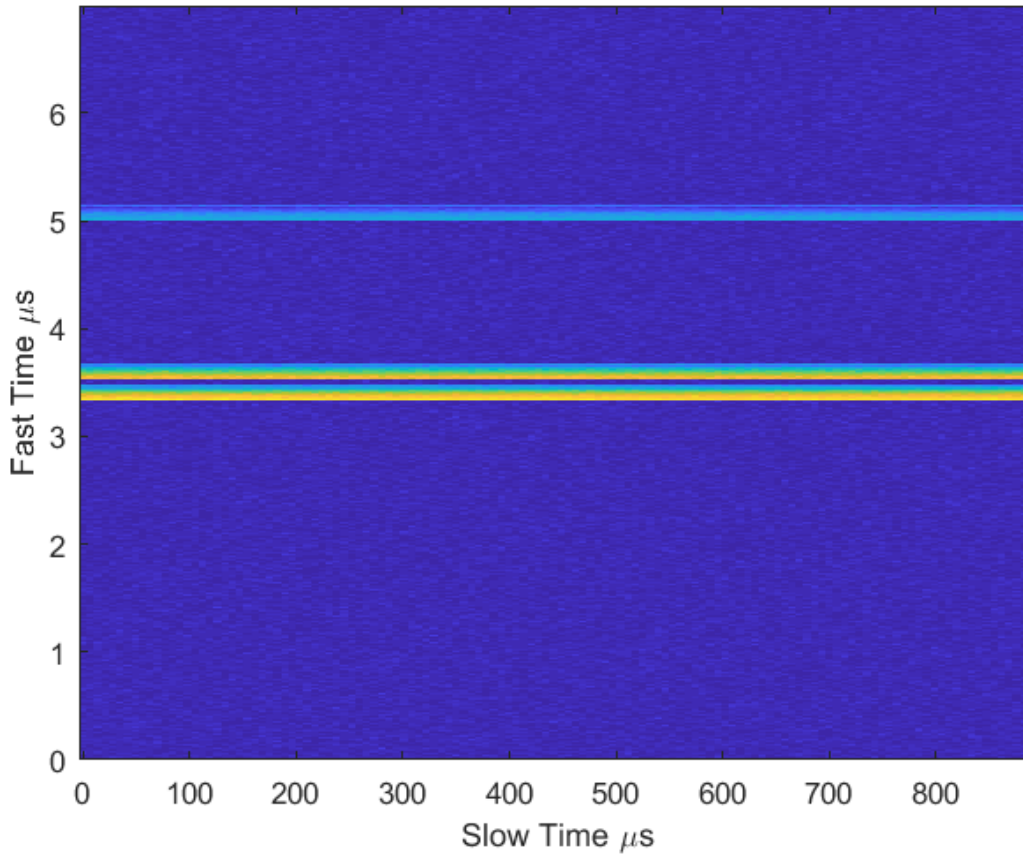
1. Move the radar and targets.
2. Transmit a waveform.
3. Propagate the waveform signal to the target.
4. Reflect the signal from the target.

5. Propagate the waveform back to the radar. Two-way propagation enables enables you to combine the return propagation with the outbound propagation.
6. Receive the signal at the radar.
7. Load the signal into the data cube.

```
Np = 128;
dt = pri;
cube = zeros(Nr,Np);
for n = 1:Np
    [sensorpos,sensorvel] = radarmotion(dt);
    [tgtpos,tgtvel] = tgtmotion(dt);
    [tgtrng,tgtang] = rangeangle(tgtpos,sensorpos);
    sig = waveform();
    [txsig,txstatus] = transmitter(sig);
    txsig = radiator(txsig,tgtang);
    txsig = channel(txsig,sensorpos,tgtpos,sensorvel,tgtvel);
    tgtsig = target(txsig);
    rxcol = collector(tgtsig,tgtang);
    rxsig = receiver(rxcol);
    cube(:,n) = rxsig;
end
```

Display the data cube containing signals per pulse.

```
imagesc([0:(Np-1)]*pri*1e6,[0:(Nr-1)]/fs*1e6,abs(cube))
xlabel('Slow Time {\mu}s')
ylabel('Fast Time {\mu}s')
axis xy
```



Create and display the range-Doppler image for 128 Doppler bins. The image shows range vertically and speed horizontally. Use the linear FM waveform for match filtering. The image is here is the range-Doppler map.

```
ndop = 128;
rangedopresp = phased.RangeDopplerResponse('SampleRate',fs, ...
    'PropagationSpeed',c,'DopplerFFTLengthSource','Property', ...
    'DopplerFFTLength',ndop,'DopplerOutput','Speed', ...
    'OperatingFrequency',fc);
matchingcoeff = getMatchedFilter(waveform);
[rngdopresp,rnggrid,dopgrid] = rangedopresp(cube,matchingcoeff);
```

```
imagesc(dopgrid,rnggrid,10*log10(abs(rngdopresp)))
xlabel('Closing Speed (m/s)')
ylabel('Range (m)')
axis xy
```

Because the targets lie along the positive *x*-axis, positive velocity in the global coordinate system corresponds to negative closing speed. Negative velocity in the global coordinate system corresponds to positive closing speed.

Estimate the noise power after matched filtering. Create a constant noise background image for simulation purposes.

```
mfgain = matchingcoeff'*matchingcoeff;
dopgain = Np;
noisebw = fs;
noisepower = noisepow(noisebw,receiver.NoiseFigure,receiver.ReferenceTemperature);
noisepowerprc = mfgain*dopgain*noisepower;
noise = noisepowerprc*ones(size(rngdopresp));
```

Create the range and Doppler estimator objects.

```
rangeestimator = phased.RangeEstimator('NumEstimatesSource','Auto', ...
    'VarianceOutputPort',true,'NoisePowerSource','Input port', ...
    'RMSResolution',rngrms);
dopestimator = phased.DopplerEstimator('VarianceOutputPort',true, ...
    'NoisePowerSource','Input port','NumPulses',Np);
```

Locate the target indices in the range-Doppler image. Instead of using a CFAR detector, for simplicity, use the known locations and speeds of the targets to obtain the corresponding index in the range-Doppler image.

```
detidx = NaN(2,Numtgts);
tgtrng = rangeangle(tgtpos,radarpos);
tgtspd = radialspeed(tgtpos,tgtvel,radarpos,radarvel);
tgtdop = 2*speed2dop(tgtspd,c/fc);
for m = 1:numel(tgtrng)
    [~,iMin] = min(abs(rnggrid-tgtrng(m)));
    detidx(1,m) = iMin;
    [~,iMin] = min(abs(dopgrid-tgtspd(m)));
    detidx(2,m) = iMin;
end
```

Find the noise power at the detection locations.

```
ind = sub2ind(size(noise),detidx(1,:),detidx(2,:));
```

Estimate the range and range variance at the detection locations. The estimated ranges agree with the postulated ranges.

```
[rngest,rngvar] = rangeestimator(rngdopresp,rnggrid,detidx,noise(ind))
```

```
rngest =

  499.7911
  529.8380
  750.0983
```

```
rngvar =

   1.0e-04 *

    0.0273
    0.0276
    0.2094
```

Estimate the speed and speed variance at the detection locations. The estimated speeds agree with the predicted speeds.

```
[spdest,spdvar] = dopestimator(rngdopresp,dopgrid,detidx,noise(ind))
```

```
spdest =

   60.5241
  -19.6167
  -39.5838

spdvar =

   1.0e-05 *

    0.0806
    0.0816
    0.6188
```

phased.RangeResponse System object

Package: phased

Range response

Description

The `phased.RangeResponse` System object performs range filtering on fast-time (range) data, using either a matched filter or an FFT-based algorithm. The output is typically used as input to a detector. Matched filtering improves the SNR of pulsed waveforms. For continuous FM signals, FFT processing extracts the beat frequency of FMCW waveforms. Beat frequency is directly related to range.

The input to the range response object is a radar data cube. The organization of the data cube follows the Phased Array System Toolbox convention.

- The first dimension of the cube represents the fast-time samples or ranges of the received signals.
- The second dimension represents multiple spatial channels, such as different sensors or beams.
- The third dimension, slow-time, represent pulses.

Range filtering operates along the fast-time dimension of the cube. Processing along the other dimensions is not performed. If the data contains only one channel or pulse, the data cube can contain fewer than three dimensions. Because this object performs no Doppler processing, you can use the object to process noncoherent radar pulses.

The output of the range response object is also a data cube with the same number of dimensions as the input. Its first dimension contains range-processed data but its length can differ from the first dimension of the input data cube.

To compute the range response:

1. Define and set up your `phased.RangeResponse` System object. See "Construction" on page 1-1557.
2. Call the step method to compute the range response using the properties you specify for the `phased.RangeResponse` System object.

Note: Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`response = phased.RangeResponse` creates a range response System object, `response`.

`response = phased.RangeResponse(Name,Value)` creates a System object, `response`, with each specified property `Name` set to the specified `Value`. You can specify additional name and value pair arguments in any order as (`Name1,Value1,...,NameN,ValueN`).

Properties

`RangeMethod` — Range processing method

`'Matched filter'` (default) | `'FFT'`

Range processing method, specified as `'Matched filter'` or `'FFT'`.

- `'Matched filter'` — The object match-filters the incoming signal. This approach is commonly used for pulsed signals, where the matched filter is the time reverse of the transmitted signal.
- `'FFT'` — The object applies an FFT to the input signal. This approach is commonly used for chirped signals such as FMCW and linear FM pulsed signals.

Example: `'Matched filter'`

Data Types: `char`

`PropagationSpeed` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. Units are in m/s. The default value of the speed of light is the value returned by `physconst('LightSpeed')`.

Example: `3e8`

Data Types: `double`

`SampleRate` — Signal sample rate

`1e6` (default) | positive real-valued scalar

Signal sample rate, specified as a positive real-valued scalar. Units are in hertz.

Example: `1e6`

Data Types: `double`

`SweepSlope` — Linear FM sweep slope

`1.0e9` (default) | scalar

Linear FM sweep slope, specified as a scalar. The fast-time dimension of the `signal` input argument to `step` must correspond to sweeps having this slope.

Example: `1.5e9`

Dependencies

To enable this property, set the `RangeMethod` property to `'FFT'`.

Data Types: `double`

`DechirpInput` — Enable dechirping of input signals

`false` (default) | `true`

Option to enable dechirping of input signals, specified as `false` or `true`. Set this property to `false` to indicate that the input signal is already dechirped and no dechirp operation is necessary. Set this property to `true` when the input signal requires dechirping.

Dependencies

To enable this property, set the `RangeMethod` property to `'FFT'`.

Data Types: `logical`

`DecimationFactor` — Decimation factor for dechirped signals

`1` (default) | positive integer

Decimation factor for dechirped signals, specified as a positive integer. The decimation algorithm uses a 30th-order FIR filter generated by `fir1(30,1/D)`, where `D` is the decimation factor. The default value of `1` implies no decimation.

When processing FMCW signals, decimating the dechirped signal is useful for reducing the load on A/D converters.

Dependencies

To enable this property, set the `RangeMethod` property to `'FFT'` and the `DechirpInput` property to `true`.

Data Types: `double`

`RangeFFTLengthSource` — Source of FFT length for range processing of dechirped signals

`'Auto'` (default) | `'Property'`

Source of the FFT length used for the range processing of dechirped signals, specified as `'Auto'` or `'Property'`.

- `'Auto'` — The FFT length equals the length of the fast-time dimension of the input data cube.
- `'Property'` — Specify the FFT length by using the `RangeFFTLength` property.

Dependencies

To enable this property, set the `RangeMethod` property to `'FFT'`.

Data Types: `char`

`RangeFFTLength` — FFT length used for range processing

1024 (default) | positive integer

FFT length used for range processing, specified as a positive integer.

Dependencies

To enable this property, set the `RangeMethod` property to `'FFT'` and the `RangeFFTLengthSource` property to `'Property'`

Data Types: `double`

`RangeWindow` — FFT weighting window for range processing

`'None'` (default) | `'Hamming'` | `'Chebyshev'` | `'Hann'` | `'Kaiser'` | `'Taylor'` | `'Custom'`

FFT weighting window for range processing, specified as `'None'`, `'Hamming'`, `'Chebyshev'`, `'Hann'`, `'Kaiser'`, `'Taylor'`, or `'Custom'`.

If you set this property to `'Taylor'`, the generated Taylor window has four nearly constant sidelobes next to the mainlobe.

Dependencies

To enable this property, set the `RangeMethod` property to `'FFT'`.

Data Types: `char`

`RangeSidelobeAttenuation` — Sidelobe attenuation for range processing

`30` (default) | positive scalar

Sidelobe attenuation for range processing, specified as a positive scalar. Attenuation applies to Kaiser, Chebyshev, or Taylor windows. Units are in dB.

Dependencies

To enable this property, set the `RangeMethod` property to `'FFT'` and the `RangeWindow` property to `'Kaiser'`, `'Chebyshev'`, or `'Taylor'`.

`CustomRangeWindow` — Custom window for range processing

`@hamming` (default) | function handle | cell array

Custom window for range processing, specified as a function handle or a cell array containing a function handle as its first entry. If you do not specify a window length, the object computes the window length and passes that into the function. If you specify a cell array, the remaining cells of the array can contain arguments to the function. If you use only the function handle without passing in arguments, all arguments take their default values.

If you write your own window function, the first argument must be the length of the window.

Note: Instead of using a cell array, you can pass in all arguments by constructing a handle to an anonymous function. For example, you can set the value of `CustomRangeWindow` to `@(n)taylorwin(n,nbar,sll)`, where you have previously set the values of `nbar` and `sll`.

Example: `{@taylor,5,-35}`

Dependencies

To enable this property, set the `RangeMethod` property to `'FFT'` and the `RangeWindow` property to `'Custom'`.

Data Types: `function_handle | cell`

`MaximumNumInputSamplesSource` — Source of maximum number of samples

`'Auto'` (default) | `'Property'`

The source of the maximum number of samples of the input signal, specified as `'Auto'` or `'Property'`. When you set this property to `'Auto'`, the object automatically allocates enough memory to buffer the input signal. When you set this property to `'Property'`, you specify the maximum number of samples in the input signal using the `MaximumNumInputSamples` property. Any input signal longer than that value is truncated.

When you this object with variable-size signals in a MATLAB Simulink function block, you must set `MaximumNumInputSamples` to `'Property'` and set the `MaximumNumInputSamples` property.

Example: `'Property'`

Dependencies

To enable this property, set `RangeMethod` to `'Matched Filter'`.

`MaximumNumInputSamples` — Maximum number of input signal samples

100 (default) | positive integer

Maximum number of samples in the input signal, specified as a positive integer. Any input signal longer than this value is truncated. The input signal is the first argument to the `step` method. The number of samples is the number of rows in the input.

Example: 2048

Dependencies

To enable this property, set the `RangeMethod` property to `'Matched filter'` and `MaximumNumInputSamplesSource` property to `'Property'`.

Methods

plotResponse	Plot range response
step	Range response

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Range Response of Three Targets

Compute the radar range response of three targets by using the `phased.RangeResponse` System object™. The transmitter and receiver are collocated

isotropic antenna elements forming a monostatic radar system. The transmitted signal is a linear FM waveform with a pulse repetition interval of 7.0 μs and a duty cycle of 2%. The operating frequency is 77 GHz and the sample rate is 150 MHz.

```
fs = 150e6;
c = physconst('LightSpeed');
fc = 77e9;
pri = 7e-6;
prf = 1/pri;
```

Set up the scenario parameters. The radar transmitter and receiver are stationary and located at the origin. The targets are 500, 530, and 750 meters from the radars on the *x*-axis. The targets move along the *x*-axis at speeds of −60, 20, and 40 m/s. All three targets have a nonfluctuating radar cross-section (RCS) of 10 dB.

Create the target and radar platforms.

```
Numtgts = 3;
tgtpos = zeros(Numtgts);
tgtpos(1,:) = [500 530 750];
tgtvel = zeros(3,Numtgts);
tgtvel(1,:) = [-60 20 40];
tgtrcs = db2pow(10)*[1 1 1];
tgtmotion = phased.Platform(tgtpos,tgtvel);
target = phased.RadarTarget('PropagationSpeed',c,'OperatingFrequency',fc, ...
    'MeanRCS',tgtrcs);
radarpos = [0;0;0];
radarvel = [0;0;0];
radarmotion = phased.Platform(radarpos,radarvel);
```

Create the transmitter and receiver antennas.

```
txantenna = phased.IsotropicAntennaElement;
rxantenna = clone(txantenna);
```

Set up the transmitter-end signal processing. Create an upsweep linear FM signal with a bandwidth of half the sample rate. Find the length of the pri in samples and then estimate the rms bandwidth and range resolution.

```
bw = fs/2;
waveform = phased.LinearFMWaveform('SampleRate',fs, ...
    'PRF',prf,'OutputFormat','Pulses','NumPulses',1,'SweepBandwidth',fs/2, ...
    'DurationSpecification','Duty cycle','DutyCycle',0.02);
sig = waveform();
```

```
Nr = length(sig);
bwrms = bandwidth(waveform)/sqrt(12);
rngrms = c/bwrms;
```

Set up the transmitter and radiator System object properties. The peak output power is 10 W and the transmitter gain is 36 dB.

```
peakpower = 10;
txgain = 36.0;
transmitter = phased.Transmitter( ...
    'PeakPower',peakpower, ...
    'Gain',txgain, ...
    'InUseOutputPort',true);
radiator = phased.Radiator( ...
    'Sensor',txantenna, ...
    'PropagationSpeed',c, ...
    'OperatingFrequency',fc);
```

Create a free-space propagation channel in two-way propagation mode.

```
channel = phased.FreeSpace( ...
    'SampleRate',fs, ...
    'PropagationSpeed',c, ...
    'OperatingFrequency',fc, ...
    'TwoWayPropagation',true);
```

Set up the receiver-end processing. The receiver gain is 42 dB and noise figure is 10.

```
collector = phased.Collector( ...
    'Sensor',rxantenna, ...
    'PropagationSpeed',c, ...
    'OperatingFrequency',fc);
rxgain = 42.0;
noisefig = 10;
receiver = phased.ReceiverPreamp( ...
    'SampleRate',fs, ...
    'Gain',rxgain, ...
    'NoiseFigure',noisefig);
```

Loop over 128 pulses to build a data cube. For each step of the loop, move the target and propagate the signal. Then put the received signal into the data cube. The data cube contains the received signal per pulse. Ordinarily, a data cube has three dimensions, where last dimension corresponds to antennas or beams. Because only one sensor is used in this example, the cube has only two dimensions.

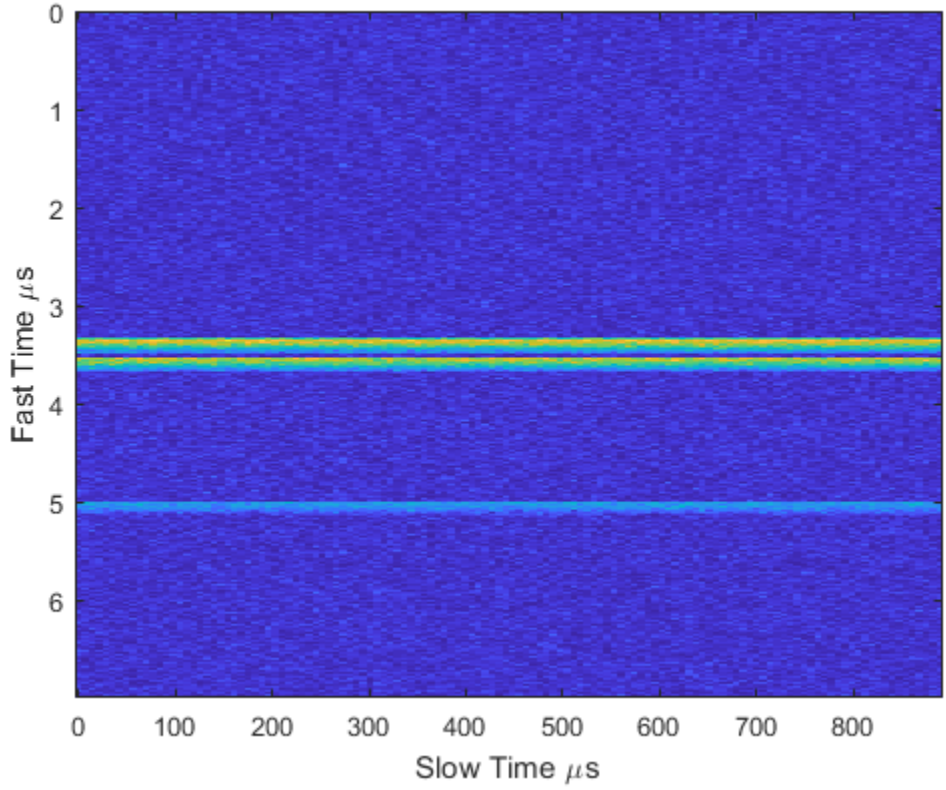
The processing steps are:

1. Move the radar and targets.
2. Transmit a waveform.
3. Propagate the waveform signal to the target.
4. Reflect the signal from the target.
5. Propagate the waveform back to the radar. Two-way propagation mode enables you to combine the returned propagation with the outbound propagation.
6. Receive the signal at the radar.
7. Load the signal into the data cube.

```
Np = 128;
cube = zeros(Nr,Np);
for n = 1:Np
    [sensorpos,sensorvel] = radarmotion(pri);
    [tgtpos,tgtvel] = tgtmotion(pri);
    [tgtrng,tgtang] = rangeangle(tgtpos,sensorpos);
    sig = waveform();
    [txsig,txstatus] = transmitter(sig);
    txsig = radiator(txsig,tgtang);
    txsig = channel(txsig,sensorpos,tgtpos,sensorvel,tgtvel);
    tgtsig = target(txsig);
    rxcol = collector(tgtsig,tgtang);
    rxsig = receiver(rxcol);
    cube(:,n) = rxsig;
end
```

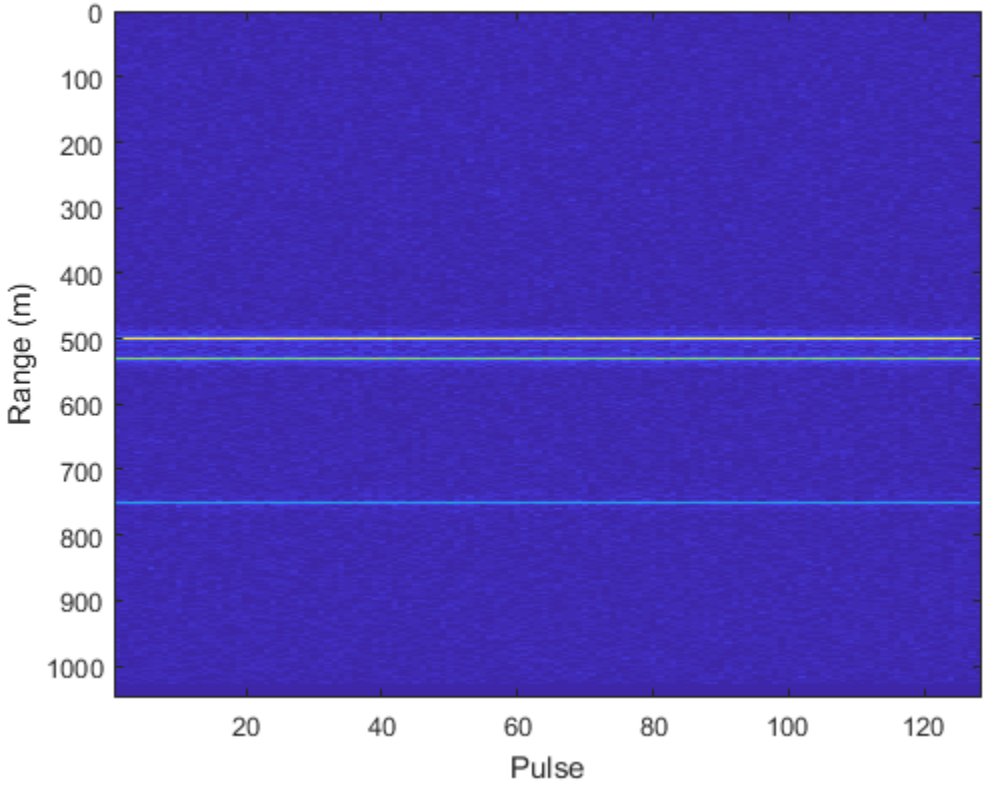
Display the image of the data cube containing signals per pulse.

```
imagesc([0:(Np-1)]*pri*1e6,[0:(Nr-1)]/fs*1e6,abs(cube))
xlabel('Slow Time {\mu}s')
ylabel('Fast Time {\mu}s')
```



Create a `phased.RangeResponse` System object in matched filter mode. Then, display the range response image for the 128 pulses. The image shows range vertically and pulse number horizontally.

```
matchingcoeff = getMatchedFilter(waveform);
ndop = 128;
rangeresp = phased.RangeResponse('SampleRate',fs,'PropagationSpeed',c);
[resp,rnggrid] = rangeresp(cube,matchingcoeff);
imagesc([1:Np],rnggrid,abs(resp))
xlabel('Pulse')
ylabel('Range (m)')
```



Integrate 20 pulses noncoherently.

```
intpulse = pulsint(resp(:,1:20),'noncoherent');
plot(rnggrid,abs(intpulse))
xlabel('Range (m)')
title('Noncoherent Integration of 20 Pulses')
```

plotResponse

System object: phased.RangeResponse
Package: phased

Plot range response

Syntax

```
plotResponse(response,x)
plotResponse(response,x,xref)
plotResponse(response,x,coeff)
plotResponse(response,___,Name,Value)
```

Description

`plotResponse(response,x)` plots the range response of a dechirped input signal, `x`. This syntax applies when you set the `RangeMethod` property to `'FFT'` and the `DechirpInput` property to `false`.

`plotResponse(response,x,xref)` plots the range response `x`, after performing a dechirp operation using the reference signal, `xref`. This syntax applies when you set the `RangeMethod` property to `'FFT'` and the `DechirpInput` property to `true`.

`plotResponse(response,x,coeff)` plots the range response of `x` after match filtering using the match filter coefficients, `coeff`. This syntax applies when you set the `RangeMethod` property to `'Matched filter'`.

`plotResponse(response,___,Name,Value)` plots the range response with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`response` — Range response

`phased.RangeResponse` System object

Range response, specified as a `phased.RangeResponse` System object.

Example: `phased.RangeResponse`

x — Input radar data cube

complex-valued *K*-element column vector | complex-valued *K*-by-*L* matrix | complex-valued *K*-by-*N*-by-*L* array

Input radar data cube, specified as a complex-valued *K*-by-1 column vector, a *K*-by-*L* matrix, or *K*-by-*N*-by-*L* array.

- *K* is the number of fast-time or range samples.
- *N* is the number of independent spatial channels such as sensors or directions.
- *L* is the slow-time dimension that corresps to the number of pulses or sweeps in the input signal.

See “Radar Data Cube”.

Each *K*-element fast-time dimension is processed independently.

For FMCW waveforms with a triangle sweep, the sweeps alternate between positive and negative slopes. However, `phased.RangeResponse` is designed to process consecutive sweeps of the same slope. To apply `phased.RangeResponse` for a triangle-sweep system, use one of the following approaches:

- Specify a positive `SweepSlope` property value, with `x` corresponding to upsweeps only. After obtaining the Doppler or speed values, divide them by 2.
- Specify a negative `SweepSlope` property value, with `x` corresponding to downsweeps only. After obtaining the Doppler or speed values, divide them by 2.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Data Types: `double`
Complex Number Support: Yes

xref — Reference signal used for dechirping

complex-valued *K*-by-1 column vector

Reference signal used for dechirping, specified as a complex-valued *K*-by-1 column vector. The value of *K* must equal the length of the first dimension of `x`.

Dependencies

To enable this input argument, set the value of `RangeMethod` to `'FFT'` and `DechirpInput` to `true`.

Data Types: `double`
Complex Number Support: Yes

`coeff` — Matched filter coefficients

complex-valued *P*-by-1 column vector

Matched filter coefficients, specified as a complex-valued *P*-by-1 column vector. *P* must be less than or equal to *K*, the length of the fast-time dimension.

Dependencies

To enable this input argument, set `RangeMethod` property to `'Matched filter'`.

Data Types: `double`
Complex Number Support: Yes

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Unit'` — Vertical axes units

`'db'` (default) | `'mag'` | `'pow'`

Units for vertical axis of plot, specified as `'db'`, `'mag'`, or `'pow'`.

Example: `'pow'`

Data Types: `char`

Examples

Plot Range Response of Three Targets

Plot the radar range response of three targets usin the `plotResponse` method of the `phased.RangeResponse` System object™. The transmitter and receiver are collocated isotropic antenna elements forming a monostatic radar system. The transmitted signal is a linear FM waveform with a pulse repetition interval of 7.0 μs and a duty cycle of 2%. The operating frequency is 77 GHz and the sample rate is 150 Mhz.

```
fs = 150e6;fs = 150e6;
c = physconst('LightSpeed');
fc = 77e9;
pri = 7e-6;
prf = 1/pri;
```

Set up the scenario parameters. The radar transmitter and receiver are stationary and located at the origin. The targets are 500, 530, and 750 meters from the radars on the *x*-axis. The targets move along the *x*-axis at speeds of −60, 20, and 40 m/s. All three targets have a nonfluctuating RCS of 10 dB.

Create the target and radar platforms.

```
Numtgts = 3;
tgtpos = zeros(Numtgts);
tgtpos(1,:) = [500 530 750];
tgtvel = zeros(3,Numtgts);
tgtvel(1,:) = [-60 20 40];
tgtrcs = db2pow(10)*[1 1 1];
tgtmotion = phased.Platform(tgtpos,tgtvel);
target = phased.RadarTarget('PropagationSpeed',c,'OperatingFrequency',fc, ...
    'MeanRCS',tgtrcs);
radarpos = [0;0;0];
radarvel = [0;0;0];
radarmotion = phased.Platform(radarpos,radarvel);
```

Create the transmitter and receiver antennas.

```
txantenna = phased.IsotropicAntennaElement;
rxantenna = clone(txantenna);
```

Set up the transmitter-end signal processing. Construct an upsweep linear FM signal with a bandwidth of half the sample rate. Find the length of the pri in samples and then the rms bandwidth and rms range resolution.

```
bw = fs/2;
waveform = phased.LinearFMWaveform('SampleRate',fs,...
    'PRF',prf,'OutputFormat','Pulses','NumPulses',1,'SweepBandwidth',fs/2,...
    'DurationSpecification','Duty cycle','DutyCycle',.02);
sig = waveform();
Nr = length(sig);
bwrms = bandwidth(waveform)/sqrt(12);
rngrms = c/bwrms;
```

Set up the transmitter and radiator System object properties. The peak output power is 10 W and the transmitter gain is 36 dB.

```
peakpower = 10;
txgain = 36.0;
transmitter = phased.Transmitter(...
    'PeakPower',peakpower,...
    'Gain',txgain,...
    'InUseOutputPort',true);
radiator = phased.Radiator(...
    'Sensor',txantenna,...
    'PropagationSpeed',c,...
    'OperatingFrequency',fc);
```

Create a free-space propagation channel in two-way propagation mode.

```
channel = phased.FreeSpace(...
    'SampleRate',fs,...
    'PropagationSpeed',c,...
    'OperatingFrequency',fc,...
    'TwoWayPropagation',true);
```

Set up the receiver-end processing. The receiver gain is 42 dB and noise figure is 10.

```
collector = phased.Collector(...
    'Sensor',rxantenna,...
    'PropagationSpeed',c,...
    'OperatingFrequency',fc);
rxgain = 42.0;
noisefig = 10;
receiver = phased.ReceiverPreamp(...
    'SampleRate',fs,...
    'Gain',rxgain,...
    'NoiseFigure',noisefig);
```

Loop over 128 pulses to build a data cube. For each step of the loop, move the target and propagate the signal. Then put the received signal into the data cube. The data cube

contains the received signal per pulse. Ordinarily, a data cube has three dimensions. The last dimension corresponds to antennas or beams. Because only one sensor is used in this example, the cube has only two dimensions.

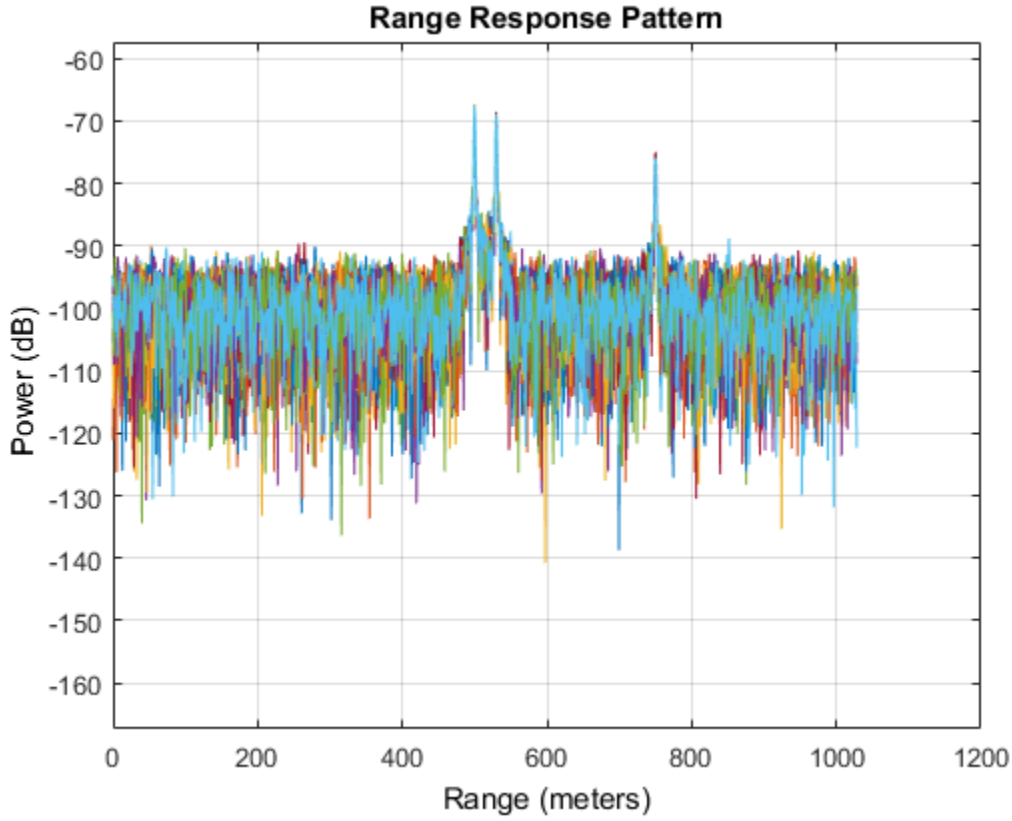
The processing steps are:

1. Move the radar and targets.
2. Transmit a waveform.
3. Propagate the waveform signal to the target.
4. Reflect the signal from the target.
5. Propagate the waveform back to the radar. Two-way propagation mode allows the return propagation to be combined with the outbound propagation.
6. Receive the signal at the radar.
7. Load the signal into the data cube.

```
Np = 128;
cube = zeros(Nr,Np);
for n = 1:Np
    [sensorpos,sensorvel] = radarmotion(pri);
    [tgtpos,tgtvel] = tgtmotion(pri);
    [tgtrng,tgtang] = rangeangle(tgtpos,sensorpos);
    sig = waveform();
    [txsig,txstatus] = transmitter(sig);
    txsig = radiator(txsig,tgtang);
    txsig = channel(txsig,sensorpos,tgtpos,sensorvel,tgtvel);
    tgtsig = target(txsig);
    rxcol = collector(tgtsig,tgtang);
    rxsig = receiver(rxcol);
    cube(:,n) = rxsig;
end
```

Create a `phased.RangeResponse` System object in matched filter mode. Then, call the `plotResponse` method to show the first 20 pulses.

```
matchcoeff = getMatchedFilter(waveform);
rangeresp = phased.RangeResponse('SampleRate',fs,'PropagationSpeed',c);
plotResponse(rangeresp,cube(:,1:20),matchcoeff);
```



Introduced in R2017a

step

System object: phased.RangeResponse
Package: phased

Range response

Syntax

```
[resp,rnggrid] = step(response,x)
[resp,rnggrid] = step(response,x,xref)
[resp,rnggrid] = step(response,x,coeff)
```

Description

Note: Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[resp,rnggrid] = step(response,x)` computes the range response, `resp`, for the input signal, `x`, and the range values, rnggrid, corresponding to the response. This syntax applies when you set `RangeMethod` to `'FFT'` and `DechirpInput` to `false`. This syntax assumes that the input signal has already been dechirped. This syntax is most commonly used with FMCW signals.

`[resp,rnggrid] = step(response,x,xref)` computes the range response of the input signal, `x` using the reference signal, `xref`. This syntax applies when you set `RangeMethod` to `'FFT'` and `DechirpInput` to `true`. Often, the reference signal is the transmitted signal. This syntax assumes that the input signal has not been dechirped. This syntax is most commonly used with FMCW signals.

`[resp,rnggrid] = step(response,x,coeff)` computes the range response of `x` using the matched filter `coeff`. This syntax applies when you set `RangeMethod` to `'Matched filter'`. This syntax is most commonly used with pulsed signals.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`response` — Range response

`phased.RangeResponse` System object

Range response, specified as a `phased.RangeResponse` System object.

Example: `phased.RangeResponse`

`x` — Input radar data cube

complex-valued *K*-element column vector | complex-valued *K*-by-*L* matrix | complex-valued *K*-by-*N*-by-*L* array

Input radar data cube, specified as a complex-valued *K*-by-1 column vector, a *K*-by-*L* matrix, or *K*-by-*N*-by-*L* array.

- *K* is the number of fast-time or range samples.
- *N* is the number of independent spatial channels such as sensors or directions.
- *L* is the slow-time dimension that corresps to the number of pulses or sweeps in the input signal.

See “Radar Data Cube”.

Each *K*-element fast-time dimension is processed independently.

For FMCW waveforms with a triangle sweep, the sweeps alternate between positive and negative slopes. However, `phased.RangeResponse` is designed to process consecutive sweeps of the same slope. To apply `phased.RangeResponse` for a triangle-sweep system, use one of the following approaches:

- Specify a positive `SweepSlope` property value, with `x` corresponding to upsweeps only. After obtaining the Doppler or speed values, divide them by 2.
- Specify a negative `SweepSlope` property value, with `x` corresponding to downsweeps only. After obtaining the Doppler or speed values, divide them by 2.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Data Types: `double`
Complex Number Support: Yes

`xref` — Reference signal used for dechirping

complex-valued *K*-by-1 column vector

Reference signal used for dechirping, specified as a complex-valued *K*-by-1 column vector. The number of rows must equal the length of the fast-time dimension of `x`.

Dependencies

To enable this input argument, set the value of `RangeMethod` to `'FFT'` and `DechirpInput` to `true`.

Data Types: `double`
Complex Number Support: Yes

`coeff` — Matched filter coefficients

complex-valued *P*-by-1 column vector

Matched filter coefficients, specified as a complex-valued *P*-by-1 column vector. *P* must be less than or equal to *K*. *K* is the number of fast-time or range sample.

Dependencies

To enable this input argument, set the value of `RangeMethod` to `'Matched filter'`.

Data Types: `double`
Complex Number Support: Yes

Output Arguments

`resp` — Range response data cube

complex-valued *M*-element column vector | complex-valued *M*-by-*L* matrix | complex-valued *M*-by-*N* by-*L* array

Range response data cube, returned as one of the following:

- Complex-valued *M*-element column vector
- Complex-valued *M*-by-*L* matrix
- Complex-valued *M*-by-*N* by-*L* array

The value of *M* depends on the type of processing

RangeMethod Property	DechirpInput Property	Value of *M*
`'FFT'`	`false`	If you set the `RangeFFTLength` property to `'Auto'`, $M = K$, the length of the fast-time dimension of `x`. Otherwise, *M* equals the value of the `RangeFFTLength` property.
	`true`	*M* equals the quotient of the number of rows, *K*, of the input signal by the value of the decimation factor, *D*, specified in `DecimationFactor`.
`'Matched filter'`	n/a	$M = K$, the length of the fast-time dimension of `x`.

Data Types: `double`
Complex Number Support: Yes

`rnggrid` — Range values along range dimension

real-valued *M*-by-1 column vector

Range values along range dimension, returned as a real-valued *M*-by-1 column vector. `rnggrid` defines the ranges corresponding to the fast-time dimension of the `resp` output data cube. *M* is the length of the fast-time dimension of `resp`. Range values are monotonically increasing and equally spaced. Units are in meters.

Example: `[0,0.1,0.2,0.3]`

Data Types: `double`

Examples

Range Response of Three Targets

Compute the radar range response of three targets by using the `phased.RangeResponse` System object™. The transmitter and receiver are collocated isotropic antenna elements forming a monostatic radar system. The transmitted signal is a linear FM waveform with a pulse repetition interval of 7.0 μs and a duty cycle of 2%. The operating frequency is 77 GHz and the sample rate is 150 MHz.

```
fs = 150e6;
c = physconst('LightSpeed');
fc = 77e9;
pri = 7e-6;
prf = 1/pri;
```

Set up the scenario parameters. The radar transmitter and receiver are stationary and located at the origin. The targets are 500, 530, and 750 meters from the radars on the *x*-axis. The targets move along the *x*-axis at speeds of −60, 20, and 40 m/s. All three targets have a nonfluctuating radar cross-section (RCS) of 10 dB.

Create the target and radar platforms.

```
Numtgts = 3;
tgtpos = zeros(Numtgts);
tgtpos(1,:) = [500 530 750];
tgtvel = zeros(3,Numtgts);
tgtvel(1,:) = [-60 20 40];
tgtrcs = db2pow(10)*[1 1 1];
tgtmotion = phased.Platform(tgtpos,tgtvel);
target = phased.RadarTarget('PropagationSpeed',c,'OperatingFrequency',fc, ...
    'MeanRCS',tgtrcs);
radarpos = [0;0;0];
radarvel = [0;0;0];
radarmotion = phased.Platform(radarpos,radarvel);
```

Create the transmitter and receiver antennas.

```
txantenna = phased.IsotropicAntennaElement;
rxantenna = clone(txantenna);
```

Set up the transmitter-end signal processing. Create an upsweep linear FM signal with a bandwidth of half the sample rate. Find the length of the pri in samples and then estimate the rms bandwidth and range resolution.

```
bw = fs/2;
waveform = phased.LinearFMWaveform('SampleRate',fs, ...
    'PRF',prf,'OutputFormat','Pulses','NumPulses',1,'SweepBandwidth',fs/2, ...
    'DurationSpecification','Duty cycle','DutyCycle',0.02);
sig = waveform();
Nr = length(sig);
bwrms = bandwidth(waveform)/sqrt(12);
rngrms = c/bwrms;
```

Set up the transmitter and radiator System object properties. The peak output power is 10 W and the transmitter gain is 36 dB.

```
peakpower = 10;
txgain = 36.0;
transmitter = phased.Transmitter( ...
    'PeakPower',peakpower, ...
    'Gain',txgain, ...
    'InUseOutputPort',true);
radiator = phased.Radiator( ...
    'Sensor',txantenna, ...
    'PropagationSpeed',c, ...
    'OperatingFrequency',fc);
```

Create a free-space propagation channel in two-way propagation mode.

```
channel = phased.FreeSpace( ...
    'SampleRate',fs, ...
    'PropagationSpeed',c, ...
    'OperatingFrequency',fc, ...
    'TwoWayPropagation',true);
```

Set up the receiver-end processing. The receiver gain is 42 dB and noise figure is 10.

```
collector = phased.Collector( ...
    'Sensor',rxantenna, ...
    'PropagationSpeed',c, ...
    'OperatingFrequency',fc);
rxgain = 42.0;
noisefig = 10;
receiver = phased.ReceiverPreamp( ...
    'SampleRate',fs, ...
    'Gain',rxgain, ...
    'NoiseFigure',noisefig);
```

Loop over 128 pulses to build a data cube. For each step of the loop, move the target and propagate the signal. Then put the received signal into the data cube. The data cube

contains the received signal per pulse. Ordinarily, a data cube has three dimensions, where last dimension corresponds to antennas or beams. Because only one sensor is used in this example, the cube has only two dimensions.

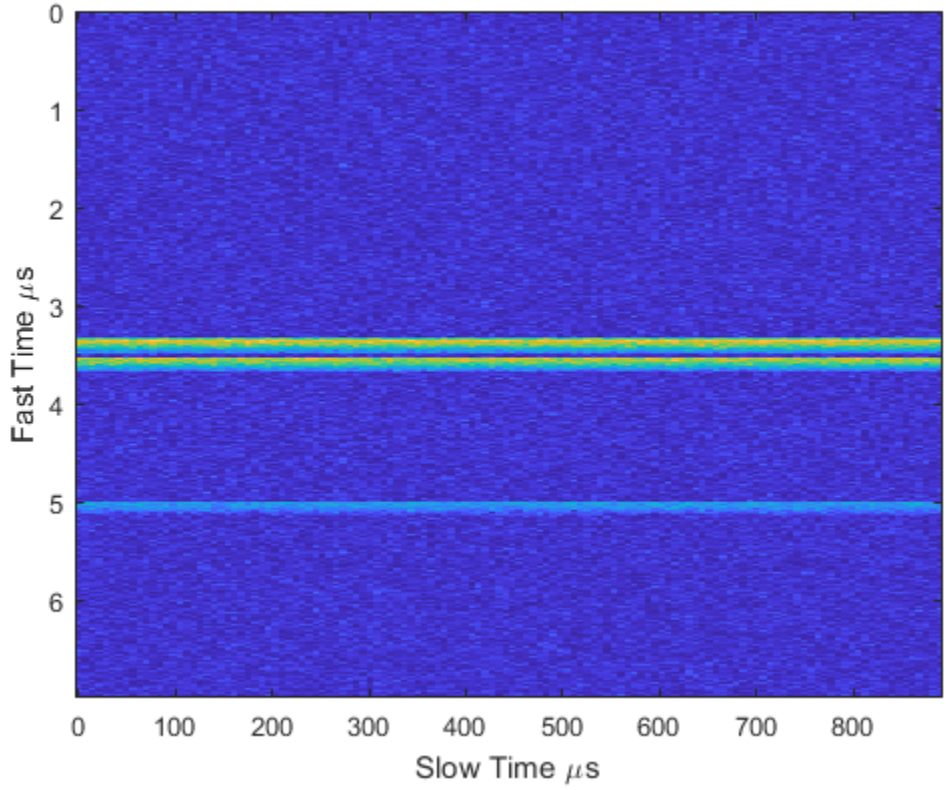
The processing steps are:

1. Move the radar and targets.
2. Transmit a waveform.
3. Propagate the waveform signal to the target.
4. Reflect the signal from the target.
5. Propagate the waveform back to the radar. Two-way propagation mode enables you to combine the returned propagation with the outbound propagation.
6. Receive the signal at the radar.
7. Load the signal into the data cube.

```
Np = 128;
cube = zeros(Nr,Np);
for n = 1:Np
    [sensorpos,sensorvel] = radarmotion(pri);
    [tgtpos,tgtvel] = tgtmotion(pri);
    [tgtrng,tgtang] = rangeangle(tgtpos,sensorpos);
    sig = waveform();
    [txsig,txstatus] = transmitter(sig);
    txsig = radiator(txsig,tgtang);
    txsig = channel(txsig,sensorpos,tgtpos,sensorvel,tgtvel);
    tgtsig = target(txsig);
    rxcol = collector(tgtsig,tgtang);
    rxsig = receiver(rxcol);
    cube(:,n) = rxsig;
end
```

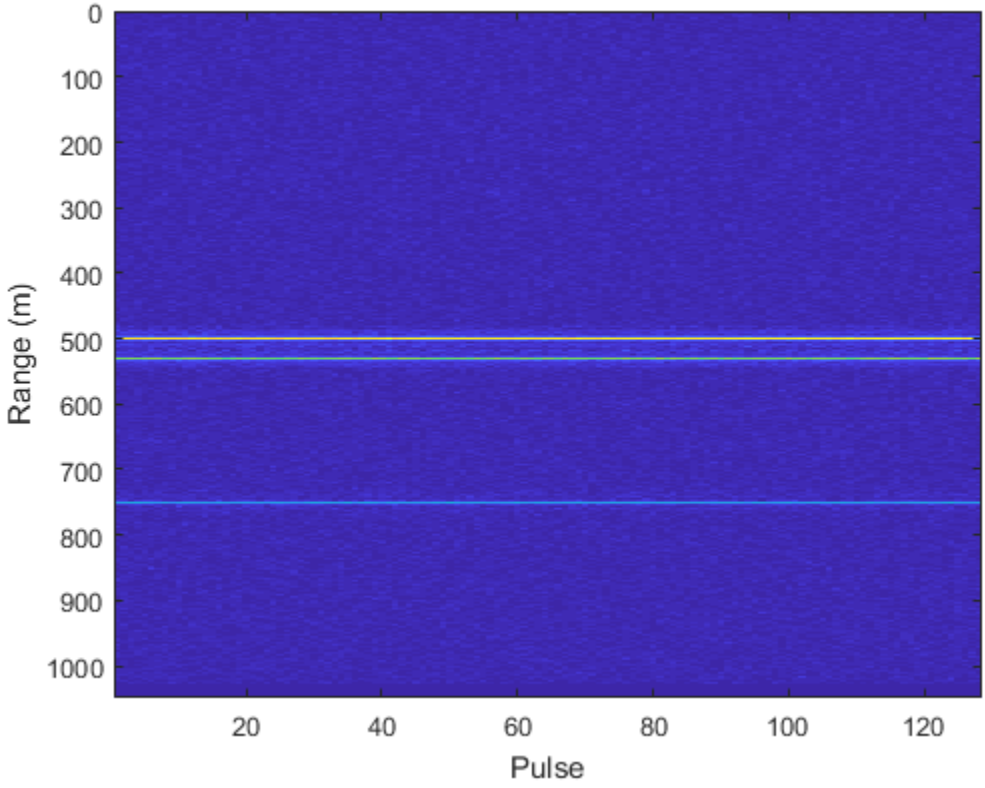
Display the image of the data cube containing signals per pulse.

```
imagesc([0:(Np-1)]*pri*1e6,[0:(Nr-1)]/fs*1e6,abs(cube))
xlabel('Slow Time {\mu}s')
ylabel('Fast Time {\mu}s')
```



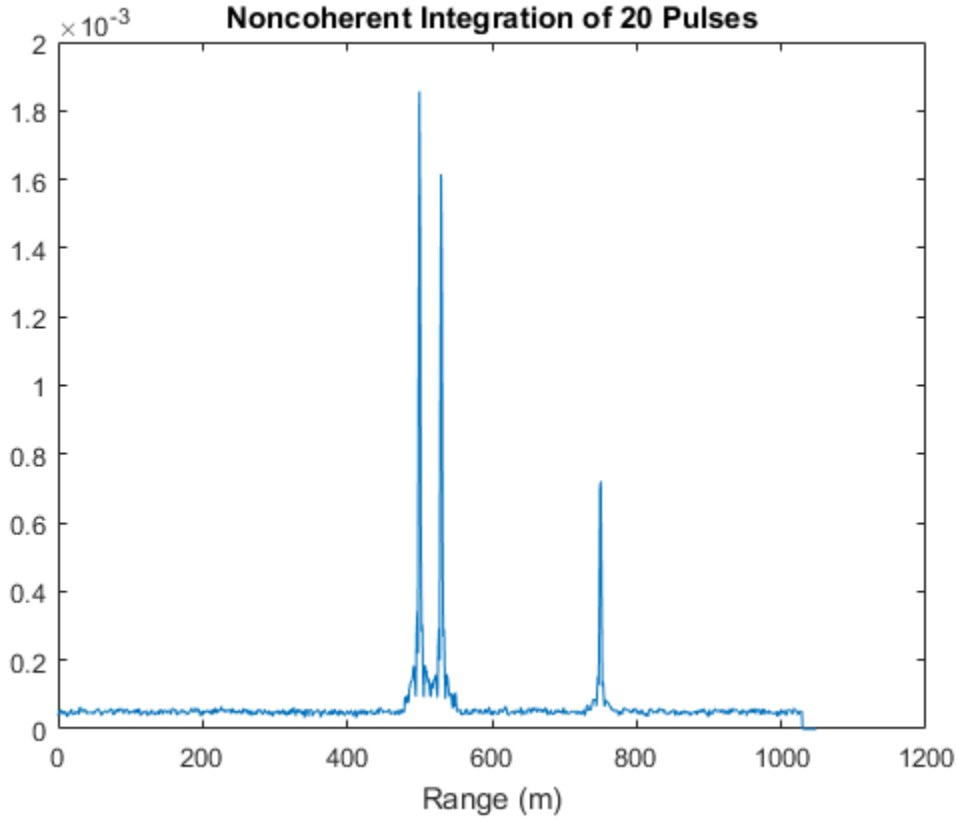
Create a `phased.RangeResponse` System object in matched filter mode. Then, display the range response image for the 128 pulses. The image shows range vertically and pulse number horizontally.

```
matchingcoeff = getMatchedFilter(waveform);
ndop = 128;
rangeresp = phased.RangeResponse('SampleRate',fs,'PropagationSpeed',c);
[resp,rnggrid] = rangeresp(cube,matchingcoeff);
imagesc([1:Np],rnggrid,abs(resp))
xlabel('Pulse')
ylabel('Range (m)')
```



Integrate 20 pulses noncoherently.

```
intpulse = pulsint(resp(:,1:20),'noncoherent');
plot(rnggrid,abs(intpulse))
xlabel('Range (m)')
title('Noncoherent Integration of 20 Pulses')
```



Introduced in R2017a

phased.ReceiverPreamp System object

Package: phased

Receiver preamp

Description

The `ReceiverPreamp` System object implements a model of a receiver preamplifer. The object receives incoming signals, multiplies them by the amplifier gain and divides by system losses. Finally, Gaussian white noise is added to the signal.

To model a receiver preamp:

1. Define and set up your receiver preamp. See "Construction" on page 1-1587.
2. Call step to amplify the input signal according to the properties of `phased.ReceiverPreamp`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.ReceiverPreamp` creates a receiver preamp System object, `H`.

`H = phased.ReceiverPreamp(Name,Value)` creates a receiver preamp object, `H`, with each specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`Gain`

Gain of receiver

A scalar containing the gain (in decibels) of the receiver preamp.

Default: `20`

`LossFactor`

Loss factor of receiver

A scalar containing the loss factor (in decibels) of the receiver preamp.

Default: `0`

`NoiseMethod`

Noise specification method

Specify how to compute noise power using one of `'Noise power' | 'Noise temperature'`. If you set this property to `'Noise temperature'`, complex baseband noise is added to the input signal with noise power computed from the `ReferenceTemperature`, `NoiseFigure`, and `SampleRate` properties. If you set this property to `'Noise power'`, noise is added to the signal with power specified in the `NoisePower` property.

Default: `'Noise temperature'`

`NoiseFigure`

Noise figure of receiver

A scalar containing the noise figure (in decibels) of the receiver preamp. If the receiver has multiple channels/sensors, the noise figure applies to each channel/sensor. This property is only applicable when you set the `NoiseMethod` property to `'Noise temperature'`.

Default: `0`

`ReferenceTemperature`

Reference temperature of receiver

A scalar containing the reference temperature of the receiver (in kelvin). If the receiver has multiple channels/sensors, the reference temperature applies to each channel/sensor.

This property is only applicable when you set the `NoiseMethod` property to `'Noise temperature'`.

Default: `290`

`SampleRate`

Sample rate

Specify the sample rate, in hertz, as a positive scalar. This property is only applicable when you set the `NoiseMethod` property to `'Noise temperature'`. The `SampleRate` property also specifies the noise bandwidth.

Default: `1e6`

`NoisePower`

Noise power

Specify the noise power (in Watts) as a positive scalar. This property is only applicable when you set the `NoiseMethod` property to `'Noise power'`.

Default: `1.0`

`NoiseComplexity`

Noise complexity

Specify the noise complexity as one of `'Complex' | 'Real'`. When you set this property to `'Complex'`, the noise power is evenly divided between real and imaginary channels. Usually, complex-valued baseband signals require the addition of complex-valued noise. On occasion, when the signal is real-valued, you can use this option to specify that the noise is real-valued as well.

Default: `'Complex'`

`EnableInputPort`

Add input to specify enabling signal

To specify a receiver enabling signal, set this property to `true` and use the corresponding input argument when you invoke step. If you do not want to specify a receiver enabling signal, set this property to `false`.

Default: `false`

`PhaseNoiseInputPort`

Add input to specify phase noise

To specify the phase noise for each incoming sample, set this property to `true` and use the corresponding input argument when you invoke step. You can use this information to emulate coherent-on-receive systems. If you do not want to specify phase noise, set this property to `false`.

Default: `false`

`SeedSource`

Source of seed for random number generator

Specify how the object generates random numbers. Values of this property are:

`'Auto'`	The default MATLAB random number generator produces the random numbers. Use `'Auto'` if you are using this object with Parallel Computing Toolbox software.
`'Property'`	The object uses its own private random number generator to produce random numbers. The `Seed` property of this object specifies the seed of the random number generator. Use `'Property'` if you want repeatable results and are not using this object with Parallel Computing Toolbox software.

Default: `'Auto'`

`Seed`

Seed for random number generator

Specify the seed for the random number generator as a scalar integer between 0 and 2^{32}–1. This property applies when you set the `SeedSource` property to `'Property'`.

Default: `0`

Methods

reset	Reset random number generator for noise generation
step	Receive incoming signal

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Preamplify Signal

This example shows how to use a `phased.ReceiverPreamp` System object™ to amplify a sine wave.

Create the System object.

```
receiver = phased.ReceiverPreamp('NoiseFigure',10);
```

Create the input signal.

```
Fs = 100;
t = linspace(0,1-1/Fs,100);
x = 1e-6*sin(2*pi*5*t);
```

Amplify the signal and compare with the input signal.

```
y = receiver(x);
plot(t,x,t,real(y))
xlabel('Time (s)')
ylabel('Amplitude')
legend('Original signal','Received signal')
```

reset

System object: phased.ReceiverPreamp
Package: phased

Reset random number generator for noise generation

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `ReceiverPreamp` object, `H`. This method resets the random number generator state if the `SeedSource` property is set to `'Property'`.

step

System object: phased.ReceiverPreamp
Package: phased

Receive incoming signal

Syntax

```
Y = step(H,X)
Y = step(H,X,EN_RX)
Y = step(H,X,PHNOISE)
Y = step(H,X,EN_RX,PHNOISE)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` applies the receiver gain and the receiver noise to the input signal, `X`, and returns the resulting output signal, `Y`.

`Y = step(H,X,EN_RX)` uses input `EN_RX` as the enabling signal when the `EnableInputPort` property is set to `true`.

`Y = step(H,X,PHNOISE)` uses input `PHNOISE` as the phase noise for each sample in `X` when the `PhaseNoiseInputPort` is set to `true`. The phase noise is the same for all channels in `X`. The elements in `PHNOISE` represent the random phases the transmitter adds to the transmitted pulses. The receiver preamp object removes these random phases from all received samples returned within corresponding pulse intervals. Such setup is often referred to as *coherent on receive*.

`Y = step(H,X,EN_RX,PHNOISE)` combines all input arguments. This syntax is available when you configure `H` so that `H.EnableInputPort` is `true` and `H.PhaseNoiseInputPort` is `true`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`H`

Receiver object.

`X`

Input signal

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

`EN_RX`

Enabling signal, specified as a column vector whose length equals the number of rows in `X`. The data type of `EN_RN` is `double` or `logical`. Every element of `EN_RX` that equals `0` or `false` indicates that the receiver is turned off, and no input signal passes through the receiver. Every element of `EN_RX` that is nonzero or `true` indicates that the receiver is turned on, and the input passes through.

`PHNOISE`

Phase noise for each sample in `X`, specified as a column vector whose length equals the number of rows in `X`. You can obtain `PHNOISE` as an optional output argument from the `step` method of phased.Transmitter.

Output Arguments

`Y`

Output signal. `Y` has the same dimensions as `X`.

Examples

Preamplify Cosine Signal

This example shows how to construct a `phased.ReceiverPreamp` System object™ with a noise figure of 5 dB and a bandwidth of 1 MHz. Then use the object to amplify the signal.

Construct the Receiver Preamp system object.

```
receiver = phased.ReceiverPreamp('NoiseFigure',5,'SampleRate',1e6);
```

Create the signal.

```
Fs = 1e3;
t = linspace(0,1,1e3);
x = cos(2*pi*200*t)';
```

Use the `step` method to amplify the signal and then plot the first 100 samples.

```
y = receiver(x);
idx = [1:100];
plot(t(idx),x(idx),t(idx),real(y(idx)))
xlabel('Time (s)')
ylabel('Amplitude')
legend('Original signal','Received signal')

phased.RectangularWaveform System object

Package: phased

Rectangular pulse waveform

Description

The `RectangularWaveform` object creates a rectangular pulse waveform.

To obtain waveform samples:

1. Define and set up your rectangular pulse waveform. See "Construction" on page 1-1599.
2. Call step to generate the rectangular pulse waveform samples according to the properties of `phased.RectangularWaveform`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations. When the only argument to the `step` method is the System object itself, replace `y = step(obj)` by `y = obj()`.

Construction

`H = phased.RectangularWaveform` creates a rectangular pulse waveform System object, `H`. The object generates samples of a rectangular pulse.

`H = phased.RectangularWaveform(Name,Value)` creates a rectangular pulse waveform object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`SampleRate`

Sample rate

Signal sample rate, specified as a positive scalar. Units are Hertz. The ratio of sample rate to pulse repetition frequency *(PRF)* must be a positive integer — each pulse must contain an integer number of samples.

Default: `1e6`

`DurationSpecification`

Method to set pulse duration

Method to set pulse duration (pulse width), specified as `'Pulse width'` or `'Duty cycle'`. This property determines how you set the pulse duration. When you set this property to `'Pulse width'`, then you set the pulse duration directly using the `PulseWidth` property. When you set this property to `'Duty cycle'`, you set the pulse duration from the values of the `PRF` and `DutyCycle` properties. The pulse width is equal to the duty cycle divided by the *PRF*.

Default: `'Pulse width'`

`PulseWidth`

Pulse width

Specify the length of each pulse (in seconds) as a positive scalar. The value must satisfy `PulseWidth <= 1./PRF`.

Default: `50e-6`

`DutyCycle`

Waveform duty cycle

Waveform duty cycle, specified as a scalar from 0 through 1, inclusive. This property applies when you set the `DurationSpecification` property to `'Duty cycle'`. The pulse width is the value of the `DutyCycle` property divided by the value of the `PRF` property.

Default: `0.5`

`PRF`

Pulse repetition frequency

Pulse repetition frequency, *PRF*, specified as a scalar or a row vector. Units are in Hz. The pulse repetition interval *PRI* is the inverse of the *PRF*. The value of the `PRF` property must satisfy these constraints:

- The product of *PRF* and *PulseWidth* must be less than or equal to one. This is equivalent to the requirement that the pulse width is less than a pulse repetition interval. For the phase-coded waveform, the pulse width is the product of the chip width and number of chips.
- The ratio of sample rate to PRF must be an integer. This is equivalent to requiring that the number of samples in one pulse repetition interval be an integer.

You can select the value of *PRF* by using property settings or input arguments.

- When `PRFSelectionInputPort` is `false`, you set the *PRF* using properties
  - implement a constant *PRF* by specifying `PRF` as a positive real-valued scalar.
  - implement a staggered *PRF* by specifying `PRF` as a row vector with positive real-valued entries. Then, each call to the `step` method uses successive elements of this vector for the *PRF*. If the last element of the vector is reached, the process continues cyclically with the first element of the vector.
- When `PRFSelectionInputPort` is `true`, you can implement a selectable *PRF* by specifying `PRF` as a row vector with positive real-valued entries. But this time, when you execute the `step` method, select a *PRF* by passing an index into the *PRF* vector as an argument.

In all cases, when you use a varying *PRF* and choose the `OutputFormat` property as `'Pulses'`, the number of samples per pulse can vary as well. When you choose `'Samples'` the number of samples per pulse is fixed.

Default: `10e3`

`PRFSelectionInputPort`

Enable PRF selection input

Enable the PRF selection input, specified as `true` or `false`. When you set this property to `false`, the step method uses the values set in the `PRF` property in order. When you set this property to `true`, you can pass an additional argument into the `step` method to select any value from the PRF vector.

Default: `false`

`OutputFormat`

Output signal format

Specify the format of the output signal as `'Pulses'` or `'Samples'`. When you set the `OutputFormat` property to `'Pulses'`, the output of the `step` method takes the form of multiple pulses specified by the value of the `NumPulses` property. The number of samples per pulse can vary if you change the pulse repetition frequency during the simulation.

When you set the `OutputFormat` property to `'Samples'`, the output of the `step` method is in the form of multiple samples. In this case, the number of output signal samples is the value of the `NumSamples` property and is fixed.

Default: `'Pulses'`

`NumSamples`

Number of samples in output

Specify the number of samples in the output of the `step` method as a positive integer. This property applies only when you set the `OutputFormat` property to `'Samples'`.

Default: `100`

`NumPulses`

Number of pulses in output

Specify the number of pulses in the output of the `step` method as a positive integer. This property applies only when you set the `OutputFormat` property to `'Pulses'`.

Default: `1`

Methods

bandwidth	Bandwidth of rectangular pulse waveform
getMatchedFilter	Matched filter coefficients for waveform
plot	Plot rectangular pulse waveform
reset	Reset states of rectangular waveform object
step	Samples of rectangular pulse waveform

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Plot Rectangular Waveform and Spectrum

Create and plot a rectangular pulse waveform object and then plot its spectrum.

Plot the waveform

Create and plot a pulse waveform. The sample rate is 500 kHz, the pulse width is 0.1 millisecond. The pulse repetition interval is twice the pulse duration.

```
fs = 500e3;
```

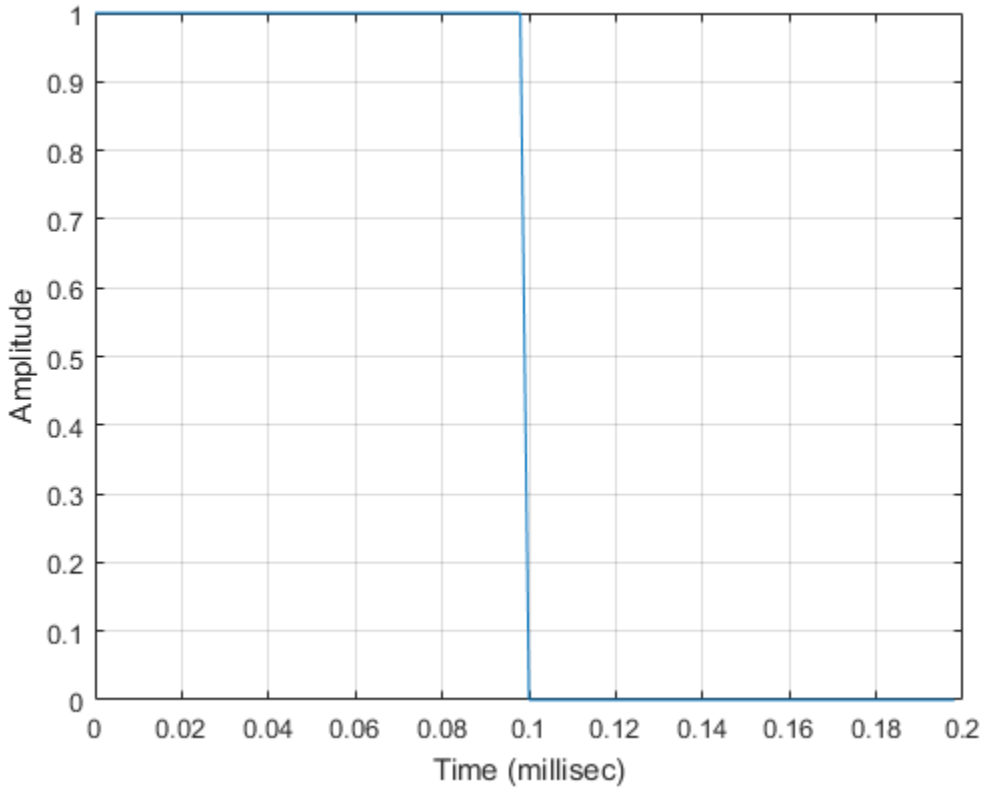
Create the rectangular waveform System object™.

```
sWF = phased.RectangularWaveform('SampleRate',fs,'PulseWidth',1e-4,'PRF',5000.0);
```

Use the step method to obtain the waveform. Then, plot the waveform.

```
rectwav = step(sWF);
```

```
nsamp = size(rectwav,1);
t = [0:(nsamp-1)]/fs;
plot(t*1000,real(rectwav))
xlabel('Time (millisec)')
ylabel('Amplitude')
grid
```

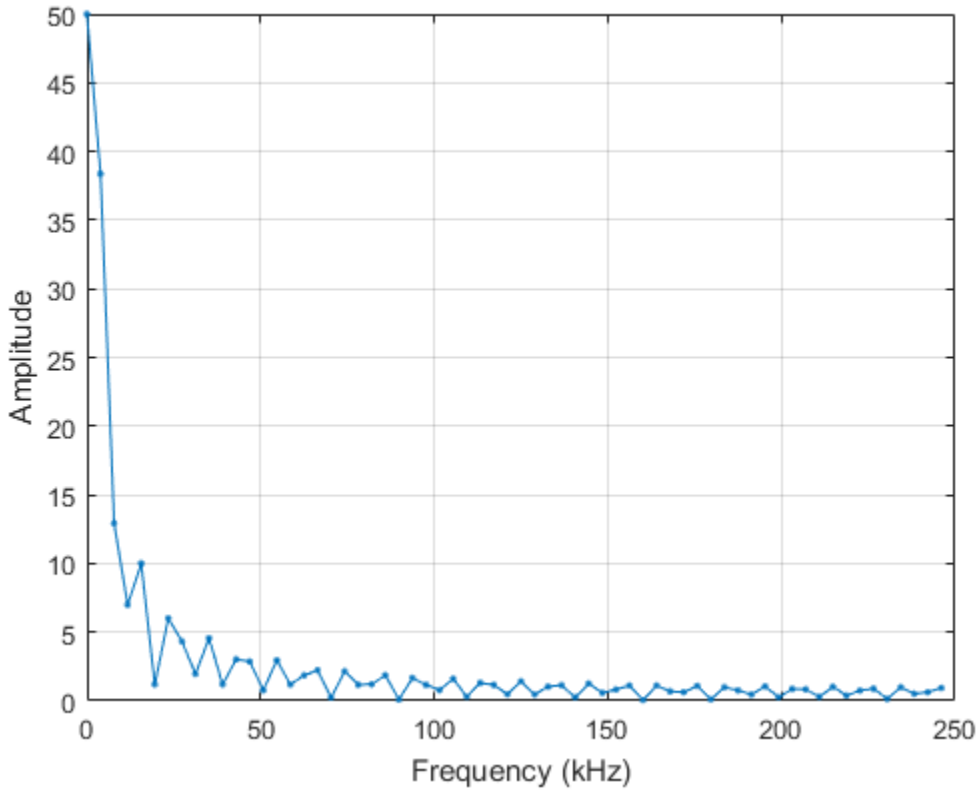


Plot the spectrum

Compute the Fourier transform of the complex signal. Then show the spectrum.

```
nfft = 2^nextpow2(nsamp);
Z = fft(real(rectwav),nfft);
```

```
fr = [0:(nfft/2-1)]/nfft*fs;
plot(fr/1000,abs(Z(1:nfft/2)),'.-')
xlabel('Frequency (kHz)')
ylabel('Amplitude')
grid
```

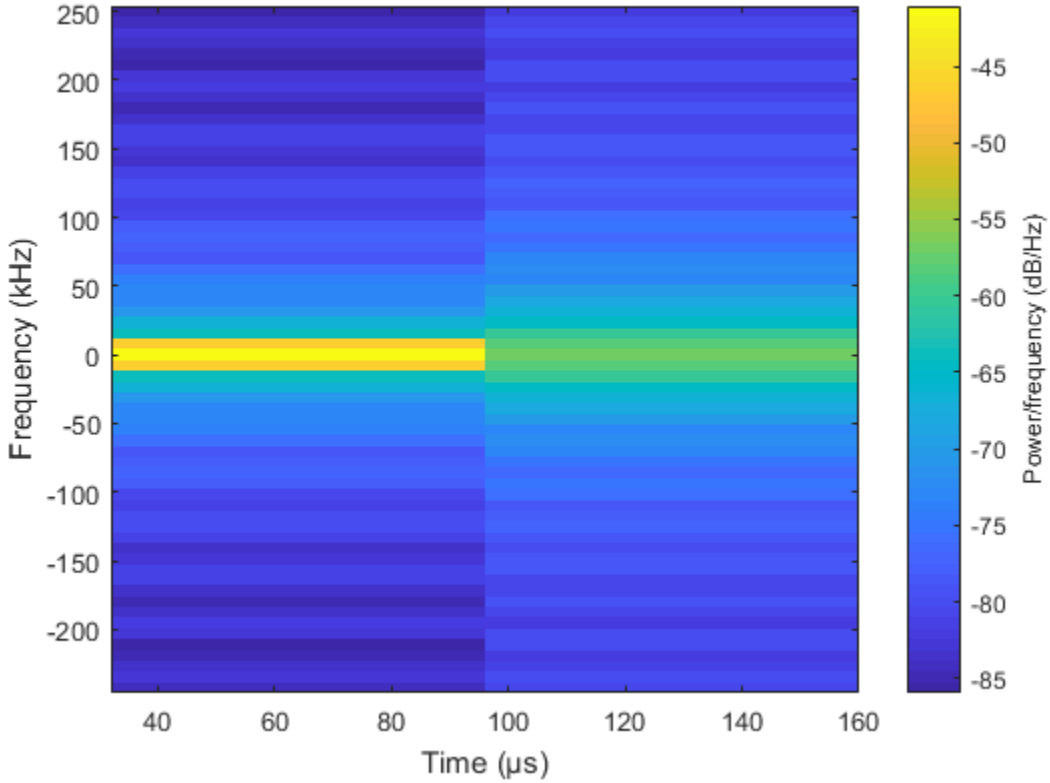


Plot the spectrogram

Plot a spectrogram of the function with a window size of 64 samples and 50% overlap. Window the signal with a Hamming function.

```
nfft1 = 64;
nov = floor(0.5*nfft1);
```

```
spectrogram(rectwav,hamming(nfft1),nov,nfft1,fs,'centered','yaxis')
```



This plot shows the constant frequency of the signal.

Waveform Analysis Using the Ambiguity Function

Introduced in R2012a

bandwidth

System object: phased.RectangularWaveform
Package: phased

Bandwidth of rectangular pulse waveform

Syntax

```
BW = bandwidth(H)
```

Description

`BW = bandwidth(H)` returns the bandwidth (in hertz) of the pulses for the rectangular pulse waveform, `H`. The bandwidth equals the reciprocal of the pulse width.

Input Arguments

`H`

Rectangular pulse waveform object.

Output Arguments

`BW`

Bandwidth of the pulses, in hertz.

Examples

Find Bandwidth of Rectangular Pulse

Determine the bandwidth of a rectangular pulse waveform.

```
waveform = phased.RectangularWaveform;
bw = bandwidth(waveform)
```

```
bw =

        20000
```

getMatchedFilter

System object: phased.RectangularWaveform
Package: phased

Matched filter coefficients for waveform

Syntax

```
Coeff = getMatchedFilter(H)
```

Description

`Coeff = getMatchedFilter(H)` returns the matched filter coefficients for the rectangular waveform object `H`. `Coeff` is a column vector.

Examples

Matched Filter Coefficients for Rectangular Pulse

Get the matched filter coefficients for a rectangular pulse waveform.

```
waveform = phased.RectangularWaveform('PulseWidth',1e-5,...
    'OutputFormat','Pulses','NumPulses',1);
coeff = getMatchedFilter(waveform)
```

```
coeff =

     1
     1
     1
     1
     1
     1
     1
     1
     1

plot

System object: phased.RectangularWaveform
Package: phased

Plot rectangular pulse waveform

Syntax

```
plot(Hwav)
plot(Hwav,Name,Value)
plot(Hwav,Name,Value,LineSpec)
h = plot( ___ )
```

Description

`plot(Hwav)` plots the real part of the waveform specified by `Hwav`.

`plot(Hwav,Name,Value)` plots the waveform with additional options specified by one or more `Name,Value` pair arguments.

`plot(Hwav,Name,Value,LineSpec)` specifies the same line color, line style, or marker options as are available in the MATLAB `plot` function.

`h = plot( ___ )` returns the line handle in the figure.

Input Arguments

`Hwav`

Waveform object. This variable must be a scalar that represents a single waveform object.

`LineSpec`

Character vector to specifies the same line color, style, or marker options as are available in the MATLAB `plot` function. If you specify a `PlotType` value of `'complex'`, then `LineSpec` applies to both the real and imaginary subplots.

Default: `'b'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'PlotType'`

Specifies whether the function plots the real part, imaginary part, or both parts of the waveform. Valid values are `'real'`, `'imag'`, and `'complex'`.

Default: `'real'`

`'PulseIdx'`

Index of the pulse to plot. This value must be a scalar.

Default: `1`

Output Arguments

`h`

Handle to the line or lines in the figure. For a `PlotType` value of `'complex'`, `h` is a column vector. The first and second elements of this vector are the handles to the lines in the real and imaginary subplots, respectively.

Examples

Plot Rectangular Waveform

Create and plot a 100 µs rectangular pulse waveform.

```
waveform = phased.RectangularWaveform('PulseWidth',100e-6);
plot(waveform);
```

reset

System object: phased.RectangularWaveform
Package: phased

Reset states of rectangular waveform object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `RectangularWaveform` object, `H`. Afterward, if the `PRF` property is a vector, the next call to `step` uses the first PRF value in the vector.

step

System object: phased.RectangularWaveform
Package: phased

Samples of rectangular pulse waveform

Syntax

```
Y = step(sRFM)
Y = step(sRFM,prfidx)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations. When the only argument to the `step` method is the System object itself, replace `y = step(obj)` by `y = obj()`.

`Y = step(sRFM)` returns samples of a rectangular pulse in the column vector `Y`.

`Y = step(sRFM,prfidx)`, uses the `prfidx` index to select the PRF from the predefined vector of values specified by in the `PRF` property. This syntax applies when you set the `PRFSelectionInputPort` property to `true`.

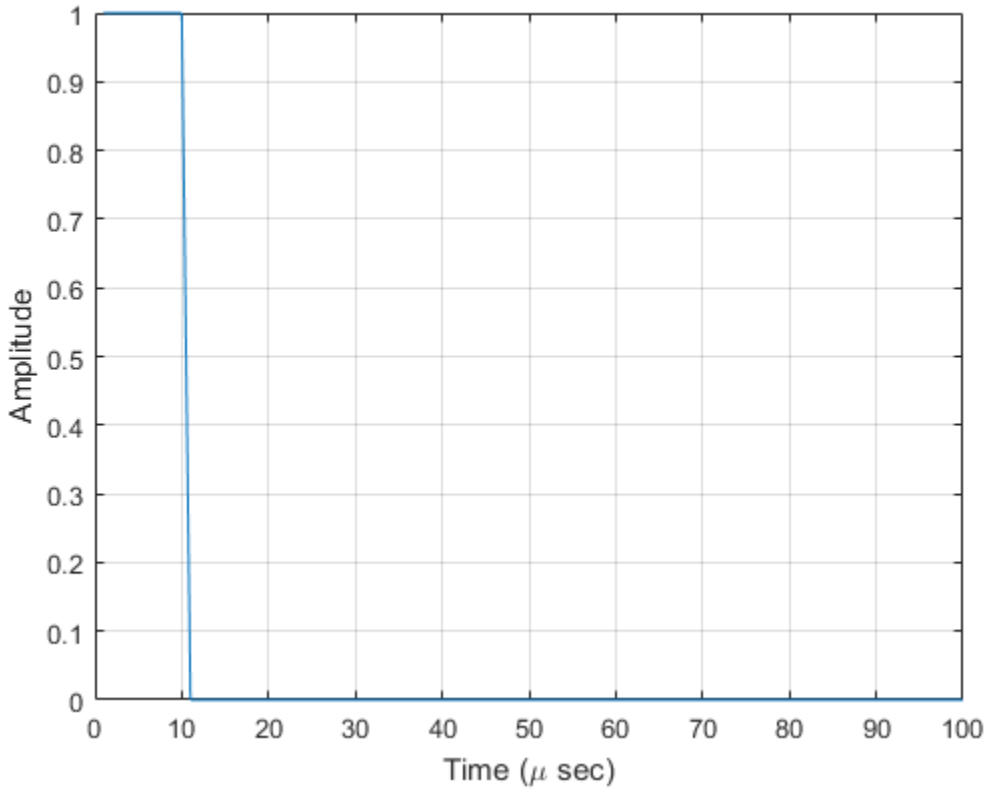
Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Examples

Create Rectangular Waveform Pulse

Construct a 10 microseconds rectangular pulse with a pulse repetition interval of 100 microseconds.

```
Pulsewidth = 10e-6;
PRI = 100e-6;
sRFM = phased.RectangularWaveform('PulseWidth',Pulsewidth,...
    'OutputFormat','Pulses','NumPulses',1,...
    'SampleRate',1e6,'PRF',1/PRI);
wav = step(sRFM);
plot(wav)
xlabel('Time (\mu sec)')
ylabel('Amplitude')
grid
```



Create Rectangular Pulses with Variable PRF

Construct rectangular waveforms with two pulses each. Set the sample rate to 1 MHz, a pulse width of 50 microseconds, and a duty cycle of 20%. Vary the pulse repetition frequency.

Set the sample rate and PRF. The ratio of sample rate to PRF must be an integer.

```
fs = 1e6;
PRF = [10000,25000];
waveform = phased.RectangularWaveform('OutputFormat','Pulses','SampleRate',fs,...
    'DurationSpecification','Duty Cycle','DutyCycle',.2,...
    'PRF',PRF,'NumPulses',2,'PRFSelectionInputPort',true);
```

Obtain and plot the rectangular waveforms. For the first call to the `step` method, set the PRF to 10kHz using the PRF index. For the next call, set the PRF to 25 kHz. For the final call, set the PRF to 10kHz.

```
wav = [];
wav1 = waveform(1);
wav = [wav; wav1];
wav1 = waveform(2);
wav = [wav; wav1];
wav1 = waveform(1);
wav = [wav; wav1];
nsamps = size(wav,1);
t = [0:(nsamps-1)]/waveform.SampleRate;
plot(t*1e6,real(wav))
xlabel('Time (\mu sec)')
ylabel('Amplitude')
grid
```

phased.ReplicatedSubarray System object

Package: phased

Phased array formed by replicated subarrays

Description

The `ReplicatedSubarray` object represents a phased array that contains copies of a subarray.

To obtain the response of the subarrays:

1. Define and set up your phased array containing replicated subarrays. See "Construction" on page 1-1621.
2. Call step to compute the response of the subarrays according to the properties of `phased.ReplicatedSubarray`. The behavior of `step` is specific to each object in the toolbox.

You can also use a `ReplicatedSubarray` object as the value of the `SensorArray` or `Sensor` property of objects that perform beamforming, steering, and other operations.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.ReplicatedSubarray` creates a replicated subarray System object, `H`. This object represents an array that contains copies of a subarray.

`H = phased.ReplicatedSubarray(Name,Value)` creates a replicated subarray object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`Subarray`

Subarray to replicate

Specify the subarray you use to form the array. The subarray must be a `phased.ULA`, `phased.URA`, or `phased.ConformalArray` object.

Default: phased.ULA with default property values

`Layout`

Layout of subarrays

Specify the layout of the replicated subarrays as `'Rectangular'` or `'Custom'`.

Default: `'Rectangular'`

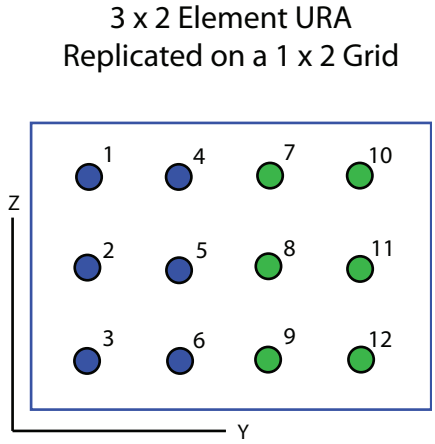
`GridSize`

Size of rectangular grid

Specify the size of the rectangular grid as a single positive integer or 1-by-2 positive integer row vector. This property applies only when you set the `Layout` property to `'Rectangular'`.

If `GridSize` is a scalar, the array has the same number of subarrays in each row and column.

If `GridSize` is a 1-by-2 vector, the vector has the form `[NumberOfRows, NumberOfColumns]`. The first entry is the number of subarrays along each column, while the second entry is the number of subarrays in each row. A row is along the local *y*-axis, and a column is along the local *z*-axis. This figure shows how a 3-by-2 URA subarray is replicated using a `GridSize` value of `[1,2]`.



Default: `[2 1]`

`GridSpacing`

Spacing of rectangular grid

Specify the rectangular grid spacing of subarrays as a positive real-valued scalar, a 1-by-2 row vector, or `'Auto'`. This property applies only when you set the `Layout` property to `'Rectangular'`. Grid spacing units are expressed in meters.

If `GridSpacing` is a scalar, the spacing along the row and the spacing along the column is the same.

If `GridSpacing` is a length-2 row vector, it has the form `[SpacingBetweenRows, SpacingBetweenColumn]`. The first entry specifies the spacing between rows along a column. The second entry specifies the spacing between columns along a row.

If `GridSpacing` is `'Auto'`, the replication preserves the element spacing in both row and column. This option is available only if you use a `phased.ULA` or `phased.URA` object as the subarray.

Default: `'Auto'`

`SubarrayPosition`

Subarray positions in custom grid

Specify the positions of the subarrays in the custom grid. This property value is a 3-by-N matrix, where N indicates the number of subarrays in the array. Each column of the matrix represents the position of a single subarray in the array's local coordinate system, in meters, using the form [x; y; z].

This property applies when you set the `Layout` property to `'Custom'`.

Default: `[0 0; -0.5 0.5; 0 0]`

`SubarrayNormal`

Subarray normal directions in custom grid

Specify the normal directions of the subarrays in the array. This property value is a 2-by-N matrix, where N is the number of subarrays in the array. Each column of the matrix specifies the normal direction of the corresponding subarray, in the form [azimuth; elevation]. Each angle is in degrees and is defined in the local coordinate system.

You can use the `SubarrayPosition` and `SubarrayNormal` properties to represent any arrangement in which pairs of subarrays differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal.

This property applies when you set the `Layout` property to `'Custom'`.

Default: `[0 0; 0 0]`

`SubarraySteering`

Subarray steering method

Specify the method of steering the subarray as one of `'None' | 'Phase' | 'Time'`.

Default: `'None'`

`PhaseShifterFrequency`

Subarray phase shifter frequency

Specify the operating frequency of phase shifters that perform subarray steering. The property value is a positive scalar in hertz. This property applies when you set the `SubarraySteering` property to `'Phase'`.

Default: `3e8`

`NumPhaseShifterBits`

Number of phase shifter quantization bits

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

Default: `0`

Methods

directivity	Directivity of replicated subarray
collectPlaneWave	Simulate received plane waves
getElementPosition	Positions of array elements
getNumElements	Number of elements in array
getNumSubarrays	Number of subarrays in array
getSubarrayPosition	Positions of subarrays in array
isPolarizationCapable	Polarization capability
pattern	Plot replicated subarray directivity and patterns
patternAzimuth	Plot replicated subarray directivity or pattern versus azimuth
patternElevation	Plot replicated subarray directivity or pattern versus elevation
plotResponse	Plot response pattern of array
step	Output responses of subarrays
viewArray	View array geometry

Common to All System Objects	
`clone`	Create System object with same property values

Common to All System Objects	
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

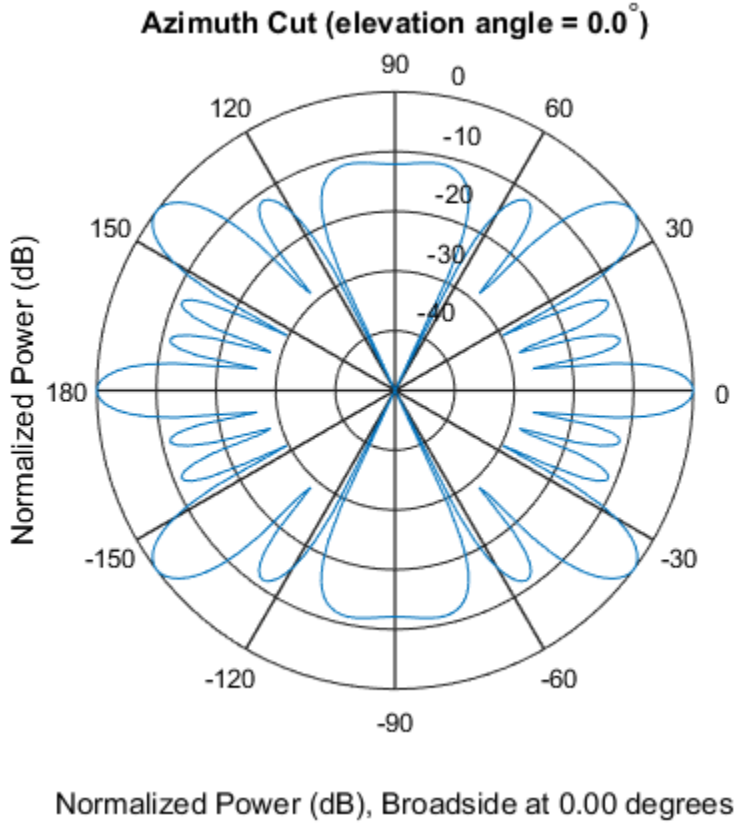
Azimuth Response of Array with Subarrays

Plot the azimuth response of a 4-element ULA composed of two 2-element ULAs. By default, the antenna elements are isotropic.

```
sArray = phased.ULA('NumElements',2,'ElementSpacing',0.5);
sRSA = phased.ReplicatedSubarray('Subarray',sArray,...
   'Layout','Rectangular','GridSize',[1 2],...
   'GridSpacing','Auto');
```

Plot the azimuth response of the array. Assume the operating frequency is 1 GHz and the wave propagation speed is the speed of light.

```
fc = 1.0e9;
pattern(sRSA,fc,[-180:180],0,...
    'PropagationSpeed',physconst('LightSpeed'),...
    'Type','powerdb',...
    'Normalize',true,...
    'CoordinateSystem','polar')
```



Response of Subarrays with Polarized Antenna Elements

Create a 4-element ULA from two 2-element ULA subarrays consisting of short-dipole antenna elements. Then, calculate the response at boresight. Because the array elements support polarization, the response consists of horizontal and vertical components.

Create the arrays from subarrays.

```
sSD = phased.ShortDipoleAntennaElement;
sULA = phased.ULA('Element',sSD,...
    'NumElements',2,...
    'ElementSpacing',0.5);
sRSA = phased.ReplicatedSubarray('Subarray',sULA,...

directivity

System object: phased.ReplicatedSubarray
Package: phased

Directivity of replicated subarray

Syntax

```
D = directivity(H,FREQ,ANGLE)
D = directivity(H,FREQ,ANGLE,Name,Value)
```

Description

`D = directivity(H,FREQ,ANGLE)` returns the "Directivity (dBi)" on page 1-1634 of a replicated array of antenna or microphone element, `H`, at frequencies specified by `FREQ` and in angles of direction specified by `ANGLE`.

`D = directivity(H,FREQ,ANGLE,Name,Value)` returns the directivity with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`H` — Replicated subarray

System object

Replicated subarray, specified as a phased.ReplicatedSubarray System object.

Example: `H = phased.ReplicatedSubarray;`

`FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector`

property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.

- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

`ANGLE` — Angles for computing directivity

1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Angles for computing directivity, specified as a 1-by-*M* real-valued row vector or a 2-by-*M* real-valued matrix, where *M* is the number of angular directions. Angle units are in degrees. If `ANGLE` is a 2-by-*M* matrix, then each column specifies a direction in azimuth and elevation, `[az;el]`. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°.

If `ANGLE` is a 1-by-*M* vector, then each entry represents an azimuth angle, with the elevation angle assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis.

Example: `[45 60; 0 10]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'PropagationSpeed'` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

`'Weights'` — Subarray weights

1 (default) | *N*-by-1 complex-valued column vector | *N*-by-*L* complex-valued matrix

Subarray weights, specified as the comma-separated pair consisting of `'Weights'` and an *N*-by-1 complex-valued column vector or *N*-by-*M* complex-valued matrix. The dimension *N* is the number of subarrays in the array. The dimension *L* is the number of frequencies specified by the `FREQ` argument.

`Weights` dimension	`FREQ` dimension	Purpose
N-by-1 complex-valued column vector	Scalar or 1-by-*L* row vector	Applies a set of weights for the single frequency or for all *L* frequencies.
N-by-*L* complex-valued matrix	1-by-*L* row vector	Applies each of the *L* columns of `'Weights'` for the corresponding frequency in the `FREQ` argument.

Example: `'Weights',ones(N,M)`

Data Types: `double`

`'SteerAngle'` — Subarray steering angle

`[0;0]` (default) | scalar | 2-element column vector

Subarray steering angle, specified as the comma-separated pair consisting of `'SteerAngle'` and a scalar or a 2-by-1 column vector.

If `'SteerAngle'` is a 2-by-1 column vector, it has the form `[azimuth; elevation]`. The azimuth angle must be between –180° and 180°, inclusive. The elevation angle must be between –90° and 90°, inclusive.

If `'SteerAngle'` is a scalar, it specifies the azimuth angle only. In this case, the elevation angle is assumed to be 0.

This option applies only when the `'SubarraySteering'` property of the System object is set to `'Phase'` or `'Time'`.

Example: `'SteerAngle',[20;30]`

Data Types: `double`

Output Arguments

`D` — Directivity

M-by-*L* matrix

Directivity, returned as an *M*-by-*L* matrix whose columns contain the directivities at the *M* angles specified by `ANGLE`. Each column corresponds to one of the *L* frequency values specified in `FREQ`. Directivity units are in dBi.

Examples

Directivity of Replicated Subarray

Compute the directivity of an array built up from ULA subarrays. Determine the directivity of the replicated subarray when the array is steered to towards 30 degrees azimuth.

Set the signal propagation speed to the speed of light. Set the signal frequency to 300 MHz.

```
c = physconst('LightSpeed');
fc = 3e8;
lambda = c/fc;
```

Create a 4-element ULA of isotropic antenna elements spaced 0.4-wavelength apart.

```
myArray = phased.ULA;
myArray.NumElements = 4;
myArray.ElementSpacing = 0.4*lambda;
```

Construct a 2-by-1 replicated subarray.

```
myRepArray = phased.ReplicatedSubarray;
myRepArray.Subarray = myArray;
myRepArray.Layout = 'Rectangular';
myRepArray.GridSize = [2 1];
myRepArray.GridSpacing = 'Auto';
```

```
myRepArray.SubarraySteering = 'Time';
```

Steer the array to 30 degrees azimuth and zero degrees elevation.

```
ang = [30;0];
mySV = phased.SteeringVector;
mySV.SensorArray = myRepArray;
mySV.PropagationSpeed = c;
```

Find the directivity at 30 degrees azimuth.

```
d = directivity(myRepArray,fc,ang,...
    'PropagationSpeed',c,...
    'Weights',step(mySV,fc,ang),...
    'SteerAngle',ang)
```

```
d =

    7.4776
```

Definitions

Directivity (dBi)

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission.

When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element directivity” and “Array directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

phased.ReplicatedSubarray.plotResponse

collectPlaneWave

System object: phased.ReplicatedSubarray
Package: phased

Simulate received plane waves

Syntax

```
Y = collectPlaneWave(H,X,ANG)
Y = collectPlaneWave(H,X,ANG,FREQ)
Y = collectPlaneWave(H,X,ANG,FREQ,C)
```

Description

`Y = collectPlaneWave(H,X,ANG)` returns the received signals at the sensor array, `H`, when the input signals indicated by `X` arrive at the array from the directions specified in `ANG`.

`Y = collectPlaneWave(H,X,ANG,FREQ)`, in addition, specifies the incoming signal carrier frequency in `FREQ`.

`Y = collectPlaneWave(H,X,ANG,FREQ,C)`, in addition, specifies the signal propagation speed in `C`.

Input Arguments

`H`

Array object.

`X`

Incoming signals, specified as an M-column matrix. Each column of `X` represents an individual incoming signal.

ANG

Directions from which incoming signals arrive, in degrees. ANG can be either a 2-by-M matrix or a row vector of length M.

If ANG is a 2-by-M matrix, each column specifies the direction of arrival of the corresponding signal in X. Each column of ANG is in the form `[azimuth; elevation]`. The azimuth angle must be between –180° and 180°, inclusive. The elevation angle must be between –90° and 90°, inclusive.

If ANG is a row vector of length M, each entry in ANG specifies the azimuth angle. In this case, the corresponding elevation angle is assumed to be 0°.

FREQ

Carrier frequency of signal in hertz. FREQ must be a scalar.

Default: `3e8`

C

Propagation speed of signal in meters per second.

Default: Speed of light

Output Arguments

Y

Received signals. Y is an N-column matrix, where N is the number of subarrays in the array H. Each column of Y is the received signal at the corresponding subarray, with all incoming signals combined.

Examples

Plane Waves Received at Array of Subarrays

Simulate the received signal at a 16-element ULA composed of four 4-element ULAs.

```
array = phased.ULA('NumElements',4);
```

```
subarrays = phased.ReplicatedSubarray('Subarray',array,'GridSize',[4 1]);
```

Simulate two signals received from 10° azimuth and 30° azimuth. Both signals have an elevation angle of 0°. Assume the propagation speed is the speed of light and the carrier frequency of the signal is 100 MHz.

```
y = collectPlaneWave(subarrays,randn(4,2),[10 30],100.0e6,...
    physconst('LightSpeed'));
```

Algorithms

`collectPlaneWave` modulates the input signal with a phase corresponding to the delay caused by the direction of arrival. This method does not account for the response of individual elements in the array and only models the array factor among subarrays. Therefore, the result does not depend on whether the subarray is steered.

getElementPosition

System object: phased.ReplicatedSubarray
Package: phased

Positions of array elements

Syntax

```
POS = getElementPosition(H)
```

Description

`POS = getElementPosition(H)` returns the element positions in the array `H`.

Input Arguments

`H`

Array object consisting of replicated subarrays.

Output Arguments

`POS`

Element positions in array. `POS` is a 3-by-N matrix, where N is the number of elements in `H`. Each column of `POS` defines the position of an element in the local coordinate system, in meters, using the form [x; y; z].

Examples

Positions of Elements in Array with Replicated Subarrays

Create an array with two copies of a 3-element ULA, and obtain the positions of the elements.

```
subarrays = phased.ReplicatedSubarray('Subarray',...
    phased.ULA('NumElements',3),'GridSize',[1 2]);
pos = getElementPosition(subarrays)
```

```
pos =

         0         0         0         0         0         0
   -1.2500   -0.7500   -0.2500    0.2500    0.7500    1.2500
         0         0         0         0         0         0
```

getSubarrayPosition

getNumElements

System object: phased.ReplicatedSubarray
Package: phased

Number of elements in array

Syntax

```
N = getNumElements(H)
```

Description

`N = getNumElements(H)` returns the number of elements in the array object `H`. This number includes the elements in all subarrays of the array.

Input Arguments

`H`

Array object consisting of replicated subarrays.

Examples

Number of Elements in Array with Replicated Subarrays

Create an array with two copies of a 3-element ULA, and obtain the total number of elements.

```
subarray = phased.ReplicatedSubarray('Subarray',...
    phased.ULA('NumElements',3),'GridSize',[1 2]);
N = getNumElements(subarray)
```

```
N =
```

getNumSubarrays

getNumSubarrays

System object: phased.ReplicatedSubarray
Package: phased

Number of subarrays in array

Syntax

```
N = getNumSubarrays(H)
```

Description

`N = getNumSubarrays(H)` returns the number of subarrays in the array object `H`.

Input Arguments

`H`

Array object consisting of replicated subarrays.

Examples

Number of Subarrays in Array

Create an array by tiling copies of a ULA in a 2-by-5 grid. Then, obtain the number of subarrays.

```
subarrays = phased.ReplicatedSubarray('Subarray',...
    phased.ULA('NumElements',3),'GridSize',[2 5]);
N = getNumSubarrays(subarrays)
```

```
N =

    10

getNumElements

getSubarrayPosition

System object: phased.ReplicatedSubarray
Package: phased

Positions of subarrays in array

Syntax

```
POS = getSubarrayPosition(H)
```

Description

`POS = getSubarrayPosition(H)` returns the subarray positions in the array `H`.

Input Arguments

H

Partitioned array object.

Output Arguments

POS

Subarrays positions in array. `POS` is a 3-by-N matrix, where N is the number of subarrays in `H`. Each column of `POS` defines the position of a subarray in the local coordinate system, in meters, using the form [x; y; z].

Examples

Replicated Subarray Positions

Create an array with two copies of a 3-element ULA, and obtain the positions of the subarrays.

```
subarray = phased.ReplicatedSubarray('Subarray',...
    phased.ULA('NumElements',3),'GridSize',[1 2]);
pos = getSubarrayPosition(subarray)
```

```
pos =

         0         0
   -0.7500    0.7500
         0         0
```

getElementPosition

isPolarizationCapable

System object: phased.ReplicatedSubarray
Package: phased

Polarization capability

Syntax

```
flag = isPolarizationCapable(h)
```

Description

`flag = isPolarizationCapable(h)` returns a Boolean value, `flag`, indicating whether the array supports polarization. An array supports polarization if all of its constituent sensor elements support polarization.

Input Arguments

`h` — Replicated subarray

Replicated subarray specified as a phased.ReplicatedSubarray System object.

Output Arguments

`flag` — Polarization-capability flag

Polarization-capability flag returned as a Boolean value `true` if the array supports polarization or `false` if it does not.

Examples

Replicated Array of Short Dipoles Supports Polarization

Verify that a replicated subarray of short-dipole antenna elements supports polarization.

```
antenna = phased.ShortDipoleAntennaElement('FrequencyRange',[1e9 10e9]);
array = phased.URA([3,2],'Element',antenna);
reparray = phased.ReplicatedSubarray('Subarray',array, ...
    'Layout','Rectangular','GridSize',[1,2],'GridSpacing','Auto');
isPolarizationCapable(reparray)

ans =

  logical

   1
```

pattern

System object: phased.ReplicatedSubarray
Package: phased

Plot replicated subarray directivity and patterns

Syntax

```
pattern(sArray,FREQ)
pattern(sArray,FREQ,AZ)
pattern(sArray,FREQ,AZ,EL)
pattern( ___ ,Name,Value)
[PAT,AZ_ANG,EL_ANG] = pattern( ___ )
```

Description

`pattern(sArray,FREQ)` plots the 3-D array directivity pattern (in dBi) for the array specified in `sArray`. The operating frequency is specified in `FREQ`.

`pattern(sArray,FREQ,AZ)` plots the array directivity pattern at the specified azimuth angle.

`pattern(sArray,FREQ,AZ,EL)` plots the array directivity pattern at specified azimuth and elevation angles.

`pattern( ___ ,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`[PAT,AZ_ANG,EL_ANG] = pattern( ___ )` returns the array pattern in `PAT`. The `AZ_ANG` output contains the coordinate values corresponding to the rows of `PAT`. The `EL_ANG` output contains the coordinate values corresponding to the columns of `PAT`. If the `'CoordinateSystem'` parameter is set to `'uv'`, then `AZ_ANG` contains the *U* coordinates of the pattern and `EL_ANG` contains the *V* coordinates of the pattern. Otherwise, they are in angular units in degrees. *UV* units are dimensionless.

Note: This method replaces the `plotResponse` method. See "Convert plotResponse to pattern" on page 1-1659 for guidelines on how to use `pattern` in place of `plotResponse`.

Input Arguments

`sArray` — Replicated subarray

System object

Replicated subarray, specified as a phased.ReplicatedSubarray System object.

Example: `sArray= phased.ReplicatedSubarray;`

`FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `-Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `-Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

`AZ` — Azimuth angles

`[-180:180]` (default) | 1-by-*M* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a 1-by-*M* real-valued row vector where *M* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, this angle is positive.

Example: `[-45:2:45]`

Data Types: `double`

`EL` — Elevation angles

`[-90:90]` (default) | 1-by-*N* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a 1-by-*N* real-valued row vector where *N* is the number of desired elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and *xy*-plane. When measured towards the *z*-axis, this angle is positive.

Example: `[-75:1:70]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'CoordinateSystem'` — Plotting coordinate system

`'polar'` (default) | `'rectangular'` | `'uv'`

Plotting coordinate system of the pattern, specified as the comma-separated pair consisting of `'CoordinateSystem'` and one of `'polar'`, `'rectangular'`, or `'uv'`. When `'CoordinateSystem'` is set to `'polar'` or `'rectangular'`, the `AZ` and `EL` arguments specify the pattern azimuth and elevation, respectively. `AZ` values must lie between –180° and 180°. `EL` values must lie between –90° and 90°. If `'CoordinateSystem'` is set to `'uv'`, `AZ` and `EL` then specify *U* and *V* coordinates, respectively. `AZ` and `EL` must lie between -1 and 1.

Example: `'uv'`

Data Types: `char`

'Type' — Displayed pattern type

'directivity' (default) | 'efield' | 'power' | 'powerdb'

Displayed pattern type, specified as the comma-separated pair consisting of 'Type' and one of

- 'directivity' — directivity pattern measured in dBi.
- 'efield' — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- 'power' — power pattern of the sensor or array defined as the square of the field pattern.
- 'powerdb' — power pattern converted to dB.

Example: 'powerdb'

Data Types: char

'Normalize' — Display normalize pattern

true (default) | false

Display normalized pattern, specified as the comma-separated pair consisting of 'Normalize' and a Boolean. Set this parameter to true to display a normalized pattern. When you set 'Type' to 'directivity', this parameter does not apply. Directivity patterns are already normalized.

Example:

Data Types: logical

'PlotStyle' — Plotting style

'overlay' (default) | 'waterfall'

Plotting style, specified as the comma-separated pair consisting of 'Plotstyle' and either 'overlay' or 'waterfall'. This parameter applies when you specify multiple frequencies in FREQ in 2-D plots. You can draw 2-D plots by setting one of the arguments AZ or EL to a scalar.

Example:

Data Types: char

'Polarization' — Polarized field component

'combined' (default) | 'H' | 'V'

Polarized field component to display, specified as the comma-separated pair consisting of 'Polarization' and `'combined'`, `'H'`, or `'V'`. This parameter applies only when the sensors are polarization-capable and when the `'Type'` parameter is not set to `'directivity'`. This table shows the meaning of the display options

`'Polarization'`	Display
`'combined'`	Combined *H* and *V* polarization components
`'H'`	*H* polarization component
`'V'`	*V* polarization component

Example: `'V'`

Data Types: `char`

`'PropagationSpeed'` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

`'Weights'` — Subarray weights

1 (default) | *N*-by-1 complex-valued column vector | *N*-by-*L* complex-valued matrix

Subarray weights, specified as the comma-separated pair consisting of `'Weights'` and an *N*-by-1 complex-valued column vector or *N*-by-*M* complex-valued matrix. The dimension *N* is the number of subarrays in the array. The dimension *L* is the number of frequencies specified by the `FREQ` argument.

`Weights` dimension	`FREQ` dimension	Purpose
N-by-1 complex-valued column vector	Scalar or 1-by-*L* row vector	Applies a set of weights for the single frequency or for all *L* frequencies.
N-by-*L* complex-valued matrix	1-by-*L* row vector	Applies each of the *L* columns of `'Weights'` for the corresponding frequency in the `FREQ` argument.

Example: `'Weights',ones(N,M)`

Data Types: `double`

`'SteerAngle'` — Subarray steering angle

`[0;0]` (default) | scalar | 2-element column vector

Subarray steering angle, specified as the comma-separated pair consisting of `'SteerAngle'` and a scalar or a 2-by-1 column vector.

If `'SteerAngle'` is a 2-by-1 column vector, it has the form `[azimuth; elevation]`. The azimuth angle must be between –180° and 180°, inclusive. The elevation angle must be between –90° and 90°, inclusive.

If `'SteerAngle'` is a scalar, it specifies the azimuth angle only. In this case, the elevation angle is assumed to be 0.

This option applies only when the `'SubarraySteering'` property of the System object is set to `'Phase'` or `'Time'`.

Example: `'SteerAngle',[20;30]`

Data Types: `double`

Output Arguments

`PAT` — Array pattern

M-by-*N* real-valued matrix

Array pattern, returned as an *M*-by-*N* real-valued matrix. The dimensions of `PAT` correspond to the dimensions of the output arguments `AZ_ANG` and `EL_ANG`.

`AZ_ANG` — Azimuth angles

scalar | 1-by-*M* real-valued row vector

Azimuth angles for displaying directivity or response pattern, returned as a scalar or 1-by-*M* real-valued row vector corresponding to the dimension set in `AZ`. The rows of `PAT` correspond to the values in `AZ_ANG`.

`EL_ANG` — Elevation angles

scalar | 1-by-*N* real-valued row vector

Elevation angles for displaying directivity or response, returned as a scalar or 1-by-*N* real-valued row vector corresponding to the dimension set in EL. The columns of PAT correspond to the values in EL_ANG.

Examples

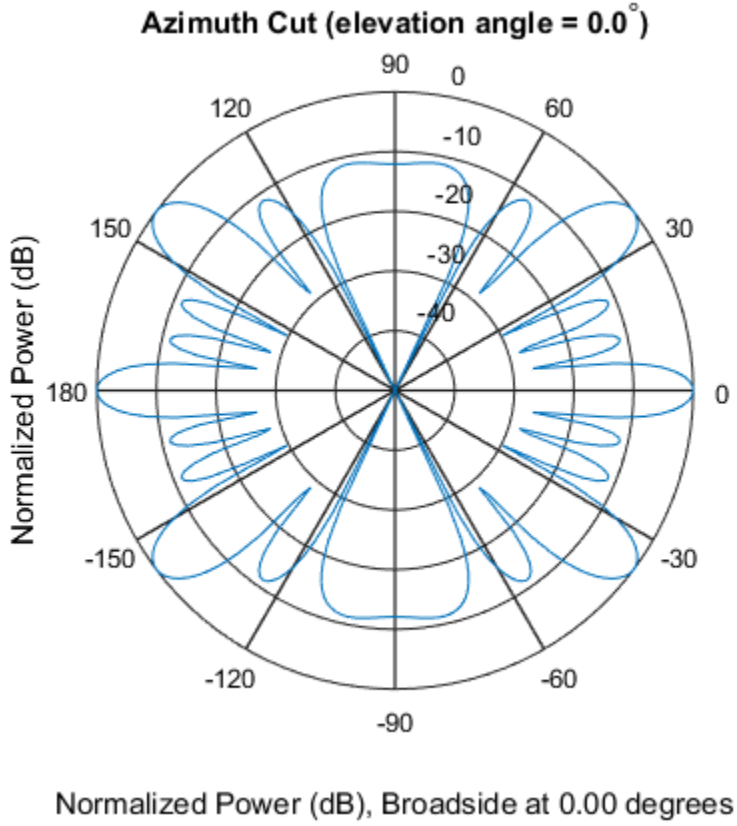
Azimuth Response of Array with Subarrays

Plot the azimuth response of a 4-element ULA composed of two 2-element ULAs. By default, the antenna elements are isotropic.

```
sArray = phased.ULA('NumElements',2,'ElementSpacing',0.5);
sRSA = phased.ReplicatedSubarray('Subarray',sArray,...
   'Layout','Rectangular','GridSize',[1 2],...
   'GridSpacing','Auto');
```

Plot the azimuth response of the array. Assume the operating frequency is 1 GHz and the wave propagation speed is the speed of light.

```
fc = 1.0e9;
pattern(sRSA,fc,[-180:180],0,...
    'PropagationSpeed',physconst('LightSpeed'),...
    'Type','powerdb',...
    'Normalize',true,...
    'CoordinateSystem','polar')
```



Directivity of Array with Subarrays

Create a 2-by-2-element URA of isotropic antenna elements, and arrange four copies to form a 16-element URA. Plot the 3-D directivity pattern.

Create the array

```
fmin = 1e9;
fmax = 6e9;
c = physconst('LightSpeed');
lam = c/fmax;
sIso = phased.IsotropicAntennaElement(...
    'FrequencyRange',[fmin,fmax],...
    'BackBaffled',false);
```

```
sURA = phased.URA('Element',sIso,...
    'Size',[2 2],...
    'ElementSpacing',lam/2);
sRS = phased.ReplicatedSubarray('Subarray',sURA,...
    'Layout','Rectangular','GridSize',[2 2],...
    'GridSpacing','Auto');
```

Plot 3-D directivity pattern

```
fc = 1e9;
wts = [0.862,1.23,1.23,0.862]';
pattern(sRS,fc,[-180:180],[-90:90],...
    'PropagationSpeed',physconst('LightSpeed'),....
    'Type','directivity',...

More About

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on "Element directivity" and "Array directivity".

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

Convert plotResponse to pattern

For antenna, microphone, and array System objects, the `pattern` method replaces the `plotResponse` method. In addition, two new simplified methods exist just to draw 2-D azimuth and elevation pattern plots. These methods are `azimuthPattern` and `elevationPattern`.

The following table is a guide for converting your code from using `plotResponse` to `pattern`. Notice that some of the inputs have changed from *input arguments* to *Name-Value* pairs and conversely. The general `pattern` method syntax is

```
pattern(H,FREQ,AZ,EL,'Name1','Value1',...,'NameN','ValueN')
```

plotResponse Inputs	plotResponse Description	pattern Inputs
`H` argument	Antenna, microphone, or array System object.	`H` argument (no change)
`FREQ` argument	Operating frequency.	`FREQ` argument (no change)

plotResponse Inputs	plotResponse Description	pattern Inputs
`V` argument	Propagation speed. This argument is used only for arrays.	`'PropagationSpeed'` name-value pair. This parameter is only used for arrays.

<table>
<tr><th>plotResponse Inputs</th><th>plotResponse Description</th><th>pattern Inputs</th></tr>
<tr>
<td>'Format' and 'RespCut' name-value pairs</td>
<td>These options work together to let you create a plot in angle space (line or polar style) or UV space. They also determine whether the plot is 2-D or 3-D. This table shows you how to create different types of plots using plotResponse.
<table>
<tr><th>Display space</th><th></th></tr>
<tr><td>Angle space (2D)</td><td>Set 'RespCut' to 'Az' or 'El'. Set 'Format' to 'line' or 'polar'.

Set the display axis using either the the 'AzimuthAngl or 'ElevationAn name-value pairs.</td></tr>

If you set CoordinateSystem to 'uv', enter the UV grid values using AZ and EL.</td></tr>
<tr><td>'CutAngle' name-value pair</td><td>Constant angle at to take an azimuth or elevation cut. When producing a 2-D plot and when 'RespCut' is set to 'Az' or 'El', use 'CutAngle' to set the slice across which to view the plot.</td><td>No equivalent name-value pair. To create a cut, specify either AZ or EL as a scalar, not a vector.</td></tr>
</table>

plotResponse Inputs	plotResponse Description	pattern Inputs
`'NormalizeResponse'` name-value pair	Normalizes the plot. When `'Unit'` is set to `'dbi'`, you cannot specify `'NormalizeResponse'`.	`'Normalize'` name-value pair. When `'Type'` is set to `'directivity'`, you cannot specify `'Normalize'`. .
`'OverlayFreq'` name-value pair	Plot multiple frequencies on the same 2-D plot. Available only when `'Format'` is set to `'line'` or `'uv'` and `'RespCut'` is not set to `'3D'`. The value `true` produces an overlay plot and the value `false` produces a waterfall plot.	`'PlotStyle'` name-value pair plots multiple frequencies on the same 2-D plot. The values `'overlay'` and `'waterfall'` correspond to `'OverlayFreq'` values of `true` and `false`. The option `'waterfall'` is allowed only when `'CoordinateSystem'` is set to `'rectangular'` or `'uv'`.
`'Polarization'` name-value pair	Determines how to plot polarized fields. Options are `'None'`, `'Combined'`, `'H'`, or `'V'`.	`'Polarization'` name-value pair determines how to plot polarized fields. The `'None'` option is removed. The options `'Combined'`, `'H'`, or `'V'` are unchanged.

`'Unit'` name-value pair	Determines the plot units. Choose `'db'`, `'mag'`, `'pow'`, or `'dbi'`, where the default is `'db'`.	`'Type'` name-value pair, uses equivalent options with different names
		
		plotResponse pattern
		`'db'` `'powerdb'`
		`'mag'` `'efield'`
		`'pow'` `'power'`
		`'dbi'` `'directivity'`

`'Weights'` name-value pair	Array element tapers (or weights).	`'Weights'` name-value pair (no change).

plotResponse Inputs	plotResponse Description	pattern Inputs
`'AzimuthAngles'` name-value pair	Azimuth angles used to display the antenna or array response.	`AZ` argument
`'ElevationAngles'` name-value pair	Elevation angles used to display the antenna or array response.	`EL` argument
`'UGrid'` name-value pair	Contains *U* coordinates in *UV*-space.	`AZ` argument when `'CoordinateSystem'` name-value pair is set to `'uv'`
`'VGrid'` name-value pair	Contains *V*-coordinates in *UV*-space.	`EL` argument when `'CoordinateSystem'` name-value pair is set to `'uv'`

phased.ReplicatedSubarray.patternAzimuth | phased.ReplicatedSubarray.patternElevation

Introduced in R2015a

patternAzimuth

System object: phased.ReplicatedSubarray
Package: phased

Plot replicated subarray directivity or pattern versus azimuth

Syntax

```
patternAzimuth(sArray,FREQ)
patternAzimuth(sArray,FREQ,EL)
patternAzimuth(sArray,FREQ,EL,Name,Value)
PAT = patternAzimuth( ___ )
```

Description

`patternAzimuth(sArray,FREQ)` plots the 2-D array directivity pattern versus azimuth (in dBi) for the array `sArray` at zero degrees elevation angle. The argument `FREQ` specifies the operating frequency.

`patternAzimuth(sArray,FREQ,EL)`, in addtion, plots the 2-D array directivity pattern versus azimuth (in dBi) for the array `sArray` at the elevation angle specified by `EL`. When `EL` is a vector, multiple overlaid plots are created.

`patternAzimuth(sArray,FREQ,EL,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternAzimuth( ___ )` returns the array pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Azimuth'` parameter and the `EL` input argument.

Input Arguments

`sArray` — Replicated subarray

System object

Replicated subarray, specified as a phased.ReplicatedSubarray System object.

Example: `sArray= phased.ReplicatedSubarray;`

`FREQ` — Frequency for computing directivity and pattern
positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

`EL` — Elevation angles
1-by-*N* real-valued row vector

Elevation angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector. The quantity *N* is the number of requested elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and the *xy* plane. When measured toward the *z*-axis, this angle is positive.

Example: `[0,10,20]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'Type' — Displayed pattern type

'directivity' (default) | 'efield' | 'power' | 'powerdb'

Displayed pattern type, specified as the comma-separated pair consisting of 'Type' and one of

- 'directivity' — directivity pattern measured in dBi.
- 'efield' — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- 'power' — power pattern of the sensor or array defined as the square of the field pattern.
- 'powerdb' — power pattern converted to dB.

Example: 'powerdb'

Data Types: char

'PropagationSpeed' — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of 'PropagationSpeed' and a positive scalar in meters per second.

Example: 'PropagationSpeed',physconst('LightSpeed')

Data Types: double

'Weights' — Subarray weights

M-by-1 complex-valued column vector

Subarray weights, specified as the comma-separated pair consisting of 'Weights' and an *M*-by-1 complex-valued column vector. Subarray weights are applied to the subarrays of the array to produce array steering, tapering, or both. The dimension *M* is the number of subarrays in the array.

Example: 'Weights',ones(10,1)

Data Types: double
Complex Number Support: Yes

'SteerAngle' — Subarray steering angle

[0;0] (default) | scalar | 2-element column vector

Subarray steering angle, specified as the comma-separated pair consisting of `'SteerAngle'` and a scalar or a 2-by-1 column vector.

If `'SteerAngle'` is a 2-by-1 column vector, it has the form `[azimuth; elevation]`. The azimuth angle must be between –180° and 180°, inclusive. The elevation angle must be between –90° and 90°, inclusive.

If `'SteerAngle'` is a scalar, it specifies the azimuth angle only. In this case, the elevation angle is assumed to be 0.

This option applies only when the `'SubarraySteering'` property of the System object is set to `'Phase'` or `'Time'`.

Example: `'SteerAngle',[20;30]`

Data Types: `double`

`'Azimuth'` — Azimuth angles

`[-180:180]` (default) | 1-by-*P* real-valued row vector

Azimuth angles, specified as the comma-separated pair consisting of `'Azimuth'` and a 1-by-*P* real-valued row vector. Azimuth angles define where the array pattern is calculated.

Example: `'Azimuth',[-90:2:90]`

Data Types: `double`

Output Arguments

`PAT` — Array directivity or pattern

L-by-*N* real-valued matrix

Array directivity or pattern, returned as an *L*-by-*N* rea-valued matrix. The dimension *L* is the number of azimuth values determined by the `'Azimuth'` name-value pair argument. The dimension *N* is the number of elevation angles, as determined by the `EL` input argument.

Examples

Azimuth Pattern of Array with Subarrays

Create a 2-element ULA of isotropic antenna elements, and arrange three copies to form a 6-element ULA. Plot the directivity azimuth pattern within a restricted range of azimuth angles from -30 to 30 degrees in 0.1 degree increments. Plot directivity for 0 degrees and 45 degrees elevation.

Create the array

```
fmin = 1e9;
fmax = 6e9;
c = physconst('LightSpeed');
lam = c/fmax;
sIso = phased.IsotropicAntennaElement(...
    'FrequencyRange',[fmin,fmax],...
    'BackBaffled',false);
sULA = phased.ULA('Element',sIso,...
    'NumElements',2,'ElementSpacing',0.5);
sRS = phased.ReplicatedSubarray('Subarray',sULA,...
    'Layout','Rectangular','GridSize',[1 3],...
    'GridSpacing','Auto');
```

Plot azimuth directivity pattern

```
fc = 1e9;
wts = [0.862,1.23,0.862]';
patternAzimuth(sRS,fc,[0,45],'PropagationSpeed',physconst('LightSpeed'),...
    'Azimuth',[-30:0.1:30],...
    'Type','directivity',...
    'Weights',wts);
```

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on "Element directivity" and "Array directivity".

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

phased.ReplicatedSubarray.pattern | phased.ReplicatedSubarray.patternElevation

Introduced in R2015a

patternElevation

System object: phased.ReplicatedSubarray
Package: phased

Plot replicated subarray directivity or pattern versus elevation

Syntax

```
patternElevation(sArray,FREQ)
patternElevation(sArray,FREQ,AZ)
patternElevation(sArray,FREQ,AZ,Name,Value)
PAT = patternElevation( ___ )
```

Description

`patternElevation(sArray,FREQ)` plots the 2-D array directivity pattern versus elevation (in dBi) for the array `sArray` at zero degrees azimuth angle. When `AZ` is a vector, multiple overlaid plots are created. The argument `FREQ` specifies the operating frequency.

`patternElevation(sArray,FREQ,AZ)`, in addition, plots the 2-D element directivity pattern versus elevation (in dBi) at the azimuth angle specified by `AZ`. When `AZ` is a vector, multiple overlaid plots are created.

`patternElevation(sArray,FREQ,AZ,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternElevation( ___ )` returns the array pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Elevation'` parameter and the `AZ` input argument.

Input Arguments

`sArray` — Replicated subarray

System object

Replicated subarray, specified as a phased.ReplicatedSubarray System object.

Example: `sArray= phased.ReplicatedSubarray;`

`FREQ` — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

`AZ` — Azimuth angles for computing directivity and pattern

1-by-*N* real-valued row vector

Azimuth angles for computing sensor or array directivities and patterns, specified as a 1-by-*M* real-valued row vector where *N* is the number of desired azimuth directions. Angle units are in degrees. The azimuth angle must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `[0,10,20]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'Type' — Displayed pattern type

'directivity' (default) | 'efield' | 'power' | 'powerdb'

Displayed pattern type, specified as the comma-separated pair consisting of 'Type' and one of

- 'directivity' — directivity pattern measured in dBi.
- 'efield' — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- 'power' — power pattern of the sensor or array defined as the square of the field pattern.
- 'powerdb' — power pattern converted to dB.

Example: 'powerdb'

Data Types: char

'PropagationSpeed' — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of 'PropagationSpeed' and a positive scalar in meters per second.

Example: 'PropagationSpeed',physconst('LightSpeed')

Data Types: double

'Weights' — Subarray weights

M-by-1 complex-valued column vector

Subarray weights, specified as the comma-separated pair consisting of 'Weights' and an *M*-by-1 complex-valued column vector. Subarray weights are applied to the subarrays of the array to produce array steering, tapering, or both. The dimension *M* is the number of subarrays in the array.

Example: 'Weights',ones(10,1)

Data Types: double
Complex Number Support: Yes

'SteerAngle' — Subarray steering angle

[0;0] (default) | scalar | 2-element column vector

Subarray steering angle, specified as the comma-separated pair consisting of `'SteerAngle'` and a scalar or a 2-by-1 column vector.

If `'SteerAngle'` is a 2-by-1 column vector, it has the form `[azimuth; elevation]`. The azimuth angle must be between –180° and 180°, inclusive. The elevation angle must be between –90° and 90°, inclusive.

If `'SteerAngle'` is a scalar, it specifies the azimuth angle only. In this case, the elevation angle is assumed to be 0.

This option applies only when the `'SubarraySteering'` property of the System object is set to `'Phase'` or `'Time'`.

Example: `'SteerAngle',[20;30]`

Data Types: `double`

`'Elevation'` — Elevation angles

`[-90:90]` (default) | 1-by-*P* real-valued row vector

Elevation angles, specified as the comma-separated pair consisting of `'Elevation'` and a 1-by-*P* real-valued row vector. Elevation angles define where the array pattern is calculated.

Example: `'Elevation',[-90:2:90]`

Data Types: `double`

Output Arguments

`PAT` — Array directivity or pattern

L-by-*N* real-valued matrix

Array directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of elevation angles determined by the `'Elevation'` name-value pair argument. The dimension *N* is the number of azimuth angles determined by the `AZ` argument.

Examples

Elevation Pattern of Array with Subarrays

Create a 2-by-2-element URA of isotropic antenna elements, and arrange four copies to form a 16-element URA. Plot the elevation directivity pattern within a restricted range of elevation angles from -45 to 45 degrees in 0.1 degree increments. Plot directivity for 0 degrees and 15 degrees azimuth.

Create the array

```
fmin = 1e9;
fmax = 6e9;
c = physconst('LightSpeed');
lam = c/fmax;
sIso = phased.IsotropicAntennaElement(...
    'FrequencyRange',[fmin,fmax],...
    'BackBaffled',false);
sURA = phased.URA('Element',sIso,...
    'Size',[2 2],...
    'ElementSpacing',lam/2);
sRS = phased.ReplicatedSubarray('Subarray',sURA,...
    'Layout','Rectangular','GridSize',[2 2],...
    'GridSpacing','Auto');
```

Plot elevation directivity pattern

```
fc = 1e9;
wts = [0.862,1.23,1.23,0.862]';
patternElevation(sRS,fc,[0,15],...
    'PropagationSpeed',physconst('LightSpeed'),...
    'Elevation',[-45:0.1:45],...
    'Type','directivity',...
    'Weights',wts);
```

phased.ReplicatedSubarray.pattern | phased.ReplicatedSubarray.patternAzimuth

Introduced in R2015a

plotResponse

System object: phased.ReplicatedSubarray
Package: phased

Plot response pattern of array

Syntax

```
plotResponse(H,FREQ,V)
plotResponse(H,FREQ,V,Name,Value)
hPlot = plotResponse( ___ )
```

Description

`plotResponse(H,FREQ,V)` plots the array response pattern along the azimuth cut, where the elevation angle is 0. The operating frequency is specified in `FREQ`. The propagation speed is specified in `V`.

`plotResponse(H,FREQ,V,Name,Value)` plots the array response with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = plotResponse( ___ )` returns handles of the lines or surface in the figure window, using any of the input arguments in the previous syntaxes.

Input Arguments

`H`

Array object.

`FREQ`

Operating frequency, in hertz. Typical values are within the range specified by a property of `H.Subarray.Element`. That property is named `FrequencyRange` or `FrequencyVector`, depending on the type of element in the array. The element has zero

response at frequencies outside that range. If FREQ is a nonscalar row vector, the plot shows multiple frequency responses on the same axes.

V

Propagation speed in meters per second.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

'CutAngle'

Cut angle specified as a scalar. This argument is applicable only when RespCut is 'Az' or 'El'. If RespCut is 'Az', CutAngle must be between –90 and 90. If RespCut is 'El', CutAngle must be between –180 and 180.

Default: 0

'Format'

Format of the plot, using one of 'Line', 'Polar', or 'UV'. If you set Format to 'UV', FREQ must be a scalar.

Default: 'Line'

'NormalizeResponse'

Set this value to true to normalize the response pattern. Set this value to false to plot the response pattern without normalizing it. This parameter is not applicable when you set the Unit parameter value to 'dbi'.

Default: true

'OverlayFreq'

Set this value to true to overlay pattern cuts in a 2-D line plot. Set this value to false to plot pattern cuts against frequency in a 3-D waterfall plot. If this value is false, then FREQ must be a vector with at least two entries.

This parameter applies only when `Format` is not `'Polar'` and `RespCut` is not `'3D'`.

Default: `true`

`'Polarization'`

Specify the polarization options for plotting the array response pattern. The allowable values are `|'None' | 'Combined' | 'H' | 'V' |` where:

- `'None'` specifies plotting a nonpolarized response pattern
- `'Combined'` specifies plotting a combined polarization response pattern
- `'H'` specifies plotting the horizontal polarization response pattern
- `'V'` specifies plotting the vertical polarization response pattern

For arrays that do not support polarization, the only allowed value is `'None'`. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

Default: `'None'`

`'RespCut'`

Cut of the response. Valid values depend on `Format`, as follows:

- If `Format` is `'Line'` or `'Polar'`, the valid values of `RespCut` are `'Az'`, `'El'`, and `'3D'`. The default is `'Az'`.
- If `Format` is `'UV'`, the valid values of `RespCut` are `'U'` and `'3D'`. The default is `'U'`.

If you set `RespCut` to `'3D'`, `FREQ` must be a scalar.

`'SteerAng'`

Subarray steering angle. `SteerAng` can be either a 2-element column vector or a scalar.

If `SteerAng` is a 2-element column vector, it has the form [azimuth; elevation]. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

If `SteerAng` is a scalar, it specifies the azimuth angle. In this case, the elevation angle is assumed to be 0.

This option is applicable only if the `SubarraySteering` property of `H` is `'Phase'` or `'Time'`.

Default: `[0;0]`

`'Unit'`

The unit of the plot. Valid values are `'db'`, `'mag'`, `'pow'`, or `'dbi'`. This parameter determines the type of plot that is produced.

Unit value	Plot type
`db`	power pattern in dB scale
`mag`	field pattern
`pow`	power pattern
`dbi`	directivity

Default: `'db'`

`'Weights'`

Weight values applied to the array, specified as a length-*N* column vector or *N*-by-*M* matrix. The dimension *N* is the number of subarrays in the array. The interpretation of *M* depends upon whether the input argument `FREQ` is a scalar or row vector.

Weights Dimension	FREQ Dimension	Purpose
N-by-1 column vector	Scalar or 1-by-*M* row vector	Apply one set of weights for the same single frequency or all *M* frequencies.
N-by-*M* matrix	Scalar	Apply all of the *M* different columns in `Weights` for the same single frequency.
	1-by-*M* row vector	Apply each of the *M* different columns in `Weights` for the corresponding frequency in `FREQ`.

`'AzimuthAngles'`

Azimuth angles for plotting subarray response, specified as a row vector. The `AzimuthAngles` parameter sets the display range and resolution of azimuth angles for

visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'Az'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of azimuth angles should lie between –180° and 180° and must be in nondecreasing order. When you set the `RespCut` parameter to `'3D'`, you can set the `AzimuthAngles` and `ElevationAngles` parameters simultaneously.

Default: `[-180:180]`

`'ElevationAngles'`

Elevation angles for plotting subarray response, specified as a row vector. The `ElevationAngles` parameter sets the display range and resolution of elevation angles for visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'El'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of elevation angles should lie between –90° and 90° and must be in nondecreasing order. When you set the `RespCut` parameter to `'3D'`, you can set the `ElevationAngles` and `AzimuthAngles` parameters simultaneously.

Default: `[-90:90]`

`'UGrid'`

U coordinate values for plotting subarray response, specified as a row vector. The `UGrid` parameter sets the display range and resolution of the *U* coordinates for visualizing the radiation pattern in *U*/*V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'U'` or `'3D'`. The values of `UGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set the `UGrid` and `VGrid` parameters simultaneously.

Default: `[-1:0.01:1]`

`'VGrid'`

V coordinate values for plotting subarray response, specified as a row vector. The `VGrid` parameter sets the display range and resolution of the *V* coordinates for visualizing the radiation pattern in *U*/*V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'3D'`. The values of `VGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set the `VGrid` and `UGrid` parameters simultaneously.

Default: `[-1:0.01:1]`

Examples

Azimuth Response and Directivity of ULA with Subarrays

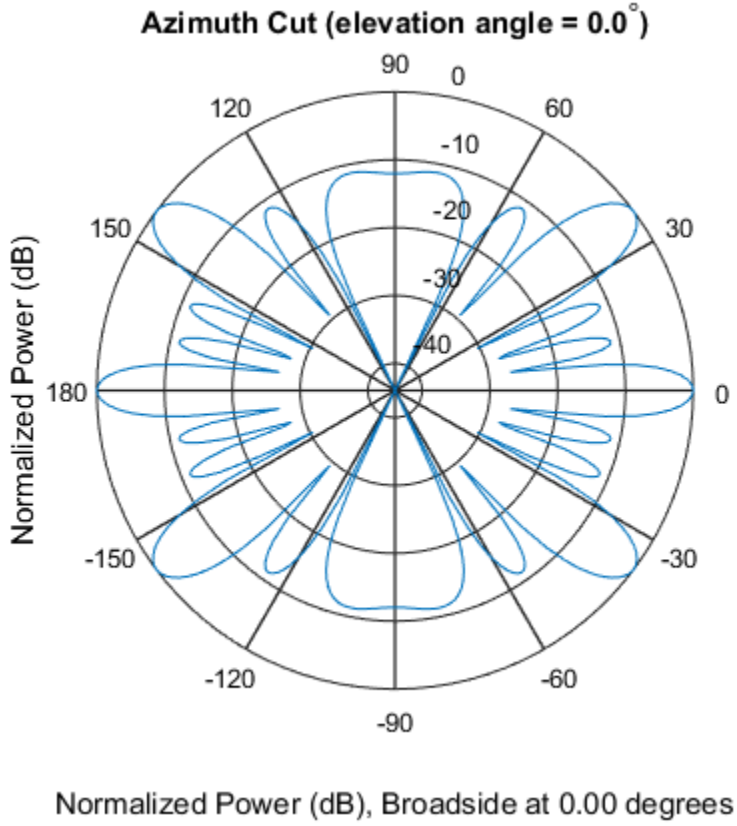
Plot the azimuth response of a 4-element ULA composed of two 2-element ULAs.

Create a 2-element ULA, and arrange two copies to form a 4-element ULA.

```
h = phased.ULA('NumElements',2,'ElementSpacing',0.5);
ha = phased.ReplicatedSubarray('Subarray',h,...
    'Layout','Rectangular','GridSize',[1 2],...
    'GridSpacing','Auto');
```

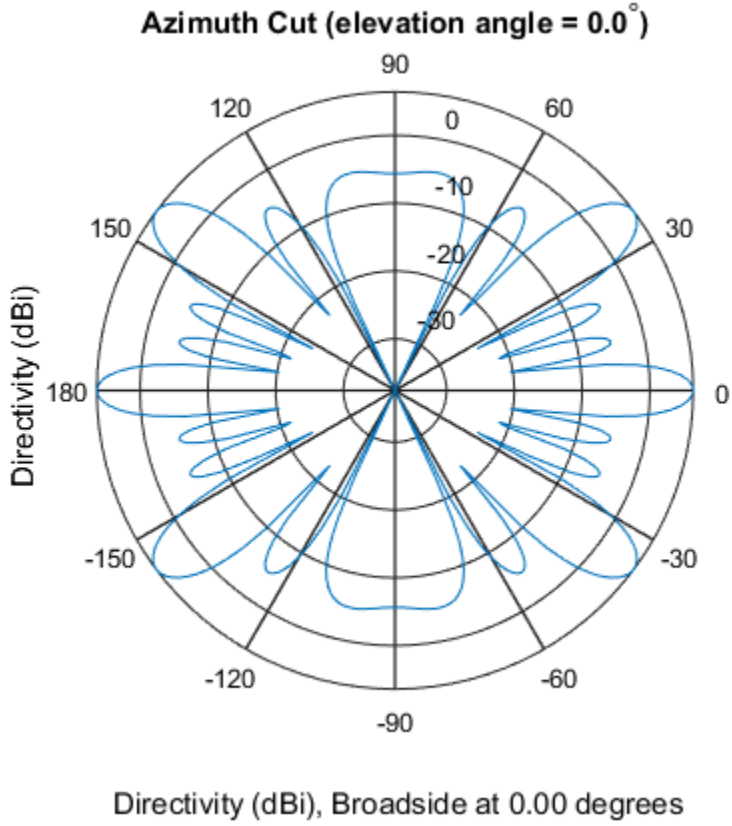
Plot the azimuth response of the array. Assume the operating frequency is 1 GHz and the wave propagation speed is 3e8 m/s.

```
plotResponse(ha,1e9,3e8,'RespCut','Az','Format','Polar');
```



Plot the azimuth directivity of the array.

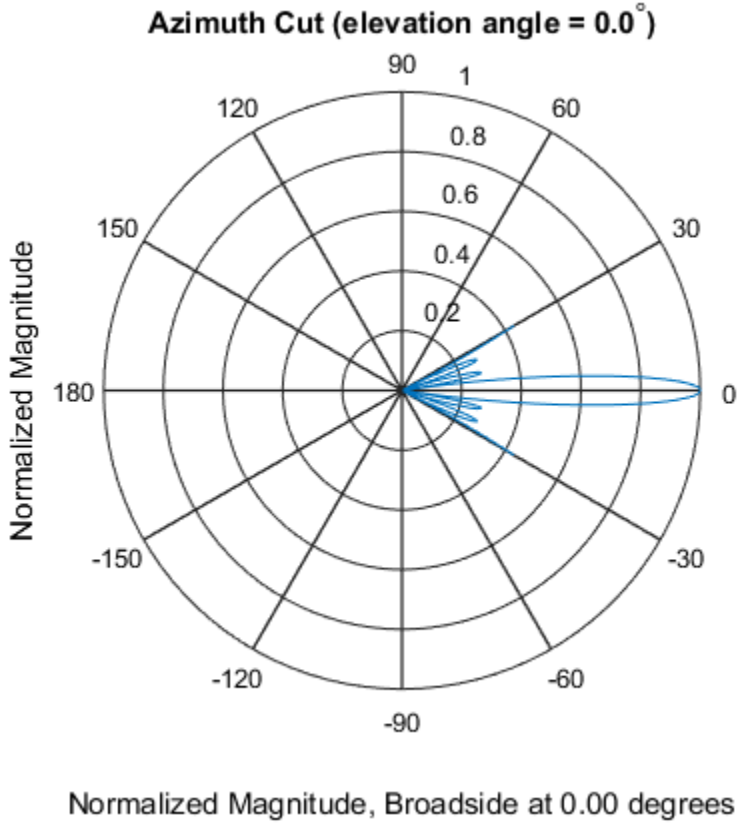
```
plotResponse(ha,1e9,3e8,'RespCut','Az','Format','Polar','Unit','dbi');
```



Display Azimuth Response of Array with Subarrays Between -30 and 30 Degrees

Create a 2-element ULA, and arrange two copies to form a 4-element ULA. Using the `AzimuthAngles` parameter, plot the response within a restricted range of azimuth angles from -30 to 30 degrees in 0.1 degree increments.

```
h = phased.ULA('NumElements',2,'ElementSpacing',0.5);
ha = phased.ReplicatedSubarray('Subarray',h,...
    'Layout','Rectangular','GridSize',[1 2],...
    'GridSpacing','Auto');
plotResponse(ha,1e9,3e8,'RespCut','Az','Format','Polar',...
    'AzimuthAngles',[-30:0.1:30],'Unit','mag');
```



Apply Two Sets of Weights at a Single Frequency

Construct an array of replicated subarrays. Start with a 2-element uniform line array (ULA), and duplicate it 5 times to create a 10-element ULA. Apply both uniform weights and tapered weights. Then, use `plotResponse` to show that the tapered set of weights reduces the adjacent sidelobes while broadening the main lobe.

```
h = phased.ULA('NumElements',2,'ElementSpacing',0.2);
ha = phased.ReplicatedSubarray('Subarray',h,...
    'Layout','Rectangular','GridSize',[1 5],...
    'GridSpacing',0.4);
c = physconst('LightSpeed');
fc = 1e9;
wts1 = [0.2,0.2,0.2,0.2,0.2]';
```

```
wts2 = [0.1,0.23333,.33333,0.23333,0.1]';
plotResponse(ha,fc,c,'RespCut','Az','Format','Polar',...
    'Weights',[wts1,wts2]);
```

step

System object: phased.ReplicatedSubarray
Package: phased

Output responses of subarrays

Syntax

```
RESP = step(H,FREQ,ANG,V)
RESP = step(H,FREQ,ANG,V,STEERANGLE)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`RESP = step(H,FREQ,ANG,V)` returns the responses, `RESP`, of the subarrays in the array, at operating frequencies specified in `FREQ` and directions specified in `ANG`. `V` is the propagation speed. The elements within each subarray are connected to the subarray phase center using an equal-path feed.

`RESP = step(H,FREQ,ANG,V,STEERANGLE)` uses `STEERANGLE` as the subarray's steering direction. This syntax is available when you set the `SubarraySteering` property to either `'Phase'` or `'Time'`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

H

Phased array formed by replicated subarrays.

FREQ

Operating frequencies of array in hertz. `FREQ` is a row vector of length L. Typical values are within the range specified by a property of `H.Subarray.Element`. That property is named `FrequencyRange` or `FrequencyVector`, depending on the type of element in the array. The element has zero response at frequencies outside that range.

ANG

Directions in degrees. `ANG` can be either a 2-by-M matrix or a row vector of length M.

If `ANG` is a 2-by-M matrix, each column of the matrix specifies the direction in the form [azimuth; elevation]. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

If `ANG` is a row vector of length M, each element specifies a direction's azimuth angle. In this case, the corresponding elevation angle is assumed to be 0.

V

Propagation speed in meters per second. This value must be a scalar.

STEERANGLE

Subarray steering direction. `STEERANGLE` can be either a 2-element column vector or a scalar.

If `STEERANGLE` is a 2-element column vector, it has the form [azimuth; elevation]. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

If `STEERANGLE` is a scalar, it specifies the direction's azimuth angle. In this case, the elevation angle is assumed to be 0.

Output Arguments

RESP

Voltage responses of the subarrays of the phased array. The output depends on whether the array supports polarization or not.

- If the array is not capable of supporting polarization, the voltage response, `RESP`, has the dimensions *N*-by-*M*-by-*L*. The first dimension, *N* , represents the number of subarrays in the phased array, the second dimension, *M*, represents the number of angles specified in `ANG`, while *L* represents the number of frequencies specified in `FREQ`. Each column of `RESP` contains the responses of the subarrays for the corresponding direction specified in `ANG`. Each of the *L* pages of `RESP` contains the responses of the subarrays for the corresponding frequency specified in `FREQ`.
- If the array is capable of supporting polarization, the voltage response, `RESP`, is a MATLAB `struct` containing two fields, `RESP.H` and `RESP.V`, each having dimensions *N*-by-*M*-by-*L*. The field, `RESP.H`, represents the array's horizontal polarization response, while `RESP.V` represents the array's vertical polarization response. The first dimension, *N* , represents the number of subarrays in the phased array, the second dimension, *M*, represents the number of angles specified in `ANG`, while *L* represents the number of frequencies specified in `FREQ`. Each of the *M* columns contains the responses of the subarrays for the corresponding direction specified in `ANG`. Each of the *L* pages contains the responses of the subarrays for the corresponding frequency specified in `FREQ`.

Examples

Subarray Response

Calculate the response at boresight for two 2-element ULA arrays that form subarrays of a 4-element ULA array of short-dipole antenna elements.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Create a two-element ULA of short-dipole antenna elements. Then, arrange two copies to form a 4-element ULA.

```
antenna = phased.ShortDipoleAntennaElement;
```

```
array = phased.ULA('Element',antenna,'NumElements',2,'ElementSpacing',0.5);
replicatedarray = phased.ReplicatedSubarray('Subarray',array,...
    'Layout','Rectangular','GridSize',[1 2],...
    'GridSpacing','Auto');
```

Find the response of each subarray at boresight. Assume the operating frequency is 1 GHz and the wave propagation speed is the speed of light.

```
c = physconst('LightSpeed');
resp = replicatedarray(1.0e9,[0;0],c)
```

```
resp =

  struct with fields:

    H: [2×1 double]
    V: [2×1 double]
```

viewArray

System object: phased.ReplicatedSubarray
Package: phased

View array geometry

Syntax

```
viewArray(H)
viewArray(H,Name,Value)
hPlot = viewArray( ___ )
```

Description

`viewArray(H)` plots the geometry of the array specified in `H`.

`viewArray(H,Name,Value)` plots the geometry of the array, with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = viewArray( ___ )` returns the handles of the array elements in the figure window. All input arguments described for the previous syntaxes also apply here.

Input Arguments

`H`

Array object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'ShowIndex'`

Vector specifying the element indices to show in the figure. Each number in the vector must be an integer between 1 and the number of elements. You can also specify the value as `'All'` to show indices of all elements of the array or `'None'` to suppress indices.

Default: `'None'`

`'ShowNormals'`

Set this value to `true` to show the normal directions of all elements of the array. Set this value to `false` to plot the elements without showing normal directions.

Default: `false`

`'ShowTaper'`

Set this value to `true` to specify whether to change the element color brightness in proportion to the element taper magnitude. When this value is set to `false`, all elements are drawn with the same color.

Default: `false`

`'ShowSubarray'`

Vector specifying the indices of subarrays to highlight in the figure. Each number in the vector must be an integer between 1 and the number of subarrays. You can also specify the value as `'All'` to highlight all subarrays of the array or `'None'` to suppress subarray highlighting. Highlighting uses different colors for different subarrays.

Default: `'All'`

`'Title'`

Character vector specifying the title of the plot.

Default: `'Array Geometry'`

Output Arguments

`hPlot`

Handles of array elements in figure window.

Examples

Array of Replicated Hexagonal Arrays on a Sphere

This example shows how to construct a full array by replicating subarrays.

Create a hexagonal array to use as a subarray.

```
Nmin = 9;
Nmax = 17;
dy = 0.5;
dz = 0.5*sin(pi/3);
rowlengths = [Nmin:Nmax Nmax-1:-1:Nmin];
numels_hex = sum(rowlengths);
stopvals = cumsum(rowlengths);
startvals = stopvals-rowlengths+1;
pos = zeros(3,numels_hex);
rowidx = 0;
for m = Nmin-Nmax:Nmax-Nmin
    rowidx = rowidx+1;
    idx = startvals(rowidx):stopvals(rowidx);
    pos(2,idx) = (-(rowlengths(rowidx)-1)/2:...
        (rowlengths(rowidx)-1)/2) * dy;
    pos(3,idx) = m*dz;
end
hexa = phased.ConformalArray('ElementPosition',pos,...
    'ElementNormal',zeros(2,numels_hex));
```

Arrange copies of the hexagonal array on a sphere.

```
radius = 9;
az = [-180 -180 -180 -120 -120 -60 -60   0  0  60 60 120 120 180];
el = [-90   -30   30  -30   30 -30  30 -30 30 -30 30 -30  30  90];
numsubarrays = size(az,2);
[x,y,z] = sph2cart(deg2rad(az),deg2rad(el),...
    radius*ones(1,numsubarrays));
ha = phased.ReplicatedSubarray('Subarray',hexa,...
    'Layout','Custom',...
    'SubarrayPosition',[x; y; z], ...
    'SubarrayNormal',[az; el]);
```

Display the geometry of the array, highlighting selected subarrays with different colors.

```
viewArray(ha,'ShowSubarray',3:2:13,...
    'Title','Hexagonal Subarrays on a Sphere');
```

```
view(0,90)
```

phased.RootMUSICEstimator System object

Package: phased

Root MUSIC direction of arrival (DOA) estimator for ULA and UCA

Description

The `RootMUSICEstimator` object implements the root multiple signal classification (root-MUSIC) direction of arrival estimator for uniform linear arrays (ULA) and uniform circular arrays (UCA). When a uniform circular array is used, the algorithm transforms the input to a ULA-like structure using the *phase mode excitation* technique [2].

To estimate the direction of arrival (DOA):

1. Define and set up your DOA estimator. See "Construction" on page 1-1697.
2. Call step to estimate the DOA according to the properties of `phased.RootMUSICEstimator`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.RootMUSICEstimator` creates a root MUSIC DOA estimator System object, `H`. The object estimates the signal's direction of arrival using the root MUSIC algorithm with a uniform linear array (ULA).

`H = phased.RootMUSICEstimator(Name,Value)` creates object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`SensorArray`

Sensor array System object

Sensor array specified as a System object. The sensor array must be a phased.ULA object or a phased.UCA object.

Default: `phased.ULA` with default property values

`PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

Default: Speed of light

`OperatingFrequency`

System operating frequency

Specify the operating frequency of the system in hertz as a positive scalar. The default value corresponds to 300 MHz.

Default: `3e8`

`ForwardBackwardAveraging`

Perform forward-backward averaging

Set this property to `true` to use forward-backward averaging to estimate the covariance matrix for sensor arrays with conjugate symmetric array manifold.

Default: `false`

`SpatialSmoothing`

Spatial smoothing

The averaging number used by spatial smoothing to estimate the covariance matrix, specified as a strictly positive integer. Each additional smoothing value handles one

additional coherent source, but reduces the effective number of elements by one. The maximum value of this property is *M-2*. For a ULA, *M* is the number of sensors. For a UCA, *M* is the size of the internal ULA-like array structure defined by the phase mode excitation technique. The default value of zero indicates that no spatial smoothing is employed.

Default: `0`

`NumSignalsSource`

Source of number of signals

Specify the source of the number of signals as one of `'Auto'` or `'Property'`. If you set this property to `'Auto'`, the number of signals is estimated by the method specified by the `NumSignalsMethod` property.

When spatial smoothing is employed on a UCA, you cannot set the `NumSignalsSource` property to`'Auto'` to estimate the number of signals. You can use the functions `aictest` or `mdltest` independently to determine the number of signals.

Default: `'Auto'`

`NumSignalsMethod`

Method to estimate number of signals

Specify the method to estimate the number of signals as one of `'AIC'` or `'MDL'`. `'AIC'` uses the Akaike Information Criterion and `'MDL'` uses Minimum Description Length Criterion. This property applies when you set the `NumSignalsSource` property to `'Auto'`.

Default: `'AIC'`

`NumSignals`

Number of signals

Specify the number of signals as a positive integer scalar. This property applies when you set the `NumSignalsSource` property to `'Property'`. The number of signals must be smaller than the number of elements in the array specified in the `SensorArray` property.

Default: `1`

Methods

step Perform DOA estimation

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Root-MUSIC Estimation of DOA for ULA

Estimate the DOA's of two signals received by a standard 10-element uniform linear array (ULA) having an element spacing of 1 meter. The antenna operating frequency is 150 MHz. The actual direction of the first signal is 10 degrees in azimuth and 20 degrees in elevation. The direction of the second signal is 45 degrees in azimuth and 60 degrees in elevation.

```
fs = 8000;
t = (0:1/fs:1).';
x1 = cos(2*pi*t*300);
x2 = cos(2*pi*t*400);
sULA = phased.ULA('NumElements',10,...
    'ElementSpacing',1);
sULA.Element.FrequencyRange = [100e6 300e6];
fc = 150e6;
x = collectPlaneWave(sULA,[x1 x2],[10 20;45 60]',fc);
rng default;
noise = 0.1/sqrt(2)*(randn(size(x))+1i*randn(size(x)));
sDOA = phased.RootMUSICEstimator('SensorArray',sULA,...
    'OperatingFrequency',fc,...
    'NumSignalsSource','Property',...
    'NumSignals',2);
doas = step(sDOA,x + noise);
az = broadside2az(sort(doas),[20 60])
```

```
az =

   10.0001   45.0107
```

step

System object: phased.RootMUSICEstimator
Package: phased

Perform DOA estimation

Syntax

```
ANG = step(H,X)
ANG = step(H,X,ElAng)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`ANG = step(H,X)` estimates the direction of arrivals (DOA's) from a signal `X` using the DOA estimator `H`. `X` is a matrix whose columns correspond to the signal channels. `ANG` is a row vector of the estimated broadside angles (in degrees).

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

`ANG = step(H,X,ElAng)` specifies, in addition, the assumed elevation angles of the signals. This syntax is only applicable when the `SensorArray` property of the object specifies a uniform circular array (UCA). `ElAng` is a scalar between -90° and 90° and is applied to all signals. The elevation angles for all signals must be the same as required by the *phase mode excitation* algorithm.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a

nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Examples

Root-MUSIC Estimation of DOA for ULA

Estimate the DOA's of two signals received by a standard 10-element uniform linear array (ULA) having an element spacing of 1 meter. The antenna operating frequency is 150 MHz. The actual direction of the first signal is 10 degrees in azimuth and 20 degrees in elevation. The direction of the second signal is 45 degrees in azimuth and 60 degrees in elevation.

```
fs = 8000;
t = (0:1/fs:1).';
x1 = cos(2*pi*t*300);
x2 = cos(2*pi*t*400);
sULA = phased.ULA('NumElements',10,...
    'ElementSpacing',1);
sULA.Element.FrequencyRange = [100e6 300e6];
fc = 150e6;
x = collectPlaneWave(sULA,[x1 x2],[10 20;45 60]',fc);
rng default;
noise = 0.1/sqrt(2)*(randn(size(x))+1i*randn(size(x)));
sDOA = phased.RootMUSICEstimator('SensorArray',sULA,...
    'OperatingFrequency',fc,...
    'NumSignalsSource','Property',...
    'NumSignals',2);
doas = step(sDOA,x + noise);
az = broadside2az(sort(doas),[20 60])

az =

   10.0001   45.0107
```

Root-MUSIC Estimation of DOA for UCA

Using the root-MUSIC algorithm, estimate the azimuth angle of arrival of two signals received by a 15-element UCA having a 1.5 meter radius. The antenna operating

frequency is 150 MHz. The actual direction of arrival of the first signal is 10 degrees in azimuth and 4 degrees in elevation. The direction of arrival of the second signal is 45 degrees in azimuth and -2 degrees in elevation. In estimating the directions of arrival, assume the signals arrive from 0 degrees elevation.

Set the frequencies of the signals to 500 and 600 Hz. Set the sample rate to 8 kHz and the operating frequency to 150 MHz. Then, create the baseband signals, the UCA array and the plane wave signals.

```
fs = 8000;
fc = 150e6;
t = (0:1/fs:1).';
x1 = cos(2*pi*t*500);
x2 = cos(2*pi*t*600);
sUCA = phased.UCA('NumElements',15,...
    'Radius',1.5);
x = collectPlaneWave(sUCA,[x1 x2],[10 4; 45 -2]',fc);
```

Add random complex gaussian white noise to the signals.

```
rs = RandStream('mt19937ar','Seed',0);
noise = 0.1/sqrt(2)*(randn(rs,size(x))+1i*randn(rs,size(x)));
```

Create the phased.RootMUSICEstimator System object

```
sDOA = phased.RootMUSICEstimator('SensorArray',sUCA,...
    'OperatingFrequency',fc,...
    'NumSignalsSource','Property',...
    'NumSignals',2);
```

Solve for the azimuth angles for zero degrees elevation.

```
elang = 0;
doas = step(sDOA, x + noise, elang);
az = sort(doas)
```

```
az =

```

phased.RootWSFEstimator System object

Package: phased

Root WSF direction of arrival (DOA) estimator for ULA

Description

The `RootWSFEstimator` object implements a root weighted subspace fitting direction of arrival algorithm.

To estimate the direction of arrival (DOA):

1. Define and set up your root WSF DOA estimator. See "Construction" on page 1-1705.
2. Call step to estimate the DOA according to the properties of `phased.RootWSFEstimator`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.RootWSFEstimator` creates a root WSF DOA estimator System object, `H`. The object estimates the signal's direction of arrival using the root weighted subspace fitting (WSF) algorithm with a uniform linear array (ULA).

`H = phased.RootWSFEstimator(Name,Value)` creates object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`SensorArray`

Handle to sensor array

Specify the sensor array as a handle. The sensor array must be a `phased.ULA` object.

Default: phased.ULA with default property values

`PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

Default: Speed of light

`OperatingFrequency`

System operating frequency

Specify the operating frequency of the system in hertz as a positive scalar. The default value corresponds to 300 MHz.

Default: `3e8`

`NumSignalsSource`

Source of number of signals

Specify the source of the number of signals as one of `'Auto'` or `'Property'`. If you set this property to `'Auto'`, the number of signals is estimated by the method specified by the `NumSignalsMethod` property.

Default: `'Auto'`

`NumSignalsMethod`

Method to estimate number of signals

Specify the method to estimate the number of signals as one of `'AIC'` or `'MDL'`. `'AIC'` uses the Akaike Information Criterion and `'MDL'` uses the Minimum Description Length

Criterion. This property applies when you set the `NumSignalsSource` property to `'Auto'`.

Default: `'AIC'`

`NumSignals`

Number of signals

Specify the number of signals as a positive integer scalar. This property applies when you set the `NumSignalsSource` property to `'Property'`.

Default: `1`

`Method`

Iterative method

Specify the iterative method as one of `'IMODE'` or `'IQML'`.

Default: `'IMODE'`

`MaximumIterationCount`

Maximum number of iterations

Specify the maximum number of iterations as a positive integer scalar or `'Inf'`. This property is tunable.

Default: `'Inf'`

Methods

step	Perform DOA estimation

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object

Common to All System Objects	
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Estimate DOA of Two Signals Arriving at ULA

Estimate the DOAs of two signals received by a 10-element ULA with a 1 m element spacing. The antenna operating frequency is 150 MHz. The actual direction of the first signal is 10° in azimuth and 20° in elevation. The direction of the second signal is 45° in azimuth and 60° degrees in elevation.

```
fs = 8000;
t = (0:1/fs:1).';
x1 = cos(2*pi*t*300);
x2 = cos(2*pi*t*400);
array = phased.ULA('NumElements',10,'ElementSpacing',1);
array.Element.FrequencyRange = [100e6 300e6];
fc = 150e6;
x = collectPlaneWave(array,[x1 x2],[10 20;45 60]',fc);
noise = 0.1/sqrt(2)*(randn(size(x))+1i*randn(size(x)));
estimator = phased.RootWSFEstimator('SensorArray',array,...
    'OperatingFrequency',fc,...
    'NumSignalsSource','Property','NumSignals',2);
doas = estimator(x + noise);
az = broadside2az(sort(doas),[20 60])
```

```
az =

   10.0001   45.0107
```

`broadside2az` | phased.RootMUSICEstimator

Introduced in R2012a

step

System object: phased.RootWSFEstimator
Package: phased

Perform DOA estimation

Syntax

```
ANG = step(H,X)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`ANG = step(H,X)` estimates the DOAs from `X` using the DOA estimator `H`. `X` is a matrix whose columns correspond to channels. `ANG` is a row vector of the estimated broadside angles (in degrees).

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Examples

Estimate DOA of Two Signals Using WSF

First, estimate the DOAs of two signals received by a standard 10-element ULA with element spacing of 1 meter. The antenna operating frequency is 150 MHz. The actual direction of the first signal is 10° in azimuth and 20° in elevation. The direction of the second signal is 45° in azimuth and −5° in elevation.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Create the signals with added noise. Then, create the ULA System object™.

Construct WSF estimator System object.

Estimate the DOAs.

```
doas =

   10.0002   20.7934
```

phased.ScenarioViewer System object

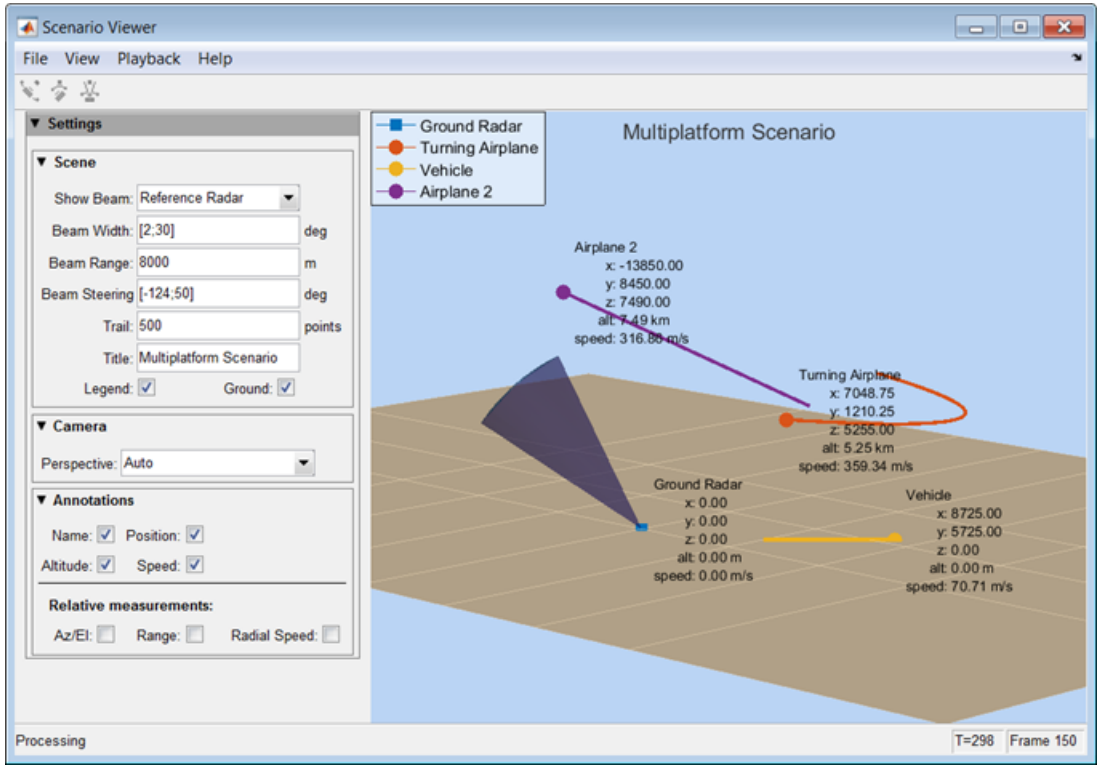
Package: phased

Display motion of radars and targets

Description

The `phased.ScenarioViewer` System object creates a 3-D viewer to display the motion of radars and targets that you model in your radar simulation. You can display current positions and velocities, object tracks, position and speed annotations, radar beam directions, and other object parameters. You can change radar features such as beam range and beam width during the simulation. You can use the phased.Platform System object to model moving objects or you can supply your own dynamic models.

This figure shows a four-object scenario consisting of a ground radar, two airplanes, and a ground vehicle. You can view the code that generated this figure in the “Visualize Multiplatform Scenario” on page 1-1726 example.



To create a scenario viewer:

1. Define and set up the `phased.ScenarioViewer` System object. See "Construction" on page 1-1714. You can set System object properties at construction time or leave them to their default values. Some properties that you set at construction time can be changed later. These properties are *tunable*.
2. Call the phased.ScenarioViewer.step method to update radar and target displayed positions according to the properties of the `phased.ScenarioViewer` System object. You can change tunable properties at any time.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`sIS = phased.ScenarioViewer` creates a scenario viewer System object, `sIS` having default property values.

`sIS = phased.ScenarioViewer(Name,Value)` returns a scenario viewer System object, `sIS`, with any specified property `Name` set to a specified `Value`. `Name` must appear inside single quotes (`''`). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Properties

`Name` — Window caption name

`'Scenario Viewer'` (default) | character vector

Window caption name, specified as a character vector. The `Name` property and the `Title` property are different.

Example: `'Multitarget Viewer'`

Data Types: `char`

`ReferenceRadar` — Reference radar index

`1` (default) | positive integer

Reference radar index, specified as a positive integer. This property selects one of the radars as the reference radar. Its value must be less than or equal to the number of radars that you specify in the `radar_pos` argument of the phased.ScenarioViewer.step method. This property is tunable. Target range, radial speed, azimuth, and elevation are defined with respect to this radar.

Example: `2`

Data Types: `double`

`ShowBeam` — Show radar beams

`'ReferenceRadar'` (default) | `'None'` | `'All'`

Enable the display of radar beams, specified as `'ReferenceRadar'`, `'None'`, or `'All'`. This option determines which radar beams to show.

Option	Beams to show
`'ReferenceRadar'`	Show the beam of the radar specified in the `ReferenceRadar` property.
`'None'`	Do not show any radar beams.
`'All'`	Show the beams for all radars.

This property is tunable.

Example: `'All'`

Data Types: `char`

`BeamWidth` — Vertical and horizontal radar beam widths

15 (default) | positive, real-valued scalar | positive, real-valued 2-element column vector | positive, real-valued *N*-element row vector | positive, real-valued 2-by-*N* matrix

Vertical and horizontal radar beam widths, specified as a positive real-valued scalar, a 2-element column vector, an *N*-element row vector, or a 2-by-*N* matrix. *N* is the number of radars. All scalar, vector, and matrix entries are positive, real-valued numbers between 0–360°. Units are in degrees.

Value Specification	Interpretation
Scalar	The horizontal and vertical radar beam widths are equal and identical for all radars.
2-element column vector	The first row specifies the horizontal beam width. The second row specifies the vertical beam width. These values are identical for all radars.
N-element row vector	Each element applies to one radar. Vertical and horizontal beam widths for each radar are equal.
2-by-*N* matrix	Each column applies to one radar. The first row specifies the horizontal beam width and the second row specifies the vertical beam width for each radar.

When `CameraPerspective` is set to `'Radar'`, the System object uses this property to calculate the value of `CameraViewAngle`. This property is tunable.

Example: `[20 10; 18 9]`

Data Types: `double`

`BeamRange` — Radar beam range

1000 (default) | positive scalar | real-valued *N*- element row vector of positive values

Radar beam range, specified as a positive scalar or an *N*-element row vector, where *N* is the number of radars. Units are in meters. When specified as a scalar, all radars have the same beam range. When specified as a vector, each element corresponds to one radar. This property is tunable.

Example: `[1000 1500 850]`

Data Types: `double`

`BeamSteering` — Beam steering direction

`[0;0]` (default) | positive real-valued 2-element column vector | positive real-valued *N*-element row vector

Beam steering directions of radars, specified as a real-valued 2-element column vector of positive values or 2-by-*N* real-valued matrix of positive values. *N* is the number of radars. Beam steering angles are relative to the local coordinate axes of each radar. Units are in degrees. Each column takes the form `[azimuthangle;elevationangle]`. When only one column is specified, the beam steering directions of all radars are the same. Azimuth angles are from –180° to 180°, and the elevation angles are from –90° to 90°. This property is tunable.

Example: `[20 60 35; 5 0 10]`

Data Types: `double`

`VelocityInputPort` — Enable velocity input

`true` (default) | `false`

Enable the velocity input arguments, `radar_velocity` and `tgt_velocity`, of the phased.ScenarioViewer.step method, specified as `true` or `false`. Setting this property to `true` enables the input arguments. When this property is `false`, velocity vectors are estimated from the position change between consecutive updates divided by the update interval. The update interval is the inverse of the `UpdateRate` value.

Example: `false`

Data Types: `logical`

`OrientationInputPort` — Enable orientation input

`false` (default) | `true`

Enable the input of local coordinate system orientation axes, `radar_laxes` and `tgt_laxes`, to the phased.ScenarioViewer.step method, specified as `false` or `true`. Setting this property to `true` enables the input arguments. When this property is `false`, the orientation axes are aligned with the global coordinate axes.

Example: `true`

Data Types: `logical`

`UpdateRate` — Update rate of scenario viewer

1 (default) | `positive scalar`

Update rate of scenario viewer, specified as a positive scalar. Units are in hertz.

Example: `2.5`

Data Types: `double`

`Title` — Display title

`''` (default) | character vector

Display title, specified as a character vector. The `Title` property and the `Name` property are different. The display title appears within the figure at the top. The name appears at the top of the figure window. This property is tunable.

Example: `'Radar and Target Display'`

Data Types: `char`

`PlatformNames` — Names of radars and targets

`'Auto'` (default) | 1-by-*(N+M)* cell array of character vectors

Names assigned to radars and targets, specified as a 1-by-*(N+M)* cell array of character vectors. *N* is the number of radars and *M* is the number of targets. Order the cell entries by radar names, followed by target names. Names appear in the legend and annotations. When you set `PlatformNames` to `'Auto'`, names are created sequentially starting from `'Radar 1'` for radars and `'Target 1'` for targets.

Example: `{'Stationary Radar','Mobile Radar','Airplane'}`

Data Types: `cell`

`TrailLength` — Length of visible tracks

`500` (default) | positive integer | *(N+M)*-length vector of positive integers

Length of the visibility of object tracks, specified as a positive integer or *(N+M)*-length vector of positive integers. *N* is the number of radars and *M* is the number of targets. When `TrailLength` is a scalar, all tracks have the same length. When `TrailLength` is a vector, each element of the vector specifies the length of the corresponding radar or target trajectory. Order the entries by radars, followed by targets. Each call to the phased.ScenarioViewer.step method generates a new visible point. This property is tunable.

Example: `[100,150,100]`

Data Types: `double`

`CameraPerspective` — Camera perspective

`'Auto'` (default) | `'Custom'` | `'Radar'`

Camera perspective, specified as `'Auto'`, `'Custom'`, or `'Radar'`. When you set this property to `'Auto'`, the System object estimates appropriate values for the camera position, orientation, and view angle to show all tracks. When you set this property to `'Custom'`, you can set the camera position, orientation, and angles using camera properties or the camera toolbar. When you set this property to `'Radar'`, the System object determines the camera position, orientation, and angles from the radar position and the radar beam steering direction. This property is tunable.

Example: `'Radar'`

Data Types: `char`

`CameraPosition` — Camera position

`[x,y,z]` vector of real-values

Camera position, specified as an `[x,y,z]` vector of real values. Units are in meters. This property applies when you set `CameraPerspective` to `'Custom'`. When you do not specify this property, the System object chooses values based on your display configuration. This property is tunable.

Example: `[100,50,40]`

Data Types: `double`

`CameraOrientation` — Camera orientation

`[pan,tilt,roll]` vector of positive, real values

Camera orientation, specified as a `[pan,tilt,roll]` vector of positive, real values. Units are in degrees. Pan and roll angles take values from *–180°* to *180°*. The tilt angle takes values from *–90°* to *90°*. Camera rotations are performed in the order: pan, tilt, and roll. This property applies when you set `CameraPerspective` to `'Custom'`. When you do not specify this property, the System object chooses values based on your display configuration. This property is tunable.

Example: `[180,45,30]`

Data Types: `double`

`CameraViewAngle` — Camera view angle

real-valued scalar from 0° to 360°

Camera view angle, specified as a real-valued scalar. Units are in degrees. View angle values are in the range 0° to 360°. This property applies when you set `CameraPerspective` to `'Custom'`. When you do not specify this property, the System object chooses values based on your display configuration. This property is tunable.

Example: `75`

Data Types: `double`

`ShowLegend` — Show viewer legend

`false` (default) | `true`

Option to show the viewer legend, specified as `false` or `true`. This property is tunable.

Example: `true`

Data Types: `logical`

`ShowGround` — Show ground plane of scenario

`true` (default) | `false`

Option to show the ground plane of the viewer scenario, specified as `true` or `false`. This property is tunable.

Example: `false`

Data Types: `logical`

`ShowName` — Option to annotate radar and target tracks with names

`true` (default) | `false`

Annotate radar and target tracks with names, specified as `true` or `false`. You can define custom platform names using `PlatformNames`. This property is tunable.

Example: `false`

Data Types: `logical`

`ShowPosition` — Annotate radar and target tracks with positions
`false` (default) | `true`

Option to annotate radar and target tracks with positions, specified as `false` or `true`. This property is tunable.

Example: `true`

Data Types: `logical`

`ShowRange` — Annotate radar and target tracks with ranges
`false` (default) | `true`

Option to annotate radar and target tracks with the range from the reference radar, specified as `false` or `true`. This property is tunable.

Example: `true`

Data Types: `logical`

`ShowAltitude` — Annotate radar and target tracks with altitude
`false` (default) | `true`

Option to annotate radar and target tracks with altitude, specified as `false` or `true`. This property is tunable.

Example: `true`

Data Types: `logical`

`ShowSpeed` — Annotate radar and target tracks with speed
`false` (default) | `true`

Option to annotate radar and target tracks with speed, specified as `false` or `true`. This property is tunable.

Example: `true`

Data Types: `logical`

`ShowRadialSpeed` — Annotate radar and target tracks with radial speed

`false` (default) | `true`

Option to annotate radar and target tracks with radial speed, specified as `false` or `true`. Radial speed is relative to the reference radar. This property is tunable.

Example: `true`

Data Types: `logical`

`ShowAzEl` — Annotate radar and target tracks with azimuth and elevation

`false` (default) | `true`

Option to annotate radar and target tracks with azimuth and elevation angles relative to the reference radar, specified as `false` or `true`. This property is tunable.

Example: `true`

Data Types: `logical`

`Position` — Viewer window size and position

`[left bottom width height]` vector of positive, real values

Scenario viewer window size and position, specified as a `[left bottom width height]` vector of positive, real values. Units are in pixels.

- `left` sets the position of the left edge of the window.
- `bottom` sets the position of the bottom edge of the window.
- `width` sets the width of the window.
- `height` sets the height of the window.

When you do not specify this property, the window is positioned at the center of the screen, with `width` and `height` taking the values `410` and `300` pixels, respectively. This property is tunable.

Example: `[100,200,800,500]`

Data Types: `double`

`ReducePlotRate` — Enable reduced plot rate

`true` (default) | `false`

Option to reduce the plot rate to improve performance, specified as `true` or `false`. Set this property to `true` to update the viewer at a reduced rate. Set this property to `false`

to update the viewer with each call to the phased.ScenarioViewer.step method. This mode adversely affects viewer performance. This property is tunable.

Example: `false`

Data Types: `logical`

Methods

hide	Hide scenario viewer window
reset	Reset state of the System object
show	Show scenario viewer window
step	Update scenario viewer display

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

View Tracks of Stationary Radar and One Target

Visualize the tracks of a radar and a single airplane target. The radar is stationary and the airplane is moving in a straight line. Maintain the radar beam pointing at the airplane.

Create the radar and airplane platform System objects. Set the update rate to 0.1 s.

```
updateRate = 0.1;
radarPlatform = phased.Platform(...
    'InitialPosition',[0;0;10], ...
```

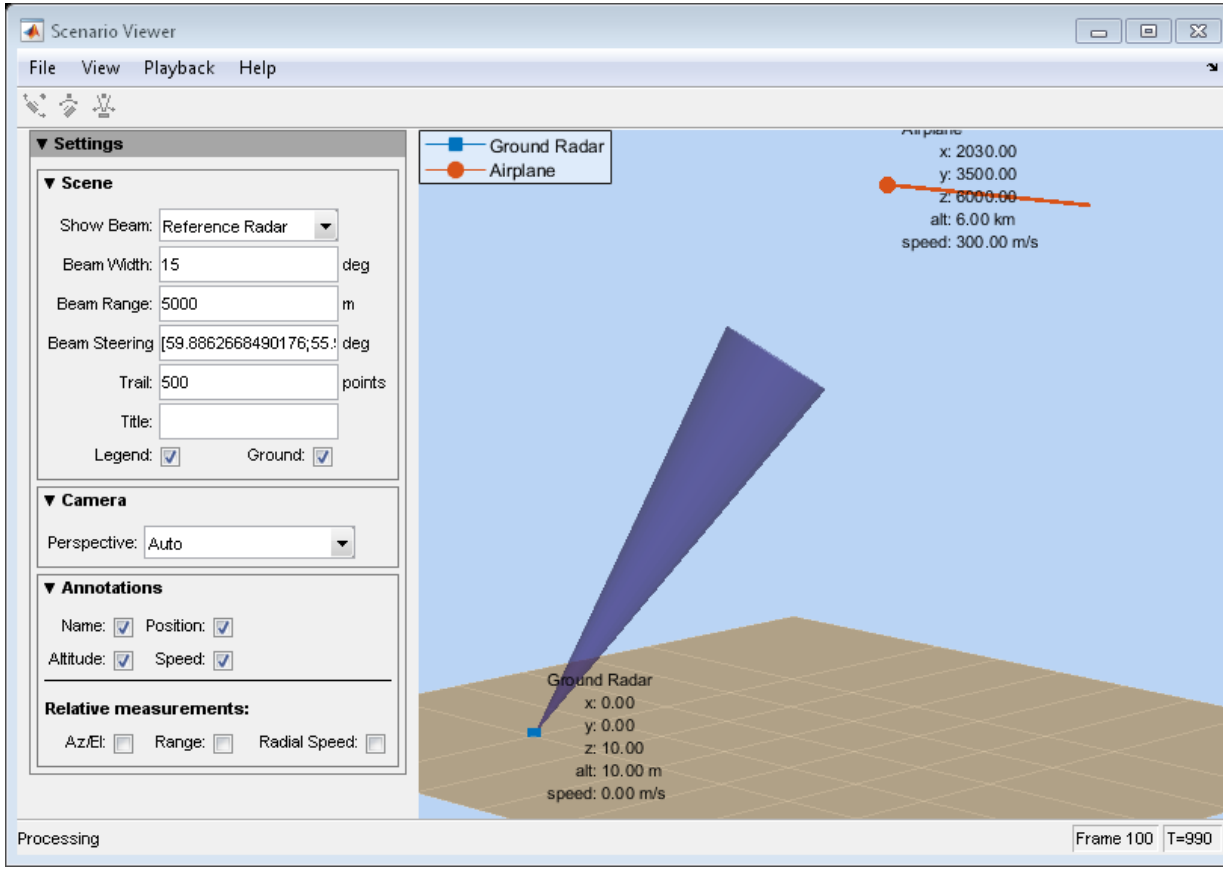
```
    'Velocity',[0;0;0]);
airplanePlatforms = phased.Platform(...
    'InitialPosition',[5000.0;3500.0;6000.0],...
    'Velocity',[-300;0;0]);
```

Create the `phased.ScenarioViewer` System object™. Show the radar beam and annotate the tracks with position, speed, and altitude.

```
sSV = phased.ScenarioViewer('BeamRange',5000.0,'UpdateRate',updateRate,...
    'PlatformNames',{'Ground Radar','Airplane'},'ShowPosition',true,...
    'ShowSpeed',true,'ShowAltitude',true,'ShowLegend',true);
```

Run the scenario. At each step, compute the angle to the target. Then, use that angle to steer the radar beam toward the target.

```
for i = 1:100
    [radar_pos,radar_vel] = step(radarPlatform,updateRate);
    [tgt_pos,tgt_vel] = step(airplanePlatforms,updateRate);
    [rng,ang] = rangeangle(tgt_pos,radar_pos);
    sSV.BeamSteering = ang;
    step(sSV,radar_pos,radar_vel,tgt_pos,tgt_vel);
    pause(0.1);
end
```



View Tracks of Airborne Radar and Ground Target

Visualize the tracks of an airborne radar and a ground vehicle target. The airborne radar is carried by a drone flying at 5 km altitude.

Create the drone radar and ground vehicle using `phased.Platform` System objects. Set the update rate to 0.1 s.

```
updateRate = 0.1;
drone = phased.Platform(...
    'InitialPosition',[100;1000;5000], ...
    'Velocity',[400;0;0]);
vehicle = phased.Platform('MotionModel','Acceleration',...
```

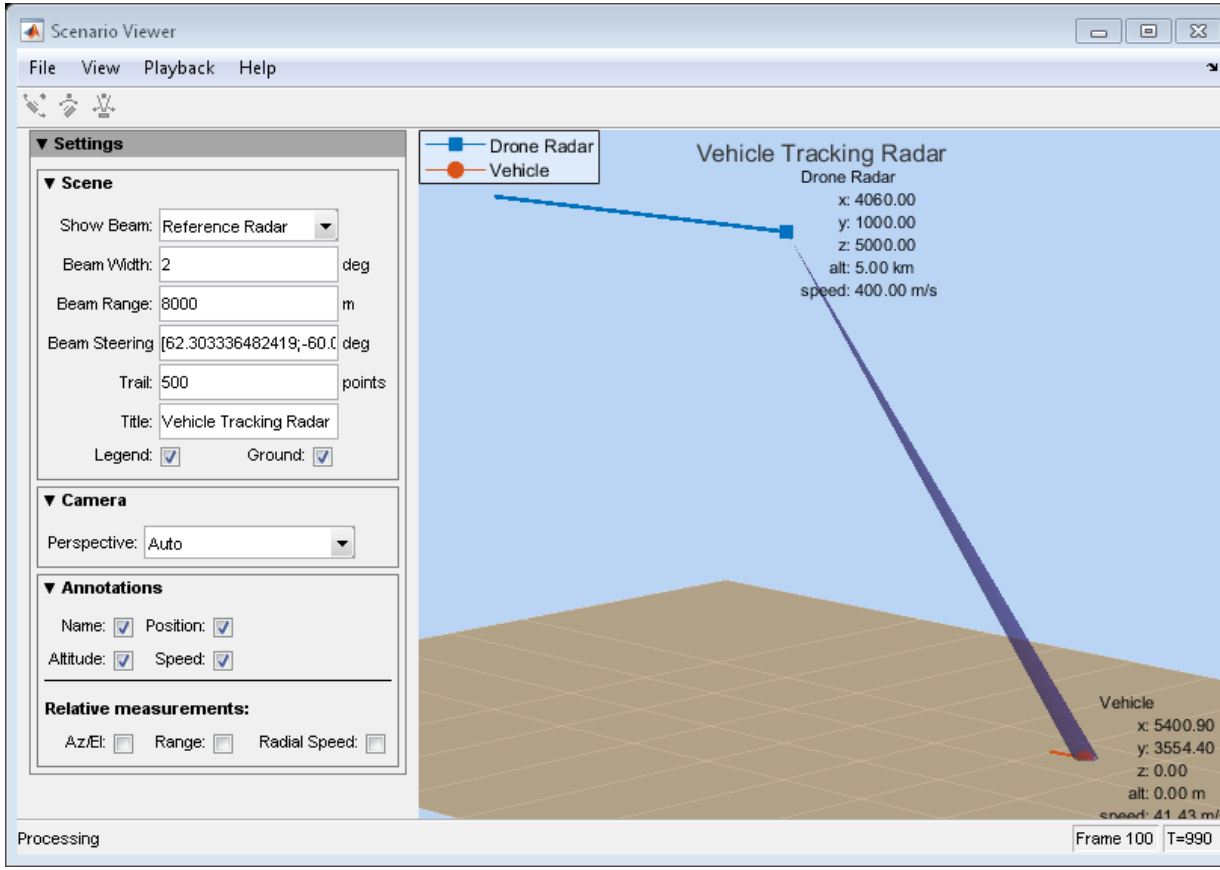
```
    'InitialPosition',[5000.0;3500.0;0.0],...
    'InitialVelocity',[40;5;0],'Acceleration',[0.1;0.1;0]);
```

Create the `phased.ScenarioViewer` System object™. Show the radar beam and annotate the tracks with position, speed, and, altitude.

```
viewer = phased.ScenarioViewer('BeamRange',8000.0,'BeamWidth',2,'UpdateRate',updateRate
    'PlatformNames',{'Drone Radar','Vehicle'},'ShowPosition',true,...
    'ShowSpeed',true,'ShowAltitude',true,'ShowLegend',true,'Title','Vehicle Tracking Ra
```

Run the scenario. At each step, compute the angle to the target. Then, use that angle to steer the radar beam toward the target.

```
for i = 1:100
    [radar_pos,radar_vel] = step(drone,updateRate);
    [tgt_pos,tgt_vel] = step(vehicle,updateRate);
    [rng,ang] = rangeangle(tgt_pos,radar_pos);
    viewer.BeamSteering = ang;
    viewer(radar_pos,radar_vel,tgt_pos,tgt_vel)
    pause(.1)
end
```



Visualize Multiplatform Scenario

This example shows how to create and display a multiplatform scenario containing a ground-based stationary radar, a turning airplane, a constant-velocity airplane, and a moving ground vehicle. The turning airplane follows a parabolic flight path while descending at a rate of 20 m/s.

Specify the scenario refresh rate at 0.5 Hz. For 150 steps, the time duration of the scenario is 300 s.

```
updateRate = 0.5;
N = 150;
```

Set up the turning airplane using the `Acceleration` model of the `phased.Platform` System object™. Specify the initial position of the airplane by range and azimuth from the ground-based radar and its elevation. The airplane is 10 km from the radar at 60° azimuth and has an altitude of 6 km. The airplane is accelerating at 10 m/s^2 in the negative *x*-direction.

```
airplane1range = 10.0e3;
airplane1Azimuth = 60.0;
airplane1alt = 6.0e3;
airplane1Pos0 = [cosd(airplane1Azimuth)*airplane1range;...
    sind(airplane1Azimuth)*airplane1range;airplane1alt];
airplane1Vel0 = [400.0;-100.0;-20];
airplane1Accel = [-10.0;0.0;0.0];
airplane1platform = phased.Platform('MotionModel','Acceleration',...
    'AccelerationSource','Input port','InitialPosition',airplane1Pos0,...
    'InitialVelocity',airplane1Vel0,'OrientationAxesOutputPort',true,...
    'InitialOrientationAxes',eye(3));
```

Set up the stationary ground radar at the origin of the global coordinate system. To simulate a rotating radar, change the ground radar beam steering angle in the processing loop.

```
groundRadarPos = [0,0,0]';
groundRadarVel = [0,0,0]';
groundradarplatform = phased.Platform('MotionModel','Velocity',...
    'InitialPosition',groundRadarPos,'Velocity',groundRadarVel,...
    'InitialOrientationAxes',eye(3));
```

Set up the ground vehicle to move at a constant velocity.

```
groundVehiclePos = [5e3,2e3,0]';
groundVehicleVel = [50,50,0]';
groundvehicleplatform = phased.Platform('MotionModel','Velocity',...
    'InitialPosition',groundVehiclePos,'Velocity',groundVehicleVel,...
    'InitialOrientationAxes',eye(3));
```

Set up the second airplane to also move at constant velocity.

```
airplane2Pos = [8.5e3,1e3,6000]';
airplane2Vel = [-300,100,20]';
airplane2platform = phased.Platform('MotionModel','Velocity',...
    'InitialPosition',airplane2Pos,'Velocity',airplane2Vel,...
    'InitialOrientationAxes',eye(3));
```

Set up the scenario viewer. Specity the radar as having a beam range of 8 km, a vertical beam width of 30°, and a horizontal beam width of 2°. Annotate the tracks with position, speed, altitude, and range.

```
BeamSteering = [0;50];
viewer = phased.ScenarioViewer('BeamRange',8.0e3,'BeamWidth',[2;30],'UpdateRate',update
    'PlatformNames',{'Ground Radar','Turning Airplane','Vehicle','Airplane 2'},'ShowPos
    'ShowSpeed',true,'ShowAltitude',true,'ShowLegend',true,'ShowRange',true,...
    'Title','Multiplatform Scenario','BeamSteering',BeamSteering);
```

Step through the display processing loop, updating radar and target positions. Rotate the ground-based radar steering angle by four degrees at each step.

```
for n = 1:N
    [groundRadarPos,groundRadarVel] = groundradarplatform(updateRate);
    [airplane1Pos,airplane1Vel,airplane1Axes] = airplane1platform(updateRate,airplane1A
    [vehiclePos,vehicleVel] = groundvehicleplatform(updateRate);
    [airplane2Pos,airplane2Vel] = airplane2platform(updateRate);
    viewer(groundRadarPos,groundRadarVel,[airplane1Pos,vehiclePos,airplane2Pos],...
        [airplane1Vel,vehicleVel,airplane2Vel]);
    BeamSteering = viewer.BeamSteering(1);
    BeamSteering = mod(BeamSteering + 4,360.0);
    if BeamSteering > 180.0
        BeamSteering = BeamSteering - 360.0;
    end
    viewer.BeamSteering(1) = BeamSteering;
    pause(0.2);
end
```

“Visualizing Radar and Target Trajectories in System Simulation”

Introduced in R2016a

hide

System object: phased.ScenarioViewer
Package: phased

Hide scenario viewer window

Syntax

```
hide(sSV)
```

Description

`hide(sSV)` hides the display window of the `phased.ScenarioViewer` System object, `sSV`.

Input Arguments

sSV — Scenario viewer

`phased.ScenarioViewer` System object

Scenario viewer, specified as a phased.ScenarioViewer System object.

Example: `phased.ScenarioViewer`

Introduced in R2016a

reset

System object: phased.ScenarioViewer
Package: phased

Reset state of the System object

Syntax

```
reset(sSV)
```

Description

`reset(sSV)` resets the internal state of the `phased.ScenarioViewer` System object, `sSV`, to its initial value.

Input Arguments

sSV — Scenario viewer

`phased.ScenarioViewer` System object

Scenario viewer, specified as a phased.ScenarioViewer System object.

Example: `phased.ScenarioViewer`

Introduced in R2016a

show

System object: phased.ScenarioViewer
Package: phased

Show scenario viewer window

Syntax

```
show(sSV)
```

Description

`show(sSV)` shows the display window of the `phased.ScenarioViewer` System object, `sSV`.

Input Arguments

sSV — Scenario viewer

`phased.ScenarioViewer` System object

Scenario viewer, specified as a phased.ScenarioViewer System object.

Example: `phased.ScenarioViewer`

Introduced in R2016a

step

System object: phased.ScenarioViewer
Package: phased

Update scenario viewer display

Syntax

```
step(sSV,radar_pos,tgt_pos)
step(sSV,radar_pos,tgt_pos,radar_velocity,tgt_velocity)
step(sSV,radar_pos,radar_laxes,tgt_pos,tgt_laxes)
step(sSV,radar_pos,radar_velocity,radar_laxes,tgt_pos,tgt_velocity,
tgt_laxes)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`step(sSV,radar_pos,tgt_pos)` updates the scenario viewer display with new radar positions, `radar_pos`, and target positions, `tgt_pos`. This syntax applies when `VelocityInputPort` and `OrientationInputPort` are set to `false`.

`step(sSV,radar_pos,tgt_pos,radar_velocity,tgt_velocity)` also specifies the radar velocity, `radar_velocity`, and target velocity, `tgt_velocity`. This syntax applies when `VelocityInputPort` is set to `true` and `OrientationInputPort` is set to `false`.

`step(sSV,radar_pos,radar_laxes,tgt_pos,tgt_laxes)` also specifies the radar orientation axes, `radar_laxes`, and the target orientation axes, `tgt_laxes`. This syntax applies when `VelocityInputPort` is set to `false` and `OrientationInputPort` is set to `true`.

`step(sSV,radar_pos,radar_velocity,radar_laxes,tgt_pos,tgt_velocity, tgt_laxes)` also specifies velocity and orientation axes when `VelocityInputPort` and `OrientationInputPort` are set to `true`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`sSV` — Scenario viewer

`phased.ScenarioViewer` System object

Scenario viewer, specified as a phased.ScenarioViewer System object.

Example: `phased.ScenarioViewer`

`radar_pos` — Radar positions

real-valued 3-by-*N* matrix

Radar positions, specified as a real-valued 3-by-*N* matrix. *N* is the number of radar tracks and must be equal to or greater than one. Each column has the form `[x;y;z]`. Position units are in meters.

Example: `[100,250,75;0,20,49;300,5,120]`

Data Types: `double`

`tgt_pos` — Target positions

real-valued 3-by-*M* matrix

Target positions, specified as a real-valued 3-by-*N* matrix. *M* is the number of target tracks and must be equal to or greater than one. Each column has the form `[x;y;z]`. Position units are in meters.

Example: `[200,40;10,40;305,15]`

Data Types: `double`

`radar_velocity` — Radar velocities

real-valued 3-by-*N* matrix

Radar velocities, specified as a real-valued 3-by-*N* matrix. *N* is the number of radar tracks and must be equal to or greater than one. Each column has the form `[vx;vy;vz]`. The dimensions of `radar_velocity` must match the dimensions of `radar_pos`. Velocity units are in meters per second.

Example: `[100,10,0;4,0,7;100,500,0]`

Data Types: `double`

`tgt_velocity` — Target velocities

real-valued 3-by-*M* matrix

Target velocities, specified as a real-valued 3-by-*M* matrix. *M* is the number of target tracks and must be equal to or greater than one. Each column has the form `[vx;vy;vz]`. The dimensions of `tgt_velocity` must match the dimensions of `target_position`. Velocity units are in meters per second.

Example: `[100,10,0;4,0,7;100,500,0]`

Data Types: `double`

`radar_laxes` — Radar local coordinate axes

real-valued 3-by-3-by-*N* array

Local coordinate axes of radar, specified as a real-valued 3-by-3-by-*N* array. *N* is the number of radar tracks. Each page (third index) represents a 3-by-3 orthogonal matrix that specifies the local coordinate axes of one radar. The columns are the unit vectors that form the *x*, *y*, and *z* axes of the local coordinate system. Array units are dimensionless.

Example: `[100,10,0;4,0,7;100,500,0]`

Data Types: `double`

`tgt_laxes` — Target local coordinate axes

real-valued 3-by-3-by-*M* array

Local coordinate axes of targer, specified as a real-valued 3-by-3-by-*M* array. *M* is the number of target tracks. Each page (third index) represents a 3-by-3 orthogonal matrix that specifies the local coordinate axes of one radar. The columns are the unit vectors that form the *x*, *y*, and *z* axes of the local coordinate system. Array units are dimensionless.

Example: `[100,10,0;4,0,7;100,500,0]`

Data Types: `double`

Examples

View Tracks of Stationary Radar and One Target

Visualize the tracks of a radar and a single airplane target. The radar is stationary and the airplane is moving in a straight line. Maintain the radar beam pointing at the airplane.

Create the radar and airplane platform System objects. Set the update rate to 0.1 s.

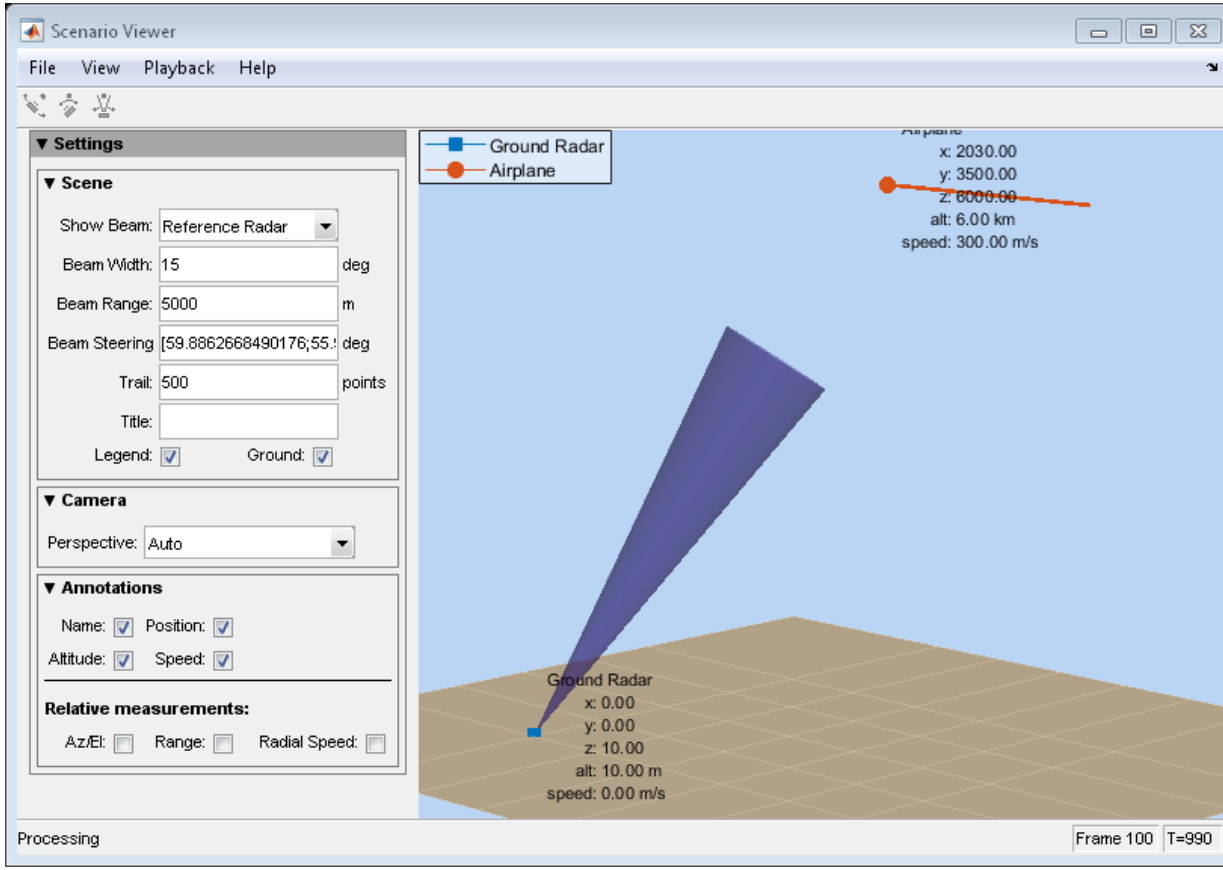
```
updateRate = 0.1;
radarPlatform = phased.Platform(...
    'InitialPosition',[0;0;10], ...
    'Velocity',[0;0;0]);
airplanePlatforms = phased.Platform(...
    'InitialPosition',[5000.0;3500.0;6000.0],...
    'Velocity',[-300;0;0]);
```

Create the `phased.ScenarioViewer` System object™. Show the radar beam and annotate the tracks with position, speed, and altitude.

```
sSV = phased.ScenarioViewer('BeamRange',5000.0,'UpdateRate',updateRate,...
    'PlatformNames',{'Ground Radar','Airplane'},'ShowPosition',true,...
    'ShowSpeed',true,'ShowAltitude',true,'ShowLegend',true);
```

Run the scenario. At each step, compute the angle to the target. Then, use that angle to steer the radar beam toward the target.

```
for i = 1:100
    [radar_pos,radar_vel] = step(radarPlatform,updateRate);
    [tgt_pos,tgt_vel] = step(airplanePlatforms,updateRate);
    [rng,ang] = rangeangle(tgt_pos,radar_pos);
    sSV.BeamSteering = ang;
    step(sSV,radar_pos,radar_vel,tgt_pos,tgt_vel);
    pause(0.1);
end
```



View Tracks of Airborne Radar and Ground Target

Visualize the tracks of an airborne radar and a ground vehicle target. The airborne radar is carried by a drone flying at 5 km altitude.

Create the drone radar and ground vehicle using `phased.Platform` System objects. Set the update rate to 0.1 s.

```
updateRate = 0.1;
drone = phased.Platform(...
    'InitialPosition',[100;1000;5000], ...
    'Velocity',[400;0;0]);
vehicle = phased.Platform('MotionModel','Acceleration',...
```

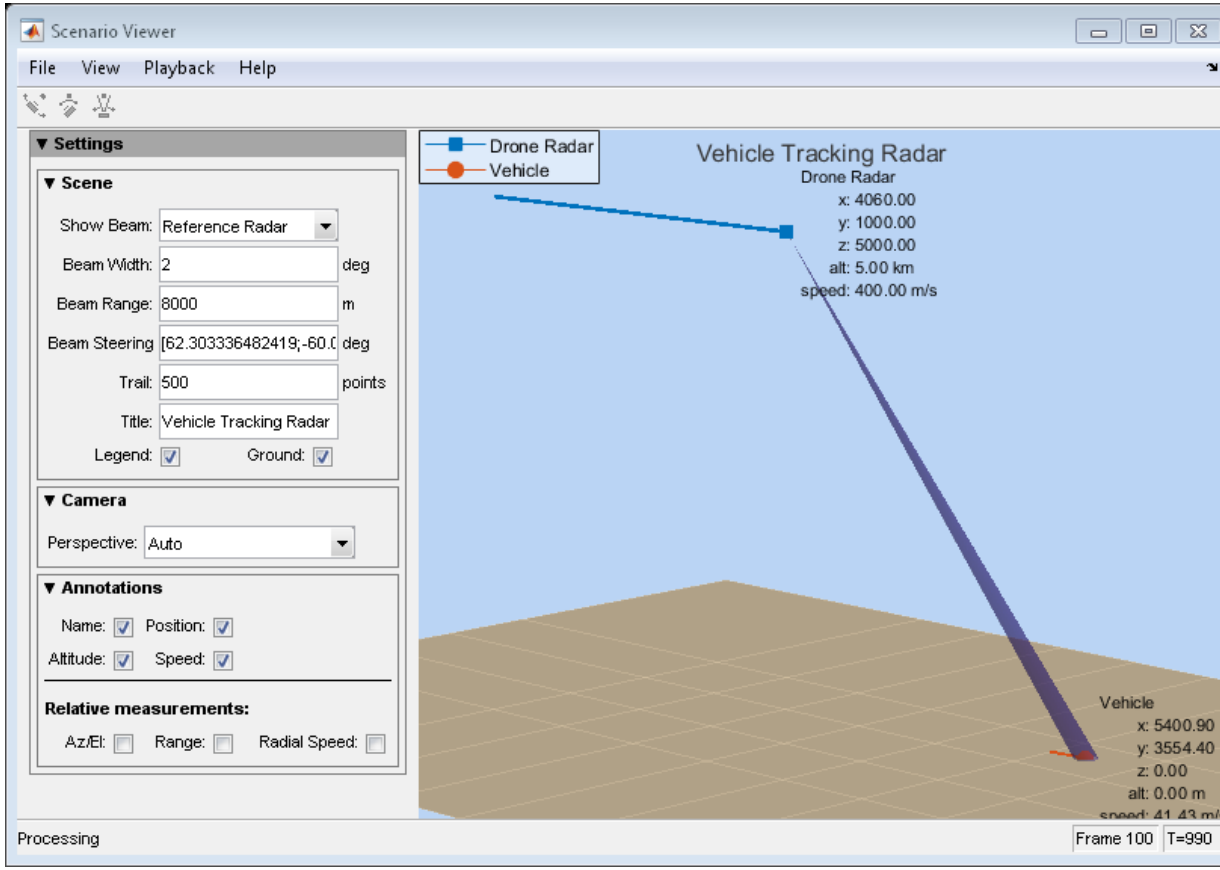
```
    'InitialPosition',[5000.0;3500.0;0.0],...
    'InitialVelocity',[40;5;0],'Acceleration',[0.1;0.1;0]);
```

Create the `phased.ScenarioViewer` System object™. Show the radar beam and annotate the tracks with position, speed, and, altitude.

```
viewer = phased.ScenarioViewer('BeamRange',8000.0,'BeamWidth',2,'UpdateRate',updateRate
    'PlatformNames',{'Drone Radar','Vehicle'},'ShowPosition',true,...
    'ShowSpeed',true,'ShowAltitude',true,'ShowLegend',true,'Title','Vehicle Tracking Ra
```

Run the scenario. At each step, compute the angle to the target. Then, use that angle to steer the radar beam toward the target.

```
for i = 1:100
    [radar_pos,radar_vel] = step(drone,updateRate);
    [tgt_pos,tgt_vel] = step(vehicle,updateRate);
    [rng,ang] = rangeangle(tgt_pos,radar_pos);
    viewer.BeamSteering = ang;
    viewer(radar_pos,radar_vel,tgt_pos,tgt_vel)
    pause(.1)
end
```



Visualize Multiplatform Scenario

This example shows how to create and display a multiplatform scenario containing a ground-based stationary radar, a turning airplane, a constant-velocity airplane, and a moving ground vehicle. The turning airplane follows a parabolic flight path while descending at a rate of 20 m/s.

Specify the scenario refresh rate at 0.5 Hz. For 150 steps, the time duration of the scenario is 300 s.

```
updateRate = 0.5;
N = 150;
```

Set up the turning airplane using the `Acceleration` model of the `phased.Platform` System object™. Specify the initial position of the airplane by range and azimuth from the ground-based radar and its elevation. The airplane is 10 km from the radar at 60° azimuth and has an altitude of 6 km. The airplane is accelerating at 10 m/s^2 in the negative *x*-direction.

```
airplane1range = 10.0e3;
airplane1Azimuth = 60.0;
airplane1alt = 6.0e3;
airplane1Pos0 = [cosd(airplane1Azimuth)*airplane1range;...
    sind(airplane1Azimuth)*airplane1range;airplane1alt];
airplane1Vel0 = [400.0;-100.0;-20];
airplane1Accel = [-10.0;0.0;0.0];
airplane1platform = phased.Platform('MotionModel','Acceleration',...
    'AccelerationSource','Input port','InitialPosition',airplane1Pos0,...
    'InitialVelocity',airplane1Vel0,'OrientationAxesOutputPort',true,...
    'InitialOrientationAxes',eye(3));
```

Set up the stationary ground radar at the origin of the global coordinate system. To simulate a rotating radar, change the ground radar beam steering angle in the processing loop.

```
groundRadarPos = [0,0,0]';
groundRadarVel = [0,0,0]';
groundradarplatform = phased.Platform('MotionModel','Velocity',...
    'InitialPosition',groundRadarPos,'Velocity',groundRadarVel,...
    'InitialOrientationAxes',eye(3));
```

Set up the ground vehicle to move at a constant velocity.

```
groundVehiclePos = [5e3,2e3,0]';
groundVehicleVel = [50,50,0]';
groundvehicleplatform = phased.Platform('MotionModel','Velocity',...
    'InitialPosition',groundVehiclePos,'Velocity',groundVehicleVel,...
    'InitialOrientationAxes',eye(3));
```

Set up the second airplane to also move at constant velocity.

```
airplane2Pos = [8.5e3,1e3,6000]';
airplane2Vel = [-300,100,20]';
airplane2platform = phased.Platform('MotionModel','Velocity',...
    'InitialPosition',airplane2Pos,'Velocity',airplane2Vel,...
    'InitialOrientationAxes',eye(3));
```

Set up the scenario viewer. Specity the radar as having a beam range of 8 km, a vertical beam width of 30°, and a horizontal beam width of 2°. Annotate the tracks with position, speed, altitude, and range.

```
BeamSteering = [0;50];
viewer = phased.ScenarioViewer('BeamRange',8.0e3,'BeamWidth',[2;30],'UpdateRate',update
    'PlatformNames',{'Ground Radar','Turning Airplane','Vehicle','Airplane 2'},'ShowPos
    'ShowSpeed',true,'ShowAltitude',true,'ShowLegend',true,'ShowRange',true,...
    'Title','Multiplatform Scenario','BeamSteering',BeamSteering);
```

Step through the display processing loop, updating radar and target positions. Rotate the ground-based radar steering angle by four degrees at each step.

```
for n = 1:N
    [groundRadarPos,groundRadarVel] = groundradarplatform(updateRate);
    [airplane1Pos,airplane1Vel,airplane1Axes] = airplane1platform(updateRate,airplane1A
    [vehiclePos,vehicleVel] = groundvehicleplatform(updateRate);
    [airplane2Pos,airplane2Vel] = airplane2platform(updateRate);
    viewer(groundRadarPos,groundRadarVel,[airplane1Pos,vehiclePos,airplane2Pos],...
        [airplane1Vel,vehicleVel,airplane2Vel]);
    BeamSteering = viewer.BeamSteering(1);
    BeamSteering = mod(BeamSteering + 4,360.0);
    if BeamSteering > 180.0
        BeamSteering = BeamSteering - 360.0;
    end
    viewer.BeamSteering(1) = BeamSteering;
    pause(0.2);
end
```

Introduced in R2016a

phased.STAPSMIBeamformer System object

Package: phased

Sample matrix inversion (SMI) beamformer

Description

The `SMIBeamformer` object implements a sample matrix inversion space-time adaptive beamformer. The beamformer works on the space-time covariance matrix.

To compute the space-time beamformed signal:

1. Define and set up your SMI beamformer. See "Construction" on page 1-1744.
2. Call step to execute the SMI beamformer algorithm according to the properties of `phased.STAPSMIBeamformer`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.STAPSMIBeamformer` creates a sample matrix inversion (SMI) beamformer System object, `H`. The object performs the SMI space-time adaptive processing (STAP) on the input data.

`H = phased.STAPSMIBeamformer(Name,Value)` creates an SMI object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`SensorArray`

Sensor array

Sensor array specified as an array System object belonging to the `phased` package. A sensor array can contain subarrays.

Default: phased.ULA with default property values

`PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

Default: Speed of light

`OperatingFrequency`

System operating frequency

Specify the operating frequency of the system in hertz as a positive scalar. The default value corresponds to 300 MHz.

Default: `3e8`

`PRF`

Pulse repetition frequency

Specify the pulse repetition frequency (PRF) of the received signal in hertz as a scalar.

Default: `1`

`DirectionSource`

Source of targeting direction

Specify whether the targeting direction for the STAP processor comes from the `Direction` property of this object or from an input argument in step. Values of this property are:

`'Property'`	The `Direction` property of this object specifies the targeting direction.
`'Input port'`	An input argument in each invocation of `step` specifies the targeting direction.

Default: `'Property'`

`Direction`

Targeting direction

Specify the targeting direction of the SMI processor as a column vector of length 2. The direction is specified in the format of `[AzimuthAngle; ElevationAngle]` (in degrees). Azimuth angle should be between –180 and 180. Elevation angle should be between –90 and 90. This property applies when you set the `DirectionSource` property to `'Property'`.

Default: `[0; 0]`

`NumPhaseShifterBits`

Number of phase shifter quantization bits

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

Default: `0`

`DopplerSource`

Source of targeting Doppler

Specify whether the targeting Doppler for the STAP processor comes from the `Doppler` property of this object or from an input argument in step. Values of this property are:

`'Property'`	The `Doppler` property of this object specifies the Doppler.
`'Input port'`	An input argument in each invocation of `step` specifies the Doppler.

Default: `'Property'`

`Doppler`

Targeting Doppler frequency

Specify the targeting Doppler of the STAP processor as a scalar. This property applies when you set the `DopplerSource` property to `'Property'`.

Default: `0`

`WeightsOutputPort`

Output processing weights

To obtain the weights used in the STAP processor, set this property to `true` and use the corresponding output argument when invoking step. If you do not want to obtain the weights, set this property to `false`.

Default: `false`

`NumGuardCells`

Number of guarding cells

Specify the number of guard cells used in the training as an even integer. This property specifies the total number of cells on both sides of the cell under test.

Default: `2`, indicating that there is one guard cell at both the front and back of the cell under test

`NumTrainingCells`

Number of training cells

Specify the number of training cells used in the training as an even integer. Whenever possible, the training cells are equally divided before and after the cell under test.

Default: `2`, indicating that there is one training cell at both the front and back of the cell under test

Methods

step	Perform SMI STAP processing on input data

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Process Data Cube Using SMI

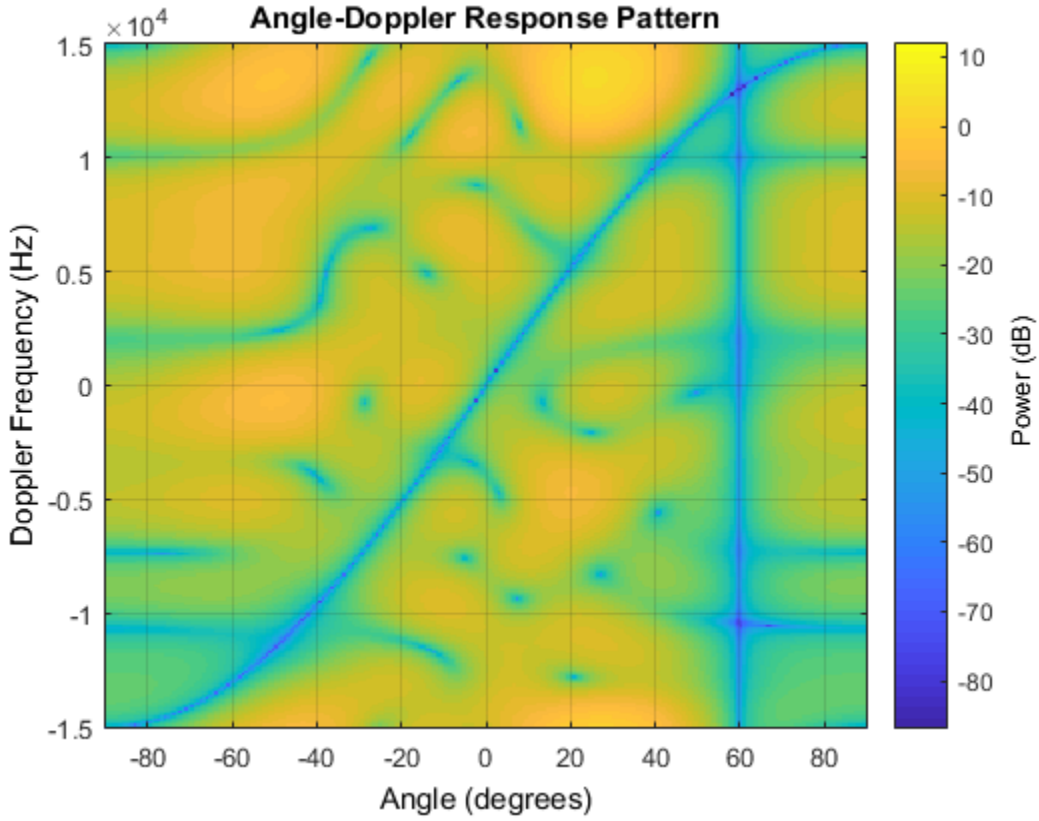
Process a data cube using an SMI beamformer. The weights are calculated for the 71st cell of a collected data cube pointing in the azimuth and elevation direction *(45°,-35°)* and with a Doppler of 12.980 kHz.

Load the cube data and create the SMI beamformer.

```
load STAPExampleData;
beamformer = phased.STAPSMIBeamformer('SensorArray',STAPEx_HArray, ...
    'PRF',STAPEx_PRF,'PropagationSpeed',STAPEx_PropagationSpeed, ...
    'OperatingFrequency',STAPEx_OperatingFrequency, ...
    'NumTrainingCells',100,'WeightsOutputPort',true, ...
    'DirectionSource','Input port','DopplerSource','Input port');
[y,w] = beamformer(STAPEx_ReceivePulse,71,[45;-35],12.980e3);
```

Plot the angle-doppler response.

```
response = phased.AngleDopplerResponse( ...
    'SensorArray',beamformer.SensorArray, ...
    'OperatingFrequency',beamformer.OperatingFrequency, ...
    'PRF',beamformer.PRF,'PropagationSpeed',beamformer.PropagationSpeed);
plotResponse(response,w)
```



Algorithms

The optimum beamformer weights are

$$w = kR^{-1}v$$

where:

- k is a scalar
- R represents the space-time covariance matrix
- v indicates the space-time steering vector

Because the space-time covariance matrix is unknown, you must estimate that matrix from the data. The sample matrix inversion (SMI) algorithm estimates the covariance matrix by designating a number of range gates to be training cells. Because you use the training cells to estimate the interference covariance, these cells should not contain target returns. To prevent target returns from contaminating the estimate of the interference covariance, you can specify insertion of a number of guard cells before and after the designated target cell.

To use the general algorithm for estimating the space-time covariance matrix:

1. Assume you have a M-by-N-by-K matrix. M represents the number of slow-time samples, and N is the number of array sensors. K is the number of training cells (range gates for training). Also assume that the number of training cells is an even integer and that you can designate K/2 training cells before and after the target range gate excluding the guard cells. Reshape the M-by-N-by-K matrix into a MN-by-K matrix by letting X denote the MN-by-K matrix.
2. Estimate the space-time covariance matrix as

   $$\frac{1}{K}XX^H$$

3. Invert the space-time covariance matrix estimate.
4. Obtain the beamforming weights by multiplying the sample space-time covariance matrix inverse by the space-time steering vector.

Introduced in R2012a

step

System object: phased.STAPSMIBeamformer
Package: phased

Perform SMI STAP processing on input data

Syntax

```
Y = step(H,X,CUTIDX)
Y = step(H,X,CUTIDX,ANG)
Y = step(H,X,CUTIDX,DOP)
[Y,W] = step( ___ )
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X,CUTIDX)` applies SMI processing to the input data, `X`. `X` must be a 3-dimensional M-by-N-by-P numeric array whose dimensions are (range, channels, pulses). The processing weights are calculated according to the range cell specified by `CUTIDX`. The targeting direction and the targeting Doppler are specified by `Direction` and `Doppler` properties, respectively. `Y` is a column vector of length M. This syntax is available when the `DirectionSource` property is `'Property'` and the `DopplerSource` property is `'Property'`.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

`Y = step(H,X,CUTIDX,ANG)` uses `ANG` as the targeting direction. This syntax is available when the `DirectionSource` property is `'Input port'`. `ANG` must be a 2-by-1 vector in the form of `[AzimuthAngle; ElevationAngle]` (in degrees). The azimuth angle must be between –180 and 180. The elevation angle must be between –90 and 90.

`Y = step(H,X,CUTIDX,DOP)` uses `DOP` as the targeting Doppler frequency (in hertz). This syntax is available when the `DopplerSource` property is `'Input port'`. `DOP` must be a scalar.

You can combine optional input arguments when their enabling properties are set: `Y = step(H,X,CUTIDX,ANG,DOP)`

`[Y,W] = step( ___ )` returns the additional output, `W`, as the processing weights. This syntax is available when the `WeightsOutputPort` property is `true`. `W` is a column vector of length N*P.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Examples

Process Data Cube Using SMI

Process a data cube using an SMI beamformer. The weights are calculated for the 71st cell of a collected data cube pointing in the azimuth and elevation direction *(45°,-35°)* and with a Doppler of 12.980 kHz.

Load the cube data and create the SMI beamformer.

```
load STAPExampleData;
beamformer = phased.STAPSMIBeamformer('SensorArray',STAPEx_HArray, ...
    'PRF',STAPEx_PRF,'PropagationSpeed',STAPEx_PropagationSpeed, ...
    'OperatingFrequency',STAPEx_OperatingFrequency, ...
    'NumTrainingCells',100,'WeightsOutputPort',true, ...
    'DirectionSource','Input port','DopplerSource','Input port');
[y,w] = beamformer(STAPEx_ReceivePulse,71,[45;-35],12.980e3);
```

Plot the angle-doppler response.

```
response = phased.AngleDopplerResponse( ...
    'SensorArray',beamformer.SensorArray, ...
```

```
    'OperatingFrequency',beamformer.OperatingFrequency, ...
    'PRF',beamformer.PRF,'PropagationSpeed',beamformer.PropagationSpeed);
plotResponse(response,w)
```

phased.ShortDipoleAntennaElement System object

Package: phased

Short-dipole antenna element

Description

The `phased.ShortDipoleAntennaElement` object models a short-dipole antenna element. A short-dipole antenna is a center-fed wire whose length is much shorter than one wavelength. This antenna object only supports polarized fields.

To compute the response of the antenna element for specified directions:

1. Define and set up your short-dipole antenna element. See "Construction" on page 1-1755 .
2. Call step to compute the antenna response according to the properties of `phased.ShortDipoleAntennaElement`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`h = phased.ShortDipoleAntennaElement` creates the system object, `h`, to model a short-dipole antenna element.

`h = phased.ShortDipoleAntennaElement(Name,Value)` creates the system object, `h`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`FrequencyRange`

Antenna operating frequency range

Antenna operating frequency range specified as a 1-by-2 row vector in the form of `[LowerBound HigherBound]`. This vector defines the frequency range over which the antenna has a response. The antenna element has zero response outside this specified frequency range.

Default: `[0 1e20]`

`AxisDirection`

Dipole axis direction

Dipole axis direction, specified as one of `'X'`, `'Y'` or `'Z'`. The dipole axis defines the direction of the dipole current with respect to the local coordinate system. `'X'` specifies a dipole along the *x*-axis, `'Y'` specifies a dipole along the *y*-axis, and `'Z'` specifies a dipole along the *z*-axis.

Default: `'Z'`

Methods

directivity	Directivity of short-dipole antenna element
isPolarizationCapable	Polarization capability
pattern	Plot short-dipole antenna element directivity and patterns
patternAzimuth	Plot short-dipole antenna element directivity or pattern versus azimuth
patternElevation	Plot short-dipole antenna element directivity or pattern versus elevation
plotResponse	Plot response pattern of antenna
step	Output response of antenna element

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Short-dipole Antenna Aligned Along the Y-Axis

Specify a short-dipole antenna with the dipole oriented along the *y*-axis and operating at 250 MHz. Then, plot the 3-D responses for both the horizontal and vertical polarizations.

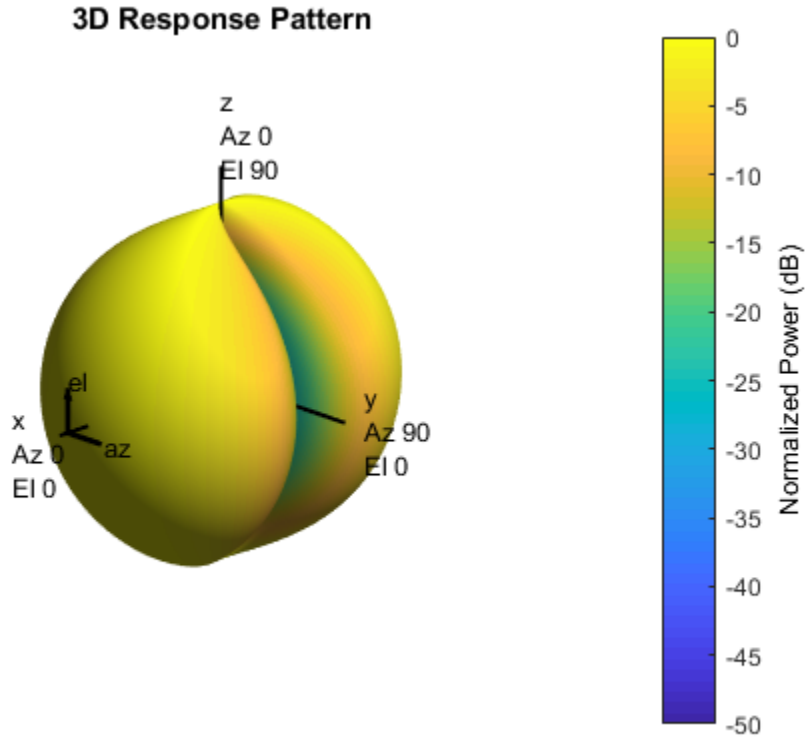
Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Create the short-dipole antenna element System object™.

```
antenna = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[100e6,600e6],'AxisDirection','Y');
fc = 250.0e6;
```

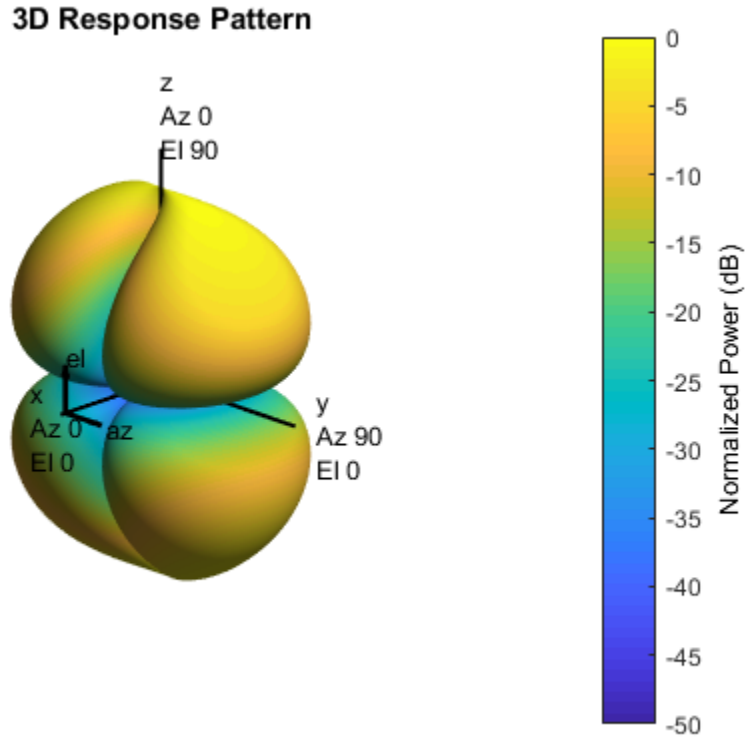
Plot the horizontal polarization response.

```
pattern(antenna,fc,-180:180,[-90:90],'CoordinateSystem','polar',...
    'Type','powerdb','Polarization','H');
```



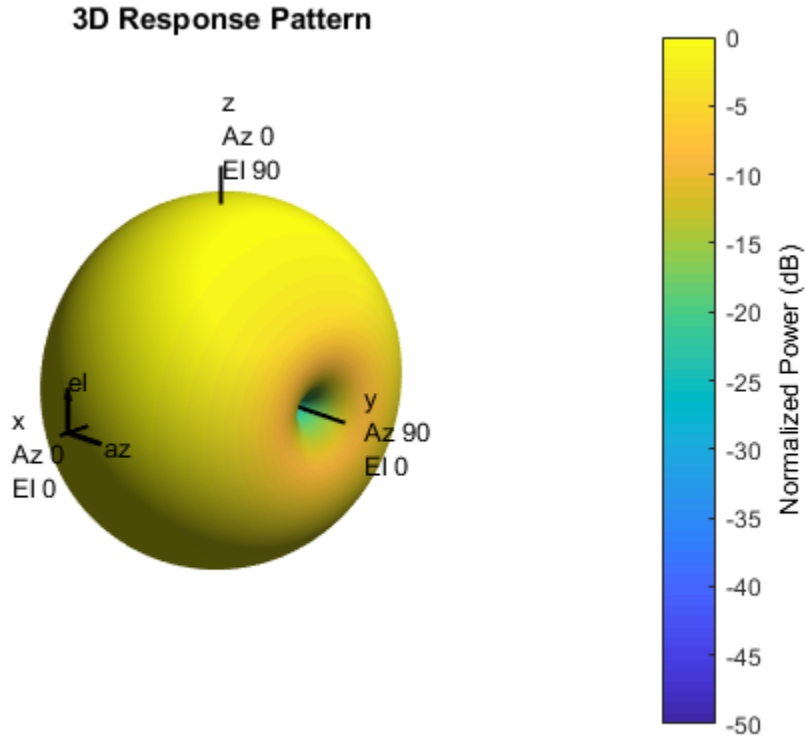
Plot the vertical polarization response.

```
pattern(antenna,fc,-180:180,[-90:90],'CoordinateSystem','polar',...
    'Type','powerdb','Polarization','V');
```



Plot the combined response.

```
pattern(antenna,fc,-180:180,[-90:90],'CoordinateSystem','polar',...
    'Type','powerdb','Polarization','C');
```



Algorithms

The total response of a short-dipole antenna element is a combination of its frequency response and spatial response. This System object calculates both responses using nearest neighbor interpolation and then multiplies the responses to form the total response.

directivity

System object: phased.ShortDipoleAntennaElement
Package: phased

Directivity of short-dipole antenna element

Syntax

```
D = directivity(H,FREQ,ANGLE)
```

Description

`D = directivity(H,FREQ,ANGLE)` returns the "Directivity (dBi)" on page 1-1765 of a short-dipole antenna element, `H`, at frequencies specified by `FREQ` and in direction angles specified by `ANGLE`.

Input Arguments

`H` — Short-dipole antenna element

System object

Short-dipole antenna element specified as a phased.ShortDipoleAntennaElement System object.

Example: `H = phased.ShortDipoleAntennaElement;`

`FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the

directivity is returned as `-Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.

- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `-Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

`ANGLE` — Angles for computing directivity

1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Angles for computing directivity, specified as a 1-by-*M* real-valued row vector or a 2-by-*M* real-valued matrix, where *M* is the number of angular directions. Angle units are in degrees. If `ANGLE` is a 2-by-*M* matrix, then each column specifies a direction in azimuth and elevation, `[az;el]`. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°.

If `ANGLE` is a 1-by-*M* vector, then each entry represents an azimuth angle, with the elevation angle assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis.

Example: `[45 60; 0 10]`

Data Types: `double`

Output Arguments

`D` — Directivity

M-by-*L* matrix

Directivity, returned as an *M*-by-*L* matrix whose columns contain the directivities at the *M* angles specified by `ANGLE`. Each column corresponds to one of the *L* frequency values specified in `FREQ`. Directivity units are in dBi.

Examples

Directivity of Short-Dipole Antenna Element

Compute the directivity of a z-directed short-dipole antenna element as a function of elevation.

Create the crossed-dipole antenna element system object.

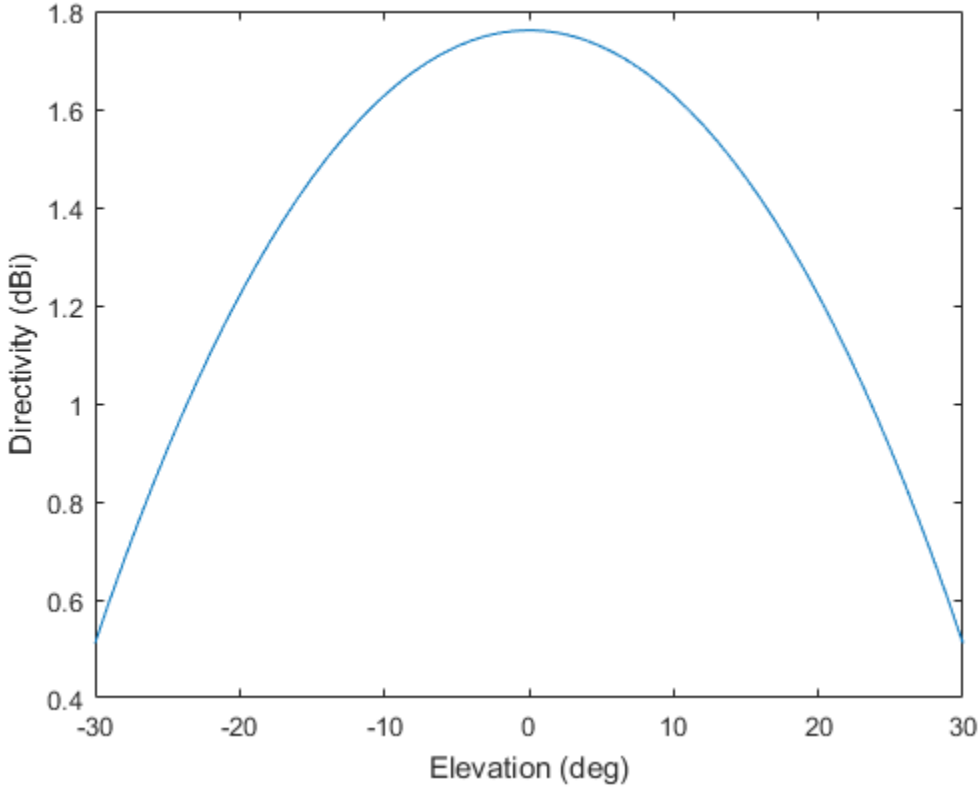
```
myAnt = phased.ShortDipoleAntennaElement;
myAnt.AxisDirection = 'Z';
myAnt.FrequencyRange = [0,10e9];
```

Select the desired angles of interest to be at constant azimuth angle at zero degrees. Set the elevation angles to center around boresight (zero degrees azimuth and zero degrees elevation). Set the frequency to 1 GHz.

```
elev = [-30:30];
azm = zeros(size(elev));
ang = [azm;elev];
freq = 1e9;
```

Plot the directivity along the constant azimuth cut.

```
d = directivity(myAnt,freq,ang);
plot(elev,d)
xlabel('Elevation (deg)');
ylabel('Directivity (dBi)');
```



Definitions

Directivity (dBi)

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on "Element directivity" and "Array directivity".

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

phased.ShortDipoleAntennaElement.plotResponse

isPolarizationCapable

System object: phased.ShortDipoleAntennaElement
Package: phased

Polarization capability

Syntax

```
flag = isPolarizationCapable(h)
```

Description

`flag = isPolarizationCapable(h)` returns a Boolean value, `flag`, indicating whether the phased.ShortDipoleAntennaElement antenna element supports polarization or not. An antenna element supports polarization if it can create or respond to polarized fields. The phased.ShortDipoleAntennaElement object always supports polarization.

Input Arguments

`h` — Short-dipole antenna element

Short-dipole antenna element specified as a phased.ShortDipoleAntennaElement System object.

Output Arguments

`flag` — Polarization-capability flag

Polarization-capability returned as a Boolean value `true` if the antenna element supports polarization or `false` if it does not. Because the short-dipole antenna element supports polarization, the returned value is always `true`.

Examples

Short-Dipole Antenna Supports Polarization

Show that a `phased.ShortDipoleAntennaElement` antenna supports polarization.

```
antenna = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[100e6 1e9],...
    'AxisDirection','Z');
isPolarizationCapable(antenna)
```

```
ans =

  logical

   1
```

The returned value of 1 shows that this antenna supports polarization.

pattern

System object: phased.ShortDipoleAntennaElement
Package: phased

Plot short-dipole antenna element directivity and patterns

Syntax

```
pattern(sElem,FREQ)
pattern(sElem,FREQ,AZ)
pattern(sElem,FREQ,AZ,EL)
pattern( ___ ,Name,Value)
[PAT,AZ_ANG,EL_ANG] = pattern( ___ )
```

Description

`pattern(sElem,FREQ)` plots the 3-D array directivity pattern (in dBi) for the element specified in `sElem`. The operating frequency is specified in `FREQ`.

`pattern(sElem,FREQ,AZ)` plots the element directivity pattern at the specified azimuth angle.

`pattern(sElem,FREQ,AZ,EL)` plots the element directivity pattern at specified azimuth and elevation angles.

`pattern( ___ ,Name,Value)` plots the element pattern with additional options specified by one or more `Name,Value` pair arguments.

`[PAT,AZ_ANG,EL_ANG] = pattern( ___ )` returns the element pattern in `PAT`. The `AZ_ANG` output contains the coordinate values corresponding to the rows of `PAT`. The `EL_ANG` output contains the coordinate values corresponding to the columns of `PAT`. If the `'CoordinateSystem'` parameter is set to `'uv'`, then `AZ_ANG` contains the *U* coordinates of the pattern and `EL_ANG` contains the *V* coordinates of the pattern. Otherwise, they are in angular units in degrees. *UV* units are dimensionless.

Note: This method replaces the `plotResponse` method. See "Convert plotResponse to pattern" on page 1-1780 for guidelines on how to use `pattern` in place of `plotResponse`.

Input Arguments

`sElem` — Short-dipole antenna element

System object

Short-dipole antenna element, specified as a phased.ShortDipoleAntennaElement System object.

Example: `sElem = phased.ShortDipoleAntennaElement;`

`FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `-Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `-Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

`AZ` — Azimuth angles

`[-180:180]` (default) | 1-by-*M* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a 1-by-*M* real-valued row vector where *M* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, this angle is positive.

Example: `[-45:2:45]`

Data Types: `double`

`EL` — Elevation angles

`[-90:90]` (default) | 1-by-*N* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a 1-by-*N* real-valued row vector where *N* is the number of desired elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and *xy*-plane. When measured towards the *z*-axis, this angle is positive.

Example: `[-75:1:70]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'CoordinateSystem'` — Plotting coordinate system

`'polar'` (default) | `'rectangular'` | `'uv'`

Plotting coordinate system of the pattern, specified as the comma-separated pair consisting of `'CoordinateSystem'` and one of `'polar'`, `'rectangular'`, or `'uv'`. When `'CoordinateSystem'` is set to `'polar'` or `'rectangular'`, the `AZ` and `EL` arguments specify the pattern azimuth and elevation, respectively. `AZ` values must lie between –180° and 180°. `EL` values must lie between –90° and 90°. If `'CoordinateSystem'` is set to `'uv'`, `AZ` and `EL` then specify *U* and *V* coordinates, respectively. `AZ` and `EL` must lie between -1 and 1.

Example: `'uv'`

Data Types: `char`

'Type' — Displayed pattern type
'directivity' (default) | 'efield' | 'power' | 'powerdb'

Displayed pattern type, specified as the comma-separated pair consisting of 'Type' and one of

- 'directivity' — directivity pattern measured in dBi.
- 'efield' — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- 'power' — power pattern of the sensor or array defined as the square of the field pattern.
- 'powerdb' — power pattern converted to dB.

Example: 'powerdb'

Data Types: char

'Normalize' — Display normalize pattern
true (default) | false

Display normalized pattern, specified as the comma-separated pair consisting of 'Normalize' and a Boolean. Set this parameter to true to display a normalized pattern. When you set 'Type' to 'directivity', this parameter does not apply. Directivity patterns are already normalized.

Example:

Data Types: logical

'PlotStyle' — Plotting style
'overlay' (default) | 'waterfall'

Plotting style, specified as the comma-separated pair consisting of 'Plotstyle' and either 'overlay' or 'waterfall'. This parameter applies when you specify multiple frequencies in FREQ in 2-D plots. You can draw 2-D plots by setting one of the arguments AZ or EL to a scalar.

Example:

Data Types: char

'Polarization' — Polarized field component
'combined' (default) | 'H' | 'V'

Polarized field component to display, specified as the comma-separated pair consisting of 'Polarization' and `'combined'`, `'H'`, or `'V'`. This parameter applies only when the sensors are polarization-capable and when the `'Type'` parameter is not set to `'directivity'`. This table shows the meaning of the display options

`'Polarization'`	Display
`'combined'`	Combined *H* and *V* polarization components
`'H'`	*H* polarization component
`'V'`	*V* polarization component

Example: `'V'`

Data Types: `char`

Output Arguments

PAT — Element pattern

M-by-*N* real-valued matrix

Element pattern, returned as an *M*-by-*N* real-valued matrix. The dimensions of PAT correspond to the dimensions of the output arguments AZ_ANG and EL_ANG.

AZ_ANG — Azimuth angles

scalar | 1-by-*M* real-valued row vector

Azimuth angles for displaying directivity or response pattern, returned as a scalar or 1-by-*M* real-valued row vector corresponding to the dimension set in AZ. The rows of PAT correspond to the values in AZ_ANG.

EL_ANG — Elevation angles

scalar | 1-by-*N* real-valued row vector

Elevation angles for displaying directivity or response, returned as a scalar or 1-by-*N* real-valued row vector corresponding to the dimension set in EL. The columns of PAT correspond to the values in EL_ANG.

Examples

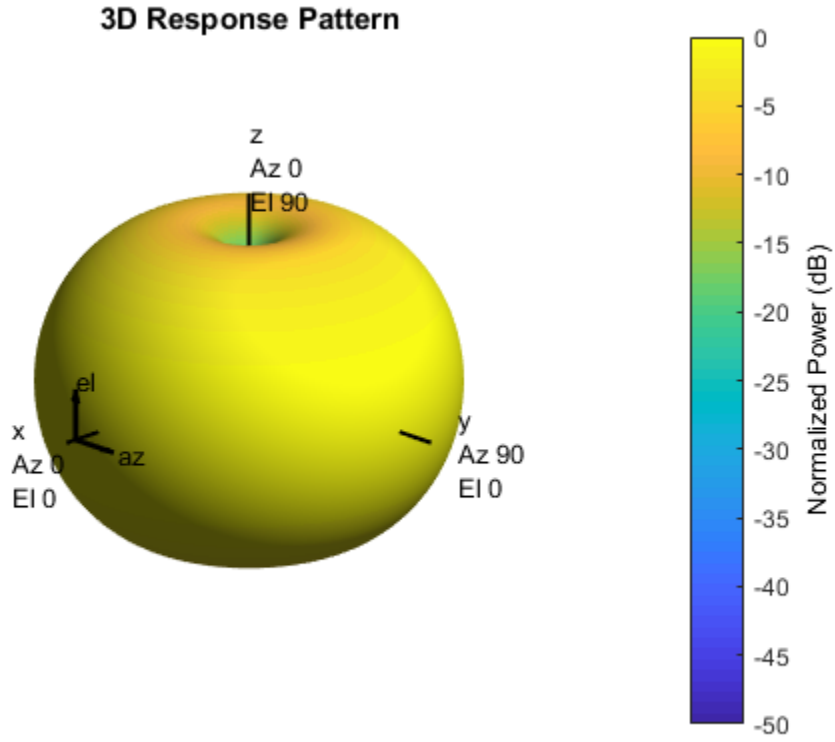
Pattern of Short-Dipole Antenna Oriented Along the Z-Axis

Specify a short-dipole antenna element with its dipole axis pointing along the z-axis. To do so, set the `'AxisDirection'` value to `'Z'`.

```
sSD = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[100 900]*1e6,'AxisDirection','Z');
```

Plot the antenna's vertical polarization power pattern at 200 MHz as a 3-D polar plot.

```
fc = 200e6;
pattern(sSD,fc,[-180:180],[-90:90],...
    'CoordinateSystem','polar',...
    'Type','powerdb',...
    'Polarization','V')
```



As the above figure shows, the antenna pattern is that of a vertically-oriented dipole and has its maximum at the equator and nulls at the poles.

Short-Dipole Antenna Element Pattern Over Selected Range

Specify a short-dipole antenna element with its dipole axis pointing along the z-axis. Then, plot the magnitude pattern over a selected range of angles. The antenna operating frequency spans the range 100 to 900 MHz.

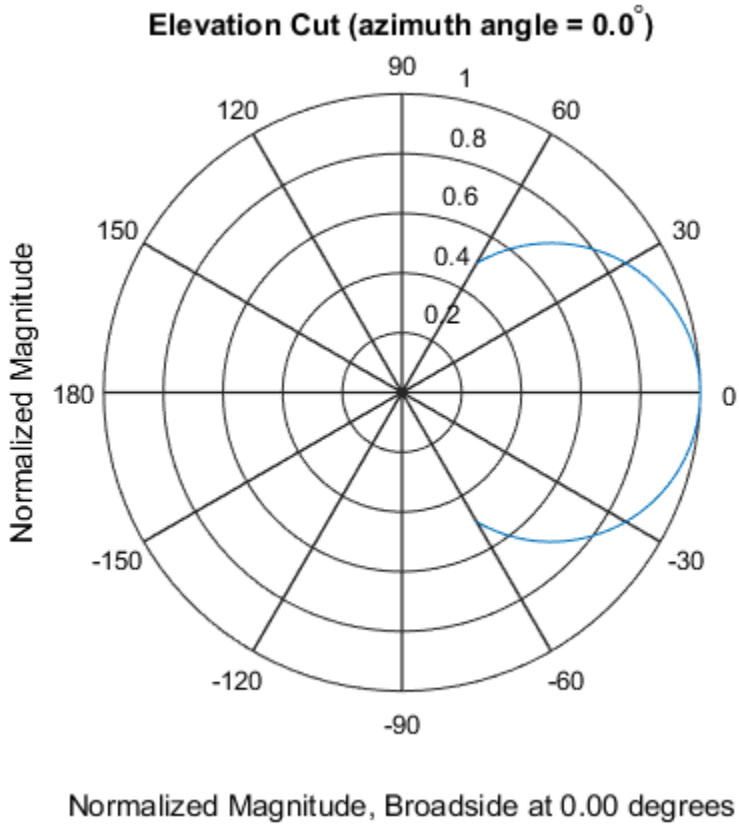
To construct a z-directed short-dipole antenna, set the `'AxisDirection'` value to `'Z'`.

```
sSD = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[100 900]*1e6,...
```

```
    'AxisDirection','Z');
```

Plot the antenna's vertical polarization response at 200 MHz as an elevation cut at zero degrees azimuth angle. Restrict the plot from -60 to 60 degrees elevation in 0.1 degree increments.

```
fc = 200e6;
pattern(sSD,fc,0,[-60:0.1:60],...
    'CoordinateSystem','polar',...
    'Type','efield',...
    'Polarization','V')
```



Short-Dipole Antenna Element Directivity

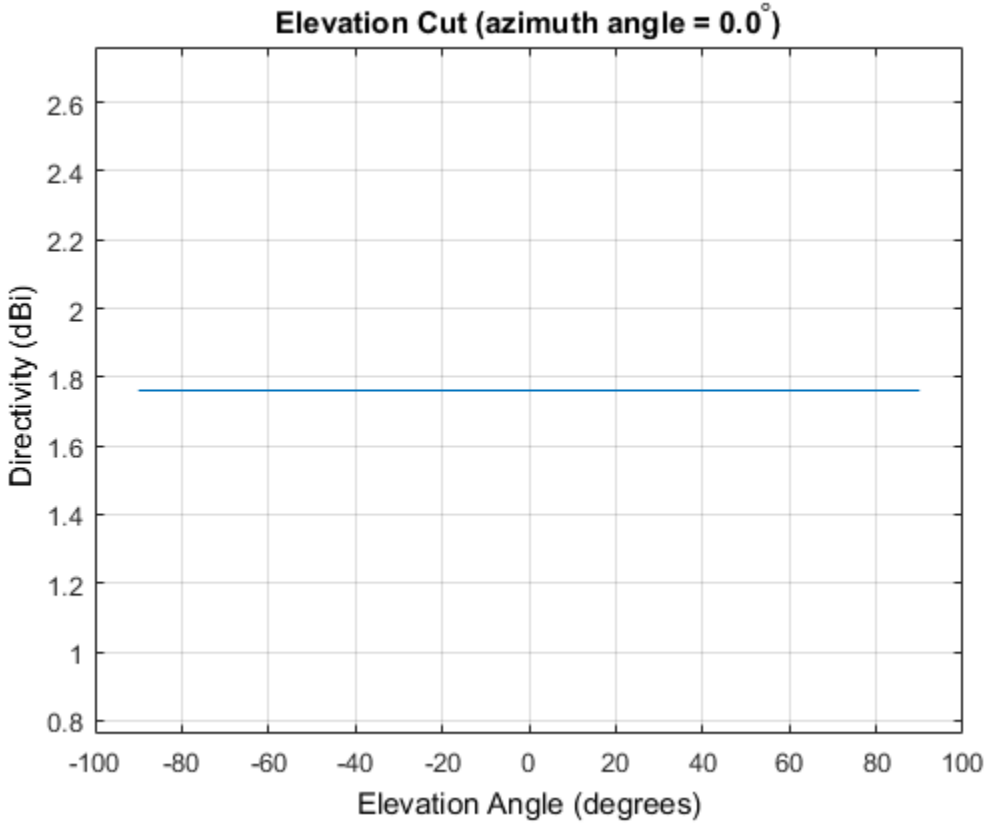
Specify a short-dipole antenna element with its dipole axis pointing along the y-axis. Then, plot the directivity. The antenna operating frequency spans the range 100 to 900 MHz.

Construct a y-directed short-dipole antenna by setting the `'AxisDirection'` value to `'Y'`.

```
sSD = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[100 900]*1e6,...
    'AxisDirection','Y');
```

Plot the antenna's directivity at 500 MHz as an elevation cut at zero degrees azimuth angle.

```
fc = 500e6;
pattern(sSD,fc,0,[-90:90],...
    'CoordinateSystem','rectangular',...
    'Type','directivity')
```



More About

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on "Element directivity" and "Array directivity".

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

Convert plotResponse to pattern

For antenna, microphone, and array System objects, the `pattern` method replaces the `plotResponse` method. In addition, two new simplified methods exist just to draw 2-D azimuth and elevation pattern plots. These methods are `azimuthPattern` and `elevationPattern`.

The following table is a guide for converting your code from using `plotResponse` to `pattern`. Notice that some of the inputs have changed from *input arguments* to *Name-Value* pairs and conversely. The general `pattern` method syntax is

```
pattern(H,FREQ,AZ,EL,'Name1','Value1',...,'NameN','ValueN')
```

plotResponse Inputs	plotResponse Description	pattern Inputs
`H` argument	Antenna, microphone, or array System object.	`H` argument (no change)
`FREQ` argument	Operating frequency.	`FREQ` argument (no change)

plotResponse Inputs	plotResponse Description	pattern Inputs
`V` argument	Propagation speed. This argument is used only for arrays.	`'PropagationSpeed'` name-value pair. This parameter is only used for arrays.

<table>
<tr><th>plotResponse Inputs</th><th>plotResponse Description</th><th>pattern Inputs</th></tr>
<tr>
<td>'Format' and 'RespCut' name-value pairs</td>
<td>These options work together to let you create a plot in angle space (line or polar style) or UV space. They also determine whether the plot is 2-D or 3-D. This table shows you how to create different types of plots using plotResponse.
<table>
<tr><th>Display space</th><th></th></tr>
<tr><td>Angle space (2D)</td><td>Set 'RespCut' to 'Az' or 'El'. Set 'Format' to 'line' or 'polar'.

When producing a 2-D plot and when 'RespCut' is set to 'Az' or 'El', use 'CutAngle' to set the slice across which to view the plot.</td><td>No equivalent name-value pair. To create a cut, specify either AZ or EL as a scalar, not a vector.</td></tr>
</table>

plotResponse Inputs	plotResponse Description	pattern Inputs
`'NormalizeResponse'` name-value pair	Normalizes the plot. When `'Unit'` is set to `'dbi'`, you cannot specify `'NormalizeResponse'`.	`'Normalize'` name-value pair. When `'Type'` is set to `'directivity'`, you cannot specify `'Normalize'`. .
`'OverlayFreq'` name-value pair	Plot multiple frequencies on the same 2-D plot. Available only when `'Format'` is set to `'line'` or `'uv'` and `'RespCut'` is not set to `'3D'`. The value `true` produces an overlay plot and the value `false` produces a waterfall plot.	`'PlotStyle'` name-value pair plots multiple frequencies on the same 2-D plot. The values `'overlay'` and `'waterfall'` correspond to `'OverlayFreq'` values of `true` and `false`. The option `'waterfall'` is allowed only when `'CoordinateSystem'` is set to `'rectangular'` or `'uv'`.
`'Polarization'` name-value pair	Determines how to plot polarized fields. Options are `'None'`, `'Combined'`, `'H'`, or `'V'`.	`'Polarization'` name-value pair determines how to plot polarized fields. The `'None'` option is removed. The options `'Combined'`, `'H'`, or `'V'` are unchanged.

`'Unit'` name-value pair	Determines the plot units. Choose `'db'`, `'mag'`, `'pow'`, or `'dbi'`, where the default is `'db'`.	`'Type'` name-value pair, uses equivalent options with different names
		
		plotResponse pattern
		`'db'` `'powerdb'`
		`'mag'` `'efield'`
		`'pow'` `'power'`
		`'dbi'` `'directivity'`

`'Weights'` name-value pair	Array element tapers (or weights).	`'Weights'` name-value pair (no change).

plotResponse Inputs	plotResponse Description	pattern Inputs
`'AzimuthAngles'` name-value pair	Azimuth angles used to display the antenna or array response.	`AZ` argument
`'ElevationAngles'` name-value pair	Elevation angles used to display the antenna or array response.	`EL` argument
`'UGrid'` name-value pair	Contains *U* coordinates in *UV*-space.	`AZ` argument when `'CoordinateSystem'` name-value pair is set to `'uv'`
`'VGrid'` name-value pair	Contains *V*-coordinates in *UV*-space.	`EL` argument when `'CoordinateSystem'` name-value pair is set to `'uv'`

phased.ShortDipoleAntennaElement.patternAzimuth | phased.ShortDipoleAntennaElement.patternElevation

Introduced in R2015a

patternAzimuth

System object: phased.ShortDipoleAntennaElement
Package: phased

Plot short-dipole antenna element directivity or pattern versus azimuth

Syntax

```
patternAzimuth(sElem,FREQ)
patternAzimuth(sElem,FREQ,EL)
patternAzimuth(sElem,FREQ,EL,Name,Value)
PAT = patternAzimuth( ___ )
```

Description

`patternAzimuth(sElem,FREQ)` plots the 2-D element directivity pattern versus azimuth (in dBi) for the element `sElem` at zero degrees elevation angle. The argument `FREQ` specifies the operating frequency.

`patternAzimuth(sElem,FREQ,EL)`, in addition, plots the 2-D element directivity pattern versus azimuth (in dBi) at the elevation angle specified by `EL`. When `EL` is a vector, multiple overlaid plots are created.

`patternAzimuth(sElem,FREQ,EL,Name,Value)` plots the element pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternAzimuth( ___ )` returns the element pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Azimuth'` parameter and the `EL` input argument.

Input Arguments

`sElem` — Short-dipole antenna element

System object

Short-dipole antenna element, specified as a phased.ShortDipoleAntennaElement System object.

Example: `sElem = phased.ShortDipoleAntennaElement;`

`FREQ` — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

`EL` — Elevation angles

1-by-*N* real-valued row vector

Elevation angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector. The quantity *N* is the number of requested elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and the *xy* plane. When measured toward the *z*-axis, this angle is positive.

Example: `[0,10,20]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'Type' — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

'Azimuth' — Azimuth angles

`[-180:180]` (default) | 1-by-*P* real-valued row vector

Azimuth angles, specified as the comma-separated pair consisting of `'Azimuth'` and a 1-by-*P* real-valued row vector. Azimuth angles define where the array pattern is calculated.

Example: `'Azimuth',[-90:2:90]`

Data Types: `double`

Output Arguments

PAT — Element directivity or pattern

L-by-*N* real-valued matrix

Element directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of azimuth values determined by the `'Azimuth'` name-value pair argument. The dimension *N* is the number of elevation angles, as determined by the `EL` input argument.

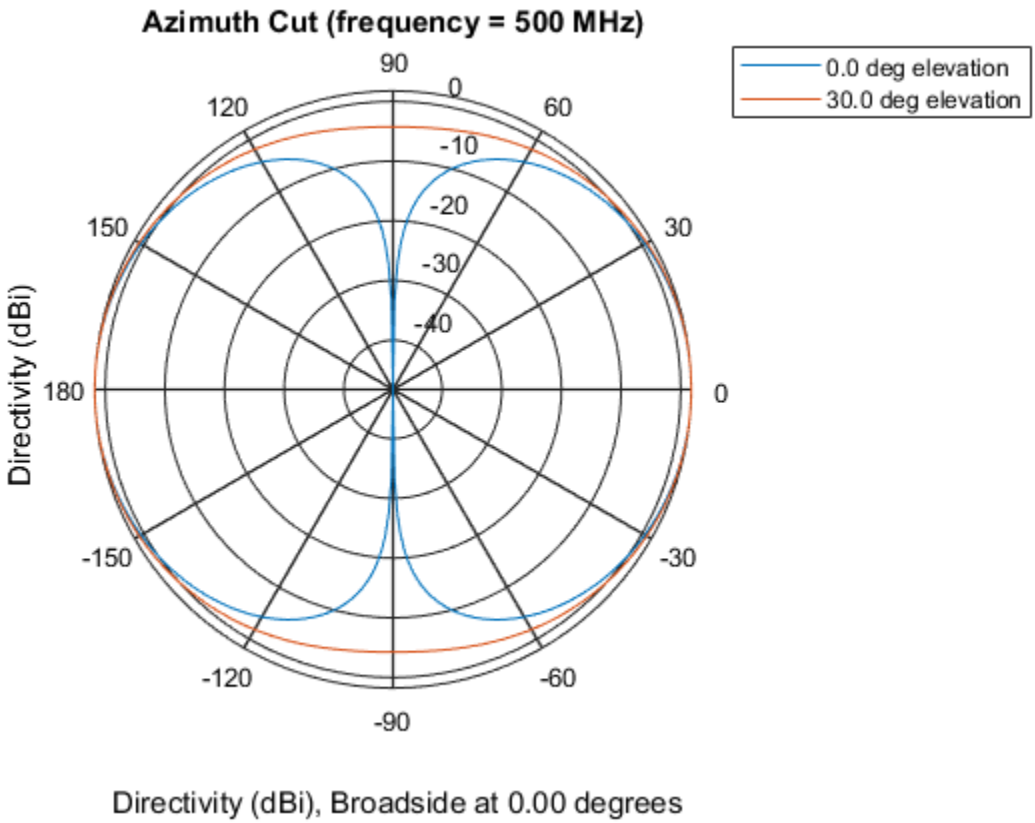
Examples

Azimuth Directivity of Short-Dipole Antenna Element at Two Elevations

Specify a short-dipole antenna element having a direction along the y-axis. Then, plot an azimuth cut of the directivity at 0 and 30 degrees elevation. Assume the operating frequency is 500 MHz.

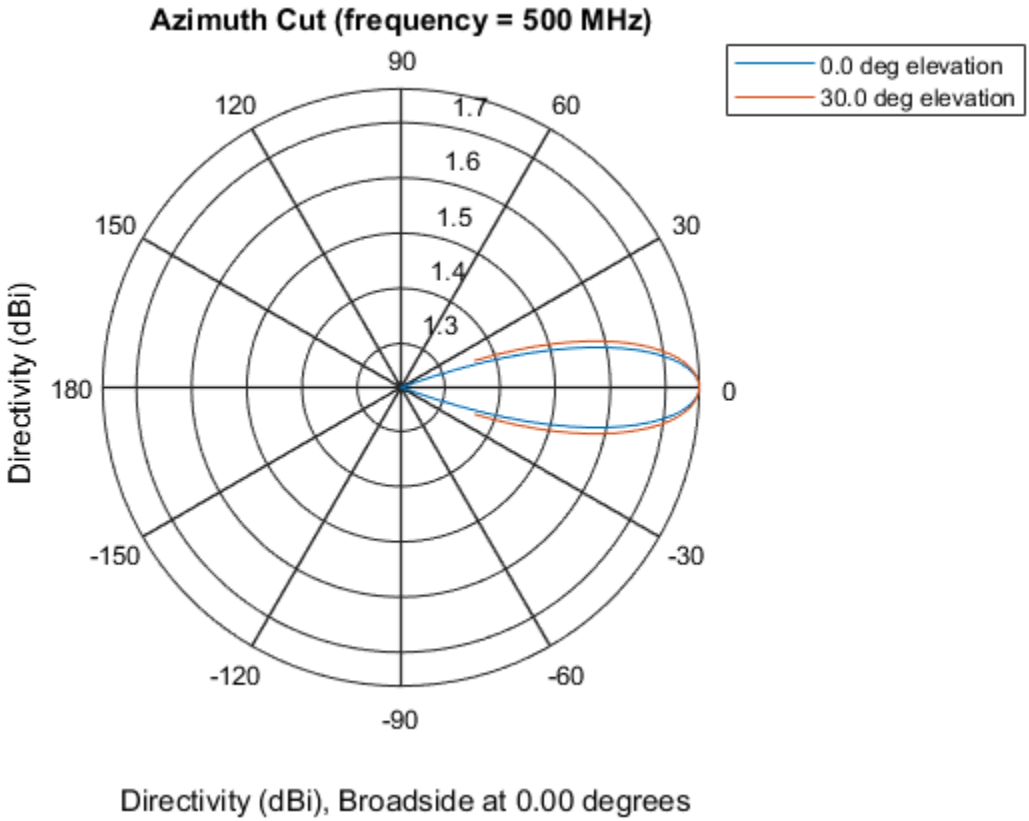
Create the antenna element.

```
fc = 500e6;
sSD = phased.ShortDipoleAntennaElement('FrequencyRange',[100,900]*1e6,...
    'AxisDirection','y');
patternAzimuth(sSD,fc,[0 30])
```



Plot a reduced range of azimuth angles using the `Azimuth` parameter. Notice the change in scale.

```
patternAzimuth(sSD,fc,[0 30],'Azimuth',[-20:20])
```



Definitions

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit

more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on "Element directivity" and "Array directivity".

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

phased.ShortDipoleAntennaElement.pattern |
phased.ShortDipoleAntennaElement.patternElevation

Introduced in R2015a

patternElevation

System object: phased.ShortDipoleAntennaElement
Package: phased

Plot short-dipole antenna element directivity or pattern versus elevation

Syntax

```
patternElevation(sElem,FREQ)
patternElevation(sElem,FREQ,AZ)
patternElevation(sElem,FREQ,AZ,Name,Value)
PAT = patternElevation( ___ )
```

Description

`patternElevation(sElem,FREQ)` plots the 2-D element directivity pattern versus elevation (in dBi) for the element `sElem` at zero degrees azimuth angle. The argument `FREQ` specifies the operating frequency.

`patternElevation(sElem,FREQ,AZ)`, in addition, plots the 2-D element directivity pattern versus elevation (in dBi) at the azimuth angle specified by `AZ`. When `AZ` is a vector, multiple overlaid plots are created.

`patternElevation(sElem,FREQ,AZ,Name,Value)` plots the element pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternElevation( ___ )` returns the element pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Elevation'` parameter and the `AZ` input argument.

Input Arguments

`sElem` — Short-dipole antenna element

System object

Short-dipole antenna element, specified as a phased.ShortDipoleAntennaElement System object.

Example: `sElem = phased.ShortDipoleAntennaElement;`

`FREQ` — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

`AZ` — Azimuth angles for computing directivity and pattern

1-by-*N* real-valued row vector

Azimuth angles for computing sensor or array directivities and patterns, specified as a 1-by-*M* real-valued row vector where *N* is the number of desired azimuth directions. Angle units are in degrees. The azimuth angle must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `[0,10,20]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Type'` — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

`'Elevation'` — Elevation angles

`[-90:90]` (default) | 1-by-*P* real-valued row vector

Elevation angles, specified as the comma-separated pair consisting of `'Elevation'` and a 1-by-*P* real-valued row vector. Elevation angles define where the array pattern is calculated.

Example: `'Elevation',[-90:2:90]`

Data Types: `double`

Output Arguments

`PAT` — Element directivity or pattern

L-by-*N* real-valued matrix

Element directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of elevation angles determined by the `'Elevation'` name-value pair argument. The dimension *N* is the number of azimuth angles determined by the `AZ` argument.

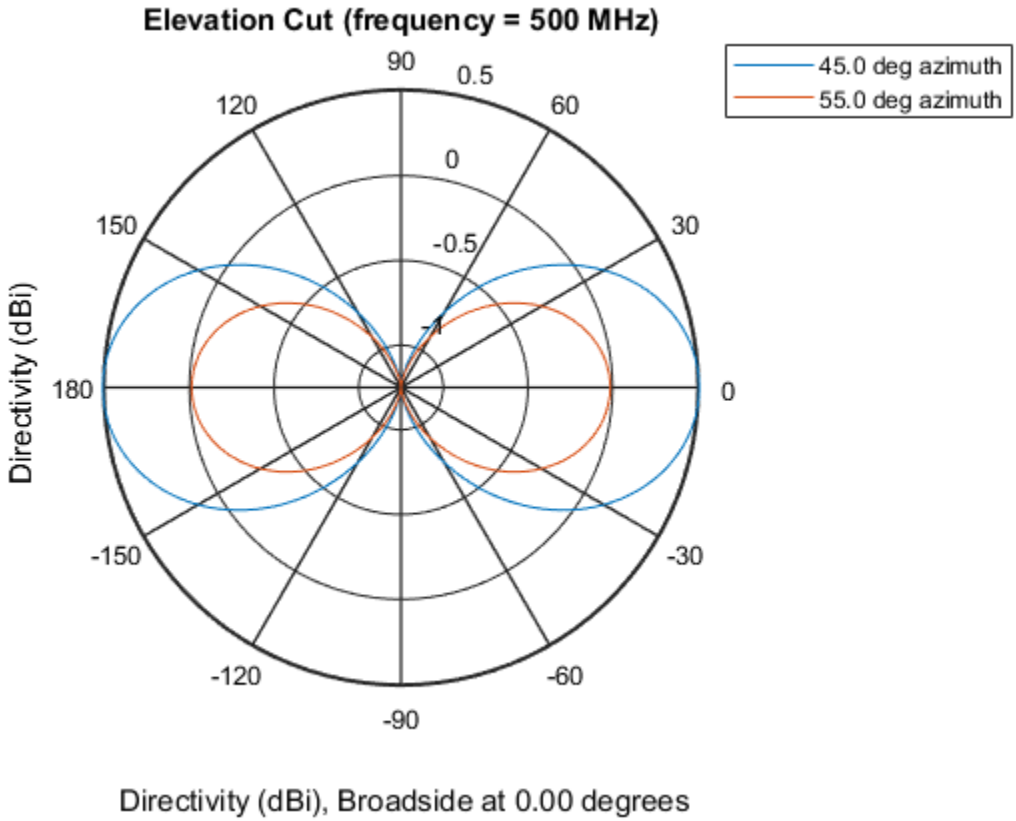
Examples

Reduced Elevation Pattern of Crossed-Dipole Antenna Element

Plot an elevation cut of directivity of a crossed dipole antenna element at 45 and 55 degrees azimuth. Assume the operating frequency is 500 MHz.

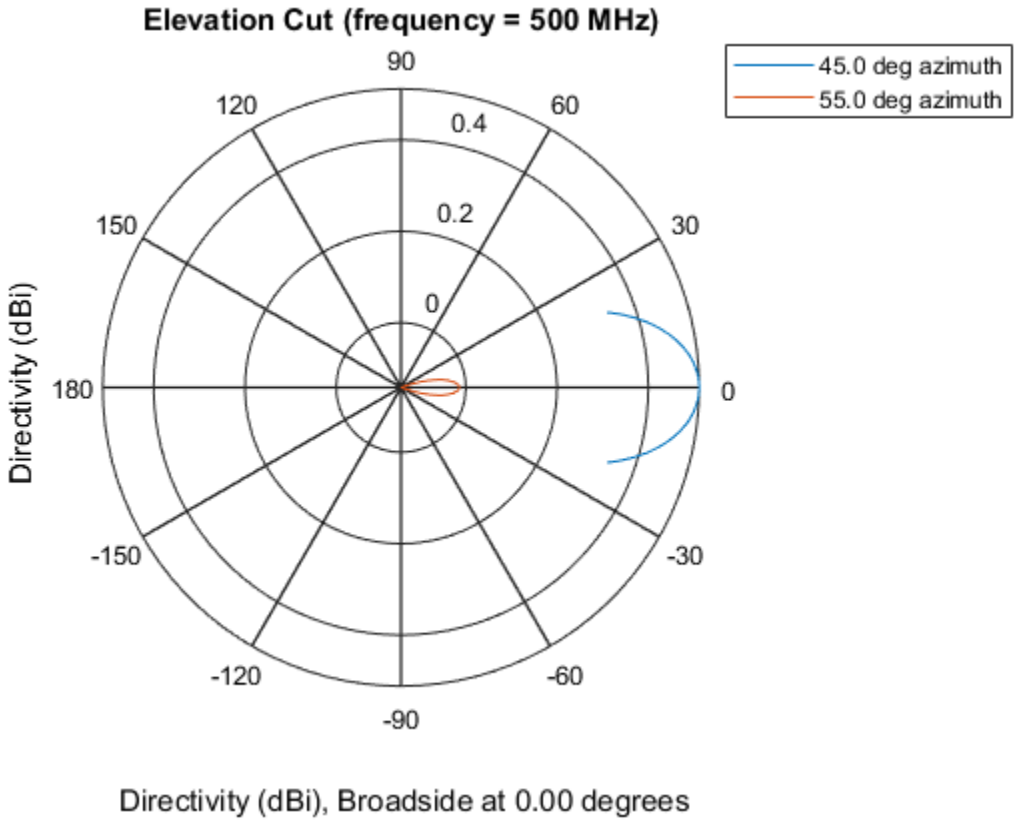
Create the antenna element

```
fc = 500e6;
sCD = phased.CrossedDipoleAntennaElement('FrequencyRange',[100,900]*1e6);
patternElevation(sCD,fc,[45 55])
```



Plot a reduced range of elevation angles using the `Elevation` parameter. Notice the change in scale.

```
patternElevation(sCD,fc,[45 55],'Elevation',[-20:20])
```



Definitions

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit

more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on "Element directivity" and "Array directivity".

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

phased.ShortDipoleAntennaElement.patternAzimuth

Introduced in R2015a

plotResponse

System object: phased.ShortDipoleAntennaElement
Package: phased

Plot response pattern of antenna

Syntax

```
plotResponse(H,FREQ)
plotResponse(H,FREQ,Name,Value)
hPlot = plotResponse( ___ )
```

Description

`plotResponse(H,FREQ)` plots the element response pattern along the azimuth cut, where the elevation angle is 0. The operating frequency is specified in `FREQ`.

`plotResponse(H,FREQ,Name,Value)` plots the element response with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = plotResponse( ___ )` returns handles of the lines or surface in the figure window, using any of the input arguments in the previous syntaxes.

Input Arguments

`H`

Element System object

`FREQ`

Operating frequency in Hertz specified as a scalar or 1–by-*K* row vector. `FREQ` must lie within the range specified by the `FrequencyVector` property of `H`. If you set the `'RespCut'` property of `H` to `'3D'`, `FREQ` must be a scalar. When `FREQ` is a row vector, `plotResponse` draws multiple frequency responses on the same axes.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'CutAngle'`

Cut angle specified as a scalar. This argument is applicable only when `RespCut` is `'Az'` or `'El'`. If `RespCut` is `'Az'`, `CutAngle` must be between –90 and 90. If `RespCut` is `'El'`, `CutAngle` must be between –180 and 180.

Default: `0`

`'Format'`

Format of the plot, using one of `'Line'`, `'Polar'`, or `'UV'`. If you set `Format` to `'UV'`, `FREQ` must be a scalar.

Default: `'Line'`

`'NormalizeResponse'`

Set this value to `true` to normalize the response pattern. Set this value to `false` to plot the response pattern without normalizing it. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

Default: `true`

`'OverlayFreq'`

Set this value to `true` to overlay pattern cuts in a 2-D line plot. Set this value to `false` to plot pattern cuts against frequency in a 3-D waterfall plot. If this value is `false`, `FREQ` must be a vector with at least two entries.

This parameter applies only when `Format` is not `'Polar'` and RespCut is not `'3D'`.

Default: `true`

`'Polarization'`

Specify the polarization options for plotting the antenna response pattern. The allowable values are `|'None' | 'Combined' | 'H' | 'V' |` where

- 'None' specifies plotting a nonpolarized response pattern
- 'Combined' specifies plotting a combined polarization response pattern
- 'H' specifies plotting the horizontal polarization response pattern
- 'V' specifies plotting the vertical polarization response pattern

For antennas that do not support polarization, the only allowed value is 'None'. This parameter is not applicable when you set the Unit parameter value to 'dbi'.

Default: 'None'

'RespCut'

Cut of the response. Valid values depend on Format, as follows:

- If Format is 'Line' or 'Polar', the valid values of RespCut are 'Az', 'El', and '3D'. The default is 'Az'.
- If Format is 'UV', the valid values of RespCut are 'U' and '3D'. The default is 'U'.

If you set RespCut to '3D', FREQ must be a scalar.

'Unit'

The unit of the plot. Valid values are 'db', 'mag', 'pow', or 'dbi'. This parameter determines the type of plot that is produced.

Unit value	Plot type
db	power pattern in dB scale
mag	field pattern
pow	power pattern
dbi	directivity

Default: 'db'

'AzimuthAngles'

Azimuth angles for plotting element response, specified as a row vector. The AzimuthAngles parameter sets the display range and resolution of azimuth angles for

visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'Az'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of azimuth angles should lie between –180° and 180° and must be in nondecreasing order. When you set the `RespCut` parameter to `'3D'`, you can set the `AzimuthAngles` and `ElevationAngles` parameters simultaneously.

Default: `[-180:180]`

`'ElevationAngles'`

Elevation angles for plotting element response, specified as a row vector. The `ElevationAngles` parameter sets the display range and resolution of elevation angles for visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'El'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of elevation angles should lie between –90° and 90° and must be in nondecreasing order. When you set the `RespCut` parameter to `'3D'`, you can set the `ElevationAngles` and `AzimuthAngles` parameters simultaneously.

Default: `[-90:90]`

`'UGrid'`

U coordinate values for plotting element response, specified as a row vector. The `UGrid` parameter sets the display range and resolution of the *U* coordinates for visualizing the radiation pattern in *U*/*V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'U'` or `'3D'`. The values of `UGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set the `UGrid` and `VGrid` parameters simultaneously.

Default: `[-1:0.01:1]`

`'VGrid'`

V coordinate values for plotting element response, specified as a row vector. The `VGrid` parameter sets the display range and resolution of the *V* coordinates for visualizing the radiation pattern in *U*/*V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'3D'`. The values of `VGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set the `VGrid` and `UGrid` parameters simultaneously.

Default: `[-1:0.01:1]`

Examples

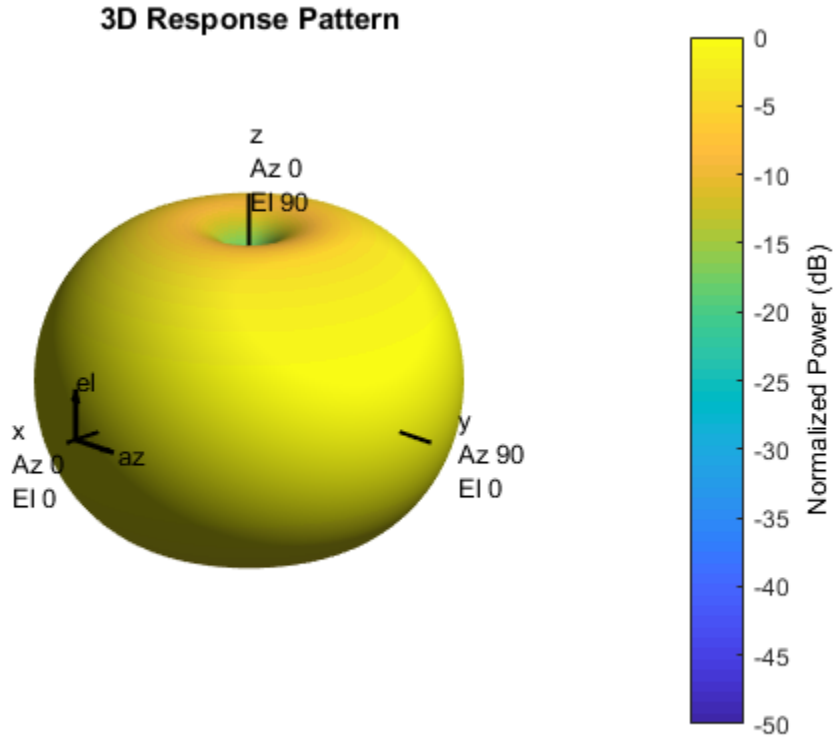
Response of Short-Dipole Antenna Oriented Along the Z-Axis

Specify a short-dipole antenna element with its dipole axis pointing along the z-axis. To do so, set the `'AxisDirection'` value to `'Z'`.

```
sSD = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[100 900]*1e6,'AxisDirection','Z');
```

Plot the antenna's vertical polarization response at 200 MHz as a 3-D polar plot.

```
fc = 200e6;
plotResponse(sSD,fc,'Format','Polar',...
    'RespCut','3D','Polarization','V');
```



As the above figure shows, the antenna pattern is that of a vertically-oriented dipole and has its maximum at the equator and nulls at the poles.

Plot Short-Dipole Antenna Element Response Over Selected Range

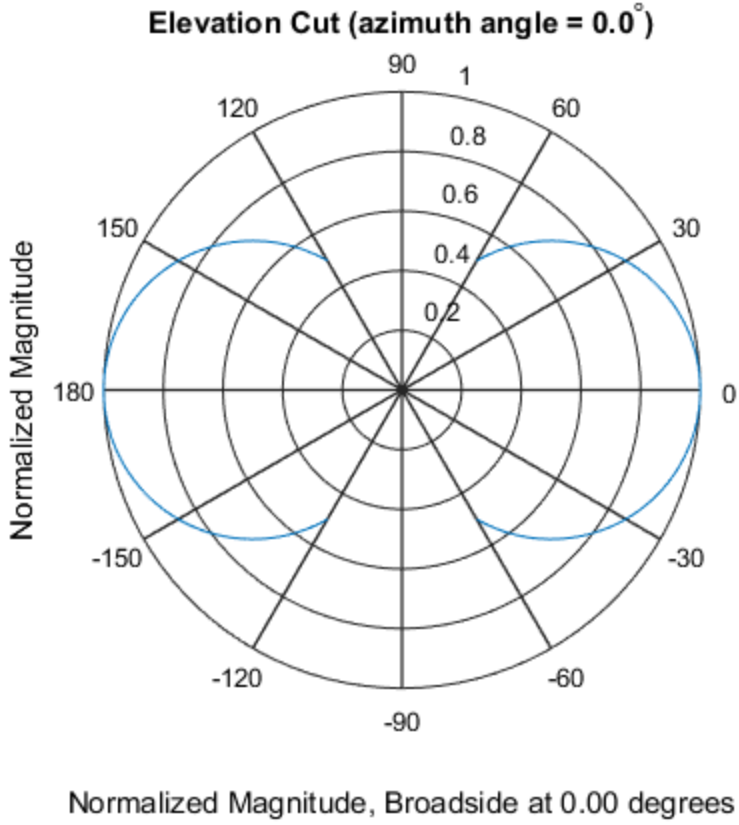
This example shows how to construct a short-dipole antenna element with its dipole axis pointing along the z-axis and how to plot the response over a selected range of angles. The antenna operating frequency spans the range 100 to 900 MHz.

To construct a z-directed short-dipole antenna, set the `'AxisDirection'` value to `'Z'`.

```
sSD = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[100 900]*1e6,'AxisDirection','Z');
```

Plot the antenna's vertical polarization response at 200 MHz as an elevation cut at a fixed azimuth angle. Use the 'ElevationAngles' property to restrict the plot from -60 to 60 degrees elevation in 0.1 degree increments.

```
plotResponse(sSD,200e6,'Format','Polar',...
    'RespCut','El','Polarization','V',...
    'ElevationAngles',[-60:0.1:60],'Unit','mag');
```



Plot Short-Dipole Antenna Element Directivity

This example shows how to construct a short-dipole antenna element with its dipole axis pointing along the y-axis and how to plot the directivity. The antenna operating frequency spans the range 100 to 900 MHz.

To construct a y-directed short-dipole antenna, set the `'AxisDirection'` value to `'Y'`.

```
sSD = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[100 900]*1e6,'AxisDirection','Y');
```

Plot the antenna's directivity at 500 MHz as an elevation cut at a fixed azimuth angle.

```
plotResponse(sSD,500e6,'Format','Line',...
    'RespCut','El','Unit','dbi');
```

`azel2uv` | `uv2azel`

step

System object: phased.ShortDipoleAntennaElement
Package: phased

Output response of antenna element

Syntax

```
RESP = step(H,FREQ,ANG)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`RESP = step(H,FREQ,ANG)` returns the antenna's voltage response, `RESP`, at the operating frequencies specified in `FREQ` and in the directions specified in `ANG`. For the short-dipole antenna element object, `RESP` is a MATLAB `struct` containing two fields, `RESP.H` and `RESP.V`, representing the horizontal and vertical polarization components of the antenna's response. Each field is an *M*-by-*L* matrix containing the antenna response at the *M* angles specified in `ANG` and at the *L* frequencies specified in `FREQ`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

H

Antenna element object.

FREQ

Operating frequencies of antenna in hertz. FREQ is a row vector of length L.

ANG

Directions in degrees. ANG can be either a 2-by-M matrix or a row vector of length M.

If ANG is a 2-by-M matrix, each column of the matrix specifies the direction in the form [azimuth; elevation]. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

If ANG is a row vector of length M, each element specifies a direction's azimuth angle. In this case, the corresponding elevation angle is assumed to be 0.

Output Arguments

RESP

Voltage response of antenna element returned as a MATLAB `struct` with fields RESP.H and RESP.V. Both RESP.H and RESP.V contain responses for the horizontal and vertical polarization components of the antenna radiation pattern. Both RESP.H and RESP.V are *M*-by-*L* matrices. In these matrices, *M* represents the number of angles specified in ANG, and *L* represents the number of frequencies specified in FREQ.

Examples

Response of Short-Dipole Antenna

Find the response of a short-dipole antenna element at boresight, (0°,0°), and off boresight, (30°,0°). The antenna operates at 256 MHz.

```
antenna = phased.ShortDipoleAntennaElement(...
```

```
    'FrequencyRange',[100 900]*1e6,'AxisDirection','Y');
ang = [0 30;0 0];
fc = 250e6;
resp = antenna(fc,ang)
```

```
resp =

  struct with fields:

    H: [2×1 double]
    V: [2×1 double]
```

Horizontal response.

```
disp(resp.H)
```

```
   -1.2247
   -1.0607
```

Vertical response.

```
disp(resp.V)
```

```
     0
     0
```

Algorithms

The total response of a short-dipole antenna element is a combination of its frequency response and spatial response. This System object calculates both responses using nearest neighbor interpolation and then multiplies the responses to form the total response.

phased.ScatteringMIMOChannel System object

Package: phased

Scattering MIMO channel

Description

The `phased.ScatteringMIMOChannel` System object models a multipath propagation channel in which radiated signals from a transmitting array are reflected from multiple scatterers back toward a receiving array. In this channel, propagation paths are line of sight from point to point. The object models range-dependent time delay, gain, Doppler shift, phase change, and atmospheric loss due to gases, rain, fog, and clouds.

The attenuation models for atmospheric gases and rain are valid for electromagnetic signals in the frequency range 1–1000 GHz. The attenuation model for fog and clouds is valid from 10–1000 GHz. Outside these frequency ranges, the object uses the nearest valid value.

To compute the multipath propagation for specified source and receiver points:

1. Define and set up your scattering MIMO channel using the "Construction" on page 1-1810 procedure. You can set the System object properties during construction or leave them at their default values.
2. Call the `step` method to compute the propagated signals using the properties of the `phased.ScatteringMIMOChannel` System object. You can change tunable properties before or after any call to the `step` method.

Note: Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`channel = phased.ScatteringMIMOChannel` creates a scattering MIMO propagation channel System object, `channel`.

`channel = phased.ScatteringMIMOChannel(Name,Value)` creates a System object, `channel`, with each specified property `Name` set to the specified `Value`. You can specify additional name and value pair arguments in any order as (`Name1,Value1,...,NameN,ValueN`).

Properties

`TransmitArray` — Transmitting array

Phased Array System Toolbox antenna array System object

Transmitting array, specified as a Phased Array System Toolbox antenna array System object.

Example: `phased.URA`

`ReceiveArray` — Receiving array

Phased Array System Toolbox antenna array System object

Receiving array, specified as a Phased Array System Toolbox antenna array System object.

Example: `phased.URA`

`PropagationSpeed` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. Units are in m/s. The default value of the speed of light is the value returned by `physconst('LightSpeed')`.

Example: `3e8`

Data Types: `double`

`CarrierFrequency` — Signal carrier frequency

`300e6` (default) | positive real-valued scalar

Signal carrier frequency, specified as a positive real-valued scalar. Units are in Hz.

Example: `100e6`

Data Types: `double`

`SpecifyAtmosphere` — Enable atmospheric attenuation model

`false` (default) | `true`

Option to enable the atmospheric attenuation model, specified as a `false` or `true`. Set this property to `true` to add signal attenuation caused by atmospheric gases, rain, fog, or clouds. Set this property to `false` to ignore atmospheric effects in propagation.

Setting `SpecifyAtmosphere` to `true`, enables the `Temperature`, `DryAirPressure`, `WaterVapourDensity`, `LiquidWaterDensity`, and `RainRate` properties.

Data Types: `logical`

`Temperature` — Ambient temperature

`15` (default) | real-valued scalar

Ambient temperature, specified as a real-valued scalar. Units are in degrees Celsius.

Example: `20.0`

Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

`DryAirPressure` — Atmospheric dry air pressure

`101.325e3` (default) | positive real-valued scalar

Atmospheric dry air pressure, specified as a positive real-valued scalar. Units are in pascals (Pa). The default value of this property corresponds to one standard atmosphere.

Example: `101.0e3`

Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

`WaterVapourDensity` — Atmospheric water vapor density

`7.5` (default) | positive real-valued scalar

Atmospheric water vapor density, specified as a positive real-valued scalar. Units are in g/m^3.

Example: `7.4`

Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

`LiquidWaterDensity` — Liquid water density

`0.0` (default) | nonnegative real-valued scalar

Liquid water density of fog or clouds, specified as a nonnegative real-valued scalar. Units are in g/m^3. Typical values for liquid water density are 0.05 for medium fog and 0.5 for thick fog.

Example: `0.1`

Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

`RainRate` — Rainfall rate

`0.0` (default) | nonnegative scalar

Rainfall rate, specified as a nonnegative scalar. Units are in mm/hr.

Example: `10.0`

Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

`SampleRate` — Sample rate of signal

`1e6` (default) | positive scalar

Sample rate of signal, specified as a positive scalar. Units are in Hz. The System object uses this quantity to calculate the propagation delay in units of samples.

Example: `1e6`

Data Types: `double`

`SimulateDirectPath` — Enable propagation along direct path
`false` (default) | `true`

Option to enable signal propagation along the direct path, specified as `false` or `true`. The direct path is a line-of-sight path from the transmitting array to the receiving array with no scattering.

Data Types: `logical`

`ChannelResponseOutputPort` — Enable output of channel response
`false` (default) | `true`

Option to enable output of channel response, specified as `false` or `true`. Set this property to `true`to output the channel response and time delay by using the `chmatrix` and `tau` output arguments of the step method.

Data Types: `logical`

`MaximumDelaySource` — Source of maximum delay
`'Auto'` (default) | `'Property'`

Source of the maximum delay value, specified as `'Auto'` or `'Property'`. When you set this property to `'Auto'`, the channel automatically allocates enough memory to simulate the propagation delay. When you set this property to `'Property'`, you can specify the maximum delay by using the `MaximumDelay` property. Signals arriving after the maximum delay are ignored.

`MaximumDelay` — Maximum signal delay
`10e-6` (default) | positive scalar

Maximum signal delay, specified as a positive scalar. Delays greater than this value are ignored. Units are in seconds.

Dependencies

To enable this property, set the `MaximumDelaySource` property to `'Property'`.

Data Types: `double`

`TransmitArrayMotionSource` — Source of transmitting array motion parameters
`'Property'` (default) | `'Input port'`

Source of the transmitting array motion parameters, specified as `'Property'` or `'Input port'`.

- When you set this property to `'Property'`, the transmitting array is stationary. Then, you can specify the location and orientation of the array using the `TransmitArrayPosition` and `TransmitArrayOrientationAxes` properties.
- When you set this property to `'Input port'`, specify the transmitting array location, velocity, and orientation by using the `txpos`, `txvel`, and `txaxes` input arguments of the step method.

Data Types: `char`

`TransmitArrayPosition` — Position of transmitting array phase center

`[0;0;0]` (default) | real-valued three-element vector

Position of the transmitting array phase center, specified as a real-valued three-element vector in Cartesian form, `[x;y;z]`, with respect to the global coordinate system. Units are in meters.

Example: `[1000;-200;55]`

Dependencies

To enable this property, set the `TransmitArrayMotionSource` property to `'Property'`.

Data Types: `double`

`TransmitArrayOrientationAxes` — Orientation of transmitting array

`eye(3,3)` (default) | real-valued 3-by-3 orthonormal matrix

Orientation of transmitting array, specified as a real-valued 3-by-3 orthonormal matrix. The matrix specifies the three axes, *(x,y,z)*, that define the local coordinate system of the array with respect to the global coordinate system. Each column corresponds to an axis.

Example: `rotz(45)`

Dependencies

To enable this property, set the `TransmitArrayMotionSource` property to `'Property'`.

Data Types: `double`

`ReceiveArrayMotionSource` — Source of receiving array motion parameters

`'Property'` (default) | `'Input port'`

Source of the receiving array motion parameters, specified as `'Property'` or `'Input port'`.

- When you set this property to `'Property'`, the receiving array is stationary. Then, you can specify the location and orientation of the array by using the `ReceiveArrayPosition` and `ReceiveArrayOrientationAxes` properties.
- When you set this property to `'Input port'`, you can specify the receiving array location, velocity, and orientation by using the `rxpos`, `rxvel`, and `rxaxes` input arguments of the step method.

Data Types: `char`

`ReceiveArrayPosition` — Position of receiving array

`[0;0;0]` (default) | real-valued three-element vector

Position of the receiving array phase center, specified as a real-valued three-element vector in Cartesian form,`[x;y;z]`, with respect to the global coordinate system. Units are in meters.

Example: `[1000;-200;55]`

Dependencies

To enable this property, set the `ReceiveArrayMotionSource` property to `'Property'`.

Data Types: `double`

`ReceiveArrayOrientationAxes` — Orientation of receiving array

`eye(3,3)` (default) | real-valued 3-by-3 orthonormal matrix

Orientation of receiving array, specified as a real-valued 3-by-3 orthonormal matrix. The matrix specifies the three axes, *(x,y,z)*, that define the local coordinate system of the array with respect to the global coordinate system. Each column corresponds to an axis.

Example: `roty(60)`

Dependencies

To enable this property, set the `ReceiveArrayMotionSource` property to `'Property'`.

Data Types: `double`

`ScattererSpecificationSource` — Source of scatterer parameters

`'Auto'` (default) | `'Property'` | `'Input port'`

Source of scatterer parameters, specified as `'Auto'`, `'Property'`, `'Input port'`.

- When you set this property to `'Auto'`, all scatterer positions and coefficients are randomly generated. Scatterer velocities are zero. The generated positions are contained within the region that is defined by the `ScattererPositionBoundary`. To set the number of scatterers, use the `NumScatterers` property.
- When you set this property to `'Property'`, you can set the scatterer positions by using the `ScattererPosition` property and the scattering coefficients by using the `ScattererCoefficient` property. All scatterer velocities are zero.
- When you set this property to `'Input port'`, you can specify the scatterer positions, velocities, and scattering coefficients using the `scatpos`, `scatvel`, and `scatcoef` input arguments of the step method.

Example: `'Input port'`

Data Types: `char`

`NumScatterers` — Number of scatterers

`1` (default) | nonnegative integer

Number of scatterers, specified as a nonnegative integer.

Example: `9`

Dependencies

To enable this property, set the `ScattererSpecificationSource` property to `'Auto'`.

Data Types: `double`

`ScattererPositionBoundary` — Boundary of scatterer positions

`[0,1000]` (default) | 1-by-2 real-valued vector | 3-by-2 real-valued matrix

Boundary of the scatterer positions, specified as a 1-by-2 real-valued row vector or a 3-by-2 real-valued matrix. The vector specifies the minimum and maximum, `[minbdry maxbdry]`, for all three dimensions. The matrix specifies boundaries in all three dimensions in the form `[x_minbdry x_maxbdry;y_minbdry y_maxbdry; z_minbdry z_maxbdry]`.

Example: `[-1000 500;-100 100;-200 0]`

Dependencies

To enable this property, set the `ScattererSpecificationSource` property to `'Auto'`.

Data Types: `double`

`ScattererPosition` — Positions of scatterers

`[0;0;0]` (default) | real-valued 3-by-*K* matrix

Positions of the scatterers, specified as real-valued 3-by-*K* matrix. *K* is the number of scatterers. Each column represents a different scatterer and has the Cartesian form `[x;y;z]` with respect to the global coordinate system. Units are in meters.

Example: `[1050 -100;-300 55;0 -75]`

Dependencies

To enable this property, set the `ScattererSpecificationSource` property to `'Property'`.

Data Types: `double`

`ScattererCoefficient` — Scattering coefficients

1 (default) | complex-valued 1-by-*K* vector

Scattering coefficients, specified as a complex-valued 1-by-*K* vector. *K* is the number of scatterers. Units are dimensionless.

Example: `2+1i`

Dependencies

To enable this property, set the `ScattererSpecificationSource` property to `'Property'`.

Data Types: `double`
Complex Number Support: Yes

`SeedSource` — Source of random number generator seed

`'Auto'` (default) | `'Property'`

Source of random number generator seed, specified as `'Auto'` or `'Property'`.

- When you set this property to `'Auto'`, random numbers are generated using the default MATLAB random number generator.
- When you set this property to `'Property'`, the object uses a private random number generator with the seed specified by the value of the `Seed` property.

To use this object with Parallel Computing Toolbox software, set this property to `'Auto'`.

Dependencies

To enable this property, set the `ScattererSpecificationSource` property to `'Auto'`.

`Seed` — Random number generator seed

`0` (default) | nonnegative integer

Random number generator seed, specified as a nonnegative integer less than 2^{32}.

Example: `5005`

Dependencies

To enable this property, set the `ScattererSpecificationSource` property to `'Auto'` and the `SeedSource` property to `'Property'`.

Data Types: `double`

Methods

reset	Reset state of the System object
step	Propagate signals in scattering MIMO channel

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Propagate Signals in MIMO Channel

Create a 30 GHz MIMO channel with random scatterers. The scenario contains a stationary 21-element transmitting ULA array and a stationary 15-element receiving ULA array. The transmitting antennas have cosine responses and the receiving antennas are isotropic. Element spacing for both arrays is less than one-half wavelength. The channel has 50 randomly generated static scatterers within a specified bounding box. The transmit array is located at [0;20;50] meters and the receive array is located at [200;10;10] meters. Compute the propagated signal through this channel. The sample rate for the signal is 10 MHz.

```
fc = 30e9;
c = physconst('LightSpeed');
lambda = c/fc;
fs = 10e6;
txarray = phased.ULA('Element',phased.CosineAntennaElement,...
    'NumElements',21,'ElementSpacing',0.45*lambda);
rxarray = phased.ULA('Element',phased.IsotropicAntennaElement,...
    'NumElements',15,'ElementSpacing',0.45*lambda);

channel = phased.ScatteringMIMOChannel('TransmitArray',txarray,...
    'ReceiveArray',rxarray,'PropagationSpeed',c,'CarrierFrequency',fc,...
```

```
    'SampleRate',fs,'TransmitArrayPosition',[0;20;50],...
    'ReceiveArrayPosition',[200;10;10],'NumScatterers',50,...
    'ScattererPositionBoundary',[10 180; -30 30; -30 30]);
```

Create a random data signal of ones and zeros for each transmitter.

```
x = randi(2,[100 21]) - 1;
```

Compute the received signals after propagating through the channel.

```
y = channel(x);
```

Propagate Signals in MIMO Channel from Moving Transmitter

Create a MIMO channel containing 3 fixed scatterers. The scenario contains a 21-element transmitting ULA array operating at 72 GHz, and a 15-element receiving ULA array. The transmitting elements have cosine response shapes and the receiving antennas are isotropic. Only the transmitting antenna is moving. Element spacing for both arrays is less than one-half wavelength. The transmitting array starts at (0,20,50) meters and moves towards the receiver at 2 m/s. The receiving array is located at (200,10,10) meters. Compute the propagated signal through this channel. The sample rate for the signal is 10 MHz.

```
fc = 72e9;
c = physconst('LightSpeed');
lambda = c/fc;
fs = 10e6;
txplatform = phased.Platform('MotionModel','Velocity','InitialPosition', ...
    [0;20;50],'Velocity',[2;0;0]);
txarray = phased.ULA('Element',phased.CosineAntennaElement, ...
    'NumElements',21,'ElementSpacing',0.45*lambda);
rxarray = phased.ULA('Element',phased.IsotropicAntennaElement, ...
    'NumElements',15,'ElementSpacing',0.45*lambda);
channel = phased.ScatteringMIMOChannel('TransmitArray',txarray, ...
    'ReceiveArray',rxarray,'PropagationSpeed',c,'CarrierFrequency',fc,...
    'SampleRate',fs,'TransmitArrayMotionSource','Input port', ...
    'ReceiveArrayMotionSource','Property','ReceiveArrayPosition',[200;10;10],...
    'ReceiveArrayOrientationAxes',rotz(180),...
    'ScattererSpecificationSource','Property','ScattererPosition', ...
    [75 100 120; -10 20 12; 5 -5 8],'ScattererCoefficient',[1i,2+3i,-1+1i]);
```

Move the platforms for two time steps at one second intervals. For each time instance:

- Create a random data signal of ones and zeros for each transmitter element.

- Move the transmitter and receiver. The orientations are fixed.
- Propagate the signals from transmitters to scatterers to receiver.

```
for k =1:2
    x = randi(2,[100 21]) - 1;
    [txpos,txvel] = txplatform(1);
    txaxes = eye(3);
    y = channel(x,txpos,txvel,txaxes);
end
```

Propagate Signals Through MIMO Channel to Moving Receiver

Create a MIMO channel containing 3 fixed scatterers. The scenario contains a 21-element transmitting ULA array and a 15-element receiving ULA array. Both arrays operating at 72 GHz. The transmitting elements have cosine response shapes and the receiving antennas are isotropic. Only the receiving antenna is moving. Element spacing for both arrays is less than one-half wavelength. The transmitting array is located at (0,20,50) meters. The receiving array starts at (200,10,10) meters and moves toward the transmitter at 2 m/s. Compute the propagated signal through this channel. The sample rate for the signal is 10 MHz.

```
fc = 72e9;
c = physconst('LightSpeed');
lambda = c/fc;
fs = 10e6;
rxplatform = phased.Platform('MotionModel','Velocity','InitialPosition',...
    [200;10;10],'Velocity',[-2;0;0]);
txarray = phased.ULA('Element',phased.CosineAntennaElement, ...
    'NumElements',21,'ElementSpacing',0.45*lambda);
rxarray = phased.ULA('Element',phased.IsotropicAntennaElement, ...
    'NumElements',15,'ElementSpacing',0.45*lambda);
channel = phased.ScatteringMIMOChannel('TransmitArray',txarray, ...
    'ReceiveArray',rxarray,'PropagationSpeed',c,'CarrierFrequency',fc, ...
    'SampleRate',fs,'TransmitArrayMotionSource','Property',...
    'TransmitArrayPosition',[0;20;50],'TransmitArrayOrientationAxes',eye(3,3), ...
    'ReceiveArrayMotionSource','Input port','ScattererSpecificationSource', ...
    'Property','ScattererPosition',[75 100 120; -10 20 12; 5 -5 8], ...
    'ScattererCoefficient',[1i,2+3i,-1+1i],'SpecifyAtmosphere',false);
```

Move the platforms for two time steps at one-second intervals. For each time instance:

- Create a random data signal of ones and zeros for each transmitter element.
- Move the transmitter and receiver. Fix the array orientations.

- Propagate the signals from transmitters to scatterers to receiver.

```
for k =1:2
    x = randi(2,[100 21]) - 1;
    [rxpos,rxvel] = rxplatform(1);
    rxaxes = rotz(45);
    y = channel(x,rxpos,rxvel,rxaxes);
end
```

Definitions

Attenuation and Loss Factors

Attenuation or path loss in the scattering MIMO channel consists of four components. $L = L_{fsp}L_gL_cL_r$, where:

- L_{fsp} is the free-space path attenuation.
- L_g is the atmospheric path attenuation.
- L_c is the fog and cloud path attenuation.
- L_r is the rain path attenuation.

Each component is in magnitude units, not in dB.

Free-Space Time Delay and Loss

When the origin and destination are stationary relative to each other, you can write the output signal of a free-space channel as $Y(t) = x(t-\tau)/L_{fsp}$. The quantity τ is the signal delay and L_{fsp} is the free-space path loss. The delay τ is given by R/c, where R is the propagation distance and c is the propagation speed. The free-space path loss is given by

$$L_{fsp} = \frac{(4\pi R)^2}{\lambda^2},$$

where λ is the signal wavelength.

This formula assumes that the target is in the far field of the transmitting element or array. In the near field, the free-space path loss formula is not valid and can result in a

loss smaller than one, equivalent to a signal gain. Therefore, the loss is set to unity for range values, $R \le \lambda/4\pi$.

When the origin and destination have relative motion, the processing also introduces a Doppler frequency shift. The frequency shift is v/λ for one-way propagation and $2v/\lambda$ for two-way propagation. The quantity v is the relative speed of the destination with respect to the origin.

For more details on free space channel propagation, see [8]

Atmospheric Gas Attenuation Model

This model calculates the attenuation of signals that propagate through atmospheric gases.

Electromagnetic signals attenuate when they propagate through the atmosphere. This effect is due primarily to the absorption resonance lines of oxygen and water vapor, with smaller contributions coming from nitrogen gas. The model also includes a continuous absorption spectrum below 10 GHz. Phased Array System Toolbox uses the ITU model *Recommendation ITU-R P.676-10: Attenuation by atmospheric gases*. The model computes the specific attenuation (attenuation per kilometer) as a function of temperature, pressure, water vapor density, and signal frequency. The atmospheric gas model is valid for frequencies from 1–1000 GHz and applies to polarized and nonpolarized fields.

The formula for specific attenuation at each frequency is

$$\gamma = \gamma_o(f) + \gamma_w(f) = 0.1820 f N''(f).$$

The quantity $N''()$ is the imaginary part of the complex atmospheric refractivity. It consists of a spectral line component and a continuous component:

$$N''(f) = \sum_i S_i F_i + N_D''(f)$$

The spectral component consists of a sum of discrete spectrum terms composed of a localized frequency bandwidth function, $F(f)_i$, multiplied by a spectral line strength, S_i. For atmospheric oxygen, each spectral line strength is

$$S_i = a_1 \times 10^{-7} \left(\frac{300}{T} \right)^3 \exp\left[a_2 (1 - \left(\frac{300}{T} \right) \right] P.$$

For atmospheric water vapor, each spectral line strength is

$$S_i = b_1 \times 10^{-1} \left(\frac{300}{T} \right)^{3.5} \exp\left[b_2 (1 - \left(\frac{300}{T} \right) \right] W.$$

P is the atmospheric pressure, W is the water vapor density, and T is the ambient temperature.

For each oxygen line, S_i depends on constants a_1 and a_2. Similarly, each water vapor line has constants b_1 and b_2. The ITU documentation cited at the end of this section contains tabulations of these constants.

The localized frequency bandwidth functions $F_i(f)$ are complicated functions of frequency described in the ITU references cited below. The functions depend on empirical model parameters that are also tabulated in the reference.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length, R. Then, the total attenuation is $L_g = R(\gamma_o + \gamma_w)$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

For a complete description of this models, see [4].

Fog and Cloud Attenuation Model

This model calculates the attenuation of signals that propagate through fog or clouds.

Fog and cloud attenuation are the same atmospheric phenomenon. Phased Array System Toolbox uses the ITU model, *Recommendation ITU-R P.840-6: Attenuation due to clouds and fog*. The model computes the specific attenuation (attenuation per kilometer), of a signal as a function of liquid water density, signal frequency, and temperature. The model applies to polarized and nonpolarized fields. The formula for specific attenuation at each frequency is

$$\gamma_c = K_l(f)M,$$

where M is the liquid water density in gm/m^3. The quantity $K_l(f)$ is the specific attenuation coefficient and depends on frequency. The cloud and fog attenuation model is valid for frequencies 10–1000 GHz. Units for the specific attenuation coefficient are (dB/km)/(g/m^3).

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length R. Total attenuation is $L_c = R\gamma_c$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply narrowband attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

For a complete description of this model, see [5]

Rainfall Attenuation Model

This model calculates the attenuation of signals that propagate through regions of rainfall.

Electromagnetic signals are attenuate when propagating through a region of rainfall. Rainfall attenuation is computed according to the ITU rainfall model *Recommendation ITU-R P.838-3: Specific attenuation model for rain for use in prediction methods*. The model computes the specific attenuation (attenuation per kilometer) of a signal as a function of rainfall rate, signal frequency, polarization, and path elevation angle. To compute the attenuation, this model uses

$$\gamma_r = kr^{\alpha},$$

where r is the rain rate in mm/hr. The parameter k and exponent α depend on the frequency, the polarization state, and the elevation angle of the signal path. The specific attenuation model is valid for frequencies from 1–1000 GHz.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by a propagation distance, R. Then, total attenuation is $L_r = R\gamma_r$. Instead of using geometric range as the propagation distance, the toolbox uses a modified range. The modified range is the geometric range multiplied by a range factor

$$\frac{1}{1+\frac{R}{R_0}}$$

where

$$R_0 = 35e^{-0.015r}$$

is the effective path length in kilometers (see Seybold, J. *Introduction to RF Propagation*.) When there is no rain, the effective path length is 35 km. When the rain rate is, for example, 10 mm/hr, the effective path length is 30.1 km. At short range, the propagation distance is approximately the geometric range. For longer ranges, the propagation distance asymptotically approaches the effective path length.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

reset

System object: phased.ScatteringMIMOChannel
Package: phased

Reset state of the System object

Syntax

```
reset(channel)
```

Description

`reset(channel)` resets the internal state of the `phased.ScatteringMIMOChannel` System object, `channel`.

Input Arguments

`channel` — Spatial MIMO channel

`phased.ScatteringMIMOChannel` System object

Scattering MIMO channel, specified as a `phased.ScatteringMIMOChannel` System object.

Introduced in R2017a

step

System object: phased.ScatteringMIMOChannel
Package: phased

Propagate signals in scattering MIMO channel

Syntax

```
rxsig = step(channel,txsig)
rxsig = step(channel,txsig,txpos,txvel,txaxes)
rxsig = step(channel,txsig,rxpos,rxvel,rxaxes)
rxsig = step(channel,txsig,scatpos,scatvel,scatcoef)
[rxsig,chmatrix,tau] = step(channel,___)
[rxsig,chmatrix,tau] = step(channel,txsig,txpos,txvel,txaxesrxpos,
rxvel,rxaxes,scatpos,scatvel,scatcoef)
```

Description

Note: Instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`rxsig = step(channel,txsig)` uses the scattering MIMO channel, `channel`, to propagate a signal, `txsig`, from a transmitting array towards multiple scatterers, and returns the scattered signals, `rxsig`, to a receiving array.

To enable this syntax, set the `TransmitArrayMotionSource`, `ReceiveArrayMotionSource`, and `ScattererSpecificationSource` properties to `'Property'`.

`rxsig = step(channel,txsig,txpos,txvel,txaxes)` also specifies the transmitting array position, velocity, and axes orientation.

To enable these inputs, set the `ReceiveArrayMotionSource` and `ScattererSpecificationSource` properties to `'Property'` and set `TransmitArrayMotionSource` to `'Input port'`.

`rxsig = step(channel,txsig,rxpos,rxvel,rxaxes)` specifies the receiving array position, velocity, and axes orientation.

To enable these inputs, set the `TransmitArrayMotionSource` and `ScattererSpecificationSource` properties to `'Property'` and set `ReceiveArrayMotionSource` to `'Input port'`.

`rxsig = step(channel,txsig,scatpos,scatvel,scatcoef)` specifies the scatterer positions and velocities, and the scattering coefficients.

To enable these inputs, set the `TransmitArrayMotionSource`and `ReceiveArrayMotionSource` properties to `'Property'` and set `ScattererSpecificationSource` to `'Input port'`.

`[rxsig,chmatrix,tau] = step(channel, ___ )` also returns the channel response matrix, `chmatrix`, and the channel path delays, `tau`, using any of the previous input argument combinations.

To enable these outputs, set the `ChannelResponseOutputPort` property to `true`.

You can combine optional input arguments when their enabling properties are set. For example, `[rxsig,chmatrix,tau] = step(channel,txsig,txpos,txvel,txaxes rxpos,rxvel,rxaxes,scatpos,scatvel,scatcoef)`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`channel` — Scattering MIMO channel

`phased.ScatteringMIMOChannel` System object

Scattering MIMO channel, specified as a `phased.ScatteringMIMOChannel` System object.

Example: `phased.ScatteringMIMOChannel`

`txsig` — Transmitted narrowband signal
M-by-N_t complex-valued matrix

Transmitted narrowband signal, specified as an M-by-N_t complex-valued matrix. The quantity M is the number of samples in the signal, and N_t is the number of transmitting array elements. Each column represents the signal transmitted by the corresponding array element.

Example: `[1,1;j,1;0.5,0]`

Data Types: `double`
Complex Number Support: Yes

`txpos` — Position of transmitting antenna array
real-valued three-element column vector

Position of transmitting antenna array, specified real-valued three-element column vector taking the form `[x;y;z]`. The vector elements correspond to the x, y, and z positions of the array. Units are in meters.

Example: `[1000;100;500]`

Dependencies

To enable this argument, set the `TransmitArrayMotionSource` property to `'Input port'`.

Data Types: `double`

`txvel` — Velocity of transmitting antenna array
real-valued three-element column vector

Velocity of transmitting antenna array, specified as a real-valued three-element column vector taking the form `[vx;vy;vz]`. The vector elements correspond to the x, y, and z velocities of the array. Units are in meters per second.

Example: `[10;0;5]`

Dependencies

To enable this argument, set the `TransmitArrayMotionSource` property to `'Input port'`.

Data Types: `double`

`txaxes` — Axes orientation of transmitting antenna array

3-by-3 real orthonormal matrix

Axes orientation of transmitting antenna array, specified as a 3-by-3 real orthonormal matrix. The matrix defines the orientation of the array local coordinate system with respect to the global coordinates. Matrix columns correspond to the directions of the *x*, *y*, and *z* axes of the local coordinate system. Units are dimensionless.

Example: `rotx(35)`

Dependencies

To enable this argument, set the `TransmitArrayMotionSource` property to `'Input port'`.

Data Types: `double`

`rxpos` — Position of receiving antenna array

real-valued three-element column vector

Position of receiving antenna array, specified as a real-valued three-element column vector taking the form `[x;y;z]`. The vector elements correspond to the *x*, *y*, and *z* positions of the array. Units are in meters.

Example: `[1000;100;500]`

Dependencies

To enable this argument, set the `ReceiveArrayMotionSource` property to `'Input port'`.

Data Types: `double`

`rxvel` — Velocity of receiving antenna array

real-valued three-element column vector

Velocity of receiving antenna array, specified real-valued three-element column vector taking the form `[vx;vy;vz]`. The vector elements correspond to the *x*, *y*, and *z* velocities of the array. Units are in meters per second.

Example: `[10;0;5]`

Dependencies

To enable this argument, set the `ReceiveArrayMotionSource` property to `'Input port'`.

Data Types: `double`

`rxaxes` — Axes orientation of receiving antenna array

3-by-3 real orthonormal matrix

Axes orientation of receiving antenna array, specified as a 3-by-3 real orthonormal matrix. The matrix defines the orientation of the array local coordinate system with respect to the global coordinates. Matrix columns correspond to the directions of the *x*, *y*, and *z* axes of the local coordinate system. Units are dimensionless.

Example: `rotx(35)`

Dependencies

To enable this argument, set the `ReceiveArrayMotionSource` property to `'Input port'`.

Data Types: `double`

`scatpos` — Positions of scatterers

3-by-N_s real-valued matrix

Positions of scatterers, specified as a 3-by-N_s real-valued matrix. The matrix contains the *(x,y,z)* positions of scatterers. Each column of the matrix specifies a different scatterer and takes the form `[x;y;z]`. Units are in meters.

Example: `[1000;100;500]`

Dependencies

To enable this argument, set the `ScattererSpecificationSource` property to `'Input port'`.

Data Types: `double`

`scatvel` — Velocities of scatterers

3-by-N_s real-valued matrix

Velocities of scatterers, specified as a 3-by-N_s real-valued matrix. The matrix contains the (v_x,v_y,v_z) positions of scatterers. Each column of the matrix specifies a different scatterer and takes the form `[vx;vy;vz]` Units are in meters per second.

Example: `[1000;100;500]`

Dependencies

To enable this argument, set the `ScattererSpecificationSource` property to `'Input port'`.

Data Types: `double`

`scatcoef` — Scattering coefficients

1-by-N_s complex-valued row vector

Scattering coefficients, specified as a 1-by-N_s complex-valued row vector. Each vector element specifies the scattering coefficient of the corresponding scatterer. Units are dimensionless.

Example: `[5+3*1i;4+1i;2]`

Dependencies

To enable this argument, set the `ScattererSpecificationSource` property to `'Input port'`.

Data Types: `double`
Complex Number Support: Yes

Output Arguments

`rxsig` — Received narrowband signal

M-by-N_r complex-valued matrix

Received narrowband signal, returned as an M-by-N_r complex-valued matrix. M is the number of samples in the signal, and N_r is the number of receiving array elements. Each column represents the signal received by the corresponding array element.

Example: `[1,1;j,1;0.5,0]`

Data Types: `double`
Complex Number Support: Yes

`chmatrix` — Channel response

N_t-by-N_r-by-N_s complex-valued MATLAB array

Channel response, returned as an N_t-by-N_r-by-N_s complex-valued MATLAB array. N_t is the number of transmitting array elements. N_r is the number of receiving array elements. N_s is the number of scatterers. Each page of the array corresponds to the channel response matrix for a specific scatterer.

Dependencies

To enable this argument, set the `ChannelResponseOutputPort` property to `true`.

Data Types: `double`
Complex Number Support: Yes

`tau` — Path delays

1-by-N_s real-valued vector

Path delays, returned as a 1-by-N_s real-valued vector. N_s is the number of scatterers. Each element corresponds to the path time delay from the transmitting array phase center to a scatterer and then to the receiving array phase center.

Dependencies

To enable this argument, set the `ChannelResponseOutputPort` property to `true`.

Data Types: `double`

Examples

Propagate Signals in MIMO Channel

Create a 30 GHz MIMO channel with random scatterers. The scenario contains a stationary 21-element transmitting ULA array and a stationary 15-element receiving ULA array. The transmitting antennas have cosine responses and the receiving antennas are isotropic. Element spacing for both arrays is less than one-half wavelength. The channel has 50 randomly generated static scatterers within a specified bounding box. The transmit array is located at [0;20;50] meters and the receive array is located at [200;10;10] meters. Compute the propagated signal through this channel. The sample rate for the signal is 10 MHz.

```
fc = 30e9;
c = physconst('LightSpeed');
lambda = c/fc;
fs = 10e6;
txarray = phased.ULA('Element',phased.CosineAntennaElement,...
    'NumElements',21,'ElementSpacing',0.45*lambda);
rxarray = phased.ULA('Element',phased.IsotropicAntennaElement,...
    'NumElements',15,'ElementSpacing',0.45*lambda);

channel = phased.ScatteringMIMOChannel('TransmitArray',txarray,...
    'ReceiveArray',rxarray,'PropagationSpeed',c,'CarrierFrequency',fc,...
    'SampleRate',fs,'TransmitArrayPosition',[0;20;50],...
    'ReceiveArrayPosition',[200;10;10],'NumScatterers',50,...
    'ScattererPositionBoundary',[10 180; -30 30; -30 30]);
```

Create a random data signal of ones and zeros for each transmitter.

```
x = randi(2,[100 21]) - 1;
```

Compute the received signals after propagating through the channel.

```
y = channel(x);
```

Propagate Signals in MIMO Channel from Moving Transmitter

Create a MIMO channel containing 3 fixed scatterers. The scenario contains a 21-element transmitting ULA array operating at 72 GHz, and a 15-element receiving ULA array. The transmitting elements have cosine response shapes and the receiving antennas are isotropic. Only the transmitting antenna is moving. Element spacing for both arrays is less than one-half wavelength. The transmitting array starts at (0,20,50)

meters and moves towards the receiver at 2 m/s. The receiving array is located at (200,10,10) meters. Compute the propagated signal through this channel. The sample rate for the signal is 10 MHz.

```
fc = 72e9;
c = physconst('LightSpeed');
lambda = c/fc;
fs = 10e6;
txplatform = phased.Platform('MotionModel','Velocity','InitialPosition', ...
    [0;20;50],'Velocity',[2;0;0]);
txarray = phased.ULA('Element',phased.CosineAntennaElement, ...
    'NumElements',21,'ElementSpacing',0.45*lambda);
rxarray = phased.ULA('Element',phased.IsotropicAntennaElement, ...
    'NumElements',15,'ElementSpacing',0.45*lambda);
channel = phased.ScatteringMIMOChannel('TransmitArray',txarray, ...
    'ReceiveArray',rxarray,'PropagationSpeed',c,'CarrierFrequency',fc,...
    'SampleRate',fs,'TransmitArrayMotionSource','Input port', ...
    'ReceiveArrayMotionSource','Property','ReceiveArrayPosition',[200;10;10],...
    'ReceiveArrayOrientationAxes',rotz(180),...
    'ScattererSpecificationSource','Property','ScattererPosition', ...
    [75 100 120; -10 20 12; 5 -5 8],'ScattererCoefficient',[1i,2+3i,-1+1i]);
```

Move the platforms for two time steps at one second intervals. For each time instance:

- Create a random data signal of ones and zeros for each transmitter element.
- Move the transmitter and receiver. The orientations are fixed.
- Propagate the signals from transmitters to scatterers to receiver.

```
for k =1:2
    x = randi(2,[100 21]) - 1;
    [txpos,txvel] = txplatform(1);
    txaxes = eye(3);
    y = channel(x,txpos,txvel,txaxes);
end
```

Propagate Signals Through MIMO Channel to Moving Receiver

Create a MIMO channel containing 3 fixed scatterers. The scenario contains a 21-element transmitting ULA array and a 15-element receiving ULA array. Both arrays operating at 72 GHz. The transmitting elements have cosine response shapes and the receiving antennas are isotropic. Only the receiving antenna is moving. Element spacing for both arrays is less than one-half wavelength. The transmitting array is located at (0,20,50) meters. The receiving array starts at (200,10,10) meters and moves toward the

transmitter at 2 m/s. Compute the propagated signal through this channel. The sample rate for the signal is 10 MHz.

```
fc = 72e9;
c = physconst('LightSpeed');
lambda = c/fc;
fs = 10e6;
rxplatform = phased.Platform('MotionModel','Velocity','InitialPosition',...
    [200;10;10],'Velocity',[-2;0;0]);
txarray = phased.ULA('Element',phased.CosineAntennaElement, ...
    'NumElements',21,'ElementSpacing',0.45*lambda);
rxarray = phased.ULA('Element',phased.IsotropicAntennaElement, ...
    'NumElements',15,'ElementSpacing',0.45*lambda);
channel = phased.ScatteringMIMOChannel('TransmitArray',txarray, ...
    'ReceiveArray',rxarray,'PropagationSpeed',c,'CarrierFrequency',fc, ...
    'SampleRate',fs,'TransmitArrayMotionSource','Property',...
    'TransmitArrayPosition',[0;20;50],'TransmitArrayOrientationAxes',eye(3,3), ...
    'ReceiveArrayMotionSource','Input port','ScattererSpecificationSource', ...
    'Property','ScattererPosition',[75 100 120; -10 20 12; 5 -5 8], ...
    'ScattererCoefficient',[1i,2+3i,-1+1i],'SpecifyAtmosphere',false);
```

Move the platforms for two time steps at one-second intervals. For each time instance:

- Create a random data signal of ones and zeros for each transmitter element.
- Move the transmitter and receiver. Fix the array orientations.
- Propagate the signals from transmitters to scatterers to receiver.

```
for k =1:2
    x = randi(2,[100 21]) - 1;
    [rxpos,rxvel] = rxplatform(1);
    rxaxes = rotz(45);
    y = channel(x,rxpos,rxvel,rxaxes);
end
```

Compute Propagated Signals Through MIMO Channel with Moving Scatterers

Create a MIMO channel containing 3 moving scatterers. The scenario contains a 21-element transmitting ULA array and a 15-element receiving ULA array. Both arrays operate at 72 GHz. The transmitting elements have cosine responses and the receiving antennas are isotropic. Element spacing for both arrays is less than one-half wavelength. The transmitting array is located at (0,20,50) meters. The receiving array is located at (200,10,10) meters. Compute the propagated signal through this channel. The sample rate for the signal is 10 MHz. Obtain the channel response matrix and time delays.

```
fc = 30e9;
c = physconst('LightSpeed');
lambda = c/fc;
fs = 10e6;
txarray = phased.ULA('Element',phased.CosineAntennaElement, ...
    'NumElements',21,'ElementSpacing',0.45*lambda);
rxarray = phased.ULA('Element',phased.IsotropicAntennaElement, ...
    'NumElements',15,'ElementSpacing',0.45*lambda);
channel = phased.ScatteringMIMOChannel('TransmitArray',txarray, ...
    'ReceiveArray',rxarray,'PropagationSpeed',c,'CarrierFrequency',fc, ...
    'SampleRate',fs,'TransmitArrayPosition',[0;20;50], ...
    'ReceiveArrayPosition',[200;10;10],'ScattererSpecificationSource','Input port', ...
    'ChannelResponseOutputPort',true);
```

Create a random data signal of ones and zeros for each transmitter.

```
x = randi(2,[100 21]) - 1;
```

Compute the received signals after propagating through the channel. Also return the channel matrix and delays.

```
scatpos = [75 100 120; -10 20 12; 5 -5 8];
scatvel = [0 0.5 0; -0.1 1.2 0.04; .05 -0.45 0.8];
scatcoef = [1i,2+3i,-1+1i];
[y,chmat,delays] = channel(x,scatpos,scatvel,scatcoef);
```

Display the dimensions of the channel matrix.

```
size(chmat)
```

```
ans =

    21    15     3
```

Display the time delays in microseconds.

```
delays*1e6
```

```
ans =

    0.7310    0.7196    0.6919
```

Introduced in R2017a

phased.SteeringVector System object

Package: phased

Sensor array steering vector

Description

The `SteeringVector` object calculates the steering vector for a sensor array.

To compute the steering vector of the array for specified directions:

1. Define and set up your steering vector calculator. See "Construction" on page 1-1842.
2. Call step to compute the steering vector according to the properties of `phased.SteeringVector`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.SteeringVector` creates a steering vector System object, `H`. The object calculates the steering vector of the given sensor array for the specified directions.

`H = phased.SteeringVector(Name,Value)` creates a steering vector object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`SensorArray`

Handle to sensor array used to calculate steering vector

Specify the sensor array as a handle. The sensor array must be an array object in the `phased` package. The array can contain subarrays.

Default: phased.ULA with default property values

`PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

Default: Speed of light

`IncludeElementResponse`

Include individual element response in the steering vector

If this property is `true`, the steering vector includes the individual element responses.

If this property is `false`, the computation of the steering vector assumes the elements are isotropic. The steering vector does not include the individual element responses. Furthermore, if the `SensorArray` property contains subarrays, the steering vector is the array factor among the subarrays. If `SensorArray` does not contain subarrays, the steering vector is the array factor among the array elements.

Default: `false`

`NumPhaseShifterBits`

Number of phase shifter quantization bits

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

Default: `0`

`EnablePolarization`

Enable polarization simulation

Set to this property to `true`, to enable the steering vector to simulate polarization. Set this property to `false` to ignore polarization. This property applies only when the array

specified in the `SensorArray` property is capable of simulating polarization and you have set the `IncludeElementResponse` property to `true`.

Default: `false`

Methods

step	Calculate steering vector

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Steering Vector for Uniform Linear Array

Calculate and display the steering vector for a 4-element uniform linear array in the direction of 30 degrees azimuth and 20 degrees elevation. Assume the array's operating frequency is 300 MHz.

```
hULA = phased.ULA('NumElements',4);
hsv = phased.SteeringVector('SensorArray',hULA);
Fc = 3e8;
ANG = [30; 20];
sv = step(hsv,Fc,ANG)
```

```
sv =

  -0.6011 - 0.7992i
   0.7394 - 0.6732i
   0.7394 + 0.6732i
  -0.6011 + 0.7992i
```

Beam Pattern With and Without Steering

Calculate the steering vector for a 4-element uniform linear array (ULA) in the direction of 30 degrees azimuth and 20 degrees elevation. Assume the array's operating frequency is 300 MHz.

```
fc = 3e8;
array = phased.ULA('NumElements',4);
steervec = phased.SteeringVector('SensorArray',array);
sv = steervec(fc,[30; 20]);
```

Plot the beam patterns for the uniform linear array when no steering vector is applied (steered broadside) and when a steering vector is applied.

```
c = steervec.PropagationSpeed;
subplot(211)
plotResponse(array,fc,c,'RespCut','Az')
title('Without steering')
subplot(212)
plotResponse(array,fc,c,'RespCut','Az','Weights',sv)
title('With steering')
```

phased.ArrayGain | phased.ArrayResponse | phased.ElementDelay

Introduced in R2012a

step

System object: phased.SteeringVector
Package: phased

Calculate steering vector

Syntax

```
SV = step(H,FREQ,ANG)
SV = step(H,FREQ,ANG,STEERANGLE)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`SV = step(H,FREQ,ANG)` returns the steering vector `SV` of the array for the directions specified in `ANG`. The operating frequencies are specified in `FREQ`. The meaning of `SV` depends on the `IncludeElementResponse` property of `H`, as follows:

- If `IncludeElementResponse` is `true`, `SV` includes the individual element responses.
- If `IncludeElementResponse` is `false`, the computation assumes the elements are isotropic and `SV` does not include the individual element responses. Furthermore, if the `SensorArray` property of `H` contains subarrays, `SV` is the array factor among the subarrays and the phase center of each subarray is at its geometric center. If `SensorArray` does not contain subarrays, `SV` is the array factor among the elements.

`SV = step(H,FREQ,ANG,STEERANGLE)` uses `STEERANGLE` as the subarray steering angle. This syntax is available when you configure `H` so that `H.Sensor` is an array that contains subarrays, `H.Sensor.SubarraySteering` is either `'Phase'` or `'Time'`, and `H.IncludeElementResponse` is `true`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

H

Steering vector object.

FREQ

Operating frequencies in hertz. `FREQ` is a row vector of length L.

ANG

Directions in degrees. `ANG` can be either a 2-by-M matrix or a row vector of length M.

If `ANG` is a 2-by-M matrix, each column of the matrix specifies the direction in space in the form `[azimuth; elevation]`. The azimuth angle must be between –180 and 180 degrees, and the elevation angle must be between –90 and 90 degrees.

If `ANG` is a row vector of length M, each element specifies a direction's azimuth angle. In this case, the corresponding elevation angle is assumed to be 0.

STEERANGLE

Subarray steering angle in degrees. `STEERANGLE` can be a length-2 column vector or a scalar.

If `STEERANGLE` is a length-2 vector, it has the form [azimuth; elevation]. The azimuth angle must be between –180 and 180 degrees, and the elevation angle must be between –90 and 90 degrees.

If `STEERANGLE` is a scalar, it represents the azimuth angle. In this case, the elevation angle is assumed to be 0.

Output Arguments

SV

Steering vector. The form of the steering vector depends upon whether the `EnablePolarization` property is set to `true` or `false`.

- If `EnablePolarization` is set to `false`, the steering vector, `SV`, has the dimensions *N*-by-*M*-by-*L*. The first dimension, *N*, is the number of elements of the phased array or, if `H.SensorArray` contains subarrays, the number of subarrays. Each column of `SV` contains the steering vector of the array for the corresponding direction specified in `ANG`. Each of the *L* pages of `SV` contains the steering vectors of the array for the corresponding frequency specified in `FREQ`.

  If you set the `H.IncludeElementResponse` property to `true`, the steering vector includes the individual element responses. If you set the `H.IncludeElementResponse` property to `false`, the elements are assumed to be isotropic. Then, the steering vector does not include individual element responses.
- If `EnablePolarization` is set to `true`, `SV` is a MATLAB `struct` containing two fields, `SV.H` and `SV.V`. These fields represent the steering vector's horizontal and vertical polarization components. Each field has the dimensions *N*-by-*M*-by-*L*. The first dimension, *N*, is the number of elements of the phased array or, if `H.SensorArray` contains subarrays, the number of subarrays. Each column of `SV` contains the steering vector of the array for the corresponding direction specified in `ANG`. Each of the *L* pages of `SV` contains the steering vectors of the array for the corresponding frequency specified in `FREQ`.

  If you set the `EnablePolarization` to `false` for an array that supports polarization, then all polarization information is discarded. The combined pattern from both `H` and `V` polarizations is used at each element to compute the steering vector.

  Simulating polarization also requires that the sensor array specified in the `SensorArray` property is capable of simulating polarization, and the `IncludeElementResponse` property is set to `true`.

Examples

Steering Vector for Uniform Linear Array

Calculate the steering vector for a uniform linear array in the direction of 30° azimuth and 20° elevation. Assume the array' operates at 300 MHz.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
array = phased.ULA('NumElements',2);
steeringvector = phased.SteeringVector('SensorArray',array);
fc = 300.0e6;
ang = [30;20];
sv = steeringvector(fc,ang);
```

phased.SteppedFMWaveform System object

Package: phased

Stepped FM pulse waveform

Description

The `SteppedFMWaveform` object creates a stepped FM pulse waveform.

To obtain waveform samples:

1. Define and set up your stepped FM pulse waveform. See "Construction" on page 1-1852.
2. Call step to generate the stepped FM pulse waveform samples according to the properties of `phased.SteppedFMWaveform`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations. When the only argument to the `step` method is the System object itself, replace `y = step(obj)` by `y = obj()`.

Construction

`sSFM = phased.SteppedFMWaveform` creates a stepped FM pulse waveform System object, `sSFM`. The object generates samples of a linearly stepped FM pulse waveform.

`sSFM = phased.SteppedFMWaveform(Name,Value)` creates a stepped FM pulse waveform object, `sSFM`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`SampleRate`

Sample rate

Signal sample rate, specified as a positive scalar. Units are Hertz. The ratio of sample rate to pulse repetition frequency *(PRF)* must be a positive integer — each pulse must contain an integer number of samples.

Default: `1e6`

`DurationSpecification`

Method to set pulse duration

Method to set pulse duration (pulse width), specified as `'Pulse width'` or `'Duty cycle'`. This property determines how you set the pulse duration. When you set this property to `'Pulse width'`, then you set the pulse duration directly using the `PulseWidth` property. When you set this property to `'Duty cycle'`, you set the pulse duration from the values of the `PRF` and `DutyCycle` properties. The pulse width is equal to the duty cycle divided by the *PRF*.

Default: `'Pulse width'`

`PulseWidth`

Pulse width

Specify the length of each pulse (in seconds) as a positive scalar. The value must satisfy `PulseWidth <= 1./PRF`.

Default: `50e-6`

`DutyCycle`

Waveform duty cycle

Waveform duty cycle, specified as a scalar from 0 through 1, inclusive. This property applies when you set the `DurationSpecification` property to `'Duty cycle'`. The pulse width is the value of the `DutyCycle` property divided by the value of the `PRF` property.

Default: `0.5`

PRF

Pulse repetition frequency

Pulse repetition frequency, *PRF*, specified as a scalar or a row vector. Units are in Hz. The pulse repetition interval *PRI* is the inverse of the *PRF*. The value of the `PRF` property must satisfy these constraints:

- The product of *PRF* and *PulseWidth* must be less than or equal to one. This is equivalent to the requirement that the pulse width is less than a pulse repetition interval. For the phase-coded waveform, the pulse width is the product of the chip width and number of chips.
- The ratio of sample rate to PRF must be an integer. This is equivalent to requiring that the number of samples in one pulse repetition interval be an integer.

You can select the value of *PRF* by using property settings or input arguments.

- When `PRFSelectionInputPort` is `false`, you set the *PRF* using properties
  - implement a constant *PRF* by specifying `PRF` as a positive real-valued scalar.
  - implement a staggered *PRF* by specifying `PRF` as a row vector with positive real-valued entries. Then, each call to the `step` method uses successive elements of this vector for the *PRF*. If the last element of the vector is reached, the process continues cyclically with the first element of the vector.
- When `PRFSelectionInputPort` is `true`, you can implement a selectable *PRF* by specifying `PRF` as a row vector with positive real-valued entries. But this time, when you execute the `step` method, select a *PRF* by passing an index into the *PRF* vector as an argument.

In all cases, when you use a varying *PRF* and choose the `OutputFormat` property as `'Pulses'`, the number of samples per pulse can vary as well. When you choose `'Samples'` the number of samples per pulse is fixed.

Default: `10e3`

PRFSelectionInputPort

Enable PRF selection input

Enable the PRF selection input, specified as `true` or `false`. When you set this property to `false`, the step method uses the values set in the `PRF` property in order. When you

set this property to `true`, you can pass an additional argument into the `step` method to select any value from the PRF vector.

Default: `false`

`FrequencyStep`

Linear frequency step size

Specify the linear frequency step size (in hertz) as a positive scalar. The default value of this property corresponds to 20 kHz.

Default: `20e3`

`NumSteps`

Specify the number of frequency steps as a positive integer. When `NumSteps` is 1, the stepped FM waveform reduces to a rectangular waveform.

Default: `5`

`OutputFormat`

Output signal format

Specify the format of the output signal as `'Pulses'` or `'Samples'`. When you set the `OutputFormat` property to `'Pulses'`, the output of the `step` method takes the form of multiple pulses specified by the value of the `NumPulses` property. The number of samples per pulse can vary if you change the pulse repetition frequency during the simulation.

When you set the `OutputFormat` property to `'Samples'`, the output of the `step` method is in the form of multiple samples. In this case, the number of output signal samples is the value of the `NumSamples` property and is fixed.

Default: `'Pulses'`

`NumSamples`

Number of samples in output

Specify the number of samples in the output of the `step` method as a positive integer. This property applies only when you set the `OutputFormat` property to `'Samples'`.

Default: `100`

`NumPulses`

Number of pulses in output

Specify the number of pulses in the output of the `step` method as a positive integer. This property applies only when you set the `OutputFormat` property to `'Pulses'`.

Default: 1

Methods

bandwidth	Bandwidth of stepped FM pulse waveform
getMatchedFilter	Matched filter coefficients for waveform
plot	Plot stepped FM pulse waveform
reset	Reset state of stepped FM pulse waveform object
step	Samples of stepped FM pulse waveform

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Plot Stepped-FM Waveform and Spectrum

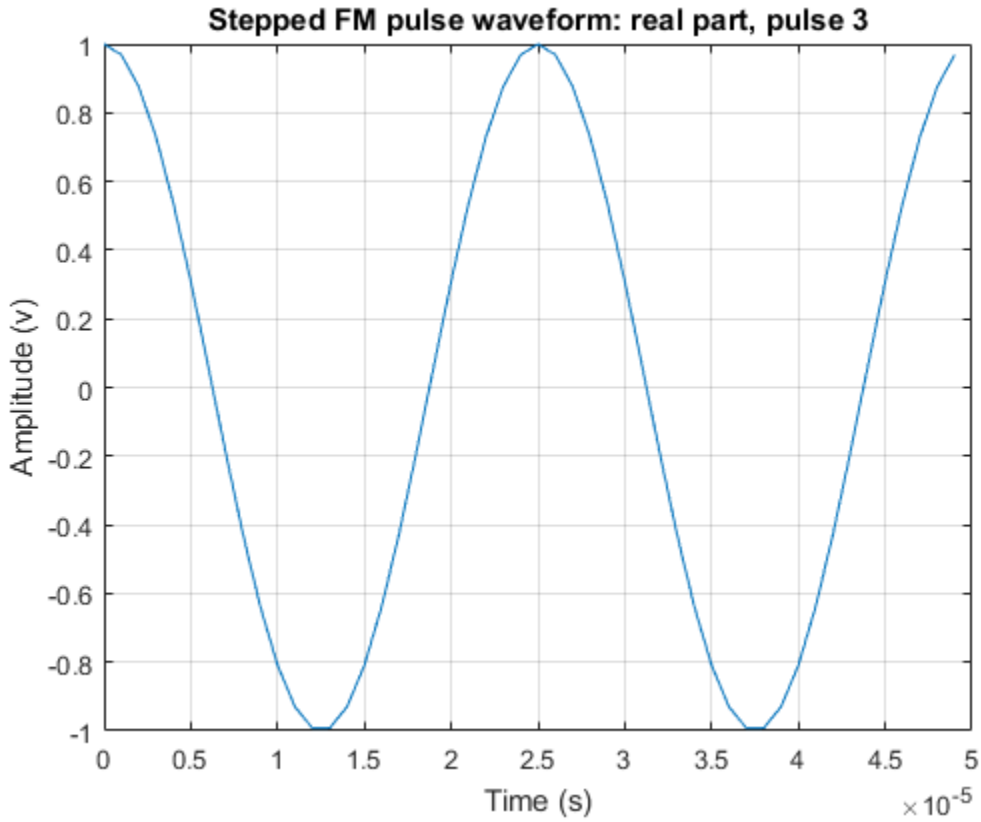
Create a stepped frequency pulse waveform object. Assume the default value, 1 MHz, for the sample rate. Then, plot the waveform.

Create the SteppedFMWaveform System object™ with 20 kHz frequency step size.

```
sSFM = phased.SteppedFMWaveform('NumSteps',3,'FrequencyStep',20e3);
fs = sSFM.SampleRate;
```

Plot the third pulse of the wave using the `phased.SteppedFMWaveform.plot` method. Pass in the pulse number using the `'PulseIdx'` name-value pair.

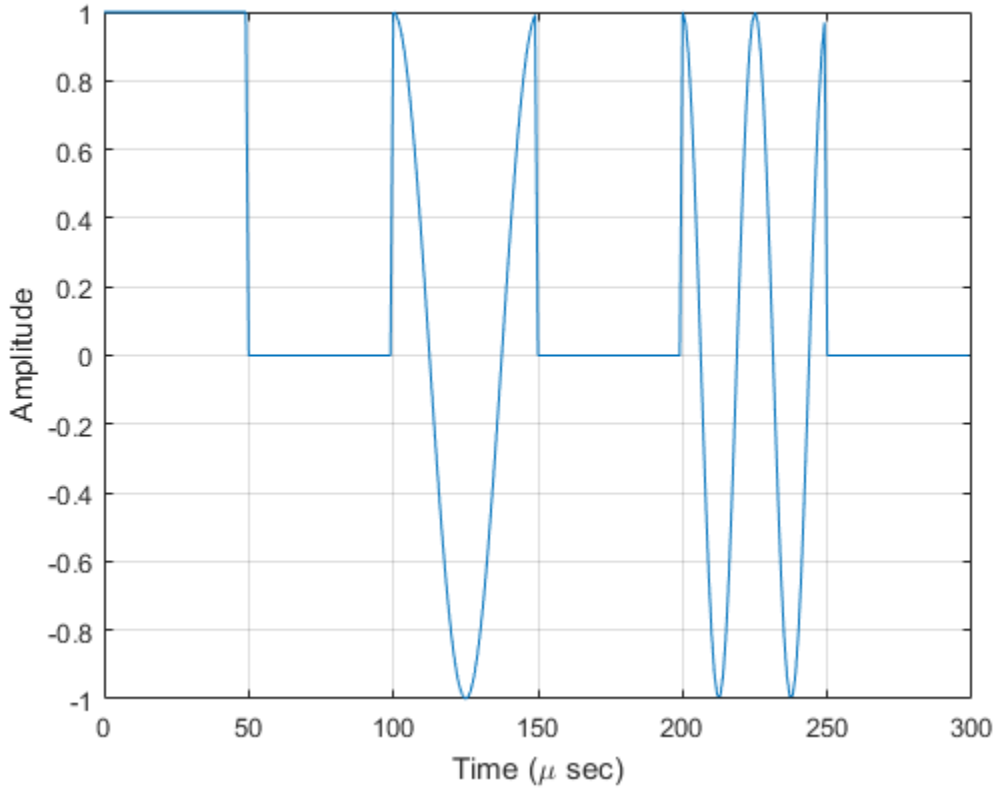
```
plot(sSFM,'PulseIdx',3);
```



Alternatively, call the `step` method three times to obtain three pulses. Collect the three pulses in a single time series. Then plot the waveform using the `plot` function. You can see the full duty cycles of the pulses.

```
wavfull = [];
wav = step(sSFM);
wavfull = [wavfull;wav];
wav = step(sSFM);
wavfull = [wavfull;wav];
```

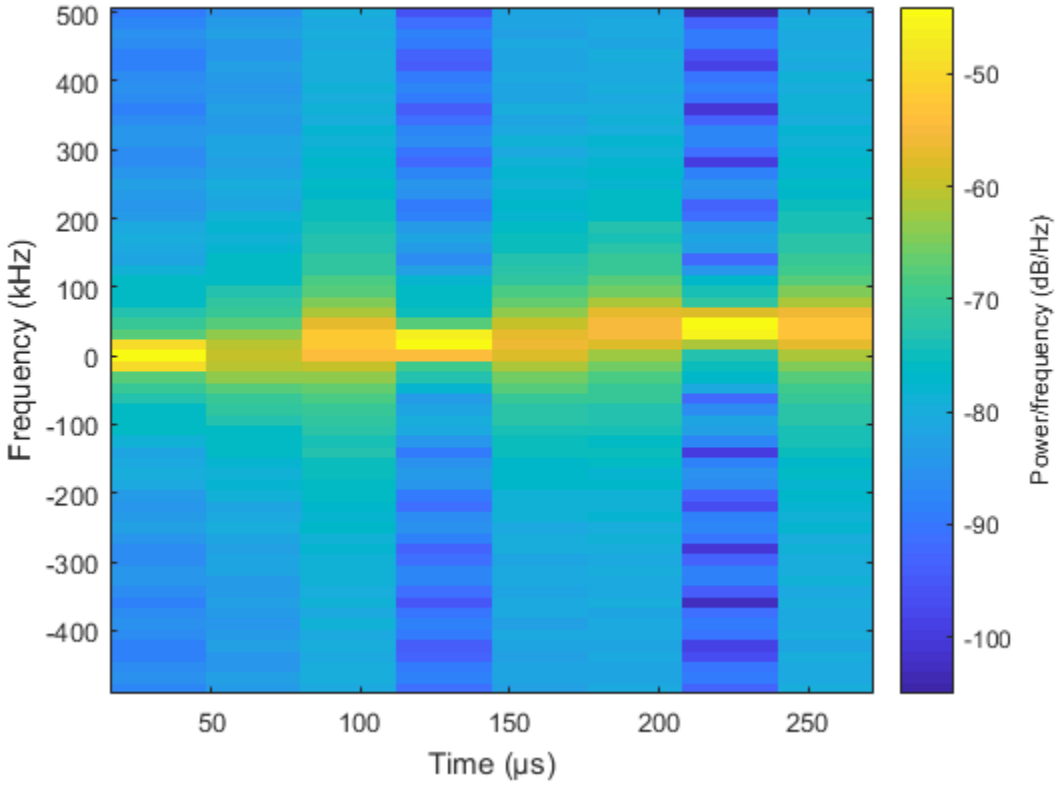
```
wav = step(sSFM);
wavfull = [wavfull;wav];
nsamps = size(wavfull,1);
t = [0:(nsamps-1)]/fs*1e6;
plot(t,real(wavfull))
xlabel('Time (\mu sec)')
ylabel('Amplitude')
grid
```



Plot the spectrum using the `spectrogram` function. Assume an fft of 64 samples and a 50% overlap. Window the signal with a hamming function.

```
nfft1 = 64;
nov = floor(0.5*nfft1);
```

```
spectrogram(wavfull,hamming(nfft1),nov,nfft1,fs,'centered','yaxis')
```



- Waveform Analysis Using the Ambiguity Function

Definitions

Stepped FM Waveform

In a stepped FM waveform, a group of pulses together sweep a certain bandwidth. Each pulse in this group occupies a given center frequency and these center frequencies are uniformly located within the total bandwidth.

Topics

Waveform Analysis Using the Ambiguity Function

Introduced in R2012a

bandwidth

System object: phased.SteppedFMWaveform
Package: phased

Bandwidth of stepped FM pulse waveform

Syntax

```
BW = bandwidth(H)
```

Description

`BW = bandwidth(H)` returns the bandwidth (in hertz) of the pulses for the stepped FM pulse waveform `H`. If there are N frequency steps, the bandwidth equals N times the value of the `FrequencyStep` property. If there is no frequency stepping, the bandwidth equals the reciprocal of the pulse width.

Input Arguments

`H`

Stepped FM pulse waveform object.

Output Arguments

`BW`

Bandwidth of the pulses, in hertz.

Examples

Bandwidth of Stepped FM Waveform.

Determine the bandwidth of a stepped FM waveform.

```
waveform = phased.SteppedFMWaveform;
bw = bandwidth(waveform)

bw =

       100000
```

getMatchedFilter

System object: phased.SteppedFMWaveform
Package: phased

Matched filter coefficients for waveform

Syntax

```
Coeff = getMatchedFilter(H)
```

Description

`Coeff = getMatchedFilter(H)` returns the matched filter coefficients for the stepped FM waveform object `H`. `Coeff` is a matrix whose columns correspond to the different frequency pulses in the stepped FM waveform.

Examples

Matched Filter Coefficients for Stepped FM Pulse

Get the matched filter coefficients for a stepped FM pulse waveform.

```
waveform = phased.SteppedFMWaveform(...
    'NumSteps',3,'FrequencyStep',2e4,...
    'OutputFormat','Pulses','NumPulses',3);
coeff = getMatchedFilter(waveform);
```

Show the first four coefficients for each step.

```
coeff(1:4,:)
```

```
ans =

   1.0000 + 0.0000i   0.9921 + 0.1253i   0.9686 + 0.2487i
   1.0000 + 0.0000i   0.9686 + 0.2487i   0.8763 + 0.4818i
   1.0000 + 0.0000i   0.9298 + 0.3681i   0.7290 + 0.6845i
```

```
1.0000 + 0.0000i   0.8763 + 0.4818i   0.5358 + 0.8443i
```

plot

System object: phased.SteppedFMWaveform
Package: phased

Plot stepped FM pulse waveform

Syntax

```
plot(Hwav)
plot(Hwav,Name,Value)
plot(Hwav,Name,Value,LineSpec)
h = plot( ___ )
```

Description

`plot(Hwav)` plots the real part of the waveform specified by `Hwav`.

`plot(Hwav,Name,Value)` plots the waveform with additional options specified by one or more `Name,Value` pair arguments.

`plot(Hwav,Name,Value,LineSpec)` specifies the same line color, line style, or marker options as are available in the MATLAB `plot` function.

`h = plot( ___ )` returns the line handle in the figure.

Input Arguments

`Hwav`

Waveform object. This variable must be a scalar that represents a single waveform object.

`LineSpec`

Character vector to specifies the same line color, style, or marker options as are available in the MATLAB `plot` function. If you specify a `PlotType` value of `'complex'`, then `LineSpec` applies to both the real and imaginary subplots.

Default: `'b'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'PlotType'`

Specifies whether the function plots the real part, imaginary part, or both parts of the waveform. Valid values are `'real'`, `'imag'`, and `'complex'`.

Default: `'real'`

`'PulseIdx'`

Index of the pulse to plot. This value must be a scalar.

Default: 1

Output Arguments

`h`

Handle to the line or lines in the figure. For a `PlotType` value of `'complex'`, `h` is a column vector. The first and second elements of this vector are the handles to the lines in the real and imaginary subplots, respectively.

Examples

Plot Stepped FM Waveform

Create and plot a stepped frequency pulse waveform.

```
waveform = phased.SteppedFMWaveform('NumSteps',3);
plot(waveform);
```

reset

System object: phased.SteppedFMWaveform
Package: phased

Reset state of stepped FM pulse waveform object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `SteppedFMWaveform` object, `H`. Afterward, if the `PRF` property is a vector, the next call to `step` uses the first PRF value in the vector.

step

System object: phased.SteppedFMWaveform
Package: phased

Samples of stepped FM pulse waveform

Syntax

```
Y = step(sSFM)
Y = step(sSFM,prfidx)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations. When the only argument to the `step` method is the System object itself, replace `y = step(obj)` by `y = obj()`.

`Y = step(sSFM)` returns samples of the stepped FM pulses in a column vector, `Y`. The output, `Y`, results from increasing the frequency of the preceding output by an amount specified by the `FrequencyStep` property. If the total frequency increase is larger than the value specified by the `SweepBandwidth` property, the samples of a rectangular pulse are returned.

`Y = step(sSFM,prfidx)`, uses the `prfidx` index to select the PRF from the predefined vector of values specified by in the `PRF` property. This syntax applies when you set the `PRFSelectionInputPort` property to `true`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To

change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Examples

Create Stepped Frequency Pulse Waveform

Create a stepped frequency pulse waveform object with a frequency step of 40 kHz and four frequency steps.

```
waveform = phased.SteppedFMWaveform(...
    'NumSteps',4,'FrequencyStep',40e3,...
    'OutputFormat','Pulses','NumPulses',1);
fs = waveform.SampleRate;
```

Use the `waveform` method to obtain the pulses.

First, generate pulse 1.

```
pulse1 = waveform();
```

Then, generate pulse 2, incremented by the frequency step 40 kHz

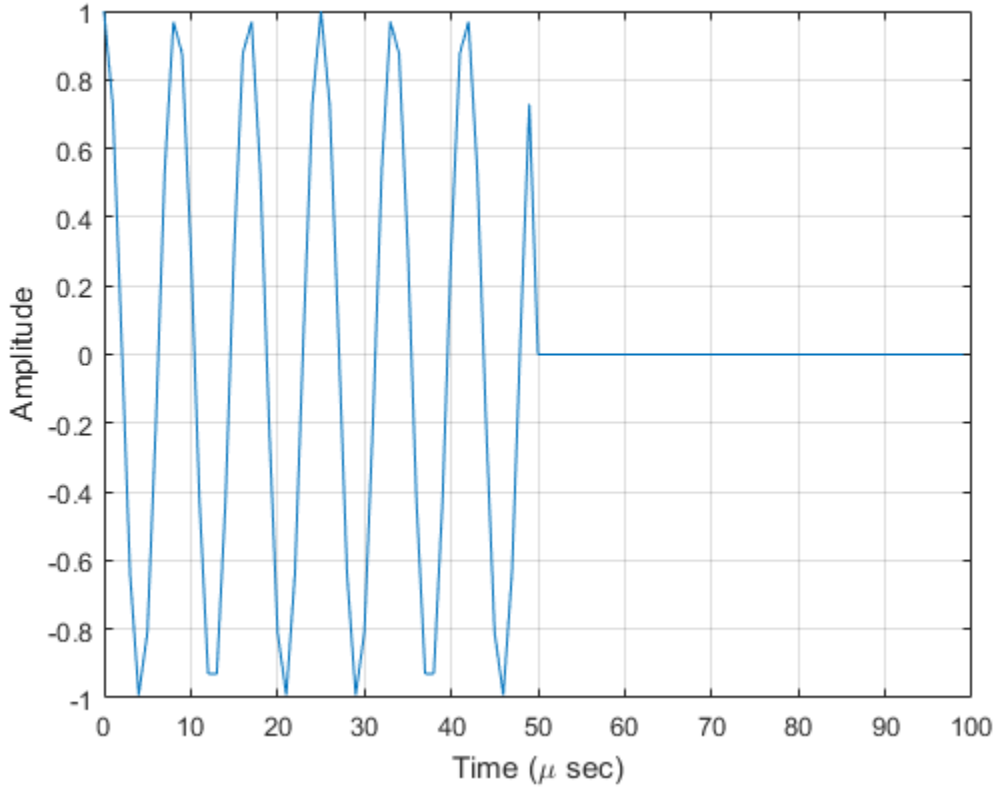
```
pulse2 = waveform();
```

Next, generate pulse 3, incremented by the frequency step 40 kHz

```
pulse3 = waveform();
```

Finally, generate pulse 4, incremented by the frequency step 40 kHz

```
pulse4 = waveform();
nsamps = size(pulse4,1);
t = [0:(nsamps-1)]/fs*1e6;
plot(t,real(pulse4))
xlabel('Time (\mu sec)')
ylabel('Amplitude')
grid
```



Definitions

Stepped FM Waveform

In a stepped FM waveform, a group of pulses together sweep a certain bandwidth. Each pulse in this group occupies a given center frequency and these center frequencies are uniformly located within the total bandwidth.

phased.StretchProcessor System object

Package: phased

Stretch processor for linear FM waveform

Description

The `StretchProcessor` object performs stretch processing on data from a linear FM waveform.

To perform stretch processing:

1. Define and set up your stretch processor. See "Construction" on page 1-1872.
2. Call step to perform stretch processing on input data according to the properties of `phased.StretchProcessor`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.StretchProcessor` creates a stretch processor System object, `H`. The object performs stretch processing on data from a linear FM waveform.

`H = phased.StretchProcessor(Name,Value)` creates a stretch processor object, `H`, with additional options specified by one or more `Name,Value` pair arguments. `Name` is a property name, and `Value` is the corresponding value. `Name` must appear inside single quotes (`''`). You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

Properties

`SampleRate`

Sample rate

Signal sample rate, specified as a positive scalar. Units are Hertz. The ratio of sample rate to pulse repetition frequency *(PRF)* must be a positive integer — each pulse must contain an integer number of samples.

Default: `1e6`

`PulseWidth`

Pulse width

Specify the length of each pulse (in seconds) as a positive scalar. The value must satisfy `PulseWidth <= 1./PRF`.

Default: `50e-6`

`PRF`

Pulse repetition frequency

Pulse repetition frequency, *PRF*, specified as a scalar or a row vector. Units are in Hz. The pulse repetition interval *PRI* is the inverse of the *PRF*. The value of the `PRF` property must satisfy these constraints:

- The product of *PRF* and *PulseWidth* must be less than or equal to one. This is equivalent to the requirement that the pulse width is less than a pulse repetition interval. For the phase-coded waveform, the pulse width is the product of the chip width and number of chips.
- The ratio of sample rate to PRF must be an integer. This is equivalent to requiring that the number of samples in one pulse repetition interval be an integer.

You can select the value of *PRF* by using property settings or input arguments.

- When `PRFSelectionInputPort` is `false`, you set the *PRF* using properties
  - implement a constant *PRF* by specifying `PRF` as a positive real-valued scalar.

  - implement a staggered *PRF* by specifying `PRF` as a row vector with positive real-valued entries. Then, each call to the `step` method uses successive elements of this vector for the *PRF*. If the last element of the vector is reached, the process continues cyclically with the first element of the vector.
- When `PRFSelectionInputPort` is `true`, you can implement a selectable *PRF* by specifying `PRF` as a row vector with positive real-valued entries. But this time, when you execute the `step` method, select a *PRF* by passing an index into the *PRF* vector as an argument.

In all cases, when you use a varying *PRF* and choose the `OutputFormat` property as `'Pulses'`, the number of samples per pulse can vary as well. When you choose `'Samples'` the number of samples per pulse is fixed.

Default: `10e3`

`SweepSlope`

FM sweep slope

Specify the slope of the linear FM sweeping, in hertz per second, as a scalar.

Default: `2e9`

`SweepInterval`

Location of FM sweep interval

Specify the linear FM sweeping interval using the value `'Positive'` or `'Symmetric'`. If `SweepInterval` is `'Positive'`, the waveform sweeps in the interval between 0 and B, where B is the sweeping bandwidth. If `SweepInterval` is `'Symmetric'`, the waveform sweeps in the interval between –B/2 and B/2.

Default: `'Positive'`

`PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

Default: Speed of light

`ReferenceRange`

Reference range of stretch processing

Specify the center of ranges of interest, in meters, as a positive scalar. The reference range must be within the unambiguous range of one pulse. This property is tunable.

Default: `5000`

`RangeSpan`

Span of ranges of interest

Specify the length of the interval for ranges of interest, in meters, as a positive scalar. The range span is centered at the range value specified in the `ReferenceRange` property.

Default: `500`

Methods

step	Perform stretch processing for linear FM waveform

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Detect a Target Using Stretch Processing

Use stretch processing to locate a target at a range of 4950 m.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Simulate the signal.

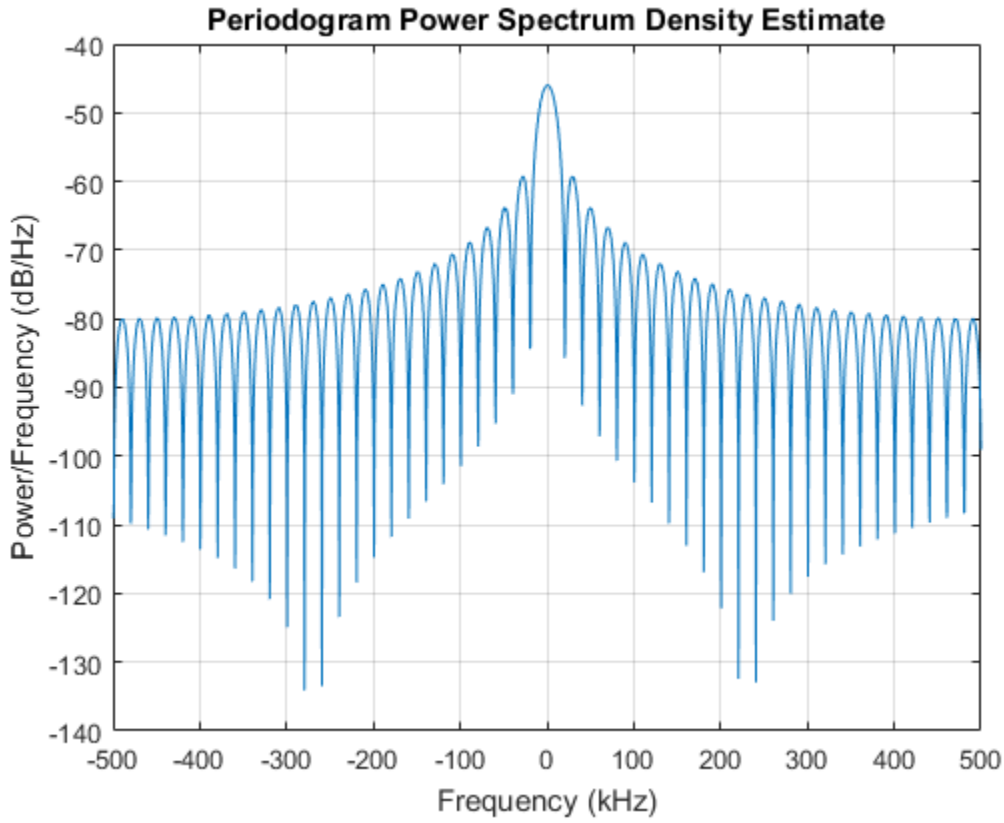
```
waveform = phased.LinearFMWaveform;
x = waveform();
c = physconst('LightSpeed');
rng = 4950.0;
num_samples = round(rng/(c/(2*waveform.SampleRate)));
x = circshift(x,num_samples);
```

Perform stretch processing.

```
stretchproc = getStretchProcessor(waveform,5000,200,c);
y = stretchproc(x);
```

Plot the spectrum of the resulting signal.

```
[Pxx,F] = periodogram(y,[],2048,stretchproc.SampleRate,'centered');
plot(F/1000,10*log10(Pxx))
grid
xlabel('Frequency (kHz)')
ylabel('Power/Frequency (dB/Hz)')
title('Periodogram Power Spectrum Density Estimate')
```



Detect the range.

```
[~,rngidx] = findpeaks(pow2db(Pxx/max(Pxx)),'MinPeakHeight',-5);
rngfreq = F(rngidx);
rng = stretchfreq2rng(rngfreq,stretchproc.SweepSlope,stretchproc.ReferenceRange,c)
```

```
rng =

   4.9634e+03
```

Perform stretch processing for linear FM waveform

Syntax

```
Y = step(H,X)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` applies stretch processing along the first dimension of `X`. Each column of `X` represents one receiving pulse.

Input Arguments

`H`

Stretch processor object.

`X`

Input signal matrix. Each column represents one received pulse.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Output Arguments

Y

Result of stretch processing. The dimensions of `Y` match the dimensions of `X`.

Examples

Detect a Target Using Stretch Processing

Use stretch processing to locate a target at a range of 4950 m.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Simulate the signal.

```
waveform = phased.LinearFMWaveform;
x = waveform();
c = physconst('LightSpeed');
rng = 4950.0;
num_samples = round(rng/(c/(2*waveform.SampleRate)));
x = circshift(x,num_samples);

phased.SubbandMVDRBeamformer System object

Package: phased

Subband MVDR (Capon) beamformer

Description

The `phased.SubbandMVDRBeamformer` System object implements a minimum variance distortionless response beamformer (MVDR). The beamformer performs wideband beamforming using the subband processing technique. This type of beamformer is also called a Capon beamformer.

To compute the beamformed signal:

1. Define and set up your subband MVDR beamformer as shown in the "Construction" on page 1-1185 section.
2. Call step to perform the beamforming operation according to the properties of `phased.SubbandMVDRBeamformer`.

   The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`sMVDR = phased.SubbandMVDRBeamformer` creates a subband MVDR beamformer System object, `sMVDR`. The object performs subband MVDR beamforming on the received signal.

`sMVDR = phased.SubbandMVDRBeamformer(Name,Value)` creates a subband MVDR beamformer System object, `sMVDR`, with each specified property `Name` set to the

specified `Value`. You can specify additional name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Properties

`SensorArray` — Sensor array

`phased.ULA` (default) | Phased Array System Toolbox sensor array System object

Sensor array, specified as a Phased Array System Toolbox System object. The default value is a phased.ULA System object taking its default values.

Example: `phased.URA`

`PropagationSpeed` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. Units are in m/s. The default value of the speed of light is the value returned by `physconst('LightSpeed')`.

Example: `3e8`

Data Types: `double`

`OperatingFrequency` — Operating frequency

`300e6` (default) | positive real-valued scalar

Operating frequency of beamformer, specified as a positive real-valued scalar. Units are in hertz.

Example: 1e9

Data Types: `double`

`SampleRate` — Signal sample rate

`1e6` (default) | positive real-valued scalar

Signal sample rate, specified as a real-valued positive scalar. Units are hertz.

Example: `20e6`

Data Types: `double`

`NumSubbands` — Number of subbands

64 (default) | positive integer

Number of processing subbands, specified as a positive integer. See "Subband Frequency Processing" on page 1-1890

Example: `64`

Data Types: `double`

`DirectionSource` — Beamforming direction source

`'Property'` (default) | `'Input port'`

Beamforming direction source, specified as either `'Property'` or `'Input port'`. This property determines how to supply beamforming direction information to the beamformer.

`'Property'`	Use the `Direction` property of the object to determine the beamforming direction.
`'Input port'`	Use the input argument `ang` of the `step` method to determine the beamforming direction.

`DiagonalLoadingFactor` — Diagonal loading factor

`0` (default) | positive real-valued scalar

Diagonal loading factor, specified as a positive real-valued scalar. *Diagonal loading* (see "Diagonal Loading" on page 1-1889) is a technique used to achieve robust beamforming performance, especially when the sample support is small. This property is tunable.

Example: `0.5`

Data Types: `double`

`Direction` — Beamforming directions

`[0;0]` (default) | 2-by-1 real-valued vector | 2-by-*M* real-valued matrix

Beamforming directions, specified as a 2-by-1 real-valued vector or 2-by-*M* real-valued matrix. Each column of the matrix has the form `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. Azimuth angles lie between –180° and 180° and elevation angles lie between –90° and 90°. All angles are defined with respect to the local coordinate system of the array. This property applies only when you set the `DirectionSource` property to `'Property'`

Example: `[40;20]`

Data Types: `double`

`TrainingInputPort` — Option to use separate training data

`false` (default) | `true`

Option to use separate training data, specified as either `true` or `false`. Set this property to `true` and then use the corresponding input argument `XT` of the step method. To use the input signal as training data, set this property to `false`.

Example: `true`

Data Types: `logical`

`WeightsOutputPort` — Option to enable beamforming weights output

`false` (default) | `true`

Option to enable beamforming weights output, specified as either `true` or `false`. To obtain the weights used by the beamformer, set this property to `true` and use the corresponding output argument `Wts` when calling the step method.

Example: `true`

Data Types: `logical`

`SubbandsOutputPort` — Option to enable output of subband center frequencies

`false` (default) | `true`

Option to enable output of subband center frequencies, specified as either `true` or `false`. To obtain the subband center frequencies, set this property to `true` and use the corresponding output argument `Freq` when calling step.

Example: `true`

Data Types: `logical`

Methods

reset	Reset states of System object
step	Wideband MVDR beamforming

Common to All System Objects	
`clone`	Create System object with same property values

Common to All System Objects	
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Subband MVDR Beamforming of ULA

Apply subband MVDR beamforming to an underwater acoustic 11-element ULA. The incident angle of the signal is 10 degrees in azimuth and 30 degrees in elevation. The signal is an FM chirp having a bandwidth of 1 kHz. The speed of sound is 1500 meters per second.

Simulate the Signal

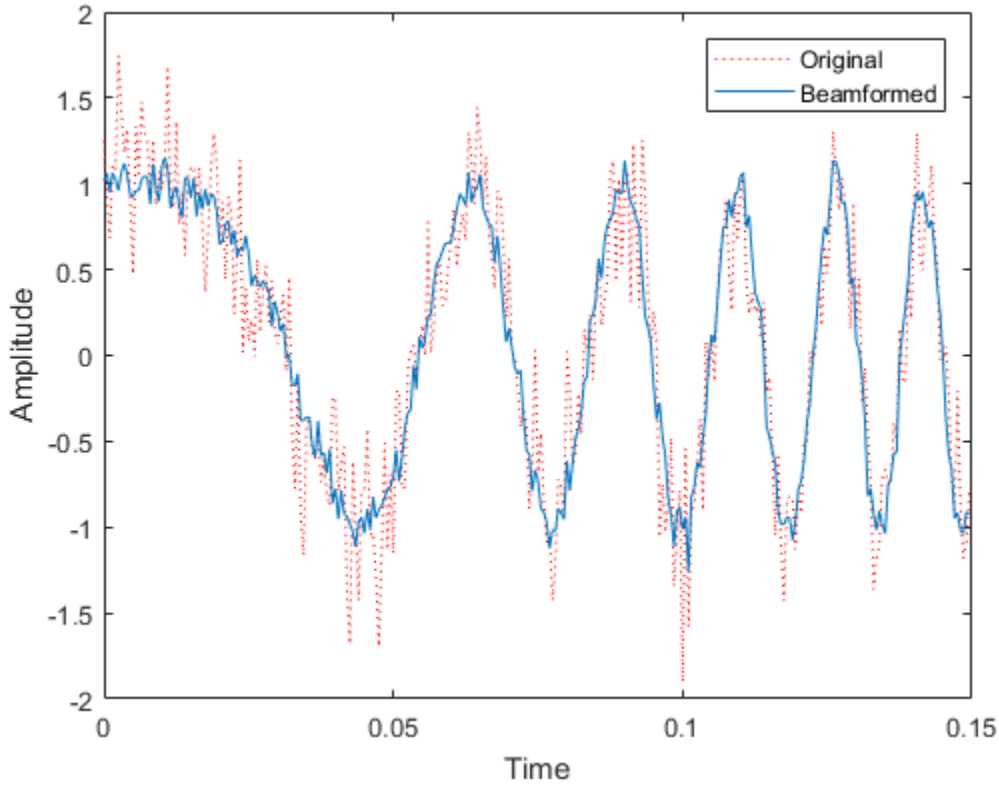
```
sULA = phased.ULA('NumElements',11,'ElementSpacing',0.3);
fs = 2e3;
carrierFreq = 2000;
t = (0:1/fs:2)';
sig = chirp(t,0,2,fs/2);
c = 1500;
sCol = phased.WidebandCollector('Sensor',sULA,'PropagationSpeed',c,...
    'SampleRate',fs,'ModulatedInput',true,...
    'CarrierFrequency',carrierFreq);
incidentAngle = [10;0];
sig1 = step(sCol,sig,incidentAngle);
noise = 0.3*(randn(size(sig1)) + 1j*randn(size(sig1)));
rx = sig1 + noise;
```

Apply MVDR Beamforming

```
sMVDR = phased.SubbandMVDRBeamformer('SensorArray',sULA,...
    'Direction',incidentAngle,'OperatingFrequency',carrierFreq,...
    'PropagationSpeed',c,'SampleRate',fs,'TrainingInputPort',true, ...
    'SubbandsOutputPort',true,'WeightsOutputPort',true);
[y,w,subbandfreq] = step(sMVDR, rx, noise);
```

Plot the signal that is input to the middle sensor (6) against the beamformer output.

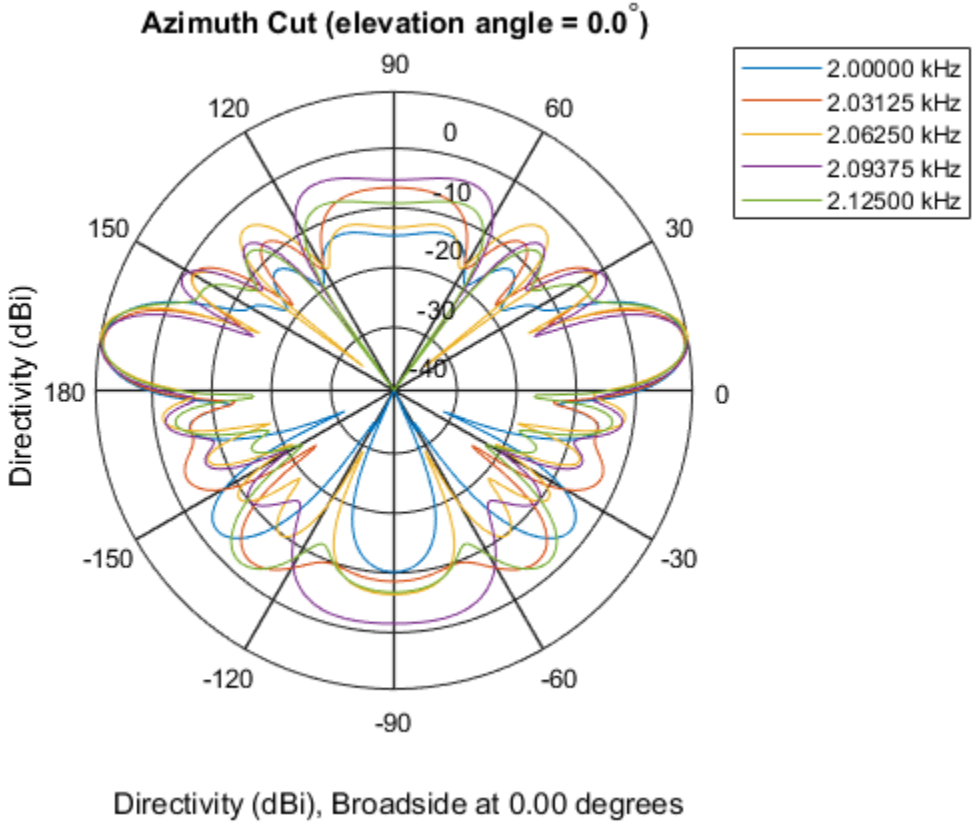
```
plot(t(1:300),real(rx(1:300,6)),'r:',t(1:300),real(y(1:300)))
xlabel('Time')
ylabel('Amplitude')
legend('Original','Beamformed');
```



Plot Array Response

Plot the response pattern for five bands

```
pattern(sULA,subbandfreq(1:5).',-180:180,0,...
    'PropagationSpeed',c,'Weights',w(:,1:5));
```



Definitions

Diagonal Loading

Diagonal loading is a technique to improve beamformer robustness when stability issues arise from steering vector errors or finite sample size effects. This technique adds a positive real-valued multiple of the identity matrix to the correlation matrix of the received array data vector. You can apply diagonal loading using the `DiagonalLoadingFactor` property.

Subband Frequency Processing

Subband processing decomposes a wideband signal into multiple subbands and applies narrowband processing to the signal in each subband. The signals for all subbands are summed to form the output signal.

When using wideband frequency System objects or blocks, you specify the number of subbands, N_b, in which to decompose the wideband signal. Subband center frequencies and widths are automatically computed from the total bandwidth and number of subbands. The total frequency band is centered on the carrier or operating frequency, f_c. The overall bandwidth is given by the sample rate, f_s. Frequency subband widths are $\Delta f = f_s/N_B$. The center frequencies of the subbands are

$$f_m = \begin{cases} f_c - \dfrac{f_s}{2} + (m-1)\Delta f, & N_B \text{ even} \\ f_c - \dfrac{(N-1)f_s}{2N} + (m-1)\Delta f, & N_B \text{ odd} \end{cases}, m = 1,\ldots,N_B$$

Some System objects let you obtain the subband center frequencies as output from the `step` method. The returned subband frequencies are ordered consistent with the ordering of the discrete Fourier transform. Frequencies above the carrier appear first, followed by frequencies below the carrier.

The `phased.SubbandMVDRBeamformer` System object uses the narrowband MVDR algorithm for each subband.

Introduced in R2015b

reset

System object: phased.SubbandMVDRBeamformer
Package: phased

Reset states of System object

Syntax

```
reset(sMVDR)
```

Description

`reset(sMVDR)` resets the internal state of the `phased.SubbandMVDRBeamformer` object, `sWBFS`. If the `SeedSource` property applies and has the value `'Property'`, then this method resets the state of the random number generator.

Input Arguments

`sMVDR` — Subband MVDR beamformer

System object

Subband MVDR beamformer, specified as a System object.

Example: `phased.SubbandMVDRBeamformer`

Introduced in R2015b

step

System object: phased.SubbandMVDRBeamformer
Package: phased

Wideband MVDR beamforming

Syntax

```
Y = step(sMVDR,X)
Y = step(sMVDR,X,XT)
Y = step(sMVDR,X,ang)
[Y,Wts] = step(sMVDR,___)
[Y,Freq] = step(sMVDR,___)
[Y,Wts,Freq] = step(sMVDR,X,XT,ang)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(sMVDR,X)` performs wideband MVDR beamforming on the input, `X`, and returns the beamformed output in `Y`. This syntax uses `X` for training samples to calculate the beamforming weights. Use the `Direction` property to specify the beamforming direction.

`Y = step(sMVDR,X,XT)` uses `XT` as the training samples to calculate the beamforming weights. This syntax applies only when you set the `TrainingInputPort` property to `true`. Use the `Direction` property to specify the beamforming direction.

`Y = step(sMVDR,X,ang)` uses `ang` as the beamforming direction. This syntax applies only when you set the `DirectionSource` property to `'Input port'`.

`[Y,Wts] = step(sMVDR,___)` returns the beamforming weights, `Wts`, when you set the `WeightsOutputPort` property to `true`.

`[Y,Freq] = step(sMVDR, ___ )` returns the center frequencies of the subbands, `Freq`, when you set the `SubbandsOutputPort` property to true. `Freq` is a length-K column vector where, K is the number of subbands specified in the `NumSubbands` property.

You can combine optional input arguments when you set their enabling properties. Optional input arguments must be listed in the same order as their enabling properties. For example, `[Y,Wts,Freq] = step(sMVDR,X,XT,ang)` is valid when you specify `TrainingInputPort` to `true` and specify `DirectionSource` to `'Input port'`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`sMVDR` — Subband MVDR beamformer

System object

Subband MVDR beamformer, specified as a System object.

Example: `phased.SubbandMVDRBeamformer`

`X` — Wideband input field

M-by-N complex-valued matrix

Wideband input field, specified as an M-by-N matrix, where N is the number of array elements. If the sensor array consists of subarrays, N is then the number of subarrays. M is the number of samples in the data.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

If you set the `TrainingInputPort` to `false`, then `step` uses `X` as training data. In this case, the dimension M must be greater than $N \times NB$. where NB is the number of subbands specified in the `NumSubbands` property.

If you set `TrainingInputPort` to `true`, use the `XT` argument to supply training data. In this case, the dimension M can be any positive integer.

Example: `[1,1;j,1;0.5,0]`

Data Types: `double`
Complex Number Support: Yes

`XT` — Wideband training samples

P-by-*N* complex-valued matrix

Wideband training samples, specified as a *P*-by-*N* matrix where *N* is the number of elements. If the sensor array consists of subarrays, then *N* represents the number of subarrays.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

This argument applies when you set `TrainingInputPort` to `true`. The dimension *P* is the number of samples in the training data. *P* must be larger than *N*×*NB*, where *NB* is the number of subbands specified in the `NumSubbands` property.

Example: `FT = [1,1;j,1;0.5,0]`

Data Types: `double`
Complex Number Support: Yes

`ang` — Beamforming direction

2-by-*L* real-valued matrix

Beamforming direction, specified as a *2*-by-*L* real-valued matrix, where *L* is the number of beamforming directions. This argument applies only when you set the `DirectionSource` property to `'Input port'`. Each column takes the form of `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°. Angles are defined with respect to the local coordinate system of the array.

Example: `F = [40 30; 0 10]`

Data Types: `double`

Output Arguments

`Y` — Beamformed output

M-by-*L* complex-valued matrix

Beamformed output, returned as an *M*-by-*L* complex-valued matrix. The quantity *M* is the number of signal samples and *L* is the number of beamforming directions specified in the `ang` argument.

`Wts` — Beamforming weights

N-by-*K*-by-*L* complex-valued matrix

Beamforming weights, returned as an *N*-by-*K*-by-*L* complex-valued matrix. The quantity *N* is the number of sensor elements or subarrays and *K* is the number of subbands specified by the `NumSubbands` property. The quantity *L* is the number of beamforming directions. Each column of `Wts` contains the narrowband beamforming weights used in the corresponding subband for the corresponding directions. This output applies only when you set the `WeightsOutputPort` property to `true`.

`Freq` — Center frequencies of subbands

K-by-1 real-valued column vector

Center frequencies of subbands, returned as a *K*-by-1 real-valued column vector. The quantity *K* is the number of subbands specified by the `NumSubbands` property. To return this output, set the `SubbandsOutputPort` property to `true`.

Examples

Subband MVDR Beamforming of ULA

Apply subband MVDR beamforming to an underwater acoustic 11-element ULA. The incident angle of the signal is 10 degrees in azimuth and 30 degrees in elevation. The signal is an FM chirp having a bandwidth of 1 kHz. The speed of sound is 1500 meters per second.

Simulate the Signal

```
sULA = phased.ULA('NumElements',11,'ElementSpacing',0.3);
fs = 2e3;
carrierFreq = 2000;
t = (0:1/fs:2)';
sig = chirp(t,0,2,fs/2);
c = 1500;
sCol = phased.WidebandCollector('Sensor',sULA,'PropagationSpeed',c,...
    'SampleRate',fs,'ModulatedInput',true,...
```

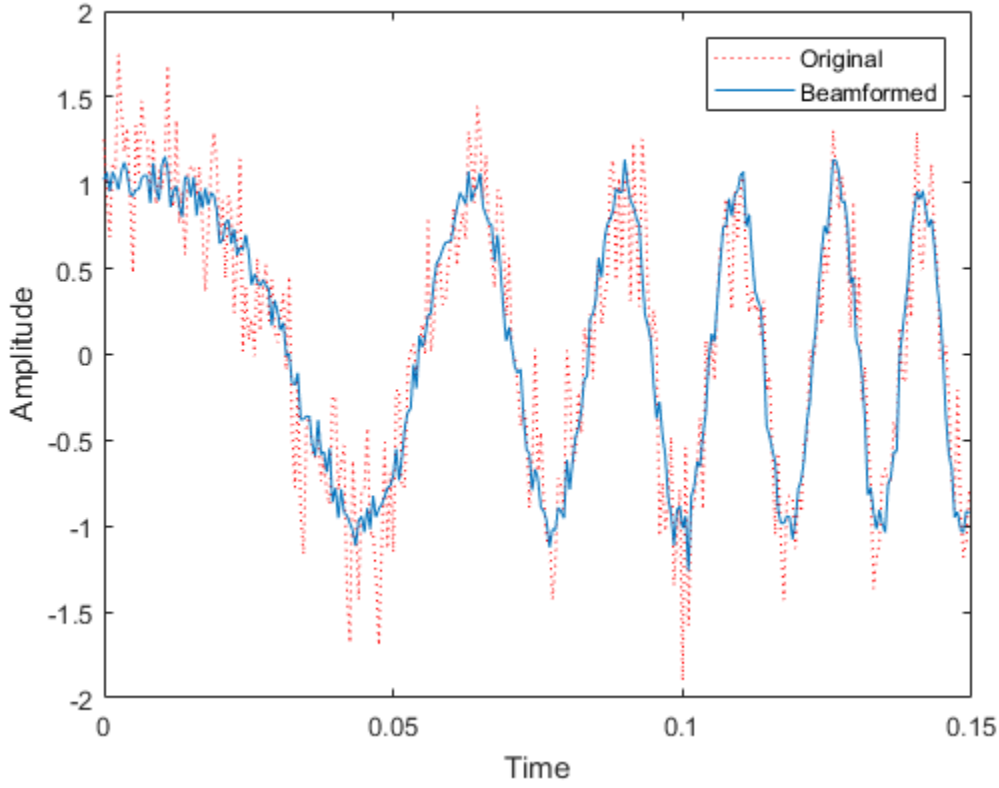
```
    'CarrierFrequency',carrierFreq);
incidentAngle = [10;0];
sig1 = step(sCol,sig,incidentAngle);
noise = 0.3*(randn(size(sig1)) + 1j*randn(size(sig1)));
rx = sig1 + noise;
```

Apply MVDR Beamforming

```
sMVDR = phased.SubbandMVDRBeamformer('SensorArray',sULA,...
    'Direction',incidentAngle,'OperatingFrequency',carrierFreq,...
    'PropagationSpeed',c,'SampleRate',fs,'TrainingInputPort',true, ...
    'SubbandsOutputPort',true,'WeightsOutputPort',true);
[y,w,subbandfreq] = step(sMVDR, rx, noise);
```

Plot the signal that is input to the middle sensor (6) against the beamformer output.

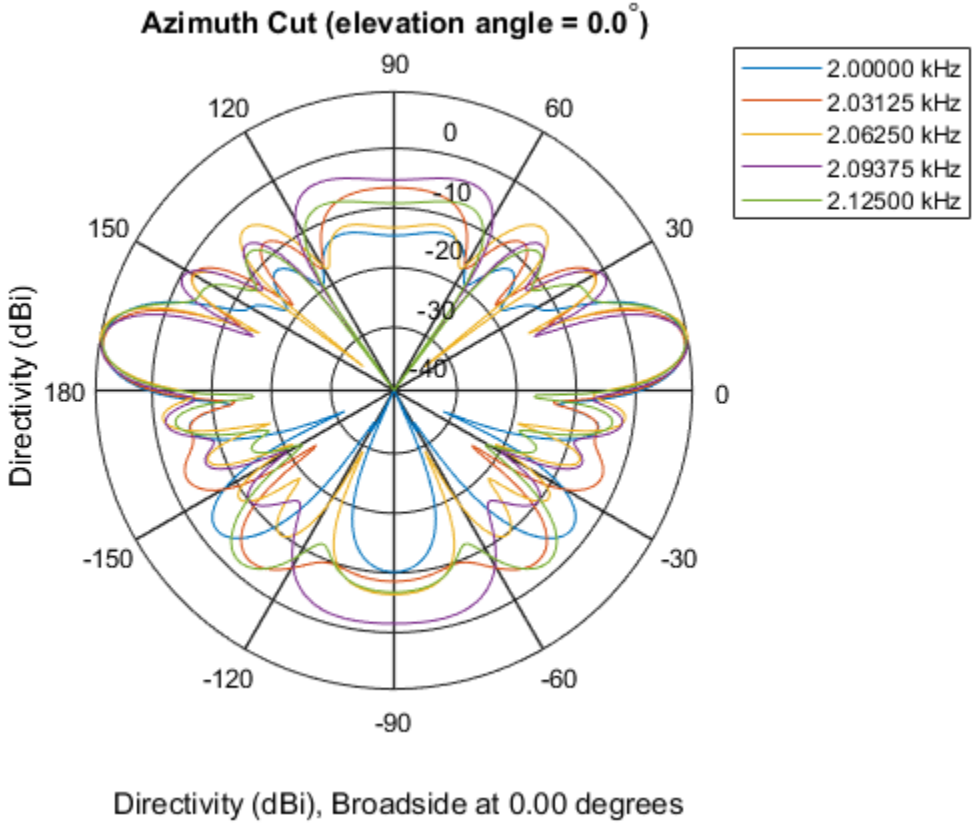
```
plot(t(1:300),real(rx(1:300,6)),'r:',t(1:300),real(y(1:300)))
xlabel('Time')
ylabel('Amplitude')
legend('Original','Beamformed');
```



Plot Array Response

Plot the response pattern for five bands

```
pattern(sULA,subbandfreq(1:5).',-180:180,0,...
    'PropagationSpeed',c,'Weights',w(:,1:5));
```



Subband MVDR Beamforming of Array with Interference

Apply subband MVDR beamforming to an underwater acoustic 11-element ULA. Beamform the arriving signals to optimize the gain of a linear FM chirp signal arriving from 0 degrees azimuth and 0 degrees elevation. The signal has a bandwidth of 2.0 kHz. In addition, there unit amplitude 2.250 kHz interfering sine wave arriving from 28 degrees azimuth and 0 degrees elevation. Show how the MVDR beamformer nulls the interfering signal. Display the array pattern for several frequencies in the neighborhood of 2.250 kHz. The speed of sound is 1500 meters/sec.

Simulate Arriving Signal and Noise

```
array = phased.ULA('NumElements',11,'ElementSpacing',0.3);
fs = 2000;
```

```
carrierFreq = 2000;
t = (0:1/fs:2)';
sig = chirp(t,0,2,fs/2);
c = 1500;
collector = phased.WidebandCollector('Sensor',array,'PropagationSpeed',c,...
    'SampleRate',fs,'ModulatedInput',true,...
    'CarrierFrequency',carrierFreq);
incidentAngle = [0;0];
sig1 = collector(sig,incidentAngle);
noise = 0.3*(randn(size(sig1)) + 1j*randn(size(sig1)));
```

Simulate Interfering Signal

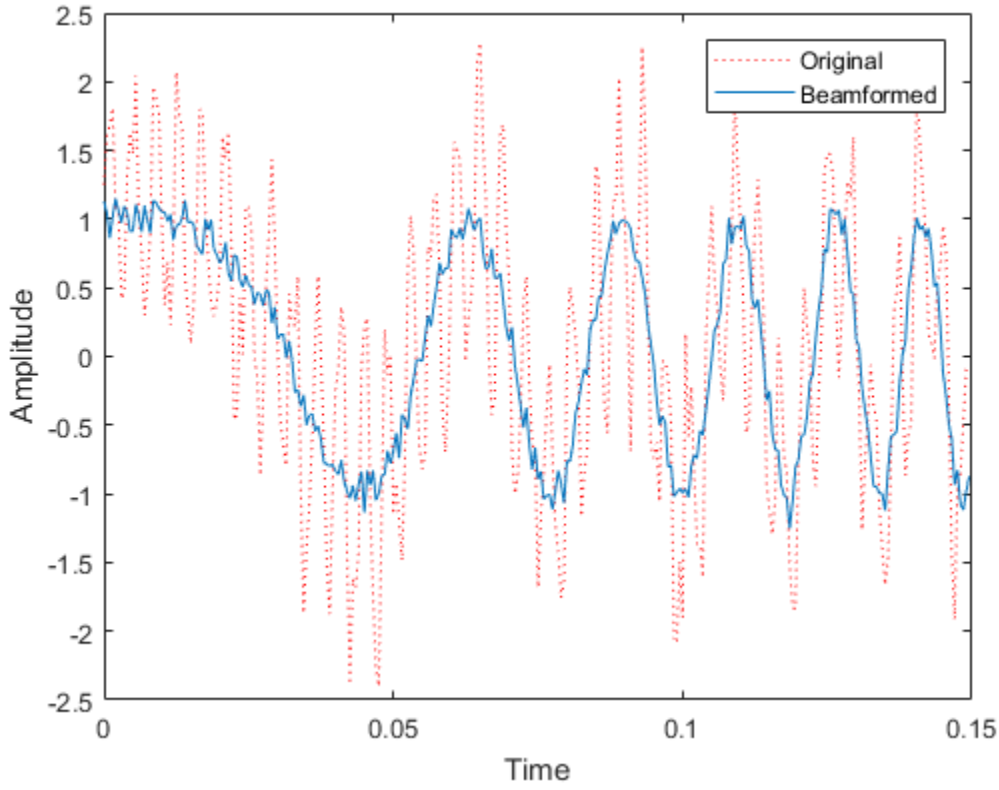
Combine both the desired and interfering signals.

```
fint = 250;
sigint = sin(2*pi*fint*t);
interfangle = [28;0];
sigint1 = collector(sigint,interfangle);
rx = sig1 + sigint1 + noise;
```

Apply MVDR beamforming

Use the combined noise and interfering signal as training data.

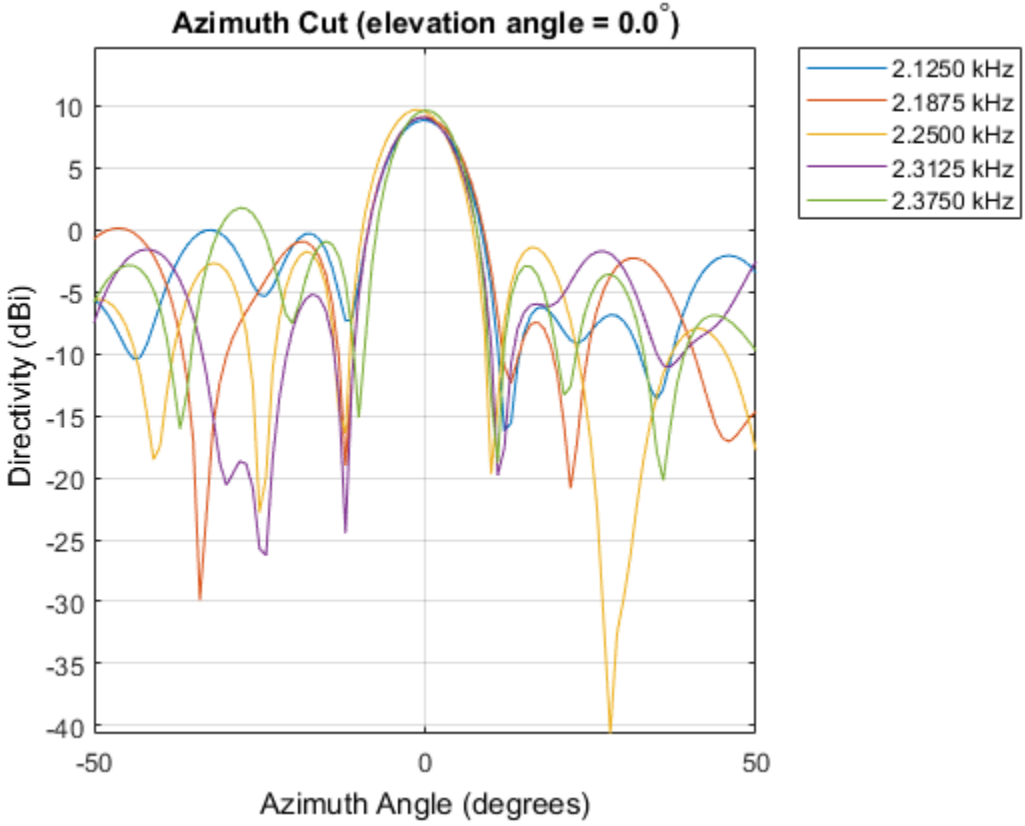
```
beamformer = phased.SubbandMVDRBeamformer('SensorArray',array,...
    'Direction',incidentAngle,'OperatingFrequency',carrierFreq,...
    'PropagationSpeed',c,'SampleRate',fs,'TrainingInputPort',true,...
    'NumSubbands',64,...
    'SubbandsOutputPort',true,'WeightsOutputPort',true);
[y,w,subbandfreq] = beamformer(rx,sigint1 + noise);
tidx = [1:300];
plot(t(tidx),real(rx(tidx,6)),'r:',t(tidx),real(y(tidx)))
xlabel('Time')
ylabel('Amplitude')
legend('Original','Beamformed')
```



Plot Array Response Showing Beampattern Null

Plot the response pattern for five bands near 2.250 kHz.

```
fdx = [5,7,9,11,13];
pattern(array,subbandfreq(fdx).',-50:50,0,...
    'PropagationSpeed',c,'Weights',w(:,fdx),...
    'CoordinateSystem','rectangular');
```



The beamformer places a null at 28 degrees for the subband containing 2.250 kHz.

Introduced in R2015b

phased.SubbandPhaseShiftBeamformer System object

Package: phased

Subband phase shift beamformer

Description

The `SubbandPhaseShiftBeamformer` object implements a subband phase shift beamformer.

To compute the beamformed signal:

1. Define and set up your subband phase shift beamformer. See "Construction" on page 1-1904.
2. Call step to perform the beamforming operation according to the properties of `phased.SubbandPhaseShiftBeamformer`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.SubbandPhaseShiftBeamformer` creates a subband phase shift beamformer System object, `H`. The object performs subband phase shift beamforming on the received signal.

`H = phased.SubbandPhaseShiftBeamformer(Name,Value)` creates a subband phase shift beamformer object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`SensorArray`

Sensor array

Sensor array specified as an array System object belonging to the `phased` package. A sensor array can contain subarrays.

Default: phased.ULA with default property values

`PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

Default: Speed of light

`OperatingFrequency`

System operating frequency

Specify the operating frequency of the beamformer in hertz as a scalar. The default value of this property corresponds to 300 MHz.

Default: `3e8`

`SampleRate`

Signal sampling rate

Specify the signal sampling rate (in hertz) as a positive scalar.

Default: `1e6`

`NumSubbands`

Number of subbands

Specify the number of subbands used in the subband processing as a positive integer.

Default: 64

`DirectionSource`

Source of beamforming direction

Specify whether the beamforming direction for the beamformer comes from the `Direction` property of this object or from an input argument in step. Values of this property are:

`'Property'`	The `Direction` property of this object specifies the beamforming direction.
`'Input port'`	An input argument in each invocation of `step` specifies the beamforming direction.

Default: `'Property'`

`Direction`

Beamforming directions

Specify the beamforming directions of the beamformer as a two-row matrix. Each column of the matrix has the form [AzimuthAngle; ElevationAngle] (in degrees). Each azimuth angle must be between –180 and 180 degrees, and each elevation angle must be between –90 and 90 degrees. This property applies when you set the `DirectionSource` property to `'Property'`.

Default: `[0; 0]`

`WeightsOutputPort`

Output beamforming weights

To obtain the weights used in the beamformer, set this property to `true` and use the corresponding output argument when invoking step. If you do not want to obtain the weights, set this property to `false`.

Default: `false`

`SubbandsOutputPort`

Output subband center frequencies

To obtain the center frequencies of each subband, set this property to `true` and use the corresponding output argument when invoking step. If you do not want to obtain the center frequencies, set this property to `false`.

Default: `false`

Methods

step — Beamforming using subband phase shifting

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Subband Phase-Shift Beamformer for Underwater ULA

Apply subband phase-shift beamforming to an 11-element underwater ULA. The incident angle of a wideband signal is 10° in azimuth and 30° in elevation. The carrier frequency is 2 kHz.

Create the ULA.

```
antenna = phased.ULA('NumElements',11,'ElementSpacing',0.3);
antenna.Element.FrequencyRange = [20 20000];
```

Create a chirp signal with noise.

```
fs = 1e3;
carrierFreq = 2e3;
```

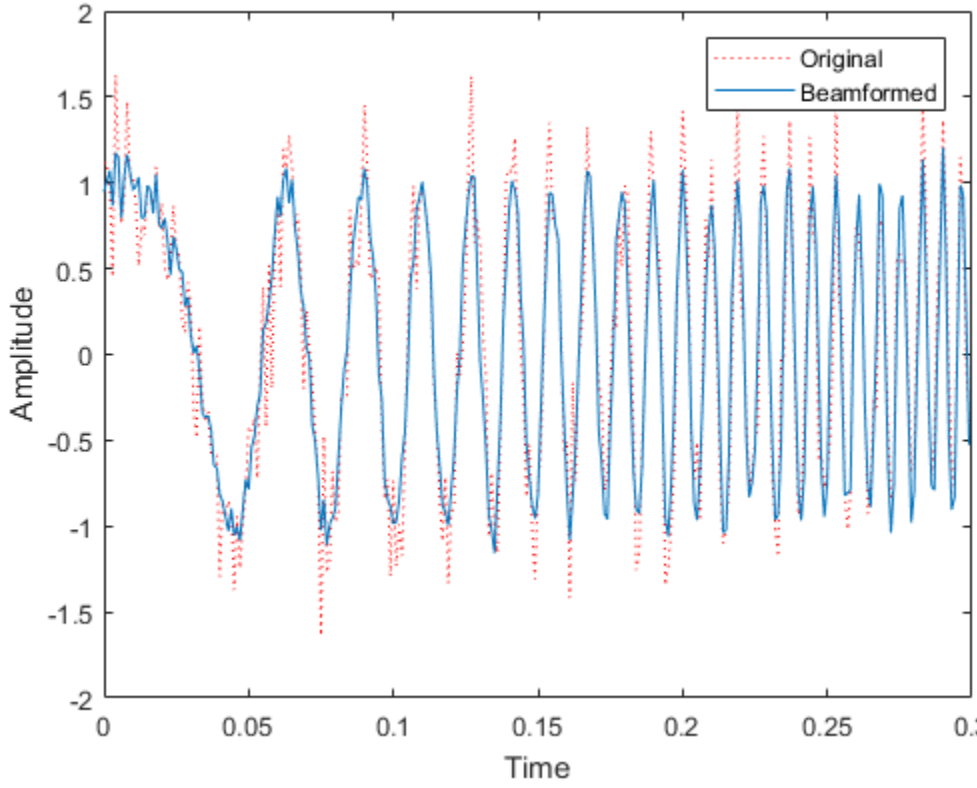
```
t = (0:1/fs:2)';
x = chirp(t,0,2,fs);
c = 1500;
collector = phased.WidebandCollector('Sensor',antenna, ...
    'PropagationSpeed',c,'SampleRate',fs,...
    'ModulatedInput',true,'CarrierFrequency',carrierFreq);
incidentAngle = [10;30];
x = collector(x,incidentAngle);
noise = 0.3*(randn(size(x)) + 1j*randn(size(x)));
rx = x + noise;
```

Beamform in the direction of the incident angle.

```
beamformer = phased.SubbandPhaseShiftBeamformer('SensorArray',antenna, ...
    'Direction',incidentAngle,'OperatingFrequency',carrierFreq, ...
    'PropagationSpeed',c,'SampleRate',fs,'SubbandsOutputPort',true, ...
    'WeightsOutputPort',true);
[y,w,subbandfreq] = beamformer(rx);
```

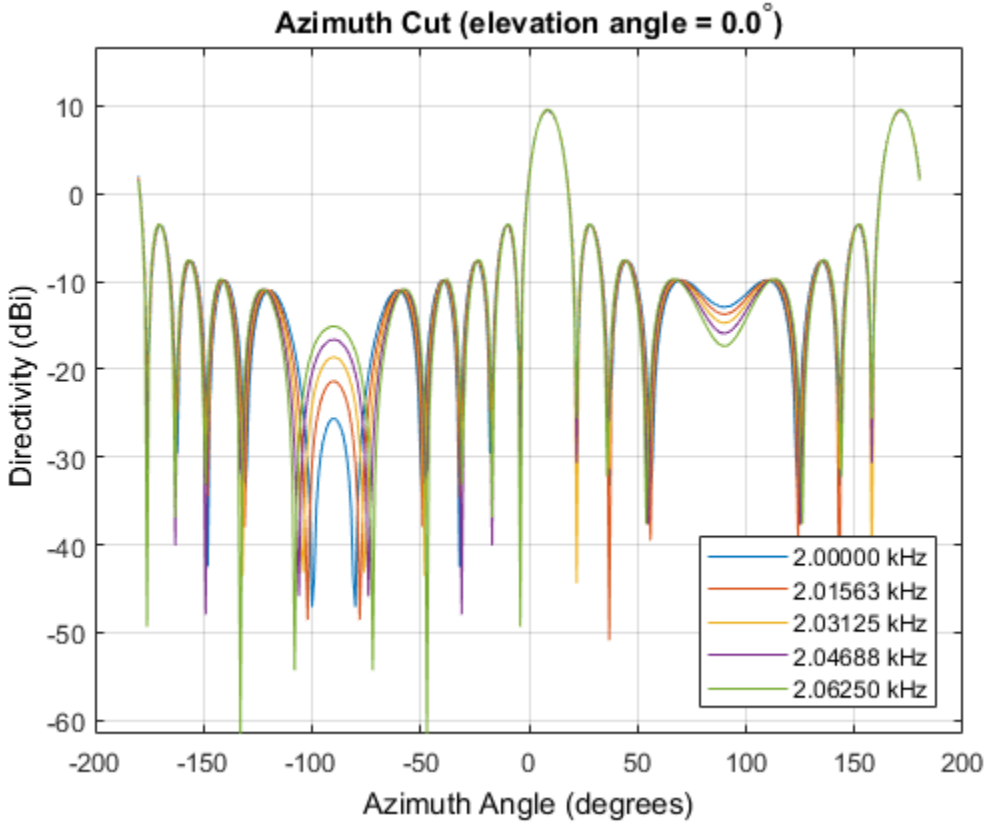
Plot the real part of the original and beamformed signals.

```
plot(t(1:300),real(rx(1:300,6)),'r:',t(1:300),real(y(1:300)))
xlabel('Time')
ylabel('Amplitude')
legend('Original','Beamformed')
```



Plot the response pattern for five frequency bands.

```
pattern(antenna,subbandfreq(1:5).',[-180:180],0,'PropagationSpeed',c, ...
    'CoordinateSystem','rectangular','Weights',w(:,1:5))
legend('location','SouthEast')
```



- “Wideband Beamforming”

Algorithms

The subband phase shift beamformer separates the signal into several subbands and applies narrowband phase shift beamforming to the signal in each subband. The beamformed signals in all the subbands are regrouped to form the output signal.

“Wideband Beamforming”

Introduced in R2012a

step

System object: phased.SubbandPhaseShiftBeamformer
Package: phased

Beamforming using subband phase shifting

Syntax

```
Y = step(H,X)
Y = step(H,X,ANG)
[Y,W] = step( ___ )
[Y,FREQ] = step( ___ )
[Y,W,FREQ] = step( ___ )
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` performs subband phase shift beamforming on the input, `X`, and returns the beamformed output in `Y`.

`Y = step(H,X,ANG)` uses `ANG` as the beamforming direction. This syntax is available when you set the `DirectionSource` property to `'Input port'`.

`[Y,W] = step( ___ )` returns the beamforming weights, `W`. This syntax is available when you set the `WeightsOutputPort` property to `true`.

`[Y,FREQ] = step( ___ )` returns the center frequencies of subbands, `FREQ`. This syntax is available when you set the `SubbandsOutputPort` property to `true`.

`[Y,W,FREQ] = step( ___ )` returns beamforming weights and center frequencies of subbands. This syntax is available when you set the `WeightsOutputPort` property to `true` and set the `SubbandsOutputPort` property to `true`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`H`

Beamformer object.

`X`

Input signal, specified as an *M*-by-*N* matrix. If the sensor array contains subarrays, *N* is the number of subarrays; otherwise, *N* is the number of elements.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

`ANG`

Beamforming directions, specified as a two-row matrix. Each column has the form [AzimuthAngle; ElevationAngle], in degrees. Each azimuth angle must be between –180 and 180 degrees, and each elevation angle must be between –90 and 90 degrees.

Output Arguments

`Y`

Beamformed output. `Y` is an *M*-by-*L* matrix, where *M* is the number of rows of `X` and *L* is the number of beamforming directions.

`W`

Beamforming weights. `W` has dimensions *N*-by-*K*-by-*L*. *K* is the number of subbands in the `NumSubbands` property. *L* is the number of beamforming directions. If the sensor array contains subarrays, *N* is the number of subarrays; otherwise, *N* is the number of

elements. Each column of `W` specifies the narrowband beamforming weights used in the corresponding subband for the corresponding direction.

`FREQ`

Center frequencies of subbands. `FREQ` is a column vector of length K, where K is the number of subbands in the `NumSubbands` property.

Examples

Subband Phase-Shift Beamformer for Underwater ULA

Apply subband phase-shift beamforming to an 11-element underwater ULA. The incident angle of a wideband signal is 10° in azimuth and 30° in elevation. The carrier frequency is 2 kHz.

Create the ULA.

```
antenna = phased.ULA('NumElements',11,'ElementSpacing',0.3);
antenna.Element.FrequencyRange = [20 20000];
```

Create a chirp signal with noise.

```
fs = 1e3;
carrierFreq = 2e3;
t = (0:1/fs:2)';
x = chirp(t,0,2,fs);
c = 1500;
collector = phased.WidebandCollector('Sensor',antenna, ...
    'PropagationSpeed',c,'SampleRate',fs,...
    'ModulatedInput',true,'CarrierFrequency',carrierFreq);
incidentAngle = [10;30];
x = collector(x,incidentAngle);
noise = 0.3*(randn(size(x)) + 1j*randn(size(x)));
rx = x + noise;
```

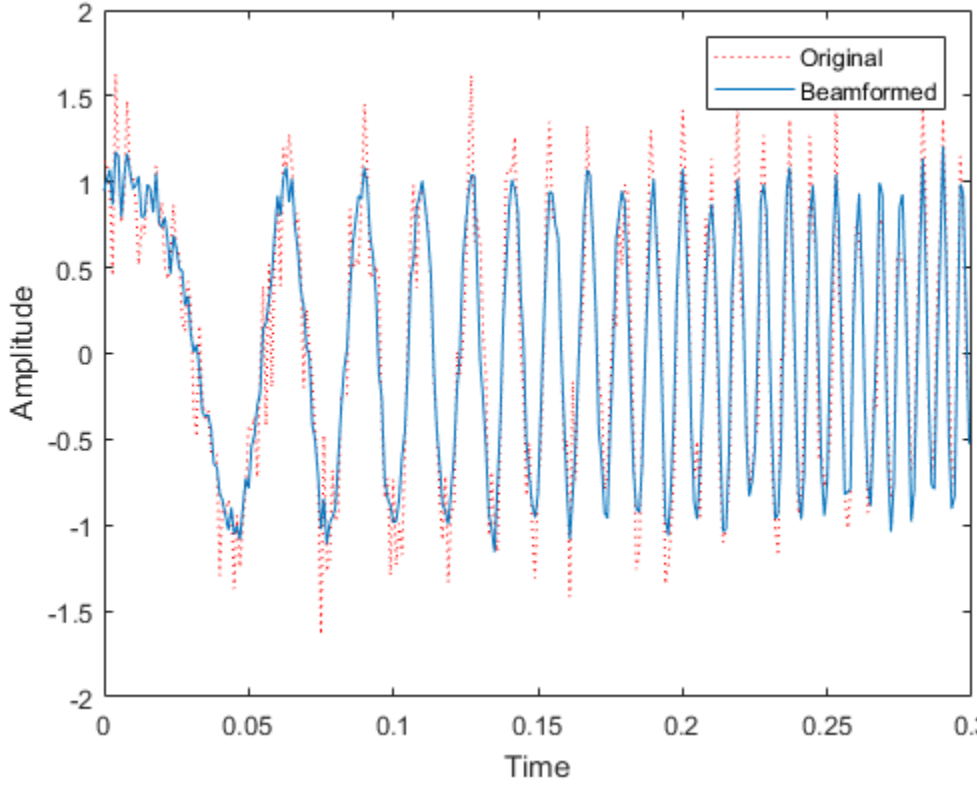
Beamform in the direction of the incident angle.

```
beamformer = phased.SubbandPhaseShiftBeamformer('SensorArray',antenna, ...
    'Direction',incidentAngle,'OperatingFrequency',carrierFreq, ...
    'PropagationSpeed',c,'SampleRate',fs,'SubbandsOutputPort',true, ...
    'WeightsOutputPort',true);
```

```
[y,w,subbandfreq] = beamformer(rx);
```

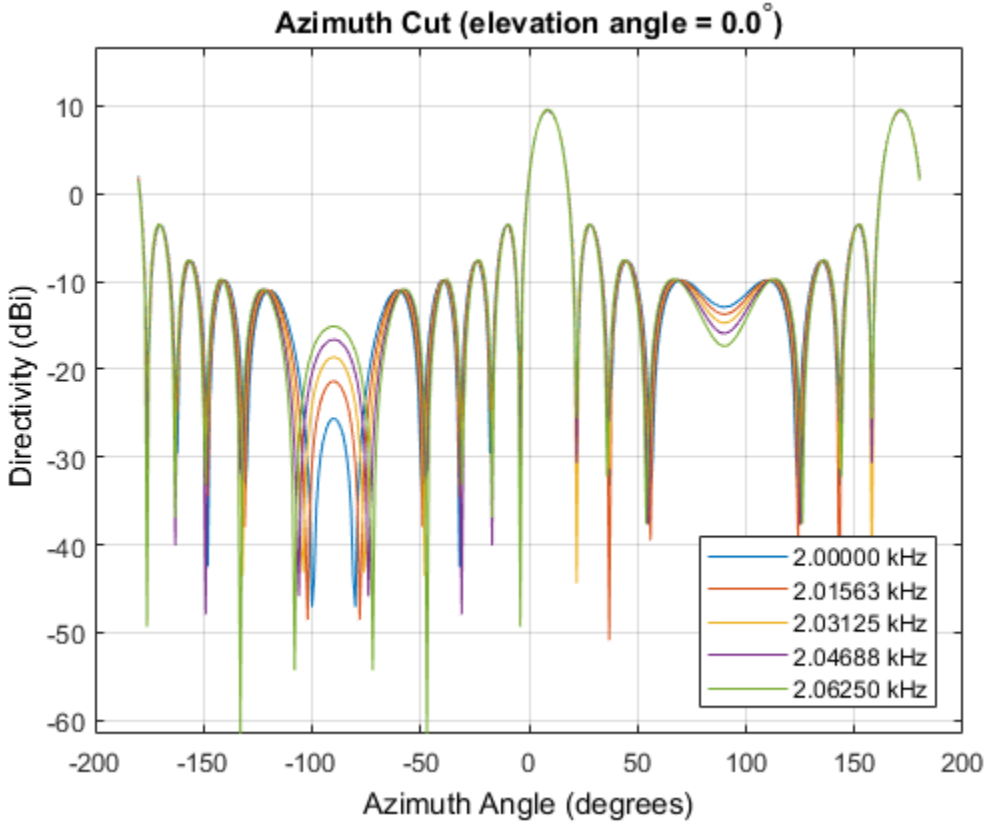
Plot the real part of the original and beamformed signals.

```
plot(t(1:300),real(rx(1:300,6)),'r:',t(1:300),real(y(1:300)))
xlabel('Time')
ylabel('Amplitude')
legend('Original','Beamformed')
```



Plot the response pattern for five frequency bands.

```
pattern(antenna,subbandfreq(1:5).',[-180:180],0,'PropagationSpeed',c, ...
    'CoordinateSystem','rectangular','Weights',w(:,1:5))
legend('location','SouthEast')
```



Algorithms

The subband phase shift beamformer separates the signal into several subbands and applies narrowband phase shift beamforming to the signal in each subband. The beamformed signals in all the subbands are regrouped to form the output signal.

phased.SumDifferenceMonopulseTracker System object

Package: phased

Sum and difference monopulse for ULA

Description

The `SumDifferenceMonopulseTracker` object implements a sum and difference monopulse algorithm on a uniform linear array.

To estimate the direction of arrival (DOA):

1. Define and set up your sum and difference monopulse DOA estimator. See "Construction" on page 1-1918.
2. Call step to estimate the DOA according to the properties of `phased.SumDifferenceMonopulseTracker`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.SumDifferenceMonopulseTracker` creates a tracker System object, `H`. The object uses sum and difference monopulse algorithms on a uniform linear array (ULA).

`H = phased.SumDifferenceMonopulseTracker(Name,Value)` creates a ULA monopulse tracker object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`SensorArray`

Handle to sensor array

Specify the sensor array as a handle. The sensor array must be a `phased.ULA` object.

Default: phased.ULA with default property values

`PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

Default: Speed of light

`OperatingFrequency`

System operating frequency

Specify the operating frequency of the system in hertz as a positive scalar. The default value corresponds to 300 MHz.

Default: `3e8`

`NumPhaseShifterBits`

Number of phase shifter quantization bits

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

Default: `0`

Methods

step	Perform monopulse tracking using ULA

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object

Examples

Find Target Direction Using Monopulse Tracker

Determine the direction of a target at a 60.1° broadside angle to a ULA starting with an approximate direction of 60°

```
array = phased.ULA('NumElements',4);
steervec = phased.SteeringVector('SensorArray',array);
tracker = phased.SumDifferenceMonopulseTracker('SensorArray',array);
x = steervec(tracker.OperatingFrequency,60.1).';
est_dir = tracker(x,60)
```

```
est_dir =

   60.1000
```

- “Target Tracking Using Sum-Difference Monopulse Radar”

Algorithms

The sum-and-difference monopulse algorithm is used to the estimate the arrival direction of a narrowband signal impinging upon a uniform linear array (ULA). First, compute the conventional response of an array steered to an arrival direction φ_0. For a ULA, the arrival direction is specified by the broadside angle. To specify that the maximum response axis (MRA) point towards the φ_0 direction, set the weights to be

$$\mathbf{w}_s = \left(1, e^{ikd\sin\phi_0}, e^{ik2d\sin\phi_0}, \ldots, e^{ik(N-1)d\sin\phi_0}\right)$$

where d is the element spacing and $k = 2\pi/\lambda$ is the wavenumber. An incoming plane wave, coming from any arbitrary direction φ, is represented by

$$\mathbf{v} = \left(1, e^{ikd\sin\phi}, e^{ik2d\sin\phi}, \ldots, e^{ik(N-1)d\sin\phi}\right)$$

The conventional response of this array to any incoming plane wave is given by $\mathbf{w}_s^H\mathbf{v}(\varphi)$ and is shown in the polar plot below as the *Sum Pattern*. The array is designed to steer towards $\varphi_0 = 30°$.

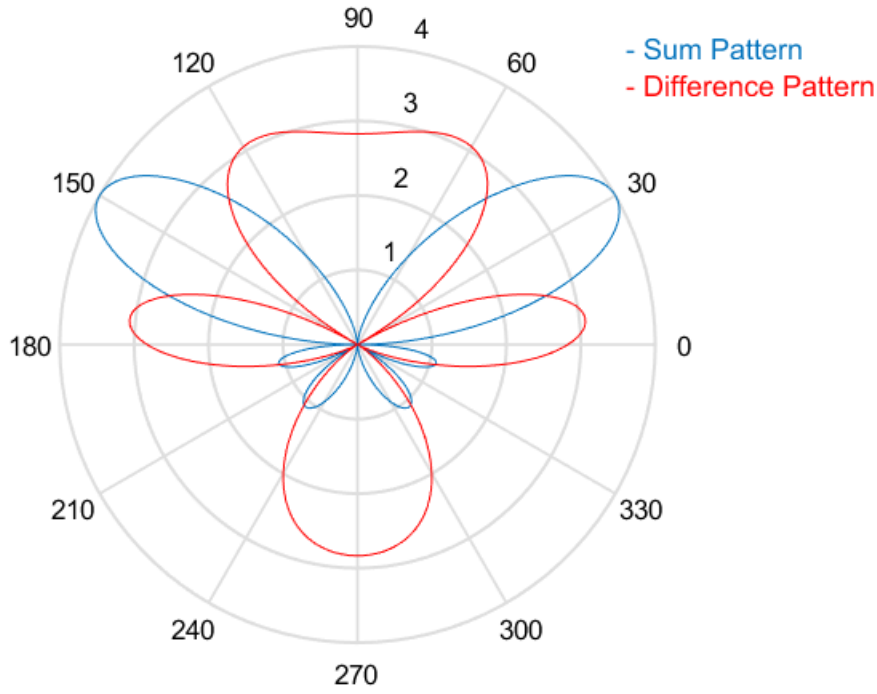
The second pattern, called the *Difference Pattern*, is obtained by using phased-reversed weights. The weights are determined by phase-reversing the latter half of the conventional steering vector. For an array with an even number of elements, the phase-reversed weights are

$$\mathbf{w}_d = -i\left(1, e^{ikd\sin\phi_0}, e^{ik2d\sin\phi_0}, \ldots, e^{ikN/2d\sin\phi_0}, -e^{ik(N/2+1)d\sin\phi_0}, \ldots, -e^{ik(N-1)d\sin\phi_0}\right)$$

(For an array with an odd number of elements, the middle weight is set to zero). The multiplicative factor $-i$ is used for convenience. The response of the difference array to the incoming vector is

$$\mathbf{w}_d^H\mathbf{v}(\varphi)$$

and is show in the polar plot below



The monopulse response curve is obtained by dividing the difference pattern by the sum pattern and taking the real part.

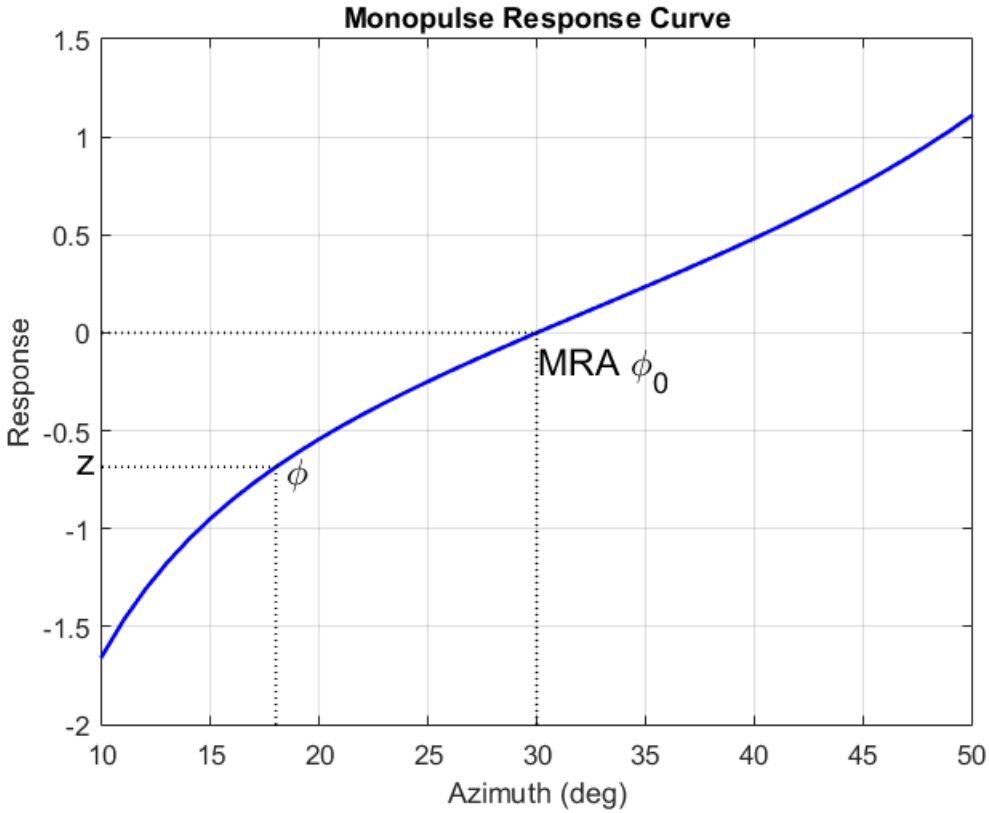
$$R(\varphi) = Re\left(\frac{\mathbf{w}_d^H \mathbf{v}(\varphi)}{\mathbf{w}_s^H \mathbf{v}(\varphi)}\right)$$

To use the monopulse response curve to obtain the arrival angle of a narrowband signal, **x**, compute

$$z = Re\left(\frac{\mathbf{w}_d^H \mathbf{x}}{\mathbf{w}_s^H \mathbf{x}}\right)$$

and invert the response curve, $\varphi = R^{-1}(z)$, to obtain φ.

The response curve is not single valued and can be inverted only when arrival angles lie within the mainlobe. The figure below shows the center portion of the monopulse response curve in the mainlobe for a 4-element ULA array.



There are two desirable properties of the monopulse response curve. The first is that it have a steep slope. A steep slope insures robustness against noise. The second property is that the mainlobe be as wide as possible. A steep slope is ensure by a larger array but leads to a smaller mainlobe. You will need to trade off one property with the other.

For further details, see [1].

“Target Tracking Using Sum-Difference Monopulse Radar”

Introduced in R2012a

step

System object: phased.SumDifferenceMonopulseTracker
Package: phased

Perform monopulse tracking using ULA

Syntax

```
ESTANG = step(H,X,STANG)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`ESTANG = step(H,X,STANG)` estimates the incoming direction `ESTANG` of the input signal, `X`, based on an initial guess of the direction.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

H

Tracker object of type `phased.SumDifferenceMonopulseTracker`.

X

Input signal, specified as a row vector whose number of columns corresponds to number of channels.

STANG

Initial guess of the direction, specified as a scalar that represents the broadside angle in degrees. A typical initial guess is the current steering angle. The value of `STANG` is between –90 and 90. The angle is defined in the array's local coordinate system. For details regarding the local coordinate system of the ULA, type `phased.ULA.coordinateSystemInfo`.

Output Arguments

ESTANG

Estimate of incoming direction, returned as a scalar that represents the broadside angle in degrees. The value is between –90 and 90. The angle is defined in the array's local coordinate system.

Examples

Find Target Direction Using Monopulse Tracker

Determine the direction of a target at a 60.1° broadside angle to a ULA starting with an approximate direction of 60°

```
array = phased.ULA('NumElements',4);
steervec = phased.SteeringVector('SensorArray',array);
tracker = phased.SumDifferenceMonopulseTracker('SensorArray',array);
x = steervec(tracker.OperatingFrequency,60.1).';
est_dir = tracker(x,60)
```

```
est_dir =

   60.1000
```

Algorithms

The sum-and-difference monopulse algorithm is used to the estimate the arrival direction of a narrowband signal impinging upon a uniform linear array (ULA). First, compute the conventional response of an array steered to an arrival direction φ_0. For a ULA, the arrival direction is specified by the broadside angle. To specify that the maximum response axis (MRA) point towards the φ_0 direction, set the weights to be

$$\mathbf{w}_s = \left(1, e^{ikd\sin\phi_0}, e^{ik2d\sin\phi_0}, \ldots, e^{ik(N-1)d\sin\phi_0}\right)$$

where d is the element spacing and $k = 2\pi/\lambda$ is the wavenumber. An incoming plane wave, coming from any arbitrary direction φ, is represented by

$$\mathbf{v} = \left(1, e^{ikd\sin\phi}, e^{ik2d\sin\phi}, \ldots, e^{ik(N-1)d\sin\phi}\right)$$

The conventional response of this array to any incoming plane wave is given by $\mathbf{w}_s^H\mathbf{v}(\varphi)$ and is shown in the polar plot below as the *Sum Pattern*. The array is designed to steer towards $\varphi_0 = 30°$.

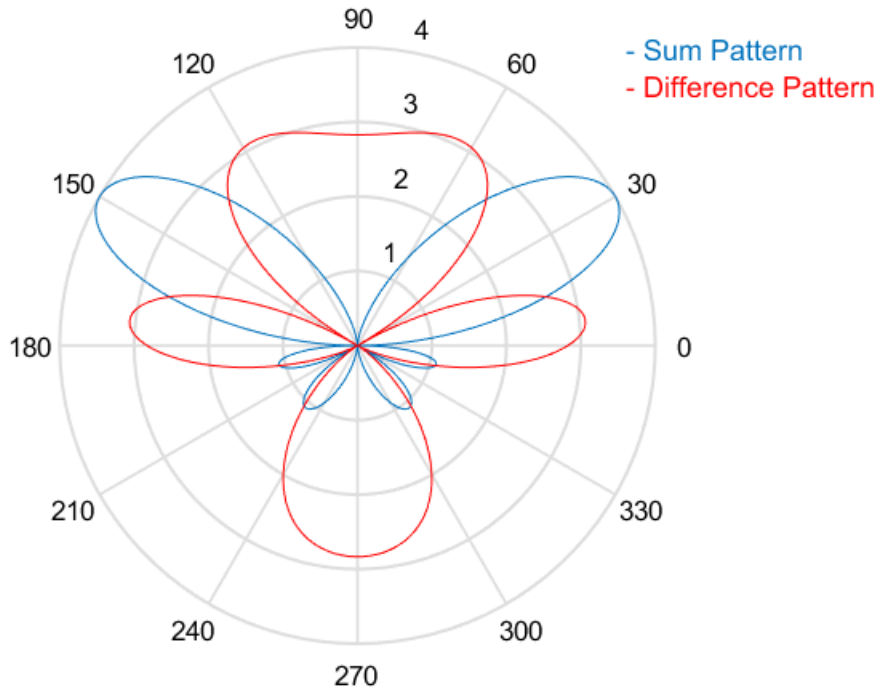
The second pattern, called the *Difference Pattern*, is obtained by using phased-reversed weights. The weights are determined by phase-reversing the latter half of the conventional steering vector. For an array with an even number of elements, the phase-reversed weights are

$$\mathbf{w}_d = -i\left(1, e^{ikd\sin\phi_0}, e^{ik2d\sin\phi_0}, \ldots, e^{ikN/2d\sin\phi_0}, -e^{ik(N/2+1)d\sin\phi_0}, \ldots, -e^{ik(N-1)d\sin\phi_0}\right)$$

(For an array with an odd number of elements, the middle weight is set to zero). The multiplicative factor $-i$ is used for convenience. The response of the difference array to the incoming vector is

$$\mathbf{w}_d^H \mathbf{v}(\varphi)$$

and is show in the polar plot below



The monopulse response curve is obtained by dividing the difference pattern by the sum pattern and taking the real part.

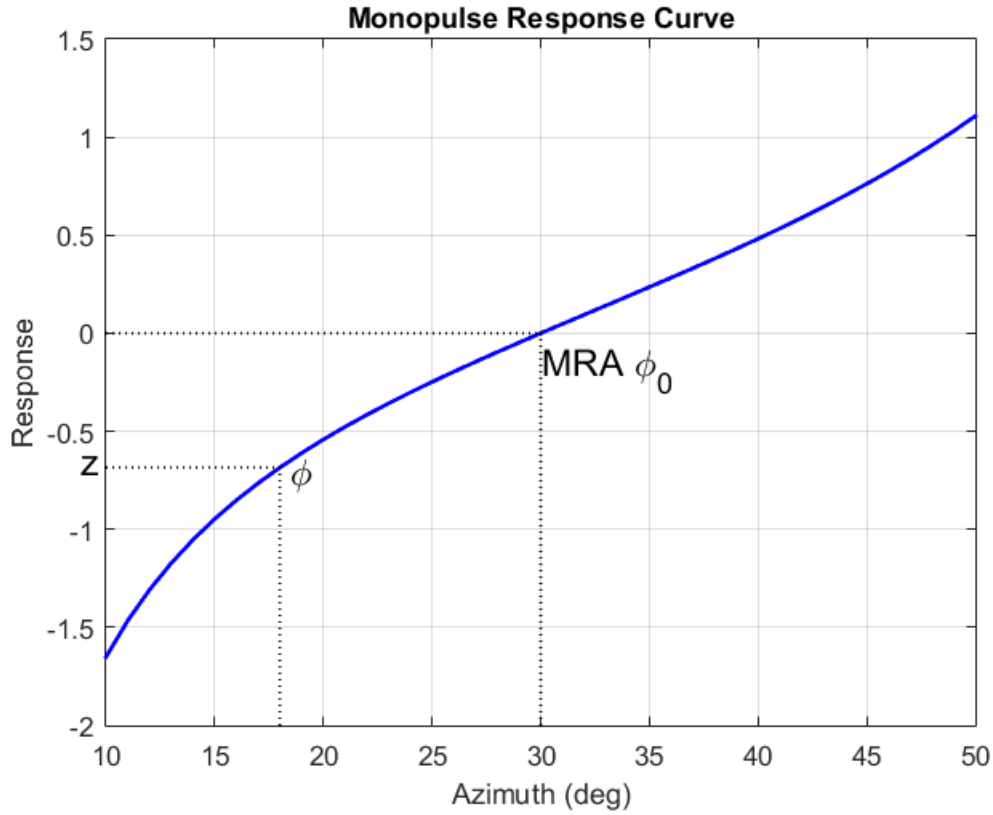
$$R(\varphi) = Re\left(\frac{\mathbf{w}_d^H \mathbf{v}(\varphi)}{\mathbf{w}_s^H \mathbf{v}(\varphi)}\right)$$

To use the monopulse response curve to obtain the arrival angle of a narrowband signal, **x**, compute

$$z = Re\left(\frac{\mathbf{w}_d^H \mathbf{x}}{\mathbf{w}_s^H \mathbf{x}}\right)$$

and invert the response curve, $\varphi = R^{-1}(z)$, to obtain φ.

The response curve is not single valued and can be inverted only when arrival angles lie within the mainlobe. The figure below shows the center portion of the monopulse response curve in the mainlobe for a 4-element ULA array.



There are two desirable properties of the monopulse response curve. The first is that it have a steep slope. A steep slope insures robustness against noise. The second property

is that the mainlobe be as wide as possible. A steep slope is ensure by a larger array but leads to a smaller mainlobe. You will need to trade off one property with the other.

For further details, see [1].

phased.SumDifferenceMonopulseTracker2D System object

Package: phased

Sum and difference monopulse for URA

Description

The `SumDifferenceMonopulseTracker2D` object implements a sum and difference monopulse algorithm for a uniform rectangular array.

To estimate the direction of arrival (DOA):

1. Define and set up your sum and difference monopulse DOA estimator. See "Construction" on page 1-1931.
2. Call step to estimate the DOA according to the properties of `phased.SumDifferenceMonopulseTracker2D`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.SumDifferenceMonopulseTracker2D` creates a tracker System object, `H`. The object uses sum and difference monopulse algorithms on a uniform rectangular array (URA).

`H = phased.SumDifferenceMonopulseTracker2D(Name,Value)` creates a URA monopulse tracker object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`SensorArray`

Handle to sensor array

Specify the sensor array as a handle. The sensor array must be a `phased.URA` object.

Default: phased.URA with default property values

`PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

Default: Speed of light

`OperatingFrequency`

System operating frequency

Specify the operating frequency of the system in hertz as a positive scalar. The default value corresponds to 300 MHz.

Default: `3e8`

`NumPhaseShifterBits`

Number of phase shifter quantization bits

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

Default: `0`

Methods

step	Perform monopulse tracking using URA

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Find Target Direction Using Sum-Difference 2D Monopulse Tracker

Using a URA, determine the direction of a target at approximately 60° azimuth and 20° elevation.

```
array = phased.URA('Size',4);
steeringvec = phased.SteeringVector('SensorArray',array);
tracker = phased.SumDifferenceMonopulseTracker2D('SensorArray',array);
x = steeringvec(tracker.OperatingFrequency,[60.1; 19.5]).';
est_dir = tracker(x,[60; 20])
```

```
est_dir =

   60.1000
   19.5000
```

Algorithms

The sum-and-difference monopulse algorithm is used to the estimate the arrival direction of a narrowband signal impinging upon a uniform linear array (ULA). First, compute the conventional response of an array steered to an arrival direction φ_0. For a ULA, the arrival direction is specified by the broadside angle. To specify that the maximum response axis (MRA) point towards the φ_0 direction, set the weights to be

$$\mathbf{w}_s = \left(1, e^{ikd\sin\phi_0}, e^{ik2d\sin\phi_0}, \ldots, e^{ik(N-1)d\sin\phi_0}\right)$$

where d is the element spacing and $k = 2\pi/\lambda$ is the wavenumber. An incoming plane wave, coming from any arbitrary direction φ, is represented by

$$\mathbf{v} = \left(1, e^{ikd\sin\phi}, e^{ik2d\sin\phi}, \ldots, e^{ik(N-1)d\sin\phi}\right)$$

The conventional response of this array to any incoming plane wave is given by $\mathbf{w}_s^H\mathbf{v}(\varphi)$ and is shown in the polar plot below as the *Sum Pattern*. The array is designed to steer towards $\varphi_0 = 30°$.

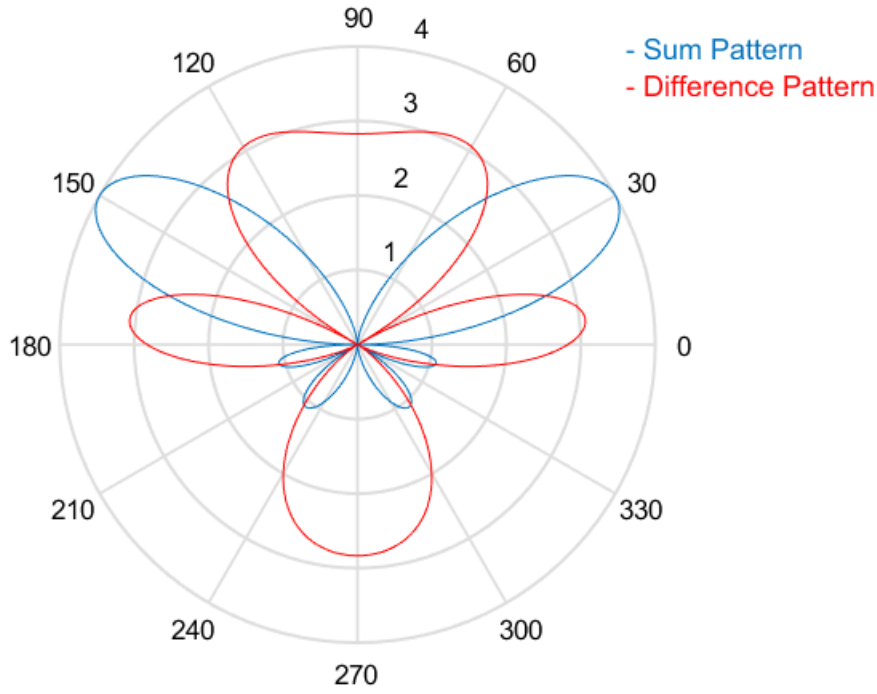
The second pattern, called the *Difference Pattern*, is obtained by using phased-reversed weights. The weights are determined by phase-reversing the latter half of the conventional steering vector. For an array with an even number of elements, the phase-reversed weights are

$$\mathbf{w}_d = -i\left(1, e^{ikd\sin\phi_0}, e^{ik2d\sin\phi_0}, \ldots, e^{ikN/2d\sin\phi_0}, -e^{ik(N/2+1)d\sin\phi_0}, \ldots, -e^{ik(N-1)d\sin\phi_0}\right)$$

(For an array with an odd number of elements, the middle weight is set to zero). The multiplicative factor $-i$ is used for convenience. The response of the difference array to the incoming vector is

$$\mathbf{w}_d^H\mathbf{v}(\varphi)$$

and is show in the polar plot below



The monopulse response curve is obtained by dividing the difference pattern by the sum pattern and taking the real part.

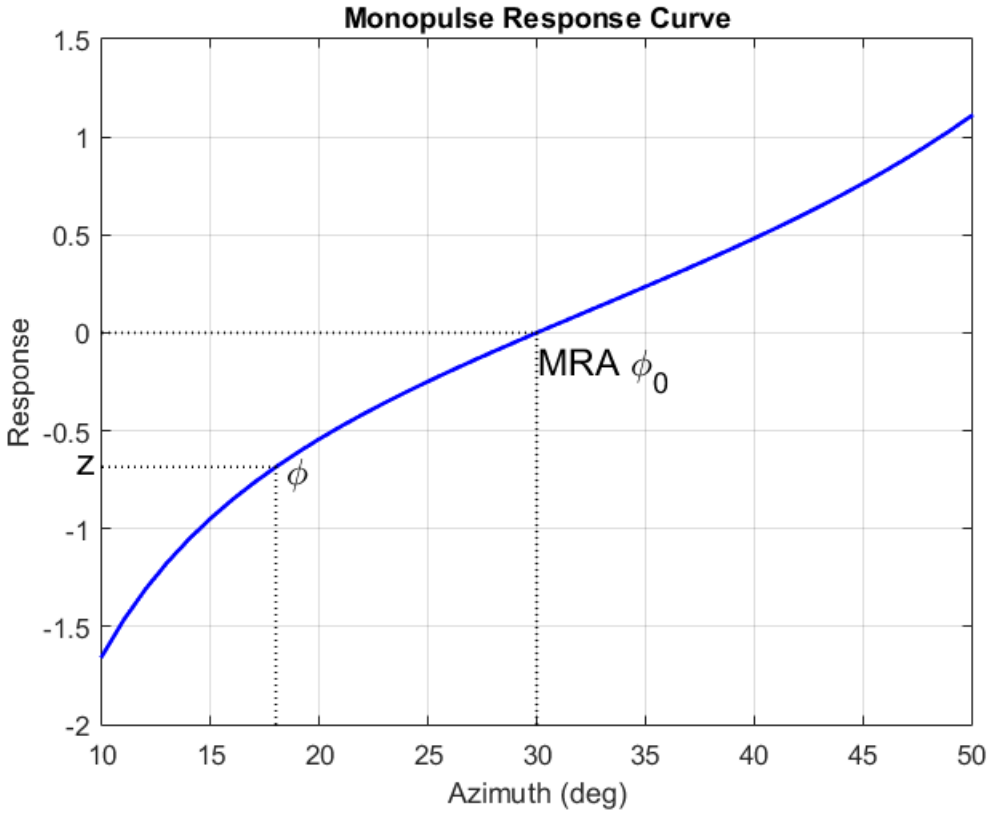
$$R(\varphi) = Re\left(\frac{\mathbf{w}_d^H \mathbf{v}(\varphi)}{\mathbf{w}_s^H \mathbf{v}(\varphi)}\right)$$

To use the monopulse response curve to obtain the arrival angle of a narrowband signal, $\mathbf{x}$, compute

$$z = Re\left(\frac{\mathbf{w}_d^H \mathbf{x}}{\mathbf{w}_s^H \mathbf{x}}\right)$$

and invert the response curve, $\varphi = R^{-1}(z)$, to obtain φ.

The response curve is not single valued and can be inverted only when arrival angles lie within the mainlobe. The figure below shows the center portion of the monopulse response curve in the mainlobe for a 4-element ULA array.



There are two desirable properties of the monopulse response curve. The first is that it have a steep slope. A steep slope insures robustness against noise. The second property is that the mainlobe be as wide as possible. A steep slope is ensure by a larger array but leads to a smaller mainlobe. You will need to trade off one property with the other.

For further details, see [1].

Introduced in R2012a

step

System object: phased.SumDifferenceMonopulseTracker2D
Package: phased

Perform monopulse tracking using URA

Syntax

```
ESTANG = step(H,X,STANG)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`ESTANG = step(H,X,STANG)` estimates the incoming direction `ESTANG` of the input signal, `X`, based on an initial guess of the direction.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`H`

Tracker object of type `phased.SumDifferenceMonopulseTracker2D`.

X

Input signal, specified as a row vector whose number of columns corresponds to number of channels.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

STANG

Initial guess of the direction, specified as a 2-by-1 vector in the form `[AzimuthAngle; ElevationAngle]` in degrees. A typical initial guess is the current steering angle. Azimuth angles must be between –180 and 180. Elevation angles must be between –90 and 90. Angles are measured in the local coordinate system of the array. For details regarding the local coordinate system of the URA, type `phased.URA.coordinateSystemInfo`.

Output Arguments

ESTANG

Estimate of incoming direction, returned as a 2-by-1 vector in the form `[AzimuthAngle; ElevationAngle]` in degrees. Azimuth angles are between –180 and 180. Elevation angles are between –90 and 90. Angles are measured in the local coordinate system of the array.

Examples

Find Target Direction Using Sum-Difference 2D Monopulse Tracker

Using a URA, determine the direction of a target at approximately 60° azimuth and 20° elevation.

```
array = phased.URA('Size',4);
steeringvec = phased.SteeringVector('SensorArray',array);
tracker = phased.SumDifferenceMonopulseTracker2D('SensorArray',array);
x = steeringvec(tracker.OperatingFrequency,[60.1; 19.5]).';
est_dir = tracker(x,[60; 20])
```

```
est_dir =

   60.1000
   19.5000
```

Algorithms

The sum-and-difference monopulse algorithm is used to the estimate the arrival direction of a narrowband signal impinging upon a uniform linear array (ULA). First, compute the conventional response of an array steered to an arrival direction φ_0. For a ULA, the arrival direction is specified by the broadside angle. To specify that the maximum response axis (MRA) point towards the φ_0 direction, set the weights to be

$$\mathbf{w}_s = \left(1, e^{ikd\sin\phi_0}, e^{ik2d\sin\phi_0}, \ldots, e^{ik(N-1)d\sin\phi_0}\right)$$

where d is the element spacing and $k = 2\pi/\lambda$ is the wavenumber. An incoming plane wave, coming from any arbitrary direction φ, is represented by

$$\mathbf{v} = \left(1, e^{ikd\sin\phi}, e^{ik2d\sin\phi}, \ldots, e^{ik(N-1)d\sin\phi}\right)$$

The conventional response of this array to any incoming plane wave is given by $\mathbf{w}_s^H\mathbf{v}(\varphi)$ and is shown in the polar plot below as the *Sum Pattern*. The array is designed to steer towards $\varphi_0 = 30°$.

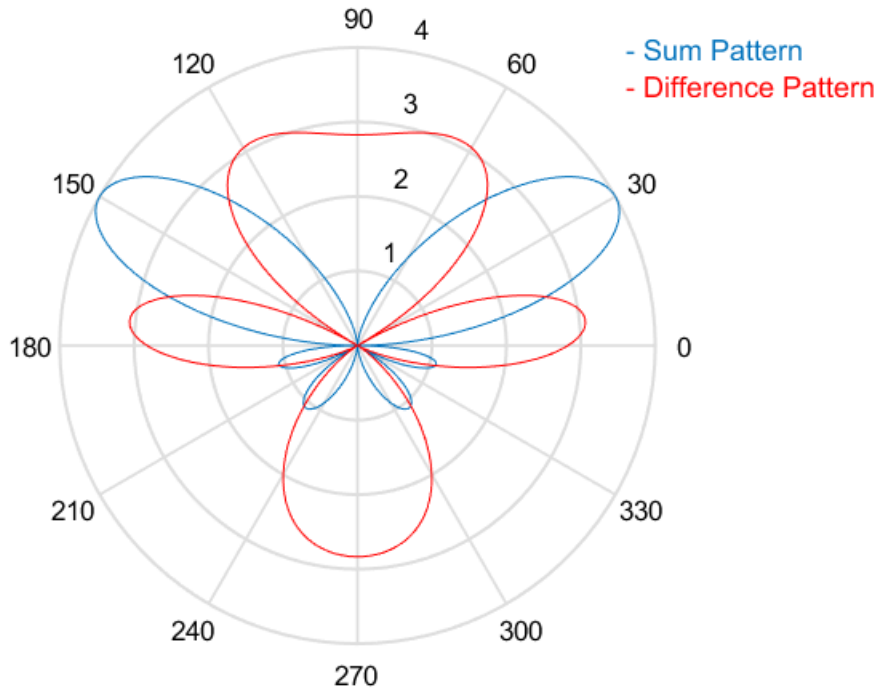
The second pattern, called the *Difference Pattern*, is obtained by using phased-reversed weights. The weights are determined by phase-reversing the latter half of the conventional steering vector. For an array with an even number of elements, the phase-reversed weights are

$$\mathbf{w}_d = -i\left(1, e^{ikd\sin\phi_0}, e^{ik2d\sin\phi_0}, \ldots, e^{ikN/2d\sin\phi_0}, -e^{ik(N/2+1)d\sin\phi_0}, \ldots, -e^{ik(N-1)d\sin\phi_0}\right)$$

(For an array with an odd number of elements, the middle weight is set to zero). The multiplicative factor $-i$ is used for convenience. The response of the difference array to the incoming vector is

$$\mathbf{w}_d^H \mathbf{v}(\varphi)$$

and is show in the polar plot below



The monopulse response curve is obtained by dividing the difference pattern by the sum pattern and taking the real part.

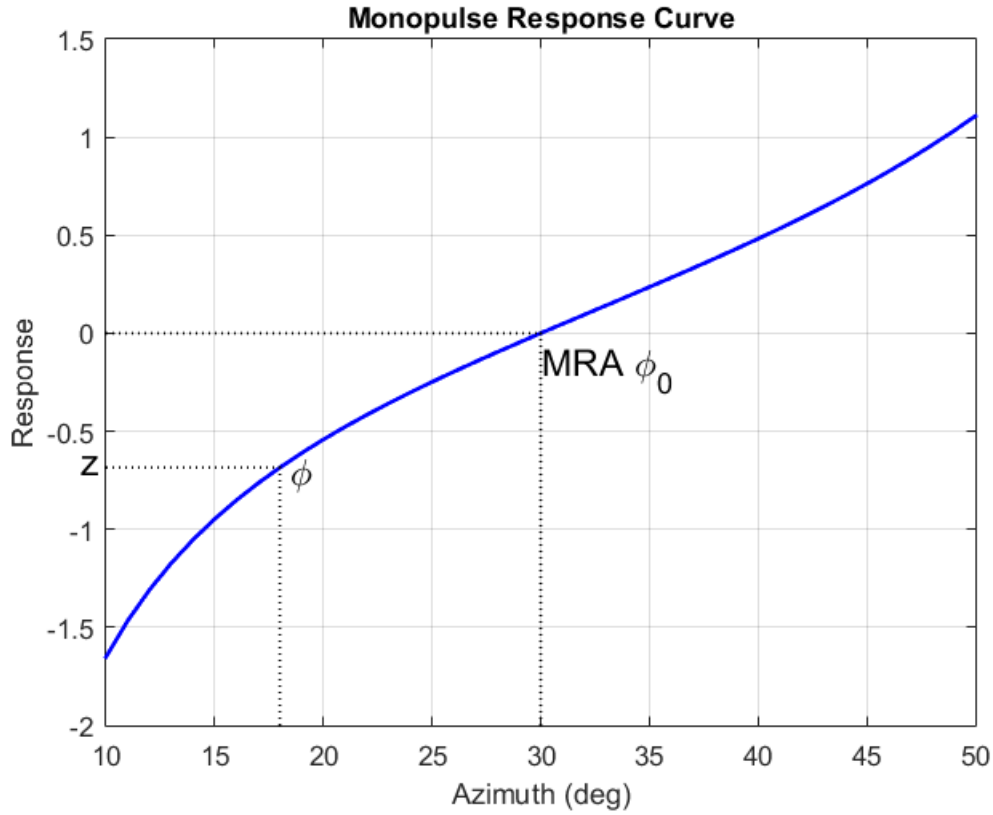
$$R(\varphi) = Re\left(\frac{\mathbf{w}_d^H \mathbf{v}(\varphi)}{\mathbf{w}_s^H \mathbf{v}(\varphi)}\right)$$

To use the monopulse response curve to obtain the arrival angle of a narrowband signal, **x**, compute

$$z = Re\left(\frac{\mathbf{w}_d^H \mathbf{x}}{\mathbf{w}_s^H \mathbf{x}}\right)$$

and invert the response curve, $\varphi = R^{-1}(z)$, to obtain φ.

The response curve is not single valued and can be inverted only when arrival angles lie within the mainlobe. The figure below shows the center portion of the monopulse response curve in the mainlobe for a 4-element ULA array.



There are two desirable properties of the monopulse response curve. The first is that it have a steep slope. A steep slope insures robustness against noise. The second property

is that the mainlobe be as wide as possible. A steep slope is ensure by a larger array but leads to a smaller mainlobe. You will need to trade off one property with the other.

phased.TimeDelayBeamformer System object

Package: phased

Time delay beamformer

Description

The `TimeDelayBeamformer` object implements a time delay beamformer.

To compute the beamformed signal:

1. Define and set up your time delay beamformer. See "Construction" on page 1-1944.
2. Call step to perform the beamforming operation according to the properties of `phased.TimeDelayBeamformer`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.TimeDelayBeamformer` creates a time delay beamformer System object, `H`. The object performs delay and sum beamforming on the received signal using time delays.

`H = phased.TimeDelayBeamformer(Name,Value)` creates a time delay beamformer object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`SensorArray`

Handle to sensor array

Specify the sensor array as a handle. The sensor array must be an array object in the `phased` package. The array cannot contain subarrays.

Default: phased.ULA with default property values

`PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

Default: Speed of light

`SampleRate`

Signal sampling rate

Specify the signal sampling rate (in hertz) as a positive scalar.

Default: `1e6`

`DirectionSource`

Source of beamforming direction

Specify whether the beamforming direction comes from the `Direction` property of this object or from an input argument in step. Values of this property are:

`'Property'`	The `Direction` property of this object specifies the beamforming direction.
`'Input port'`	An input argument in each invocation of `step` specifies the beamforming direction.

Default: `'Property'`

`Direction`

Beamforming direction

Specify the beamforming direction of the beamformer as a column vector of length 2. The direction is specified in the format of `[AzimuthAngle; ElevationAngle]` (in degrees). The azimuth angle should be between –180 and 180. The elevation angle should be between –90 and 90. This property applies when you set the `DirectionSource` property to `'Property'`.

Default: `[0; 0]`

`WeightsOutputPort`

Output beamforming weights

To obtain the weights used in the beamformer, set this property to `true` and use the corresponding output argument when invoking step. If you do not want to obtain the weights, set this property to `false`.

Default: `false`

Methods

step	Perform time delay beamforming

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Time-Delay Beamformer Applied to ULA

Apply a time-delay beamformer to an 11-element uniform linear acoustic array. The arrival angle of the signal is -50 degrees in azimuth and 30 degrees in elevation. The

arriving signal is a 0.3 second segment of a linear FM chirp having a 500 Hz bandwidth. Assume the speed of sound in air is 340.0 m/s.

Simulate the arriving signal at the wideband collector.

```
microphone = phased.CustomMicrophoneElement('FrequencyVector',[20,20000],'FrequencyResp
array = phased.ULA('Element',microphone,'NumElements',11,'ElementSpacing',0.04);
fs = 8000;
t = 0:1/fs:0.3;
x = chirp(t,0,1,500);
c = 340;
collector = phased.WidebandCollector('Sensor',array,...
    'PropagationSpeed',c,'SampleRate',fs,'ModulatedInput',false);
incidentAngle = [-50;30];
x = collector(x.',incidentAngle);
```

Add white gaussian random noise to the signal.

```
sigma = 0.2;
noise = sigma*randn(size(x));
rx = x + noise;
```

Beamform the incident signals using a time-delay beamformer.

```
beamformer = phased.TimeDelayBeamformer('SensorArray',array,...
    'SampleRate',fs,'PropagationSpeed',c,...
    'Direction',incidentAngle);
y = beamformer(rx);
```

Plot the beamformed signal against the incident signal at the middle sensor of the array.

```
plot(t,rx(:,6),'r:',t,y)
xlabel('Time (sec)')
ylabel('Amplitude')
legend('Original','Beamformed')
```

step

System object: phased.TimeDelayBeamformer
Package: phased

Perform time delay beamforming

Syntax

```
Y = step(H,X)
Y = step(H,X,ANG)
[Y,W] = step( ___ )
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` performs time delay beamforming on the input, `X`, and returns the beamformed output in `Y`. `X` is an M-by-N matrix where N is the number of elements of the sensor array. `Y` is a column vector of length M.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

`Y = step(H,X,ANG)` uses `ANG` as the beamforming direction. This syntax is available when you set the `DirectionSource` property to `'Input port'`. `ANG` is a column vector of length 2 in the form of `[AzimuthAngle; ElevationAngle]` (in degrees). The azimuth angle must be between –180 and 180 degrees, and the elevation angle must be between –90 and 90 degrees.

`[Y,W] = step( ___ )` returns additional output, `W`, as the beamforming weights. This syntax is available when you set the `WeightsOutputPort` property to `true`. `W`

is a column vector of length N. For a time delay beamformer, the weights are constant because the beamformer simply adds all the channels together and scales the result to preserve the signal power.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Examples

phased.TimeDelayLCMVBeamformer System object

Package: phased

Time delay LCMV beamformer

Description

The `TimeDelayLCMVBeamformer` object implements a time-delay linear constraint minimum variance beamformer.

To compute the beamformed signal:

1. Define and set up your time-delay LCMV beamformer. See "Construction" on page 1-1954.
2. Call step to perform the beamforming operation according to the properties of `phased.TimeDelayLCMVBeamformer`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.TimeDelayLCMVBeamformer` creates a time-delay linear constraint minimum variance (LCMV) beamformer System object, `H`. The object performs time delay LCMV beamforming on the received signal.

`H = phased.TimeDelayLCMVBeamformer(Name,Value)` creates a time-delay LCMV beamformer object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`SensorArray`

Handle to sensor array

Specify the sensor array as a handle. The sensor array must be an array object in the `phased` package. The array cannot contain subarrays.

Default: phased.ULA with default property values

`PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

Default: Speed of light

`SampleRate`

Signal sampling rate

Specify the signal sampling rate (in hertz) as a positive scalar.

Default: `1e6`

`FilterLength`

FIR filter length

Specify the length of the FIR filter behind each sensor element in the array as a positive integer.

Default: `2`

`Constraint`

Constraint matrix

Specify the constraint matrix used for time-delay LCMV beamformer as an *M*-by-*K* matrix. Each column of the matrix is a constraint and *M* is the number of degrees of

freedom of the beamformer. For a time-delay LCMV beamformer, the number of degrees of freedom is given by the product of the number of elements of the array and the filter length specified by the value of the `FilterLength` property.

Default: `[1;1]`

`DesiredResponse`

Desired response vector

Specify the desired response used for time-delay LCMV beamformer as a column vector of length *K*, where *K* is the number of constraints in the `Constraint` property. Each element in the vector defines the desired response of the constraint specified in the corresponding column of the `Constraint` property.

Default: 1, which is equivalent to a distortionless response

`DiagonalLoadingFactor`

Diagonal loading factor

Specify the diagonal loading factor as a positive scalar. Diagonal loading is a technique used to achieve robust beamforming performance, especially when the sample support is small. This property is tunable.

Default: `0`

`TrainingInputPort`

Add input to specify training data

To specify additional training data, set this property to `true` and use the corresponding input argument when you invoke step. To use the input signal as the training data, set this property to `false`.

Default: `false`

`DirectionSource`

Source of beamforming direction

Specify whether the beamforming direction comes from the `Direction` property of this object or from an input argument in step. Values of this property are:

`'Property'`	The `Direction` property of this object specifies the beamforming direction.
`'Input port'`	An input argument in each invocation of `step` specifies the beamforming direction.

Default: `'Property'`

`Direction`

Beamforming direction

Specify the beamforming direction of the beamformer as a column vector of length 2. The direction is specified in the format of `[AzimuthAngle; ElevationAngle]` (in degrees). The azimuth angle should be between –180° and 180°. The elevation angle should be between –90° and 90°. This property applies when you set the `DirectionSource` property to `'Property'`.

Default: `[0; 0]`

`WeightsOutputPort`

Output beamforming weights

To obtain the weights used in the beamformer, set this property to `true` and use the corresponding output argument when invoking step. If you do not want to obtain the weights, set this property to `false`.

Default: `false`

Methods

step — Perform time-delay LCMV beamforming

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Time-Delay LCMV Beamformer

Apply a time delay LCMV beamformer to an 11-element acoustic ULA array. The elements are omnidirectional microphones. The incident angle of the signal is -50 degrees in azimuth and 30 degrees in elevation. The incident signal is an FM chirp with 500 Hz bandwidth. The propagation speed is a typical speed of sound in air, 340 m/s.

Simulate the signal and add noise.

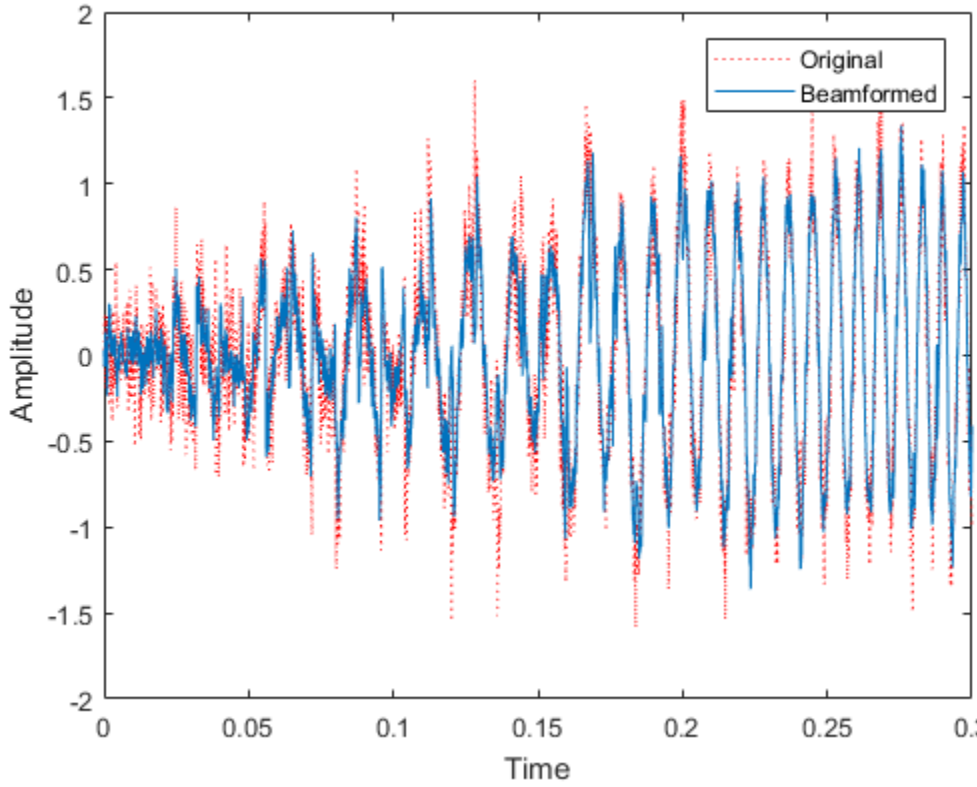
```
nElem = 11;
microphone = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[20 20000]);
array = phased.ULA('Element',microphone,'NumElements',nElem,'ElementSpacing',0.04);
fs = 8000;
t = 0:1/fs:0.3;
x = chirp(t,0,1,500);
c = 340;
collector = phased.WidebandCollector('Sensor',array,...
    'PropagationSpeed',c,'SampleRate',fs,...
    'ModulatedInput',false);
incidentAngle = [-50;30];
x = collector(x.',incidentAngle);
noise = 0.2*randn(size(x));
rx = x + noise;
```

Create and apply the time-delay LCMV beamformer. Specify a filterlength of 5.

```
filterLength = 5;
constraintMatrix = kron(eye(filterLength),ones(nElem,1));
desiredResponseVector = eye(filterLength,1);
beamformer = phased.TimeDelayLCMVBeamformer('SensorArray',array,...
    'PropagationSpeed',c,'SampleRate',fs,'FilterLength',filterLength,...
    'Direction',incidentAngle,'Constraint',constraintMatrix,...
    'DesiredResponse',desiredResponseVector);
y = beamformer(rx);
```

Compare the beamformer output to the input to the middle sensor.

```
plot(t,rx(:,6),'r:',t,y)
xlabel('Time')
ylabel('Amplitude')
legend('Original','Beamformed')
```



- “Wideband Beamforming”

Algorithms

The beamforming algorithm is the time-domain counterpart of the narrowband linear constraint minimum variance (LCMV) beamformer. The algorithm does the following:

1. Steers the array to the beamforming direction.
2. Applies an FIR filter to the output of each sensor to achieve the specified constraints. The filter is specific to each sensor.

Y = step(H,X,ANG)
[Y,W] = step( ___ )
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` performs time-delay LCMV beamforming on the input, `X`, and returns the beamformed output in `Y`. `X` is an *M*-by-*N* matrix where *N* is the number of elements of the sensor array. *M* must be larger than the FIR filter length specified in the `FilterLength` property. `Y` is a column vector of length *M*.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

`Y = step(H,X,XT)` uses `XT` as the training samples to calculate the beamforming weights when you set the `TrainingInputPort` property to `true`. `XT` is an *M*-by-*N* matrix where *N* is the number of elements of the sensor array. *M* must be larger than the FIR filter length specified in the `FilterLength` property.

`Y = step(H,X,ANG)` uses `ANG` as the beamforming direction, when you set the `DirectionSource` property to `'Input port'`. `ANG` is a column vector of length 2 in the

form of `[AzimuthAngle; ElevationAngle]` (in degrees). The azimuth angle must be between –180° and 180°, and the elevation angle must be between –90° and 90°.

You can combine optional input arguments when their enabling properties are set: `Y = step(H,X,XT,ANG)`

`[Y,W] = step( ___ )` returns additional output, `W`, as the beamforming weights when you set the `WeightsOutputPort` property to `true`. `W` is a column vector of length L, where L is the number of degrees of freedom of the beamformer. For a time-delay LCMV beamformer, the number of degrees of freedom is given by the product of the number of elements of the array and the filter length specified by the value of the `FilterLength` property.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Examples

Time-Delay LCMV Beamformer

Apply a time delay LCMV beamformer to an 11-element acoustic ULA array. The elements are omnidirectional microphones. The incident angle of the signal is -50 degrees in azimuth and 30 degrees in elevation. The incident signal is an FM chirp with 500 Hz bandwidth. The propagation speed is a typical speed of sound in air, 340 m/s.

Simulate the signal and add noise.

```
nElem = 11;
microphone = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[20 20000]);
array = phased.ULA('Element',microphone,'NumElements',nElem,'ElementSpacing',0.04);
fs = 8000;
t = 0:1/fs:0.3;
x = chirp(t,0,1,500);
c = 340;
```

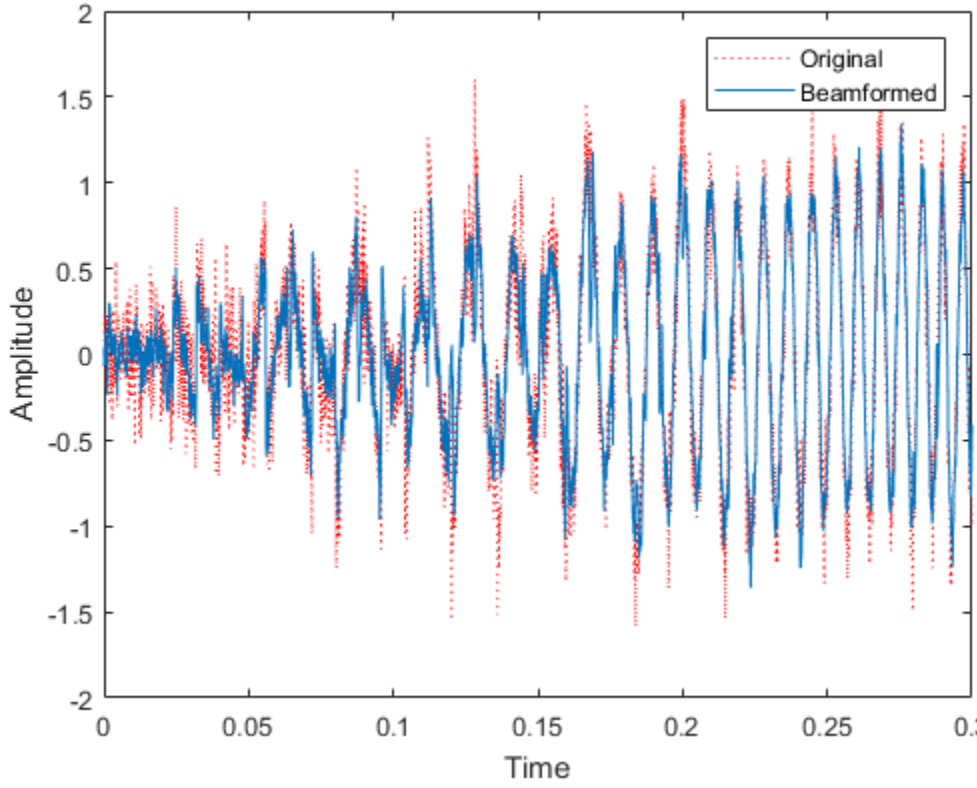
```
collector = phased.WidebandCollector('Sensor',array,...
    'PropagationSpeed',c,'SampleRate',fs,...
    'ModulatedInput',false);
incidentAngle = [-50;30];
x = collector(x.',incidentAngle);
noise = 0.2*randn(size(x));
rx = x + noise;
```

Create and apply the time-delay LCMV beamformer. Specify a filterlength of 5.

```
filterLength = 5;
constraintMatrix = kron(eye(filterLength),ones(nElem,1));
desiredResponseVector = eye(filterLength,1);
beamformer = phased.TimeDelayLCMVBeamformer('SensorArray',array,...
    'PropagationSpeed',c,'SampleRate',fs,'FilterLength',filterLength,...
    'Direction',incidentAngle,'Constraint',constraintMatrix,...
    'DesiredResponse',desiredResponseVector);
y = beamformer(rx);
```

Compare the beamformer output to the input to the middle sensor.

```
plot(t,rx(:,6),'r:',t,y)
xlabel('Time')
ylabel('Amplitude')
legend('Original','Beamformed')
```



Algorithms

The beamforming algorithm is the time-domain counterpart of the narrowband linear constraint minimum variance (LCMV) beamformer. The algorithm does the following:

1. Steers the array to the beamforming direction.
2. Applies an FIR filter to the output of each sensor to achieve the specified constraints. The filter is specific to each sensor.

phased.TimeVaryingGain System object

Package: phased

Time varying gain control

Description

The `TimeVaryingGain` object applies a time varying gain to input signals. Time varying gain (TVG) is sometimes called automatic gain control (AGC).

To apply the time varying gain to the signal:

1. Define and set up your time varying gain controller. See "Construction" on page 1-1967.
2. Call step to apply the time varying gain according to the properties of `phased.TimeVaryingGain`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.TimeVaryingGain` creates a time varying gain control System object, `H`. The object applies a time varying gain to the input signal to compensate for the signal power loss due to the range.

`H = phased.TimeVaryingGain(Name,Value)` creates an object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

RangeLossSource

Source of range losses

Specify the source of range losses as either `'Property'` or `'Input port'`. When you specify `RangeLossSource` as `'Property'`, the range loss for each sample is set in the `RangeLoss` property. When you specify the `RangeLossSource` as `'Input port'`, the range losses are specified using an input argument to the `step` method.

Default: `'Property'`

RangeLoss

Loss at each input sample range

Specify the loss due to range as a vector — elements correspond to the samples in the input signal. Units are in dB.

Default: `0`

ReferenceLoss

Loss at reference range

Specify the loss at a given reference range as a scalar. Units are in dB.

Default: `0`

Methods

step	Apply time varying gains to input signal

Common to All System Objects	
`clone`	Create System object with same property values

Common to All System Objects	
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Apply Time Varying Gain to Adjust for Range Loss

Apply time varying gain to a signal to compensate for signal power loss due to range.

First, create a signal with range loss. Set the reference loss to 16 dB.

```
rngloss = 10:22;
refloss = 16;
t = (1:length(rngloss))';
x = 1./db2mag(rngloss(:));
```

Then add gain to compensate for range loss.

```
gain = phased.TimeVaryingGain('RangeLoss',rngloss,'ReferenceLoss',refloss);
y = gain(x);
```

Plot the signal with loss and the compensated signal.

```
tref = find(rngloss==refloss);
stem([t t],[abs(x) abs(y)])
hold on
stem(tref,x(tref),'filled','r')
xlabel('Time (s)'); ylabel('Magnitude (V)')
grid on
legend('Before time varying gain','After time varying gain',...
    'Reference range')
```

step

System object: phased.TimeVaryingGain
Package: phased

Apply time varying gains to input signal

Syntax

```
Y = step(H,X)
Y = step(H,X,L)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` applies time varying gains to the input signal matrix `X`. The process equalizes power levels across all samples to match a given reference range. The compensated signal is returned in `Y`. `X` can be a column vector, a matrix, or a cube. The gain is applied to each column in `X` independently. The number of rows in `X` cannot exceed the length of the loss vector specified in the `RangeLoss` property. `Y` has the same dimensionality as `X`.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

`Y = step(H,X,L)` in addition, specifies the range loss, `L` as a columns vector. Use this argument only when you set the `RangeLossSource` property to `'Input port'`. The length of `L` must be equal to or greater than the number of rows of `X`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications,

such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

phased.Transmitter System object

Package: phased

Transmitter

Description

The `Transmitter` object implements a waveform transmitter.

To compute the transmitted signal:

1. Define and set up your waveform transmitter. See "Construction" on page 1-1975.
2. Call step to compute the transmitted signal according to the properties of `phased.Transmitter`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.Transmitter` creates a transmitter System object, `H`. This object transmits the input waveform samples with specified peak power.

`H = phased.Transmitter(Name,Value)` creates a transmitter object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`PeakPower`

Peak power

Specify the transmit peak power (in watts) as a positive scalar.

Default: `5000`

`Gain`

Transmit gain

Specify the transmit gain (in decibels) as a real scalar.

Default: `20`

`LossFactor`

Loss factor

Specify the transmit loss factor (in decibels) as a nonnegative scalar.

Default: `0`

`InUseOutputPort`

Enable transmitter status output

To obtain the transmitter in-use status for each output sample, set this property to `true` and use the corresponding output argument when invoking step. In this case, 1's indicate the transmitter is on, and 0's indicate the transmitter is off. If you do not want to obtain the transmitter in-use status, set this property to `false`.

Default: `false`

`CoherentOnTransmit`

Preserve coherence among pulses

Specify whether to preserve coherence among transmitted pulses. When you set this property to `true`, the transmitter does not introduce any random phase to the output pulses. When you set this property to `false`, the transmitter adds a random phase noise to each transmitted pulse. The random phase noise is introduced by multiplication of the pulse by $e^{j\phi}$ where ϕ is a uniform random variable on the interval $[0,2\pi]$.

Default: `true`

PhaseNoiseOutputPort

Enable pulse phase noise output

To obtain the introduced transmitter random phase noise for each output sample, set this property to `true` and use the corresponding output argument when invoking step. You can use in the receiver to simulate coherent on receive systems. If you do not want to obtain the random phase noise, set this property to `false`. This property applies when you set the `CoherentOnTransmit` property to `false`.

Default: `false`

SeedSource

Source of seed for random number generator

`'Auto'`	The default MATLAB random number generator produces the random numbers. Use `'Auto'` if you are using this object with Parallel Computing Toolbox software.
`'Property'`	The object uses its own private random number generator to produce random numbers. The `Seed` property of this object specifies the seed of the random number generator. Use `'Property'` if you want repeatable results and are not using this object with Parallel Computing Toolbox software.

This property applies when you set the `CoherentOnTransmit` property to `false`.

Default: `'Auto'`

Seed

Seed for random number generator

Specify the seed for the random number generator as a scalar integer between 0 and $2^{32}-1$. This property applies when you set the `CoherentOnTransmit` property to `false` and the `SeedSource` property to `'Property'`.

Default: `0`

Methods

reset	Reset states of transmitter object
step	Transmit pulses

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Transmit LFM Pulse

Transmit a pulse containing a linear FM waveform with a bandwidth of 5 MHz. The sample rate is 10 MHz and the pulse repetition frequency is 10 kHz.

```
fs = 1e7;
waveform = phased.LinearFMWaveform('SampleRate',fs, ...
    'PulseWidth',1e-5,'SweepBandwidth',5e6);
x = waveform();
transmitter = phased.Transmitter('PeakPower',5e3);
y = transmitter(x);
```

reset

System object: phased.Transmitter
Package: phased

Reset states of transmitter object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `Transmitter` object, `H`. This method resets the random number generator state if the `SeedSource` property is applicable and has the value `'Property'`.

step

System object: phased.Transmitter
Package: phased

Transmit pulses

Syntax

```
Y = step(H,X)
[Y,STATUS] = step(H,X)
[Y,PHNOISE] = step(H,X)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` returns the transmitted signal `Y`, based on the input waveform `X`. `Y` is the amplified `X` where the amplification is based on the characteristics of the transmitter, such as the peak power and the gain.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

`[Y,STATUS] = step(H,X)` returns additional output `STATUS` as the on/off status of the transmitter when the `InUseOutputPort` property is `true`. `STATUS` is a logical vector where `true` indicates the transmitter is on for the corresponding sample time, and `false` indicates the transmitter is off.

`[Y,PHNOISE] = step(H,X)` returns the additional output `PHNOISE` as the random phase noise added to each transmitted sample when the `CoherentOnTransmit` property is `false` and the `PhaseNoiseOutputPort` property is `true`. `PHNOISE` is a vector which

has the same dimension as Y. Each element in `PHNOISE` contains the random phase between 0 and 2*pi, added to the corresponding sample in `Y` by the transmitter.

You can combine optional output arguments when their enabling properties are set. Optional outputs must be listed in the same order as the order of the enabling properties. For example:

```
[Y,STATUS,PHNOISE] = step(H,X)
```

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Examples

Transmit LFM Pulse

Transmit a pulse containing a linear FM waveform with a bandwidth of 5 MHz. The sample rate is 10 MHz and the pulse repetition frequency is 10 kHz.

```
fs = 1e7;
waveform = phased.LinearFMWaveform('SampleRate',fs, ...
    'PulseWidth',1e-5,'SweepBandwidth',5e6);
x = waveform();
transmitter = phased.Transmitter('PeakPower',5e3);
y = transmitter(x);
```

phased.TwoRayChannel System object

Package: phased

Two-ray propagation channel

Description

The `phased.TwoRayChannel` models a narrowband two-ray propagation channel. A two-ray propagation channel is the simplest type of multipath channel. You can use a two-ray channel to simulate propagation of signals in a homogeneous, isotropic medium with a single reflecting boundary. This type of medium has two propagation paths: a line-of-sight (direct) propagation path from one point to another and a ray path reflected from the boundary. You can use this System object for short-range radar and mobile communications applications where the signals propagate along straight paths and the earth is assumed to be flat. You can also use this object for sonar and microphone applications. For acoustic applications, you can choose the fields to be non-polarized and adjust the propagation speed to be the speed of sound in air or water. You can use `phased.TwoRayChannel` to model propagation from several points simultaneously.

While the System object works for all frequencies, the attenuation models for atmospheric gases and rain are valid for electromagnetic signals in the frequency range 1–1000 GHz only. The attenuation model for fog and clouds is valid for 10–1000 GHz. Outside these frequency ranges, the System object uses the nearest valid value.

The `phased.TwoRayChannel` System object applies range-dependent time delays to the signals, and as well as gains or losses, phase shifts, and boundary reflection loss. The System object applies Doppler shift when either the source or destination is moving.

Signals at the channel output can be kept *separate* or be *combined* — controlled by the `CombinedRaysOutput` property. In the *separate* option, both fields arrive at the destination separately and are not combined. For the *combined* option, the two signals at the source propagate separately but are coherently summed at the destination into a single quantity. This option is convenient when the difference between the sensor or array gains in the directions of the two paths is not significant and need not be taken into account.

Unlike the phased.FreeSpace System object, the `phased.TwoRayChannel` System object does not support two-way propagation.

To compute the propagation delay for specified source and receiver points:

1. Define and set up your two-ray channel using the "Construction" on page 1-1984 procedure that follows.
2. Call the `step` method to compute the propagated signal using the properties of the `phased.TwoRayChannel` System object.

   The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`s2Ray = phased.TwoRayChannel` creates a two-ray propagation channel System object, `s2Ray`.

`s2Ray = phased.TwoRayChannel(Name,Value)` creates a System object, `s2Ray`, with each specified property `Name` set to the specified `Value`. You can specify additional name and value pair arguments in any order as (`Name1,Value1,...,NameN,ValueN`).

Properties

`PropagationSpeed` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. Units are in m/s. The default value of the speed of light is the value returned by `physconst('LightSpeed')`.

Example: `3e8`

Data Types: `double`

`OperatingFrequency` — Signal carrier frequency

`300e6` (default) | positive real-valued scalar

Signal carrier frequency, specified as a positive real-valued scalar. Units are in Hz.

Example: `1e9`

Data Types: `double`

`SpecifyAtmosphere` — Enable atmospheric attenuation model

`false` (default) | `true`

Option to enable the atmospheric attenuation model, specified as a `false` or `true`. Set this property to `true` to add signal attenuation caused by atmospheric gases, rain, fog, or clouds. Set this property to `false` to ignore atmospheric effects in propagation.

Setting `SpecifyAtmosphere` to `true`, enables the `Temperature`, `DryAirPressure`, `WaterVapourDensity`, `LiquidWaterDensity`, and `RainRate` properties.

Data Types: `logical`

`Temperature` — Ambient temperature

`15` (default) | real-valued scalar

Ambient temperature, specified as a real-valued scalar. Units are in degrees Celsius.

Example: `20.0`

Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

`DryAirPressure` — Atmospheric dry air pressure

`101.325e3` (default) | positive real-valued scalar

Atmospheric dry air pressure, specified as a positive real-valued scalar. Units are in pascals (Pa). The default value of this property corresponds to one standard atmosphere.

Example: `101.0e3`

Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

`WaterVapourDensity` — Atmospheric water vapor density

`7.5` (default) | positive real-valued scalar

Atmospheric water vapor density, specified as a positive real-valued scalar. Units are in g/m^3.

Example: `7.4`

Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

`LiquidWaterDensity` — Liquid water density

`0.0` (default) | nonnegative real-valued scalar

Liquid water density of fog or clouds, specified as a nonnegative real-valued scalar. Units are in g/m^3. Typical values for liquid water density are 0.05 for medium fog and 0.5 for thick fog.

Example: `0.1`

Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

`RainRate` — Rainfall rate

`0.0` (default) | nonnegative scalar

Rainfall rate, specified as a nonnegative scalar. Units are in mm/hr.

Example: `10.0`

Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

`SampleRate` — Sample rate of signal

`1e6` (default) | positive scalar

Sample rate of signal, specified as a positive scalar. Units are in Hz. The System object uses this quantity to calculate the propagation delay in units of samples.

Example: `1e6`

Data Types: `double`

`EnablePolarization` — Enable polarized fields

`false` (default) | true

Option to enable polarized fields, specified as a logical scalar. Set this property to `true` to enable polarization. Set this property to `false` to ignore polarization.

Data Types: `logical`

`GroundReflectionCoefficient` — Ground reflection coefficient

`-1` (default) | complex-valued scalar | complex-valued 1-by-*N* row vector

Ground reflection coefficient for the field at the reflection point, specified as a complex-valued scalar or a complex-valued 1-by-*N* row vector. Each coefficient has an absolute value less than or equal to one. The quantity *N* is the number of two-ray channels. Units are dimensionless. Use this property to model nonpolarized signals. To model polarized signals, use the `GroundRelativePermittivity` property.

Example: `-0.5`

Dependencies

To enable this property, set `EnablePolarization` to `false`.

Data Types: `double`
Complex Number Support: Yes

`GroundRelativePermittivity` — Ground relative permittivity

`15` (default) | positive real-valued scalar | real-valued 1-by-*N*row vector of positive values

Relative permittivity of the ground at the reflection point, specified as a positive real-valued scalar or a 1-by-*N* real-valued row vector of positive values. The dimension

N is the number of two-ray channels. Permittivity units are dimensionless. Relative permittivity is defined as the ratio of actual ground permittivity to the permittivity of free space. This property applies when you set the `EnablePolarization` property to `true`. Use this property to model polarized signals. To model nonpolarized signals, use the `GroundReflectionCoefficient` property.

Example: `5`

Dependencies

To enable this property, set `EnablePolarization` to `true`.

Data Types: `double`

`CombinedRaysOutput` — Option to combine two rays at output

`true` (default) | `false`

Option to combine the two rays at channel output, specified as `true` or `false`. When this property is `true`, the object coherently adds the line-of-sight propagated signal and the reflected path signal when forming the output signal. Use this mode when you do not need to include the directional gain of an antenna or array in your simulation.

Data Types: `logical`

`MaximumDistanceSource` — Source of maximum one-way propagation distance

`'Auto'` (default) | `'Property'`

Source of maximum one-way propagation distance, specified as `'Auto'` or `'Property'`. The maximum one-way propagation distance is used to allocate sufficient memory for signal delay computation. When you set this property to `'Auto'`, the System object automatically allocates memory. When you set this property to `'Property'`, you specify the maximum one-way propagation distance using the value of the `MaximumDistance` property.

Data Types: `char`

`MaximumDistance` — Maximum one-way propagation distance

`10000` (default) | positive real-valued scalar

Maximum one-way propagation distance, specified as a positive real-valued scalar. Units are in meters. Any signal that propagates more than the maximum one-way distance is

ignored. The maximum distance must be greater than or equal to the largest position-to-position distance.

Example: `5000`

Dependencies

To enable this property, set the `MaximumDistanceSource` property to `'Property'`.

Data Types: `double`

`MaximumNumInputSamplesSource` — Source of maximum number of samples

`'Auto'` (default) | `'Property'`

The source of the maximum number of samples of the input signal, specified as `'Auto'` or `'Property'`. When you set this property to `'Auto'`, the propagation model automatically allocates enough memory to buffer the input signal. When you set this property to `'Property'`, you specify the maximum number of samples in the input signal using the `MaximumNumInputSamples` property. Any input signal longer than that value is truncated.

When you use propagation models in MATLAB Function Block in Simulink with variable-size signals, you must set the `MaximumNumInputSamples` parameter to `'Property'` and set the `MaximumNumInputSamples` parameter accordingly.

Example: `'Property'`

Dependencies

To enable this property, set `MaximumDistanceSource` to `'Property'`.

Data Types: `char`

`MaximumNumInputSamples` — Maximum number of input signal samples

`100` (default) | positive integer

Maximum number of input signal samples, specified as a positive integer. The input signal is the first argument of the `step` method, after the System object itself. The size of the input signal is the number of rows in the input matrix. Any input signal longer than

this number is truncated. To process signals completely, ensure that this property value is greater than any maximum input signal length.

The waveform-generating System objects determine the maximum signal size:

- For any waveform, if the waveform `OutputFormat` property is set to `'Samples'`, the maximum signal length is the value specified in the `NumSamples` property.
- For pulse waveforms, if the `OutputFormat` is set to `'Pulses'`, the signal length is the product of the smallest pulse repetition frequency, the number of pulses, and the sample rate.
- For continuous waveforms, if the `OutputFormat` is set to `'Sweeps'`, the signal length is the product of the sweep time, the number of sweeps, and the sample rate.

Example: `2048`

Dependencies

To enable this property, set `MaximumNumInputSamplesSource` to `'Property'`.

Data Types: `double`

Methods

reset	Reset states of System object
step	Propagate signal from point to point using two-ray channel model

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

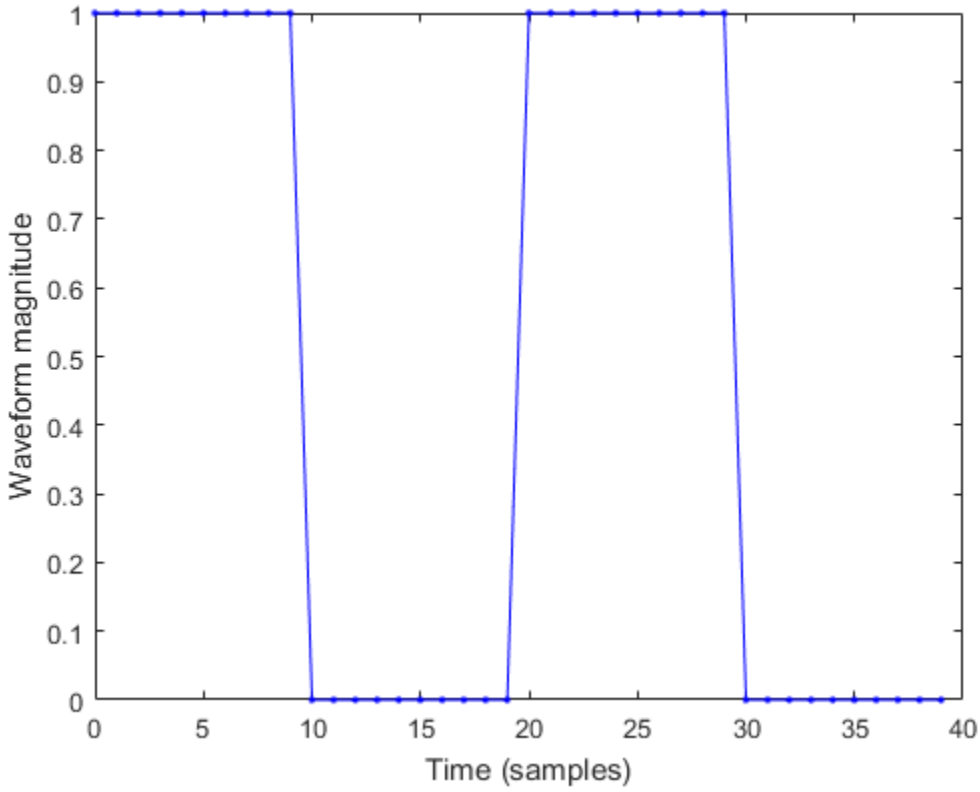
Scalar Field Propagating in Two-Ray Channel

This example illustrates the two-ray propagation of a signal, showing how the signals from the line-of-sight and reflected path arrive at the receiver at different times.

Create and Plot Propagating Signal

Create a nonpolarized electromagnetic field consisting of two rectangular waveform pulses at a carrier frequency of 100 MHz. Assume the pulse width is 10 ms and the sampling rate is 1 MHz. The bandwidth of the pulse is 0.1 MHz. Assume a 50% duty cycle in so that the pulse width is one-half the pulse repetition interval. Create a two-pulse wave train. Set the `GroundReflectionCoefficient` to 0.9 to model strong ground reflectivity. Propagate the field from a stationary source to a stationary receiver. The vertical separation of the source and receiver is approximately 10 km.

```
c = physconst('LightSpeed');
fs = 1e6;
pw = 10e-6;
pri = 2*pw;
PRF = 1/pri;
fc = 100e6;
lambda = c/fc;
waveform = phased.RectangularWaveform('SampleRate',fs,'PulseWidth',pw,...
    'PRF',PRF,'OutputFormat','Pulses','NumPulses',2);
wav = waveform();
n = size(wav,1);
figure;
plot([0:(n-1)],real(wav),'b.-');
xlabel('Time (samples)')
ylabel('Waveform magnitude')
```



Specify the Location of Source and Receiver

Place the source and receiver about 1000 meters apart horizontally and approximately 10 km apart vertically.

```
pos1 = [1000;0;10000];
pos2 = [0;100;100];
vel1 = [0;0;0];
vel2 = [0;0;0];
```

Compute the predicted signal delays in units of samples.

```
[rng,ang] = rangeangle(pos2,pos1,'two-ray');
delay = rng/c*fs
```

```
delay =

   33.1926   33.8563
```

Create a Two-Ray Channel System Object™

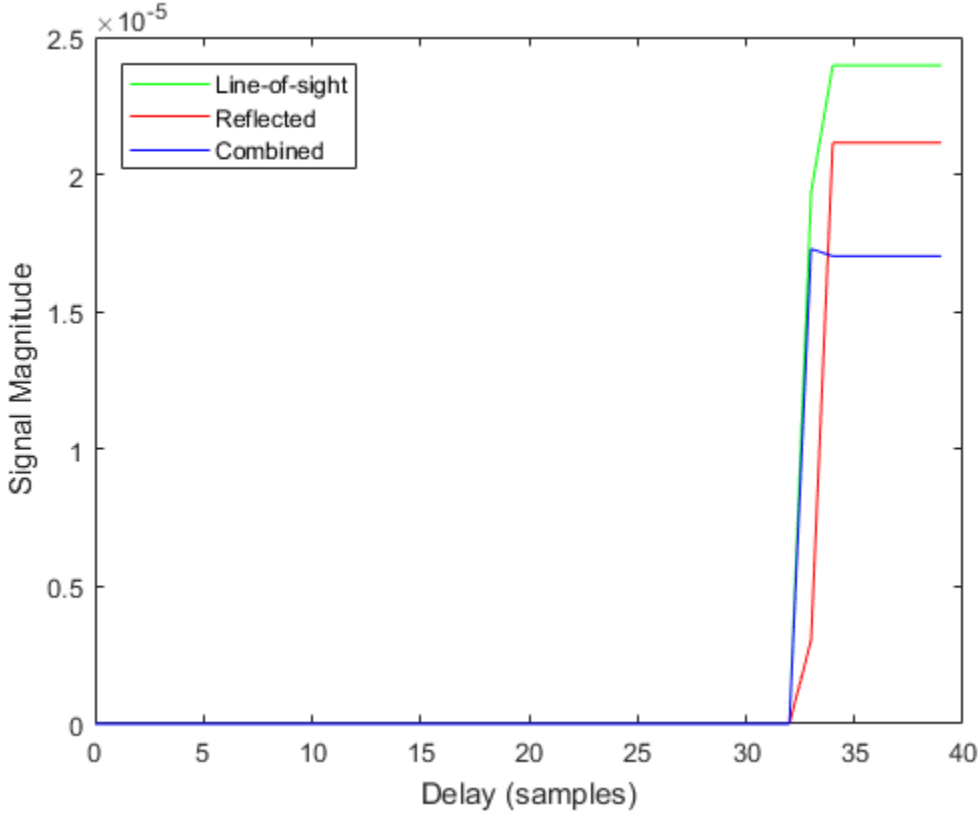
Create a two-ray propagation channel System object™ and propagate the signal along both the line-of-sight and reflected ray paths.

```
channel = phased.TwoRayChannel('SampleRate',fs,...
    'GroundReflectionCoefficient',.9,'OperatingFrequency',fc,...
    'CombinedRaysOutput',false);
prop_signal = channel([wav,wav],pos1,pos2,vel1,vel2);
```

Plot the Propagated Signals

- Plot the signal propagated along the line-of-sight.
- Then, overlay a plot of the signal propagated along the reflected path.
- Finally, overlay a plot of the coherent sum of the two signals.

```
n = size(prop_signal,1);
delay = [0:(n-1)];
plot(delay,abs([prop_signal(:,1)]),'g')
hold on
plot(delay,abs([prop_signal(:,2)]),'r')
plot(delay,abs([prop_signal(:,1) + prop_signal(:,2)]),'b')
hold off
legend('Line-of-sight','Reflected','Combined','Location','NorthWest')
xlabel('Delay (samples)')
ylabel('Signal Magnitude')
```



The plot shows that the delay of the reflected path signal agrees with the predicted delay. The magnitude of the coherently combined signal is less than either of the propagated signals indicating that there is some interference between the two signals.

Polarized Field Propagation in Two-Ray Channel

Create a polarized electromagnetic field consisting of linear FM waveform pulses. Propagate the field from a stationary source with a crossed-dipole antenna element to a stationary receiver approximately 10 km away. The transmitting antenna is 100 meters above the ground. The receiving antenna is 150 m above the ground. The receiving antenna is also a crossed-dipole. Plot the received signal.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Set Radar Waveform Parameters

Assume the pulse width is 10 µs and the sampling rate is 10 MHz. The bandwidth of the pulse is 1 MHz. Assume a 50% duty cycle in which the pulse width is one-half the pulse repetition interval. Create a two-pulse wave train. Assume a carrier frequency of 100 MHz.

```
c = physconst('LightSpeed');
fs = 10e6;
pw = 10e-6;
pri = 2*pw;
PRF = 1/pri;
fc = 100e6;
bw = 1e6;
lambda = c/fc;
```

Set Up Required System Objects

Use a `GroundRelativePermittivity` of 10.

```
waveform = phased.LinearFMWaveform('SampleRate',fs,'PulseWidth',pw,...
    'PRF',PRF,'OutputFormat','Pulses','NumPulses',2,'SweepBandwidth',bw,...
    'SweepDirection','Up','Envelope','Rectangular','SweepInterval',...
    'Positive');
antenna = phased.CrossedDipoleAntennaElement(...
    'FrequencyRange',[50,200]*1e6);
radiator = phased.Radiator('Sensor',antenna,'OperatingFrequency',fc,...
    'EnablePolarization',true);
channel = phased.TwoRayChannel('SampleRate',fs,...
    'OperatingFrequency',fc,'CombinedRaysOutput',false,...
    'EnablePolarization',true,'GroundRelativePermittivity',10);
collector = phased.Collector('Sensor',antenna,'OperatingFrequency',fc,...
    'EnablePolarization',true);
```

Set Up Scene Geometry

Specify transmitter and receiver positions, velocities, and orientations. Place the source and receiver about 1000 m apart horizontally and approximately 50 m apart vertically.

```
posTx = [0;100;100];
```

```
posRx = [1000;0;150];
velTx = [0;0;0];
velRx = [0;0;0];
laxRx = rotz(180);
laxTx = rotx(1)*eye(3);
```

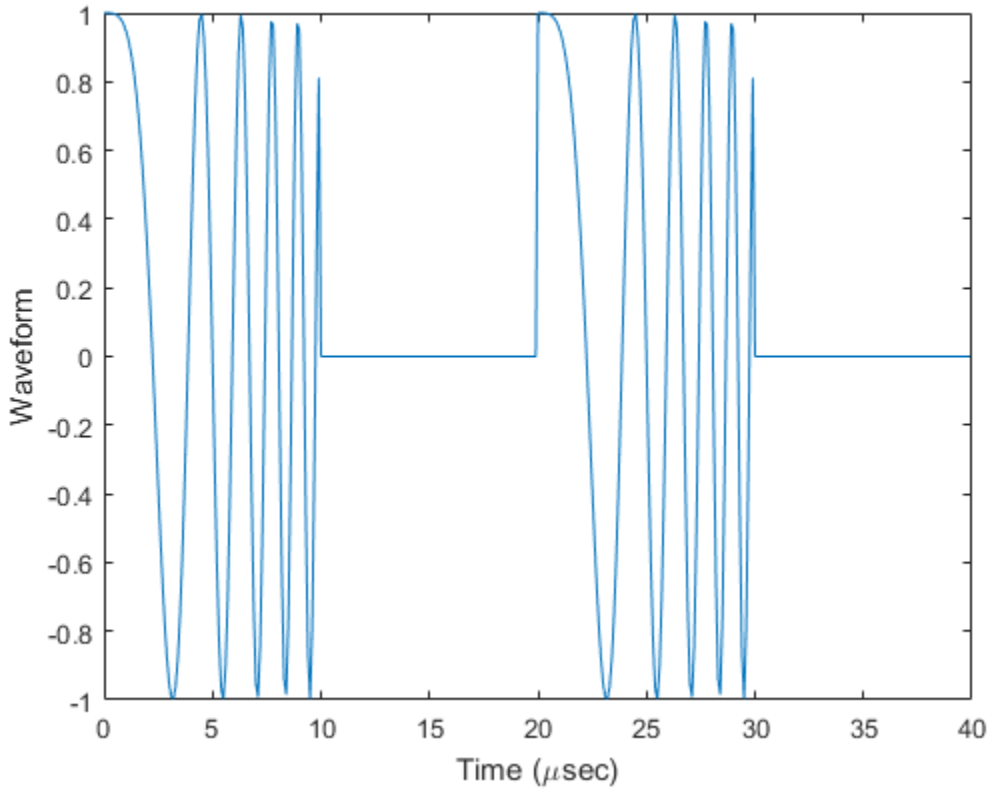
Create and Radiate Signals from Transmitter

Compute the transmission angles for the two rays traveling toward the receiver. These angles are defined with respect to the transmitter local coordinate system. The `phased.Radiator` System object™ uses these angles to apply separate antenna gains to the two signals.

```
[rng,angsTx] = rangeangle(posRx,posTx,laxTx,'two-ray');
wav = waveform();
```

Plot the transmitted Waveform

```
n = size(wav,1);
plot([0:(n-1)]/fs*1000000,real(wav))
xlabel('Time ({\mu}sec)')
ylabel('Waveform')
sig = radiator(wav,angsTx,laxTx);
```



Propagate signals to receiver via two-ray channel

```
prop_sig = channel(sig,posTx,posRx,velTx,velRx);
```

Receive Propagated Signal

Compute the reception angles for the two rays arriving at the receiver. These angles are defined with respect to the receiver local coordinate system. The `phased.Collector` System object™ uses these angles to apply separate antenna gains to the two signals.

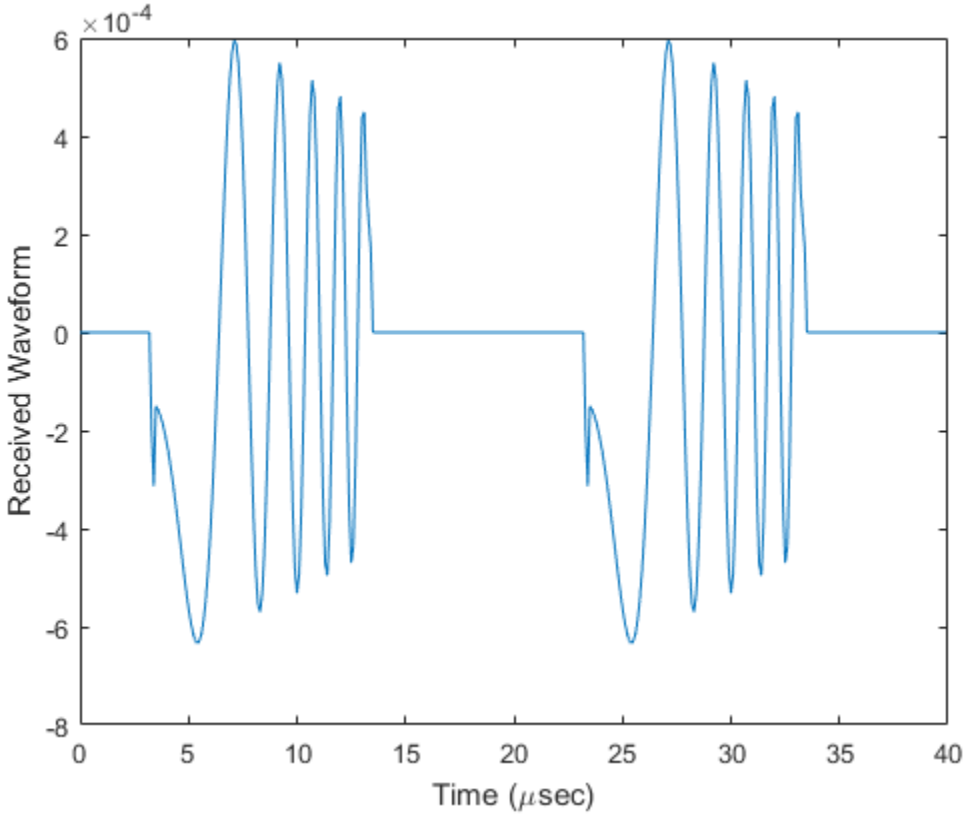
```
[~,angsRx] = rangeangle(posTx,posRx,laxRx,'two-ray');
```

Collect and combine received rays.

```
y = collector(prop_sig,angsRx,laxRx);
```

Plot received waveform

```
plot([0:(n-1)]/fs*1000000,real(y))
xlabel('Time ({\mu}sec)')
ylabel('Received Waveform')
```



Definitions

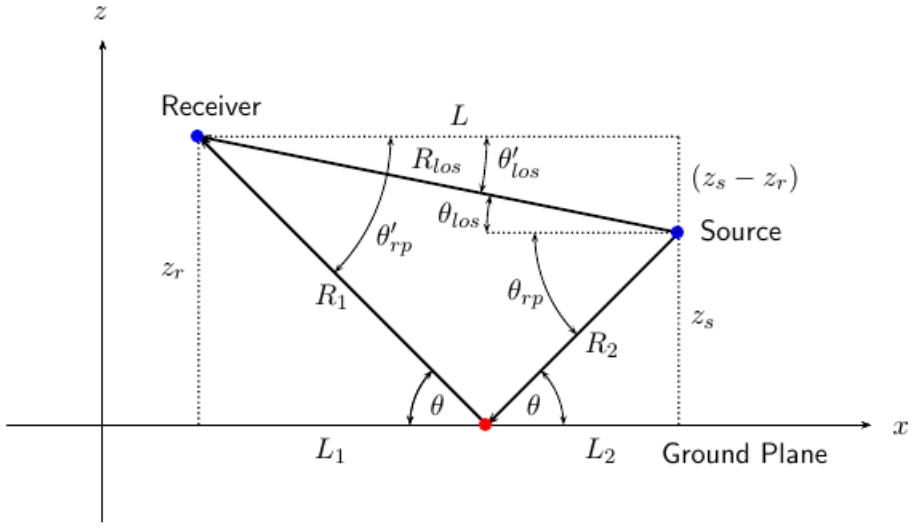
Two-Ray Propagation Paths

A two-ray propagation channel is the next step up in complexity from a free-space channel and is the simplest case of a multipath propagation environment. The free-

space channel models a straight-line *line-of-sight* path from point 1 to point 2. In a two-ray channel, the medium is specified as a homogeneous, isotropic medium with a reflecting planar boundary. The boundary is always set at $z = 0$. There are at most two rays propagating from point 1 to point 2. The first ray path propagates along the same line-of-sight path as in the free-space channel (see the phased.FreeSpace System object). The line-of-sight path is often called the *direct path*. The second ray reflects off the boundary before propagating to point 2. According to the Law of Reflection , the angle of reflection equals the angle of incidence. In short-range simulations such as cellular communications systems and automotive radars, you can assume that the reflecting surface, the ground or ocean surface, is flat.

The phased.TwoRayChannel and phased.WidebandTwoRayChannel System objects model propagation time delay, phase shift, Doppler shift, and loss effects for both paths. For the reflected path, loss effects include reflection loss at the boundary.

The figure illustrates two propagation paths. From the source position, s_s, and the receiver position, s_r, you can compute the arrival angles of both paths, θ'_{los} and θ'_{rp}. The arrival angles are the elevation and azimuth angles of the arriving radiation with respect to a local coordinate system. In this case, the local coordinate system coincides with the global coordinate system. You can also compute the transmitting angles, θ_{los} and θ_{rp}. In the global coordinates, the angle of reflection at the boundary is the same as the angles θ_{rp} and θ'_{rp}. The reflection angle is important to know when you use angle-dependent reflection-loss data. You can determine the reflection angle by using the `rangeangle` function and setting the reference axes to the global coordinate system. The total path length for the line-of-sight path is shown in the figure by R_{los} which is equal to the geometric distance between source and receiver. The total path length for the reflected path is $R_{rp} = R_1 + R_2$. The quantity L is the ground range between source and receiver.



You can easily derive exact formulas for path lengths and angles in terms of the ground range and objects heights in the global coordinate system.

$$\vec{R} = \vec{x}_s - \vec{x}_r$$

$$R_{los} = \left|\vec{R}\right| = \sqrt{\left(z_r - z_s\right)^2 + L^2}$$

$$R_1 = \frac{z_r}{z_r + z_z}\sqrt{\left(z_r + z_s\right)^2 + L^2}$$

$$R_2 = \frac{z_s}{z_s + z_r}\sqrt{\left(z_r + z_s\right)^2 + L^2}$$

$$R_{rp} = R_1 + R_2 = \sqrt{\left(z_r + z_s\right)^2 + L^2}$$

$$\tan\theta_{los} = \frac{\left(z_s - z_r\right)}{L}$$

$$\tan\theta_{rp} = -\frac{\left(z_s + z_r\right)}{L}$$

$$\theta'_{los} = -\theta_{los}$$

$$\theta'_{rp} = \theta_{rp}$$

Two-Ray Attenuation

Attenuation or path loss in the two-ray channel is the product of five components, $L = L_{tworay}\, L_G\, L_g\, L_c\, L_r$, where

- L_{tworay} is the two-ray geometric path attenuation
- L_G is the ground reflection attenuation
- L_g is the atmospheric path attenuation
- L_c is the fog and cloud path attenuation
- L_r is the rain path attenuation

Each component is in magnitude units, not in dB.

Ground Reflection and Propagation Loss

Losses occurs when a signal is reflected from a boundary. You can obtain a simple model of ground reflection loss by representing the electromagnetic field as a scalar field. This approach also works for acoustic and sonar systems. Let E be a scalar free-space electromagnetic field having amplitude E_0 at a reference distance R_0 from a transmitter

(for example, one meter). The propagating free-space field at distance R_{los} from the transmitter is

$$E_{los} = E_0 \left(\frac{R_0}{R_{los}} \right) e^{i\omega(t - R_{los}/c)}$$

for the line-of-sight path. You can express the ground-reflected E-field as

$$E_{rp} = L_G E_0 \left(\frac{R_0}{R_{rp}} \right) e^{i\omega\left(t - R_{rp}/c\right)}$$

where R_{rp} is the reflected path distance. The quantity L_G represents the loss due to reflection at the ground plane. To specify L_G, use the `GroundReflectionCoefficient` property. In general, L_G depends on the incidence angle of the field. If you have empirical information about the angular dependence of L_G, you can use `rangeangle` to compute the incidence angle of the reflected path. The total field at the destination is the sum of the line-of-sight and reflected-path fields.

For electromagnetic waves, a more complicated but more realistic model uses a vector representation of the polarized field. You can decompose the incident electric field into two components. One component, E_p, is parallel to the plane of incidence. The other component, E_s, is perpendicular to the plane of incidence. The ground reflection coefficients for these components differ and can be written in terms of the ground permittivity and incidence angle.

$$G_p = \frac{Z_1 \cos\theta_1 - Z_2 \cos\theta_2}{Z_1 \cos\theta_1 + Z_2 \cos\theta_2} = \frac{\cos\theta_1 - \frac{Z_2}{Z_1}\cos\theta_2}{\cos\theta_1 + \frac{Z_2}{Z_1}\cos\theta_2}$$

$$G_s = \frac{Z_2 \cos\theta_1 - Z_1 \cos\theta_2}{Z_2 \cos\theta_1 + Z_1 \cos\theta_2} = \frac{\cos\theta_2 - \frac{Z_2}{Z_1}\cos\theta_1}{\cos\theta_2 + \frac{Z_2}{Z_1}\cos\theta_1}$$

$$Z_1 = \sqrt{\frac{\mu_1}{\varepsilon_1}}$$

$$Z_2 = \sqrt{\frac{\mu_2}{\varepsilon_2}}$$

where Z is the impedance of the medium. Because the magnetic permeability of the ground is almost identical to that of air or free space, the ratio of impedances depends primarily on the ratio of electric permittivities

$$G_p = \frac{\sqrt{\rho}\cos\theta_1 - \cos\theta_2}{\sqrt{\rho}\cos\theta_1 + \cos\theta_2}$$

$$G_s = \frac{\sqrt{\rho}\cos\theta_2 - \cos\theta_1}{\sqrt{\rho}\cos\theta_2 + \cos\theta_1}$$

where the quantity $\rho = \varepsilon_2/\varepsilon_1$ is the *ground relative permittivity* set by the `GroundRelativePermittivity` property. The angle θ_1 is the incidence angle and the angle θ_2 is the refraction angle at the boundary. You can determine θ_2 using Snell's law of refraction.

After reflection, the full field is reconstructed from the parallel and perpendicular components. The total ground plane attenuation, L_G, is a combination of G_s and G_p.

When the origin and destination are stationary relative to each other, you can write the output `Y` of `step` as $Y(t) = F(t-\tau)/L$. The quantity τ is the signal delay and L is the free-space path loss. The delay τ is given by R/c. R is either the line-of-sight propagation path distance or the reflected path distance, and c is the propagation speed. The path loss

$$L_{tworay} = \frac{(4\pi R)^2}{\lambda^2},$$

where λ is the signal wavelength.

Atmospheric Gas Attenuation Model

This model calculates the attenuation of signals that propagate through atmospheric gases.

Electromagnetic signals attenuate when they propagate through the atmosphere. This effect is due primarily to the absorption resonance lines of oxygen and water vapor, with smaller contributions coming from nitrogen gas. The model also includes a continuous absorption spectrum below 10 GHz. Phased Array System Toolbox uses the ITU model *Recommendation ITU-R P.676-10: Attenuation by atmospheric gases*.

The model computes the specific attenuation (attenuation per kilometer) as a function of temperature, pressure, water vapor density, and signal frequency. The atmospheric gas model is valid for frequencies from 1–1000 GHz and applies to polarized and nonpolarized fields.

The formula for specific attenuation at each frequency is

$$\gamma = \gamma_o(f) + \gamma_w(f) = 0.1820 f N''(f).$$

The quantity $N''()$ is the imaginary part of the complex atmospheric refractivity. It consists of a spectral line component and a continuous component:

$$N''(f) = \sum_i S_i F_i + N_D''(f)$$

The spectral component consists of a sum of discrete spectrum terms composed of a localized frequency bandwidth function, $F(f)_i$, multiplied by a spectral line strength, S_i. For atmospheric oxygen, each spectral line strength is

$$S_i = a_1 \times 10^{-7} \left(\frac{300}{T}\right)^3 \exp\left[a_2 (1 - \left(\frac{300}{T}\right)\right] P.$$

For atmospheric water vapor, each spectral line strength is

$$S_i = b_1 \times 10^{-1} \left(\frac{300}{T}\right)^{3.5} \exp\left[b_2 (1 - \left(\frac{300}{T}\right)\right] W.$$

P is the atmospheric pressure, W is the water vapor density, and T is the ambient temperature.

For each oxygen line, S_i depends on constants a_1 and a_2. Similarly, each water vapor line has constants b_1 and b_2. The ITU documentation cited at the end of this section contains tabulations of these constants.

The localized frequency bandwidth functions $F_i(f)$ are complicated functions of frequency described in the ITU references cited below. The functions depend on empirical model parameters that are also tabulated in the reference.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length, R. Then, the total attenuation is $L_g = R(\gamma_o + \gamma_w)$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

Fog and Cloud Attenuation Model

This model calculates the attenuation of signals that propagate through fog or clouds.

Fog and cloud attenuation are the same atmospheric phenomenon. Phased Array System Toolbox uses the ITU model, *Recommendation ITU-R P.840-6: Attenuation due to clouds and fog*. The model computes the specific attenuation (attenuation per kilometer), of a signal as a function of liquid water density, signal frequency, and temperature. The model applies to polarized and nonpolarized fields. The formula for specific attenuation at each frequency is

$$\gamma_c = K_l(f)M,$$

where M is the liquid water density in gm/m^3. The quantity $K_l(f)$ is the specific attenuation coefficient and depends on frequency. The cloud and fog attenuation model is valid for frequencies 10–1000 GHz. Units for the specific attenuation coefficient are (dB/km)/(g/m^3).

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length R. Total attenuation is $L_c = R\gamma_c$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply narrowband attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

Rainfall Attenuation Model

This model calculates the attenuation of signals that propagate through regions of rainfall.

Electromagnetic signals are attenuate when propagating through a region of rainfall. Rainfall attenuation is computed according to the ITU rainfall model *Recommendation*

ITU-R P.838-3: Specific attenuation model for rain for use in prediction methods. The model computes the specific attenuation (attenuation per kilometer) of a signal as a function of rainfall rate, signal frequency, polarization, and path elevation angle. To compute the attenuation, this model uses

$$\gamma_r = kr^{\alpha},$$

where r is the rain rate in mm/hr. The parameter k and exponent α depend on the frequency, the polarization state, and the elevation angle of the signal path. The specific attenuation model is valid for frequencies from 1–1000 GHz.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by a propagation distance, R. Then, total attenuation is $L_r = R\gamma_r$. Instead of using geometric range as the propagation distance, the toolbox uses a modified range. The modified range is the geometric range multiplied by a range factor

$$\frac{1}{1+\frac{R}{R_0}}$$

where

$$R_0 = 35e^{-0.015r}$$

is the effective path length in kilometers (see Seybold, J. *Introduction to RF Propagation*.) When there is no rain, the effective path length is 35 km. When the rain rate is, for example, 10 mm/hr, the effective path length is 30.1 km. At short range, the propagation distance is approximately the geometric range. For longer ranges, the propagation distance asymptotically approaches the effective path length.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

System Objects

phased.FreeSpace | phased.LOSChannel | phased.RadarTarget | phased.WidebandFreeSpace | phased.WidebandLOSChannel | phased.WidebandTwoRayChannel

Introduced in R2015b

reset

System object: phased.TwoRayChannel
Package: phased

Reset states of System object

Syntax

```
reset(s2Ray)
```

Description

`reset(s2Ray)` resets the internal state of the `phased.TwoRayChannel` object, `S`. This method resets the random number generator state if `SeedSource` is a property of this System object and has the value `'Property'`.

Input Arguments

`s2Ray` — Two-ray channel

System object

Two-ray channel, specified as a System object.

Example: `phased.TwoRayChannel`

Introduced in R2015b

step

System object: phased.TwoRayChannel
Package: phased

Propagate signal from point to point using two-ray channel model

Syntax

```
prop_sig = step(channel,sig,origin_pos,dest_pos,origin_vel,dest_vel)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`prop_sig = step(channel,sig,origin_pos,dest_pos,origin_vel,dest_vel)` returns the resulting signal, `prop_sig`, when a narrowband signal, `sig`, propagates through a two-ray channel from the `origin_pos` position to the `dest_pos` position. Either the `origin_pos` or `dest_pos` arguments can have multiple points but you cannot specify both as having multiple points. The velocity of the signal origin is specified in `origin_vel` and the velocity of the signal destination is specified in `dest_vel`. The dimensions of `origin_vel` and `dest_vel` must agree with the dimensions of `origin_pos` and `dest_pos`, respectively.

Electromagnetic fields propagated through a two-ray channel can be polarized or nonpolarized. For, nonpolarized fields, such as an acoustic field, the propagating signal field, `sig`, is a vector or matrix. When the fields are polarized, `sig` is an array of structures. Every structure element represents an electric field vector in Cartesian form.

In the two-ray environment, there are two signal paths connecting every signal origin and destination pair. For *N* signal origins (or *N* signal destinations), there are *2N* number of paths. The signals for each origin-destination pair do not have to be related.

The signals along the two paths for any single source-destination pair can also differ due to phase or amplitude differences.

You can keep the two signals at the destination *separate* or *combined* — controlled by the `CombinedRaysOutput` property. *Combined* means that the signals at the source propagate separately along the two paths but are coherently summed at the destination into a single quantity. To use the *separate* option, set `CombinedRaysOutput` to `false`. To use the *combined* option, set `CombinedRaysOutput` to `true`. This option is convenient when the difference between the sensor or array gains in the directions of the two paths is not significant and need not be taken into account.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`channel` — Two-ray channel

System object

Two-ray channel, specified as a System object.

Example: `phased.TwoRayChannel`

`sig` — Narrowband signal

M-by-*N* complex-valued matrix | *M*-by-*2N* complex-valued matrix | 1-by-*N* `struct` array containing complex-valued fields | 1-by-*2N* `struct` array containing complex-valued fields

- Narrowband nonpolarized scalar signal, specified as an
  - *M*-by-*N* complex-valued matrix. Each column contains a common signal propagated along both the line-of-sight path and the reflected path. You can use this form when both path signals are the same.
  - *M*-by-*2N* complex-valued matrix. Each adjacent pair of columns represents a different channel. Within each pair, the first column represents the signal

propagated along the line-of-sight path and the second column represents the signal propagated along the reflected path.

- Narrowband polarized signal, specified as a
  - 1-by-*N* `struct` array containing complex-valued fields. Each `struct` contains a common polarized signal propagated along both the line-of-sight path and the reflected path. Each structure element contains an *M*-by-1 column vector of electromagnetic field components `(sig.X,sig.Y,sig.Z)`. You can use this form when both path signals are the same.
  - 1-by-*2N* `struct` array containing complex-valued fields. Each adjacent pair of array columns represents a different channel. Within each pair, the first column represents the signal along the line-of-sight path and the second column represents the signal along the reflected path. Each structure element contains an *M*-by-1 column vector of electromagnetic field components `(sig.X,sig.Y,sig.Z)`.

For nonpolarized fields, the quantity *M* is the number of samples of the signal and *N* is the number of two-ray channels. Each channel corresponds to a source-destination pair.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

For polarized fields, the `struct` element contains three *M*-by-1 complex-valued column vectors, `sig.X`, `sig.Y`, and `sig.Z`. These vectors represent the *x*, *y*, and *z* Cartesian components of the polarized signal.

The size of the first dimension of the matrix fields within the `struct` can vary to simulate a changing signal length such as a pulse waveform with variable pulse repetition frequency.

Example: `[1,1;j,1;0.5,0]`

Data Types: `double`
Complex Number Support: Yes

`origin_pos` — Origin of the signal or signals

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Origin of the signal or signals, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. The quantity *N* is the number of two-ray channels. If `origin_pos` is a column vector, it takes the form `[x;y;z]`. If `origin_pos` is a matrix, each column specifies a different signal origin and has the form `[x;y;z]`. Position units are meters.

`origin_pos` and `dest_pos` cannot both be specified as matrices — at least one must be a 3-by-1 column vector.

Example: `[1000;100;500]`

Data Types: `double`

`dest_pos` — Destination position of the signal or signals

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Destination position of the signal or signals, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. The quantity *N* is the number of two-ray channels propagating from or to *N* signal origins. If `dest_pos` is a 3-by-1 column vector, it takes the form `[x;y;z]`. If `dest_pos` is a matrix, each column specifies a different signal destination and takes the form `[x;y;z]` Position units are in meters.

You cannot specify `origin_pos` and `dest_pos` as matrices. At least one must be a 3-by-1 column vector.

Example: `[0;0;0]`

Data Types: `double`

`origin_vel` — Velocity of signal origin

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Velocity of signal origin, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. The dimensions of `origin_vel` must match the dimensions of `origin_pos`. If `origin_vel` is a column vector, it takes the form `[Vx;Vy;Vz]`. If `origin_vel` is a 3-by-*N* matrix, each column specifies a different origin velocity and has the form `[Vx;Vy;Vz]`. Velocity units are in meters per second.

Example: `[10;0;5]`

Data Types: `double`

`dest_vel` — Velocity of signal destinations

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Velocity of signal destinations, specified as a 3-by-1 real-valued column vector or 3–by-*N* real-valued matrix. The dimensions of `dest_vel` must match the dimensions of `dest_pos`. If `dest_vel` is a column vector, it takes the form `[Vx;Vy;Vz]`. If `dest_vel` is a 3-by-*N* matrix, each column specifies a different destination velocity and has the form `[Vx;Vy;Vz]` Velocity units are in meters per second.

Example: `[0;0;0]`

Data Types: `double`

Output Arguments

`prop_sig` — Propagated signal

M-by-*N* complex-valued matrix | *M*-by-*2N* complex-valued matrix | 1-by-*N* `struct` array containing complex-valued fields | 1-by-*2N* `struct` array containing complex-valued fields

- Narrowband nonpolarized scalar signal, returned as an:
  - *M*-by-*N* complex-valued matrix. To return this format, set the `CombinedRaysOutput` property to `true`. Each matrix column contains the coherently combined signals from the line-of-sight path and the reflected path.
  - *M*-by-*2N* complex-valued matrix. To return this format set the `CombinedRaysOutput` property to `false`. Alternate columns of the matrix contain the signals from the line-of-sight path and the reflected path.
- Narrowband polarized scalar signal, returned as:
  - 1-by-*N* `struct` array containing complex-valued fields. To return this format, set the `CombinedRaysOutput` property to `true`. Each column of the array contains the coherently combined signals from the line-of-sight path and the reflected path. Each structure element contains the electromagnetic field vector `(prop_sig.X,prop_sig.Y,prop_sig.Z)`.
  - 1-by-*2N* `struct` array containing complex-valued fields. To return this format, set the `CombinedRaysOutput` property to `false`. Alternate columns contains the signals from the line-of-sight path and the reflected path. Each structure element contains the electromagnetic field vector `(prop_sig.X,prop_sig.Y,prop_sig.Z)`.

The output `prop_sig` contains signal samples arriving at the signal destination within the current input time frame. Whenever it takes longer than the current time frame for the signal to propagate from the origin to the destination, the output may not contain all contributions from the input of the current time frame. The remaining output will appear in the next call to `step`.

Examples

Compare Two-Ray with Free Space Propagation

Propagate a signal in a two-ray channel environment from a radar at (0,0,10) meters to a target at (300,200,30) meters. Assume that the radar and target are stationary and that the transmitting antenna has a cosine pattern. Compare the combined signals from the two paths with the single signal resulting from free space propagation. Set the `CombinedRaysOutput` to `true` to produce a combined propagated signal.

Create a Rectangular Waveform

Set the sample rate to 2 MHz.

```
fs = 2e6;
waveform = phased.RectangularWaveform('SampleRate',fs);
wavfrm = waveform();
```

Create the Transmitting Antenna and Radiator

Set up a `phased.Radiator` System object™ to transmit from a cosine antenna

```
antenna = phased.CosineAntennaElement;
radiator = phased.Radiator('Sensor',antenna);
```

Specify Transmitter and Target Coordinates

```
posTx = [0;0;10];
posTgt = [300;200;30];
velTx = [0;0;0];
velTgt = [0;0;0];
```

Free Space Propagation

Compute the transmitting direction toward the target for the free-space model. Then, radiate the signal.

```
[~,angFS] = rangeangle(posTgt,posTx);
wavTx = radiator(wavfrm,angFS);
```

Propagate the signal to the target.

```
fschannel = phased.FreeSpace('SampleRate',waveform.SampleRate);
```

```
yfs = fschannel(wavTx,posTx,posTgt,velTx,velTgt);
release(radiator);
```

Two-Ray Propagation

Compute the two transmit angles toward the target for line-of-sight (LOS) path and reflected paths. Compute the transmitting directions toward the target for the two rays. Then, radiate the signals.

```
[~,angTwoRay] = rangeangle(posTgt,posTx,'two-ray');
wavTwoRay = radiator(wavfrm,angTwoRay);
```

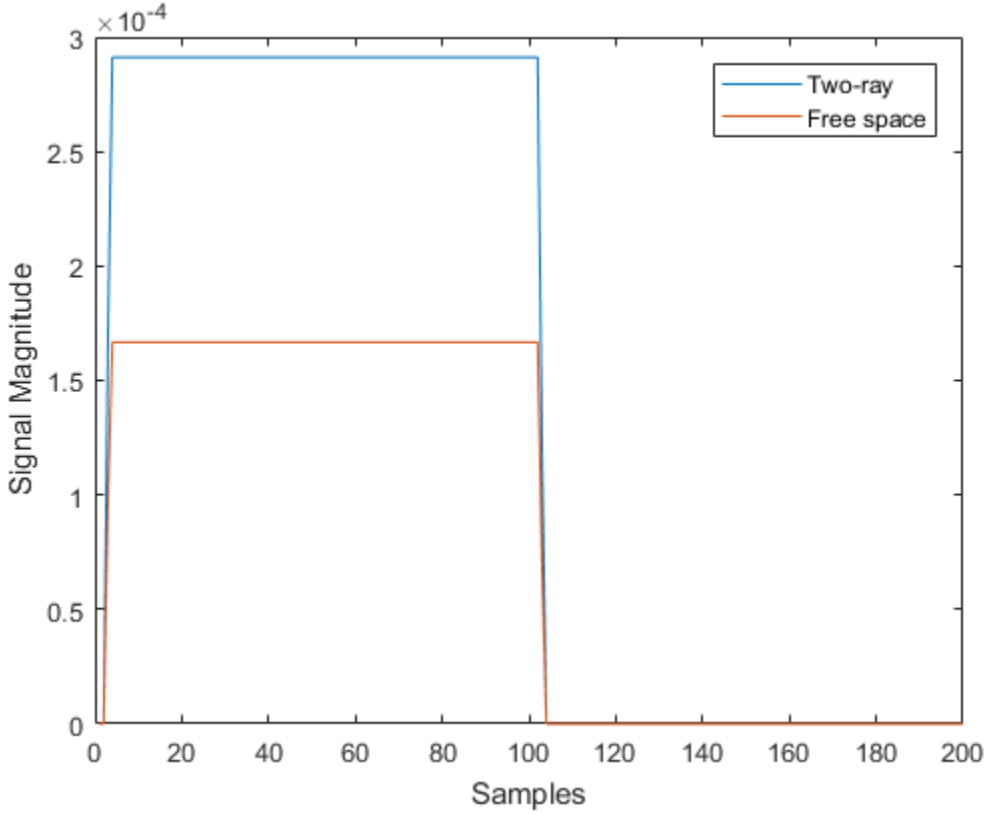
Propagate the signals to the target.

```
tworaychannel = phased.TwoRayChannel('SampleRate',waveform.SampleRate,...
    'CombinedRaysOutput',true);
y2ray = tworaychannel(wavTwoRay,posTx,posTgt,velTx,velTgt);
```

Plot the Propagated Signals

Plot the combined signal against the free-space signal

```
plot(abs([y2ray yfs]))
legend('Two-ray','Free space')
xlabel('Samples')
ylabel('Signal Magnitude')
```



Polarized Field Propagation in Two-Ray Channel

Create a polarized electromagnetic field consisting of linear FM waveform pulses. Propagate the field from a stationary source with a crossed-dipole antenna element to a stationary receiver approximately 10 km away. The transmitting antenna is 100 meters above the ground. The receiving antenna is 150 m above the ground. The receiving antenna is also a crossed-dipole. Plot the received signal.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Set Radar Waveform Parameters

Assume the pulse width is 10 μs and the sampling rate is 10 MHz. The bandwidth of the pulse is 1 MHz. Assume a 50% duty cycle in which the pulse width is one-half the pulse repetition interval. Create a two-pulse wave train. Assume a carrier frequency of 100 MHz.

```
c = physconst('LightSpeed');
fs = 10e6;
pw = 10e-6;
pri = 2*pw;
PRF = 1/pri;
fc = 100e6;
bw = 1e6;
lambda = c/fc;
```

Set Up Required System Objects

Use a `GroundRelativePermittivity` of 10.

```
waveform = phased.LinearFMWaveform('SampleRate',fs,'PulseWidth',pw,...
    'PRF',PRF,'OutputFormat','Pulses','NumPulses',2,'SweepBandwidth',bw,...
    'SweepDirection','Up','Envelope','Rectangular','SweepInterval',...
    'Positive');
antenna = phased.CrossedDipoleAntennaElement(...
    'FrequencyRange',[50,200]*1e6);
radiator = phased.Radiator('Sensor',antenna,'OperatingFrequency',fc,...
    'EnablePolarization',true);
channel = phased.TwoRayChannel('SampleRate',fs,...
    'OperatingFrequency',fc,'CombinedRaysOutput',false,...
    'EnablePolarization',true,'GroundRelativePermittivity',10);
collector = phased.Collector('Sensor',antenna,'OperatingFrequency',fc,...
    'EnablePolarization',true);
```

Set Up Scene Geometry

Specify transmitter and receiver positions, velocities, and orientations. Place the source and receiver about 1000 m apart horizontally and approximately 50 m apart vertically.

```
posTx = [0;100;100];
posRx = [1000;0;150];
velTx = [0;0;0];
velRx = [0;0;0];
laxRx = rotz(180);
```

```
laxTx = rotx(1)*eye(3);
```

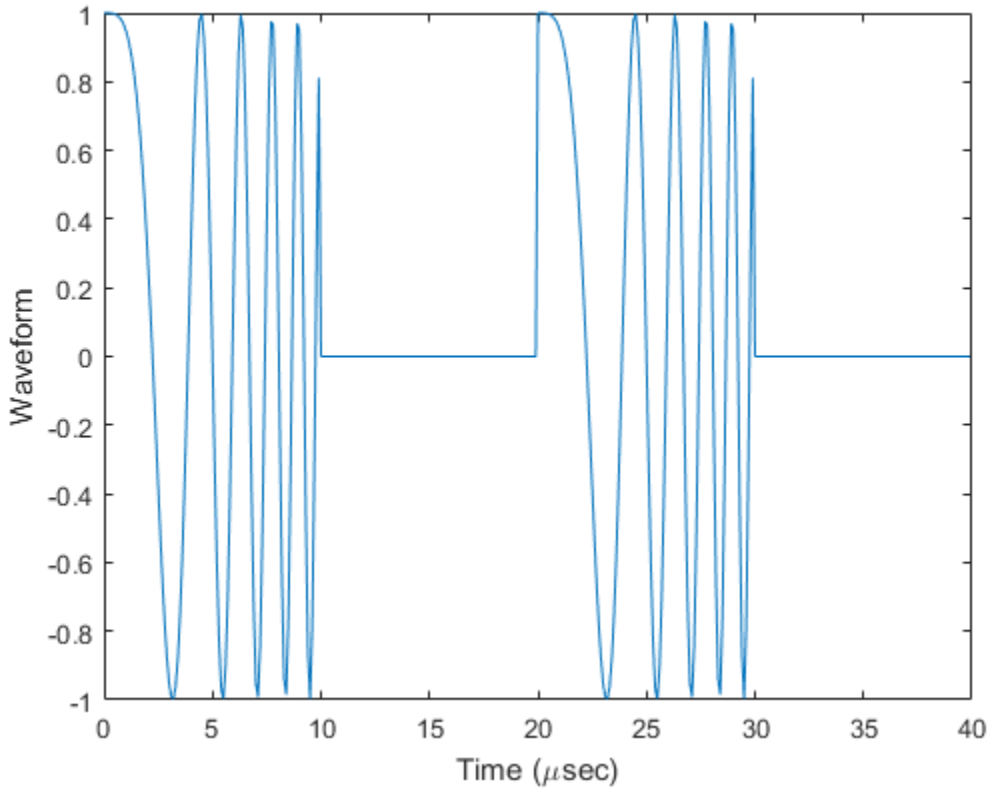
Create and Radiate Signals from Transmitter

Compute the transmission angles for the two rays traveling toward the receiver. These angles are defined with respect to the transmitter local coordinate system. The `phased.Radiator` System object™ uses these angles to apply separate antenna gains to the two signals.

```
[rng,angsTx] = rangeangle(posRx,posTx,laxTx,'two-ray');
wav = waveform();
```

Plot the transmitted Waveform

```
n = size(wav,1);
plot([0:(n-1)]/fs*1000000,real(wav))
xlabel('Time ({\mu}sec)')
ylabel('Waveform')
sig = radiator(wav,angsTx,laxTx);
```



Propagate signals to receiver via two-ray channel

```
prop_sig = channel(sig,posTx,posRx,velTx,velRx);
```

Receive Propagated Signal

Compute the reception angles for the two rays arriving at the receiver. These angles are defined with respect to the receiver local coordinate system. The `phased.Collector` System object™ uses these angles to apply separate antenna gains to the two signals.

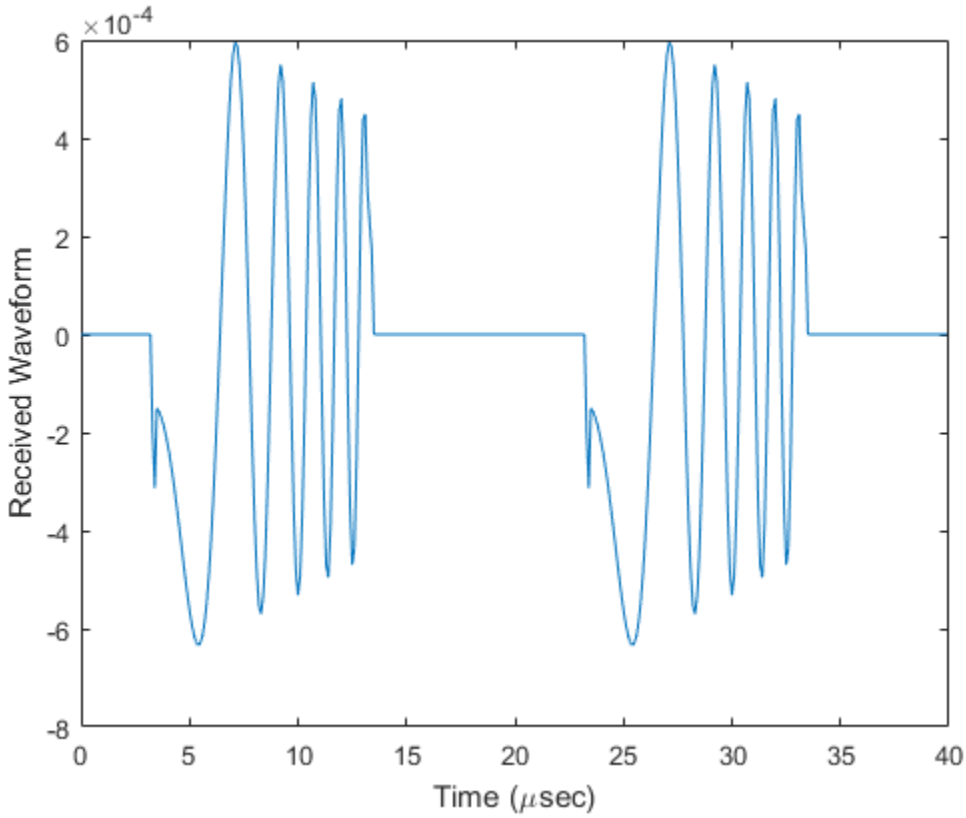
```
[~,angsRx] = rangeangle(posTx,posRx,laxRx,'two-ray');
```

Collect and combine received rays.

```
y = collector(prop_sig,angsRx,laxRx);
```

Plot received waveform

```
plot([0:(n-1)]/fs*1000000,real(y))
xlabel('Time ({\mu}sec)')
ylabel('Received Waveform')
```



Two-Ray Propagation of LFM Waveform

Propagate a linear FM signal in a two-ray channel. The signal propagates from a transmitter located at `(1000,10,10)` meters in the global coordinate system to a receiver at `(10000,200,30)` meters. Assume that the transmitter and the receiver are stationary and that they both have cosine antenna patterns. Plot the received signal.

Set up the radar scenario. First, create the required System objects.

```
waveform = phased.LinearFMWaveform('SampleRate',1000000,...
    'OutputFormat','Pulses','NumPulses',2);
fs = waveform.SampleRate;
antenna = phased.CosineAntennaElement;
radiator = phased.Radiator('Sensor',antenna);
collector = phased.Collector('Sensor',antenna);
channel = phased.TwoRayChannel('SampleRate',fs,...
    'CombinedRaysOutput',false,'GroundReflectionCoefficient',0.95);
```

Set up the scene geometry. Specify transmitter and receiver positions and velocities. The transmitter and receiver are stationary.

```
posTx = [1000;10;10];
posRx = [10000;200;30];
velTx = [0;0;0];
velRx = [0;0;0];
```

Specify the transmitting and receiving radar antenna orientations with respect to the global coordinates. The transmitting antenna points along the *+x* direction and the receiving antenna points near but not directly in the *-x* direction.

```
laxTx = eye(3);
laxRx = rotx(5)*rotz(170);
```

Compute the transmission angles which are the angles that the two rays traveling toward the receiver leave the transmitter. The phased.Radiator System object™ uses these angles to apply separate antenna gains to the two signals. Because the antenna gains depend on path direction, you must transmit and receive the two rays separately.

```
[~,angTx] = rangeangle(posRx,posTx,laxTx,'two-ray');
```

Create and radiate signals from transmitter along the transmission directions.

```
wavfrm = waveform();
wavtrans = radiator(wavfrm,angTx);
```

Propagate signals to receiver via two-ray channel.

```
wavrcv = channel(wavtrans,posTx,posRx,velTx,velRx);
```

Collect signals at the receiver. Compute the angle at which the two rays traveling from the transmitter arrive at the receiver. The `phased.Collector` System object™ uses these angles to apply separate antenna gains to the two signals.

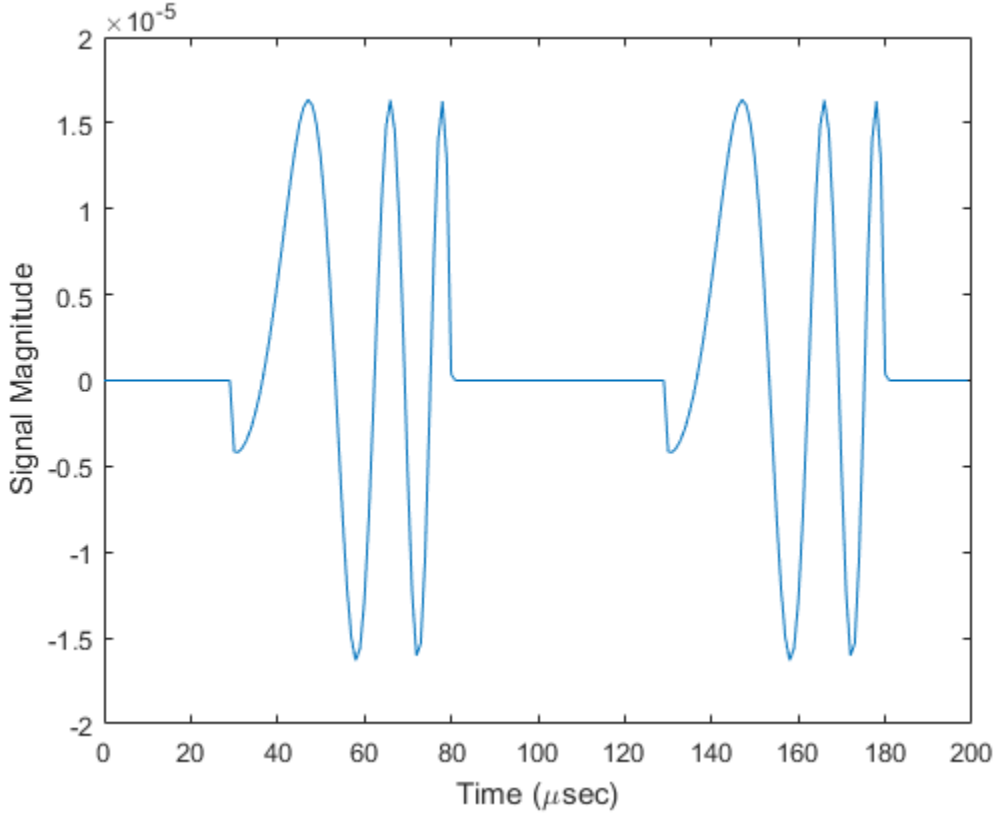
```
[~,angRcv] = rangeangle(posTx,posRx,laxRx,'two-ray');
```

Collect and combine the two received rays.

```
yR = collector(wavrcv,angRcv);
```

Plot the received signals.

```
dt = 1/fs;
n = size(yR,1);
plot([0:(n-1)]*dt*1000000,real(yR))
xlabel('Time ({\mu}sec)')
ylabel('Signal Magnitude')
```



Two-Ray Propagation of LFM Waveform with Atmospheric Losses

Propagate a linear FM signal in a two-ray channel. Assume there is signal loss caused by atmospheric gases and rain. The signal propagates from a transmitter located at `(0,0,0)` meters in the global coordinate system to a receiver at `(10000,200,30)` meters. Assume that the transmitter and the receiver are stationary and that they both have cosine antenna patterns. Plot the received signal. Set the dry air pressure to 102.0 Pa and the rain rate to 5 mm/hr.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Set Up Radar Scenario

Create the required System objects.

```
waveform = phased.LinearFMWaveform('SampleRate',1000000,...
    'OutputFormat','Pulses','NumPulses',2);
antenna = phased.CosineAntennaElement;
radiator = phased.Radiator('Sensor',antenna);
collector = phased.Collector('Sensor',antenna);
tworaychannel = phased.TwoRayChannel('SampleRate',waveform.SampleRate,...
    'CombinedRaysOutput',false,'GroundReflectionCoefficient',0.95,...
    'SpecifyAtmosphere',true,'Temperature',20,...
    'DryAirPressure',102.5,'RainRate',5.0);
```

Set up the scene geometry. Specify transmitter and receiver positions and velocities. The transmitter and receiver are stationary.

```
posTx = [0;0;0];
posRx = [10000;200;30];
velTx = [0;0;0];
velRx = [0;0;0];
```

Specify the transmitting and receiving radar antenna orientations with respect to the global coordinates. The transmitting antenna points along the +*x*-direction and the receiving antenna points close to the -*x*-direction.

```
laxTx = eye(3);
laxRx = rotx(5)*rotz(170);
```

Compute the transmission angles which are the angles that the two rays traveling toward the receiver leave the transmitter. The phased.Radiator System object™ uses these angles to apply separate antenna gains to the two signals. Because the antenna gains depend on path direction, you must transmit and receive the two rays separately.

```
[~,angTx] = rangeangle(posRx,posTx,laxTx,'two-ray');
```

Create and Radiate Signals from Transmitter

Radiate the signals along the transmission directions.

```
wavfrm = waveform();
wavtrans = radiator(wavfrm,angTx);
```

Propagate signals to receiver via two-ray channel.

```
wavrcv = tworaychannel(wavtrans,posTx,posRx,velTx,velRx);
```

Collect Signal at Receiver

Compute the angle at which the two rays traveling from the transmitter arrive at the receiver. The `phased.Collector` System object™ uses these angles to apply separate antenna gains to the two signals.

```
[~,angRcv] = rangeangle(posTx,posRx,laxRx,'two-ray');
```

Collect and combine the two received rays.

```
yR = collector(wavrcv,angRcv);
```

Plot Received Signal

```
dt = 1/waveform.SampleRate;
n = size(yR,1);
plot([0:(n-1)]*dt*1000000,real(yR))
xlabel('Time ({\mu}sec)')
ylabel('Signal Magnitude')
```

System Objects

phased.FreeSpace.step | phased.WidebandFreeSpace.step

Introduced in R2015b

phased.UCA System object

Package: phased

Uniform circular array

Description

The `phased.UCA` System object creates a *uniform circular array* (UCA) System object. A UCA is formed from identical sensor elements equally spaced around a circle.

To compute the response for each element in the array for specified directions:

1. Define and set up your uniform circular array. See "Construction" on page 1-2029.
2. Call step to compute the response according to the properties of `phased.UCA`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`sUCA = phased.UCA` creates a uniform circular array (UCA) System object, `sUCA`, consisting of five identical isotropic antenna elements,phased.IsotropicAntennaElement. The elements are equally spaced around a circle of radius 0.5 meters.

`sUCA = phased.UCA(Name,Value)` creates a System object, `sUCA`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1,Value1,...,NameN,ValueN`).

`sUCA = phased.UCA(N,R)` creates a UCA System object, `sUCA`, with the `NumElements` property set to `N` and the `Radius` property set to `R`. This syntax creates a UCA consisting of isotropic antenna elements, phased.IsotropicAntennaElement.

`sUCA = phased.UCA(N,R,Name,Value)` creates a UCA System object, `sUCA`, with the `NumElements` property set to `N`, the `Radius` property set to `R`, and other specified property Names set to the specified Values.

Properties

`Element` — Sensor array element

phased.IsotropicAntennaElement (default) | Phased Array System Toolbox antenna element | Phased Array System Toolbox microphone element

Sensor array element, specified as a Phased Array System Toolbox antenna or microphone element System object. You can specify antenna elements which do or do not support polarization.

Example: `phased.ShortDipoleAntennaElement()`

`NumElements` — Number of array elements

5 (default) | integer greater than one

Number of array elements, specified as an integer greater than one.

Example: `3`

`Radius` — Array radius

0.5 (default) | positive scalar

Array radius, specified as a positive scalar in meters.

Example: `2.5`

`ArrayNormal` — Array normal direction

`'z'` (default) | `'x'` | `'y'`

Array normal direction, specified as one of `'x'`, `'y'`, or `'z'`. UCA elements lie in a plane orthogonal to the array normal direction. Element boresight vectors lie in the same plane and point radially outward from the origin.

ArrayNormal Property Value	Element Positions and Boresight Directions
`'x'`	Array elements lie on the *yz*-plane. All element boresight vectors lie in the *yz*-plane and point outward from the array center.

ArrayNormal Property Value	Element Positions and Boresight Directions
`'y'`	Array elements lie on the *zx*-plane. All element boresight vectors lie in the *zx*-plane and point outward from the array center.
`'z'`	Array elements lie on the *xy*-plane. All element boresight vectors lie in the *xy*-plane and point outward from the array center.

Example: `'y'`

`Taper` — Element tapering

1 (default) | complex-valued scalar | complex-valued 1-by-*N* row vector | complex-valued *N*-by-1 column vector

Element tapering or weighting, specified as a complex-valued scalar, 1-by-*N* row vector, or *N*-by-1 column vector. The quantity *N* represents the number of elements of the array. Tapers, also known as weights, are applied to each sensor element in the sensor array and modify both the amplitude and phase of the received data. If `'Taper'` is a scalar, the same taper value is applied to all element. If `'Taper'` is a vector, each taper value is applied to the corresponding sensor element.

Example: `[1 2 3 2 1]`

Methods

directivity	Directivity of uniform circular array
collectPlaneWave	Simulate received plane waves
getElementNormal	Normal vectors for array elements
getElementPosition	Positions of array elements
getElementSpacing	Spacing between array elements
getNumElements	Number of elements in array
getTaper	Array element tapers
isPolarizationCapable	Polarization capability

pattern	Plot UCA array pattern
patternAzimuth	Plot UCA array directivity or pattern versus azimuth
patternElevation	Plot UCA array directivity or pattern versus elevation
step	Output responses of array elements
viewArray	View array geometry

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Pattern of 11-Element UCA Antenna Array

Create an 11-element UCA of radius 1.5 meters. Show the azimuth and elevation directivities.

Evaluate the fields at 45 degrees azimuth and 0 degrees elevation.

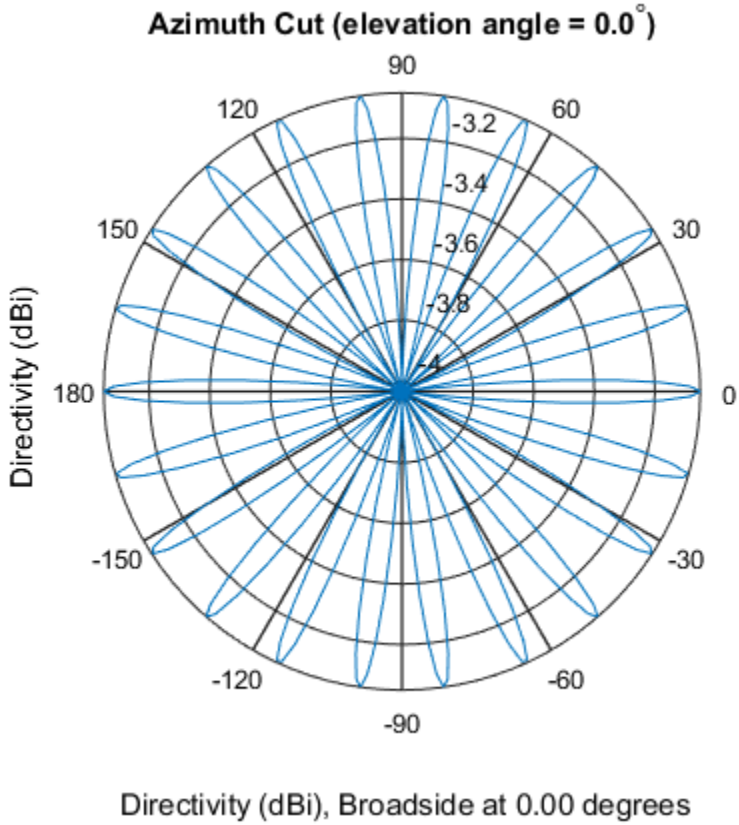
```
sSD = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[50e6,1000e6],...
    'AxisDirection','Z');
sUCA = phased.UCA('NumElements',11,'Radius',1.5,'Element',sSD);
fc = 500e6;
ang = [45;0];
resp = step(sUCA,fc,ang);
disp(resp.V)
```

```
   -1.2247
   -1.2247
   -1.2247
   -1.2247
```

```
    -1.2247
    -1.2247
    -1.2247
    -1.2247
    -1.2247
    -1.2247
    -1.2247
```

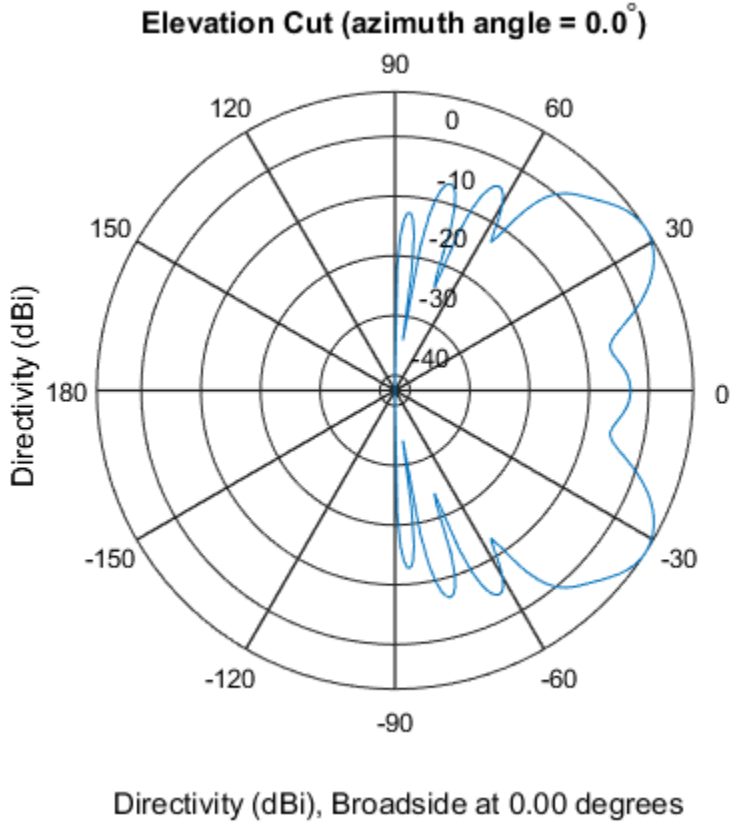
Display the azimuth directivity pattern at 500 MHz for azimuth angles between -180 and 180 degrees.

```
c = physconst('LightSpeed');
pattern(sUCA,fc,[-180:180],0,'Type','directivity','PropagationSpeed',c)
```



Display the elevation directivity pattern at 500 MHz for elevation angles between -90 and 90 degrees.

```
pattern(sUCA,fc,[0],[-90:90],'Type','directivity','PropagationSpeed',c)
```

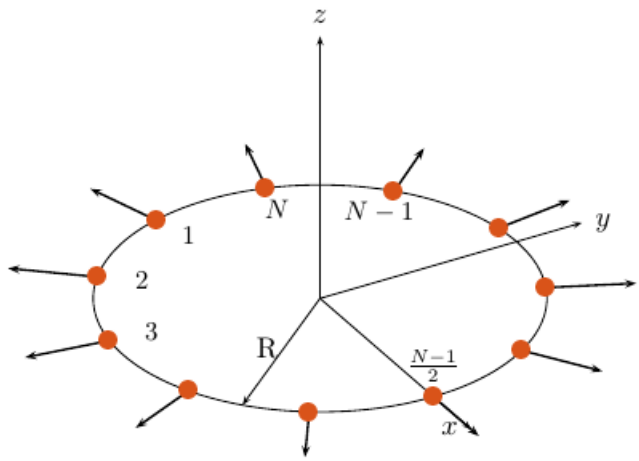


- Phased Array Gallery

Algorithms

A UCA is formed from N identical sensor elements equally spaced around a circle of radius R. The circle lies in the xy-plane of the local coordinate system whose origin lies at the center of the circle. The positions of the elements are defined with respect to the local

array coordinate system. The circular array lies in the *xy*-plane of the coordinate system. The normal to the UCA plane lies along the positive *z*-axis. The elements are oriented so that their main response directions (normals) point radially outward in the *xy*-plane.



If the number of elements of the array is odd, the middle element lies on the *x*-axis. If the number of elements is even, the midpoint between the two middle elements lies on the *x*-axis. For an array of *N* elements, the azimuth angle of the position of the *nth* element is given by

$$\varphi_n = (-(N-1)/2 + n - 1)\cdot 360/N \quad n = 1,\ldots,N$$

The azimuth angle is defined as the angle, in the *xy*-plane, from the *x*-axis toward the *y*-axis. The elevation angle is defined as the angle from the *xy*-plane toward the *z*-axis. The angular distance between any two adjacent elements is *360/N* degrees. Azimuth angle values are in degrees. Elevation angles for all array elements are zero.

directivity

System object: phased.UCA
Package: phased

Directivity of uniform circular array

Syntax

```
D = directivity(sArray,FREQ,ANGLE)
D = directivity(sArray,FREQ,ANGLE,Name,Value)
```

Description

`D = directivity(sArray,FREQ,ANGLE)` returns the "Directivity (dBi)" on page 1-2041 of a uniform circular array (UCA) of antenna or microphone elements, `sArray`, at frequencies specified by `FREQ` and in angles of direction specified by `ANGLE`.

`D = directivity(sArray,FREQ,ANGLE,Name,Value)` returns the directivity with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`sArray` — Uniform circular array

System object

Uniform circular array, specified as a phased.UCA System object.

Example: `sArray= phased.UCA;`

`FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-L real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-L real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

`ANGLE` — Angles for computing directivity

1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Angles for computing directivity, specified as a 1-by-*M* real-valued row vector or a 2-by-*M* real-valued matrix, where *M* is the number of angular directions. Angle units are in degrees. If `ANGLE` is a 2-by-*M* matrix, then each column specifies a direction in azimuth and elevation, `[az;el]`. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°.

If `ANGLE` is a 1-by-*M* vector, then each entry represents an azimuth angle, with the elevation angle assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis.

Example: `[45 60; 0 10]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'PropagationSpeed'` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

`'Weights'` — Array weights

1 (default) | *N*-by-1 complex-valued column vector | *N*-by-*L* complex-valued matrix

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *N*-by-1 complex-valued column vector or *N*-by-*L* complex-valued matrix. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *N* is the number of elements in the array. The dimension *L* is the number of frequencies specified by `FREQ`.

Weights Dimension	FREQ Dimension	Purpose
N-by-1 complex-valued column vector	Scalar or 1-by-*L* row vector	Applies a set of weights for the single frequency or for all *L* frequencies.
N-by-*L* complex-valued matrix	1-by-*L* row vector	Applies each of the *L* columns of `'Weights'` for the corresponding frequency in `FREQ`.

Note: Use complex weights to steer the array response toward different directions. You can create weights using the phased.SteeringVector System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as phased.Radiator or phased.Collector. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(N,M)`

Data Types: `double`

Complex Number Support: Yes

Output Arguments

D — Directivity

M-by-*L* matrix

Directivity, returned as an *M*-by-*L* matrix whose columns contain the directivities at the *M* angles specified by ANGLE. Each column corresponds to one of the *L* frequency values specified in FREQ. Directivity units are in dBi.

Examples

Directivity of a UCA

Compute the directivity of two uniform circular arrays (UCA) at zero degrees azimuth and elevation. The first array consists of isotropic antenna elements. The second array consists of cosine antenna elements. In addition, compute the directivity of the cosine element array steered to a 45 degrees elevation.

Array of isotropic antenna elements

First, create a 10-element UCA with a radius of one-half meter consisting of isotropic antenna elements. Set the signal frequency to 300 MHz.

```
c = physconst('LightSpeed');
fc = 300e6;
sIso = phased.IsotropicAntennaElement;
sArray = phased.UCA('Element',sIso,'NumElements',10,'Radius',0.5);
ang = [0;0];
d = directivity(sArray,fc,ang,'PropagationSpeed',c)
```

```
d =

   -1.1423
```

Array of cosine antenna elements

Next, create a 10-element UCA of cosine antenna elements also with a 0.5 meter radius.

```
sCos = phased.CosineAntennaElement('CosinePower',[3,3]);
sArray1 = phased.UCA('Element',sCos,'NumElements',10,'Radius',0.5);
ang = [0;0];
d = directivity(sArray1,fc,ang,'PropagationSpeed',c)
```

```
d =

    3.2550
```

The directivity is increased due to the added directivity of the cosine antenna elements

Steered array of cosine antenna elements

Finally, steer the cosine antenna array toward 45 degrees elevation, and then examine the directivity at 45 degrees.

```
ang = [0;45];
lambda = c/fc;
w = steervec(getElementPosition(sArray1)/lambda,ang);
d = directivity(sArray1,fc,ang,'PropagationSpeed',c,...
    'Weights',w)
```

```
d =

   -3.1410
```

The directivity is decreased because of the combined reduction of directivity of the elements and the array.

Definitions

Directivity (dBi)

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on "Element directivity" and "Array directivity".

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

phased.UCA.pattern | phased.UCA.patternAzimuth | phased.UCA.patternElevation

Introduced in R2015a

collectPlaneWave

System object: phased.UCA
Package: phased

Simulate received plane waves

Syntax

```
Y = collectPlaneWave(H,X,ANG)
Y = collectPlaneWave(H,X,ANG,FREQ)
Y = collectPlaneWave(H,X,ANG,FREQ,C)
```

Description

`Y = collectPlaneWave(H,X,ANG)` returns the received signals at the sensor array, `H`, when the input signals indicated by `X` arrive at the array from the directions specified in `ANG`.

`Y = collectPlaneWave(H,X,ANG,FREQ)`, in addition, specifies the incoming signal carrier frequency in `FREQ`.

`Y = collectPlaneWave(H,X,ANG,FREQ,C)`, in addition, specifies the signal propagation speed in `C`.

Input Arguments

`H` — Uniform circular array

System object

Uniform circular array specified as a phased.UCA System object.

Example: `H = phased.UCA();`

`X` — Incoming signals

M-column matrix

Incoming signals, specified as an *M*-column matrix. Each column of `X` represents an individual incoming signal.

Example: `[1,5;2,10;3,10]`

Data Types: `double`
Complex Number Support: Yes

ANG — Arrival directions of incoming signals

1-by-*M* real-valued vector | 2-by-*M* real-valued matrix

Arrival directions of incoming signals, specified as a 1-by-*M* vector or a 2-by-*M* matrix, where *M* is the number of incoming signals. Each column specifies the direction of arrival of the corresponding signal in `X`. If `ANG` is a 2-by-*M* matrix, each column specifies the direction in azimuth and elevation of the incoming signal `[az;el]`. Angular units are in degrees. The azimuth angle must lie between –180° and 180° and the elevation angle must lie between –90° and 90°.

If `ANG` is a 1-by-*M* vector, then each entry represents a set of azimuth angles, with the elevation angles assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the arrival direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, the azimuth angle is positive.

The elevation angle is the angle between the arrival direction vector and the *xy*-plane. When measured toward the *z* axis, the elevation angle is positive.

Example: `[20,30;15,25]`

Data Types: `double`

FREQ — Signal carrier frequency

3e8 (default) | positive scalar

Signal carrier frequency, specified as a positive scalar in hertz.

Data Types: `double`

C — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as a positive scalar in meters per second.

Example: `physconst('LightSpeed')`

Data Types: `double`

Output Arguments

Y — Received signals

N-column complex-valued row vector

Received signals, returned as an *N*-column complex-valued row vector. The quantity *N* is the number of elements in the array. Each column of `Y` contains the combined received signals at the corresponding array element.

Examples

Simulate Received Signal at 5-element UCA

Create a random signal arriving at a 5-element UCA from 10 degrees azimuth and 30 degrees azimuth. Both signals have an elevation angle of 0 degrees. Assume the propagation speed is the speed of light and the carrier frequency of the signal is 100 MHz. The signals are two random noise signals of three samples each.

```
sUCA = phased.UCA('NumElements',5,'Radius',2.0);
y = collectPlaneWave(sUCA,randn(3,2),[10 30],100e6,...
    physconst('LightSpeed'));
disp(y)
```

```
  Columns 1 through 4

  -0.8817 + 1.0528i   1.0037 - 0.3636i  -1.0579 - 0.8531i  -1.0698 + 0.5187i
  -1.6512 + 1.3471i   1.7358 + 0.7662i  -1.2932 - 1.6792i  -1.0279 + 1.6997i
   2.5071 - 2.4424i  -2.7270 - 0.2435i   2.4009 + 2.4977i   2.1808 - 2.1178i

  Column 5

  -0.6388 - 0.9769i
  -1.8283 - 0.7336i
   2.3743 + 1.8105i
```

Algorithms

`collectPlaneWave` modulates the input signal with a phase corresponding to the delay caused by the direction of arrival. The method does not account for the response of individual elements in the array.

For further details, see [1].

`phitheta2azel` | `uv2azel`

Introduced in R2015a

getElementNormal

System object: phased.UCA
Package: phased

Normal vectors for array elements

Syntax

```
normvec = getElementNormal(sArray)
normvec = getElementNormal(sArray,elemidx)
```

Description

`normvec = getElementNormal(sArray)` returns the element normals of the `phased.UCA` System object, `sArray`. `normv` is a 2-by-*N* matrix, where *N* is the number of elements in `sArray`. Each column of `normv` specifies the normal direction of the corresponding element in the local coordinate system in the form `[azimuth;elevation]`. Units are degrees. For details regarding the local coordinate system of a UCA, type

```
phased.UCA.coordinateSystemInfo;
```
at the command line.

`normvec = getElementNormal(sArray,elemidx)` returns only the normals of the elements that are specified in the element index vector `elemidx`.

Input Arguments

`sArray` — Uniform circular array

`phased.UCA` System object

Uniform circular array, specified as a phased.UCA System object.

Example: `phased.UCA`

`elemidx` — Element index vector

all elements (default) | vector of positive integers

Element index vector, specified as a vector of positive integers each of which takes a value from 1 to *N*. The dimension *N* is the number of elements of the array.

Example: `[1,2,3]`

Output Arguments

`normvec` — Normal vector

2-by-*M* real-valued matrix

Normal vector of array elements, returned as a 2-by-*M* real matrix. Each column of `normvec` specifies the normal direction of the corresponding element in the local coordinate system in the form `[azimuth;elevation]`. Units are degrees. If the input argument `elemidx` is not specified, *M* is the number of elements of the array, *N*. If `elemidx` is specified, *M* is the dimension of `elemidx`.

Examples

UCA Element Normal Vectors

Construct three different 7-element UCA with a radius of 0.5 meters, and obtain the normal vectors of the middle three elements. Choose the array normal vectors to point along the *x*-, *y*-, and *z*-axes.

First, choose the array normal along the *x*-axis.

```
sUCA1 = phased.UCA('NumElements',7,'Radius',0.5,'ArrayNormal','x');
pos = getElementPosition(sUCA1,[3,4,5])
normvec = getElementNormal(sUCA1,[3,4,5])
```

```
pos =

         0         0         0
    0.3117    0.5000    0.3117
   -0.3909         0    0.3909

normvec =
```

```
   90.0000   90.0000   90.0000
  -51.4286         0   51.4286
```

These outputs show that the array elements lie in the *yz*-plane. The normal vectors of the array elements also lie in the *yz*-plane and point outward like spokes on a wheel.

Next, choose the array normal along the *y*-axis.

```
sUCA2 = phased.UCA('NumElements',7,'Radius',0.5,'ArrayNormal','y');
pos = getElementPosition(sUCA2,[3,4,5])
normvec = getElementNormal(sUCA2,[3,4,5])
```

```
pos =

    0.3117    0.5000    0.3117
         0         0         0
   -0.3909         0    0.3909

normvec =

         0         0         0
  -51.4286         0   51.4286
```

These outputs show that the array elements lie in the *zx*-plane. The normal vectors of the array elements also lie in the *zx*-plane and also point outward.

Finally, set the array normal along the *z*-axis. This is the default value of array normal.

```
sUCA3 = phased.UCA('NumElements',7,'Radius',0.5,'ArrayNormal','z');
pos = getElementPosition(sUCA3,[3,4,5])
normvec = getElementNormal(sUCA3,[3,4,5])
```

```
pos =

    0.3117    0.5000    0.3117
   -0.3909         0    0.3909
         0         0         0

normvec =
```

```
   -51.4286         0   51.4286
         0         0         0
```

These outputs show that the array elements lie in the *xy*-plane. The normal vectors of the array elements also lie in the *xy*-plane and also point outward.

Introduced in R2015a

getElementPosition

System object: phased.UCA
Package: phased

Positions of array elements

Syntax

```
pos = getElementPosition(sUCA)
pos = getElementPosition(sUCA,elemidx)
```

Description

`pos = getElementPosition(sUCA)` returns the element positions of the `phased.UCA` System object, `sUCA`. `pos` is a 3-by-*N* matrix, where *N* is the number of elements in `sUCA`. Each column of `pos` defines the position of an element in the local coordinate system, in meters, using the form `[x;y;z]`. The origin of the local coordinate system is the center of the circular array.

`pos = getElementPosition(sUCA,elemidx)` returns only the positions of the elements that are specified in the element index vector `elemidx`.

Input Arguments

`sUCA` — Uniform circular array

`phased.UCA` System object

Uniform circular array, specified as a phased.UCA System object.

Example: `phased.UCA`

`elemidx` — Element index vector

all elements (default) | vector of positive integers

Element index vector, specified as a vector of positive integers each of which takes a value from 1 to *N*. The quantity *N* is the number of elements of the array.

Example: `[1,2,3]`

Output Arguments

`pos` — Positions of array elements

3-by-*M* real matrix

Positions of array elements, returned as a 3-by-*M* real matrix. If the input argument `elemidx` is not specified, *M* is the number of elements of the array, *N*. If `elemidx` is specified, *M* is the dimension of `elemidx`.

Examples

Positions of UCA ELements

Construct a 7-element UCA with a radius of 0.5 meters, and obtain the positions of the middle three elements.

```
sArray = phased.UCA('NumElements',7,'Radius',0.5);
pos = getElementPosition(sArray,[3,4,5])
```

```
pos =

    0.3117    0.5000    0.3117
   -0.3909         0    0.3909
         0         0         0
```

The output verifies that the position of the middle element of an array with an odd number of elements lies on the x-axis.

Introduced in R2015a

getElementSpacing

System object: phased.UCA
Package: phased

Spacing between array elements

Syntax

```
dist = getElementSpacing(sArray)
dist = getElementSpacing(sArray,disttype)
```

Description

`dist = getElementSpacing(sArray)` returns the arc length between adjacent elements of the `phased.UCA` System object, `sArray`.

`dist = getElementSpacing(sArray,disttype)` returns either the arc length or chord length between adjacent elements depending on the specification of `disttype`.

Input Arguments

`sArray` — Uniform circular array

`phased.UCA` System object

Uniform circular array, specified as a phased.UCA System object.

Example: `phased.UCA()`

`disttype` — Distance type

`'arc'` (default) | `'chord'`

Distance type to define path between adjacent array elements, specified as a either `'arc'` or `'chord'`. If `disttype` is specified as `'arc'`, the returned distance is the arc length between adjacent elements. If `disttype` is specified as `'chord'`, the returned distance is the chord length between adjacent elements.

Example: `'chord'`

Output Arguments

`spacing` — Spacing between elements

scalar

Spacing between elements, returned as a scalar. A uniform circular array has a unique distance between all pairs of adjacent elements. The distance depends only upon the radius of the array, R, and the angle between two adjacent elements, $\Delta\varphi$. The angle between two adjacent elements is computed from the number of elements, $\Delta\varphi = 2\pi/N$. If `disttype` is specified as `'arc'`, the method returns
$R\Delta\varphi$.
If `disttype` is specified as `'chord'`, the method returns
$2R\sin(\Delta\varphi/2)$.
The chord distance is always less than the arc distance.

Examples

Spacing Between UCA Elements

Construct a 10-element UCA with a radius of 1.5 meters, and obtain the arc distance between any two adjacent elements. Then, obtain the chord distance.

```
sArray = phased.UCA('NumElements',10,'Radius',1.5);
dist = getElementSpacing(sArray,'arc')
```

```
dist =

    0.9425
```

```
dist = getElementSpacing(sArray,'chord')
```

```
dist =

    0.9271
```

Introduced in R2015a

getNumElements

System object: phased.UCA
Package: phased

Number of elements in array

Syntax

```
N = getNumElements(H)
```

Description

`N = getNumElements(H)` returns the number of elements, *N*, in the UCA object `H`.

Input Arguments

`H` — Uniform circular array

`phased.UCA` System object

Uniform circular array, specified as a phased.UCA System object.

Example: `H = phased.UCA();`

Output Arguments

`N` — Number of elements

positive integer

Number of elements of array, returned as a positive integer.

Examples

Number of Elements of UCA

Create a UCA with the default number of elements. Verify that there are five elements.

```
sArray = phased.UCA();
N = getNumElements(sArray)
```

```
N =

     5
```

Introduced in R2015a

getTaper

System object: phased.UCA
Package: phased

Array element tapers

Syntax

```
WTS = getTaper(H)
```

Description

`WTS = getTaper(H)` returns the tapers, `WTS`, applied to each element of the phased uniform circular array (UCA), `H`. Tapers are often referred to as weights.

Input Arguments

`H` — Uniform circular array

System object

Uniform circular array, specified as a phased.ULA System object.

Example: `H = phased.UCA();`

Output Arguments

`WTS` — Array element tapers

N-by-1 complex-valued vector

Array element tapers, returned as an *N*-by-1 complex-valued vector, where *N* is the number of elements in the array.

Examples

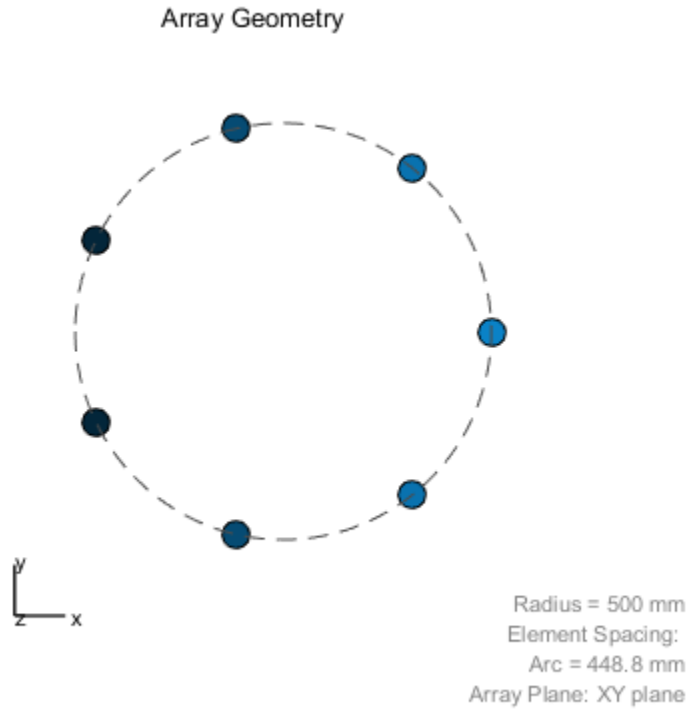
Show UCA Element Tapers

Construct a 7-element UCA array of isotropic antenna alements with a Taylor window taper. Design the array to have a radius of 0.5 meters. Then, draw the array showing the element taper shading.

```
Nelem = 7;
R = 0.5;
taper = taylorwin(Nelem);
sArray = phased.UCA(Nelem,R,'Taper',taper.');
w = getTaper(sArray)
viewArray(sArray,'ShowTaper',true);
```

```
w =

    0.4520
    0.9009
    1.3680
    1.5581
    1.3680
    0.9009
    0.4520
```



Both the output and figure above shows that the taper magnitudes are largest near the middle element.

Introduced in R2015a

isPolarizationCapable

System object: phased.UCA
Package: phased

Polarization capability

Syntax

```
flag = isPolarizationCapable(H)
```

Description

`flag = isPolarizationCapable(H)` returns a Boolean value, `flag`, indicating whether the array supports polarization. An array supports polarization when all of its constituent sensor elements support polarization.

Input Arguments

`H` — Uniform line array

System object

Uniform line array specified as a phased.UCA System object.

Output Arguments

`flag` — Polarization-capability flag

boolean

Polarization-capability flag returned as a boolean value `true` when the array supports polarization or `false` when it does not.

Examples

Show UCA is Polarization Capable

Determine whether a UCA array of short-dipole antenna elements supports polarization.

```
sSD = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[1e9 10e9]);
sUCA = phased.UCA('NumElements',7,'Radius',0.5,'Element',sSD);
isPolarizationCapable(sUCA)
```

```
ans =

  logical

   1
```

The result shows that a UCA of short-dipole antenna elements supports polarization.

Introduced in R2015a

pattern

System object: phased.UCA
Package: phased

Plot UCA array pattern

Syntax

```
pattern(sArray,FREQ)
pattern(sArray,FREQ,AZ)
pattern(sArray,FREQ,AZ,EL)
pattern( ___ ,Name,Value)
[PAT,AZ_ANG,EL_ANG] = pattern( ___ )
```

Description

`pattern(sArray,FREQ)` plots the 3-D array directivity pattern (in dBi) for the array specified in `sArray`. The operating frequency is specified in `FREQ`.

`pattern(sArray,FREQ,AZ)` plots the array directivity pattern at the specified azimuth angle.

`pattern(sArray,FREQ,AZ,EL)` plots the array directivity pattern at specified azimuth and elevation angles.

`pattern( ___ ,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`[PAT,AZ_ANG,EL_ANG] = pattern( ___ )` returns the array pattern in `PAT`. The `AZ_ANG` output contains the coordinate values corresponding to the rows of `PAT`. The `EL_ANG` output contains the coordinate values corresponding to the columns of `PAT`. If the `'CoordinateSystem'` parameter is set to `'uv'`, then `AZ_ANG` contains the *U* coordinates of the pattern and `EL_ANG` contains the *V* coordinates of the pattern. Otherwise, they are in angular units in degrees. *UV* units are dimensionless.

Input Arguments

sArray — Uniform circular array

System object

Uniform circular array, specified as a phased.UCA System object.

Example: `sArray= phased.UCA;`

FREQ — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

AZ — Azimuth angles

`[-180:180]` (default) | 1-by-*M* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a 1-by-*M* real-valued row vector where *M* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, this angle is positive.

Example: `[-45:2:45]`

Data Types: `double`

`EL` — Elevation angles

`[-90:90]` (default) | 1-by-*N* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a 1-by-*N* real-valued row vector where *N* is the number of desired elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and *xy*-plane. When measured towards the *z*-axis, this angle is positive.

Example: `[-75:1:70]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'CoordinateSystem'` — Plotting coordinate system

`'polar'` (default) | `'rectangular'` | `'uv'`

Plotting coordinate system of the pattern, specified as the comma-separated pair consisting of `'CoordinateSystem'` and one of `'polar'`, `'rectangular'`, or `'uv'`. When `'CoordinateSystem'` is set to `'polar'` or `'rectangular'`, the `AZ` and `EL` arguments specify the pattern azimuth and elevation, respectively. `AZ` values must lie between –180° and 180°. `EL` values must lie between –90° and 90°. If `'CoordinateSystem'` is set to `'uv'`, `AZ` and `EL` then specify *U* and *V* coordinates, respectively. `AZ` and `EL` must lie between -1 and 1.

Example: `'uv'`

Data Types: `char`

`'Type'` — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

`'Normalize'` — Display normalize pattern

`true` (default) | `false`

Display normalized pattern, specified as the comma-separated pair consisting of `'Normalize'` and a Boolean. Set this parameter to `true` to display a normalized pattern. When you set `'Type'` to `'directivity'`, this parameter does not apply. Directivity patterns are already normalized.

Example:

Data Types: `logical`

`'PlotStyle'` — Plotting style

`'overlay'` (default) | `'waterfall'`

Plotting style, specified as the comma-separated pair consisting of `'Plotstyle'` and either `'overlay'` or `'waterfall'`. This parameter applies when you specify multiple frequencies in `FREQ` in 2-D plots. You can draw 2-D plots by setting one of the arguments `AZ` or `EL` to a scalar.

Example:

Data Types: `char`

`'Polarization'` — Polarized field component

`'combined'` (default) | `'H'` | `'V'`

Polarized field component to display, specified as the comma-separated pair consisting of 'Polarization' and `'combined'`, `'H'`, or `'V'`. This parameter applies only when the sensors are polarization-capable and when the `'Type'` parameter is not set to `'directivity'`. This table shows the meaning of the display options

'Polarization'	Display
'combined'	Combined *H* and *V* polarization components
'H'	*H* polarization component
'V'	*V* polarization component

Example: 'V'

Data Types: char

'PropagationSpeed' — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of 'PropagationSpeed' and a positive scalar in meters per second.

Example: 'PropagationSpeed',physconst('LightSpeed')

Data Types: double

'Weights' — Array weights

1 (default) | *N*-by-1 complex-valued column vector | *N*-by-*L* complex-valued matrix

Array weights, specified as the comma-separated pair consisting of 'Weights' and an *N*-by-1 complex-valued column vector or *N*-by-*L* complex-valued matrix. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *N* is the number of elements in the array. The dimension *L* is the number of frequencies specified by FREQ.

Weights Dimension	FREQ Dimension	Purpose
N-by-1 complex-valued column vector	Scalar or 1-by-*L* row vector	Applies a set of weights for the single frequency or for all *L* frequencies.
N-by-*L* complex-valued matrix	1-by-*L* row vector	Applies each of the *L* columns of 'Weights' for the corresponding frequency in FREQ.

Note: Use complex weights to steer the array response toward different directions. You can create weights using the phased.SteeringVector System object or you can compute

your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as phased.Radiator or phased.Collector. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(N,M)`

Data Types: `double`
Complex Number Support: Yes

Output Arguments

PAT — Array pattern

M-by-*N* real-valued matrix

Array pattern, returned as an *M*-by-*N* real-valued matrix. The dimensions of PAT correspond to the dimensions of the output arguments AZ_ANG and EL_ANG.

AZ_ANG — Azimuth angles

scalar | 1-by-*M* real-valued row vector

Azimuth angles for displaying directivity or response pattern, returned as a scalar or 1-by-*M* real-valued row vector corresponding to the dimension set in AZ. The rows of PAT correspond to the values in AZ_ANG.

EL_ANG — Elevation angles

scalar | 1-by-*N* real-valued row vector

Elevation angles for displaying directivity or response, returned as a scalar or 1-by-*N* real-valued row vector corresponding to the dimension set in EL. The columns of PAT correspond to the values in EL_ANG.

Examples

Pattern of 11-Element UCA Antenna Array

Create an 11-element UCA of radius 1.5 meters. Show the azimuth and elevation directivities.

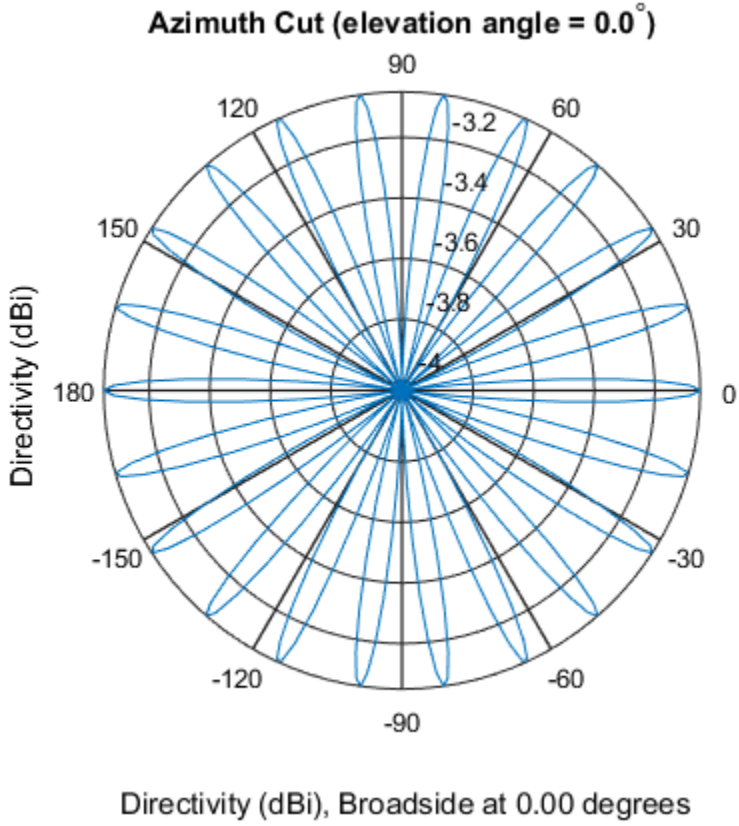
Evaluate the fields at 45 degrees azimuth and 0 degrees elevation.

```
sSD = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[50e6,1000e6],...
    'AxisDirection','Z');
sUCA = phased.UCA('NumElements',11,'Radius',1.5,'Element',sSD);
fc = 500e6;
ang = [45;0];
resp = step(sUCA,fc,ang);
disp(resp.V)
```

```
   -1.2247
   -1.2247
   -1.2247
   -1.2247
   -1.2247
   -1.2247
   -1.2247
   -1.2247
   -1.2247
   -1.2247
   -1.2247
```

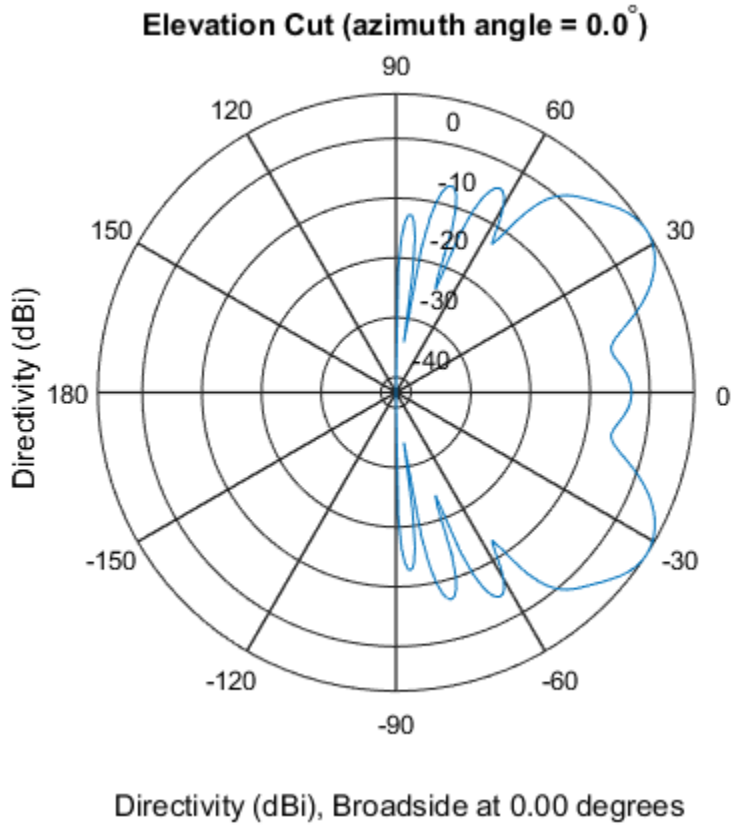
Display the azimuth directivity pattern at 500 MHz for azimuth angles between -180 and 180 degrees.

```
c = physconst('LightSpeed');
pattern(sUCA,fc,[-180:180],0,'Type','directivity','PropagationSpeed',c)
```



Display the elevation directivity pattern at 500 MHz for elevation angles between -90 and 90 degrees.

```
pattern(sUCA,fc,[0],[-90:90],'Type','directivity','PropagationSpeed',c)
```

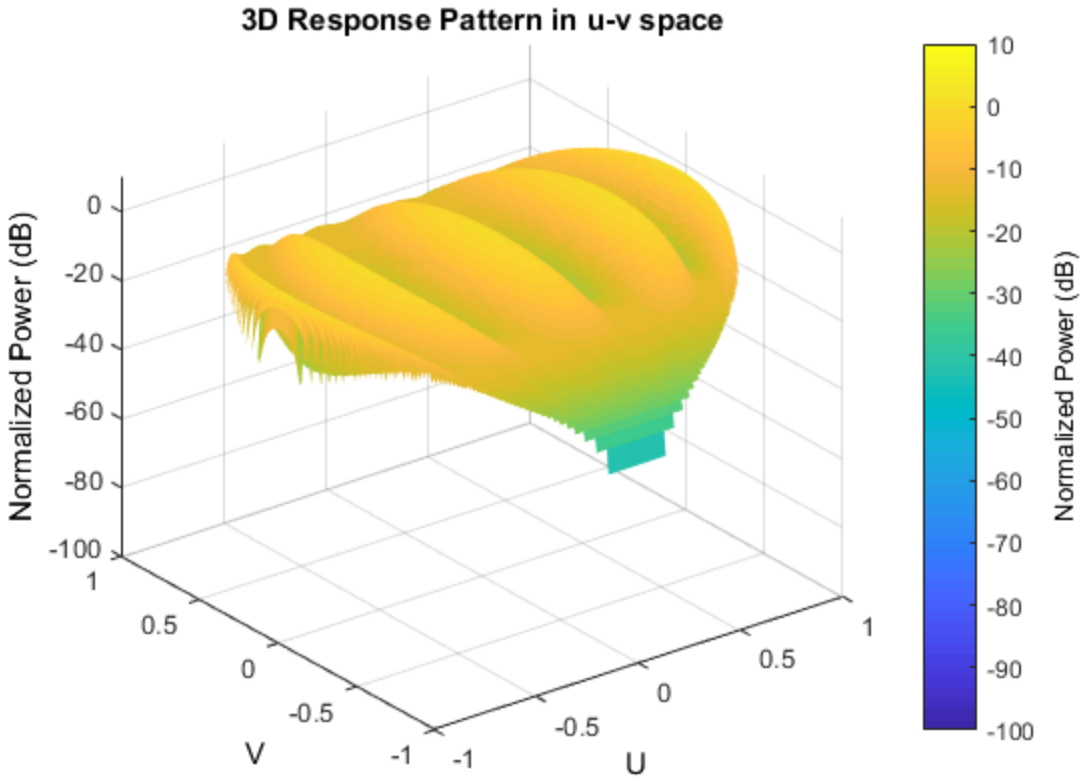


Pattern of 10-Element UCA Antenna Array in UV Space

Create a 10-element UCA antenna array consisting of cosine antenna elements. Display the 3-D power pattern in UV space.

```
sCos = phased.CosineAntennaElement('FrequencyRange',[100e6 1e9],...
    'CosinePower',[2.5,2.5]);
sUCA = phased.UCA('NumElements',10,...
    'Radius',1.5,...
    'Element',sCos);
c = physconst('LightSpeed');
fc = 500e6;
pattern(sUCA,fc,[-1:.01:1],[-1:.01:1],...
    'CoordinateSystem','uv',...
```

```
'Type','powerdb',...
'PropagationSpeed',c)
```



More About

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant

intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element directivity” and “Array directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

phased.UCA.patternAzimuth | phased.UCA.patternElevation

Introduced in R2015a

patternAzimuth

System object: phased.UCA
Package: phased

Plot UCA array directivity or pattern versus azimuth

Syntax

```
patternAzimuth(sArray,FREQ)
patternAzimuth(sArray,FREQ,EL)
patternAzimuth(sArray,FREQ,EL,Name,Value)
PAT = patternAzimuth( ___ )
```

Description

`patternAzimuth(sArray,FREQ)` plots the 2-D array directivity pattern versus azimuth (in dBi) for the array `sArray` at zero degrees elevation angle. The argument `FREQ` specifies the operating frequency.

`patternAzimuth(sArray,FREQ,EL)`, in addtion, plots the 2-D array directivity pattern versus azimuth (in dBi) for the array `sArray` at the elevation angle specified by `EL`. When `EL` is a vector, multiple overlaid plots are created.

`patternAzimuth(sArray,FREQ,EL,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternAzimuth( ___ )` returns the array pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Azimuth'` parameter and the `EL` input argument.

Input Arguments

`sArray` — Uniform circular array

System object

Uniform circular array, specified as a phased.UCA System object.

Example: `sArray= phased.UCA;`

`FREQ` — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

`EL` — Elevation angles

1-by-*N* real-valued row vector

Elevation angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector. The quantity *N* is the number of requested elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and the *xy* plane. When measured toward the *z*-axis, this angle is positive.

Example: `[0,10,20]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Type'` — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

`'PropagationSpeed'` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

`'Weights'` — Array weights

M-by-1 complex-valued column vector

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *M*-by-1 complex-valued column vector. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *M* is the number of elements in the array.

Note: Use complex weights to steer the array response toward different directions. You can create weights using the phased.SteeringVector System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as phased.Radiator or phased.Collector. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(10,1)`

Data Types: `double`
Complex Number Support: Yes

`'Azimuth'` — Azimuth angles

`[-180:180]` (default) | 1-by-*P* real-valued row vector

Azimuth angles, specified as the comma-separated pair consisting of `'Azimuth'` and a 1-by-*P* real-valued row vector. Azimuth angles define where the array pattern is calculated.

Example: `'Azimuth',[-90:2:90]`

Data Types: `double`

Output Arguments

`PAT` — Array directivity or pattern

L-by-*N* real-valued matrix

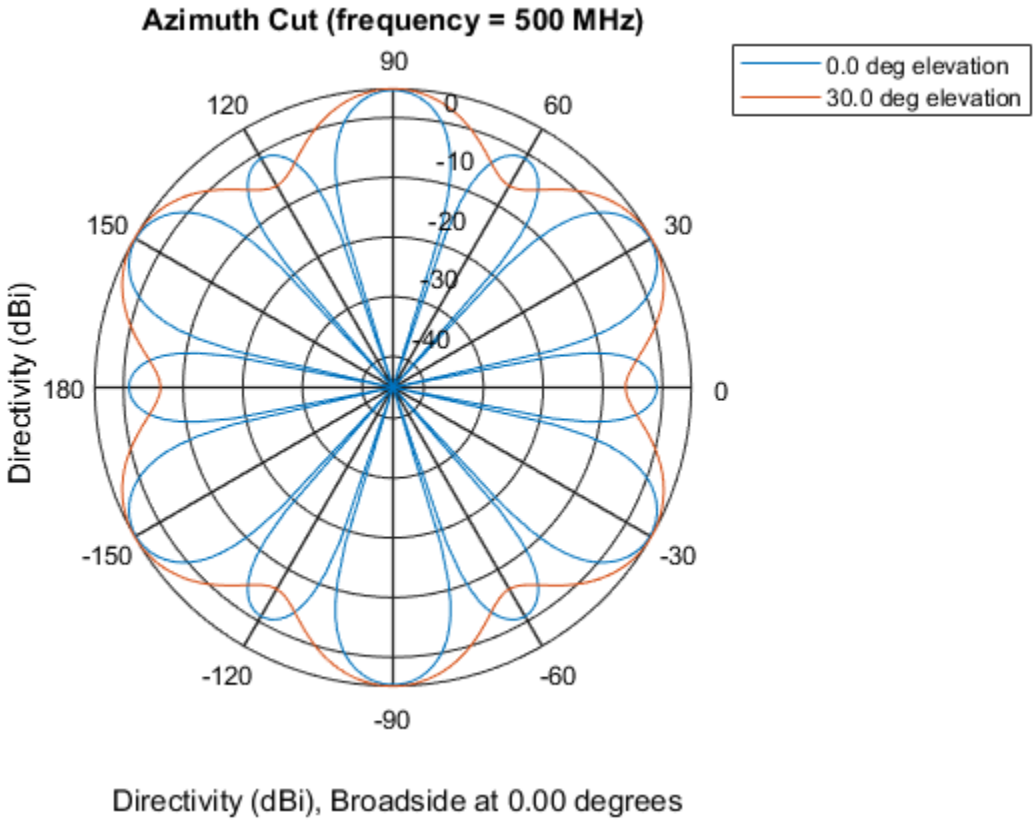
Array directivity or pattern, returned as an *L*-by-*N* rea-valued matrix. The dimension *L* is the number of azimuth values determined by the `'Azimuth'` name-value pair argument. The dimension *N* is the number of elevation angles, as determined by the `EL` input argument.

Examples

Plot Azimuth Pattern of UCA

Create a 6-element UCA of short-dipole antenna elements. Design the array to have a radius of 0.5 meters. Plot an azimuth cut of directivity at 0 and 10 degrees elevation. Assume the operating frequency is 500 MHz.

```
fc = 500e6;
sCDant = phased.ShortDipoleAntennaElement('FrequencyRange',[100,900]*1e6);
sUCA = phased.UCA('NumElements',6,'Radius',0.5,'Element',sCDant);
patternAzimuth(sUCA,fc,[0 30])
```



You can plot a smaller range of azimuth angles by setting the `Azimuth` property.

```
patternAzimuth(sUCA,fc,[0 30],'Azimuth',[-90:90])
```

phased.UCA.pattern | phased.UCA.patternElevation

Introduced in R2015a

patternElevation

System object: phased.UCA
Package: phased

Plot UCA array directivity or pattern versus elevation

Syntax

```
patternElevation(sArray,FREQ)
patternElevation(sArray,FREQ,AZ)
patternElevation(sArray,FREQ,AZ,Name,Value)
PAT = patternElevation( ___ )
```

Description

`patternElevation(sArray,FREQ)` plots the 2-D array directivity pattern versus elevation (in dBi) for the array `sArray` at zero degrees azimuth angle. When `AZ` is a vector, multiple overlaid plots are created. The argument `FREQ` specifies the operating frequency.

`patternElevation(sArray,FREQ,AZ)`, in addition, plots the 2-D element directivity pattern versus elevation (in dBi) at the azimuth angle specified by `AZ`. When `AZ` is a vector, multiple overlaid plots are created.

`patternElevation(sArray,FREQ,AZ,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternElevation( ___ )` returns the array pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Elevation'` parameter and the `AZ` input argument.

Input Arguments

`sArray` — Uniform circular array

System object

Uniform circular array, specified as a phased.UCA System object.

Example: `sArray= phased.UCA;`

FREQ — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

AZ — Azimuth angles for computing directivity and pattern

1-by-*N* real-valued row vector

Azimuth angles for computing sensor or array directivities and patterns, specified as a 1-by-*M* real-valued row vector where *N* is the number of desired azimuth directions. Angle units are in degrees. The azimuth angle must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `[0,10,20]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'Type' — Displayed pattern type

'directivity' (default) | 'efield' | 'power' | 'powerdb'

Displayed pattern type, specified as the comma-separated pair consisting of 'Type' and one of

- 'directivity' — directivity pattern measured in dBi.
- 'efield' — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- 'power' — power pattern of the sensor or array defined as the square of the field pattern.
- 'powerdb' — power pattern converted to dB.

Example: 'powerdb'

Data Types: char

'PropagationSpeed' — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of 'PropagationSpeed' and a positive scalar in meters per second.

Example: 'PropagationSpeed',physconst('LightSpeed')

Data Types: double

'Weights' — Array weights

M-by-1 complex-valued column vector

Array weights, specified as the comma-separated pair consisting of 'Weights' and an *M*-by-1 complex-valued column vector. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *M* is the number of elements in the array.

Note: Use complex weights to steer the array response toward different directions. You can create weights using the phased.SteeringVector System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as phased.Radiator or phased.Collector. However, for the directivity, pattern, patternAzimuth, and patternElevation methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(10,1)`

Data Types: `double`
Complex Number Support: Yes

`'Elevation'` — Elevation angles

`[-90:90]` (default) | 1-by-*P* real-valued row vector

Elevation angles, specified as the comma-separated pair consisting of `'Elevation'` and a 1-by-*P* real-valued row vector. Elevation angles define where the array pattern is calculated.

Example: `'Elevation',[-90:2:90]`

Data Types: `double`

Output Arguments

PAT — Array directivity or pattern

L-by-*N* real-valued matrix

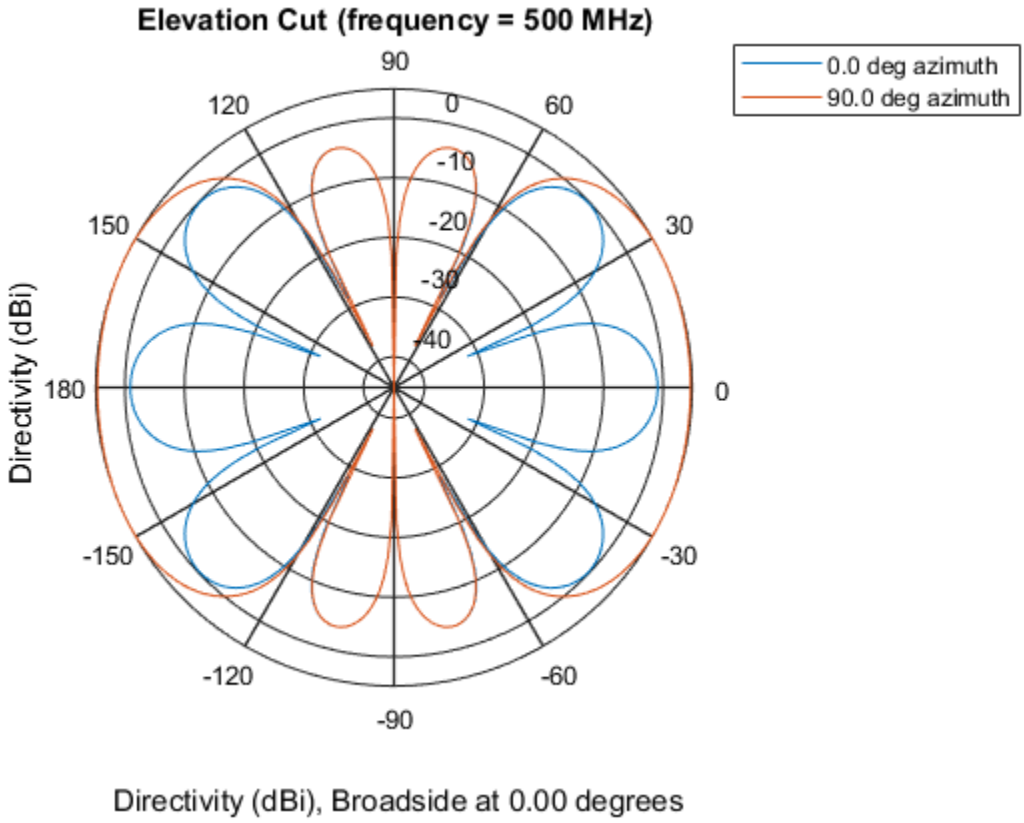
Array directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of elevation angles determined by the `'Elevation'` name-value pair argument. The dimension *N* is the number of azimuth angles determined by the AZ argument.

Examples

Plot Elevation Pattern of UCA

Create a 6-element UCA of short-dipole antenna elements. Design the array to have a radius of 0.5 meters. Plot an elevation cut of directivity at 0 and 90 degrees azimuth. Assume the operating frequency is 500 MHz.

```
fc = 500e6;
sCDant = phased.ShortDipoleAntennaElement('FrequencyRange',[100,900]*1e6);
sUCA = phased.UCA('NumElements',6,'Radius',0.5,'Element',sCDant);
patternElevation(sUCA,fc,[0 90])
```



You can plot a smaller range of elevation angles by setting the `Elevation` property.

```
patternElevation(sUCA,fc,[0 45],'Elevation',[0:90])
```

phased.UCA.pattern | phased.UCA.patternAzimuth

Introduced in R2015a

step

System object: phased.UCA
Package: phased

Output responses of array elements

Syntax

```
RESP = step(sArray,FREQ,ANG)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`RESP = step(sArray,FREQ,ANG)` returns the responses, `RESP`, of the array elements, at operating frequencies specified in `FREQ` and directions specified in `ANG`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`sArray` — Uniform circular array

System object

Uniform circular array, specified as a phased.UCA System object.

Example: `sArray= phased.UCA;`

FREQ — Operating frequency

positive scalar | 1-by-*L* real-valued row vector

Operating frequency of array specified, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For antenna or microphone elements, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the array response is returned as zero. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as zero.

Example: `[1e8 2e8]`

Data Types: `double`

ANG — Response directions

1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Response directions, specified as either a 2-by-*M* real-valued matrix or a real-valued row vector of length *M*.

If `ANG` is a 2-by-*M* matrix, each column of the matrix specifies the direction in the form `[azimuth; elevation]`. The azimuth angle must lie between –180° and 180°, inclusive. The elevation angle must lie between –90° and 90°, inclusive. Angle units are in degrees.

If `ANG` is a row vector of length *M*, each element specifies the azimuth angle of the direction. In this case, the corresponding elevation angle is assumed to be 0°.

Example: `[20;15]`

Data Types: `double`

Output Arguments

`RESP` — Voltage responses of phased array

complex-valued *N*-by-*M*-by-*L* matrix | complex-valued structure

Voltage responses of a phased array, specified as a complex-valued matrix or a `struct` with complex-valued fields. The output depends on whether the array supports polarization or not.

- If the array elements do not support polarization, the voltage response, `RESP`, has the dimensions *N*-by-*M*-by-*L*.

  - *N* (rows) is the number of elements in the array
  - *M* (columns) is the number of angles specified in `ANG`
  - *L* (pages) is the number of frequencies specified in `FREQ`

  For each array element, the columns of `RESP` contain the array element responses for the corresponding direction specified in `ANG`. Each of the *L* pages of `RESP` contains the array element responses for the corresponding frequency specified in `FREQ`.

- If the array supports polarization, `RESP` is a MATLAB `struct` containing two fields, `RESP.H` and `RESP.V`. The field, `RESP.H`, represents the array's horizontal polarization response, while `RESP.V` represents the array's vertical polarization response. Each field has the dimensions *N*-by-*M*-by-*L*.

  - *N* (rows) is the number of elements in the array
  - *M* (columns) is the number of angles specified in `ANG`
  - *L* (pages) is the number of frequencies specified in `FREQ`

  For each array element, the columns of `RESP.H` or `RESP.V` contain the array element responses for the corresponding direction specified in `ANG`. Each of the *L* pages of `RESP.H` or `RESP.V` contains the array element responses for the corresponding frequency specified in `FREQ`.

Examples

Response of UCA Array

Create a 5-element uniform circular array (UCA) of cosine antenna elements having a 0.5 meter radius. Find the element responses at the 0 degrees azimuth and elevation at a 300 MHz operating frequency.

```
c = physconst('LightSpeed');
fc = 300e6;
sCos = phased.CosineAntennaElement('CosinePower',[1,1]);
sArray = phased.UCA('Element',sCos,'NumElements',5,'Radius',0.5);
ang = [0;0];
resp = step(sArray,fc,ang)
```

```
resp =

         0
    0.3090
    1.0000
    0.3090
         0
```

Introduced in R2015a

viewArray

System object: phased.UCA
Package: phased

View array geometry

Syntax

```
viewArray(H)
viewArray(H,Name,Value)
hPlot = viewArray( ___ )
```

Description

`viewArray(H)` plots the geometry of the array specified in `H`.

`viewArray(H,Name,Value)` plots the geometry of the array, with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = viewArray( ___ )` returns the handle of the array elements in the figure window. All input arguments described for the previous syntaxes also apply here.

Input Arguments

`H` — Uniform circular array

System object

Uniform circular array specified as a phased.UCA System object.

Example: `phased.UCA()`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'ShowIndex'` — Element indices to show
`'None'` (default) | vector of positive integers | `'All'`

Element indices to show in the figure, specified as the comma-separated pair consisting of `'ShowIndex'` and a vector of positive integers. Each number in the vector must be an integer between 1 and the number of elements. To show all of indices of the array, specify `'All'`. To suppress all indices, specify `'None'`.

Example: `[1,2,3]`

Data Types: `double`

`'ShowNormals'` — Option to show normal vectors
`false` (default) | `true`

Option to show normal directions, specified as the comma-separated pair consisting of `'ShowNormals'` and a Boolean value.

- `true` — show the normal directions of all elements in the array
- `false` — plot the elements without showing normal directions

Example: `false`

Data Types: `logical`

`'ShowTaper'` — Option to show taper magnitude
`false` (default) | `true`

Option to show taper magnitude, specified as the comma-separated pair consisting of `'ShowTaper'` and a Boolean value.

- `true` — change the element color brightness in proportion to the element taper magnitude
- `false` — plot all elements using the same color

Example: `true`

Data Types: `logical`

`'Title'` — Plot title
`'Array Geometry'` (default) | character vector

Plot title, specified as a character vector.

Example: `'My array plot'`

Output Arguments

`hPlot` — Handle of array elements

scalar

Handle of array elements in the figure window, specified as a scalar.

Examples

View UCA Array

Construct an 7-element UCA of isotropic antenna elements with a Taylor window taper. Design the array to have a radius of 0.5 meters. Then, draw the array showing the element normals, element indices, and element taper shading.

```
Nelem = 7;
R = 0.5;
taper = taylorwin(Nelem);
sArray = phased.UCA(Nelem,R,'Taper',taper.');
w = getTaper(sArray);
viewArray(sArray,'ShowNormals',true,'ShowIndex','All','ShowTaper',true);
```

phased.ArrayResponse

Topics

Phased Array Gallery

Introduced in R2015a

phased.ULA System object

Package: phased

Uniform linear array

Description

The `phased.ULA` System object creates a uniform linear array (ULA).

To compute the response for each element in the array for specified directions:

1. Define and set up your uniform linear array. See "Construction" on page 1-2096.
2. Call step to compute the response according to the properties of `phased.ULA`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.ULA` creates a uniform linear array (ULA) System object, `H`. The object models a ULA formed with identical sensor elements. The origin of the local coordinate system is the phase center of the array. The positive *x*-axis is the direction normal to the array, and the elements of the array are located along the *y*-axis.

`H = phased.ULA(Name,Value)` creates object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

`H = phased.ULA(N,D,Name,Value)` creates a ULA object, `H`, with the `NumElements` property set to `N`, the `ElementSpacing` property set to `D`, and other specified property Names set to the specified Values. `N` and `D` are value-only arguments. When specifying a

value-only argument, specify all preceding value-only arguments. You can specify name-value pair arguments in any order.

Properties

`Element`

Element of array

Specify the element of the sensor array as a handle. The element must be an element object in the `phased` package.

Default: Isotropic antenna element with default array properties

`NumElements`

Number of elements

An integer containing the number of elements in the array.

Default: `2`

`ElementSpacing`

Element spacing

A scalar containing the spacing (in meters) between two adjacent elements in the array.

Default: `0.5`

`ArrayAxis`

Array axis

Array axis, specified as one of `'x'`, `'y'`, or `'z'`. ULA array elements are located along the selected coordinate system axis.

Element normal vectors are determined by the selected array axis

ArrayAxis Property Value	Element Normal Direction
`'x'`	azimuth = 90°, elevation = 0° (*y*-axis)

ArrayAxis Property Value	Element Normal Direction
`'y'`	azimuth = 0°, elevation = 0° (*x*-axis)
`'z'`	azimuth = 0°, elevation = 0° (*x*-axis)

Default: `'y'`

`Taper`

Element tapering

Element tapering or weighting, specified as a complex-valued scalar, 1-by-*N* row vector, or *N*-by-1 column vector. In this vector, *N* represents the number of elements of the array. Tapers, also known as weights, are applied to each sensor element in the sensor array and modify both the amplitude and phase of the received data. If `'Taper'` is a scalar, the same taper value is applied to all elements. If `'Taper'` is a vector, each taper value is applied to the corresponding sensor element.

Default: `1`

Methods

directivity	Directivity of uniform linear array
collectPlaneWave	Simulate received plane waves
getElementPosition	Positions of array elements
getElementNormal	Normal vector to array elements
getNumElements	Number of elements in array
getTaper	Array element tapers
isPolarizationCapable	Polarization capability
plotResponse	Plot response pattern of array
pattern	Plot array pattern
patternAzimuth	Plot ULA array directivity or pattern versus azimuth
patternElevation	Plot ULA array directivity or pattern versus elevation

plotGratingLobeDiagram	Plot grating lobe diagram of array
step	Output responses of array elements
viewArray	View array geometry

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Plot Pattern of 4-Element Antenna Array

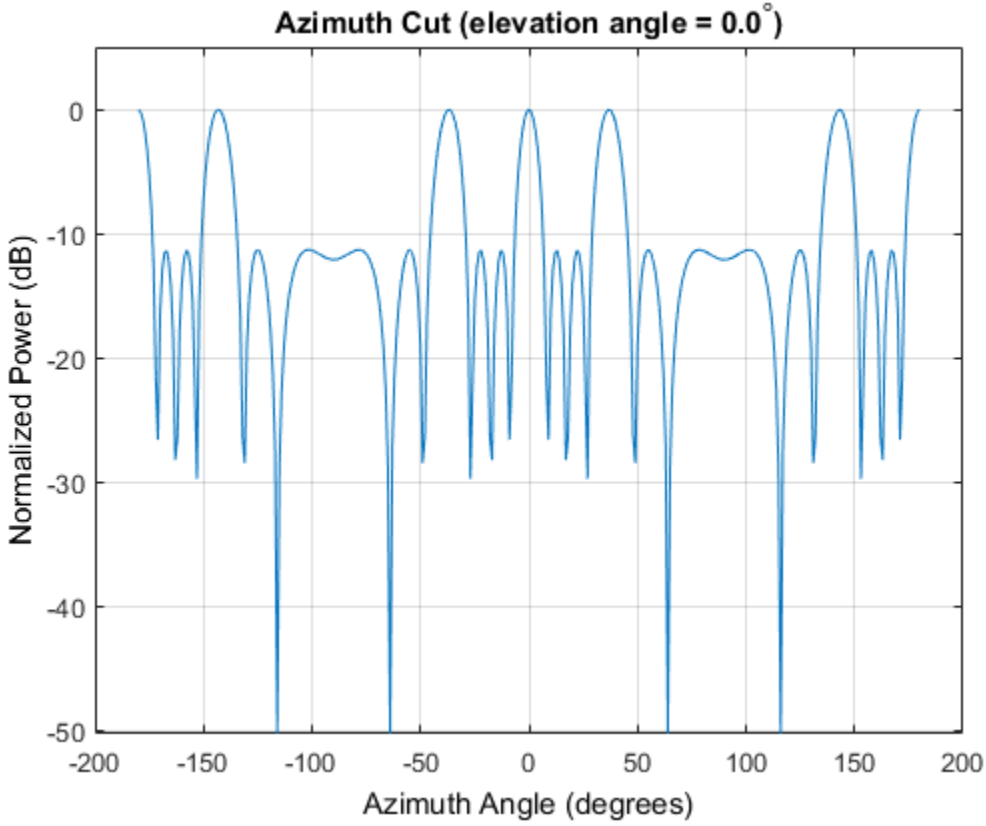
Create a 4-element undersampled ULA and find the response of each element at boresight. Plot the array pattern at 1 GHz for azimuth angles between -180 and 180 degrees. The default element spacing is 0.5 meters.

```
sULA = phased.ULA('NumElements',4);
fc = 1e9;
ang = [0;0];
resp = step(sULA,fc,ang)
```

```
resp =

     1
     1
     1
     1
```

```
c = physconst('LightSpeed');
pattern(sULA,fc,[-180:180],0,'PropagationSpeed',c,...
    'CoordinateSystem','rectangular',...
    'Type','powerdb','Normalize',true)
```

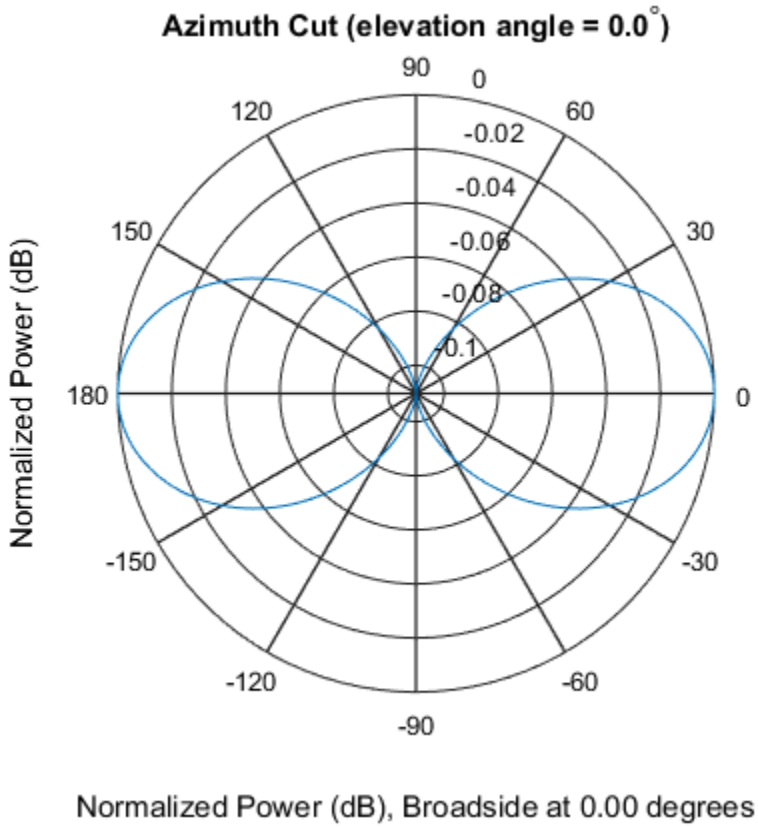


Plot Pattern of 10-Element Microphone ULA

Construct a 10-element uniform linear array of omnidirectional microphones spaced 3 cm apart. Then, plot the array pattern at 100 Hz.

```
sMic = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[20 20e3]);
Nele = 10;
sULA = phased.ULA('NumElements',Nele,...
    'ElementSpacing',3e-2,...
    'Element',sMic);
fc = 100;
ang = [0; 0];
resp = step(sULA,fc,ang);
```

```
c = 340;
pattern(sULA,fc,[-180:180],0,'PropagationSpeed',c,...
    'CoordinateSystem','polar',...
    'Type','powerdb',...
    'Normalize',true);
```



Plot Pattern of Array of Polarized Short-Dipole Antennas

Build a tapered uniform line array of 5 short-dipole sensor elements. Because short dipoles support polarization, the array should as well. Verify that it supports polarization by looking at the output of the `isPolarizationCapable` method.

```
sSD = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[100e6 1e9],'AxisDirection','Z');
```

```
sULA = phased.ULA('NumElements',5,'Element',sSD,...
    'Taper',[.5,.7,1,.7,.5]);
isPolarizationCapable(sULA)
```

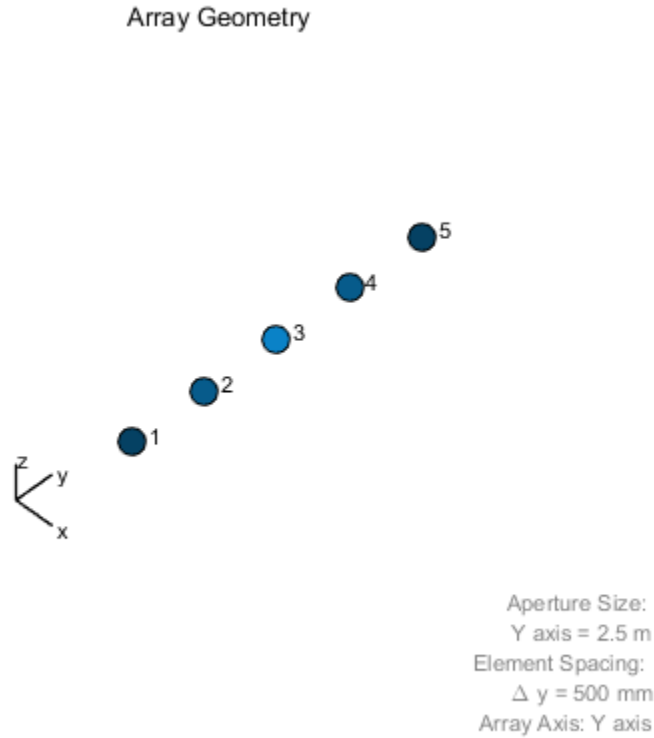
```
ans =

  logical

   1
```

Then, draw the array using the `viewArray` method.

```
viewArray(sULA,'ShowTaper',true,'ShowIndex','All')
```



Compute the horizontal and vertical responses.

```
fc = 150e6;
ang = [10];
resp = step(sULA,fc,ang);
```

Display the horizontal polarization response.

```
resp.H
```

```
ans =

     0
     0
     0
     0
     0
```

Display the vertical polarization response.

```
resp.V
```

```
ans =

   -0.6124
   -0.8573
   -1.2247
   -0.8573
   -0.6124
```

Plot an azimuth cut of the vertical polarization response.

```
c = physconst('LightSpeed');
pattern(sULA,fc,[-180:180],0,...
    'PropagationSpeed',c,...
    'CoordinateSystem','polar',...
    'Polarization','V',...
    'Type','powerdb',...
    'Normalize',true)
```

Introduced in R2012a

directivity

System object: phased.ULA
Package: phased

Directivity of uniform linear array

Syntax

```
D = directivity(H,FREQ,ANGLE)
D = directivity(H,FREQ,ANGLE,Name,Value)
```

Description

`D = directivity(H,FREQ,ANGLE)` computes the "Directivity (dBi)" on page 1-2111 of a uniform linear array (ULA) of antenna or microphone elements, `H`, at frequencies specified by `FREQ` and in angles of direction specified by `ANGLE`.

`D = directivity(H,FREQ,ANGLE,Name,Value)` returns the directivity with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`H` — Uniform linear array

System object

Uniform linear array specified as a phased.ULA System object.

Example: `H = phased.ULA;`

`FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-L real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-L real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

`ANGLE` — Angles for computing directivity

1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Angles for computing directivity, specified as a 1-by-*M* real-valued row vector or a 2-by-*M* real-valued matrix, where *M* is the number of angular directions. Angle units are in degrees. If `ANGLE` is a 2-by-*M* matrix, then each column specifies a direction in azimuth and elevation, `[az;el]`. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°.

If `ANGLE` is a 1-by-*M* vector, then each entry represents an azimuth angle, with the elevation angle assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis.

Example: `[45 60; 0 10]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'PropagationSpeed' — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of 'PropagationSpeed' and a positive scalar in meters per second.

Example: 'PropagationSpeed',physconst('LightSpeed')

Data Types: double

'Weights' — Array weights

1 (default) | *N*-by-1 complex-valued column vector | *N*-by-*L* complex-valued matrix

Array weights, specified as the comma-separated pair consisting of 'Weights' and an *N*-by-1 complex-valued column vector or *N*-by-*L* complex-valued matrix. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *N* is the number of elements in the array. The dimension *L* is the number of frequencies specified by FREQ.

Weights Dimension	FREQ Dimension	Purpose
N-by-1 complex-valued column vector	Scalar or 1-by-*L* row vector	Applies a set of weights for the single frequency or for all *L* frequencies.
N-by-*L* complex-valued matrix	1-by-*L* row vector	Applies each of the *L* columns of 'Weights' for the corresponding frequency in FREQ.

Note: Use complex weights to steer the array response toward different directions. You can create weights using the phased.SteeringVector System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as phased.Radiator or phased.Collector. However, for the directivity, pattern, patternAzimuth, and patternElevation methods of any array System object use the steering vector without conjugation.

Example: 'Weights',ones(N,M)

Data Types: double

Complex Number Support: Yes

Output Arguments

`D` — Directivity

M-by-*L* matrix

Directivity, returned as an *M*-by-*L* matrix whose columns contain the directivities at the *M* angles specified by `ANGLE`. Each column corresponds to one of the *L* frequency values specified in `FREQ`. Directivity units are in dBi.

Examples

Directivity of Uniform Linear Array

Compute the directivities of two different uniform linear arrays (ULA). One array consists of isotropic antenna elements and the second array consists of cosine antenna elements. In addition, compute the directivity when the first array is steered in a specified direction. For each case, calculated the directivities for a set of seven different azimuth directions all at zero degrees elevation. Set the frequency to 800 MHz.

Array of isotropic antenna elements

First, create a 10-element ULA of isotropic antenna elements spaced 1/2-wavelength apart.

```
c = physconst('LightSpeed');
fc = 3e8;
lambda = c/fc;
ang = [-30,-20,-10,0,10,20,30; 0,0,0,0,0,0,0];
myAnt1 = phased.IsotropicAntennaElement;
myArray1 = phased.ULA(10,lambda/2,'Element',myAnt1);
```

Compute the directivity

```
d = directivity(myArray1,fc,ang,'PropagationSpeed',c)
```

```
d =
```

```
   -6.9886
   -6.2283
   -6.5176
   10.0011
   -6.5176
   -6.2283
   -6.9886
```

Array of cosine antenna elements

Next, create a 10-element ULA of cosine antenna elements spaced 1/2-wavelength apart.

```
myAnt2 = phased.CosineAntennaElement('CosinePower',[1.8,1.8]);
myArray2 = phased.ULA(10,lambda/2,'Element',myAnt2);
```

Compute the directivity

```
d = directivity(myArray2,fc,ang,'PropagationSpeed',c)
```

```
d =

   -1.9838
    0.0529
    0.4968
   17.2548
    0.4968
    0.0529
   -1.9838
```

The directivity of the cosine ULA is greater than the directivity of the isotropic ULA because of the larger directivity of the cosine antenna element.

Steered array of isotropic antenna elements

Finally, steer the isotropic antenna array to 30 degrees in azimuth and compute the directivity.

```
w = steervec(getElementPosition(myArray1)/lambda,[30;0]);
d = directivity(myArray1,fc,ang,'PropagationSpeed',c,...
    'Weights',w)
```

```
d =

 -292.9682
  -13.9783
   -9.5713
   -6.9897
   -4.5787
   -2.0536
   10.0000
```

The directivity is greatest in the steered direction.

Definitions

Directivity (dBi)

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element directivity” and “Array directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed

using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

collectPlaneWave

System object: phased.ULA
Package: phased

Simulate received plane waves

Syntax

```
Y = collectPlaneWave(H,X,ANG)
Y = collectPlaneWave(H,X,ANG,FREQ)
Y = collectPlaneWave(H,X,ANG,FREQ,C)
```

Description

`Y = collectPlaneWave(H,X,ANG)` returns the received signals at the sensor array, `H`, when the input signals indicated by `X` arrive at the array from the directions specified in `ANG`.

`Y = collectPlaneWave(H,X,ANG,FREQ)`, in addition, specifies the incoming signal carrier frequency in `FREQ`.

`Y = collectPlaneWave(H,X,ANG,FREQ,C)`, in addition, specifies the signal propagation speed in `C`.

Input Arguments

`H`

Array object.

`X`

Incoming signals, specified as an M-column matrix. Each column of `X` represents an individual incoming signal.

ANG

Directions from which incoming signals arrive, in degrees. ANG can be either a 2-by-M matrix or a row vector of length M.

If ANG is a 2-by-M matrix, each column specifies the direction of arrival of the corresponding signal in X. Each column of ANG is in the form `[azimuth; elevation]`. The azimuth angle must be between –180° and 180°, inclusive. The elevation angle must be between –90° and 90°, inclusive.

If ANG is a row vector of length M, each entry in ANG specifies the azimuth angle. In this case, the corresponding elevation angle is assumed to be 0°.

FREQ

Carrier frequency of signal in hertz. FREQ must be a scalar.

Default: `3e8`

C

Propagation speed of signal in meters per second.

Default: Speed of light

Output Arguments

Y

Received signals. Y is an N-column matrix, where N is the number of elements in the array H. Each column of Y is the received signal at the corresponding array element, with all incoming signals combined.

Examples

Simulate Received Signals at ULA

Simulate two received random signals at a 4-element ULA. The signals arrive from 10° and 30° azimuth. Both signals have an elevation angle of 0°. Assume the propagation speed is the speed of light and the carrier frequency of the signal is 100 MHz.

```
array = phased.ULA(4);
y = collectPlaneWave(array,randn(4,2),[10 30],100e6,physconst('LightSpeed'))
```

```
y =

   0.7430 - 0.3705i   0.8433 - 0.1314i   0.8433 + 0.1314i   0.7430 + 0.3705i
   0.8418 + 0.4308i   0.5632 + 0.1721i   0.5632 - 0.1721i   0.8418 - 0.4308i
  -2.4817 + 0.9157i  -2.6683 + 0.3175i  -2.6683 - 0.3175i  -2.4817 - 0.9157i
   1.0724 - 0.4748i   1.1895 - 0.1671i   1.1895 + 0.1671i   1.0724 + 0.4748i
```

Algorithms

`collectPlaneWave` modulates the input signal with a phase corresponding to the delay caused by the direction of arrival. The method does not account for the response of individual elements in the array.

For further details, see [1].

getElementPosition

System object: phased.ULA
Package: phased

Positions of array elements

Syntax

```
pos = getElementPosition(sULA)
pos = getElementPosition(sULA,elemidx)
```

Description

`pos = getElementPosition(sULA)` returns the element positions of the `phased.ULA` System object, `sULA`. `pos` is a 3-by-*N* matrix, where *N* is the number of elements in `sULA`. Each column of `pos` defines the position of an element in the local coordinate system taking the form `[x;y;z]`. Units are meters. The origin of the local coordinate system is the phase center of the array.

`pos = getElementPosition(sULA,elemidx)` returns only the positions of the elements that are specified in the element index vector `elemidx`. This syntax can use any of the input arguments in the previous syntax.

Examples

ULA Element Positions

Construct a ULA with 5 elements along the z-axis. Obtain the element positions.

```
sULA = phased.ULA('NumElements',5,'ArrayAxis','z');
pos = getElementPosition(sULA)
```

```
pos =

         0         0         0         0         0
```

```
     0         0         0         0         0
-1.0000   -0.5000         0    0.5000    1.0000
```

getElementNormal

System object: phased.ULA
Package: phased

Normal vector to array elements

Syntax

```
normvec = getElementNormal(sULA)
normvec = getElementNormal(sULA,elemidx)
```

Description

`normvec = getElementNormal(sULA)` returns the normal vectors of the array elements of the `phased.ULA` System object, `sULA`. The output argument `normvec` is a 2-by-*N* matrix, where *N* is the number of elements in array, `sULA`. Each column of `normvec` defines the normal direction of an element in the local coordinate system in the form `[az;el]`. Units are degrees. Array elements are located along the axis selected in the `ArrayAxis` property. Element normal vectors are parallel to the array normal. The normal to a ULA array depends upon the selected `ArrayAxis` property.

ArrayAxis Property Value	Array Normal Direction
`'x'`	azimuth = 90°, elevation = 0° (*y*-axis)
`'y'`	azimuth = 0°, elevation = 0° (*x*-axis)
`'z'`	azimuth = 0°, elevation = 0° (*x*-axis)

The origin of the local coordinate system is defined by the phase center of the array.

`normvec = getElementNormal(sULA,elemidx)` returns only the normal vectors of the elements specified in the element index vector, `elemidx`. This syntax can use any of the input arguments in the previous syntax.

Input Arguments

sULA — Uniform line array

`phased.ULA` System object

Uniform line array, specified as a `phased.ULA` System object.

Example: `sULA = phased.ULA`

`elemidx` — Element indices

all array elements (default) | integer-valued 1-by-*M* row vector | integer-valued *M*-by-1 column vector

Element indices , specified as a 1-by-*M* or *M*-by-1 vector. Index values lie in the range 1 to *N* where *N* is the number of elements of the array. When `elemidx` is specified, `getElementNormal` returns the normal vectors of the elements contained in `elemidx`.

Example: `[1,5,4]`

Output Arguments

`normvec` — Element normal vectors

2-by-*P* real-valued vector

Element normal vectors, specified as a 2-by-*P* real-valued vector. Each column of `normvec` takes the form `[az,el]`. When `elemidx` is not specified, *P* equals the array dimension. When `elemidx` is specified, *P* equals the length of `elemidx`, *M*.

Examples

ULA Element Normals

Construct three ULA's with elements along the *x*-, *y*-, and *z*-axes. Obtain the element normals.

First, choose the array axis along the *x*-axis.

```
sULA1 = phased.ULA('NumElements',5,'ArrayAxis','x');
norm = getElementNormal(sULA1)
```

```
norm =

    90    90    90    90    90
     0     0     0     0     0
```

The element normal vectors point along the *y*-axis.

Next, choose the array axis along the *y*-axis.

```
sULA2 = phased.ULA('NumElements',5,'ArrayAxis','y');
norm = getElementNormal(sULA2)
```

```
norm =

     0     0     0     0     0
     0     0     0     0     0
```

The element normal vectors point along the *x*-axis.

Finally, set the array axis along the *z*-axis. Obtain the normal vectors of the odd-numbered elements.

```
sULA3 = phased.ULA('NumElements',5,'ArrayAxis','z');
norm = getElementNormal(sULA3,[1,3,5])
```

```
norm =

     0     0     0
     0     0     0
```

The element normal vectors also point along the *x*-axis.

Introduced in R2016a

getNumElements

System object: phased.ULA
Package: phased

Number of elements in array

Syntax

```
N = getNumElements(H)
```

Description

`N = getNumElements(H)` returns the number of elements, N, in the ULA object `H`.

Examples

Get Number of ULA Elements

Construct a default ULA and obtain the number of elements in that array.

```
array = phased.ULA;
N = getNumElements(array)
```

```
N =

     2
```

getTaper

System object: phased.ULA
Package: phased

Array element tapers

Syntax

```
wts = getTaper(h)
```

Description

`wts = getTaper(h)` returns the tapers, `wts`, applied to each element of the phased uniform line array (ULA), `h`. Tapers are often referred to as weights.

Input Arguments

h — Uniform line array

`phased.ULA` System object

Uniform line array specified as a phased.ULA System object.

Output Arguments

wts — Array element tapers

N-by-1 complex-valued vector

Array element tapers returned as an *N*-by-1 complex-valued vector, where *N* is the number of elements in the array.

Examples

Construct ULA with Taylor Window

Construct a 5-element ULA with a Taylor window taper. Then, obtain the element taper values.

```
taper = taylorwin(5)';
array = phased.ULA(5,'Taper',taper);
w = getTaper(array)
```

```
w =

    0.5181
    1.2029
    1.5581
    1.2029
    0.5181
```

isPolarizationCapable

System object: phased.ULA
Package: phased

Polarization capability

Syntax

```
flag = isPolarizationCapable(h)
```

Description

`flag = isPolarizationCapable(h)` returns a Boolean value, `flag`, indicating whether the array supports polarization. An array supports polarization if all of its constituent sensor elements support polarization.

Input Arguments

h — Uniform line array

Uniform line array specified as a phased.ULA System object.

Output Arguments

flag — Polarization-capability flag

Polarization-capability flag returned as a Boolean value `true` if the array supports polarization or `false` if it does not.

Examples

Short-Dipole Antenna ULA Supports Polarization

Show that an array of `phased.ShortDipoleAntennaElement` antenna elements supports polarization.

```
antenna = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[1e9 10e9]);
array = phased.ULA('NumElements',3,'Element',antenna);
isPolarizationCapable(array)

ans =

  logical

   1
```

The returned value of 1 shows that this array supports polarization.

plotResponse

System object: phased.ULA
Package: phased

Plot response pattern of array

Syntax

```
plotResponse(H,FREQ,V)
plotResponse(H,FREQ,V,Name,Value)
hPlot = plotResponse( ___ )
```

Description

`plotResponse(H,FREQ,V)` plots the array response pattern along the azimuth cut, where the elevation angle is 0. The operating frequency is specified in `FREQ`. The propagation speed is specified in `V`.

`plotResponse(H,FREQ,V,Name,Value)` plots the array response with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = plotResponse( ___ )` returns handles of the lines or surface in the figure window, using any of the input arguments in the previous syntaxes.

Input Arguments

`H`

Array object

`FREQ`

Operating frequency in Hertz specified as a scalar or 1-by-*K* row vector. Values must lie within the range specified by a property of `H`. That property is named `FrequencyRange` or `FrequencyVector`, depending on the type of element in the array. The element has no response at frequencies outside that range. If you set the `'RespCut'` property of `H` to

`'3D'`, `FREQ` must be a scalar. When `FREQ` is a row vector, `plotResponse` draws multiple frequency responses on the same axes.

`V`

Propagation speed in meters per second.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'CutAngle'`

Cut angle as a scalar. This argument is applicable only when `RespCut` is `'Az'` or `'El'`. If `RespCut` is `'Az'`, `CutAngle` must be between –90 and 90. If `RespCut` is `'El'`, `CutAngle` must be between –180 and 180.

Default: `0`

`'Format'`

Format of the plot, using one of `'Line'`, `'Polar'`, or `'UV'`. If you set `Format` to `'UV'`, `FREQ` must be a scalar.

Default: `'Line'`

`'NormalizeResponse'`

Set this value to `true` to normalize the response pattern. Set this value to `false` to plot the response pattern without normalizing it. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

Default: `true`

`'OverlayFreq'`

Set this value to `true` to overlay pattern cuts in a 2-D line plot. Set this value to `false` to plot pattern cuts against frequency in a 3-D waterfall plot. If this value is `false`, `FREQ` must be a vector with at least two entries.

This parameter applies only when `Format` is not `'Polar'` and RespCut is not `'3D'`.

Default: `true`

`'Polarization'`

Specify the polarization options for plotting the array response pattern. The allowable values are `|'None' | 'Combined' | 'H' | 'V' |` where

- `'None'` specifies plotting a nonpolarized response pattern
- `'Combined'` specifies plotting a combined polarization response pattern
- `'H'` specifies plotting the horizontal polarization response pattern
- `'V'` specifies plotting the vertical polarization response pattern

For arrays that do not support polarization, the only allowed value is `'None'`. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

Default: `'None'`

`'RespCut'`

Cut of the response. Valid values depend on `Format`, as follows:

- If `Format` is `'Line'` or `'Polar'`, the valid values of `RespCut` are `'Az'`, `'El'`, and `'3D'`. The default is `'Az'`.
- If `Format` is `'UV'`, the valid values of `RespCut` are `'U'` and `'3D'`. The default is `'U'`.

If you set `RespCut` to `'3D'`, `FREQ` must be a scalar.

`'Unit'`

The unit of the plot. Valid values are `'db'`, `'mag'`, `'pow'`, or `'dbi'`. This parameter determines the type of plot that is produced.

Unit value	Plot type
`db`	power pattern in dB scale
`mag`	field pattern
`pow`	power pattern

Unit value	Plot type
`dbi`	directivity

Default: `'db'`

`'Weights'`

Weight values applied to the array, specified as a length-*N* column vector or *N*-by-*M* matrix. The dimension *N* is the number of elements in the array. The interpretation of *M* depends upon whether the input argument `FREQ` is a scalar or row vector.

Weights Dimensions	FREQ Dimension	Purpose
N-by-1 column vector	Scalar or 1-by-*M* row vector	Apply one set of weights for the same single frequency or all *M* frequencies.
N-by-*M* matrix	Scalar	Apply all of the *M* different columns in `Weights` for the same single frequency.
	1-by-*M* row vector	Apply each of the *M* different columns in `Weights` for the corresponding frequency in `FREQ`.

`'AzimuthAngles'`

Azimuth angles for plotting array response, specified as a row vector. The `AzimuthAngles` parameter sets the display range and resolution of azimuth angles for visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'Az'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of azimuth angles should lie between –180° and 180° and must be in nondecreasing order. When you set the `RespCut` parameter to `'3D'`, you can set the `AzimuthAngles` and `ElevationAngles` parameters simultaneously.

Default: `[-180:180]`

`'ElevationAngles'`

Elevation angles for plotting array response, specified as a row vector. The `ElevationAngles` parameter sets the display range and resolution of elevation

angles for visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'El'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of elevation angles should lie between –90° and 90° and must be in nondecreasing order. When yous set the `RespCut` parameter to `'3D'`, you can set the `ElevationAngles` and `AzimuthAngles` parameters simultaneously.

Default: `[-90:90]`

`'UGrid'`

U coordinate values for plotting array response, specified as a row vector. The `UGrid` parameter sets the display range and resolution of the *U* coordinates for visualizing the radiation pattern in *U*/*V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'U'` or `'3D'`. The values of `UGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set the `UGrid` and `VGrid` parameters simultaneously.

Default: `[-1:0.01:1]`

`'VGrid'`

V coordinate values for plotting array response, specified as a row vector. The `VGrid` parameter sets the display range and resolution of the *V* coordinates for visualizing the radiation pattern in *U*/*V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'3D'`. The values of `VGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set `VGrid` and `UGrid` parameters simultaneously.

Default: `[-1:0.01:1]`

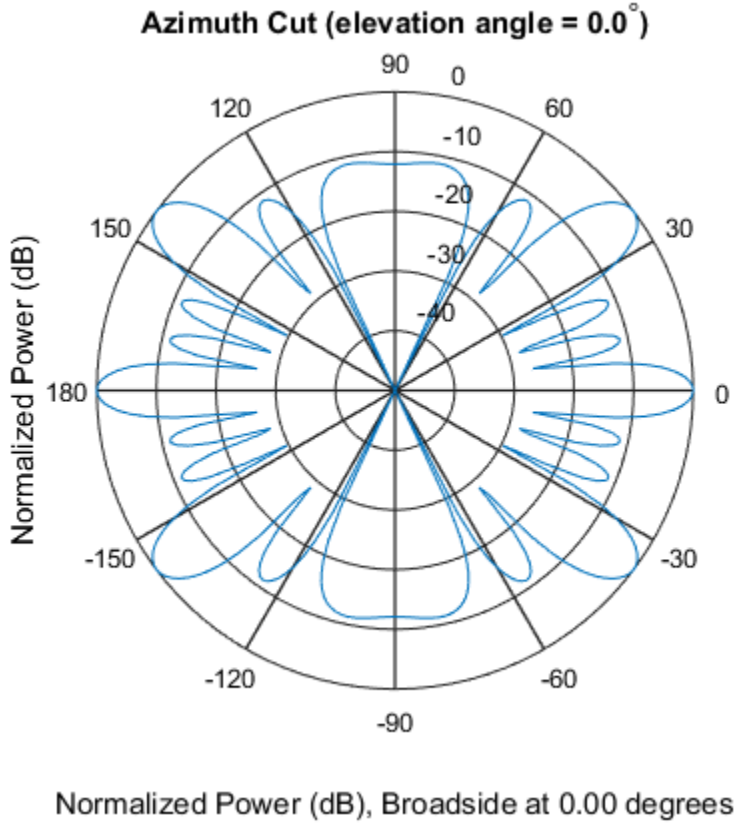
Examples

Plot Azimuth Response of 4-Element ULA

Construct a 4-element ULA of isotropic elements (the default) and plot its azimuth response in polar form. By default, the azimuth cut is at 0 degrees elevation. Assume the operating frequency is 1 GHz and the wave propagation speed is the speed of light. The nominal element spacing is 1/2 meter which means that the array is undersampled at this frequency.

```
ha = phased.ULA(4);
```

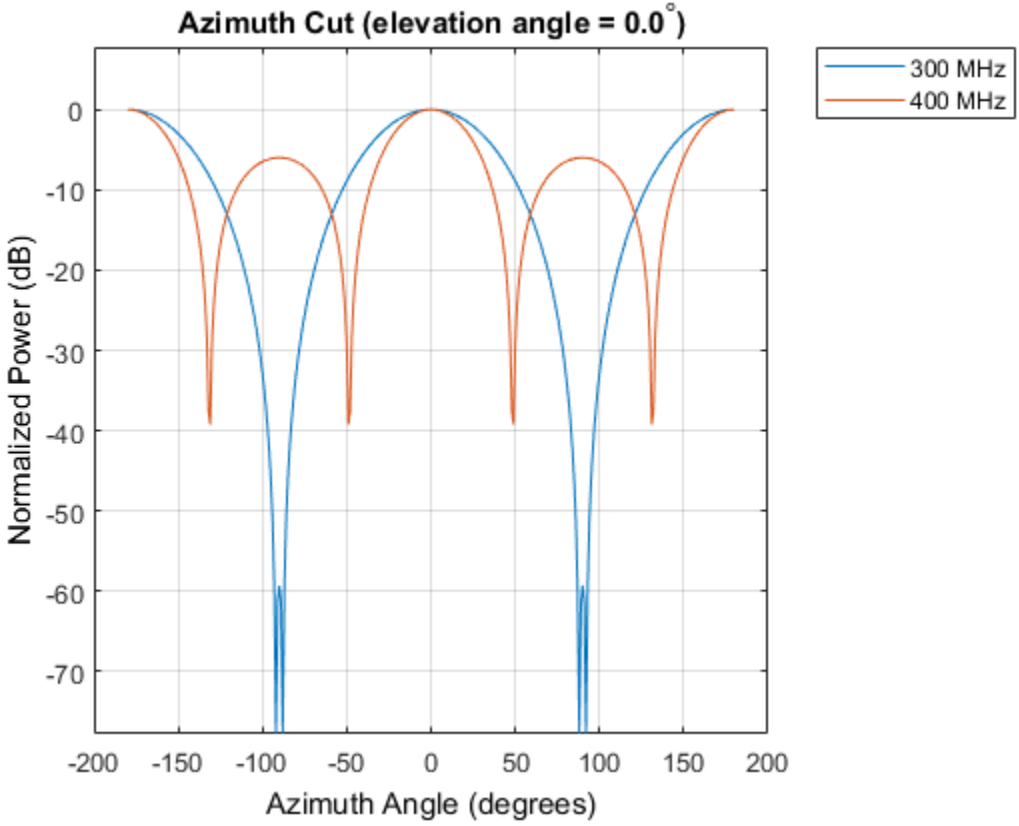
```
fc = 1e9;
c = physconst('LightSpeed');
plotResponse(ha,fc,c,'RespCut','Az','Format','Polar');
```



Plot Response of ULA at Two Frequencies

This example shows how to plot an azimuth cut of the response of a uniform linear array at 0 degrees elevation using a line plot. The plot shows the responses at operating frequencies of 300 MHz and 400 MHz.

```
h = phased.ULA;
fc = [3e8 4e8];
c = physconst('LightSpeed');
plotResponse(h,fc,c);
```

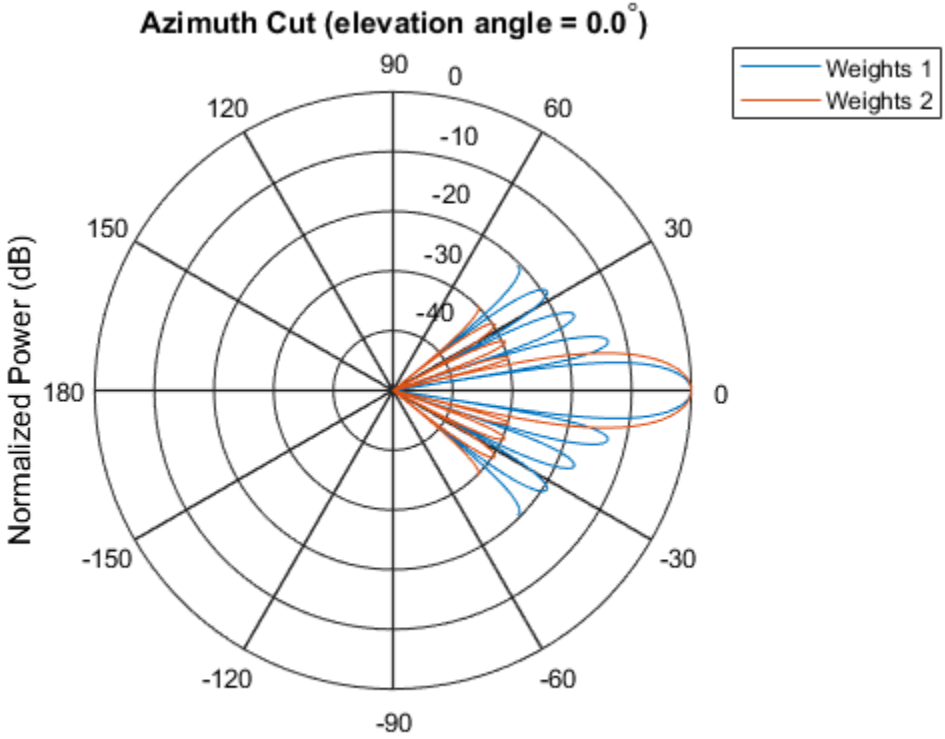


Plot Azimuth Response of Tapered 11-Element ULA

This example shows how to construct an 11-element ULA array of backbaffled omnidirectional microphones for beamforming the direction of arrival of sound in air. The elements are spaced four centimeters apart and have a frequency response lying in the 2000-8000 Hz frequency range. Use the `plotResponse` method to display an azimuth cut of the array's response at 5000 Hz. Use the `'Weights'` parameter to apply both uniform tapering and Taylor window tapering to the array at the same frequency. Finally, use the `'AzimuthAngles'` parameter to limit the display from -45 to 45 degrees in 0.1 degree increments. A typical value for the speed of sound in air is 343 meters/second.

```
s_omni = phased.OmnidirectionalMicrophoneElement(...
```

```
    'FrequencyRange',[2000,8000],...
    'BackBaffled',true);
s_ula = phased.ULA(11,'Element',s_omni,...
    'ElementSpacing',0.04);
c = 343.0;
fc = 5000;
wts = taylorwin(11);
plotResponse(s_ula,fc,c,'RespCut','Az',...
    'Format','Polar',...
    'Weights',[ones(11,1),wts],...
    'AzimuthAngles',[-45:.1:45]);
```



Normalized Power (dB), Broadside at 0.00 degrees

The plot shows that the Taylor tapered set of weights reduces the adjacent sidelobes while broadening the main lobe compared to a uniformly tapered array.

Plot Directivity of 11-Element ULA of Cosine Pattern Antennas

This example shows how to construct an 11-element ULA of cosine antenna elements that are spaced one-half wavelength apart. Then, using the `plotResponse` method, plot an azimuth cut of the array's directivity by setting the `'Unit'` parameter to `'dbi'`. Assume the operating frequency is 1.5 GHz and the wave propagation speed is the speed of light.

```
fc = 1.5e9;
c = physconst('Lightspeed');
lambda = c/fc;
sCos = phased.CosineAntennaElement('FrequencyRange',...
    [1e9 2e9],'CosinePower',[2.5,3.5]);
sULA = phased.ULA(11,0.5*lambda,'Element',sCos);
plotResponse(sULA,fc,c,'RespCut','Az','Unit','dbi');
```

pattern

System object: phased.ULA
Package: phased

Plot array pattern

Syntax

```
pattern(sArray,FREQ)
pattern(sArray,FREQ,AZ)
pattern(sArray,FREQ,AZ,EL)
pattern( ___ ,Name,Value)
[PAT,AZ_ANG,EL_ANG] = pattern( ___ )
```

Description

`pattern(sArray,FREQ)` plots the 3-D array directivity pattern (in dBi) for the array specified in `sArray`. The operating frequency is specified in `FREQ`.

`pattern(sArray,FREQ,AZ)` plots the array directivity pattern at the specified azimuth angle.

`pattern(sArray,FREQ,AZ,EL)` plots the array directivity pattern at specified azimuth and elevation angles.

`pattern( ___ ,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`[PAT,AZ_ANG,EL_ANG] = pattern( ___ )` returns the array pattern in `PAT`. The `AZ_ANG` output contains the coordinate values corresponding to the rows of `PAT`. The `EL_ANG` output contains the coordinate values corresponding to the columns of `PAT`. If the `'CoordinateSystem'` parameter is set to `'uv'`, then `AZ_ANG` contains the *U* coordinates of the pattern and `EL_ANG` contains the *V* coordinates of the pattern. Otherwise, they are in angular units in degrees. *UV* units are dimensionless.

Note: This method replaces the `plotResponse` method. See "Convert plotResponse to pattern" on page 1-2146 for guidelines on how to use `pattern` in place of `plotResponse`.

Input Arguments

`sArray` — Uniform linear array

System object

Uniform linear array, specified as a phased.ULA System object.

Example: `sArray= phased.ULA;`

`FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

`AZ` — Azimuth angles

`[-180:180]` (default) | 1-by-*M* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a 1-by-*M* real-valued row vector where *M* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, this angle is positive.

Example: `[-45:2:45]`

Data Types: `double`

`EL` — Elevation angles

`[-90:90]` (default) | 1-by-*N* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a 1-by-*N* real-valued row vector where *N* is the number of desired elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and *xy*-plane. When measured towards the *z*-axis, this angle is positive.

Example: `[-75:1:70]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'CoordinateSystem'` — Plotting coordinate system

`'polar'` (default) | `'rectangular'` | `'uv'`

Plotting coordinate system of the pattern, specified as the comma-separated pair consisting of `'CoordinateSystem'` and one of `'polar'`, `'rectangular'`, or `'uv'`. When `'CoordinateSystem'` is set to `'polar'` or `'rectangular'`, the `AZ` and `EL` arguments specify the pattern azimuth and elevation, respectively. `AZ` values must lie between –180° and 180°. `EL` values must lie between –90° and 90°. If `'CoordinateSystem'` is set to `'uv'`, `AZ` and `EL` then specify *U* and *V* coordinates, respectively. `AZ` and `EL` must lie between -1 and 1.

Example: `'uv'`

Data Types: `char`

`'Type'` — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

`'Normalize'` — Display normalize pattern

`true` (default) | `false`

Display normalized pattern, specified as the comma-separated pair consisting of `'Normalize'` and a Boolean. Set this parameter to `true` to display a normalized pattern. When you set `'Type'` to `'directivity'`, this parameter does not apply. Directivity patterns are already normalized.

Example:

Data Types: `logical`

`'PlotStyle'` — Plotting style

`'overlay'` (default) | `'waterfall'`

Plotting style, specified as the comma-separated pair consisting of `'Plotstyle'` and either `'overlay'` or `'waterfall'`. This parameter applies when you specify multiple frequencies in `FREQ` in 2-D plots. You can draw 2-D plots by setting one of the arguments `AZ` or `EL` to a scalar.

Example:

Data Types: `char`

`'Polarization'` — Polarized field component

`'combined'` (default) | `'H'` | `'V'`

Polarized field component to display, specified as the comma-separated pair consisting of 'Polarization' and `'combined'`, `'H'`, or `'V'`. This parameter applies only when the sensors are polarization-capable and when the `'Type'` parameter is not set to `'directivity'`. This table shows the meaning of the display options

`'Polarization'`	Display
`'combined'`	Combined *H* and *V* polarization components
`'H'`	*H* polarization component
`'V'`	*V* polarization component

Example: `'V'`

Data Types: `char`

`'PropagationSpeed'` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

`'Weights'` — Array weights

1 (default) | *N*-by-1 complex-valued column vector | *N*-by-*L* complex-valued matrix

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *N*-by-1 complex-valued column vector or *N*-by-*L* complex-valued matrix. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *N* is the number of elements in the array. The dimension *L* is the number of frequencies specified by `FREQ`.

Weights Dimension	FREQ Dimension	Purpose
N-by-1 complex-valued column vector	Scalar or 1-by-*L* row vector	Applies a set of weights for the single frequency or for all *L* frequencies.
N-by-*L* complex-valued matrix	1-by-*L* row vector	Applies each of the *L* columns of `'Weights'` for

Weights Dimension	FREQ Dimension	Purpose
		the corresponding frequency in FREQ.

Note: Use complex weights to steer the array response toward different directions. You can create weights using the phased.SteeringVector System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as phased.Radiator or phased.Collector. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(N,M)`

Data Types: `double`
Complex Number Support: Yes

Output Arguments

PAT — Array pattern

M-by-*N* real-valued matrix

Array pattern, returned as an *M*-by-*N* real-valued matrix. The dimensions of PAT correspond to the dimensions of the output arguments AZ_ANG and EL_ANG.

AZ_ANG — Azimuth angles

scalar | 1-by-*M* real-valued row vector

Azimuth angles for displaying directivity or response pattern, returned as a scalar or 1-by-*M* real-valued row vector corresponding to the dimension set in AZ. The rows of PAT correspond to the values in AZ_ANG.

EL_ANG — Elevation angles

scalar | 1-by-*N* real-valued row vector

Elevation angles for displaying directivity or response, returned as a scalar or 1-by-*N* real-valued row vector corresponding to the dimension set in EL. The columns of PAT correspond to the values in EL_ANG.

Examples

Plot Pattern of 9-Element ULA Antenna Array of Short Dipoles

Create an 9-element ULA of short dipole antenna elements spaced 0.2 meters apart. Display the azimuth and elevation directivities. The operating frequency is 500 MHz. Plot the directivities in polar coordinates.

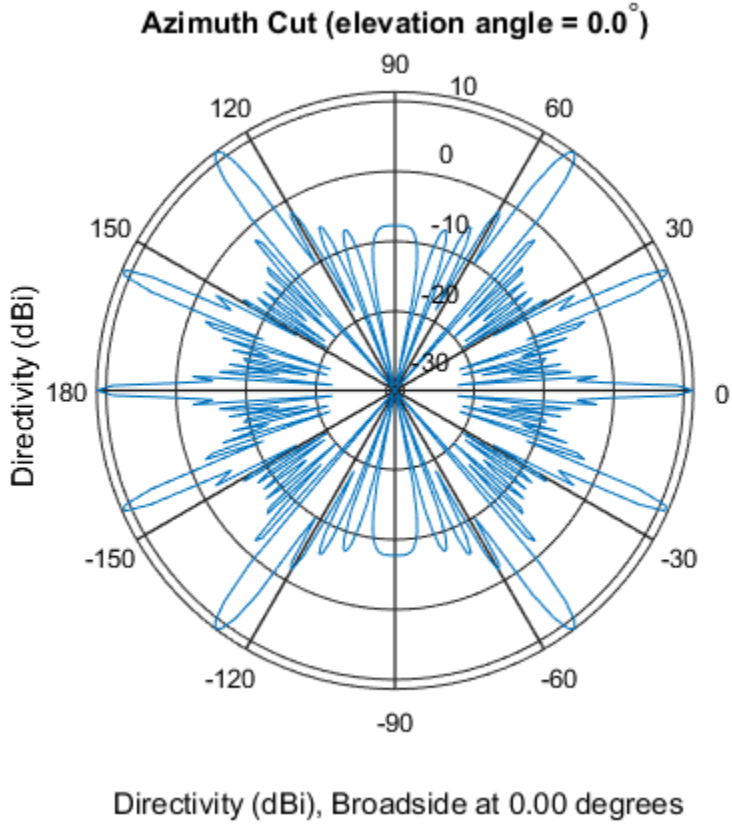
Evaluate the fields at 45 degrees azimuth and 0 degrees elevation.

```
sSD = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[50e6,1000e6],...
    'AxisDirection','Z');
sULA = phased.ULA('NumElements',9,'ElementSpacing',1.5,'Element',sSD);
fc = 500e6;
ang = [45;0];
resp = step(sULA,fc,ang);
disp(resp.V)
```

```
   -1.2247
   -1.2247
   -1.2247
   -1.2247
   -1.2247
   -1.2247
   -1.2247
   -1.2247
   -1.2247
```

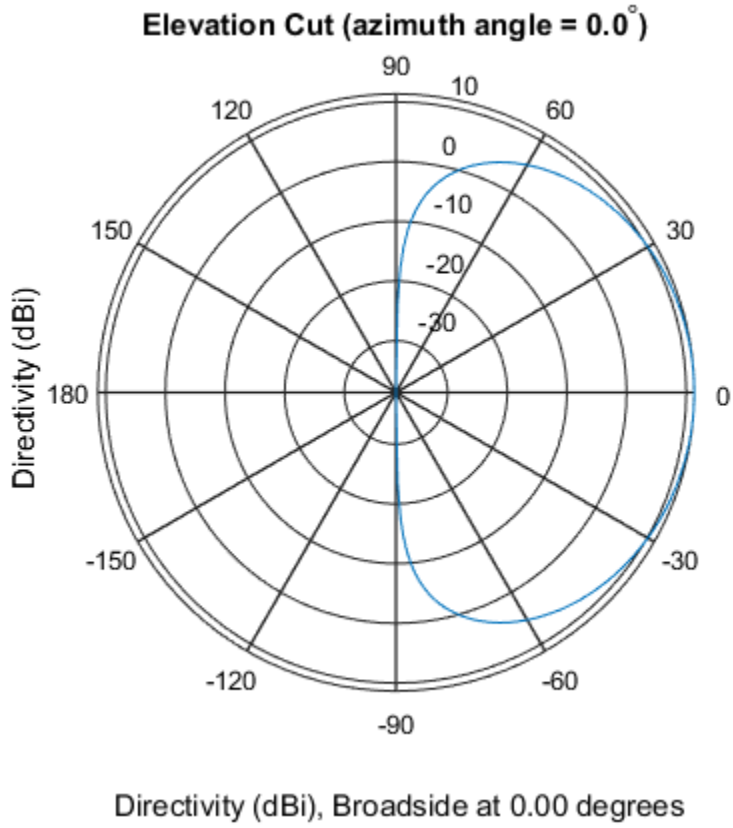
Display the azimuth directivity pattern at 500 MHz for azimuth angles between -180 and 180 degrees.

```
c = physconst('LightSpeed');
pattern(sULA,fc,[-180:180],0,...
    'Type','directivity',...
    'PropagationSpeed',c)
```



Display the elevation directivity pattern at 500 MHz for elevation angles between -90 and 90 degrees.

```
pattern(sULA,fc,[0],[-90:90],...
    'Type','directivity',...
    'PropagationSpeed',c)
```

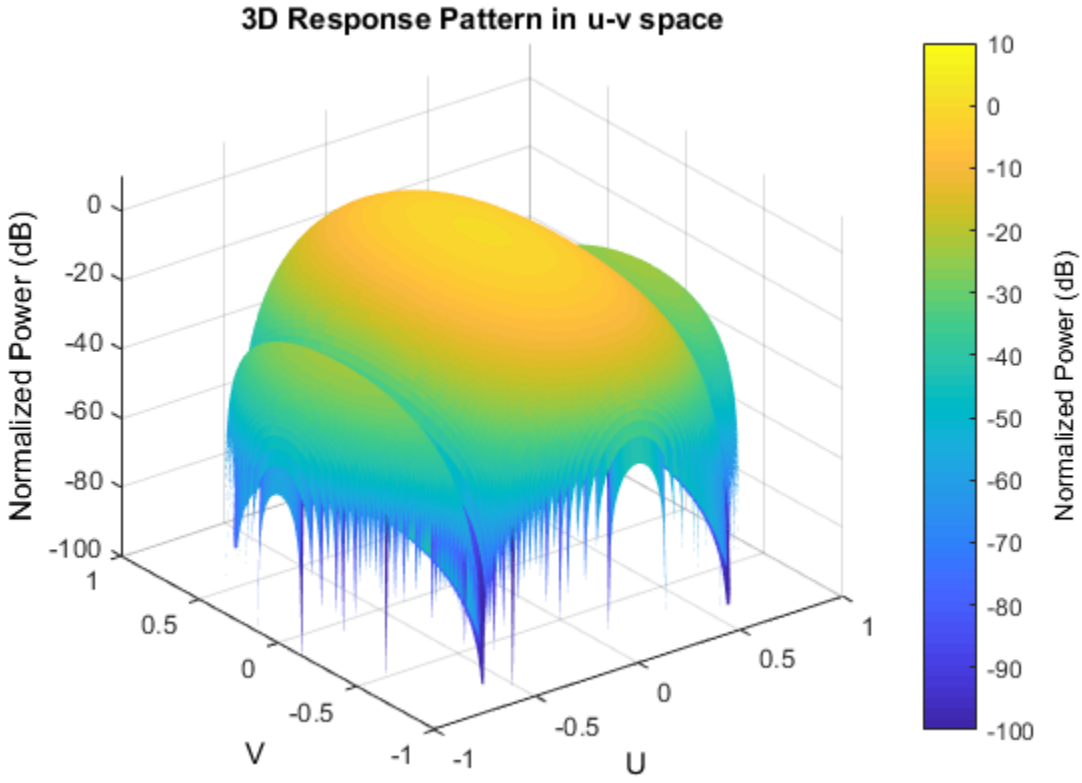


Plot Pattern of 10-Element ULA Antenna Array in UV Space

Create a 10-element ULA antenna array consisting of cosine antenna elements spaced 10 cm apart. Display the 3-D power pattern in UV space. The operating frequency is 500 MHz.

```
sCos = phased.CosineAntennaElement('FrequencyRange',[100e6 1e9],...
    'CosinePower',[2.5,2.5]);
sULA = phased.ULA('NumElements',10,...
    'ElementSpacing',.1,...
    'Element',sCos);
c = physconst('LightSpeed');
fc = 500e6;
pattern(sULA,fc,[-1:.01:1],[-1:.01:1],...
```

```
'CoordinateSystem','uv',...
'Type','powerdb',...
'PropagationSpeed',c)
```



More about

Directivity (dBi)

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant

intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on "Element directivity" and "Array directivity".

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

Convert plotResponse to pattern

For antenna, microphone, and array System objects, the `pattern` method replaces the `plotResponse` method. In addition, two new simplified methods exist just to draw 2-D azimuth and elevation pattern plots. These are the `azimuthPattern` and `elevationPattern` methods.

The following table is a guide for converting your code from using `plotResponse` to `pattern`. You should notice that some of the inputs have changed from *input arguments* to *Name-Value* pairs and vice versa. The general `pattern` method syntax is

```
pattern(H,FREQ,AZ,EL,'Name1','Value1',...,'NameN','ValueN')
```

plotResponse Inputs	plotResponse Description	pattern Inputs
`H` argument	Antenna, microphone, or array System object.	`H` argument (no change)

plotResponse Inputs	plotResponse Description	pattern Inputs
`FREQ` argument	Operating frequency.	`FREQ` argument (no change)
`V` argument	Propagation speed. This argument is used only for arrays.	`'PropagationSpeed'` name-value pair. This parameter is only used for arrays.

<table>

phased.ULA.patternAzimuth | phased.ULA.patternElevation

Introduced in R2015a

patternAzimuth

System object: phased.ULA
Package: phased

Plot ULA array directivity or pattern versus azimuth

Syntax

```
patternAzimuth(sArray,FREQ)
patternAzimuth(sArray,FREQ,EL)
patternAzimuth(sArray,FREQ,EL,Name,Value)
PAT = patternAzimuth( ___ )
```

Description

`patternAzimuth(sArray,FREQ)` plots the 2-D array directivity pattern versus azimuth (in dBi) for the array `sArray` at zero degrees elevation angle. The argument `FREQ` specifies the operating frequency.

`patternAzimuth(sArray,FREQ,EL)`, in addtion, plots the 2-D array directivity pattern versus azimuth (in dBi) for the array `sArray` at the elevation angle specified by `EL`. When `EL` is a vector, multiple overlaid plots are created.

`patternAzimuth(sArray,FREQ,EL,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternAzimuth( ___ )` returns the array pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Azimuth'` parameter and the `EL` input argument.

Input Arguments

`sArray` — Uniform linear array

System object

Uniform linear array, specified as a phased.ULA System object.

Example: `sArray= phased.ULA;`

FREQ — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

EL — Elevation angles

1-by-*N* real-valued row vector

Elevation angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector. The quantity *N* is the number of requested elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and the *xy* plane. When measured toward the *z*-axis, this angle is positive.

Example: `[0,10,20]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'Type' — Displayed pattern type

'directivity' (default) | 'efield' | 'power' | 'powerdb'

Displayed pattern type, specified as the comma-separated pair consisting of 'Type' and one of

- 'directivity' — directivity pattern measured in dBi.
- 'efield' — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- 'power' — power pattern of the sensor or array defined as the square of the field pattern.
- 'powerdb' — power pattern converted to dB.

Example: 'powerdb'

Data Types: char

'PropagationSpeed' — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of 'PropagationSpeed' and a positive scalar in meters per second.

Example: 'PropagationSpeed',physconst('LightSpeed')

Data Types: double

'Weights' — Array weights

M-by-1 complex-valued column vector

Array weights, specified as the comma-separated pair consisting of 'Weights' and an *M*-by-1 complex-valued column vector. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *M* is the number of elements in the array.

Note: Use complex weights to steer the array response toward different directions. You can create weights using the phased.SteeringVector System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as phased.Radiator or phased.Collector. However, for the directivity, pattern, patternAzimuth, and patternElevation methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(10,1)`

Data Types: `double`
Complex Number Support: Yes

`'Azimuth'` — Azimuth angles

`[-180:180]` (default) | 1-by-*P* real-valued row vector

Azimuth angles, specified as the comma-separated pair consisting of `'Azimuth'` and a 1-by-*P* real-valued row vector. Azimuth angles define where the array pattern is calculated.

Example: `'Azimuth',[-90:2:90]`

Data Types: `double`

Output Arguments

`PAT` — Array directivity or pattern

L-by-*N* real-valued matrix

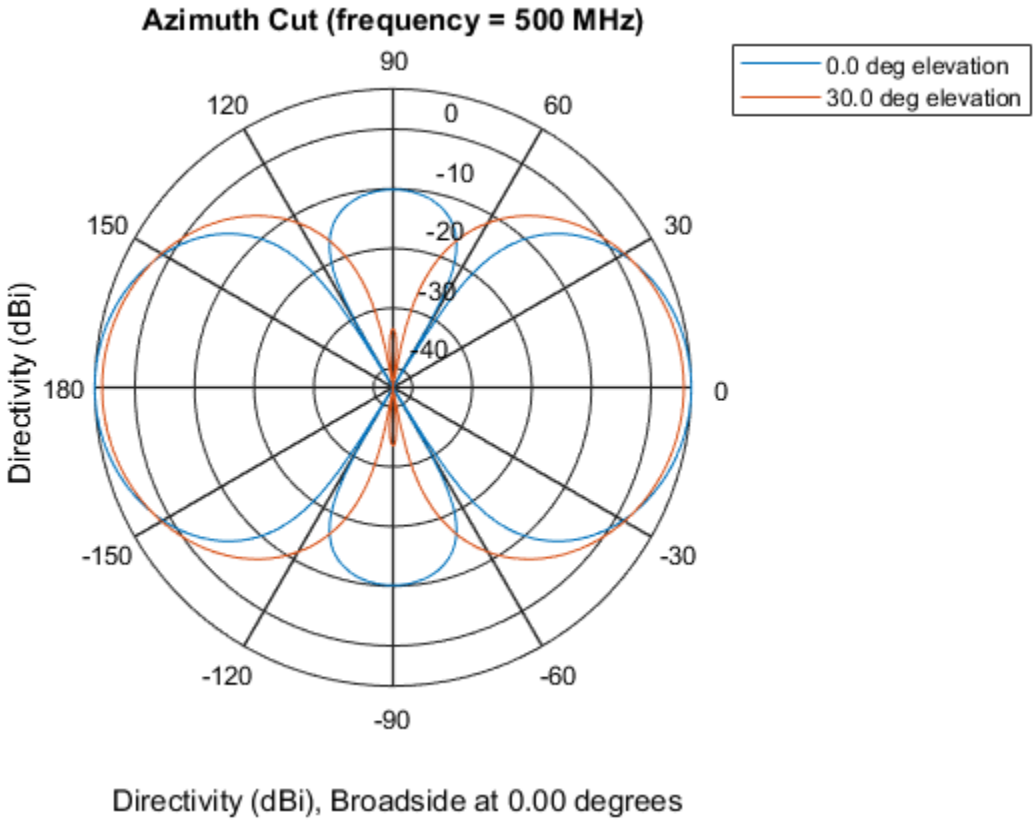
Array directivity or pattern, returned as an *L*-by-*N* rea-valued matrix. The dimension *L* is the number of azimuth values determined by the `'Azimuth'` name-value pair argument. The dimension *N* is the number of elevation angles, as determined by the `EL` input argument.

Examples

Plot Azimuth Pattern of ULA

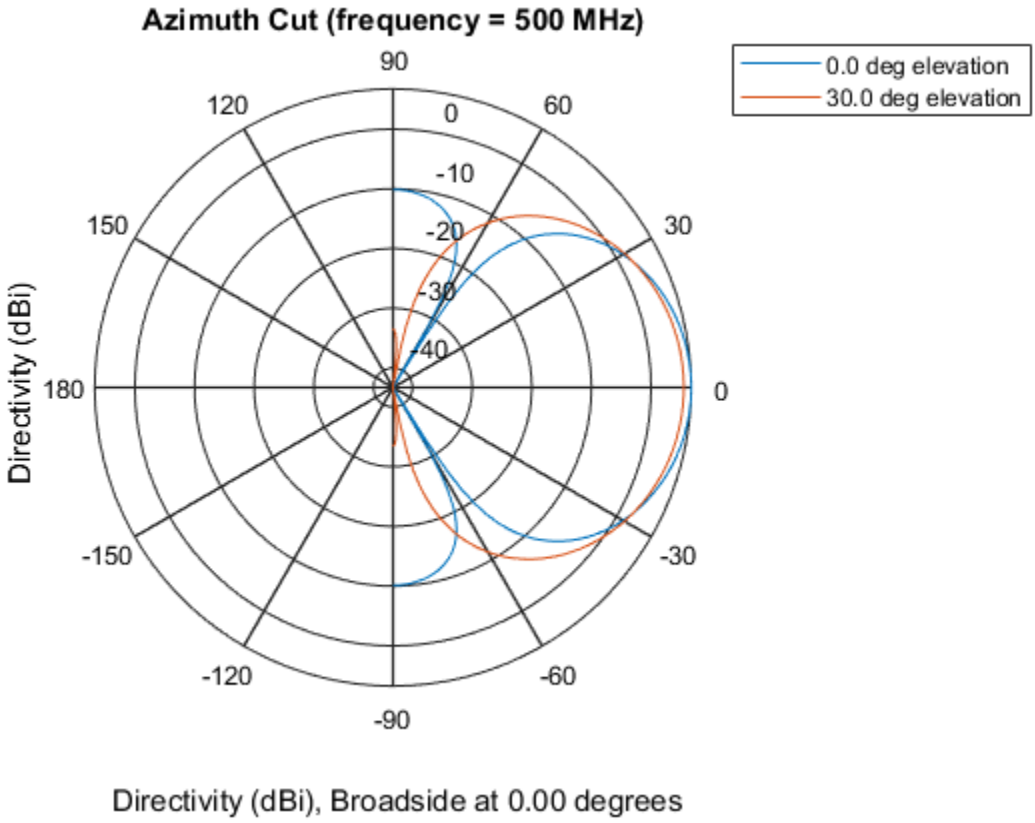
Create a 7-element ULA of short-dipole antenna elements spaced 10 cm apart. Plot an azimuth cut of directivity at 0 and 10 degrees elevation. Assume the operating frequency is 500 MHz.

```
fc = 500e6;
sCDant = phased.ShortDipoleAntennaElement('FrequencyRange',[100,900]*1e6);
sULA = phased.ULA('NumElements',7,'ElementSpacing',0.1,'Element',sCDant);
patternAzimuth(sULA,fc,[0 30])
```



You can plot a smaller range of azimuth angles by setting the `Azimuth` property.

```
patternAzimuth(sULA,fc,[0 30],'Azimuth',[-90:90])
```



Definitions

Directivity (dBi)

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on "Element directivity" and "Array directivity".

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

phased.ULA.pattern | phased.ULA.patternElevation

Introduced in R2015a

patternElevation

System object: phased.ULA
Package: phased

Plot ULA array directivity or pattern versus elevation

Syntax

```
patternElevation(sArray,FREQ)
patternElevation(sArray,FREQ,AZ)
patternElevation(sArray,FREQ,AZ,Name,Value)
PAT = patternElevation( ___ )
```

Description

`patternElevation(sArray,FREQ)` plots the 2-D array directivity pattern versus elevation (in dBi) for the array `sArray` at zero degrees azimuth angle. When `AZ` is a vector, multiple overlaid plots are created. The argument `FREQ` specifies the operating frequency.

`patternElevation(sArray,FREQ,AZ)`, in addition, plots the 2-D element directivity pattern versus elevation (in dBi) at the azimuth angle specified by `AZ`. When `AZ` is a vector, multiple overlaid plots are created.

`patternElevation(sArray,FREQ,AZ,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternElevation( ___ )` returns the array pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Elevation'` parameter and the `AZ` input argument.

Input Arguments

`sArray` — Uniform linear array

System object

Uniform linear array, specified as a phased.ULA System object.

Example: `sArray= phased.ULA;`

`FREQ` — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

`AZ` — Azimuth angles for computing directivity and pattern

1-by-*N* real-valued row vector

Azimuth angles for computing sensor or array directivities and patterns, specified as a 1-by-*M* real-valued row vector where *N* is the number of desired azimuth directions. Angle units are in degrees. The azimuth angle must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `[0,10,20]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Type'` — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

`'PropagationSpeed'` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

`'Weights'` — Array weights

M-by-1 complex-valued column vector

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *M*-by-1 complex-valued column vector. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *M* is the number of elements in the array.

Note: Use complex weights to steer the array response toward different directions. You can create weights using the phased.SteeringVector System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as phased.Radiator or phased.Collector. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(10,1)`

Data Types: `double`
Complex Number Support: Yes

`'Elevation'` — Elevation angles

`[-90:90]` (default) | 1-by-*P* real-valued row vector

Elevation angles, specified as the comma-separated pair consisting of `'Elevation'` and a 1-by-*P* real-valued row vector. Elevation angles define where the array pattern is calculated.

Example: `'Elevation',[-90:2:90]`

Data Types: `double`

Output Arguments

`PAT` — Array directivity or pattern

L-by-*N* real-valued matrix

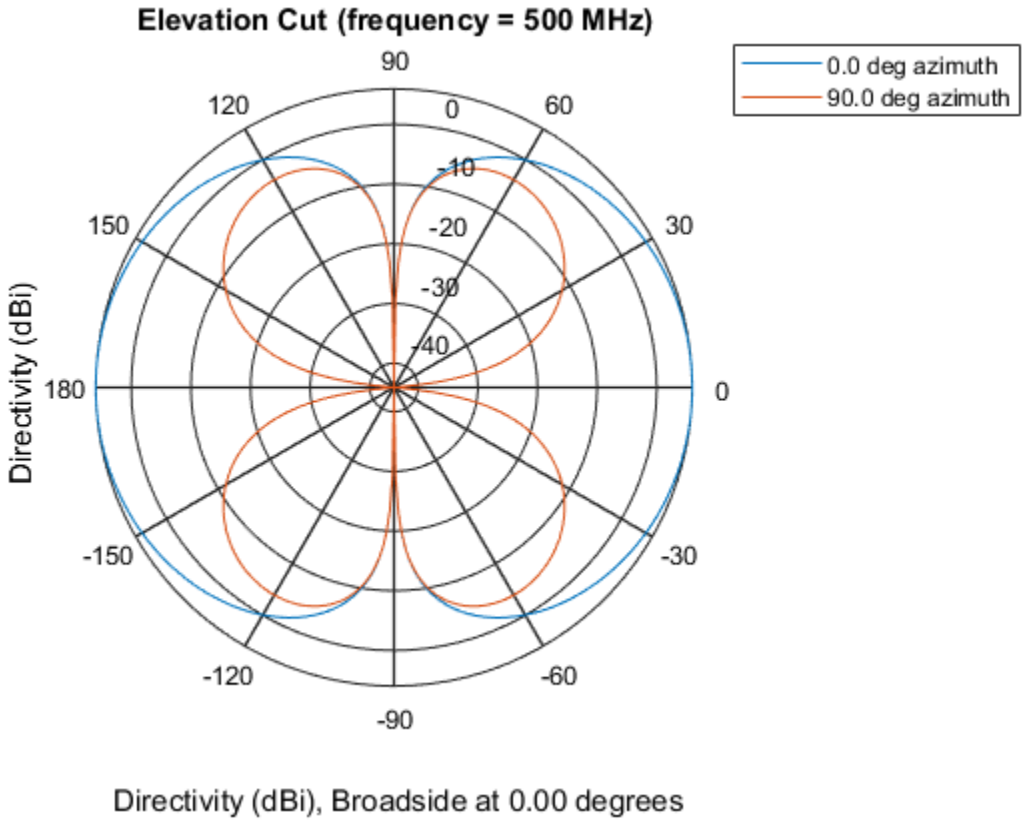
Array directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of elevation angles determined by the `'Elevation'` name-value pair argument. The dimension *N* is the number of azimuth angles determined by the `AZ` argument.

Examples

Plot Elevation Pattern of ULA

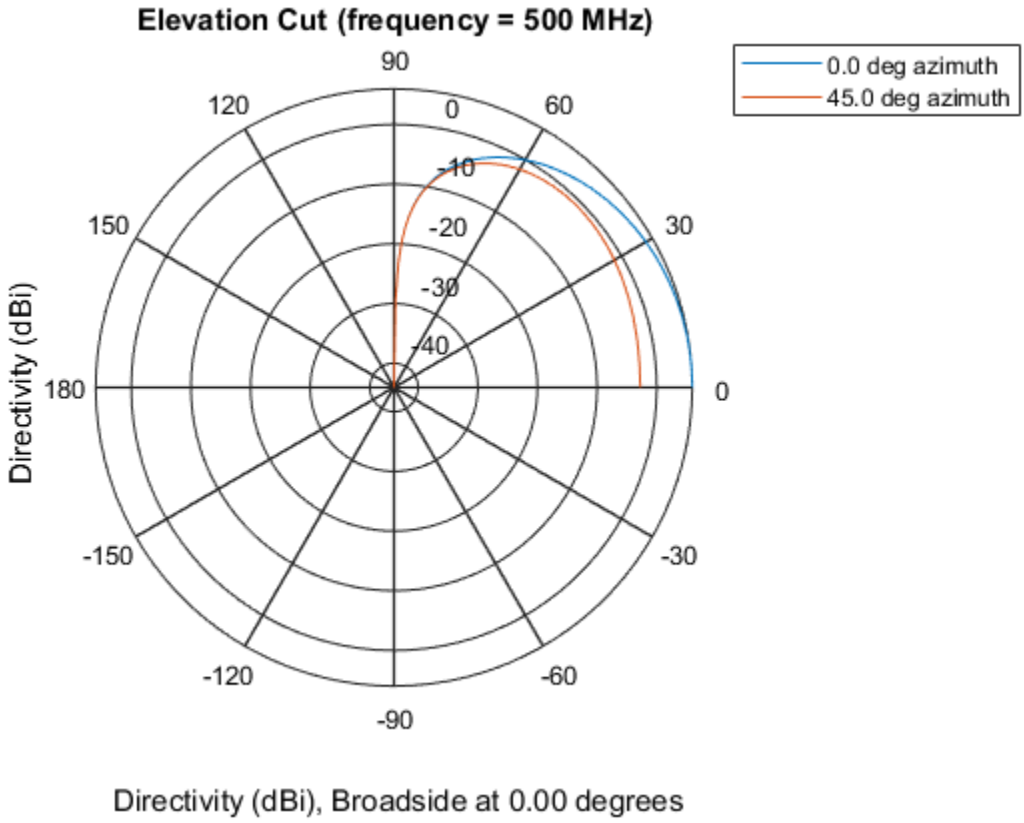
Create a 6-element ULA of short-dipole antenna elements with element spacing of 10 cm. Plot an elevation cut of directivity at 0 and 90 degrees azimuth. Assume the operating frequency is 500 MHz.

```
fc = 500e6;
c = physconst('LightSpeed');
sSD = phased.ShortDipoleAntennaElement('FrequencyRange',[100,900]*1e6);
sULA = phased.ULA('NumElements',6,'ElementSpacing',0.1,'Element',sSD);
patternElevation(sULA,fc,[0 90],'PropagationSpeed',c)
```



You can plot a smaller range of elevation angles by setting the `Elevation` property.

```
patternElevation(sULA,fc,[0 45],'Elevation',[0:90],'PropagationSpeed',c)
```



Definitions

Directivity (dBi)

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on "Element directivity" and "Array directivity".

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

phased.ULA.pattern | phased.ULA.patternAzimuth

Introduced in R2015a

plotGratingLobeDiagram

System object: phased.ULA
Package: phased

Plot grating lobe diagram of array

Syntax

```
plotGratingLobeDiagram(H,FREQ)
plotGratingLobeDiagram(H,FREQ,ANGLE)
plotGratingLobeDiagram(H,FREQ,ANGLE,C)
plotGratingLobeDiagram(H,FREQ,ANGLE,C,FO)
hPlot = plotGratingLobeDiagram(___)
```

Description

`plotGratingLobeDiagram(H,FREQ)` plots the grating lobe diagram of an array in the *u-v* coordinate system. The System object `H` specifies the array. The argument `FREQ` specifies the signal frequency and phase-shifter frequency. The array, by default, is steered to 0° azimuth and 0° elevation.

A grating lobe diagram displays the positions of the peaks of the narrowband *array pattern*. The array pattern depends only upon the geometry of the array and not upon the types of elements which make up the array. Visible and nonvisible grating lobes are displayed as open circles. Only grating lobe peaks near the location of the mainlobe are shown. The mainlobe itself is displayed as a filled circle.

`plotGratingLobeDiagram(H,FREQ,ANGLE)`, in addition, specifies the array steering angle, `ANGLE`.

`plotGratingLobeDiagram(H,FREQ,ANGLE,C)`, in addition, specifies the propagation speed by `C`.

`plotGratingLobeDiagram(H,FREQ,ANGLE,C,FO)`, in addition, specifies an array phase-shifter frequency, `FO`, that differs from the signal frequency, `FREQ`. This argument is useful when the signal no longer satisfies the narrowband assumption and, allows you to estimate the size of beam squint.

`hPlot = plotGratingLobeDiagram( ___ )` returns the handle to the plot for any of the input syntax forms.

Input Arguments

`H`

Antenna or microphone array, specified as a System object.

`FREQ`

Signal frequency, specified as a scalar. Frequency units are hertz. Values must lie within a range specified by the frequency property of the array elements contained in `H.Element`. The frequency property is named `FrequencyRange` or `FrequencyVector`, depending on the element type.

`ANGLE`

Array steering angle, specified as either a 2-by-1 vector or a scalar. If `ANGLE` is a vector, it takes the form `[azimuth;elevation]`. The azimuth angle must lie in the range `[-180°,180°]`. The elevation angle must lie in the range `[-90°,90°]`. All angle values are specified in degrees. If the argument `ANGLE` is a scalar, it specifies only the azimuth angle where the corresponding elevation angle is 0°.

Default: `[0;0]`

`C`

Signal propagation speed, specified as a scalar. Units are meters per second.

Default: Speed of light in vacuum

`FO`

Phase-shifter frequency of the array, specified as a scalar. Frequency units are hertz When this argument is omitted, the phase-shifter frequency is assumed to be the signal frequency, `FREQ`.

Default: `FREQ`

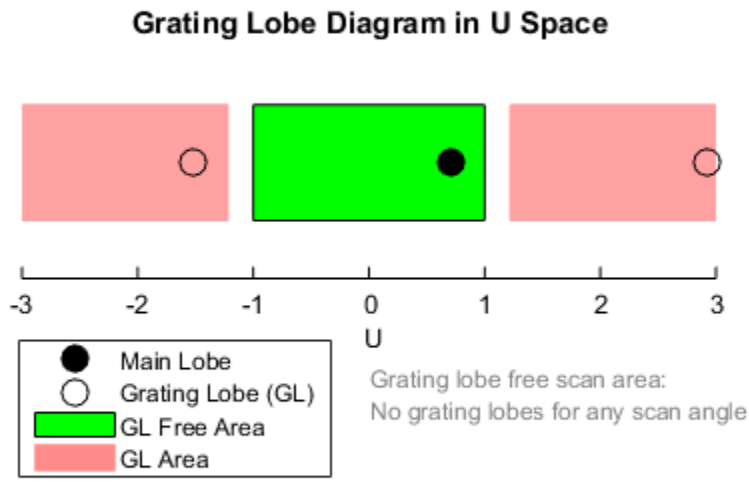
Examples

Create Grating Lobe Diagram for ULA

Plot the grating lobe diagram for a 4-element uniform linear array having element spacing less than one-half wavelength. Grating lobes are plotted in u-v coordinates.

Assume the operating frequency of the array is 3 GHz and the spacing between elements is 0.45 of the wavelength. All elements are isotropic antenna elements. Steer the array in the direction 45 degrees in azimuth and 0 degrees in elevation.

```
c = physconst('LightSpeed');
f = 3e9;
lambda = c/f;
sIso = phased.IsotropicAntennaElement;
sULA = phased.ULA('Element',sIso,'NumElements',4,...
    'ElementSpacing',0.45*lambda);
plotGratingLobeDiagram(sULA,f,[45;0],c);
```



The main lobe of the array is indicated by a filled black circle. The grating lobes in the visible and nonvisible regions are indicated by empty black circles. The visible region is defined by the direction cosine limits between [-1,1] and is marked by the two vertical black lines. Because the array spacing is less than one-half wavelength, there are no grating lobes in the visible region of space. There are an infinite number of grating lobes in the nonvisible regions, but only those in the range [-3,3] are shown.

The grating-lobe free region, shown in green, is the range of directions of the main lobe for which there are no grating lobes in the visible region. In this case, it coincides with the visible region.

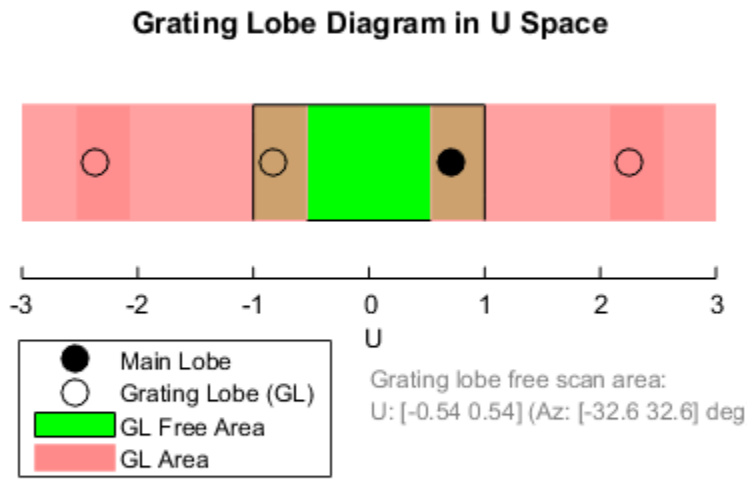
The white area of the diagram indicates a region where no grating lobes are possible.

Create Grating Lobe Diagram for Undersampled ULA

Plot the grating lobe diagram for a 4-element uniform linear array having element spacing greater than one-half wavelength. Grating lobes are plotted in u-v coordinates.

Assume the operating frequency of the array is 3 GHz and the spacing between elements is 0.65 of a wavelength. All elements are isotropic antenna elements. Steer the array in the direction 45 degrees in azimuth and 0 degrees in elevation.

```
c = physconst('LightSpeed');
f = 3e9;
lambda = c/f;
sIso = phased.IsotropicAntennaElement;
sULA = phased.ULA('Element',sIso,'NumElements',4,'ElementSpacing',0.65*lambda);
plotGratingLobeDiagram(sULA,f,[45;0],c);
```



The main lobe of the array is indicated by a filled black circle. The grating lobes in the visible and nonvisible regions are indicated by empty black circles. The visible region, marked by the two black vertical lines, corresponds to arrival angles between -90 and 90 degrees. The visible region is defined by the direction cosine limits $-1 \le u \le 1$. Because the array spacing is greater than one-half wavelength, there is now a grating lobe in the visible region of space. There are an infinite number of grating lobes in the nonvisible regions, but only those for which $-3 \le u \le 3$ are shown.

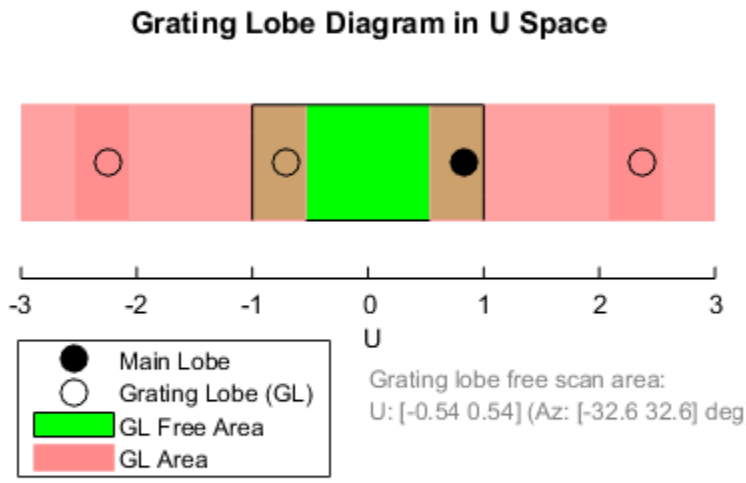
The grating-lobe free region, shown in green, is the range of directions of the main lobe for which there are no grating lobes in the visible region. In this case, it lies inside the visible region.

Create Grating Lobe Diagram for ULA With Different Phase-Shifter Frequency

Plot the grating lobe diagram for a 4-element uniform linear array having element spacing greater than one-half wavelength. Apply a phase-shifter frequency that differs from the signal frequency. Grating lobes are plotted in u-v coordinates.

Assume the signal frequency is 3 GHz and the spacing between elements is 0.65 λ. All elements are isotropic antenna elements. The phase-shifter frequency is set to 3.5 GHz. Steer the array in the direction 45° azimuth, 0° elevation.

```
c = physconst('LightSpeed');
f = 3e9;
f0 = 3.5e9;
lambda = c/f;
sIso = phased.IsotropicAntennaElement;
sULA = phased.ULA('Element',sIso,'NumElements',4,...
    'ElementSpacing',0.65*lambda );
plotGratingLobeDiagram(sULA,f,[45;0],c,f0);
```



As a result of adding the shifted frequency, the mainlobe shifts right towards larger u values. The beam no longer points toward the actual source arrival angle.

The mainlobe of the array is indicated by a filled black circle. The grating lobes in the visible and nonvisible regions are indicated by empty black circles. The visible region, marked by the two black vertical lines, corresponds to arrival angles between -90° and 90°. The visible region is defined by the direction cosine limits $-1 \le u \le 1$. Because the array spacing is greater than one-half wavelength, there is now a grating lobe in the visible region of space. There are an infinite number of grating lobes in the nonvisible regions, but only those for which $-3 \le u \le 3$ are shown.

The grating-lobe free region, shown in green, is the range of directions of the main lobe for which there are no grating lobes in the visible region. In this case, it lies inside the visible region.

Concepts

Grating Lobes

Spatial undersampling of a wavefield by an array gives rise to visible grating lobes. If you think of the wavenumber, k, as analogous to angular frequency, then you must sample the signal at spatial intervals smaller than π/k_{max} (or $\lambda_{min}/2$) in order to remove aliasing. The appearance of visible grating lobes is also known as spatial aliasing. The variable k_{max} is the largest wavenumber value present in the signal.

The directions of maximum spatial response of a ULA are determined by the peaks of the array's *array pattern* (alternatively called the *beam pattern* or *array factor*). Peaks other than the mainlobe peak are called grating lobes. For a ULA, the array pattern depends only on the wavenumber component of the wavefield along the array axis (the y-direction for the `phased.ULA` System object). The wavenumber component is related to the look-direction of an arriving wavefield by $k_y = -2\pi \sin \varphi/\lambda$. The angle φ is the broadside angle —the angle that the look-direction makes with a plane perpendicular to the array. The look-direction points away from the array to the wavefield source.

The array pattern possesses an infinite number of periodically-spaced peaks that are equal in strength to the mainlobe peak. If you steer the array to the φ_0 direction, the array pattern for a ULA has its mainlobe peak at the wavenumber value of $k_{y0} = -2\pi \sin \varphi_0/\lambda$. The array pattern has strong grating lobe peaks at $k_{ym} = k_{y0} + 2\pi m/d$, for any integer value m. Expressed in terms of direction cosines, the grating lobes occur at $u_m = u_0 + m\lambda/d$, where $u_0 = \sin \varphi_0$. The direction cosine, u_0, is the cosine of the angle that the look-direction makes with the y-axis and is equal to $\sin \varphi_0$ when expressed in terms of the look-direction.

In order to correspond to a physical look-direction, u_m must satisfy, $-1 \le u_m \le 1$. You can compute a physical look-direction angle φ_m from $\sin \varphi_m = u_m$ as long as $-1 \le u_m \le 1$. The spacing of grating lobes depends upon λ/d. When λ/d is small enough, multiple grating lobe peaks can correspond to physical look-directions.

The presence or absence of visible grating lobes for the ULA is summarized in this table.

Element Spacing	Grating Lobes
$\lambda/d \geq 2$	No visible grating lobes for any mainlobe direction.
$1 \leq \lambda/d < 2$	Visible grating lobes can exist for some range of mainlobe directions.
$\lambda/d < 1$	Visible grating lobes exist for every mainlobe direction.

step

System object: phased.ULA
Package: phased

Output responses of array elements

Syntax

```
RESP = step(H,FREQ,ANG)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`RESP = step(H,FREQ,ANG)` returns the array element responses, `RESP`, at the operating frequencies specified in `FREQ` and in directions specified in `ANG`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`H`

Array object

FREQ

Operating frequencies of array in hertz. `FREQ` is a row vector of length *L*. Typical values are within the range specified by a property of `H.Element`. That property is named `FrequencyRange` or `FrequencyVector`, depending on the type of element in the array. The element has zero response at frequencies outside that range.

ANG

Directions in degrees. `ANG` is either a 2-by-*M* matrix or a row vector of length *M*.

If `ANG` is a 2-by-*M* matrix, each column of the matrix specifies the direction in the form `[azimuth; elevation]`. The azimuth angle must lie between –180° and 180°, inclusive. The elevation angle must lie between –90° and 90°, inclusive.

If `ANG` is a row vector of length *M*, each element specifies the azimuth angle of the direction. In this case, the corresponding elevation angle is assumed to be 0°.

Output Arguments

RESP

Voltage responses of the phased array. The output depends on whether the array supports polarization or not.

- If the array is not capable of supporting polarization, the voltage response, `RESP`, has the dimensions *N*-by-*M*-by-*L*. *N* is the number of elements in the array. The dimension *M* is the number of angles specified in `ANG`. *L* is the number of frequencies specified in `FREQ`. For any element, the columns of `RESP` contain the responses of the array elements for the corresponding direction specified in `ANG`. Each of the *L* pages of `RESP` contains the responses of the array elements for the corresponding frequency specified in `FREQ`.
- If the array is capable of supporting polarization, the voltage response, `RESP`, is a MATLAB `struct` containing two fields, `RESP.H` and `RESP.V`. The field, `RESP.H`, represents the array's horizontal polarization response, while `RESP.V` represents the array's vertical polarization response. Each field has the dimensions *N*-by-*M*-by-*L*. *N* is the number of elements in the array, and *M* is the number of angles specified in `ANG`. *L* is the number of frequencies specified in `FREQ`. Each column of `RESP` contains the responses of the array elements for the corresponding direction specified in `ANG`.

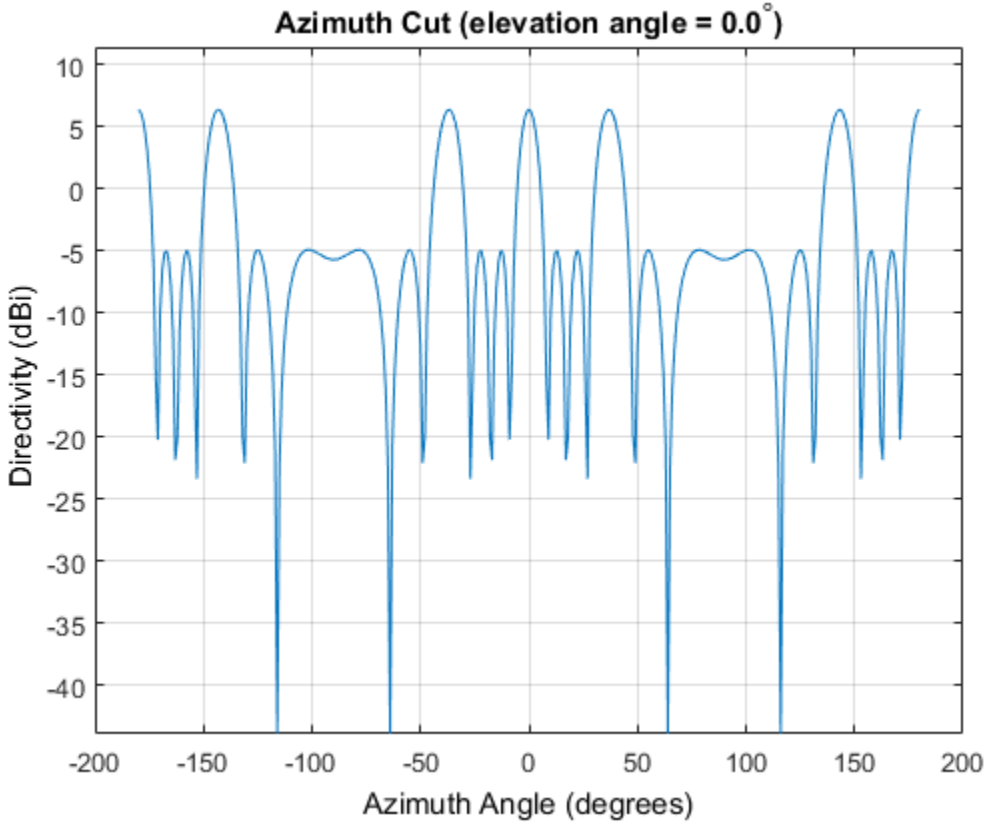
Each of the L pages of RESP contains the responses of the array elements for the corresponding frequency specified in FREQ.

Examples

Response of Antenna ULA

Create a 4-element ULA of isotropic antenna elements and find the response of each element at boresight. Plot the array response at 1 GHz for azimuth angles between -180 and 180 degrees.

```
ha = phased.ULA('NumElements',4);
fc = 1e9;
ang = [0;0];
resp = step(ha,fc,ang);
c = physconst('LightSpeed');
pattern(ha,fc,[-180:180],0,...
    'PropagationSpeed',c,...
    'CoordinateSystem','rectangular')
```



Step Response of Microphone ULA Array

Find the response of a ULA array of 10 omnidirectional microphones spaced 1.5 meters apart. Set the frequency response of the microphone to the range 20 Hz to 20 kHz and choose the signal frequency to be 100 Hz. Using the `step` method, determine the response of each element at boresight: 0 degrees azimuth and 0 degrees elevation.

```
sMic = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[20 20e3]);
Nelem = 10;
sULA = phased.ULA('NumElements',Nelem,...
    'ElementSpacing',1.5,...
    'Element',sMic);
fc = 100;
```

```
ang = [0;0];
resp = step(sULA,fc,ang)
```

```
resp =

     1
     1
     1
     1
     1
     1
     1
     1
     1
     1
```

Plot the array directivity. Assume the speed of sound in air to be 340 m/s.

```
c = 340;
pattern(sULA,fc,[-180:180],0,'PropagationSpeed',c,'CoordinateSystem','polar')
```

viewArray

System object: phased.ULA
Package: phased

View array geometry

Syntax

```
viewArray(H)
viewArray(H,Name,Value)
hPlot = viewArray( ___ )
```

Description

`viewArray(H)` plots the geometry of the array specified in `H`.

`viewArray(H,Name,Value)` plots the geometry of the array, with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = viewArray( ___ )` returns the handle of the array elements in the figure window. All input arguments described for the previous syntaxes also apply here.

Input Arguments

`H`

Array object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'ShowIndex'`

Vector specifying the element indices to show in the figure. Each number in the vector must be an integer between 1 and the number of elements. You can also specify the value `'All'` to show the indices of all elements of the array or `'None'` to suppress indices.

Default: `'None'`

`'ShowNormals'`

Set this value to `true` to show the normal directions of all elements of the array. Set this value to `false` to plot the elements without showing normal directions.

Default: `false`

`'ShowTaper'`

Set this value to `true` to specify whether to change the element color brightness in proportion to the element taper magnitude. When this value is set to `false`, all elements are drawn with the same color.

Default: `false`

`'Title'`

Character vector specifying the title of the plot.

Default: `'Array Geometry'`

Output Arguments

`hPlot`

Handle of array elements in figure window.

Examples

Geometry and Indices of ULA Elements

This example shows how to draw a 6-element ULA. Use the `'ShowIndex'` parameter to show the indices of the first and third elements.

```
sULA = phased.ULA(6);
```

```
viewArray(sULA,'ShowIndex',[1 3]);
```

phased.URA System object

Package: phased

Uniform rectangular array

Description

The `URA` object constructs a uniform rectangular array (URA).

To compute the response for each element in the array for specified directions:

1. Define and set up your uniform rectangular array. See "Construction" on page 1-2185.
2. Call step to compute the response according to the properties of `phased.URA`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.URA` creates a uniform rectangular array System object, `H`. The object models a URA formed with identical sensor elements. Array elements are distributed in the *yz*-plane in a rectangular lattice. The array look direction (boresight) is along the positive *x*-axis.

`H = phased.URA(Name,Value)` creates the object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

`H = phased.URA(SZ,D,Name,Value)` creates a URA object, `H`, with the `Size` property set to `SZ`, the `ElementSpacing` property set to `D` and other specified property Names set to the specified Values. `SZ` and `D` are value-only arguments. When specifying a value-only argument, specify all preceding value-only arguments. You can specify name-value pair arguments in any order.

Properties

`Element`

Phased array toolbox system object

Element specified as a Phased Array System Toolbox object. This object can be an antenna or microphone element.

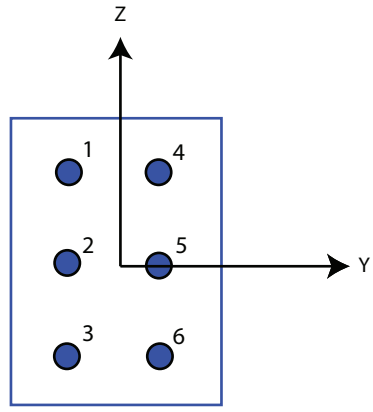
Default: Isotropic antenna element with default properties

`Size`

Size of array

A 1-by-2 integer vector or a single integer containing the size of the array. If `Size` is a 1-by-2 vector, the vector has the form `[NumberOfRows, NumberOfColumns]`. If `Size` is a scalar, the array has the same number of elements in each row and column. For a URA, array elements are indexed from top to bottom along a column and continuing to the next columns from left to right. In this illustration, a `'Size'` value of `[3,2]` array has three rows and two columns.

Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]



Default: `[2 2]`

`ElementSpacing`

Element spacing

A 1-by-2 vector or a scalar containing the element spacing of the array, expressed in meters. If `ElementSpacing` is a 1-by-2 vector, it is in the form of `[SpacingBetweenRows,SpacingBetweenColumns]`. See "Spacing Between Columns" on page 1-2193 and "Spacing Between Rows" on page 1-2193. If `ElementSpacing` is a scalar, both spacings are the same.

Default: `[0.5 0.5]`

`Lattice`

Element lattice

Specify the element lattice as one of `'Rectangular' | 'Triangular'`. When you set the `Lattice` property to `'Rectangular'`, all elements in the URA are aligned in both row and column directions. When you set the `Lattice` property to `'Triangular'`, elements in even rows are displaced toward the positive row axis direction. The displacement is one-half the element spacing along the row.

Default: `'Rectangular'`

`ArrayNormal`

Array normal direction

Array normal direction, specified as one of `'x'`, `'y'`, or `'z'`.

URA elements lie in a plane orthogonal to the selected array normal direction. Element boresight directions point along the array normal direction

ArrayNormal Property Value	Element Positions and Boresight Directions
`'x'`	Array elements lie on the *yz*-plane. All element boresight vectors point along the *x*-axis.

ArrayNormal Property Value	Element Positions and Boresight Directions
`'y'`	Array elements lie on the *zx*-plane. All element boresight vectors point along the *y*-axis.
`'z'`	Array elements lie on the *xy*-plane. All element boresight vectors point along the *z*-axis.

Default: `'x'`

`Taper`

Element tapers

Element tapers, specified as a complex-valued scalar, or 1-by-*MN* row vector, *MN*-by-1 column vector, or *M*-by-*N* matrix. Tapers are applied to each element in the sensor array. Tapers are often referred to as element *weights*. *M* is the number of elements along the *z*-axis, and *N* is the number of elements along *y*-axis. *M* and *N* correspond to the values of `[NumberofRows, NumberOfColumns]` in the `Size` property. If `Taper` is a scalar, the same taper value is applied to all elements. If the value of `Taper` is a vector or matrix, taper values are applied to the corresponding elements. Tapers are used to modify both the amplitude and phase of the received data.

Default: 1

Methods

directivity	Directivity of uniform rectangular array
collectPlaneWave	Simulate received plane waves
getElementNormal	Normal vector to array elements
getElementPosition	Positions of array elements
getNumElements	Number of elements in array
getTaper	Array element tapers
pattern	Plot URA array pattern
patternAzimuth	Plot URA array directivity or pattern versus azimuth

patternElevation	Plot URA array directivity or pattern versus elevation
isPolarizationCapable	Polarization capability
plotResponse	Plot response pattern of array
plotGratingLobeDiagram	Plot grating lobe diagram of array
step	Output responses of array elements
viewArray	View array geometry

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Azimuth Response of a 3-by-2 URA at Boresight

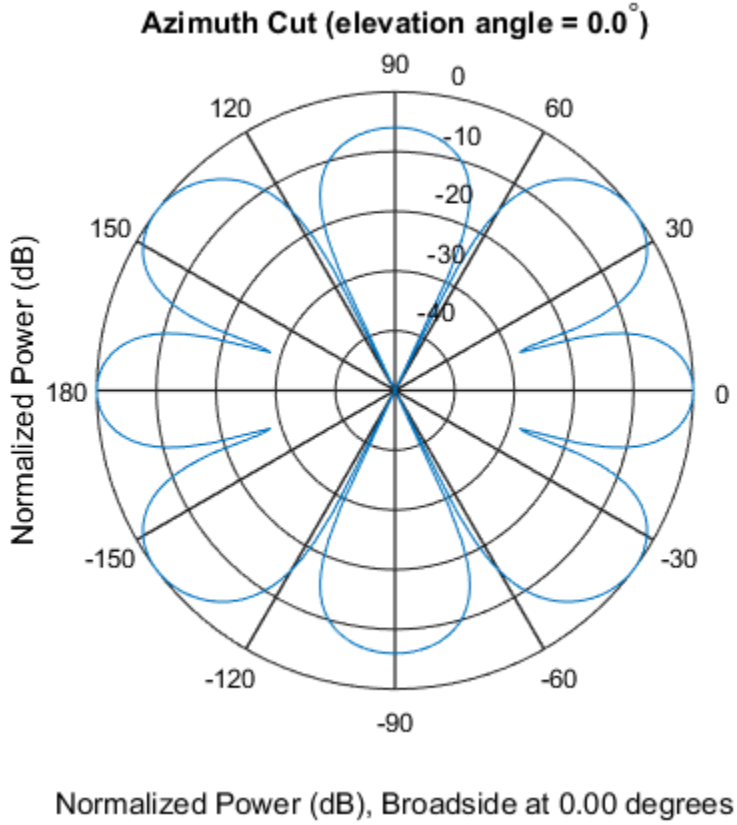
Construct a 3-by-2 rectangular lattice URA. By default, the array consists of isotropic antenna elements. Find the response of each element at boresight, 0 degrees azimuth and elevation. Assume the operating frequency is 1 GHz.

```
array = phased.URA('Size',[3 2]);
fc = 1e9;
ang = [0;0];
resp = array(fc,ang);
disp(resp)
```

```
     1
     1
     1
     1
     1
     1
```

Plot the azimuth pattern of the array.

```
c = physconst('LightSpeed');
pattern(array,fc,[-180:180],0,'PropagationSpeed',c, ...
    'CoordinateSystem','polar','Type','powerdb','Normalize',true)
```



Compare Triangular and Rectangular Lattice URA's

This example shows how to find and plot the positions of the elements of a 5-row-by-6-column URA with a triangular lattice and a URA with a rectangular lattice. The element spacing is 0.5 meters for both lattices.

Create the arrays.

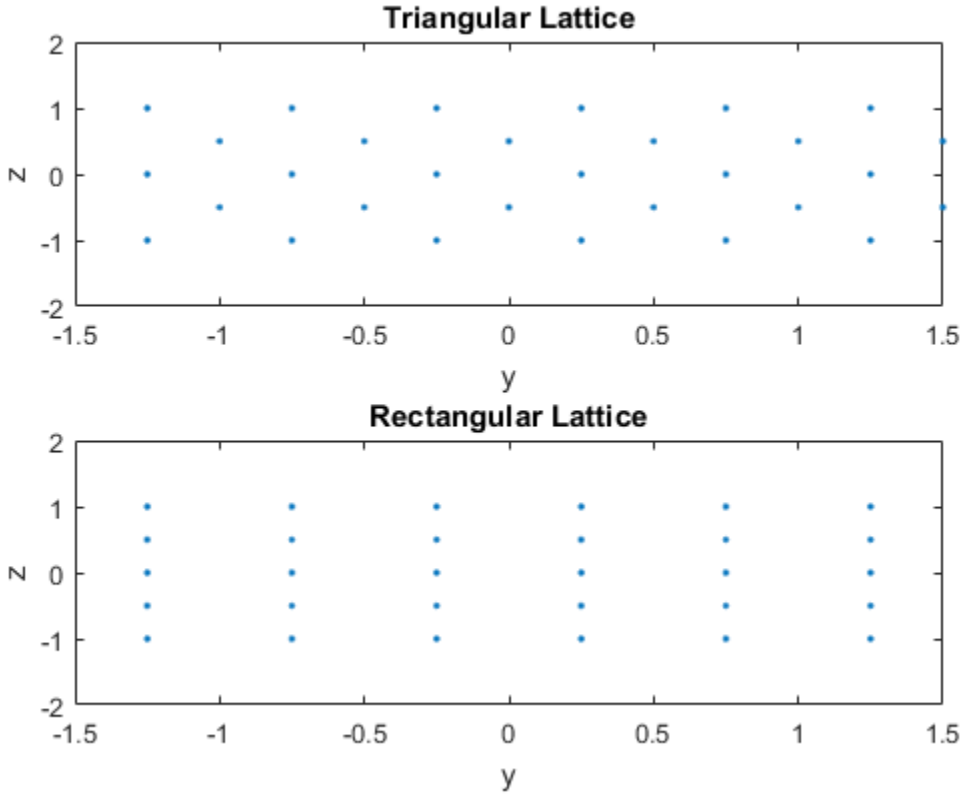
```
h_tri = phased.URA('Size',[5 6],'Lattice','Triangular');
h_rec = phased.URA('Size',[5 6],'Lattice','Rectangular');
```

Get the element y,z positions for each array. All the x coordinates are zero.

```
pos_tri = getElementPosition(h_tri);
pos_rec = getElementPosition(h_rec);
pos_yz_tri = pos_tri(2:3,:);
pos_yz_rec = pos_rec(2:3,:);
```

Plot the element positions in the yz-plane.

```
figure;
gcf.Position = [100 100 300 400];
subplot(2,1,1);
plot(pos_yz_tri(1,:), pos_yz_tri(2,:), '.')
axis([-1.5 1.5 -2 2])
xlabel('y'); ylabel('z')
title('Triangular Lattice')
subplot(2,1,2);
plot(pos_yz_rec(1,:), pos_yz_rec(2,:), '.')
axis([-1.5 1.5 -2 2])
xlabel('y'); ylabel('z')
title('Rectangular Lattice')
```



Adding Tapers to an Array

Construct a 5-by-2 element URA with a Taylor window taper along each column. The tapers form a 5-by-2 matrix.

```
taper = taylorwin(5);
ha = phased.URA([5,2],'Taper',[taper,taper]);
w = getTaper(ha)
```

```
w =

    0.5181
    1.2029
```

```
1.5581
1.2029
0.5181
0.5181
1.2029
1.5581
1.2029
0.5181
```

- Phased Array Gallery

Definitions

Spacing Between Columns

The spacing between columns is the distance between adjacent elements in the same row.

Spacing Between Rows

The spacing between rows is the distance along the column axis direction between adjacent rows.

directivity

System object: phased.URA
Package: phased

Directivity of uniform rectangular array

Syntax

```
D = directivity(H,FREQ,ANGLE)
D = directivity(H,FREQ,ANGLE,Name,Value)
```

Description

`D = directivity(H,FREQ,ANGLE)` computes the "Directivity" on page 1-2202 of a uniform rectangular array (URA) of antenna or microphone elements, `H`, at frequencies specified by the `FREQ` and in angles of direction specified by the `ANGLE`.

`D = directivity(H,FREQ,ANGLE,Name,Value)` computes the directivity with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`H` — Uniform rectangular array

System object

Uniform rectangular array specified as a phased.URA System object.

Example: `H = phased.URA`

`FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-L real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-L real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

`ANGLE` — Angles for computing directivity

1-by-*M* real-valued row vector | 2-by-*M* real-valued matrix

Angles for computing directivity, specified as a 1-by-*M* real-valued row vector or a 2-by-*M* real-valued matrix, where *M* is the number of angular directions. Angle units are in degrees. If `ANGLE` is a 2-by-*M* matrix, then each column specifies a direction in azimuth and elevation, `[az;el]`. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°.

If `ANGLE` is a 1-by-*M* vector, then each entry represents an azimuth angle, with the elevation angle assumed to be zero.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the direction vector and *xy* plane. This angle is positive when measured towards the *z*-axis.

Example: `[45 60; 0 10]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'PropagationSpeed'` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

`'Weights'` — Array weights

1 (default) | *N*-by-1 complex-valued column vector | *N*-by-*L* complex-valued matrix

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *N*-by-1 complex-valued column vector or *N*-by-*L* complex-valued matrix. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *N* is the number of elements in the array. The dimension *L* is the number of frequencies specified by `FREQ`.

Weights Dimension	FREQ Dimension	Purpose
N-by-1 complex-valued column vector	Scalar or 1-by-*L* row vector	Applies a set of weights for the single frequency or for all *L* frequencies.
N-by-*L* complex-valued matrix	1-by-*L* row vector	Applies each of the *L* columns of `'Weights'` for the corresponding frequency in `FREQ`.

Note: Use complex weights to steer the array response toward different directions. You can create weights using the phased.SteeringVector System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as phased.Radiator or phased.Collector. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(N,M)`

Data Types: `double`
Complex Number Support: Yes

Output Arguments

D — Directivity

M-by-*L* matrix

Directivity, returned as an *M*-by-*L* matrix whose columns contain the directivities at the *M* angles specified by ANGLE. Each column corresponds to one of the *L* frequency values specified in FREQ. Directivity units are in dBi.

Examples

Directivity of Uniform Rectangular Array

Compute the directivity of two uniform rectangular arrays (URA). The first array consists of isotropic antenna elements. The second array consists of cosine antenna elements. In addition, compute the directivity of the first array steered to a specific direction.

Array of isotropic antenna elements

First, create a 10-by-10-element URA of isotropic antenna elements spaced one-quarter wavelength apart. Set the signal frequency to 800 MHz.

```
c = physconst('LightSpeed');
fc = 3e8;
lambda = c/fc;
myAntIso = phased.IsotropicAntennaElement;
myArray1 = phased.URA;
myArray1.Element = myAntIso;
myArray1.Size = [10,10];
myArray1.ElementSpacing = [lambda*0.25,lambda*0.25];
ang = [0;0];
d = directivity(myArray1,fc,ang,'PropagationSpeed',c)
```

```
d =

   15.7753
```

Array of cosine antenna elements

Next, create a 10-by-10-element URA of cosine antenna elements also spaced one-quarter wavelength apart.

```
myAntCos = phased.CosineAntennaElement('CosinePower',[1.8,1.8]);
myArray2 = phased.URA;
myArray2.Element = myAntCos;
myArray2.Size = [10,10];
myArray2.ElementSpacing = [lambda*0.25,lambda*0.25];
ang = [0;0];
d = directivity(myArray2,fc,ang,'PropagationSpeed',c)
```

```
d =

   19.7295
```

The directivity is increased due to the directivity of the cosine antenna elements.

Steered array of isotropic antenna elements

Finally, steer the isotropic antenna array to 30 degrees in azimuth and examine the directivity at the steered angle.

```
ang = [30;0];
w = steervec(getElementPosition(myArray1)/lambda,ang);
d = directivity(myArray1,fc,ang,'PropagationSpeed',c,...
    'Weights',w)
```

```
d =

   15.3309
```

The directivity is maximum in the steered direction and equals the directivity of the unsteered array at boresight.

Definitions

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element directivity” and “Array directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

collectPlaneWave

System object: phased.URA
Package: phased

Simulate received plane waves

Syntax

```
Y = collectPlaneWave(H,X,ANG)
Y = collectPlaneWave(H,X,ANG,FREQ)
Y = collectPlaneWave(H,X,ANG,FREQ,C)
```

Description

`Y = collectPlaneWave(H,X,ANG)` returns the received signals at the sensor array, `H`, when the input signals indicated by `X` arrive at the array from the directions specified in `ANG`.

`Y = collectPlaneWave(H,X,ANG,FREQ)`, in addition, specifies the incoming signal carrier frequency in `FREQ`.

`Y = collectPlaneWave(H,X,ANG,FREQ,C)`, in addition, specifies the signal propagation speed in `C`.

Input Arguments

`H`

Array object.

`X`

Incoming signals, specified as an M-column matrix. Each column of `X` represents an individual incoming signal.

ANG

Directions from which incoming signals arrive, in degrees. ANG can be either a 2-by-M matrix or a row vector of length M.

If ANG is a 2-by-M matrix, each column specifies the direction of arrival of the corresponding signal in X. Each column of ANG is in the form `[azimuth; elevation]`. The azimuth angle must be between –180° and 180°, inclusive. The elevation angle must be between –90° and 90°, inclusive.

If ANG is a row vector of length M, each entry in ANG specifies the azimuth angle. In this case, the corresponding elevation angle is assumed to be 0°.

FREQ

Carrier frequency of signal in hertz. FREQ must be a scalar.

Default: `3e8`

C

Propagation speed of signal in meters per second.

Default: Speed of light

Output Arguments

Y

Received signals. Y is an N-column matrix, where N is the number of elements in the array H. Each column of Y is the received signal at the corresponding array element, with all incoming signals combined.

Examples

Simulate Received Signal at URA

Simulate two received random signals at a 6-element URA. The array has a rectangular lattice with two elements in the row direction and three elements in the column

direction. The signals arrive from 10° and 30° azimuth. Both signals have an elevation angle of 0°. Assume the propagation speed is the speed of light and the carrier frequency of the signal is 100 MHz.

```
array = phased.URA([2 3]);
fc = 100e6;
y = collectPlaneWave(array,randn(4,2),[10 30],fc,physconst('LightSpeed'));
```

Algorithms

`collectPlaneWave` modulates the input signal with a phase corresponding to the delay caused by the direction of arrival. This method does not account for the response of individual elements in the array.

For further details, see [1].

getElementNormal

System object: phased.URA
Package: phased

Normal vector to array elements

Syntax

```
normvec = getElementNormal(sURA)
normvec = getElementNormal(sURA,elemidx)
```

Description

`normvec = getElementNormal(sURA)` returns the normal vectors of the array elements of the `phased.URA` System object, `sURA`. The output argument `normvec` is a 2-by-*N* matrix, where *N* is the number of elements in array, `sURA`. Each column of `normvec` defines the normal direction of an element in the local coordinate system in the form `[az;el]`. Units are degrees. Array elements are located in the plane selected in the `ArrayNormal` property. Element normal vectors are parallel to the array normal. The normal to a URA array depends upon the selected `ArrayNormal` property.

ArrayNormal Property Value	Array Normal Direction	Array Plane
`'x'`	azimuth = 0°, elevation = 0° (*x*-axis)	*yz*
`'y'`	azimuth = 90°, elevation = 0° (*y*-axis)	*zx*
`'z'`	azimuth = 0°, elevation = 90° (*z*-axis)	*xy*

The origin of the local coordinate system is defined by the phase center of the array.

`normvec = getElementNormal(sURA,elemidx)` returns only the normal vectors of the elements specified in the element index vector, `elemidx`. This syntax can use any of the input arguments in the previous syntax.

Input Arguments

sURA — Uniform rectangular array

`phased.sURA` System object

Uniform line array, specified as a `phased.URA` System object.

Example: `sULA = phased.URA`

elemidx — Element indices

all array elements (default) | integer-valued 1-by-*M* row vector | integer-valued *M*-by-1 column vector

Element indices , specified as a 1-by-*M* or *M*-by-1 vector. Index values lie in the range 1 to *N* where *N* is the number of elements of the array. When `elemidx` is specified, `getElementNormal` returns the normal vectors of the elements contained in `elemidx`.

Example: `[1,5,4]`

Output Arguments

normvec — Element normal vectors

2-by-*P* real-valued vector

Element normal vectors, specified as a 2-by-*P* real-valued vector. Each column of `normvec` takes the form `[az,el]`. When `elemidx` is not specified, *P* equals the array dimension. When `elemidx` is specified, *P* equals the length of `elemidx`, *M*. You can determine element indices using the phased.URA.viewArray method.

Examples

URA Element Normals

Construct three 2-by-2 URA's with element normals along the *x*-, *y*-, and *z*-axes. Obtain the element positions and normal directions.

First, choose the array normal along the *x*-axis.

```
sURA1 = phased.URA('Size',[2,2],'ArrayNormal','x');
```

```
pos = getElementPosition(sURA1)
normvec = getElementNormal(sURA1)
```

```
pos =

         0         0         0         0
   -0.2500   -0.2500    0.2500    0.2500
    0.2500   -0.2500    0.2500   -0.2500

normvec =

     0     0     0     0
     0     0     0     0
```

All elements lie in the *yz*-plane and the element normal vectors point along the *x*-axis *(0°,0°)*.

Next, choose the array normal along the *y*-axis.

```
sURA2 = phased.URA('Size',[2,2],'ArrayNormal','y');
pos = getElementPosition(sURA2)
normvec = getElementNormal(sURA2)
```

```
pos =

   -0.2500   -0.2500    0.2500    0.2500
         0         0         0         0
    0.2500   -0.2500    0.2500   -0.2500

normvec =

    90    90    90    90
     0     0     0     0
```

All elements lie in the *zx*-plane and the element normal vectors point along the *y*-axis *(90°,0°)*.

Finally, set the array normal along the *z*-axis. Obtain the normal vectors of the odd-numbered elements.

```
sURA3 = phased.URA('Size',[2,2],'ArrayNormal','z');
pos = getElementPosition(sURA3)
normvec = getElementNormal(sURA3,[1,3])
```

```
pos =

   -0.2500   -0.2500    0.2500    0.2500
    0.2500   -0.2500    0.2500   -0.2500
         0         0         0         0

normvec =

     0     0
    90    90
```

All elements lie in the *xy*-plane and the element normal vectors point along the *z*-axis *(0°,90°)*.

Introduced in R2016a

getElementPosition

System object: phased.URA
Package: phased

Positions of array elements

Syntax

```
POS = getElementPosition(H)
POS = getElementPosition(H,ELEIDX)
```

Description

`POS = getElementPosition(H)` returns the element positions of the URA `H`. `POS` is a 3-by-N matrix where N is the number of elements in `H`. Each column of `POS` defines the position of an element in the local coordinate system, in meters, using the form [x; y; z].

For details regarding the local coordinate system of the URA, enter `phased.URA.coordinateSystemInfo`.

`POS = getElementPosition(H,ELEIDX)` returns the positions of the elements that are specified in the element index vector, `ELEIDX`. The index of a URA runs down each column, then to the next column to the right. For example, in a URA with 4 elements in each row and 3 elements in each column, the element in the third row and second column has an index value of 6.

Examples

Obtain URA Element Positions

Construct a default URA with a rectangular lattice, and obtain the element positions.

```
array = phased.URA;
pos = getElementPosition(array)
```

```
pos =

         0         0         0         0
   -0.2500   -0.2500    0.2500    0.2500

```

getNumElements

System object: phased.URA
Package: phased

Number of elements in array

Syntax

```
N = getNumElements(H)
```

Description

`N = getNumElements(H)` returns the number of elements, N, in the URA object `H`.

Examples

Obtain Number of URA Elements

Construct a default URA, and obtain the number of elements.

```
array = phased.URA;
N = getNumElements(array)
```

```
N =

     4
```

getTaper

System object: phased.URA
Package: phased

Array element tapers

Syntax

```
wts = getTaper(h)
```

Description

`wts = getTaper(h)` returns the tapers, `wts`, applied to each element of the phased uniform rectangular array (URA), `h`. Tapers are often referred to as *weights*.

Input Arguments

h — Uniform rectangular array

`phased.URA` System object

Uniform rectangular array specified as aphased.URA System object.

Output Arguments

wts — Array element tapers

N-by-1 complex-valued vector

Array element tapers returned as an *N*-by-1, complex-valued vector, where *N* is the number of elements in the array.

Examples

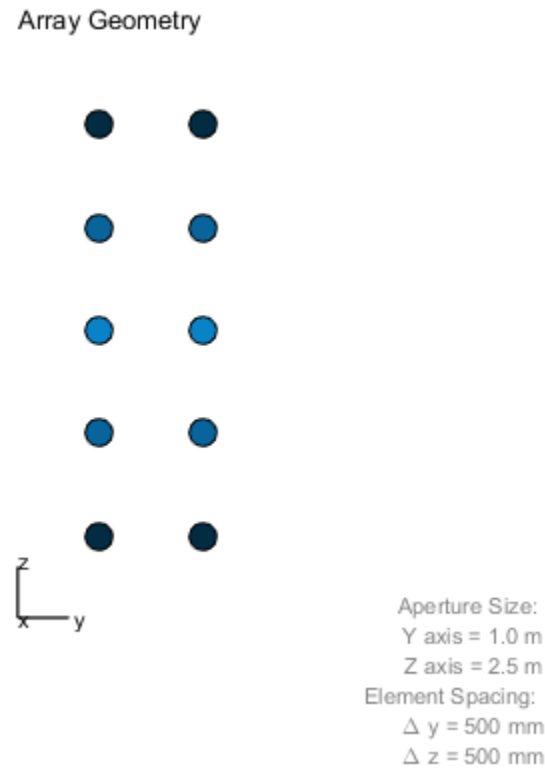
Create Tapered URA

Construct a 5-by-2 element URA with a Taylor window taper along each column. Then, draw the array showing the element taper shading.

```
taper = taylorwin(5);
array = phased.URA([5,2],'Taper',[taper,taper]);
w = getTaper(array)
viewArray(array,'ShowTaper',true)
```

```
w =

    0.5181
    1.2029
    1.5581
    1.2029
    0.5181
    0.5181
    1.2029
    1.5581
    1.2029
    0.5181
```



Array Geometry

Aperture Size:
Y axis = 1.0 m
Z axis = 2.5 m
Element Spacing:
Δ y = 500 mm
Δ z = 500 mm

pattern

System object: phased.URA
Package: phased

Plot URA array pattern

Syntax

```
pattern(sArray,FREQ)
pattern(sArray,FREQ,AZ)
pattern(sArray,FREQ,AZ,EL)
pattern( ___ ,Name,Value)
[PAT,AZ_ANG,EL_ANG] = pattern( ___ )
```

Description

`pattern(sArray,FREQ)` plots the 3-D array directivity pattern (in dBi) for the array specified in `sArray`. The operating frequency is specified in `FREQ`.

`pattern(sArray,FREQ,AZ)` plots the array directivity pattern at the specified azimuth angle.

`pattern(sArray,FREQ,AZ,EL)` plots the array directivity pattern at specified azimuth and elevation angles.

`pattern( ___ ,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`[PAT,AZ_ANG,EL_ANG] = pattern( ___ )` returns the array pattern in `PAT`. The `AZ_ANG` output contains the coordinate values corresponding to the rows of `PAT`. The `EL_ANG` output contains the coordinate values corresponding to the columns of `PAT`. If the `'CoordinateSystem'` parameter is set to `'uv'`, then `AZ_ANG` contains the *U* coordinates of the pattern and `EL_ANG` contains the *V* coordinates of the pattern. Otherwise, they are in angular units in degrees. *UV* units are dimensionless.

Note: This method replaces the `plotResponse` method. See "Convert plotResponse to pattern" on page 1-2226 for guidelines on how to use `pattern` in place of `plotResponse`.

Input Arguments

`sArray` — Uniform rectangular array

System object

Uniform rectangular array, specified as a phased.URA System object.

Example: `sArray= phased.URA;`

`FREQ` — Frequency for computing directivity and patterns

positive scalar | 1-by-*L* real-valued row vector

Frequencies for computing directivity and patterns, specified as a positive scalar or 1-by-*L* real-valued row vector. Frequency units are in hertz.

- For an antenna, microphone, or sonar hydrophone or projector element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `-Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `-Inf`.

Example: `[1e8 2e6]`

Data Types: `double`

`AZ` — Azimuth angles

`[-180:180]` (default) | 1-by-*M* real-valued row vector

Azimuth angles for computing directivity and pattern, specified as a 1-by-*M* real-valued row vector where *M* is the number of azimuth angles. Angle units are in degrees. Azimuth angles must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. When measured from the *x*-axis toward the *y*-axis, this angle is positive.

Example: `[-45:2:45]`

Data Types: `double`

`EL` — Elevation angles

`[-90:90]` (default) | 1-by-*N* real-valued row vector

Elevation angles for computing directivity and pattern, specified as a 1-by-*N* real-valued row vector where *N* is the number of desired elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and *xy*-plane. When measured towards the *z*-axis, this angle is positive.

Example: `[-75:1:70]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'CoordinateSystem'` — Plotting coordinate system

`'polar'` (default) | `'rectangular'` | `'uv'`

Plotting coordinate system of the pattern, specified as the comma-separated pair consisting of `'CoordinateSystem'` and one of `'polar'`, `'rectangular'`, or `'uv'`. When `'CoordinateSystem'` is set to `'polar'` or `'rectangular'`, the `AZ` and `EL` arguments specify the pattern azimuth and elevation, respectively. `AZ` values must lie between –180° and 180°. `EL` values must lie between –90° and 90°. If `'CoordinateSystem'` is set to `'uv'`, `AZ` and `EL` then specify *U* and *V* coordinates, respectively. `AZ` and `EL` must lie between -1 and 1.

Example: `'uv'`

Data Types: `char`

'Type' — Displayed pattern type
'directivity' (default) | 'efield' | 'power' | 'powerdb'

Displayed pattern type, specified as the comma-separated pair consisting of 'Type' and one of

- 'directivity' — directivity pattern measured in dBi.
- 'efield' — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- 'power' — power pattern of the sensor or array defined as the square of the field pattern.
- 'powerdb' — power pattern converted to dB.

Example: 'powerdb'

Data Types: char

'Normalize' — Display normalize pattern
true (default) | false

Display normalized pattern, specified as the comma-separated pair consisting of 'Normalize' and a Boolean. Set this parameter to true to display a normalized pattern. When you set 'Type' to 'directivity', this parameter does not apply. Directivity patterns are already normalized.

Example:

Data Types: logical

'PlotStyle' — Plotting style
'overlay' (default) | 'waterfall'

Plotting style, specified as the comma-separated pair consisting of 'Plotstyle' and either 'overlay' or 'waterfall'. This parameter applies when you specify multiple frequencies in FREQ in 2-D plots. You can draw 2-D plots by setting one of the arguments AZ or EL to a scalar.

Example:

Data Types: char

'Polarization' — Polarized field component
'combined' (default) | 'H' | 'V'

Polarized field component to display, specified as the comma-separated pair consisting of 'Polarization' and `'combined'`, `'H'`, or `'V'`. This parameter applies only when the sensors are polarization-capable and when the `'Type'` parameter is not set to `'directivity'`. This table shows the meaning of the display options

`'Polarization'`	Display
`'combined'`	Combined *H* and *V* polarization components
`'H'`	*H* polarization component
`'V'`	*V* polarization component

Example: `'V'`

Data Types: `char`

`'PropagationSpeed'` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

`'Weights'` — Array weights

1 (default) | *N*-by-1 complex-valued column vector | *N*-by-*L* complex-valued matrix

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *N*-by-1 complex-valued column vector or *N*-by-*L* complex-valued matrix. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *N* is the number of elements in the array. The dimension *L* is the number of frequencies specified by `FREQ`.

Weights Dimension	FREQ Dimension	Purpose
N-by-1 complex-valued column vector	Scalar or 1-by-*L* row vector	Applies a set of weights for the single frequency or for all *L* frequencies.
N-by-*L* complex-valued matrix	1-by-*L* row vector	Applies each of the *L* columns of `'Weights'` for

Weights Dimension	FREQ Dimension	Purpose
		the corresponding frequency in FREQ.

Note: Use complex weights to steer the array response toward different directions. You can create weights using the phased.SteeringVector System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as phased.Radiator or phased.Collector. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(N,M)`

Data Types: `double`
Complex Number Support: Yes

Output Arguments

PAT — Array pattern

M-by-*N* real-valued matrix

Array pattern, returned as an *M*-by-*N* real-valued matrix. The dimensions of PAT correspond to the dimensions of the output arguments AZ_ANG and EL_ANG.

AZ_ANG — Azimuth angles

scalar | 1-by-*M* real-valued row vector

Azimuth angles for displaying directivity or response pattern, returned as a scalar or 1-by-*M* real-valued row vector corresponding to the dimension set in AZ. The rows of PAT correspond to the values in AZ_ANG.

EL_ANG — Elevation angles

scalar | 1-by-*N* real-valued row vector

Elevation angles for displaying directivity or response, returned as a scalar or 1-by-*N* real-valued row vector corresponding to the dimension set in EL. The columns of PAT correspond to the values in EL_ANG.

Examples

Pattern of 5x7-Element URA Antenna Array

Create a 5x7-element URA operating at 1 GHz. Assume the elements are spaced one-half wavelength apart. Show the 3-D array patterns.

Create the array

```
sSD = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[50e6,1000e6],...
    'AxisDirection','Z');
fc = 500e6;
c = physconst('LightSpeed');
lam = c/fc;
sURA = phased.URA('Element',sSD,...
    'Size',[5,7],...
    'ElementSpacing',0.5*lam);
```

Call the `step` method

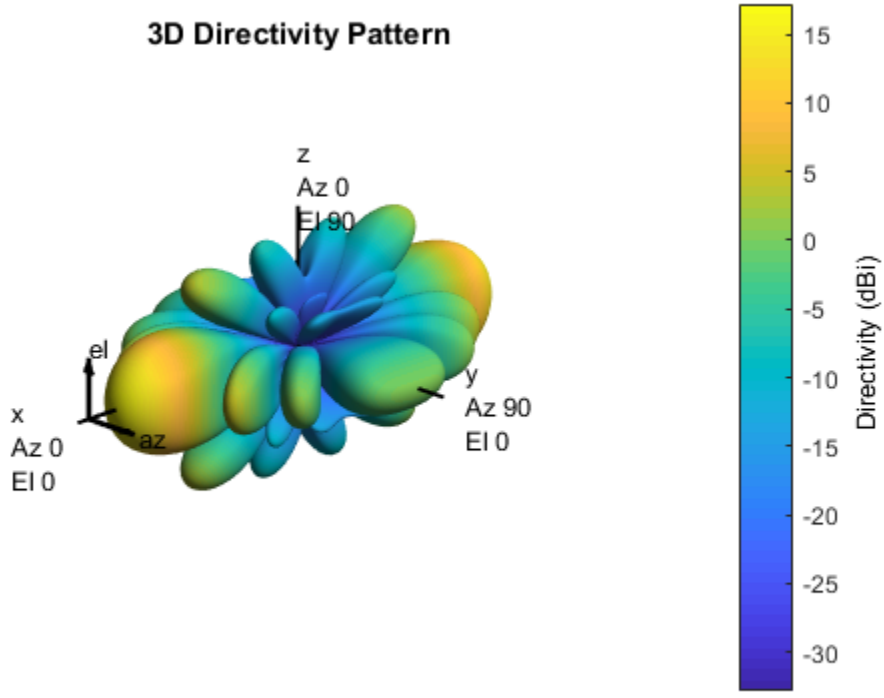
Evaluate the fields of the first five elements at 45 degrees azimuth and 0 degrees elevation.

```
ang = [45;0];
resp = step(sURA,fc,ang);
disp(resp.V(1:5))
```

```
   -1.2247
   -1.2247
   -1.2247
   -1.2247
   -1.2247
```

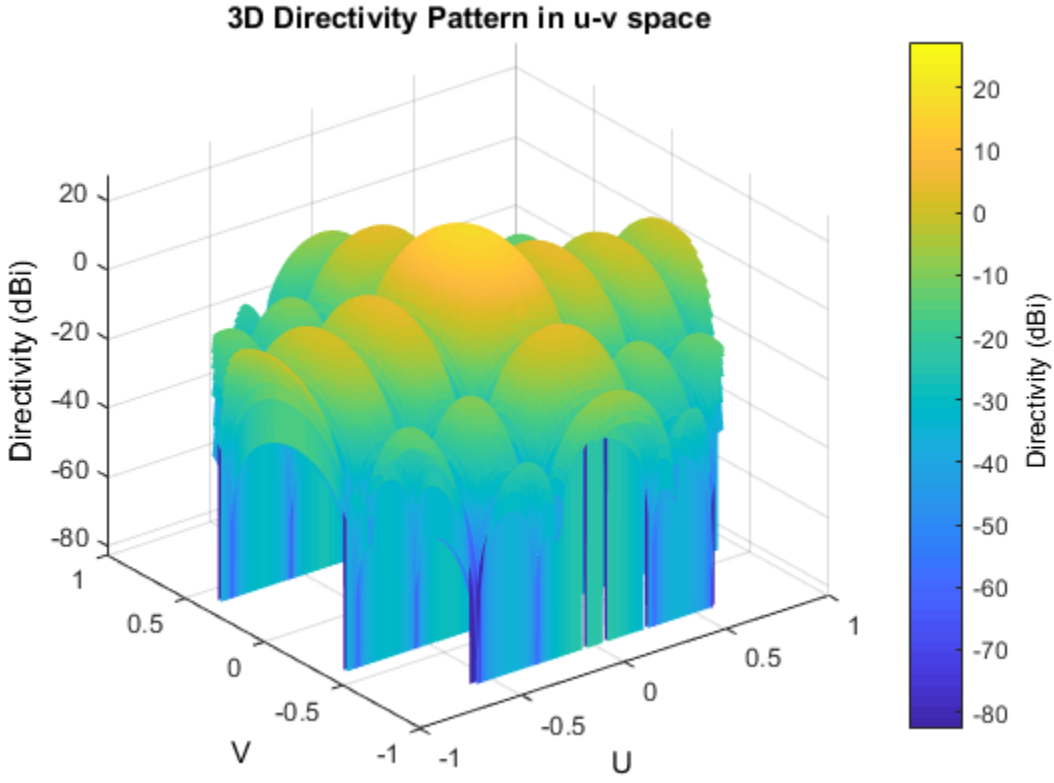
Display the 3-D directivity pattern at 1 GHz in polar coordinates

```
pattern(sURA,fc,[-180:180],[-90:90],...
    'CoordinateSystem','polar',...
    'Type','directivity','PropagationSpeed',c)
```



Display the 3-D directivity pattern at 1 GHz in UV coordinates

```
pattern(sURA,fc,[-1.0:.01:1.0],[-1.0:.01:1.0],...
    'CoordinateSystem','uv',...
    'Type','directivity','PropagationSpeed',c)
```



More About

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on "Element directivity" and "Array directivity".

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

Convert plotResponse to pattern

For antenna, microphone, and array System objects, the `pattern` method replaces the `plotResponse` method. In addition, two new simplified methods exist just to draw 2-D azimuth and elevation pattern plots. These methods are the `azimuthPattern` and `elevationPattern` methods.

The following table is a guide for converting your code from using `plotResponse` to `pattern`. Notice that some of the inputs have changed from *input arguments* to *Name-Value* pairs and conversely. The general `pattern` method syntax is

```
pattern(H,FREQ,AZ,EL,'Name1','Value1',...,'NameN','ValueN')
```

plotResponse Inputs	plotResponse Description	pattern Inputs
`H` argument	Antenna, microphone, or array System object.	`H` argument (no change)
`FREQ` argument	Operating frequency.	`FREQ` argument (no change)

plotResponse Inputs	plotResponse Description	pattern Inputs
`V` argument	Propagation speed. This argument is used only for arrays.	`'PropagationSpeed'` name-value pair. This parameter is only used for arrays.

<table>
<tr><th>plotResponse Inputs</th><th>plotResponse Description</th><th>pattern Inputs</th></tr>
<tr>
<td>'Format' and 'RespCut' name-value pairs</td>
<td>These options work together to let you create a plot in angle space (line or polar style) or UV space. They also determine whether the plot is 2-D or 3-D. This table shows you how to create different types of plots using plotResponse.
<table>

phased.URA.patternAzimuth | phased.URA.patternElevation

Introduced in R2015a

patternAzimuth

System object: phased.URA
Package: phased

Plot URA array directivity or pattern versus azimuth

Syntax

```
patternAzimuth(sArray,FREQ)
patternAzimuth(sArray,FREQ,EL)
patternAzimuth(sArray,FREQ,EL,Name,Value)
PAT = patternAzimuth( ___ )
```

Description

`patternAzimuth(sArray,FREQ)` plots the 2-D array directivity pattern versus azimuth (in dBi) for the array `sArray` at zero degrees elevation angle. The argument `FREQ` specifies the operating frequency.

`patternAzimuth(sArray,FREQ,EL)`, in addtion, plots the 2-D array directivity pattern versus azimuth (in dBi) for the array `sArray` at the elevation angle specified by `EL`. When `EL` is a vector, multiple overlaid plots are created.

`patternAzimuth(sArray,FREQ,EL,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternAzimuth( ___ )` returns the array pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Azimuth'` parameter and the `EL` input argument.

Input Arguments

`sArray` — Uniform rectangular array

System object

Uniform rectangular array, specified as a phased.URA System object.

Example: `sArray= phased.URA;`

`FREQ` — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

`EL` — Elevation angles

1-by-*N* real-valued row vector

Elevation angles for computing sensor or array directivities and patterns, specified as a 1-by-*N* real-valued row vector. The quantity *N* is the number of requested elevation directions. Angle units are in degrees. The elevation angle must lie between –90° and 90°.

The elevation angle is the angle between the direction vector and the *xy* plane. When measured toward the *z*-axis, this angle is positive.

Example: `[0,10,20]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'Type' — Displayed pattern type

'directivity' (default) | 'efield' | 'power' | 'powerdb'

Displayed pattern type, specified as the comma-separated pair consisting of 'Type' and one of

- 'directivity' — directivity pattern measured in dBi.
- 'efield' — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- 'power' — power pattern of the sensor or array defined as the square of the field pattern.
- 'powerdb' — power pattern converted to dB.

Example: 'powerdb'

Data Types: char

'PropagationSpeed' — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of 'PropagationSpeed' and a positive scalar in meters per second.

Example: 'PropagationSpeed',physconst('LightSpeed')

Data Types: double

'Weights' — Array weights

M-by-1 complex-valued column vector

Array weights, specified as the comma-separated pair consisting of 'Weights' and an *M*-by-1 complex-valued column vector. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *M* is the number of elements in the array.

Note: Use complex weights to steer the array response toward different directions. You can create weights using the phased.SteeringVector System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as phased.Radiator or phased.Collector. However, for the directivity, pattern, patternAzimuth, and patternElevation methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(10,1)`

Data Types: `double`
Complex Number Support: Yes

`'Azimuth'` — Azimuth angles

`[-180:180]` (default) | 1-by-*P* real-valued row vector

Azimuth angles, specified as the comma-separated pair consisting of `'Azimuth'` and a 1-by-*P* real-valued row vector. Azimuth angles define where the array pattern is calculated.

Example: `'Azimuth',[-90:2:90]`

Data Types: `double`

Output Arguments

`PAT` — Array directivity or pattern

L-by-*N* real-valued matrix

Array directivity or pattern, returned as an *L*-by-*N* rea-valued matrix. The dimension *L* is the number of azimuth values determined by the `'Azimuth'` name-value pair argument. The dimension *N* is the number of elevation angles, as determined by the `EL` input argument.

Examples

Azimuth Pattern of 5x7-Element URA Antenna Array

Create a 5x7-element URA of short-dipole antenna elements operating at 1 GHz. Assume the elements are spaced one-half wavelength apart. Plot the array azimuth directivity patterns for two different elevation angles, 0 and 15 degrees. The `patternAzimuth` method always plots the array pattern in polar coordinates.

Create the array

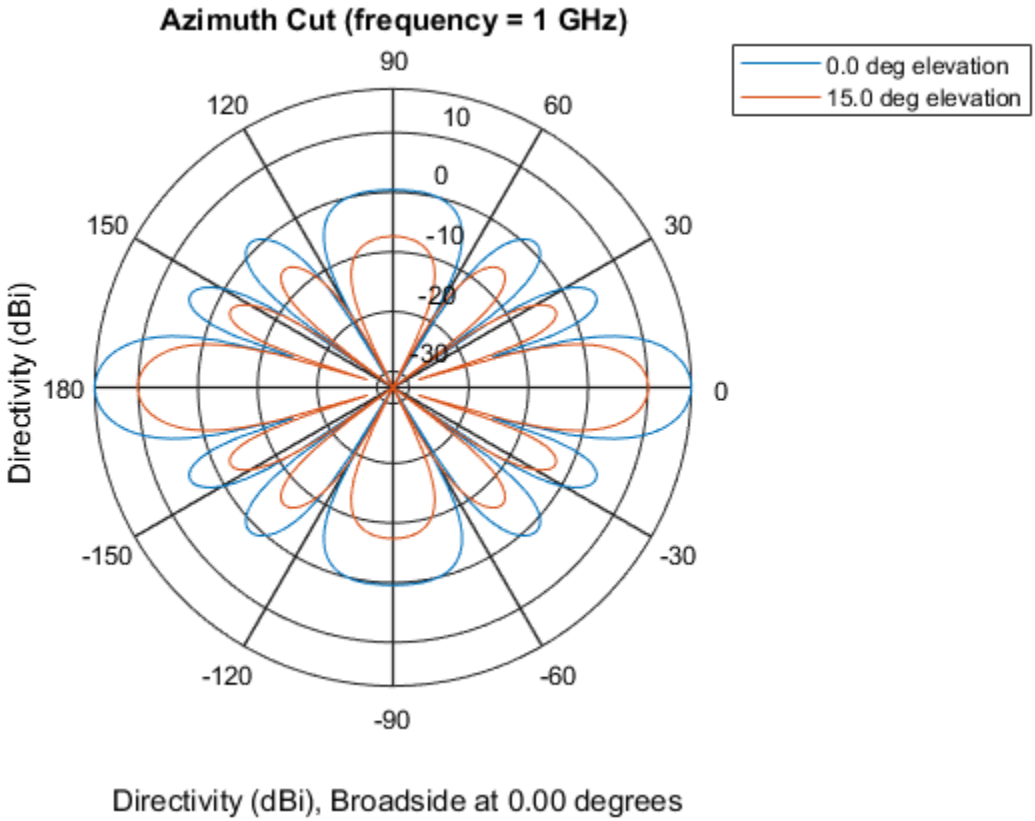
```
sSD = phased.ShortDipoleAntennaElement(...
    'FrequencyRange',[50e6,1000e6],...
    'AxisDirection','Z');
fc = 1e9;
c = physconst('LightSpeed');
lam = c/fc;
```

```
sURA = phased.URA('Element',sSD,...
    'Size',[5,7],...
    'ElementSpacing',0.5*lam);
```

Display the pattern

Display the azimuth directivity pattern at 1 GHz in polar coordinates

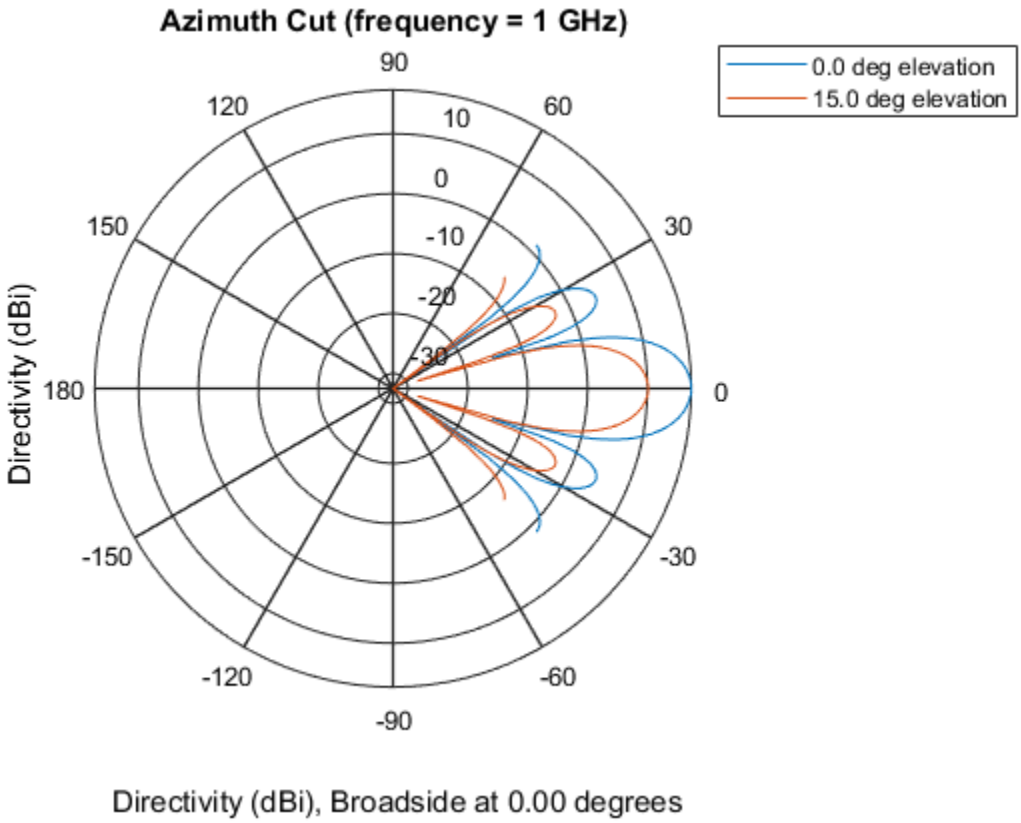
```
patternAzimuth(sURA,fc,[0 15],...
    'PropagationSpeed',c,...
    'Type','directivity')
```



Display a subset of angles

You can plot a smaller range of azimuth angles by setting the `Azimuth` parameter.

```
patternAzimuth(sURA,fc,[0 15],...
    'PropagationSpeed',c,...
    'Type','directivity',...
    'Azimuth',[-45:45])
```



Definitions

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit

more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on “Element directivity” and “Array directivity”.

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

phased.URA.pattern | phased.URA.patternElevation

Introduced in R2015a

patternElevation

System object: phased.URA
Package: phased

Plot URA array directivity or pattern versus elevation

Syntax

```
patternElevation(sArray,FREQ)
patternElevation(sArray,FREQ,AZ)
patternElevation(sArray,FREQ,AZ,Name,Value)
PAT = patternElevation( ___ )
```

Description

`patternElevation(sArray,FREQ)` plots the 2-D array directivity pattern versus elevation (in dBi) for the array `sArray` at zero degrees azimuth angle. When `AZ` is a vector, multiple overlaid plots are created. The argument `FREQ` specifies the operating frequency.

`patternElevation(sArray,FREQ,AZ)`, in addition, plots the 2-D element directivity pattern versus elevation (in dBi) at the azimuth angle specified by `AZ`. When `AZ` is a vector, multiple overlaid plots are created.

`patternElevation(sArray,FREQ,AZ,Name,Value)` plots the array pattern with additional options specified by one or more `Name,Value` pair arguments.

`PAT = patternElevation( ___ )` returns the array pattern. `PAT` is a matrix whose entries represent the pattern at corresponding sampling points specified by the `'Elevation'` parameter and the `AZ` input argument.

Input Arguments

`sArray` — Uniform rectangular array

System object

Uniform rectangular array, specified as a phased.URA System object.

Example: `sArray= phased.URA;`

FREQ — Frequency for computing directivity and pattern

positive scalar

Frequency for computing directivity and pattern, specified as a positive scalar. Frequency units are in hertz.

- For an antenna or microphone element, `FREQ` must lie within the range of values specified by the `FrequencyRange` or the `FrequencyVector` property of the element. Otherwise, the element produces no response and the directivity is returned as `–Inf`. Most elements use the `FrequencyRange` property except for phased.CustomAntennaElement and phased.CustomMicrophoneElement, which use the `FrequencyVector` property.
- For an array of elements, `FREQ` must lie within the frequency range of the elements that make up the array. Otherwise, the array produces no response and the directivity is returned as `–Inf`.

Example: `1e8`

Data Types: `double`

AZ — Azimuth angles for computing directivity and pattern

1-by-*N* real-valued row vector

Azimuth angles for computing sensor or array directivities and patterns, specified as a 1-by-*M* real-valued row vector where *N* is the number of desired azimuth directions. Angle units are in degrees. The azimuth angle must lie between –180° and 180°.

The azimuth angle is the angle between the *x*-axis and the projection of the direction vector onto the *xy* plane. This angle is positive when measured from the *x*-axis toward the *y*-axis.

Example: `[0,10,20]`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Type'` — Displayed pattern type

`'directivity'` (default) | `'efield'` | `'power'` | `'powerdb'`

Displayed pattern type, specified as the comma-separated pair consisting of `'Type'` and one of

- `'directivity'` — directivity pattern measured in dBi.
- `'efield'` — field pattern of the sensor or array. For acoustic sensors, the displayed pattern is for the scalar sound field.
- `'power'` — power pattern of the sensor or array defined as the square of the field pattern.
- `'powerdb'` — power pattern converted to dB.

Example: `'powerdb'`

Data Types: `char`

`'PropagationSpeed'` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as the comma-separated pair consisting of `'PropagationSpeed'` and a positive scalar in meters per second.

Example: `'PropagationSpeed',physconst('LightSpeed')`

Data Types: `double`

`'Weights'` — Array weights

M-by-1 complex-valued column vector

Array weights, specified as the comma-separated pair consisting of `'Weights'` and an *M*-by-1 complex-valued column vector. Array weights are applied to the elements of the array to produce array steering, tapering, or both. The dimension *M* is the number of elements in the array.

Note: Use complex weights to steer the array response toward different directions. You can create weights using the phased.SteeringVector System object or you can compute your own weights. In general, you apply Hermitian conjugation before using weights in any Phased Array System Toolbox function or System object such as phased.Radiator or phased.Collector. However, for the `directivity`, `pattern`, `patternAzimuth`, and `patternElevation` methods of any array System object use the steering vector without conjugation.

Example: `'Weights',ones(10,1)`

Data Types: `double`
Complex Number Support: Yes

`'Elevation'` — Elevation angles

`[-90:90]` (default) | 1-by-*P* real-valued row vector

Elevation angles, specified as the comma-separated pair consisting of `'Elevation'` and a 1-by-*P* real-valued row vector. Elevation angles define where the array pattern is calculated.

Example: `'Elevation',[-90:2:90]`

Data Types: `double`

Output Arguments

`PAT` — Array directivity or pattern

L-by-*N* real-valued matrix

Array directivity or pattern, returned as an *L*-by-*N* real-valued matrix. The dimension *L* is the number of elevation angles determined by the `'Elevation'` name-value pair argument. The dimension *N* is the number of azimuth angles determined by the `AZ` argument.

Examples

Elevation Pattern of 7x7-Element URA Acoustic Array

Create a 7x7-element URA of backbaffled omnidirectional transducer elements operating at 2 kHz. Assume the speed of sound in water is 1500 m/s. The elements are spaced less than one-half wavelength apart. Plot the array elevation directivity patterns for three different azimuth angles, -20, 0, and 15 degrees. The `patternElevation` method always plots the array pattern in polar coordinates.

Create the array

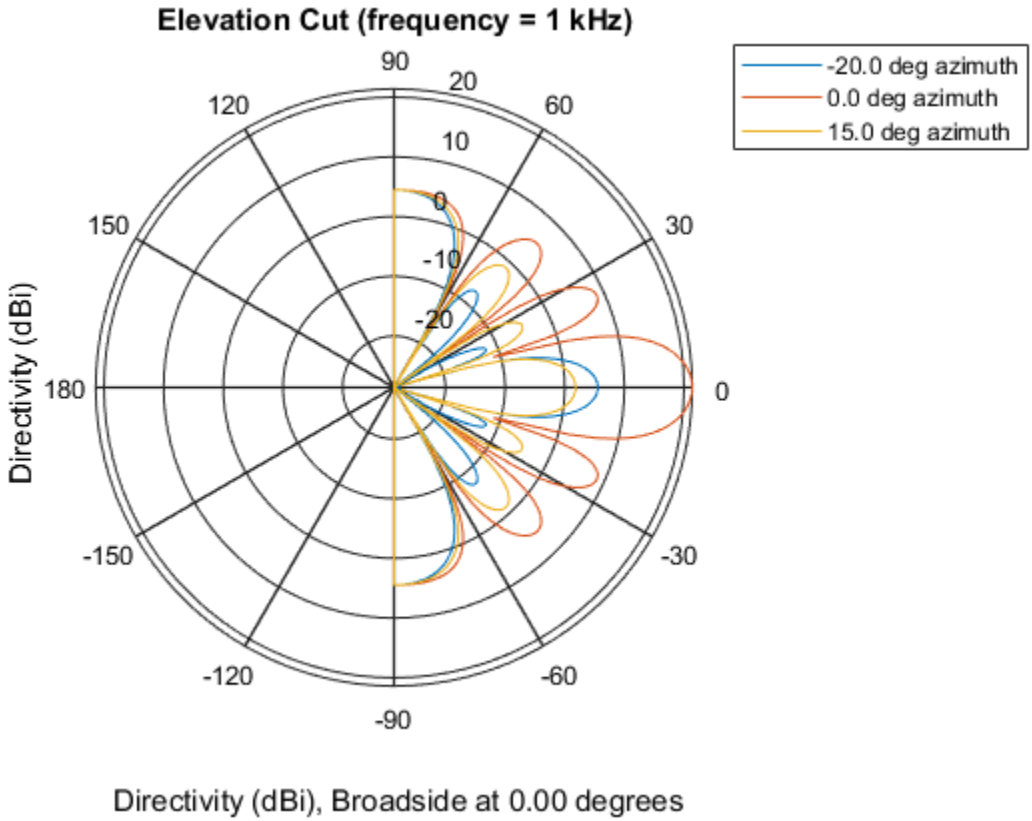
```
sSD = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[20,3000],...
    'BackBaffled',true);
```

```
fc = 1000;
c = 1500;
lam = c/fc;
sURA = phased.URA('Element',sSD,...
    'Size',[7,7],...
    'ElementSpacing',0.5*lam);
```

Display the pattern

Display the azimuth directivity pattern at 1 GHz in polar coordinates

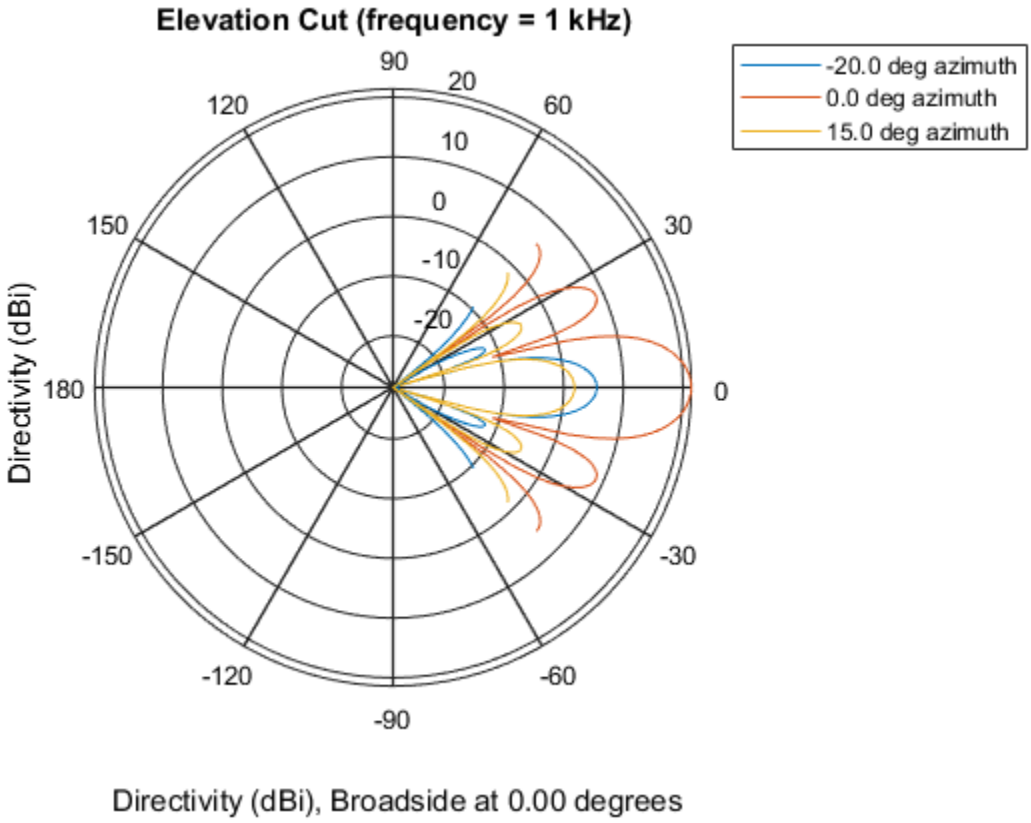
```
patternElevation(sURA,fc,[-20, 0, 15],...
    'PropagationSpeed',c,...
    'Type','directivity')
```



Display a subset of elevation angles

You can plot a smaller range of elevation angles by setting the `Elevation` parameter.

```
patternElevation(sURA,fc,[-20, 0, 15],...
    'PropagationSpeed',c,...
    'Type','directivity',...
    'Elevation',[-45:45])
```



Definitions

Directivity

Directivity describes the directionality of the radiation pattern of a sensor element or array of sensor elements. Higher directivity is desired when you want to transmit more radiation in a specific direction. Directivity is the ratio of the transmitted radiant intensity in a specified direction to the radiant intensity transmitted by an isotropic radiator with the same total transmitted power

$$D = 4\pi \frac{U_{\text{rad}}(\theta,\varphi)}{P_{\text{total}}}$$

where $U_{\text{rad}}(\theta,\varphi)$ is the radiant intensity of a transmitter in the direction (θ,φ) and P_{total} is the total power transmitted by an isotropic radiator. For a receiving element or array, directivity measures the sensitivity toward radiation arriving from a specific direction. The principle of reciprocity shows that the directivity of an element or array used for reception equals the directivity of the same element or array used for transmission. When converted to decibels, the directivity is denoted as *dBi*. For information on directivity, read the notes on "Element directivity" and "Array directivity".

Computing directivity requires integrating the far-field transmitted radiant intensity over all directions in space to obtain the total transmitted power. There is a difference between how that integration is performed when Antenna Toolbox antennas are used in a phased array and when Phased Array System Toolbox antennas are used. When an array contains Antenna Toolbox antennas, the directivity computation is performed using a triangular mesh created from 500 regularly spaced points over a sphere. For Phased Array System Toolbox antennas, the integration uses a uniform rectangular mesh of points spaced 1° apart in azimuth and elevation over a sphere. There may be significant differences in computed directivity, especially for large arrays.

Introduced in R2015a

isPolarizationCapable

System object: phased.URA
Package: phased

Polarization capability

Syntax

```
flag = isPolarizationCapable(h)
```

Description

`flag = isPolarizationCapable(h)` returns a Boolean value, `flag`, indicating whether the array supports polarization. An array supports polarization if all of its constituent sensor elements support polarization.

Input Arguments

h — Uniform rectangular array

Uniform rectangular array specified as phased.URA System object.

Output Arguments

flag — Polarization-capability flag

Polarization-capability flag returned as a Boolean value, `true`, if the array supports polarization or, `false`, if it does not.

Examples

Short-Dipole URA Supports Polarization

Show that a URA array of `phased.ShortDipoleAntennaElement` short-dipole antenna elements supports polarization.

```
antenna = phased.ShortDipoleAntennaElement('FrequencyRange',[1e9 10e9]);
array = phased.URA([3,2],'Element',antenna);
isPolarizationCapable(array)
```

```
ans =

  logical

   1
```

The returned value `1` shows that this array supports polarization.

plotResponse

System object: phased.URA
Package: phased

Plot response pattern of array

Syntax

```
plotResponse(H,FREQ,V)
plotResponse(H,FREQ,V,Name,Value)
hPlot = plotResponse( ___ )
```

Description

`plotResponse(H,FREQ,V)` plots the array response pattern along the azimuth cut, where the elevation angle is 0. The operating frequency is specified in `FREQ`. The propagation speed is specified in `V`.

`plotResponse(H,FREQ,V,Name,Value)` plots the array response with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = plotResponse( ___ )` returns handles of the lines or surface in the figure window, using any of the input arguments in the previous syntaxes.

Input Arguments

`H`

Array object

`FREQ`

Operating frequency in Hertz specified as a scalar or 1-by-*K* row vector. Values must lie within the range specified by a property of `H`. That property is named `FrequencyRange` or `FrequencyVector`, depending on the type of element in the array. The element has no response at frequencies outside that range. If you set the `'RespCut'` property of `H` to

'3D', FREQ must be a scalar. When FREQ is a row vector, plotResponse draws multiple frequency responses on the same axes.

V

Propagation speed in meters per second.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

'CutAngle'

Cut angle as a scalar. This argument is applicable only when RespCut is 'Az' or 'El'. If RespCut is 'Az', CutAngle must be between –90 and 90. If RespCut is 'El', CutAngle must be between –180 and 180.

Default: 0

'Format'

Format of the plot, using one of 'Line', 'Polar', or 'UV'. If you set Format to 'UV', FREQ must be a scalar.

Default: 'Line'

'NormalizeResponse'

Set this value to true to normalize the response pattern. Set this value to false to plot the response pattern without normalizing it. This parameter is not applicable when you set the Unit parameter value to 'dbi'.

Default: true

'OverlayFreq'

Set this value to true to overlay pattern cuts in a 2-D line plot. Set this value to false to plot pattern cuts against frequency in a 3-D waterfall plot. If this value is false, FREQ must be a vector with at least two entries.

This parameter applies only when `Format` is not `'Polar'` and RespCut is not `'3D'`.

Default: `true`

`'Polarization'`

Specify the polarization options for plotting the array response pattern. The allowable values are `|'None' | 'Combined' | 'H' | 'V' |` where

- `'None'` specifies plotting a nonpolarized response pattern
- `'Combined'` specifies plotting a combined polarization response pattern
- `'H'` specifies plotting the horizontal polarization response pattern
- `'V'` specifies plotting the vertical polarization response pattern

For arrays that do not support polarization, the only allowed value is `'None'`. This parameter is not applicable when you set the `Unit` parameter value to `'dbi'`.

Default: `'None'`

`'RespCut'`

Cut of the response. Valid values depend on `Format`, as follows:

- If `Format` is `'Line'` or `'Polar'`, the valid values of `RespCut` are `'Az'`, `'El'`, and `'3D'`. The default is `'Az'`.
- If `Format` is `'UV'`, the valid values of `RespCut` are `'U'` and `'3D'`. The default is `'U'`.

If you set `RespCut` to `'3D'`, `FREQ` must be a scalar.

`'Unit'`

The unit of the plot. Valid values are `'db'`, `'mag'`, `'pow'`, or `'dbi'`. This parameter determines the type of plot that is produced.

Unit value	Plot type
`db`	power pattern in dB scale
`mag`	field pattern
`pow`	power pattern
`dbi`	directivity

Default: `'db'`

`'Weights'`

Weight values applied to the array, specified as a length-*N* column vector or *N*-by-*M* matrix. The dimension *N* is the number of elements in the array. The interpretation of *M* depends upon whether the input argument `FREQ` is a scalar or row vector.

Weights Dimensions	FREQ Dimension	Purpose
N-by-1 column vector	Scalar or 1-by-*M* row vector	Apply one set of weights for the same single frequency or all *M* frequencies.
N-by-*M* matrix	Scalar	Apply all of the *M* different columns in `Weights` for the same single frequency.
	1-by-*M* row vector	Apply each of the *M* different columns in `Weights` for the corresponding frequency in `FREQ`.

`'AzimuthAngles'`

Azimuth angles for plotting array response, specified as a row vector. The `AzimuthAngles` parameter sets the display range and resolution of azimuth angles for visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'Az'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of azimuth angles should lie between –180° and 180° and must be in nondecreasing order. When you set the `RespCut` parameter to `'3D'`, you can set the `AzimuthAngles` and `ElevationAngles` parameters simultaneously.

Default: `[-180:180]`

`'ElevationAngles'`

Elevation angles for plotting array response, specified as a row vector. The `ElevationAngles` parameter sets the display range and resolution of elevation angles for visualizing the radiation pattern. This parameter is allowed only when the `RespCut` parameter is set to `'El'` or `'3D'` and the `Format` parameter is set to `'Line'` or `'Polar'`. The values of elevation angles should lie between –90° and 90° and must be

in nondecreasing order. When yous set the `RespCut` parameter to `'3D'`, you can set the `ElevationAngles` and `AzimuthAngles` parameters simultaneously.

Default: `[-90:90]`

`'UGrid'`

U coordinate values for plotting array response, specified as a row vector. The `UGrid` parameter sets the display range and resolution of the *U* coordinates for visualizing the radiation pattern in *U*/*V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'U'` or `'3D'`. The values of `UGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set the `UGrid` and `VGrid` parameters simultaneously.

Default: `[-1:0.01:1]`

`'VGrid'`

V coordinate values for plotting array response, specified as a row vector. The `VGrid` parameter sets the display range and resolution of the *V* coordinates for visualizing the radiation pattern in *U*/*V* space. This parameter is allowed only when the `Format` parameter is set to `'UV'` and the `RespCut` parameter is set to `'3D'`. The values of `VGrid` should be between –1 and 1 and should be specified in nondecreasing order. You can set `VGrid` and `UGrid` parameters simultaneously.

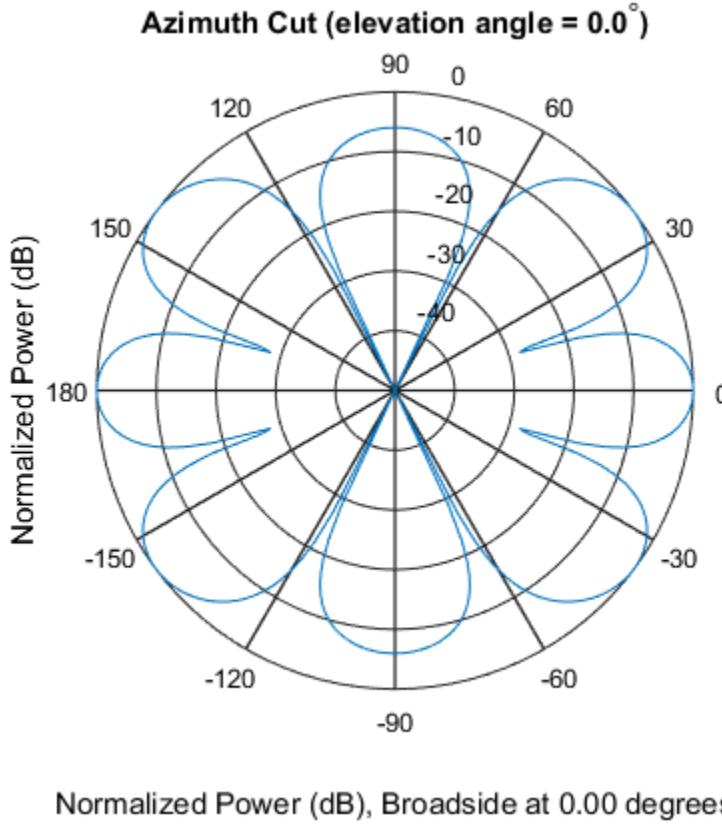
Default: `[-1:0.01:1]`

Examples

Azimuth Response of URA

This example shows how to construct a rectangular lattice 3-by-2 URA and plot that array's azimuth response.

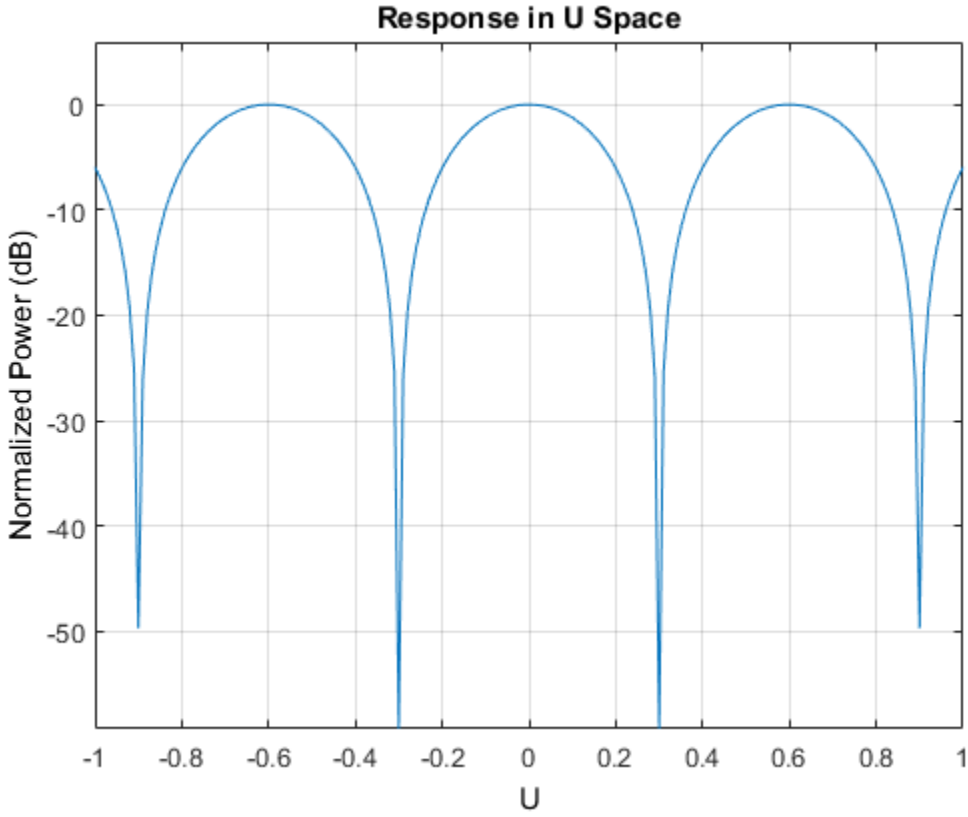
```
ha = phased.URA('Size',[3 2]);
fc = 1e9;
c = physconst('LightSpeed');
plotResponse(ha,fc,c,'RespCut','Az','Format','Polar');
```



Array Response and Directivity of URA in U/V Space

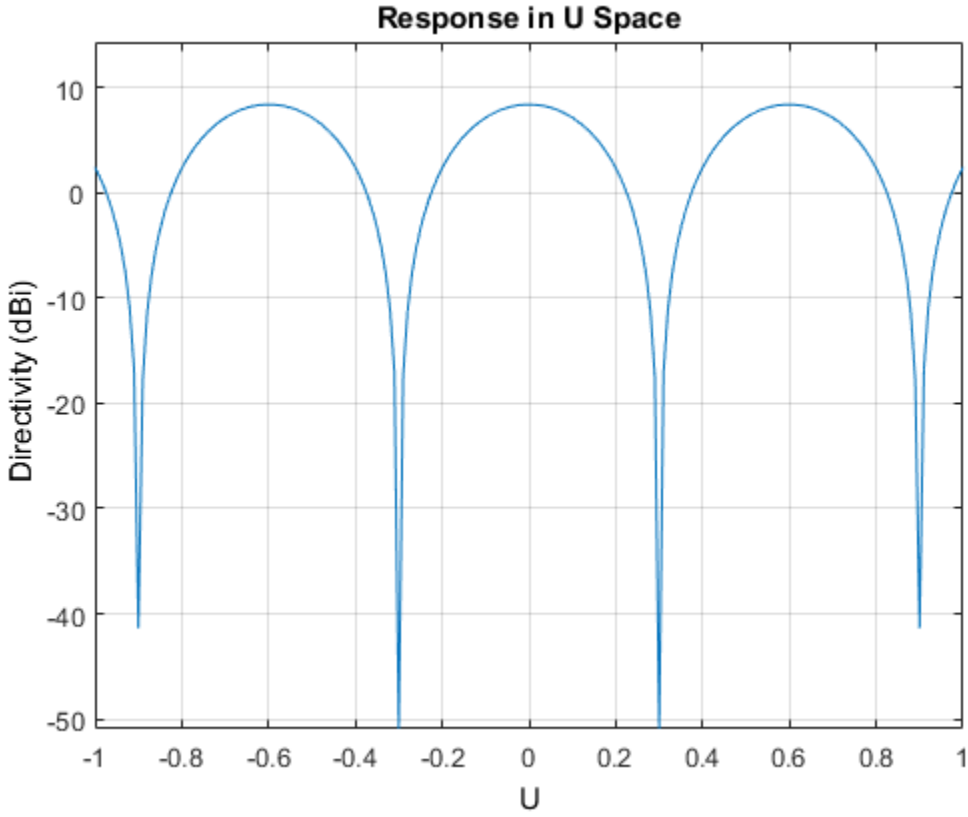
This example shows how to construct a rectangular lattice 3-by-2 URA. Plot the u cut of the array response in $u - v$ space.

```
ha = phased.URA('Size',[3 2]);
c = physconst('lightspeed');
plotResponse(ha,1e9,c,'Format','UV');
```



Plot the directivity.

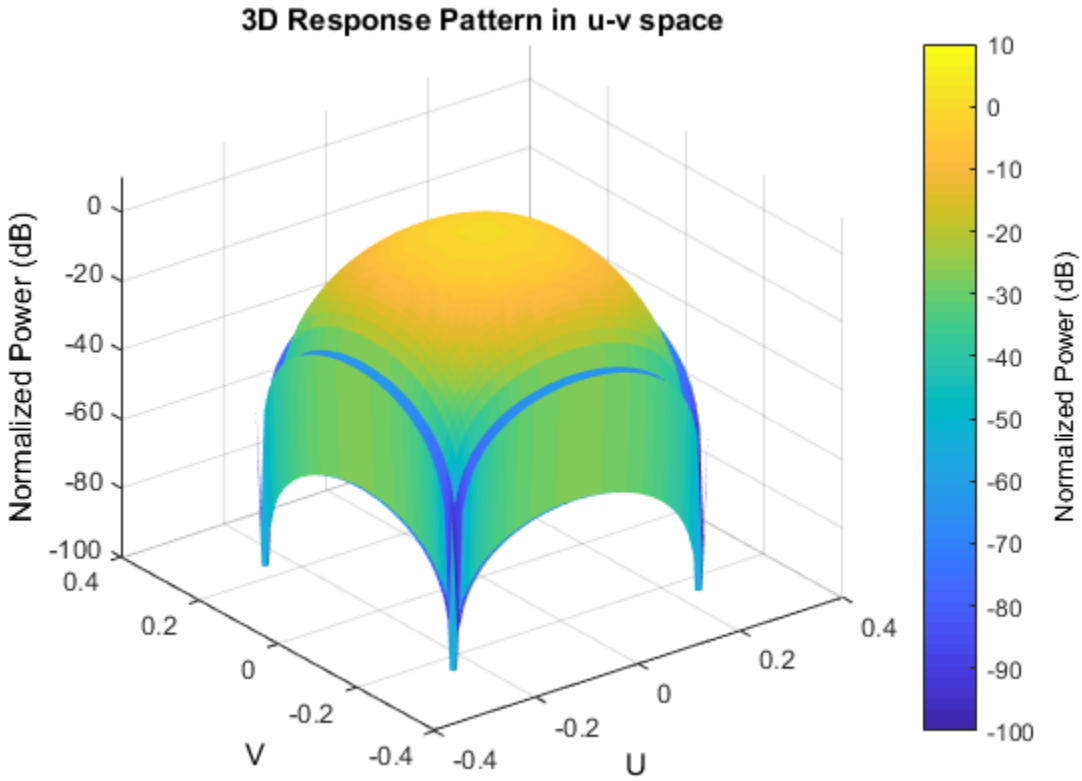
```
plotResponse(ha,1e9,c,'Format','UV','Unit','dbi');
```



Array Response of URA for Subrange of U/V Space

This example shows how to construct a 5-by-5 square URA and plot the 3-D response in u/v space. However, restrict the range in u/v space using the `UGrid` and `VGrid` parameters.

```
ha = phased.URA([5,5]);
fc = 5e8;
c = physconst('LightSpeed');
plotResponse(ha,fc,c,'RespCut','3D','Format','UV',...
    'UGrid',[-0.25:.01:.25],'VGrid',[-0.25:.01:.25]);
```



Array Response of URA with Two Sets of Weights

This example shows how to construct a square 5-by-5 URA array having elements spaced 0.3 meters apart. Apply both uniform weights and tapered weights at a single frequency using the `Weights` parameter. Choose the tapered weight values to be smallest at the edges and increasing towards the center. Then, show that the tapered weight set reduces the adjacent sidelobes while broadening the main lobe.

```
ha = phased.URA('Size',[5 5],'ElementSpacing',[0.3,0.3]);
fc = 1e9;
c = physconst('LightSpeed');
wts1 = ones(5,5);
wts1 = wts1(:);
wts1 = wts1/sum(wts1);
```

```
wts2 = 0.3*ones(5,5);
wts2(2:4,2:4) = 0.7;
wts2(3,3) = 1;
wts2 = wts2(:);
wts2 = wts2/sum(wts2);
plotResponse(ha,fc,c,'RespCut','Az','Format','Polar','Weights',[wts1,wts2]);
```

plotGratingLobeDiagram

System object: phased.URA
Package: phased

Plot grating lobe diagram of array

Syntax

```
plotGratingLobeDiagram(H,FREQ)
plotGratingLobeDiagram(H,FREQ,ANGLE)
plotGratingLobeDiagram(H,FREQ,ANGLE,C)
plotGratingLobeDiagram(H,FREQ,ANGLE,C,FO)
hPlot = plotGratingLobeDiagram( ___ )
```

Description

`plotGratingLobeDiagram(H,FREQ)` plots the grating lobe diagram of an array in the *u-v* coordinate system. The System object `H` specifies the array. The argument `FREQ` specifies the signal frequency and phase-shifter frequency. The array, by default, is steered to 0° azimuth and 0° elevation.

A grating lobe diagram displays the positions of the peaks of the narrowband *array pattern*. The array pattern depends only upon the geometry of the array and not upon the types of elements which make up the array. Visible and nonvisible grating lobes are displayed as open circles. Only grating lobe peaks near the location of the mainlobe are shown. The mainlobe itself is displayed as a filled circle.

`plotGratingLobeDiagram(H,FREQ,ANGLE)`, in addition, specifies the array steering angle, `ANGLE`.

`plotGratingLobeDiagram(H,FREQ,ANGLE,C)`, in addition, specifies the propagation speed by `C`.

`plotGratingLobeDiagram(H,FREQ,ANGLE,C,FO)`, in addition, specifies an array phase-shifter frequency, `FO`, that differs from the signal frequency, `FREQ`. This argument is useful when the signal no longer satisfies the narrowband assumption and, allows you to estimate the size of beam squint.

`hPlot = plotGratingLobeDiagram( ___ )` returns the handle to the plot for any of the input syntax forms.

Input Arguments

`H`

Antenna or microphone array, specified as a System object.

`FREQ`

Signal frequency, specified as a scalar. Frequency units are hertz. Values must lie within a range specified by the frequency property of the array elements contained in `H.Element`. The frequency property is named `FrequencyRange` or `FrequencyVector`, depending on the element type.

`ANGLE`

Array steering angle, specified as either a 2-by-1 vector or a scalar. If `ANGLE` is a vector, it takes the form `[azimuth;elevation]`. The azimuth angle must lie in the range `[-180°,180°]`. The elevation angle must lie in the range `[-90°,90°]`. All angle values are specified in degrees. If the argument `ANGLE` is a scalar, it specifies only the azimuth angle where the corresponding elevation angle is 0°.

Default: `[0;0]`

`C`

Signal propagation speed, specified as a scalar. Units are meters per second.

Default: Speed of light in vacuum

`FO`

Phase-shifter frequency of the array, specified as a scalar. Frequency units are hertz When this argument is omitted, the phase-shifter frequency is assumed to be the signal frequency, `FREQ`.

Default: `FREQ`

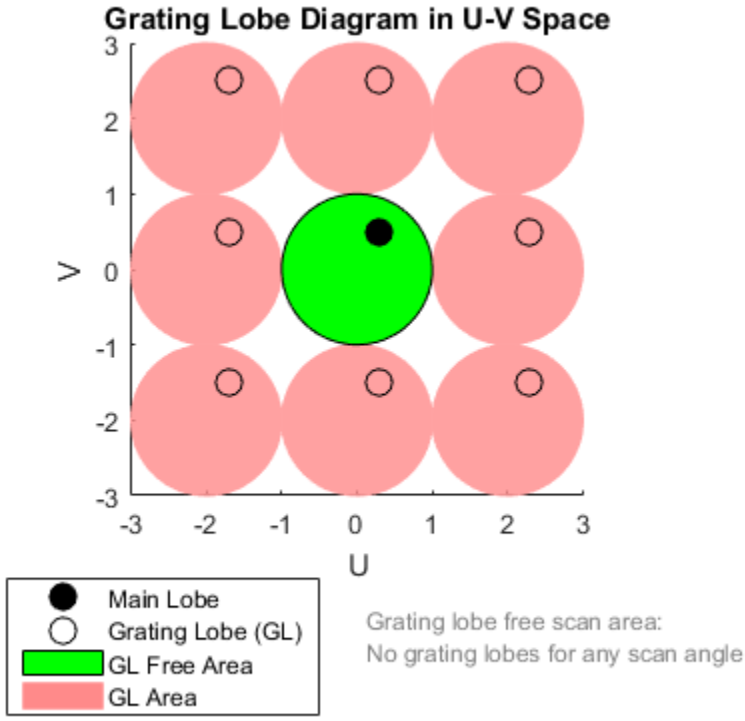
Examples

Grating Lobe Diagram for Microphone URA

Plot the grating lobe diagram for an 11-by-9-element uniform rectangular array having element spacing equal to one-half wavelength.

Assume the operating frequency of the array is 10 kHz. All elements are omnidirectional microphone elements. Steer the array in the direction 20 degrees in azimuth and 30 degrees in elevation. The speed of sound in air is 344.21 m/s at 21 deg C.

```
cair = 344.21;
f = 10.0e3;
lambda = cair/f;
microphone = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[20 20000]);
array = phased.URA('Element',microphone,'Size',[11,9],...
    'ElementSpacing',0.5*lambda*[1,1]);
plotGratingLobeDiagram(array,f,[20;30],cair);
```



Plot the grating lobes. The main lobe of the array is indicated by a filled black circle. The grating lobes in visible and nonvisible regions are indicated by unfilled black circles. The visible region is the region in u-v coordinates for which $u^2 + v^2 \leq 1$. The visible region is shown as a unit circle centered at the origin. Because the array spacing is less than one-half wavelength, there are no grating lobes in the visible region of space. There are an infinite number of grating lobes in the nonvisible regions, but only those in the range [-3,3] are shown.

The grating-lobe free region, shown in green, is the range of directions of the main lobe for which there are no grating lobes in the visible region. In this case, it coincides with the visible region.

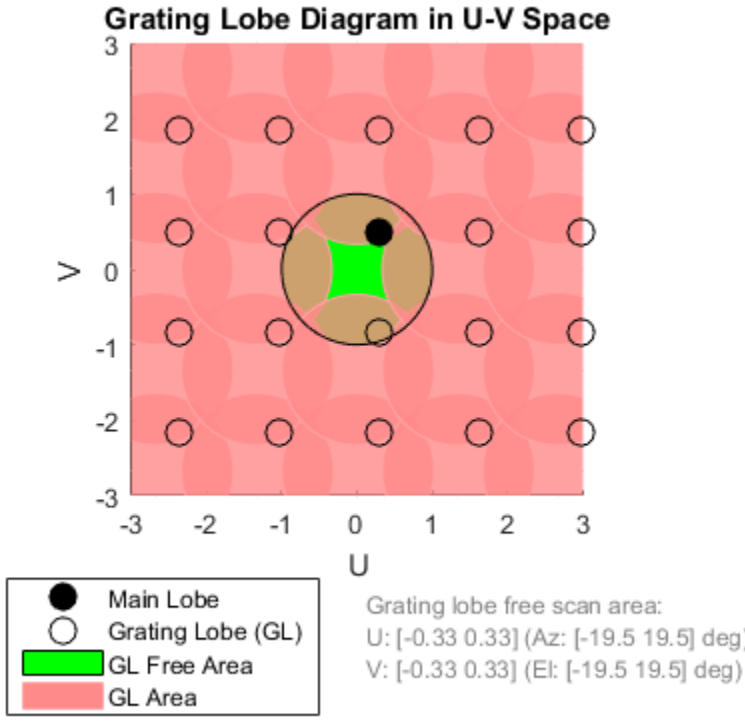
The white areas of the diagram indicate a region where no grating lobes are possible.

Create Grating Lobe Diagram for Undersampled Microphone URA

Plot the grating lobe diagram for an 11-by-9-element uniform rectangular array having element spacing greater than one-half wavelength. Grating lobes are plotted in u-v coordinates.

Assume the operating frequency of the array is 10 kHz and the spacing between elements is 0.75 of a wavelength. All elements are omnidirectional microphone elements. Steer the array in the direction 20 degrees in azimuth and 30 degrees in elevation. The speed of sound in air is 344.21 m/s at 21 deg C.

```
cair = 344.21;
f = 10000;
lambda = cair/f;
sMic = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[20 20000]);
sURA = phased.URA('Element',sMic,'Size',[11,9],...
    'ElementSpacing',0.75*lambda*[1,1]);
plotGratingLobeDiagram(sURA,f,[20;30],cair);
```



The main lobe of the array is indicated by a filled black circle. The grating lobes in visible and nonvisible regions are indicated by unfilled black circles. The visible region is the region in u-v coordinates for which $u^2 + v^2 \leq 1$. The visible region is shown as a unit circle centered at the origin. Because the array spacing is greater than one-half wavelength, there are grating lobes in the visible region of space. There are an infinite number of grating lobes in the nonvisible regions, but only those in the range [-3,3] are shown.

The grating-lobe free region, shown in green, is the range of directions of the main lobe for which there are no grating lobes in the visible region. In this case, it lies inside the

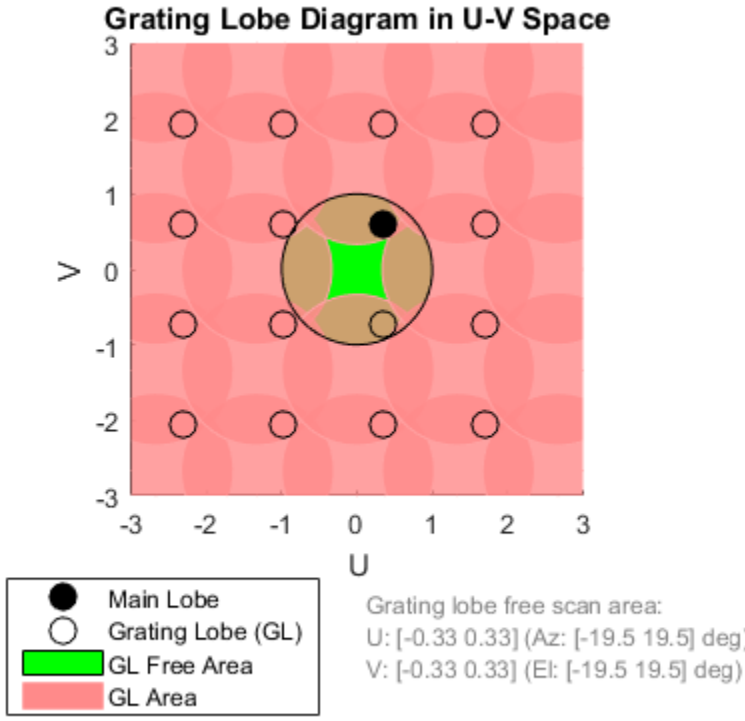
visible region. Because the mainlobe is outside the green area, there is a grating lobe within the visible region.

Create Grating Lobe Diagram for Microphone URA with Frequency Shift

Plot the grating lobe diagram for an 11-by-9-element uniform rectangular array having element spacing greater than one-half wavelength. Apply a 20% phase-shifter frequency offset. Grating lobes are plotted in u-v coordinates.

Assume the operating frequency of the array is 10 kHz and the spacing between elements is 0.75 of a wavelength. All elements are omnidirectional microphone elements. Steer the array in the direction 20 degrees in azimuth and 30 degrees in elevation. The shifted frequency is 12000 Hz. The speed of sound in air is 344.21 m/s at 21 deg C.

```
cair = 344.21;
f = 10000;
f0 = 12000;
lambda = cair/f;
sMic = phased.OmnidirectionalMicrophoneElement(...
    'FrequencyRange',[20 20000]);
sURA = phased.URA('Element',sMic,'Size',[11,9],...
    'ElementSpacing',0.75*lambda*[1,1]);
plotGratingLobeDiagram(sURA,f,[20;30],cair,f0);
```



The mainlobe of the array is indicated by a filled black circle. The mainlobe has moved from its position in the previous example due to the frequency shift. The grating lobes in visible and nonvisible regions are indicated by unfilled black circles. The visible region is the region in u-v coordinates for which $u^2 + v^2 \leq 1$. The visible region is shown as a unit circle centered at the origin. Because the array spacing is greater than one-half wavelength, there are grating lobes in the visible region of space. There are an infinite number of grating lobes in the nonvisible regions, but only those in the range [-3,3] are shown.

The grating-lobe free region, shown in green, is the range of directions of the main lobe for which there are no grating lobes in the visible region. In this case, it lies inside the

visible region. Because the mainlobe is outside the green area, there is a grating lobe within the visible region.

Concepts

Grating Lobes

Spatial undersampling of a wavefield by an array gives rise to visible grating lobes. If you think of the wavenumber, k, as analogous to angular frequency, then you must sample the signal at spatial intervals smaller than π/k_{max} (or $\lambda_{min}/2$) in order to remove aliasing. The appearance of visible grating lobes is also known as spatial aliasing. The variable k_{max} is the largest wavenumber value present in the signal.

The directions of maximum spatial response of a URA are determined by the peaks of the array's *array pattern* (alternatively called the *beam pattern* or *array factor*). Peaks other than the mainlobe peak are called grating lobes. For a URA, the array pattern depends only on the wavenumber component of the wavefield in the array plane (the y and z directions for the `phased.URA` System object). The wavenumber components are related to the look-direction of an arriving wavefield by $k_y = -2\pi \sin az \cos el/\lambda$ and $k_z = -2\pi \sin el/\lambda$. The angle az is azimuth angle of the arriving wavefield. The angle el is elevation angle of the arriving wavefield. The look-direction points away from the array to the wavefield source.

The array pattern possesses an infinite number of periodically-spaced peaks that are equal in strength to the mainlobe peak. If you steer the array to the az_0, el_0 azimuth and elevation direction, the array pattern for the URA has its mainlobe peak at the wavenumber value, $k_{y0} = -2\pi \sin az_0 \cos el_0/\lambda$, $k_{z0} = -2\pi \sin el_0/\lambda$. The array pattern has strong peaks at $k_{ym} = k_{y0} + 2\pi\, m/d_y$, $k_{zn} = k_{z0} + 2\pi\, n/d_z$. for integral values of m and n. The quantities d_y and d_z are the inter-element spacings in the y- and z-directions, respectively. Expressed in terms of direction cosines, the grating lobes occur at $u_m = u_0 - m\lambda/d_y$ and $v_n = v_0 - n\lambda/d_z$. The mainlobe direction cosines are given by $u_0 = \sin az_0 \cos el_0$ and $v_0 = \sin el_0$ when expressed in terms of the look-direction.

Grating lobes can be visible or nonvisible, depending upon the value of $u_m^2 + v_n^2$. When $u_m^2 + v_n^2 \le 1$, the look direction represent a visible direction. When the value is greater than one, the grating lobe is nonvisible. For each visible grating lobe, you can compute a look direction $(az_{m,n}, el_{m,n})$ from $u_m = \sin az_m \cos el_m$ and $v_n = \sin el_n$. The spacing of

grating lobes depends upon λ/d. When λ/d is small enough, multiple grating lobe peaks can correspond to physical look-directions.

```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`RESP = step(H,FREQ,ANG)` returns the responses of the array elements, `RESP`, at the operating frequencies specified in `FREQ` and directions specified in `ANG`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`H`

Array object

FREQ

Operating frequencies of array in hertz. `FREQ` is a row vector of length *L*. Typical values are within the range specified by a property of `H.Element`. That property is named `FrequencyRange` or `FrequencyVector`, depending on the type of element in the array. The element has zero response at frequencies outside that range.

ANG

Directions in degrees. `ANG` is either a 2-by-*M* matrix or a row vector of length *M*.

If `ANG` is a 2-by-*M* matrix, each column of the matrix specifies the direction in the form `[azimuth; elevation]`. The azimuth angle must lie between –180° and 180°, inclusive. The elevation angle must lie between –90° and 90°, inclusive.

If `ANG` is a row vector of length *M*, each element specifies the azimuth angle of the direction. In this case, the corresponding elevation angle is assumed to be 0°.

Output Arguments

RESP

Voltage responses of the phased array. The output depends on whether the array supports polarization or not.

- If the array is not capable of supporting polarization, the voltage response, `RESP`, has the dimensions *N*-by-*M*-by-*L*. *N* is the number of elements in the array. The dimension *M* is the number of angles specified in `ANG`. *L* is the number of frequencies specified in `FREQ`. For any element, the columns of `RESP` contain the responses of the array elements for the corresponding direction specified in `ANG`. Each of the *L* pages of `RESP` contains the responses of the array elements for the corresponding frequency specified in `FREQ`.
- If the array is capable of supporting polarization, the voltage response, `RESP`, is a MATLAB `struct` containing two fields, `RESP.H` and `RESP.V`. The field, `RESP.H`, represents the array's horizontal polarization response, while `RESP.V` represents the array's vertical polarization response. Each field has the dimensions *N*-by-*M*-by-*L*. *N* is the number of elements in the array, and *M* is the number of angles specified in `ANG`. *L* is the number of frequencies specified in `FREQ`. Each column of `RESP` contains the responses of the array elements for the corresponding direction specified in `ANG`.

Each of the L pages of RESP contains the responses of the array elements for the corresponding frequency specified in FREQ.

Examples

Response of 2-by-2 URA of Short-Dipole Antennas

Construct a 2-by-2 rectangular lattice URA of short-dipole antenna elements. Then, find the response of each element at boresight. Assume the operating frequency is 1 GHz.

```
sSD = phased.ShortDipoleAntennaElement;
sURA = phased.URA('Element',sSD,'Size',[2 2]);
fc = 1e9;
ang = [0;0];
resp = step(sURA,fc,ang);
disp(resp.V)
```

```
   -1.2247
   -1.2247
   -1.2247
   -1.2247
```

viewArray

System object: phased.URA
Package: phased

View array geometry

Syntax

```
viewArray(H)
viewArray(H,Name,Value)
hPlot = viewArray( ___ )
```

Description

`viewArray(H)` plots the geometry of the array specified in `H`.

`viewArray(H,Name,Value)` plots the geometry of the array, with additional options specified by one or more `Name,Value` pair arguments.

`hPlot = viewArray( ___ )` returns the handle of the array elements in the figure window. All input arguments described for the previous syntaxes also apply here.

Input Arguments

`H`

Array object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'ShowIndex'`

Vector specifying the element indices to show in the figure. Each number in the vector must be an integer between 1 and the number of elements. You can also specify the value `'All'` to show the indices of all elements of the array or `'None'` to suppress indices.

Default: `'None'`

`'ShowNormals'`

Set this value to `true` to show the normal directions of all elements of the array. Set this value to `false` to plot the elements without showing normal directions.

Default: `false`

`'ShowTaper'`

Set this value to `true` to specify whether to change the element color brightness in proportion to the element taper magnitude. When this value is set to `false`, all elements are drawn with the same color.

Default: `false`

`'Title'`

Character vector specifying the title of the plot.

Default: `'Array Geometry'`

Output Arguments

`hPlot`

Handle of array elements in figure window.

Examples

Geometry, Normal Directions, and Indices of URA Elements

This example shows how to display the element positions, normal directions, and indices for all elements of a 4-by-4 square URA.

```
ha = phased.URA(4);
```

```
viewArray(ha,'ShowNormals',true,'ShowIndex','All');
```

phased.WidebandBackscatterRadarTarget System object

Package: phased

Backscatter wideband signal from radar target

Description

The `phased.WidebandBackscatterRadarTarget` System object models the *backscattering* of a wideband signal from a target. Backscattering is a special case of radar target scattering where the incident and reflected angles are the same. This type of scattering applies to monostatic radar configurations. The radar cross-section determines the backscattering response of a target to an incoming signal. This System object lets you specify an angle-dependent radar cross-section model that covers a range of incident angles. The wideband signal is decomposed into frequency subbands which are backscattered independently and then recombined.

This System object creates a backscattered signal for polarized or nonpolarized signals. Although electromagnetic radar signals are polarized, you can often ignore polarization in your simulation and process the signals as scalars. To ignore polarization, specify the `EnablePolarization` property as `false`. To employ polarization, specify `EnablePolarization` as `true`.

For nonpolarized signals, specify the radar cross section (RCS) as an array of values at discrete azimuth and elevation angles and discrete frequencies. The System object interpolates values for incident angles between array points. For polarized signals, specify the radar scattering matrix (SCM) using three arrays defined at discrete azimuth and elevation angles and discrete frequencies. These three arrays correspond to the *HH*, *HV*, and *VV* polarization components. The *VH* component is computed from the conjugate symmetry of the *HV* component. *H* and *V* stand for the horizontal and vertical polarization components, respectively.

For both nonpolarized and polarized signals, you can employ one of four Swerling models to generate random fluctuations in the RCS or radar scattering matrix. Choose which model using the `Model` property. Then, use the `SeedSource` and `Seed` properties to randomize the fluctuations.

EnablePolarization	Radar cross-section patterns
false	RCSPattern
true	ShhPattern, SvvPattern, and ShvPattern

To compute the propagation delay for specified source and receiver points:

1. Define and set up your radar target. You can set phased.WidebandBackscatterRadarTarget System object properties at construction time or leave them set to their default values. See "Construction" on page 1-2276. Some properties that you set at construction time can be changed later. These properties are *tunable*.
2. To compute the propagated signal, call the step method of phased.WidebandBackscatterRadarTarget.step. The output of the method depends on the properties of the object. You can change tunable properties at any time.

Note: Alternatively, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, y = step(obj,x) and y = obj(x) perform equivalent operations.

Construction

target = phased.WidebandBackscatterRadarTarget creates a wideband backscatter radar target System object, target.

target = phased.WidebandBackscatterRadarTarget(Name,Value) creates a wideband backscatter radar target object, with each specified property Name set to the specified Value. You can specify additional name and value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

Properties

EnablePolarization — Enable polarized signals

false (default) | true

Option to enable processing of polarized signals, specified as `false` or `true`. Set this property to `true` to allow the target to simulate the reflection of polarized radiation. Set this property to `false` to ignore polarization.

Example: `true`

`FrequencyVector` — Wideband backscatter pattern frequencies

`[0,1e20]` (default) | real-valued row vector in strictly increasing order

Specify the wideband backscatter pattern frequencies used in the RCS or SCM matrices. The elements of this vector must be in strictly increasing order. The target has no response outside this frequency range. Frequencies are defined with respect to the physical frequency band, not the baseband. Frequency units are in hertz.

`AzimuthAngles` — Azimuth angles

`[-180:180]` (default) | 1-by-P real-valued row vector | P-by-1 real-valued column vector

Azimuth angles used to define the angular coordinates of each column of the matrices specified by the `RCSPattern`, `ShhPattern`, `ShvPattern`, or `SvvPattern` properties. Specify the azimuth angles as a length P vector. P must be greater than two. Angle units are in degrees.

Example: `[-45:0.1:45]`

Data Types: `double`

`ElevationAngles` — Elevation angles

`[-90:90]` (default) | 1-by-Q real-valued row vector | Q-by-1 real-valued column vector

Elevation angles used to define the angular coordinates of each row of the matrices specified by the `RCSPattern`, `ShhPattern`, `ShvPattern`, or `SvvPattern` properties. Specify the elevation angles as a length Q vector. Q must be greater than two. Angle units are in degrees.

Example: `[-30:0.1:30]`

Data Types: `double`

`RCSPattern` — Radar cross-section pattern

`ones(181,361)` (default) | Q-by-P complex-valued matrix | Q-by-P-by-K complex-valued array | 1-by-P-by-K complex-valued array | K-by-P complex-valued matrix

Radar cross-section pattern, specified as a complex-valued matrix or array.

Dimensions	Application
Q-by-P matrix	Specifies a matrix of RCS values as a function of Q elevation angles and P azimuth angles. The same RCS matrix is used for all frequencies.
Q-by-P-by-K array	Specifies an array of RCS patterns as a function of Q elevation angles, P azimuth angles, and K frequencies. If K = 1, the RCS pattern is equivalent to a Q-by-P matrix.
1-by-P-by-K array	Specifies a matrix of RCS values as a function of P azimuth angles and K frequencies. These dimension formats apply when there is only one elevation angle.
K-by-P matrix	

- Q is the length of the vector specified by the `ElevationAngles` property.
- P is the length of the vector specified by the `AzimuthAngles` property.
- K is the number of frequencies specified by the `FrequencyVector` property.

You can specify patterns for L targets by putting L patterns into a cell array. All patterns must have the same dimensions. The value of L must match the column dimensions of the signals passed as input into the step method. You can, however, use one pattern to model L multiple targets.

RCS units are in square meters.

Example: `[1,1;1i,1i]`

Dependencies

To enable this property, set the `EnablePolarization` property to `false`.

Data Types: `double`
Complex Number Support: Yes

`ShhPattern` — Radar scattering matrix *HH* polarization component

`ones(181,361)` (default) | Q-by-P complex-valued matrix | Q-by-P-by-K complex-valued array | 1-by-P-by-K complex-valued array | K-by-P complex-valued matrix

Radar scattering matrix (SCM) *HH* polarization component, specified as a complex-valued matrix or array.

Dimensions	Application
Q-by-*P* matrix	Specifies the scattering matrix polarization component as a function of *Q* elevation angles and *P* azimuth angles. The same SCM matrix is used for all frequencies.
Q-by-*P*-by-*K* array	Specifies the scattering matrix polarization component as a function of *Q* elevation angles, *P* azimuth angles, and *K* frequencies. If *K* = *1*, the RCS pattern is equivalent to a *Q*-by-*P* matrix.
1-by-*P*-by-*K* array	Specifies the scattering matrix polarization component as a function of *P* azimuth angles and *K* frequencies. These dimension formats apply when there is only one elevation angle.
K-by-*P* matrix	

- *Q* is the length of the vector specified by the `ElevationAngles` property.
- *P* is the length of the vector specified by the `AzimuthAngles` property.
- *K* is the number of frequencies specified by the `FrequencyVector` property.

You can specify polarization component patterns for *L* targets by putting *L* patterns into a cell array. All patterns must have the same dimensions. The value of *L* must match the column dimensions of the signals passed as input into the step method. You can, however, use one pattern to model *L* multiple targets.

SCM units are in square-meters.

Example: `[1,1;1i,1i]`

Dependencies

To enable this property, set the `EnablePolarization` property to `true`.

Data Types: `double`

Complex Number Support: Yes

`SvvPattern` — Radar scattering matrix *VV* polarization component

`ones(181,361)` (default) | *Q*-by-*P* complex-valued matrix | *Q*-by-*P*-by-*K* complex-valued array | 1-by-*P*-by-*K* complex-valued array | *K*-by-*P* complex-valued matrix

Radar scattering matrix *VV-pol* component, specified as a complex-valued vector, matrix, or array. Different dimension cases have different applications.

Dimensions	Application
Q-by-*P* matrix	Specifies the scattering matrix polarization component as a function of *Q* elevation angles and *P* azimuth angles. The same SCM matrix is used for all frequencies.
Q-by-*P*-by-*K* array	Specifies the scattering matrix polarization component as a function of *Q* elevation angles, *P* azimuth angles, and *K* frequencies. If *K* = *1*, the RCS pattern is equivalent to a *Q*-by-*P* matrix.
1-by-*P*-by-*K* array	Specifies the scattering matrix polarization component as a function of *P* azimuth angles and *K* frequencies. These dimension formats apply when there is only one elevation angle.
K-by-*P* matrix	

- *Q* is the length of the vector specified by the `ElevationAngles` property.
- *P* is the length of the vector specified by the `AzimuthAngles` property.
- *K* is the number of frequencies specified by the `FrequencyVector` property.

You can specify polarization component patterns for *L* targets by putting *L* patterns into a cell array. All patterns must have the same dimensions. The value of *L* must match the column dimensions of the signals passed as input into the step method. You can, however, use one pattern to model *L* multiple targets.

SCM units are in square-meters.

Example: `[1,1;1i,1i]`

Dependencies

To enable this property, set the `EnablePolarization` property to `true`.

Data Types: `double`
Complex Number Support: Yes

`ShvPattern` — Radar scattering matrix *HV* polarization component

`ones(181,361)` (default) | *Q*-by-*P* complex-valued matrix | *Q*-by-*P*-by-*K* complex-valued array | 1-by-*P*-by-*K* complex-valued vector | *K*-by-*P* complex-valued matrix

Radar scattering matrix (SCM) *HV-pol* component, specified as a complex-valued vector, matrix, or array. Different dimension cases have different applications.

Dimensions	Application
Q-by-*P* matrix	Specifies the scattering matrix polarization component as a function of *Q* elevation angles and *P* azimuth angles. The same SCM matrix is used for all frequencies.
Q-by-*P*-by-*K* array	Specifies the scattering matrix polarization component as a function of *Q* elevation angles, *P* azimuth angles, and *K* frequencies. If *K* = *1*, the RCS pattern is equivalent to a *Q*-by-*P* matrix.
1-by-*P*-by-*K* array	Specifies the scattering matrix polarization component as a function of *P* azimuth angles and *K* frequencies. These dimension formats apply when there is only one elevation angle.
K-by-*P* matrix	

- *Q* is the length of the vector specified by the `ElevationAngles` property.
- *P* is the length of the vector specified by the `AzimuthAngles` property.
- *K* is the number of frequencies specified by the `FrequencyVector` property.

You can specify polarization component patterns for *L* targets by putting *L* patterns into a cell array. All patterns must have the same dimensions. The value of *L* must match the column dimensions of the signals passed as input into the step method. You can, however, use one pattern to model *L* multiple targets.

SCM units are in square-meters.

Example: `[1,1;1i,1i]`

Dependencies

To enable this property, set the `EnablePolarization` property to `true`.

Data Types: `double`
Complex Number Support: Yes

`Model` — Target fluctuation model

`'Nonfluctuating'` (default) | `'Swerling1'` | `'Swerling2'` | `'Swerling3'` | `'Swerling4'`

Target fluctuation model, specified as `'Nonfluctuating'`, `'Swerling1'`, `'Swerling2'`, `'Swerling3'`, or `'Swerling4'`. If you set this property to a value other than `'Nonfluctuating'`, use the `update` input argument when calling the phased.WidebandBackscatterRadarTarget.step method.

Example: `'Swerling3'`

Data Types: `char`

`PropagationSpeed` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. Units are in m/s. The default value of the speed of light is the value returned by `physconst('LightSpeed')`.

Example: `3e8`

Data Types: `double`

`OperatingFrequency` — Signal carrier frequency

`300e6` (default) | positive real-valued scalar

Signal carrier frequency, specified as a positive real-valued scalar. Units are in Hz.

Example: `1e9`

Data Types: `double`

`SampleRate` — Signal sample rate

`1e6` (default) | positive real-valued scalar

Signal sample rate, specified as a positive real-valued scalar. Units are in hertz.

Example: `1e6`

Data Types: `double`

`NumSubbands` — Number of processing subbands

`64` (default) | positive integer

Number of processing subbands, specified as a positive integer.

Example: `128`

Data Types: `double`

`SeedSource` — Seed source of random number generator for RCS fluctuation model

`'Auto'` (default) | `'Property'`

Seed source of random number generator for RCS fluctuation model, specified as `'Auto'` or `'Property'`. When you set this property to:

- `'Auto'`, the object generates random numbers using the default MATLAB random number generator.
- `'Property'`, you specify the random number generator seed using the `Seed` property.

When using this object with Parallel Computing Toolbox software, set this property to `'Auto'`.

Dependencies

To enable this property, set the `Model` property to `'Swerling1'`, `'Swerling2'`, `'Swerling3'`, or `'Swerling4'`.

Data Types: `char`

`Seed` — Random number generator seed

`0` (default) | nonnegative integer less than 2^{32}

Random number generator seed, specified as a nonnegative integer less than 2^{32}. .

Example: `32301`

Dependencies

To enable this property, set the `SeedSource` property to `'Property'`.

Data Types: `double`

Methods

reset	Reset states of System object
step	Backscatter wideband signal from radar target

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

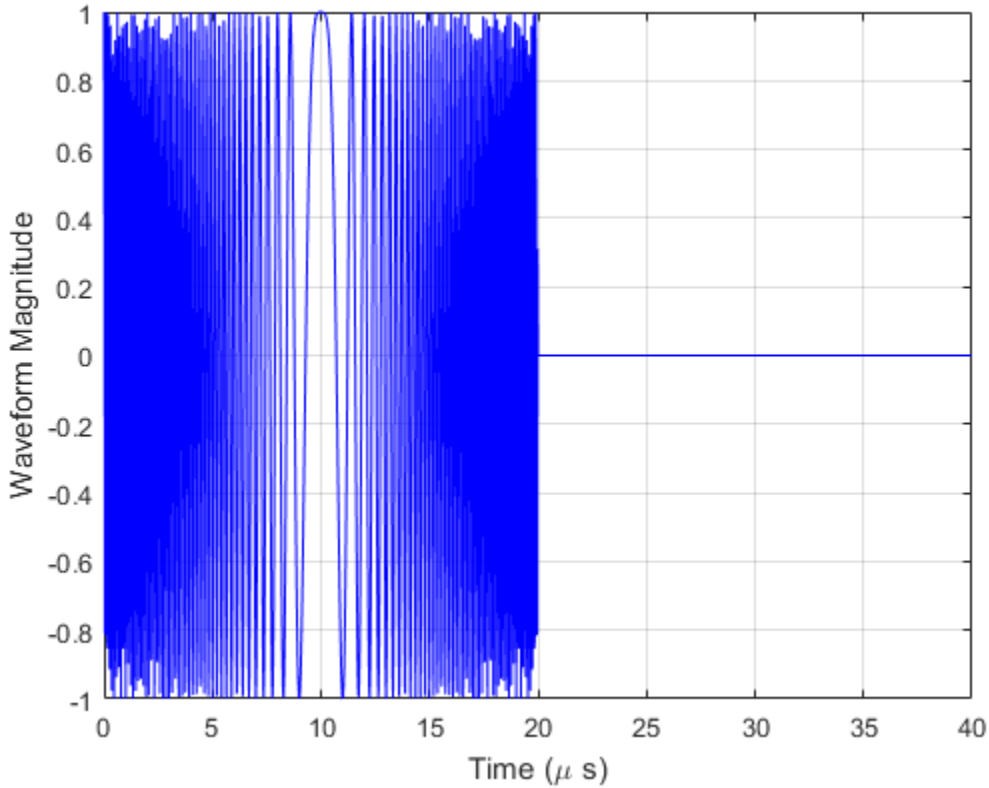
Backscatter Nonpolarized Wideband Signal

Calculate the reflected radar signal from a nonfluctuating point target having a peak RCS of 10.0 m^2. Use a simple target RCS pattern for illustrative purposes. Real RCS patterns are more complicated. The RCS pattern covers a range of angles from 10°–30° in azimuth and 5°–15° in elevation. The RCS peaks at 20° azimuth and 10° elevation. The RCS also has a frequency dependence and is specified at 5 frequencies within the signal bandwidth. Assume that the radar operating frequency is 100 MHz and that the signal is a linear FM waveform having a 20 MHz bandwidth.

Create and plot the wideband signal.

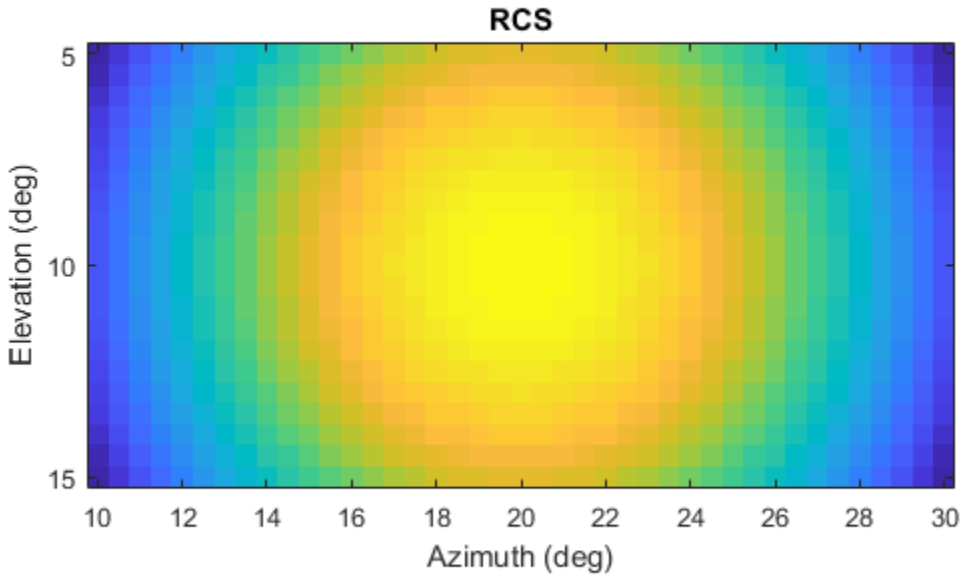
```
c = physconst('LightSpeed');
fs = 50e6;
```

```
pw = 20e-6;
PRF = 1/(2*pw);
fc = 100e6;
bw = 20e6;
waveform = phased.LinearFMWaveform('SampleRate',fs,'PulseWidth',pw, ...
    'PRF',PRF,'OutputFormat','Pulses','NumPulses',1,'SweepBandwidth',bw, ...
    'SweepDirection','Down','Envelope','Rectangular','SweepInterval', ...
    'Symmetric');
wav = waveform();
n = size(wav,1);
plot([0:(n-1)]/fs*1e6,real(wav),'b')
xlabel('Time (\mu s)')
ylabel('Waveform Magnitude')
grid
```



Create an RCS pattern at five different frequencies within the signal bandwidth using a simplified frequency dependence. The frequency dependence is is unity at the operating frequency and falls off outside that frequency. Realistic frequency dependencies are more complicated. Plot the RCS pattern for one of the frequencies.

```
fvec = fc + [-fs/2,-fs/4,0,fs/4,fs/2];
fdep = cos(3*(1 - fvec/fc));
azmax = 20.0;
elmax = 10.0;
azpattern = [10.0:0.5:30.0];
elpattern = [5.0:0.5:15.0];
rcspattern0 = 10.0*cosd(4*(elpattern - elmax))'*cosd(4*(azpattern - azmax));
for k = 1:5
    rcspattern(:,:,k) = rcspattern0*fdep(k);
end
imagesc(azpattern,elpattern,rcspattern(:,:,1))
axis image
axis tight
title('RCS')
xlabel('Azimuth (deg)')
ylabel('Elevation (deg)')
```



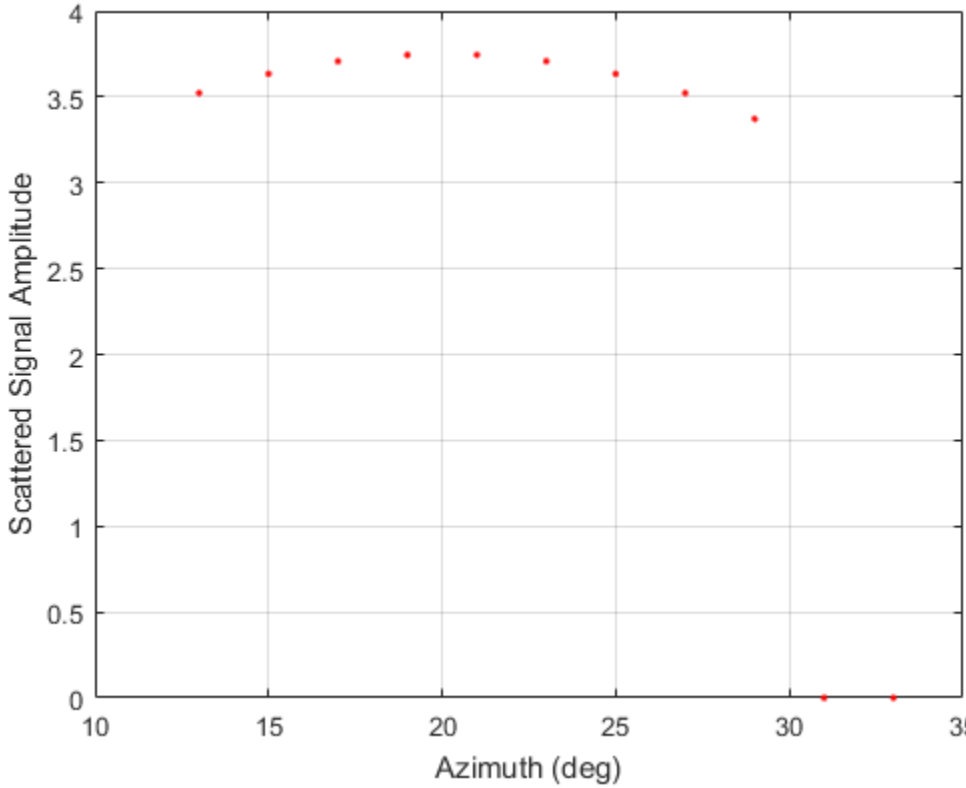
Create the `phased.WidebandBackscatterRadarTarget` System object™.

```
target = phased.WidebandBackscatterRadarTarget('Model','Nonfluctuating', ...
    'AzimuthAngles',azpattern,'ElevationAngles',elpattern,...
    'RCSPattern',rcspattern,'OperatingFrequency',fc,'NumSubbands',32, ...
    'FrequencyVector',fvec);
```

For a sequence of incident angles at different azimuth angles and at a constant elevation angle, find and plot the reflected signal amplitude.

```
az0 = 13.0;
el = 10.0;
az = az0 + [0:2:20];
naz = length(az);
```

```
magsig = zeros(1,naz);
for k = 1:naz
    y = target(wav,[az(k);el]);
    magsig(k) = max(abs(y));
end
plot(az,magsig,'r.')
xlabel('Azimuth (deg)')
ylabel('Scattered Signal Amplitude')
grid
```



Backscatter Nonpolarized Wideband Signal from Fluctuating Target

Calculate the reflected radar signal from a Swerling 4 fluctuating point target with a peak RCS of 0.1 m^2. Use a simple target RCS pattern for illustrative purposes. Real

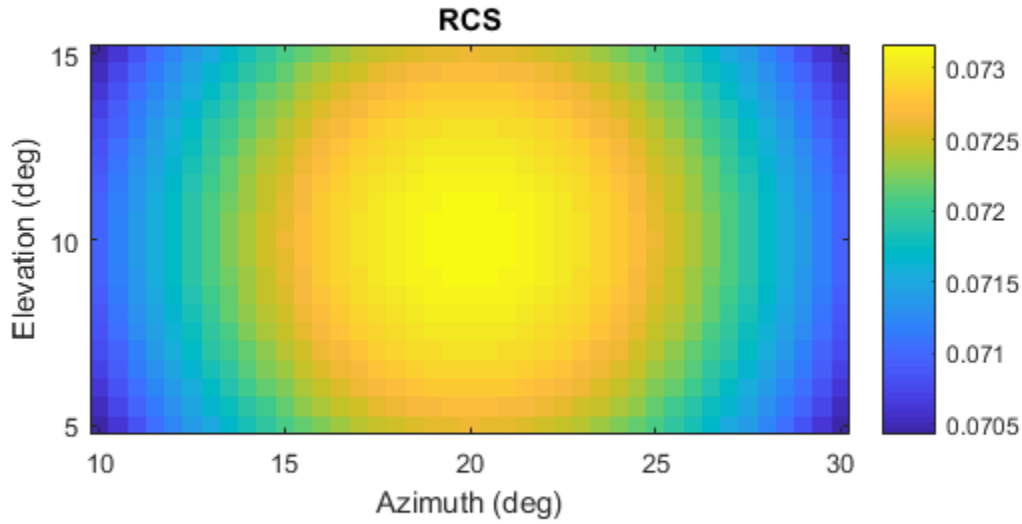
RCS patterns are more complicated. The RCS pattern covers a range of angles from 10°–30° in azimuth and 5°–15° in elevation. The RCS peaks at 20° azimuth and 10° elevation at a value of 0.1 m^2. The RCS also has a frequency dependence and is specified at five frequencies within the signal bandwidth. Assume that the radar operating frequency is 100 MHz and that the signal is a linear FM waveform with a 20 MHz bandwidth. The sampling frequency is 50 MHz.

Create and plot the wideband signal.

```
c = physconst('LightSpeed');
fs = 50e6;
pw = 20e-6;
PRF = 1/(2*pw);
fc = 100.0e6;
bw = 20.0e6;
waveform = phased.LinearFMWaveform('SampleRate',fs,'PulseWidth',pw, ...
    'PRF',PRF,'OutputFormat','Pulses','NumPulses',1,'SweepBandwidth',bw, ...
    'SweepDirection','Down','Envelope','Rectangular','SweepInterval', ...
    'Symmetric');
wav = waveform();
```

Create an RCS pattern at five different frequencies within the signal bandwidth using a simple frequency dependence. The frequency dependence is designed to be unity at the operating frequency and fall off outside that band. Realistic frequency dependencies are more complicated.

```
fvec = fc + [-fs/2,-fs/4,0,fs/4,fs/2];
fdep = cos(3*(1 - fvec/fc));
azmax = 20.0;
elmax = 10.0;
azangs = [10.0:0.5:30.0];
elangs = [5.0:0.5:15.0];
rcspattern0 = 0.1*(cosd((elangs - elmax))'*cosd((azangs - azmax))).^2;
for k = 1:5
    rcspattern(:,:,k) = rcspattern0*fdep(k);
end
imagesc(azangs,elangs,rcspattern(:,:,5))
axis image
axis xy
axis tight
title('RCS')
xlabel('Azimuth (deg)')
ylabel('Elevation (deg)')
colorbar
```



Create the `phased.WidebandBackscatterRadarTarget` System object™.

```
target = phased.WidebandBackscatterRadarTarget('Model','Swerling4', ...
    'SeedSource','Property','Seed',100213,'AzimuthAngles',azangs, ...
    'ElevationAngles',elangs,'RCSPattern',rcspattern, ...
    'OperatingFrequency',fc,'NumSubbands',32,'FrequencyVector',fvec);
```

Find and plot 100 samples of the incident signal and two sequential reflected signals at 10° azimuth and 10° elevation. Update the RCS at each execution of the System object™.

```
az = 10.0;
el = 10.0;
refl_wav1 = target(wav,[az;el],true);
refl_wav2 = target(wav,[az;el],true);
```

```
n = 100;
plot([0:(n-1)]/fs*1e6,real(wav(1:n)))
hold on
plot([0:(n-1)]/fs*1e6,real(refl_wav1(1:n)),'.')
plot([0:(n-1)]/fs*1e6,real(refl_wav2(1:n)),'.')
hold off
legend('Incident Signal','First Backscattered Signal','Second Backscattered Signal')
xlabel('Time (\mu s)')
ylabel('Waveform Magnitude')
title('Swerling 4 RCS')
```

Definitions

Backscattered Wideband Signals

Wideband signals are decomposed into narrowband signals which are reflected from the target independently.

For a narrowband nonpolarized signal, the reflected signal, *Y*, is

$$Y = \sqrt{G} \cdot X,$$

where:

- *X* is the incoming signal.
- *G* is the target gain factor, a dimensionless quantity given by

$$G = \frac{4\pi\sigma}{\lambda^2}.$$

  - σ is the mean radar cross-section (RCS) of the target.
  - λ is the wavelength of the incoming signal.

The incident signal on the target is scaled by the square root of the gain factor.

For narrowband polarized waves, the single scalar signal, *X*, is replaced by a vector signal, *(E_H, E_V)*, with horizontal and vertical components. The scattering matrix, *S*, replaces the scalar cross-section, σ. Through the scattering matrix, the incident horizontal and vertical polarized signals are converted into the reflected horizontal and vertical polarized signals.

$$\begin{bmatrix} E_H^{(scat)} \\ E_V^{(scat)} \end{bmatrix} = \sqrt{\frac{4\pi}{\lambda^2}} \begin{bmatrix} S_{HH} & S_{VH} \\ S_{HV} & S_{VV} \end{bmatrix} \begin{bmatrix} E_H^{(inc)} \\ E_V^{(inc)} \end{bmatrix} = \sqrt{\frac{4\pi}{\lambda^2}} [S] \begin{bmatrix} E_H^{(inc)} \\ E_V^{(inc)} \end{bmatrix}$$

For further details, see [1] or [2].

Subband Frequency Processing

Subband processing decomposes a wideband signal into multiple subbands and applies narrowband processing to the signal in each subband. The signals for all subbands are summed to form the output signal.

When using wideband frequency System objects or blocks, you specify the number of subbands, N_b, in which to decompose the wideband signal. Subband center frequencies and widths are automatically computed from the total bandwidth and number of subbands. The total frequency band is centered on the carrier or operating frequency, f_c. The overall bandwidth is given by the sample rate, f_s. Frequency subband widths are $\Delta f = f_s/N_B$. The center frequencies of the subbands are

$$f_m = \begin{cases} f_c - \dfrac{f_s}{2} + (m-1)\Delta f, & N_B \text{ even} \\ f_c - \dfrac{(N-1)f_s}{2N} + (m-1)\Delta f, & N_B \text{ odd} \end{cases}, m = 1,\ldots,N_B$$

Some System objects let you obtain the subband center frequencies as output from the `step` method. The returned subband frequencies are ordered consistent with the ordering of the discrete Fourier transform. Frequencies above the carrier appear first, followed by frequencies below the carrier.

Introduced in R2016b

reset

System object: phased.WidebandBackscatterRadarTarget
Package: phased

Reset states of System object

Syntax

```
reset(target)
```

Description

`reset(target)` resets the internal state of the `phased.WidebandBackscatterRadarTarget` object, `target`. This method resets the random number generator state if `SeedSource` is a property of this System object and has the value `'Property'`.

Input Arguments

`target` — Wideband backscatter radar target

`phased.WidebandBackscatterRadarTarget` System object

Wideband backscatter radar target, specified as a phased.WidebandBackscatterRadarTarget System object.

Introduced in R2016b

step

System object: phased.WidebandBackscatterRadarTarget
Package: phased

Backscatter wideband signal from radar target

Syntax

```
refl_sig = step(target,sig,ang)
refl_sig = step(target,sig,ang,update)

refl_sig = step(target,sig,ang,laxes)
refl_sig = step(target,sig,ang,laxes,update)
```

Description

Note: Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`refl_sig = step(target,sig,ang)` returns the reflected signal, `refl_sig`, of an incident nonpolarized signal, `sig`. This syntax applies when you set the `EnablePolarization` property to `false` and the `Model` property to `'Nonfluctuating'`. In this case, the values specified in the `RCSPattern` property are used to compute the RCS values for the incident and reflected directions, `ang`.

`refl_sig = step(target,sig,ang,update)` uses `update` to control whether to update the RCS values. This syntax applies when you set the `EnablePolarization` property to `false` and the `Model` property to one of the fluctuating RCS models: `'Swerling1'`, `'Swerling2'`, `'Swerling3'`, or `'Swerling4'`. If `update` is `true`, a new RCS value is generated. If `update` is `false`, the previous RCS value is used.

`refl_sig = step(target,sig,ang,laxes)` returns the reflected signal, `refl_sig`, of an incident polarized signal, `sig`. This syntax applies when you set `EnablePolarization` to `true` and the `Model` property to `'Nonfluctuating'`. The values specified in the `ShhPattern`, `SvvPattern`, and `ShvPattern` properties are

used to compute the backscattering matrices for the incident directions, `ang`. The `laxes` argument specifies a local coordinate system used to define the horizontal and vertical polarization components.

`refl_sig = step(target,sig,ang,laxes,update)` uses the `update` argument to control whether to update the scattering matrix values. This syntax applies when you set the `EnablePolarization` property to `true` and the `Model` property to one of the fluctuating RCS models: `'Swerling1'`, `'Swerling2'`, `'Swerling3'`, or `'Swerling4'`. If `update` is `true`, a new RCS value is generated. If `update` is `false`, the previous RCS value is used.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`target` — Wideband backscatter radar target

`phased.WidebandBackscatterRadarTarget` System object

Backscatter target, specified as a phased.WidebandBackscatterRadarTarget System object.

`sig` — Wideband signal

N-by-*M* complex-valued matrix | *1*-by-*M* `struct` array containing complex-valued fields

- Wideband nonpolarized signal, specified as an *N*-by-*M* complex-valued matrix. The quantity *N* is the number of signal samples and *M* is the number of independent signals reflecting off the target. Each column contains an independent signal reflected from the target.

  The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.
- Wideband polarized signal, specified as a 1-by-*M* `struct` array containing complex-valued fields. Each `struct` element contains three *N*-by-1 column vectors of electromagnetic field components `(sig.X,sig.Y,sig.Z)` representing the polarized

signal that reflects from the target. Each `struct` element contains three *N*-by-1 complex-valued column vectors, `sig.X`, `sig.Y`, and `sig.Z`. These vectors represent the *x*, *y*, and *z* Cartesian components of the polarized signal.

The size of the first dimension of the matrix fields within the `struct` can vary to simulate a changing signal length such as a pulse waveform with variable pulse repetition frequency.

Example: `[1,1;j,1;0.5,0]`

Data Types: `double`
Complex Number Support: Yes

`ang` — Incident signal direction

2-by-1 real-valued column vector of positive values | 2-by-*M* real-valued matrix of positive values

Incident signal direction, specified as a real-valued column 2-by-1 vector or 2-by-*M* matrix of positive values. Each column of `ang` specifies the incident direction of the corresponding signal in the form `[AzimuthAngle;ElevationAngle]`. The number of columns in `ang` must match the number of independent signals in `sig`. Units are in degrees.

Example: `[30;45]`

Data Types: `double`

`update` — Update RCS

`false` (default) | `true`

Option to enable the RCS values for fluctuation models to update, specified as `false` or `true`. When `update` is `true`, a new RCS value is generated with each call to the `step` method. If `update` is `false`, the RCS remains unchanged with each call to `step`.

Data Types: `logical`

`laxes` — Local coordinate matrix

`eye(3,3)` (default) | 3-by-3 real-valued orthonormal matrix | 3-by-3-by-*M* real-valued array

Local coordinate system matrix, specified as a 3-by-3 real-valued orthonormal matrix or a 3-by-3-by-*M* real-valued array. The matrix columns specify the local coordinate system orthonormal *x*-axis, *y*-axis, and *z*-axis, respectively. Each axis is a vector of the form *(x;y;z)* with respect to the global coordinate system. When `sig` has only one signal, `laxes`

is a 3-by-3 matrix. When `sig` has multiple signals, you can use a single 3-by-3 matrix for multiple signals in `sig`. In this case, all targets have the same local coordinate systems. When you specify `laxes` as a 3-by-3-by-*M* array, each page (third index) defines a 3-by-3 local coordinate matrix for the corresponding target.

Example: `[1,0,0;0,0.7071,-0.7071;0,0.7071,0.7071]`

Data Types: `double`

Output Arguments

`refl_sig` — Wideband reflected signal

N-by-*M* complex-valued matrix | *1*-by-*M* `struct` array containing complex-valued fields

- Wideband nonpolarized signal, returned as an *N*-by-*M* complex-valued matrix. Each column contains an independent signal reflected from the target.
- Wideband polarized signal, returned as a 1-by-*M* `struct` array containing complex-valued fields. Each `struct` element contains three *N*-by-1 column vectors of electromagnetic field components `(sig.X,sig.Y,sig.Z)` representing the polarized signal that reflects from the target.

The quantity *N* is the number of signal samples and *M* is the number of signals reflecting off the target. Each column corresponds to a reflecting angle.

For polarized fields, the `struct` element contains three *N*-by-1 complex-valued column vectors: `sig.X`, `sig.Y`, and `sig.Z`. These vectors represent the *x*, *y*, and *z* Cartesian components of the polarized signal.

The output `refl_sig` contains signal samples arriving at the signal destination within the current input time frame. When the propagation time from source to destination exceeds the current time frame duration, the output does not contain all contributions from the input of the current time frame. The remaining output appears in the next call to `step`.

Examples

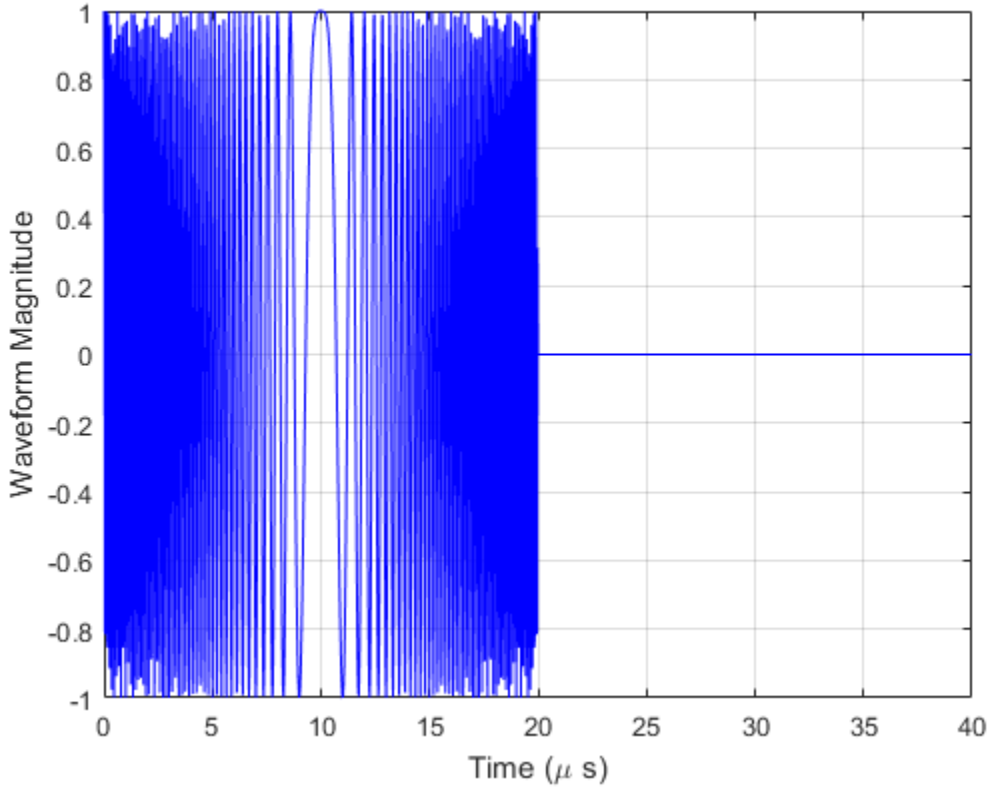
Backscatter Nonpolarized Wideband Signal

Calculate the reflected radar signal from a nonfluctuating point target having a peak RCS of 10.0 m^2. Use a simple target RCS pattern for illustrative purposes. Real RCS

patterns are more complicated. The RCS pattern covers a range of angles from 10°–30° in azimuth and 5°–15° in elevation. The RCS peaks at 20° azimuth and 10° elevation. The RCS also has a frequency dependence and is specified at 5 frequencies within the signal bandwidth. Assume that the radar operating frequency is 100 MHz and that the signal is a linear FM waveform having a 20 MHz bandwidth.

Create and plot the wideband signal.

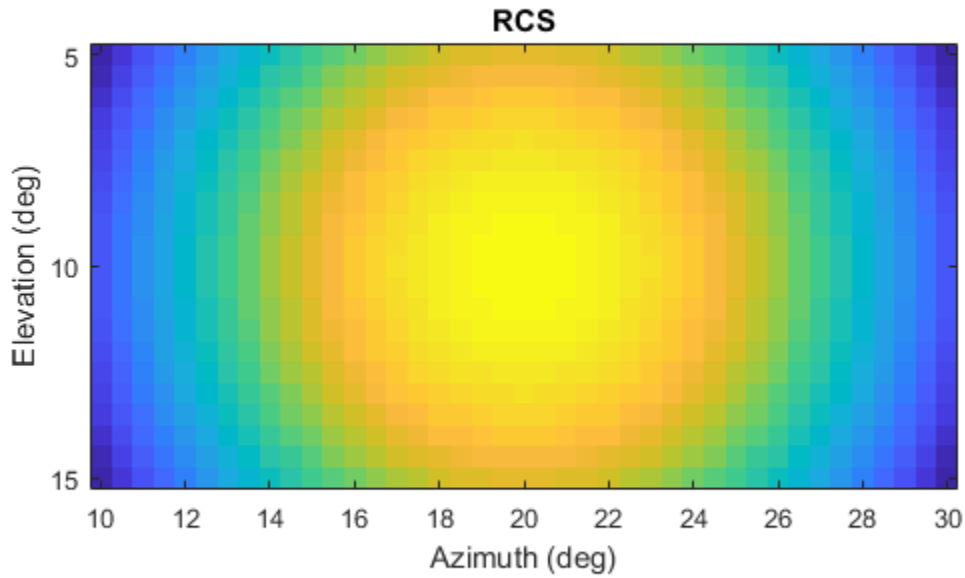
```
c = physconst('LightSpeed');
fs = 50e6;
pw = 20e-6;
PRF = 1/(2*pw);
fc = 100e6;
bw = 20e6;
waveform = phased.LinearFMWaveform('SampleRate',fs,'PulseWidth',pw, ...
    'PRF',PRF,'OutputFormat','Pulses','NumPulses',1,'SweepBandwidth',bw, ...
    'SweepDirection','Down','Envelope','Rectangular','SweepInterval', ...
    'Symmetric');
wav = waveform();
n = size(wav,1);
plot([0:(n-1)]/fs*1e6,real(wav),'b')
xlabel('Time (\mu s)')
ylabel('Waveform Magnitude')
grid
```



Create an RCS pattern at five different frequencies within the signal bandwidth using a simplified frequency dependence. The frequency dependence is is unity at the operating frequency and falls off outside that frequency. Realistic frequency dependencies are more complicated. Plot the RCS pattern for one of the frequencies.

```
fvec = fc + [-fs/2,-fs/4,0,fs/4,fs/2];
fdep = cos(3*(1 - fvec/fc));
azmax = 20.0;
elmax = 10.0;
azpattern = [10.0:0.5:30.0];
elpattern = [5.0:0.5:15.0];
rcspattern0 = 10.0*cosd(4*(elpattern - elmax))'*cosd(4*(azpattern - azmax));
for k = 1:5
    rcspattern(:,:,k) = rcspattern0*fdep(k);
```

```
end
imagesc(azpattern,elpattern,rcspattern(:,:,1))
axis image
axis tight
title('RCS')
xlabel('Azimuth (deg)')
ylabel('Elevation (deg)')
```

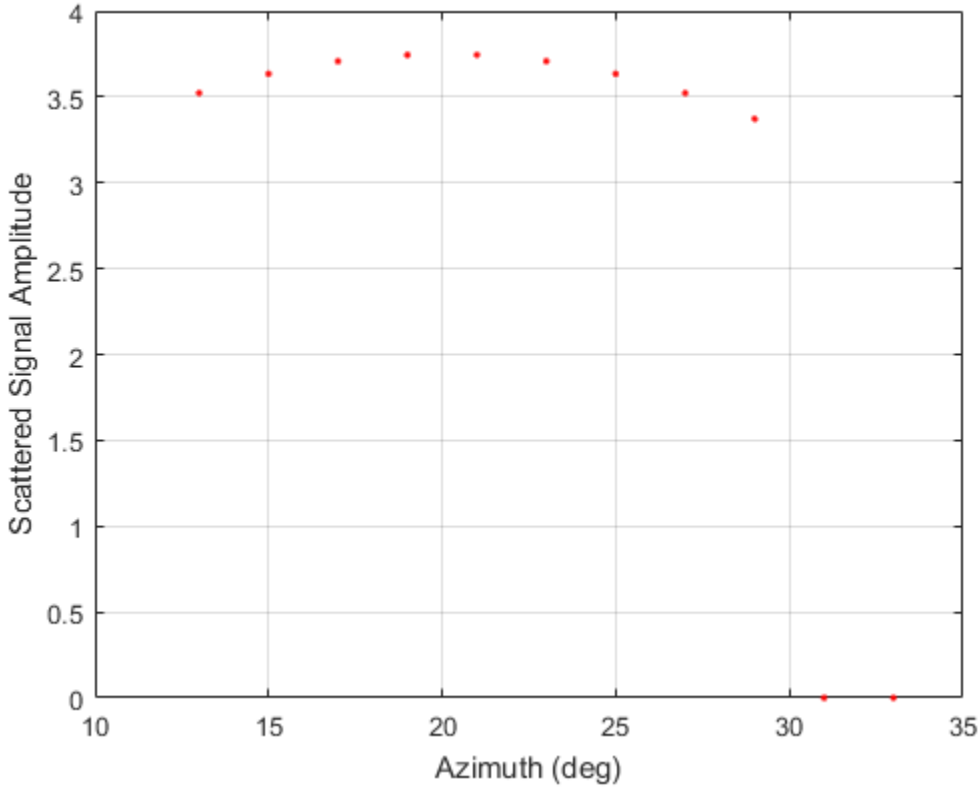


Create the `phased.WidebandBackscatterRadarTarget` System object™.

```
target = phased.WidebandBackscatterRadarTarget('Model','Nonfluctuating', ...
    'AzimuthAngles',azpattern,'ElevationAngles',elpattern,...
    'RCSPattern',rcspattern,'OperatingFrequency',fc,'NumSubbands',32, ...
    'FrequencyVector',fvec);
```

For a sequence of incident angles at different azimuth angles and at a constant elevation angle, find and plot the reflected signal amplitude.

```
az0 = 13.0;
el = 10.0;
az = az0 + [0:2:20];
naz = length(az);
magsig = zeros(1,naz);
for k = 1:naz
    y = target(wav,[az(k);el]);
    magsig(k) = max(abs(y));
end
plot(az,magsig,'r.')
xlabel('Azimuth (deg)')
ylabel('Scattered Signal Amplitude')
grid
```



Backscatter Nonpolarized Wideband Signal from Fluctuating Target

Calculate the reflected radar signal from a Swerling 4 fluctuating point target with a peak RCS of 0.1 m^2. Use a simple target RCS pattern for illustrative purposes. Real RCS patterns are more complicated. The RCS pattern covers a range of angles from 10°–30° in azimuth and 5°–15° in elevation. The RCS peaks at 20° azimuth and 10° elevation at a value of 0.1 m^2. The RCS also has a frequency dependence and is specified at five frequencies within the signal bandwidth. Assume that the radar operating frequency is 100 MHz and that the signal is a linear FM waveform with a 20 MHz bandwidth. The sampling frequency is 50 MHz.

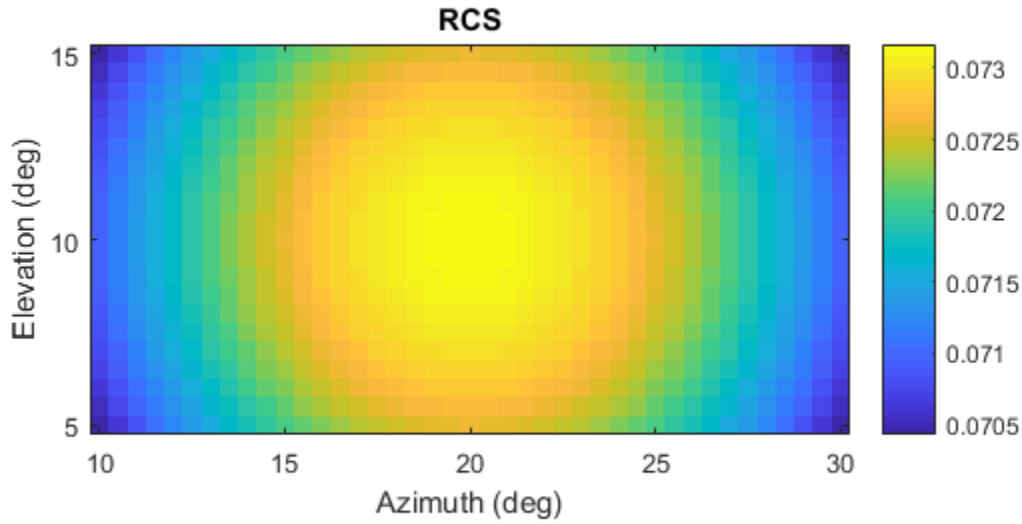
Create and plot the wideband signal.

```
c = physconst('LightSpeed');
```

```
fs = 50e6;
pw = 20e-6;
PRF = 1/(2*pw);
fc = 100.0e6;
bw = 20.0e6;
waveform = phased.LinearFMWaveform('SampleRate',fs,'PulseWidth',pw, ...
    'PRF',PRF,'OutputFormat','Pulses','NumPulses',1,'SweepBandwidth',bw, ...
    'SweepDirection','Down','Envelope','Rectangular','SweepInterval', ...
    'Symmetric');
wav = waveform();
```

Create an RCS pattern at five different frequencies within the signal bandwidth using a simple frequency dependence. The frequency dependence is designed to be unity at the operating frequency and fall off outside that band. Realistic frequency dependencies are more complicated.

```
fvec = fc + [-fs/2,-fs/4,0,fs/4,fs/2];
fdep = cos(3*(1 - fvec/fc));
azmax = 20.0;
elmax = 10.0;
azangs = [10.0:0.5:30.0];
elangs = [5.0:0.5:15.0];
rcspattern0 = 0.1*(cosd((elangs - elmax))'*cosd((azangs - azmax))).^2;
for k = 1:5
    rcspattern(:,:,k) = rcspattern0*fdep(k);
end
imagesc(azangs,elangs,rcspattern(:,:,5))
axis image
axis xy
axis tight
title('RCS')
xlabel('Azimuth (deg)')
ylabel('Elevation (deg)')
colorbar
```



Create the `phased.WidebandBackscatterRadarTarget` System object™.

```
target = phased.WidebandBackscatterRadarTarget('Model','Swerling4', ...
    'SeedSource','Property','Seed',100213,'AzimuthAngles',azangs, ...
    'ElevationAngles',elangs,'RCSPattern',rcspattern, ...
    'OperatingFrequency',fc,'NumSubbands',32,'FrequencyVector',fvec);
```

Find and plot 100 samples of the incident signal and two sequential reflected signals at 10° azimuth and 10° elevation. Update the RCS at each execution of the System object™.

```
az = 10.0;
el = 10.0;
refl_wav1 = target(wav,[az;el],true);
refl_wav2 = target(wav,[az;el],true);
```

```
n = 100;
plot([0:(n-1)]/fs*1e6,real(wav(1:n)))
hold on
plot([0:(n-1)]/fs*1e6,real(refl_wav1(1:n)),'.')
plot([0:(n-1)]/fs*1e6,real(refl_wav2(1:n)),'.')
hold off
legend('Incident Signal','First Backscattered Signal','Second Backscattered Signal')
xlabel('Time (\mu s)')
ylabel('Waveform Magnitude')
title('Swerling 4 RCS')
```

Introduced in R2016b

phased.WidebandCollector System object

Package: phased

Wideband signal collector

Description

The `WidebandCollector` object implements a wideband signal collector.

To compute the collected signal at the sensor(s):

1. Define and set up your wideband signal collector using the syntax defined in "Construction" on page 1-2309 below.
2. Call step to collect the signal according to the properties of `phased.WidebandCollector`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = phased.WidebandCollector` creates a wideband signal collector System object, `H`. The object collects incident wideband signals from given directions using a sensor array or a single element.

`H = phased.WidebandCollector(Name,Value)` creates a wideband signal collector object, `H`, with each specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`Sensor`

Sensor element or sensor array

Sensor element or sensor array specified as a System object in the Phased Array System Toolbox. A sensor array can contain subarrays.

Antenna Toolbox antenna

Default: phased.ULA with default property values

`PropagationSpeed`

Signal propagation speed

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

Default: Speed of light

`SampleRate`

Sample rate

Specify the sample rate, in hertz, as a positive scalar. The default value corresponds to 1 MHz.

Default: `1e6`

`ModulatedInput`

Assume modulated input

Set this property to `true` to indicate the input signal is demodulated at a carrier frequency.

Default: `true`

`CarrierFrequency`

Carrier frequency

Specify the carrier frequency (in hertz) as a positive scalar. The default value of this property corresponds to 1 GHz. This property applies when the `ModulatedInput` property is `true`.

Default: `1e9`

`WeightsInputPort`

Enable weights input

To specify weights, set this property to `true` and use the corresponding input argument when you invoke step. If you do not want to specify weights, set this property to `false`.

Default: `false`

`EnablePolarization`

Enable polarization

Set this property to `true` to simulate the collection of polarized waves. Set this property to `false` to ignore polarization. This property applies when the sensor specified in the `Sensor` property is capable of simulating polarization.

Default: `false`

`NumSubbands`

Number of subbands

Number of processing subbands, specified as a positive integer.

Default: `64`

`Wavefront`

Type of incoming wavefront

Specify the type of incoming wavefront as one of `'Plane'`, or `'Unspecified'`:

- If you set the `Wavefront` property to `'Plane'`, the input signals are multiple plane waves impinging on the entire array. Each plane wave is received by all collecting elements. If the `Sensor` property is an array that contains subarrays, the `Wavefront` property must be `'Plane'`.

- If you set the `Wavefront` property to `'Unspecified'`, the input signals are individual waves impinging on individual sensors.

Default: `'Plane'`

Methods

step Collect signals

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Collect Wideband Signal at Single Antenna

Use the `phased.WidebandCollector` System object™ to construct a signal arriving at a single isotropic antenna from 10° azimuth and 30° elevation.

```
antenna = phased.IsotropicAntennaElement;
collector = phased.WidebandCollector('Sensor',antenna);
x = [1;0;-1];
incidentAngle = [10;30];
y = collector(x,incidentAngle);
disp(y)
```

```
   1.0000 + 0.0000i
   0.0000 + 0.0000i
  -1.0000 - 0.0000i
```

Collect Wideband Signal at 5-Element ULA

Use the wideband collector to construct the signal impinging upon a 5-element ULA of isotropic antennas from 10 degrees azimuth and 30 degrees elevation.

```
sULA = phased.ULA('NumElements',5);
sColl = phased.WidebandCollector('Sensor',sULA);
x = [1;1;1];
incidentAngle = [10;30];
y = step(sColl,x,incidentAngle);
disp(y)
```

```
  Columns 1 through 4

  -0.9997 + 0.0102i  -0.0051 - 0.9999i   1.0000 + 0.0000i  -0.0051 + 1.0001i
  -0.9999 + 0.0102i  -0.0051 - 1.0000i   1.0000 + 0.0000i  -0.0051 + 1.0000i
  -1.0002 + 0.0102i  -0.0051 - 1.0001i   1.0000 - 0.0000i  -0.0051 + 0.9999i

  Column 5

  -1.0002 - 0.0102i
  -0.9999 - 0.0102i
  -0.9997 - 0.0102i
```

Collect Different Signals at 3-Element ULA

Collect three signals incoming into a 3-element array of isotropic antenna elements. Each antenna collects a separate input signal from a separate direction.

```
sULA = phased.ULA('NumElements',3);
sColl = phased.WidebandCollector('Sensor',sULA,...
    'Wavefront','Unspecified');
rng default
x = rand(10,3);
incidentAngles = [10 20 45; 0 5 2];
y = step(sColl,x,incidentAngles)
```

```
y =

   0.8147 + 0.0000i   0.1576 + 0.0000i   0.6557 + 0.0000i
   0.9058 + 0.0000i   0.9706 + 0.0000i   0.0357 + 0.0000i
   0.1270 + 0.0000i   0.9572 + 0.0000i   0.8491 + 0.0000i

   0.6324 + 0.0000i   0.8003 + 0.0000i   0.6787 + 0.0000i
   0.0975 + 0.0000i   0.1419 + 0.0000i   0.7577 + 0.0000i
   0.2785 + 0.0000i   0.4218 + 0.0000i   0.7431 + 0.0000i
   0.5469 + 0.0000i   0.9157 + 0.0000i   0.3922 + 0.0000i
   0.9575 + 0.0000i   0.7922 + 0.0000i   0.6555 + 0.0000i
```

```
0.9649 + 0.0000i   0.9595 + 0.0000i   0.1712 + 0.0000i
```

Definitions

Subband Frequency Processing

Subband processing decomposes a wideband signal into multiple subbands and applies narrowband processing to the signal in each subband. The signals for all subbands are summed to form the output signal.

When using wideband frequency System objects or blocks, you specify the number of subbands, N_b, in which to decompose the wideband signal. Subband center frequencies and widths are automatically computed from the total bandwidth and number of subbands. The total frequency band is centered on the carrier or operating frequency, f_c. The overall bandwidth is given by the sample rate, f_s. Frequency subband widths are $\Delta f = f_s/N_B$. The center frequencies of the subbands are

$$f_m = \begin{cases} f_c - \dfrac{f_s}{2} + (m-1)\Delta f, & N_B \text{ even} \\ f_c - \dfrac{(N-1)f_s}{2N} + (m-1)\Delta f, & N_B \text{ odd} \end{cases}, m = 1, \ldots, N_B$$

Some System objects let you obtain the subband center frequencies as output from the `step` method. The returned subband frequencies are ordered consistent with the ordering of the discrete Fourier transform. Frequencies above the carrier appear first, followed by frequencies below the carrier.

The `phased.WidebandCollector` System object uses the narrowband phased approximation of the time delays across receiving elements in the far field for each subband.

Algorithms

If the `Wavefront` property value is `'Plane'`, `phased.WidebandCollector` does the following for each plane wave signal:

1. Decomposes the signal into multiple subbands.
2. Uses the phase approximation of the time delays across collecting elements in the far field for each subband.
3. Regroups the collected signals in all the subbands to form the output signal.

If the `Wavefront` property value is `'Unspecified'`, `phased.Wideband Collector` collects each channel independently.

For further details, see [1].

phased.Collector

Introduced in R2012a

step

System object: phased.WidebandCollector
Package: phased

Collect signals

Syntax

```
Y = step(H,X,ANG)
Y = step(H,X,ANG,LAXES)
Y = step(H,X,ANG,WEIGHTS)
Y = step(H,X,ANG,STEERANGLE)
Y = step(H,X,ANG,LAXES,WEIGHTS,STEERANGLE)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X,ANG)` collects signals `X` arriving from directions `ANG`. The collection process depends on the `Wavefront` property of `H`, as follows:

- If `Wavefront` has the value `'Plane'`, each collecting element collects all the far field signals in `X`. Each column of `Y` contains the output of the corresponding element in response to all the signals in `X`.
- If `Wavefront` has the value `'Unspecified'`, each collecting element collects only one impinging signal from `X`. Each column of `Y` contains the output of the corresponding element in response to the corresponding column of `X`. The `'Unspecified'` option is available when the `Sensor` property of `H` does not contain subarrays.

`Y = step(H,X,ANG,LAXES)` uses `LAXES` as the local coordinate system axes directions. This syntax is available when you set the `EnablePolarization` property to `true`.

`Y = step(H,X,ANG,WEIGHTS)` uses `WEIGHTS` as the weight vector. This syntax is available when you set the `WeightsInputPort` property to `true`.

`Y = step(H,X,ANG,STEERANGLE)` uses `STEERANGLE` as the subarray steering angle. This syntax is available when you configure `H` so that `H.Sensor` is an array that contains subarrays and `H.Sensor.SubarraySteering` is either `'Phase'` or `'Time'`.

`Y = step(H,X,ANG,LAXES,WEIGHTS,STEERANGLE)` combines all input arguments. This syntax is available when you configure `H` so that `H.WeightsInputPort` is `true`, `H.Sensor` is an array that contains subarrays, and `H.Sensor.SubarraySteering` is either `'Phase'` or `'Time'`.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`H`

Collector object.

`X`

Arriving signals. Each column of `X` represents a separate signal. The specific interpretation of `X` depends on the `Wavefront` property of `H`.

Wavefront Property Value	Description
`'Plane'`	Each column of `X` is a far field signal.
`'Unspecified'`	Each column of `X` is the signal impinging on the corresponding element. In this case, the number of columns in `X` must equal the number of collecting elements in the `Sensor` property.

- If the `EnablePolarization` property value is set to `false`, `X` is a matrix. The number of columns of the matrix equals the number of separate signals.

  The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.
- If the `EnablePolarization` property value is set to `true`, `X` is a row vector of MATLAB `struct` type. The dimension of the `struct` array equals the number of separate signals. Each `struct` member contains three column-vector fields, `X`, `Y`, and `Z`, representing the *x*, *y*, and *z* components of the polarized wave vector signals in the global coordinate system.

  The size of the first dimension of the matrix fields within the `struct` can vary to simulate a changing signal length such as a pulse waveform with variable pulse repetition frequency.

`ANG`

Incident directions of signals, specified as a two-row matrix. Each column specifies the incident direction of the corresponding column of `X`. Each column of `ANG` has the form [azimuth; elevation], in degrees. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

`LAXES`

Local coordinate system. `LAXES` is a 3-by-3 matrix whose columns specify the local coordinate system's orthonormal *x*, *y*, and *z* axes, respectively. Each axis is specified in terms of `[x;y;z]` with respect to the global coordinate system. This argument is only used when the `EnablePolarization` property is set to `true`.

`WEIGHTS`

Vector of weights. `WEIGHTS` is a column vector of length M, where M is the number of collecting elements.

Default: `ones(M,1)`

`STEERANGLE`

Subarray steering angle, specified as a length-2 column vector. The vector has the form [azimuth; elevation], in degrees. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.

Output Arguments

Y

Collected signals. Each column of `Y` contains the output of the corresponding element. The output is the response to all the signals in `X`, or one signal in `X`, depending on the `Wavefront` property of `H`.

Examples

Collect Wideband Signal at Single Antenna

Use the `phased.WidebandCollector` System object™ to construct a signal arriving at a single isotropic antenna from 10° azimuth and 30° elevation.

```
antenna = phased.IsotropicAntennaElement;
collector = phased.WidebandCollector('Sensor',antenna);
x = [1;0;-1];
incidentAngle = [10;30];
y = collector(x,incidentAngle);
disp(y)
```

```
   1.0000 + 0.0000i
   0.0000 + 0.0000i
  -1.0000 - 0.0000i
```

Collect Wideband Signal at 5-Element ULA

Use the wideband collector to construct the signal impinging upon a 5-element ULA of isotropic antennas from 10 degrees azimuth and 30 degrees elevation.

```
sULA = phased.ULA('NumElements',5);
sColl = phased.WidebandCollector('Sensor',sULA);
x = [1;1;1];
incidentAngle = [10;30];
y = step(sColl,x,incidentAngle);
disp(y)
```

```
  Columns 1 through 4
```

```
  -0.9997 + 0.0102i  -0.0051 - 0.9999i   1.0000 + 0.0000i  -0.0051 + 1.0001i
  -0.9999 + 0.0102i  -0.0051 - 1.0000i   1.0000 + 0.0000i  -0.0051 + 1.0000i
  -1.0002 + 0.0102i  -0.0051 - 1.0001i   1.0000 - 0.0000i  -0.0051 + 0.9999i

  Column 5

  -1.0002 - 0.0102i
  -0.9999 - 0.0102i
  -0.9997 - 0.0102i
```

Collect Different Signals at 3-Element ULA

Collect three signals incoming into a 3-element array of isotropic antenna elements. Each antenna collects a separate input signal from a separate direction.

```
sULA = phased.ULA('NumElements',3);
sColl = phased.WidebandCollector('Sensor',sULA,...
    'Wavefront','Unspecified');
rng default
x = rand(10,3);
incidentAngles = [10 20 45; 0 5 2];
y = step(sColl,x,incidentAngles)
```

```
y =

   0.8147 + 0.0000i   0.1576 + 0.0000i   0.6557 + 0.0000i
   0.9058 + 0.0000i   0.9706 + 0.0000i   0.0357 + 0.0000i
   0.1270 + 0.0000i   0.9572 + 0.0000i   0.8491 + 0.0000i
   0.9134 + 0.0000i   0.4854 + 0.0000i   0.9340 + 0.0000i
   0.6324 + 0.0000i   0.8003 + 0.0000i   0.6787 + 0.0000i
   0.0975 + 0.0000i   0.1419 + 0.0000i   0.7577 + 0.0000i
   0.2785 + 0.0000i   0.4218 + 0.0000i   0.7431 + 0.0000i
   0.5469 + 0.0000i   0.9157 + 0.0000i   0.3922 + 0.0000i
   0.9575 + 0.0000i   0.7922 + 0.0000i   0.6555 + 0.0000i
   0.9649 + 0.0000i   0.9595 + 0.0000i   0.1712 + 0.0000i
```

Algorithms

If the `Wavefront` property value is `'Plane'`, `phased.WidebandCollector` does the following for each plane wave signal:

1. Decomposes the signal into multiple subbands.
2. Uses the phase approximation of the time delays across collecting elements in the far field for each subband.
3. Regroups the collected signals in all the subbands to form the output signal.

If the `Wavefront` property value is `'Unspecified'`, `phased.Wideband Collector` collects each channel independently.

For further details, see [1].

phased.WidebandFreeSpace System object

Package: phased

Wideband freespace propagation

Description

The System object models wideband signal propagation from one point to another in a free-space environment. The System object applies range-dependent time delay, gain adjustment, and phase shift to the input signal. The object accounts for doppler shift when either the source or destination is moving. A free-space environment is a boundary-free medium with a speed of signal propagation independent of position and direction. The signal propagates along a straight line from source to destination. For example, you can use this object to model the two-way propagation of a signal from a radar to a target.

For nonpolarized signals, the System object lets you propagate signals from a single point to multiple points or from multiple points to a single point. Multiple-point–to–multiple-point propagation is not supported.

To compute the propagated signal in free space:

1. Define and set up your wideband free space environment as shown in the "Construction" on page 1-2323 section.
2. Call `step` to propagate the signal through free space according to the properties of the System object. The behavior of `step` is specific to each object in the toolbox.

When propagating a round trip signal in free space, you can use one `WidebandFreeSpace` System object to compute the two-way propagation delay. Alternatively, you can use two separate `WidebandFreeSpace` System objects to compute one-way propagation delays in each direction. Due to filter distortion, the total round trip delay when you employ two-way propagation can differ from the delay when you use two one-way `phased.WidebandFreeSpace` System objects. It is more accurate to use a single two-way `phased.WidebandFreeSpace` System object. To set this option, use the `TwoWayPropagation` property.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were

a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`sWBFS = phased.WidebandFreeSpace` creates a wideband free space System object, `sWBFS`.

`sWBFS = phased.WidebandFreeSpace(Name,Value)` creates a wideband free space System object, `sWBFS`, with each specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Properties

`PropagationSpeed` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. Units are in m/s. The default value of the speed of light is the value returned by `physconst('LightSpeed')`.

Example: `3e8`

Data Types: `double`

`OperatingFrequency` — Signal carrier frequency

`300e6` (default) | positive real-valued scalar

Signal carrier frequency, specified as a positive real-valued scalar. Units are in Hz.

Example: `1e9`

Data Types: `double`

`TwoWayPropagation` — Enable two-way propagation

`false` (default) | `true`

Enable two-way propagation, specified as a `false` or `true`. Set this property to `true` to perform round-trip propagation between the signal origin and destination specified in `step`. Set this property to `false` to perform only one-way propagation from the origin to the destination.

Example: `true`

Data Types: `logical`

`SampleRate` — Sample rate of signal

`1e6` (default) | positive scalar

Sample rate of signal, specified as a positive scalar. Units are in Hz. The System object uses this quantity to calculate the propagation delay in units of samples.

Example: `1e6`

Data Types: `double`

`NumSubbands` — Number of processing subbands

`64` (default) | positive integer

Number of processing subbands, specified as a positive integer.

Example: `128`

Data Types: `double`

`MaximumDistanceSource` — Source of maximum one-way propagation distance

`'Auto'` (default) | `'Property'`

Source of maximum one-way propagation distance, specified as `'Auto'` or `'Property'`. The maximum one-way propagation distance is used to allocate sufficient memory for signal delay computation. When you set this property to `'Auto'`, the System object automatically allocates memory. When you set this property to `'Property'`, you specify the maximum one-way propagation distance using the value of the `MaximumDistance` property.

Data Types: `char`

`MaximumDistance` — Maximum one-way propagation distance

`10000` (default) | positive real-valued scalar

Maximum one-way propagation distance, specified as a positive real-valued scalar. Units are in meters. Any signal that propagates more than the maximum one-way distance is ignored. The maximum distance must be greater than or equal to the largest position-to-position distance.

Example: `5000`

Dependencies

To enable this property, set the `MaximumDistanceSource` property to `'Property'`.

Data Types: `double`

`MaximumNumInputSamplesSource` — Source of maximum number of samples

`'Auto'` (default) | `'Property'`

The source of the maximum number of samples of the input signal, specified as `'Auto'` or `'Property'`. When you set this property to `'Auto'`, the propagation model automatically allocates enough memory to buffer the input signal. When you set this property to `'Property'`, you specify the maximum number of samples in the input signal using the `MaximumNumInputSamples` property. Any input signal longer than that value is truncated.

When you use propagation models in MATLAB Function Block in Simulink with variable-size signals, you must set the `MaximumNumInputSamples` parameter to `'Property'` and set the `MaximumNumInputSamples` parameter accordingly.

Example: `'Property'`

Dependencies

To enable this property, set `MaximumDistanceSource` to `'Property'`.

Data Types: `char`

`MaximumNumInputSamples` — Maximum number of input signal samples

`100` (default) | positive integer

Maximum number of input signal samples, specified as a positive integer. The input signal is the first argument of the `step` method, after the System object itself. The size of the input signal is the number of rows in the input matrix. Any input signal longer than this number is truncated. To process signals completely, ensure that this property value is greater than any maximum input signal length.

The waveform-generating System objects determine the maximum signal size:

- For any waveform, if the waveform `OutputFormat` property is set to `'Samples'`, the maximum signal length is the value specified in the `NumSamples` property.

- For pulse waveforms, if the `OutputFormat` is set to `'Pulses'`, the signal length is the product of the smallest pulse repetition frequency, the number of pulses, and the sample rate.
- For continuous waveforms, if the `OutputFormat` is set to `'Sweeps'`, the signal length is the product of the sweep time, the number of sweeps, and the sample rate.

Example: `2048`

Dependencies

To enable this property, set `MaximumNumInputSamplesSource` to `'Property'`.

Data Types: `double`

Methods

reset	Reset states of phased.WidebandFreeSpace System object
step	Propagate wideband signal from point to point using free-space channel model

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Free-Space Propagation of Wideband Signals

Propagate a wideband signal with three tones in an underwater acoustic with constant speed of propagation. You can model this environment as free space. The center

frequency is 100 kHz and the frequencies of the three tones are 75 kHz, 100 kHz, and 125 kHz, respectively. Plot the spectrum of the original signal and the propagated signal to observe the Doppler effect. The sampling frequency is 100 kHz.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
c = 1500;
fc = 100e3;
fs = 100e3;
relfreqs = [-25000,0,25000];
```

Set up a stationary radar and moving target and compute the expected Doppler.

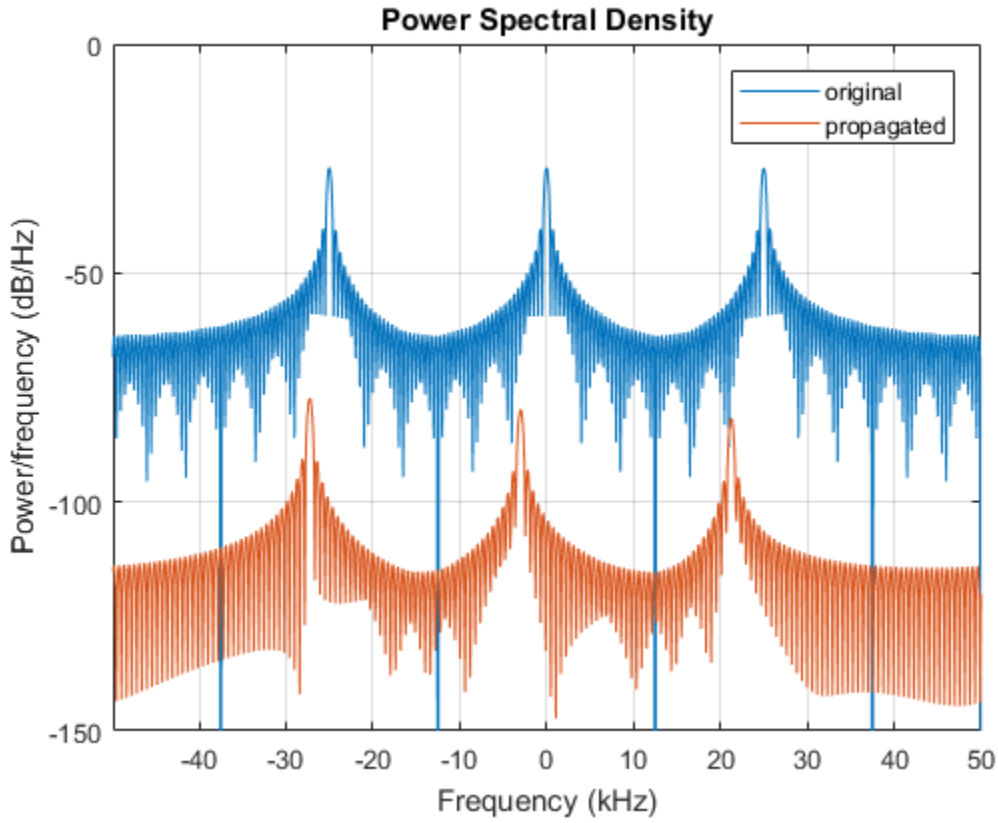
```
rpos = [0;0;0];
rvel = [0;0;0];
tpos = [30/fs*c; 0;0];
tvel = [45;0;0];
dop = -tvel(1)./(c./(relfreqs + fc));
```

Create a signal and propagate the signal to the moving target.

```
t = (0:199)/fs;
x = sum(exp(1i*2*pi*t.'*relfreqs),2);
channel = phased.WidebandFreeSpace(...
    'PropagationSpeed',c,...
    'OperatingFrequency',fc,...
    'SampleRate',fs);
y = channel(x,rpos,tpos,rvel,tvel);
```

Plot the spectra of the original signal and the Doppler-shifted signal.

```
periodogram([x y],rectwin(size(x,1)),1024,fs,'centered')
ylim([-150 0])
legend('original','propagated');
```



For this wideband signal, you can see that the magnitude of the Doppler shift increases with frequency. In contrast, for narrowband signals, the Doppler shift is assumed constant over the band.

Definitions

Freespace Time Delay and Path Loss

When the origin and destination are stationary relative to each other, you can write the output signal of a free-space channel as $Y(t) = x(t-\tau)/L_{fsp}$. The quantity τ is the signal

delay and L_{fsp} is the free-space path loss. The delay τ is given by R/c, where R is the propagation distance and c is the propagation speed. The free-space path loss is given by

$$L_{fsp} = \frac{(4\pi R)^2}{\lambda^2},$$

where λ is the signal wavelength.

This formula assumes that the target is in the far field of the transmitting element or array. In the near field, the free-space path loss formula is not valid and can result in a loss smaller than one, equivalent to a signal gain. Therefore, the loss is set to unity for range values, $R \le \lambda/4\pi$.

When the origin and destination have relative motion, the processing also introduces a Doppler frequency shift. The frequency shift is v/λ for one-way propagation and $2v/\lambda$ for two-way propagation. The quantity v is the relative speed of the destination with respect to the origin.

For more details on free space channel propagation, see [2].

Subband Frequency Processing

Subband processing decomposes a wideband signal into multiple subbands and applies narrowband processing to the signal in each subband. The signals for all subbands are summed to form the output signal.

When using wideband frequency System objects or blocks, you specify the number of subbands, N_b, in which to decompose the wideband signal. Subband center frequencies and widths are automatically computed from the total bandwidth and number of subbands. The total frequency band is centered on the carrier or operating frequency, f_c. The overall bandwidth is given by the sample rate, f_s. Frequency subband widths are $\Delta f = f_s/N_B$. The center frequencies of the subbands are

$$f_m = \begin{cases} f_c - \dfrac{f_s}{2} + (m-1)\Delta f, & N_B \text{ even} \\ f_c - \dfrac{(N-1)f_s}{2N} + (m-1)\Delta f, & N_B \text{ odd} \end{cases}, m = 1,\ldots,N_B$$

Some System objects let you obtain the subband center frequencies as output from the `step` method. The returned subband frequencies are ordered consistent with the ordering of the discrete Fourier transform. Frequencies above the carrier appear first, followed by frequencies below the carrier.

The `phased.WidebandFreeSpace` System object uses narrowband time delay and loss algorithms for each subband.

phased.TwoRayChannel | phased.FreeSpace | phased.WidebandRadiator | phased.WidebandCollector | phased.RadarTarget | `fspl`

Introduced in R2015b

reset

System object: phased.WidebandFreeSpace
Package: phased

Reset states of phased.WidebandFreeSpace System object

Syntax

```
reset(sWBFS)
```

Description

`reset(sWBFS)` resets the internal state of the `phased.WidebandFreeSpace` object, `sWBFS`. If the `SeedSource` property applies and has the value `'Property'`, then this method resets the random number generator state.

Input Arguments

`sWBFS` — Wideband free space propagator

System object

Wideband free space propagator, specified as a System object.

Example: `phased.WidebandFreeSpace`

Introduced in R2015b

step

System object: phased.WidebandFreeSpace
Package: phased

Propagate wideband signal from point to point using free-space channel model

Syntax

```
prop_sig = step(sWBFS,sig,origin_pos,dest_pos,origin_vel,dest_vel)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`prop_sig = step(sWBFS,sig,origin_pos,dest_pos,origin_vel,dest_vel)` returns the resulting signal, `prop_sig`, when a wideband signal `sig` propagates through a free-space channel from the `origin_pos` position to the `dest_pos` position. Either the `origin_pos` or `dest_pos` arguments can specify more than one point but you cannot specify both as having multiple points. The velocity of the signal origin is specified in `origin_vel` and the velocity of the signal destination is specified in `dest_vel`. The dimensions of `origin_vel` and `dest_vel` must agree with the dimensions of `origin_pos` and `dest_pos`, respectively.

Electromagnetic fields propagated through a free-space channel can be polarized or nonpolarized. For nonpolarized fields, such as acoustic fields, the propagating signal field, `sig`, is a vector or matrix. When the fields are polarized, `sig` is a `struct` array. Every structure element represents an electric field vector signal.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications,

such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`sWBFS` — Wideband free space propagator

System object

Wideband free space propagator, specified as a System object.

Example: `phased.WidebandFreeSpace`

`sig` — Wideband signal

M-by-*N* complex-valued matrix | *1*-by-*N* `struct` array containing complex-valued fields

- Wideband nonpolarized signal, specified as an *M*-by-*N* complex-valued matrix. Each column contains a signal propagated along one of the free-space paths.
- Wideband polarized signal, specified as a 1-by-*N* `struct` array containing complex-valued fields. Each `struct` element contains an *M*-by-1 column vector of electromagnetic field components `(sig.X,sig.Y,sig.Z)` representing a polarized signal propagating along one of the free-space paths.

The quantity *M* is the number of signal samples and *N* is the number of free-space channels. Each channel corresponds to a source-destination pair.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

For polarized fields, each `struct` element contains three *M*-by-1 complex-valued column vectors, `sig.X`, `sig.Y`, and `sig.Z`. These vectors represent the *x*, *y*, and *z* Cartesian components of the polarized signal.

The size of the first dimension of the matrix fields within the `struct` can vary to simulate a changing signal length such as a pulse waveform with variable pulse repetition frequency.

Example: `[1,1;j,1;0.5,0]`

Data Types: `double`

Complex Number Support: Yes

`origin_pos` — Signal origin

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Origin of the signal or signals, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. Position units are in meters. The quantity *N* is the number of free-space channels. If `origin_pos` is a column vector, it takes the form `[x;y;z]`. If `origin_pos` is a matrix, each column specifies a different signal origin and has the form `[x;y;z]`.

You cannot specify both `origin_pos` and `dest_pos` as matrices. At least one must be a 3-by-1 column vector.

Example: `[1000;100;500]`

Data Types: `double`

`dest_pos` — Signal destination

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Destination of the signal or signals, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. Position units are in meters. The quantity *N* is the number of free-space channels. If `dest_pos` is a 3-by-1 column vector, it takes the form `[x;y;z]`. If `dest_pos` is a matrix, each column specifies a different signal destination and takes the form `[x;y;z]`.

You cannot specify both `origin_pos` and `dest_pos` as matrices. At least one must be a 3-by-1 column vector.

Example: `[0;0;0]`

Data Types: `double`

`origin_vel` — Signal origin velocity

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Velocity of signal origin, specified as a real-valued 3-by-1 column vector or real-valued 3-by-*N* matrix. Velocity units are in meters per second. The dimension of `origin_vel` must match the dimension of `origin_pos`. If `origin_vel` is a column vector, it takes the form `[Vx;Vy;Vz]`. If `origin_vel` is a 3–by-*N* matrix, each column specifies a different origin velocity and has the form `[Vx;Vy;Vz]`.

Example: `[10;0;5]`

Data Types: `double`

`dest_vel` — Signal destination velocity

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Velocity of signal destinations, specified as a 3-by-1 column vector or 3–by-*N* matrix. Velocity units are in meters per second. The dimension of `dest_vel` must match the dimension of `dest_pos`. If `dest_vel` is a column vector, it takes the form `[Vx;Vy;Vz]`. If `dest_vel` is a 3–by-*N* matrix, each column specifies a different destination velocity and has the form `[Vx;Vy;Vz]`.

Example: `[0;0;0]`

Data Types: `double`

Output Arguments

`prop_sig` — Wideband propagated signal

M-by-*N* complex-valued matrix | 1-by-*N* `struct` array containing complex-valued fields

- Wideband nonpolarized signal, specified as an *M*-by-*N* complex-valued matrix. Each column contains a signal propagated along one of the free-space paths.
- Wideband polarized signal, specified as a 1-by-*N* `struct` array containing complex-valued fields. Each `struct` element contains an *M*-by-1 column vector of electromagnetic field components `(sig.X,sig.Y,sig.Z)` representing a polarized signal propagating along one of the free-space paths.

The output `prop_sig` contains signal samples arriving at the signal destination within the current `step`time frame. Whenever it takes longer than the current time frame for the signal to propagate from the origin to the destination, the output may not contain all contribution from the input. The next call to `step` will return more of the propagated signal.

Examples

Free-Space Propagation of Wideband Signals

Propagate a wideband signal with three tones in an underwater acoustic with constant speed of propagation. You can model this environment as free space. The center

frequency is 100 kHz and the frequencies of the three tones are 75 kHz, 100 kHz, and 125 kHz, respectively. Plot the spectrum of the original signal and the propagated signal to observe the Doppler effect. The sampling frequency is 100 kHz.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
c = 1500;
fc = 100e3;
fs = 100e3;
relfreqs = [-25000,0,25000];
```

Set up a stationary radar and moving target and compute the expected Doppler.

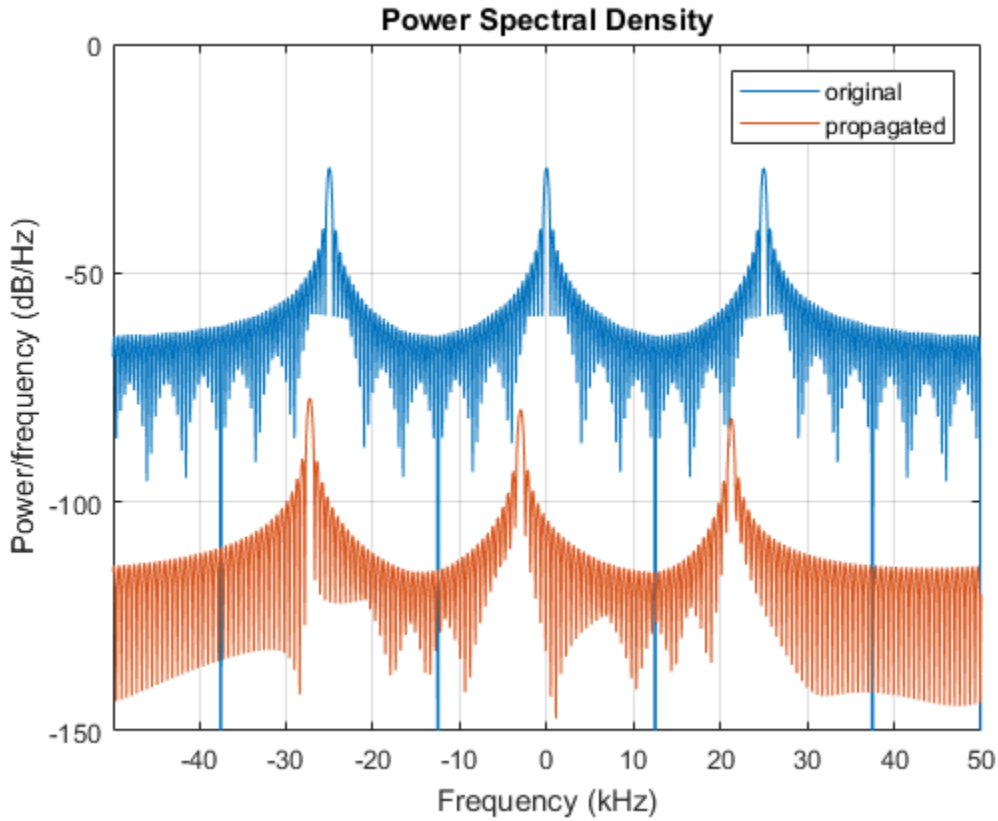
```
rpos = [0;0;0];
rvel = [0;0;0];
tpos = [30/fs*c; 0;0];
tvel = [45;0;0];
dop = -tvel(1)./(c./(relfreqs + fc));
```

Create a signal and propagate the signal to the moving target.

```
t = (0:199)/fs;
x = sum(exp(1i*2*pi*t.'*relfreqs),2);
channel = phased.WidebandFreeSpace(...
    'PropagationSpeed',c,...
    'OperatingFrequency',fc,...
    'SampleRate',fs);
y = channel(x,rpos,tpos,rvel,tvel);
```

Plot the spectra of the original signal and the Doppler-shifted signal.

```
periodogram([x y],rectwin(size(x,1)),1024,fs,'centered')
ylim([-150 0])
legend('original','propagated');
```



For this wideband signal, you can see that the magnitude of the Doppler shift increases with frequency. In contrast, for narrowband signals, the Doppler shift is assumed constant over the band.

phased.FreeSpace.step | phased.TwoRayChannel.step

Introduced in R2015b

phased.WidebandLOSChannel System object

Package: phased

Wideband LOS propagation channel

Description

The `phased.WidebandLOSChannel` models the propagation of narrowband electromagnetic signals through a line-of-sight (LOS) channel from a source to a destination. In an LOS channel, propagation paths are straight lines from point to point. The propagation model in the LOS channel includes free-space attenuation in addition to attenuation due to atmospheric gases, rain, fog, and clouds. You can use `phased.WidebandLOSChannel` to model the propagation of signals between multiple points simultaneously. The System object works for all frequencies.

While the attenuation models for atmospheric gases and rain are valid for electromagnetic signals in the frequency range 1–1000 GHz only, the attenuation model for fog and clouds is valid for 10–1000 GHz. Outside these frequency ranges, the System object uses the nearest valid value.

The `phased.WidebandLOSChannel` System object applies range-dependent time delays to the signals, as well as gains or losses. When either the source or destination is moving, the System object applies Doppler shifts.

Like the phased.WidebandFreeSpace System object, the `phased.WidebandLOSChannel` System object supports two-way propagation.

To compute the propagation delay for specified source and receiver points:

1. Define and set up your Wideband LOS channel using the "Construction" on page 1-2340 procedure. You can set the System object properties during construction or leave them at their default values.
2. Call the phased.WidebandLOSChannel.step method to compute the propagated signal using the properties of the `phased.WidebandLOSChannel` System object. You can change tunable properties before or after any call to the `step` method.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were

a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`sWBLOS = phased.WidebandLOSChannel` creates a Wideband LOS attenuating propagation channel System object, `sWBLOS`.

`sWBLOS = phased.WidebandLOSChannel(Name,Value)` creates a System object, `sWBLOS`, with each specified property `Name` set to the specified `Value`. You can specify additional name and value pair arguments in any order as (`Name1,Value1,...,NameN,ValueN`).

Properties

`PropagationSpeed` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. Units are in m/s. The default value of the speed of light is the value returned by `physconst('LightSpeed')`.

Example: `3e8`

Data Types: `double`

`OperatingFrequency` — Signal carrier frequency

`300e6` (default) | positive real-valued scalar

Signal carrier frequency, specified as a positive real-valued scalar. Units are in Hz.

Example: `1e9`

Data Types: `double`

`SpecifyAtmosphere` — Enable atmospheric attenuation model

`false` (default) | `true`

Option to enable the atmospheric attenuation model, specified as a `false` or `true`. Set this property to `true` to add signal attenuation caused by atmospheric gases, rain, fog, or clouds. Set this property to `false` to ignore atmospheric effects in propagation.

Setting `SpecifyAtmosphere` to `true`, enables the `Temperature`, `DryAirPressure`, `WaterVapourDensity`, `LiquidWaterDensity`, and `RainRate` properties.

Data Types: `logical`

`Temperature` — Ambient temperature

`15` (default) | real-valued scalar

Ambient temperature, specified as a real-valued scalar. Units are in degrees Celsius.

Example: `20.0`

Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

`DryAirPressure` — Atmospheric dry air pressure

`101.325e3` (default) | positive real-valued scalar

Atmospheric dry air pressure, specified as a positive real-valued scalar. Units are in pascals (Pa). The default value of this property corresponds to one standard atmosphere.

Example: `101.0e3`

Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

`WaterVapourDensity` — Atmospheric water vapor density

`7.5` (default) | positive real-valued scalar

Atmospheric water vapor density, specified as a positive real-valued scalar. Units are in g/m^3.

Example: `7.4`

Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

`LiquidWaterDensity` — Liquid water density

`0.0` (default) | nonnegative real-valued scalar

Liquid water density of fog or clouds, specified as a nonnegative real-valued scalar. Units are in g/m^3. Typical values for liquid water density are 0.05 for medium fog and 0.5 for thick fog.

Example: `0.1`

Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

`RainRate` — Rainfall rate

`0.0` (default) | non-negative real-valued scalar

Rainfall rate, specified as a nonnegative real-valued scalar. Units are in mm/hr. This property applies only when you set `SpecifyAtmosphere` to `true`.

Example: `10.0`

Data Types: `double`

`TwoWayPropagation` — Enable two-way propagation

`false` (default) | `true`

Enable two-way propagation, specified as a `false` or `true`. Set this property to `true` to perform round-trip propagation between the signal origin and destination specified in `step`. Set this property to `false` to perform only one-way propagation from the origin to the destination.

Example: `true`

Data Types: `logical`

`SampleRate` — Sample rate of signal

`1e6` (default) | positive scalar

Sample rate of signal, specified as a positive scalar. Units are in Hz. The System object uses this quantity to calculate the propagation delay in units of samples.

Example: `1e6`

Data Types: `double`

`NumSubbands` — Number of processing subbands

`64` (default) | positive integer

Number of processing subbands, specified as a positive integer.

Example: `128`

Data Types: `double`

`MaximumDistanceSource` — Source of maximum one-way propagation distance

`'Auto'` (default) | `'Property'`

Source of maximum one-way propagation distance, specified as `'Auto'` or `'Property'`. The maximum one-way propagation distance is used to allocate sufficient memory for signal delay computation. When you set this property to `'Auto'`, the System object automatically allocates memory. When you set this property to `'Property'`, you specify the maximum one-way propagation distance using the value of the `MaximumDistance` property.

Data Types: `char`

`MaximumDistance` — Maximum one-way propagation distance

`10000` (default) | positive real-valued scalar

Maximum one-way propagation distance, specified as a positive real-valued scalar. Units are in meters. Any signal that propagates more than the maximum one-way distance is ignored. The maximum distance must be greater than or equal to the largest position-to-position distance.

Example: `5000`

Dependencies

To enable this property, set the `MaximumDistanceSource` property to `'Property'`.

Data Types: `double`

`MaximumNumInputSamplesSource` — Source of maximum number of samples

`'Auto'` (default) | `'Property'`

The source of the maximum number of samples of the input signal, specified as `'Auto'` or `'Property'`. When you set this property to `'Auto'`, the propagation model automatically allocates enough memory to buffer the input signal. When you set this property to `'Property'`, you specify the maximum number of samples in the input signal using the `MaximumNumInputSamples` property. Any input signal longer than that value is truncated.

When you use propagation models in MATLAB Function Block in Simulink with variable-size signals, you must set the `MaximumNumInputSamples` parameter to `'Property'` and set the `MaximumNumInputSamples` parameter accordingly.

Example: `'Property'`

Dependencies

To enable this property, set `MaximumDistanceSource` to `'Property'`.

Data Types: `char`

`MaximumNumInputSamples` — Maximum number of input signal samples

`100` (default) | positive integer

Maximum number of input signal samples, specified as a positive integer. The input signal is the first argument of the `step` method, after the System object itself. The size of the input signal is the number of rows in the input matrix. Any input signal longer than this number is truncated. To process signals completely, ensure that this property value is greater than any maximum input signal length.

The waveform-generating System objects determine the maximum signal size:

- For any waveform, if the waveform `OutputFormat` property is set to `'Samples'`, the maximum signal length is the value specified in the `NumSamples` property.
- For pulse waveforms, if the `OutputFormat` is set to `'Pulses'`, the signal length is the product of the smallest pulse repetition frequency, the number of pulses, and the sample rate.

- For continuous waveforms, if the `OutputFormat` is set to `'Sweeps'`, the signal length is the product of the sweep time, the number of sweeps, and the sample rate.

Example: `2048`

Dependencies

To enable this property, set `MaximumNumInputSamplesSource` to `'Property'`.

Data Types: `double`

Methods

reset	Reset states of System object
step	Propagate signal in Wideband LOS channel

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Spectrum of Propagated Signal in Wideband LOS Channel

Propagate a wideband signal in a line-of-sight (LOS) channel from a radar at *(0,0,0)* meters to a target at *(35,0,0)* meters in medium fog. Set the fog liquid water density to 0.05 gm/m3. Assume rain is falling at 5 mm/hr. The signal carrier frequency is 20 GHz. The signal is a sum of four cw tones at 19.75, 19.875, 20.125, and 20.25 GHz. Set the signal duration to 0.5 μs and the sample rate to 2.0 GHz. Assume the radar is stationary and the target approaches the radar at 40 m/s. The atmospheric temperature is 12°C.

Set the signal parameters and create the transmitted signal.

```
c = physconst('LightSpeed');
fs = 2e9;
freq = [-0.25,-.125,0.125,0.25]*1e9;
fc = 20.0e9;
dt = 1/fs;
t = [0:dt:.5e-6];
sig = sum(exp(1i*2*pi*t.'*freq),2);
```

Specify the atmosphere parameters and create the `phased.WidebandChannel` System object™.

```
lwd = 0.05;
rainrate = 5.0;
temp = 12.0;
loschannel = phased.WidebandLOSChannel('SampleRate',fs,'PropagationSpeed',c,...
    'SpecifyAtmosphere',true,'OperatingFrequency',fc,'RainRate',rainrate,...
    'LiquidWaterDensity',lwd,'Temperature',temp);
```

Specify the radar and target positions and velocities.

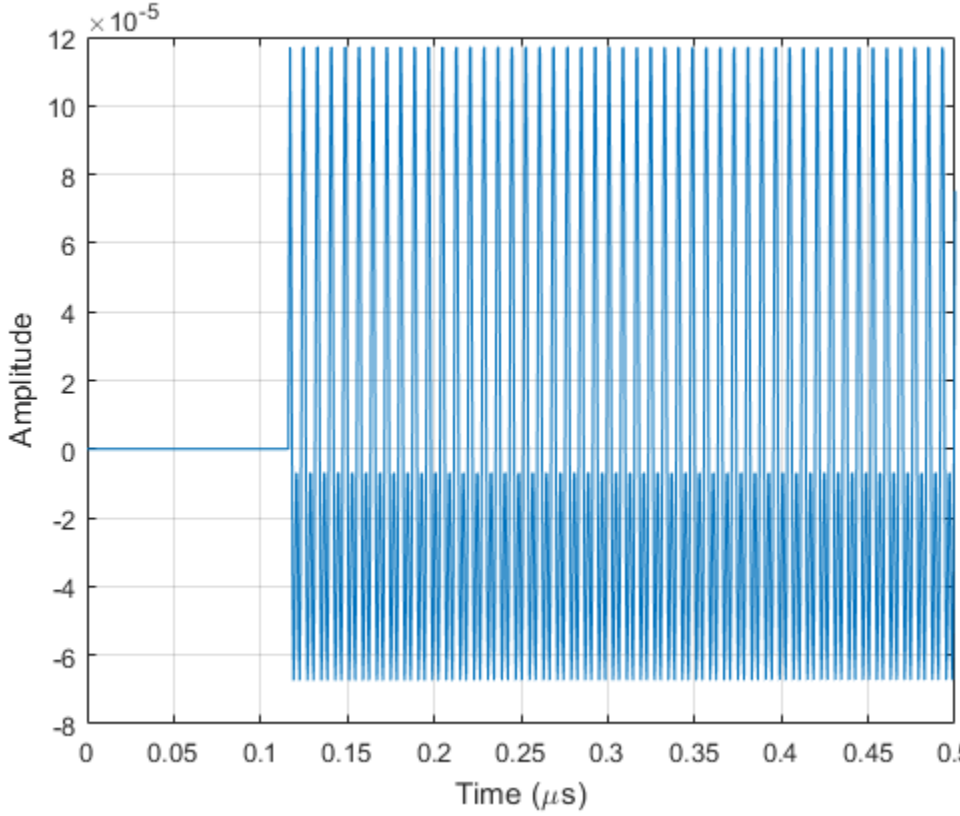
```
xradar = [0,0,0].';
vradar = [0,0,0].';
xtgt = [35,0,0].';
vtgt = [-40,0,0].';
```

Propagated the signal using the `step` method.

```
prop_sig = loschannel(sig,xradar,xtgt,vradar,vtgt);
```

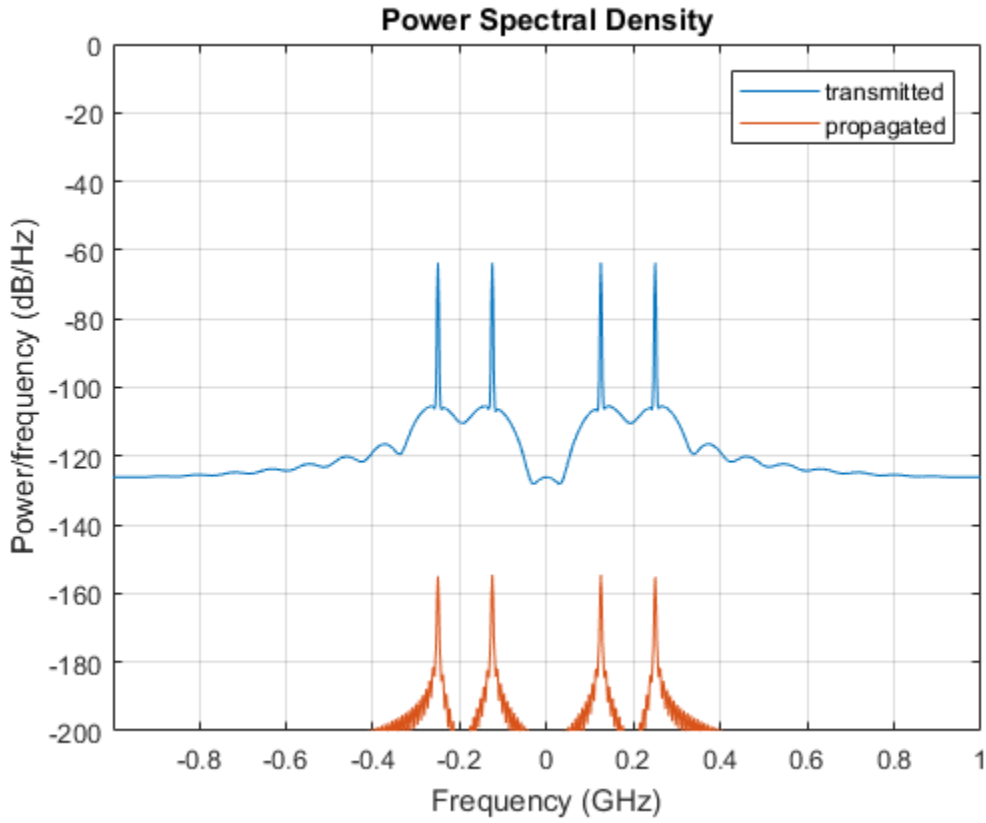
Plot the propagated signal. For a target range of 35 m, the propagation delay is 0.11 µs as seen in the plot.

```
plot(t*1e6,real(prop_sig))
grid
xlabel('Time ({\mu}s)')
ylabel('Amplitude')
```



Using the `periodogram` function with a Taylor window, plot the spectra of the original and propagated signals.

```
nfft = 1024;
nsamp = size(sig,1);
periodogram([sig prop_sig],taylorwin(nsamp),nfft,fs,'centered')
ylim([-200 0])
legend('transmitted','propagated')
```



Definitions

Attenuation and Loss Factors

Attenuation or path loss in the Wideband LOS channel consists of four components. $L = L_{fsp}L_gL_cL_r$, where

- L_{fsp} is the free-space path attenuation
- L_g is the atmospheric path attenuation
- L_c is the fog and cloud path attenuation

- L_r is the rain path attenuation

Each component is in magnitude units, not in dB.

Free-space Time Delay and Loss

When the origin and destination are stationary relative to each other, you can write the output signal of a free-space channel as $Y(t) = x(t-\tau)/L_{fsp}$. The quantity τ is the signal delay and L_{fsp} is the free-space path loss. The delay τ is given by R/c, where R is the propagation distance and c is the propagation speed. The free-space path loss is given by

$$L_{fsp} = \frac{(4\pi R)^2}{\lambda^2},$$

where λ is the signal wavelength.

This formula assumes that the target is in the far field of the transmitting element or array. In the near field, the free-space path loss formula is not valid and can result in a loss smaller than one, equivalent to a signal gain. Therefore, the loss is set to unity for range values, $R \le \lambda/4\pi$.

When the origin and destination have relative motion, the processing also introduces a Doppler frequency shift. The frequency shift is v/λ for one-way propagation and $2v/\lambda$ for two-way propagation. The quantity v is the relative speed of the destination with respect to the origin.

For more details on free space channel propagation, see [5].

Atmospheric Gas Attenuation Model

This model calculates the attenuation of signals that propagate through atmospheric gases.

Electromagnetic signals attenuate when they propagate through the atmosphere. This effect is due primarily to the absorption resonance lines of oxygen and water vapor, with smaller contributions coming from nitrogen gas. The model also includes a continuous absorption spectrum below 10 GHz. Phased Array System Toolbox uses the ITU model *Recommendation ITU-R P.676-10: Attenuation by atmospheric gases*. The model computes the specific attenuation (attenuation per kilometer) as a function of temperature, pressure, water vapor density, and signal frequency. The atmospheric

gas model is valid for frequencies from 1–1000 GHz and applies to polarized and nonpolarized fields.

The formula for specific attenuation at each frequency is

$$\gamma = \gamma_o(f) + \gamma_w(f) = 0.1820 f N''(f).$$

The quantity *N''()* is the imaginary part of the complex atmospheric refractivity. It consists of a spectral line component and a continuous component:

$$N''(f) = \sum_i S_i F_i + N_D''(f)$$

The spectral component consists of a sum of discrete spectrum terms composed of a localized frequency bandwidth function, $F(f)_i$, multiplied by a spectral line strength, S_i. For atmospheric oxygen, each spectral line strength is

$$S_i = a_1 \times 10^{-7} \left(\frac{300}{T}\right)^3 \exp\left[a_2 \left(1 - \left(\frac{300}{T}\right)\right)\right] P.$$

For atmospheric water vapor, each spectral line strength is

$$S_i = b_1 \times 10^{-1} \left(\frac{300}{T}\right)^{3.5} \exp\left[b_2 \left(1 - \left(\frac{300}{T}\right)\right)\right] W.$$

P is the atmospheric pressure, W is the water vapor density, and T is the ambient temperature.

For each oxygen line, S_i depends on constants a_1 and a_2. Similarly, each water vapor line has constants b_1 and b_2. The ITU documentation cited at the end of this section contains tabulations of these constants.

The localized frequency bandwidth functions $F_i(f)$ are complicated functions of frequency described in the ITU references cited below. The functions depend on empirical model parameters that are also tabulated in the reference.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length, R. Then, the total attenuation is $L_g = R(\gamma_o + \gamma_w)$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

Fog and Cloud Attenuation Model

This model calculates the attenuation of signals that propagate through fog or clouds.

Fog and cloud attenuation are the same atmospheric phenomenon. Phased Array System Toolbox uses the ITU model, *Recommendation ITU-R P.840-6: Attenuation due to clouds and fog*. The model computes the specific attenuation (attenuation per kilometer), of a signal as a function of liquid water density, signal frequency, and temperature. The model applies to polarized and nonpolarized fields. The formula for specific attenuation at each frequency is

$$\gamma_c = K_l(f)M,$$

where M is the liquid water density in gm/m^3. The quantity $K_l(f)$ is the specific attenuation coefficient and depends on frequency. The cloud and fog attenuation model is valid for frequencies 10–1000 GHz. Units for the specific attenuation coefficient are (dB/km)/(g/m^3).

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length R. Total attenuation is $L_c = R\gamma_c$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply narrowband attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

Rainfall Attenuation Model

This model calculates the attenuation of signals that propagate through regions of rainfall.

Electromagnetic signals are attenuate when propagating through a region of rainfall. Rainfall attenuation is computed according to the ITU rainfall model *Recommendation ITU-R P.838-3: Specific attenuation model for rain for use in prediction methods*. The model computes the specific attenuation (attenuation per kilometer) of a signal as a function of rainfall rate, signal frequency, polarization, and path elevation angle. To compute the attenuation, this model uses

$$\gamma_r = kr^{\alpha},$$

where r is the rain rate in mm/hr. The parameter k and exponent α depend on the frequency, the polarization state, and the elevation angle of the signal path. The specific attenuation model is valid for frequencies from 1–1000 GHz.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by a propagation distance, R. Then, total attenuation is $L_r = R\gamma_r$. Instead of using geometric range as the propagation distance, the toolbox uses a modified range. The modified range is the geometric range multiplied by a range factor

$$\frac{1}{1+\frac{R}{R_0}}$$

where

$$R_0 = 35e^{-0.015r}$$

is the effective path length in kilometers (see Seybold, J. *Introduction to RF Propagation*.) When there is no rain, the effective path length is 35 km. When the rain rate is, for example, 10 mm/hr, the effective path length is 30.1 km. At short range, the propagation distance is approximately the geometric range. For longer ranges, the propagation distance asymptotically approaches the effective path length.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

Subband Frequency Processing

Subband processing decomposes a wideband signal into multiple subbands and applies narrowband processing to the signal in each subband. The signals for all subbands are summed to form the output signal.

When using wideband frequency System objects or blocks, you specify the number of subbands, N_b, in which to decompose the wideband signal. Subband center frequencies and widths are automatically computed from the total bandwidth and number of subbands. The total frequency band is centered on the carrier or operating frequency, f_c.

The overall bandwidth is given by the sample rate, f_s. Frequency subband widths are $\Delta f = f_s/N_B$. The center frequencies of the subbands are

$$f_m = \begin{cases} f_c - \frac{f_s}{2} + (m-1)\Delta f, & N_B \text{ even} \\ f_c - \frac{(N-1)f_s}{2N} + (m-1)\Delta f, & N_B \text{ odd} \end{cases}, m = 1, \ldots, N_B$$

Some System objects let you obtain the subband center frequencies as output from the `step` method. The returned subband frequencies are ordered consistent with the ordering of the discrete Fourier transform. Frequencies above the carrier appear first, followed by frequencies below the carrier.

The `phased.WidebandLOSChannel` System object uses narrowband time delay and attenuation algorithms for each subband.

System Objects

phased.FreeSpace | phased.RadarTarget | phased.BackscatterRadarTarget | phased.TwoRayChannel | phased.WidebandFreeSpace | phased.LOSChannel

Introduced in R2016a

reset

System object: phased.WidebandLOSChannel
Package: phased

Reset states of System object

Syntax

```
reset(sWBLOS)
```

Description

`reset(sWBLOS)` resets the internal state of the `phased.WidebandLOSChannel` System object, `sWBLOS`. If `SeedSource` is a property of this System object and has the value `'Property'`, then this method resets the random number generator state.

Input Arguments

`sWBLOS` — Wideband LOS channel

`phased.WidebandLOSChannel` System object

Wideband LOS channel, specified as a phased.WidebandLOSChannel System object.

Example: `phased.WidebandLOSChannel`

Introduced in R2016a

step

System object: phased.WidebandLOSChannel
Package: phased

Propagate signal in Wideband LOS channel

Syntax

```
prop_sig = step(sLOS,sig,origin_pos,dest_pos,origin_vel,dest_vel)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`prop_sig = step(sLOS,sig,origin_pos,dest_pos,origin_vel,dest_vel)` returns the resulting signal, `prop_sig`, when a wideband signal, `sig`, propagates through a line-of-sight (LOS) channel from a source located at the `origin_pos` position to a destination at the `dest_pos` position. Only one of the `origin_pos` or `dest_pos` arguments can specify multiple positions. The other must contain a single position. The velocity of the signal origin is specified in `origin_vel` and the velocity of the signal destination is specified in `dest_vel`. The dimensions of `origin_vel` and `dest_vel` must match the dimensions of `origin_pos` and `dest_pos`, respectively.

Electromagnetic fields propagating through an LOS channel can be polarized or nonpolarized. For nonpolarized fields, the propagating signal field, `sig`, is a vector or matrix. For polarized fields, `sig` is an array of structures. The structure elements represent an electric field vector in Cartesian form.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a

nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`sWBLOS` — Wideband LOS channel

`phased.WidebandLOSChannel` System object

Wideband LOS channel, specified as a phased.WidebandLOSChannel System object.

Example: `phased.WidebandLOSChannel`

`sig` — Wideband signal

M-by-*N* complex-valued matrix | 1-by-*N* `struct` array containing complex-valued fields

Wideband signal, specified as a matrix or `struct` array, depending on whether is signal or polarized or nonpolarized. The quantity *M* is the number of samples in the signal, and *N* is the number of wideband LOS channels. Each channel corresponds to a source-destination pair.

- Wideband nonpolarized scalar signal. Specify `sig` as an *M*-by-*N* complex-valued matrix. Each column contains one signal propagated along the line-of-sight path.
- Wideband polarized signal. Specify `sig` as a 1-by-*N* `struct` array containing complex-valued fields. Each `struct` represents a polarized signal propagated along the line-of-sight path. Each `struct` element contains three *M*-by-1 complex-valued column vectors, `sig.X`, `sig.Y`, and `sig.Z`. These vectors represent the *x*, *y*, and *z* Cartesian components of the polarized signal.

Example: `[1,1;j,1;0.5,0]`

Data Types: `double`
Complex Number Support: Yes

`origin_pos` — Signal origins

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Origin of signals, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. The quantity *N* is the number of LOS channels. If `origin_pos` is a column vector, it takes the form `[x;y;z]`. If `origin_pos` is a matrix, each column specifies a different signal origin and has the form `[x;y;z]`. Units are in meters.

You cannot specify both `origin_pos` and `dest_pos` as matrices. At least one must be a 3-by-1 column vector.

Example: `[1000;100;500]`

Data Types: `double`

`dest_pos` — Signal destinations

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Destination position of the signal or signals, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. The quantity *N* is the number of LOS channels propagating from or to *N* signal origins. If `dest_pos` is a 3-by-1 column vector, it takes the form `[x;y;z]`. If `dest_pos` is a matrix, each column specifies a different signal destination and takes the form `[x;y;z]` Position units are in meters.

You cannot specify both `origin_pos` and `dest_pos` as matrices. At least one must be a 3-by-1 column vector.

Example: `[0;0;0]`

Data Types: `double`

`origin_vel` — Velocities of signal origins

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Velocity of signal origin, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. The dimensions of `origin_vel` must match the dimensions of `origin_pos`. If `origin_vel` is a column vector, it takes the form `[Vx;Vy;Vz]`. If `origin_vel` is a 3-by-*N* matrix, each column specifies a different origin velocity and has the form `[Vx;Vy;Vz]`. Velocity units are in meters per second.

Example: `[10;0;5]`

Data Types: `double`

`dest_vel` — Velocities of signal destinations

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Velocity of signal destinations, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. The dimensions of `dest_vel` must match the dimensions of `dest_pos`. If `dest_vel` is a column vector, it takes the form `[Vx;Vy;Vz]`. If `dest_vel` is a 3-by-*N* matrix, each column specifies a different destination velocity and has the form `[Vx;Vy;Vz]` Velocity units are in meters per second.

Example: `[0;0;0]`

Data Types: `double`

Output Arguments

`prop_sig` — Wideband propagated signal

M-by-*N* complex-valued matrix | 1-by-*N* `struct` array containing complex-valued fields

Wideband signal, returned as a matrix or `struct` array, depending on whether the signal is polarized or nonpolarized. The quantity *M* is the number of samples in the signal and *N* is the number of wideband LOS channels. Each channel corresponds to a source-destination pair.

- Wideband nonpolarized scalar signal. `prop_sig` is an *M*-by-*N* complex-valued matrix.

  The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

- Wideband polarized scalar signal. `prop_sig` is a 1-by-*N* `struct` array containing complex-valued fields. Each `struct` element contains three *M*-by-1 complex-valued column vectors, `sig.X`, `sig.Y`, and `sig.Z`. These vectors represent the *x*, *y*, and *z* Cartesian components of the polarized signal.

  The size of the first dimension of the matrix fields within the `struct` can vary to simulate a changing signal length such as a pulse waveform with variable pulse repetition frequency.

The `prop_sig` output contains signal samples arriving at the signal destination within the current time frame. The current time frame is the time frame of the input signals to `step`. Whenever it takes longer than the current time frame for the signal to propagate from the origin to the destination, the output might not contain all contributions from the input of the current time frame. The remaining output appears in the next call to `step`.

Examples

Propagate Wideband Signal in LOS Channel

Propagate a wideband signal in a line-of-sight (LOS) channel from a radar at *(0,0,0)* meters to a target at *(60,0,0)* meters in medium fog. Set the fog liquid water density to

0.05 g/m^3. Assume rain is falling at 5 mm/hr. The signal carrier frequency is 20 GHz. The signal is a sum of four cw tones at 19.75, 19.875, 20.125, and 20.25 GHz. Set the signal duration to 0.5 microsecond and the sample rate to 2.0 GHz. Assume the radar is stationary and the target approaches the radar at 40 m/s. The atmospheric temperature is 12°C and the dry air pressure is 101.300 kPa.

Set the signal parameters and create the transmitted signal.

```
c = physconst('LightSpeed');
fs = 2e9;
freq = [-0.25,-.125,0.0,0.125,0.25]*1e9;
fc = 20.0e9;
dt = 1/fs;
t = [0:dt:.5e-6];
sig = sum(exp(1i*2*pi*t.'*freq),2);
```

Specify the atmosphere parameters and create the `phased.WidebandChannel` System object™.

```
lwd = 0.05;
rainrate = 5.0;
dap = 101300.0;
temp = 12.0;
sWBLOS = phased.WidebandLOSChannel('SampleRate',fs,'PropagationSpeed',c,...
    'SpecifyAtmosphere',true,'OperatingFrequency',fc,'RainRate',rainrate,...
    'LiquidWaterDensity',lwd,'Temperature',temp,'DryAirPressure',dap);
```

Specify the radar and target positions and velocities.

```
xradar = [0,0,0].';
vradar = [0,0,0].';
xtgt = [60,0,0].';
vtgt = [-40,0,0].';
```

Propagated the signal using the `step` method.

```
prop_sig = step(sWBLOS,sig,xradar,xtgt,vradar,vtgt);
```

Plot the propagated signal. For a target range of 60 m, the propagation delay is 0.20 µs as shown in the plot.

```
plot(t*1e6,real(prop_sig))
grid
xlabel('Time (\mu sec)')
ylabel('Amplitude')
```

Introduced in R2016a

phased.WidebandRadiator System object

Package: phased

Wideband signal radiator

Description

The `phased.WidebandRadiator` object implements a wideband signal radiator. For any element, or sensor array, the wideband radiator object creates the signal field that propagates to the far field. First, the object divides the signals at each element into frequency subbands. Then, the object applies time delays using the phase-shift approximation. Finally, the delayed subbands are summed to create the output signal. The output of `phased.WidebandRadiator` represents the field in a selected direction at a reference distance from the element or array center. The radiated signal can be polarized or nonpolarized, depending on whether or not the element or array supports polarization and whether or not you enable polarization.

To compute the radiated signal from the sensor or array:

1. Define and set up a wideband radiator as shown in the "Construction" on page 1-2363 section.
2. Call `step` to compute the radiated signal as specified by the properties of `phased.WidebandRadiator`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`sWBR = phased.WidebandRadiator` creates a wideband signal radiator System object, `sWBR`. The object creates radiated signals that propagate into given directions from a sensor array or a single element.

`sWBR = phased.WidebandRadiator(Name,Value)` creates a radiator System object, `sWBR`, with each specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as `Name1`,`Value1`,...,`NameN`,`ValueN`.

Properties

`Sensor` — Sensor element or sensor array

`phased.ULA` (default) | Phased Array System Toolbox System object | Antenna Toolbox antenna

Sensor element or sensor array, specified as a Phased Array System Toolbox System object. A sensor array can consist of subarrays. The default value is a `phased.ULA` with default array property values.

Example: `phased.URA`

`PropagationSpeed` — Signal propagation speed

speed of light (default) | positive real-valued scalar

Signal propagation speed, specified as a positive real-valued scalar. Units are in meters per second.

Example: `physconst('LightSpeed')`

Data Types: `double`

`SampleRate` — Sample rate

1e6 (default) | real positive real-valued scalar

Sample rate, specified as a positive real-valued scalar. Units are in hertz.

Example: 2e6

Data Types: `double`

`CarrierFrequency` — Carrier frequency

`1e9` (default) | positive real-valued scalar

Carrier frequency, specified as a positive real-valued scalar. Units are in hertz.

Example: 1e6

Data Types: `double`

`NumSubbands` — Number of processing subbands

64 (default) | positive integer

Number of processing subbands, specified as a positive integer.

Example: `128`

Data Types: `double`

`EnablePolarization` — Option to enable polarization

`false` (default) | `true`

Option to enable polarization, specified as `true` or `false`. Set this property to `true` to simulate radiation of polarized waves. Set this property to `false` to ignore polarization. This property applies only when the sensor specified in `Sensor` can simulate polarization.

Data Types: `logical`

`WeightsInputPort` — Option to enable weights input

`false` (default) | `true`

Option to enable weights inputs, specified as `true` or `false`. Pass in weights using the `wts` input argument when you invoke step.

Methods

reset	Reset states of System object
step	Radiate wideband signals

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Radiate Wideband Energy from Array

Create a 5-by-5 URA and space the elements one-half wavelength apart. The wavelength corresponds to a design frequency of 300 MHz.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Create 5-by-5 URA Array of Cosine Elements

```
c = physconst('LightSpeed');
fc = 100e6;
lam = c/fc;
antenna = phased.CosineAntennaElement('CosinePower',[2,2]);
array = phased.URA('Element',antenna,'Size',[5,5],'ElementSpacing',[0.5,0.5]*lam);
```

Create and Radiate Wideband Signal

Radiate a wideband signal consisting of three sinusoids at 2, 10 and 11 MHz. Set the sampling rate to 25 MHz. Radiate the fields into two directions: (30,10) degrees azimuth and elevation and (20,50) degrees azimuth and elevation.

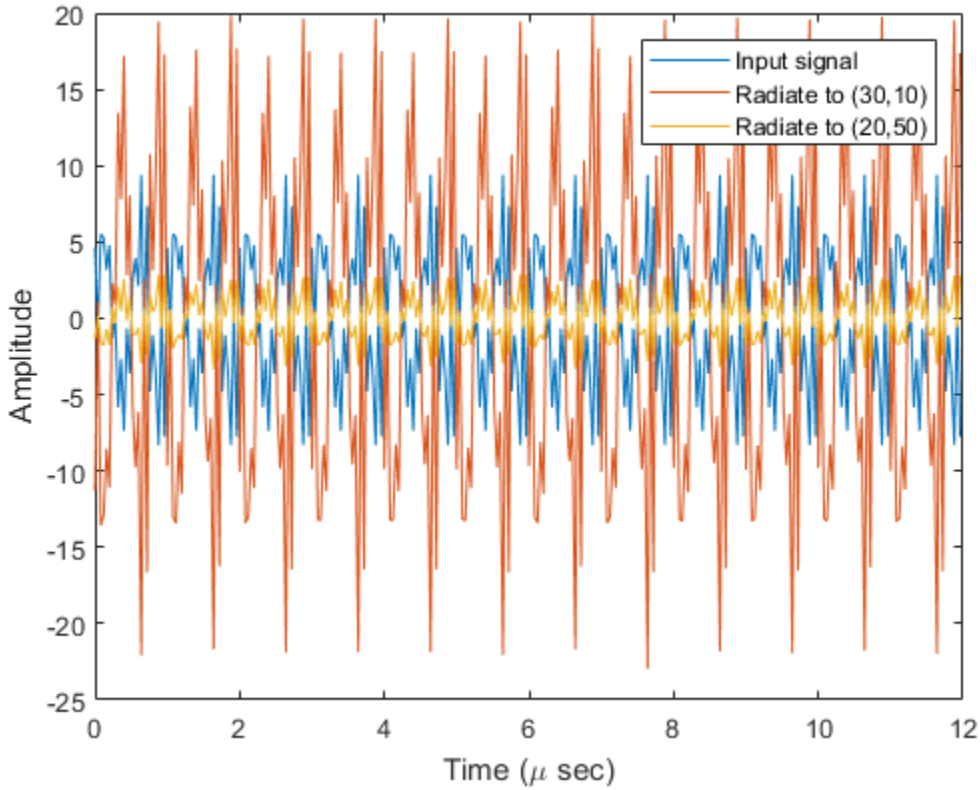
```
fs = 25e6;
f1 = 2e6;
f2 = 10e6;
f3 = 11e6;
dt = 1/fs;
Tsig = 100e-6;
t = [0:dt:Tsig];
sig = 5.0*sin(2*pi*f1*t) + 2.0*sin(2*pi*f2*t + pi/10) + 4*sin(2*pi*f3*t + pi/2);
radiatingangles = [30 10; 20 50]';
radiator = phased.WidebandRadiator('Sensor',array,'CarrierFrequency',fc,'SampleRate',fs
radsig = radiator(sig.',radiatingangles);
```

Plot Radiated Signal

Plot the input signal to the radiator and the radiated signals.

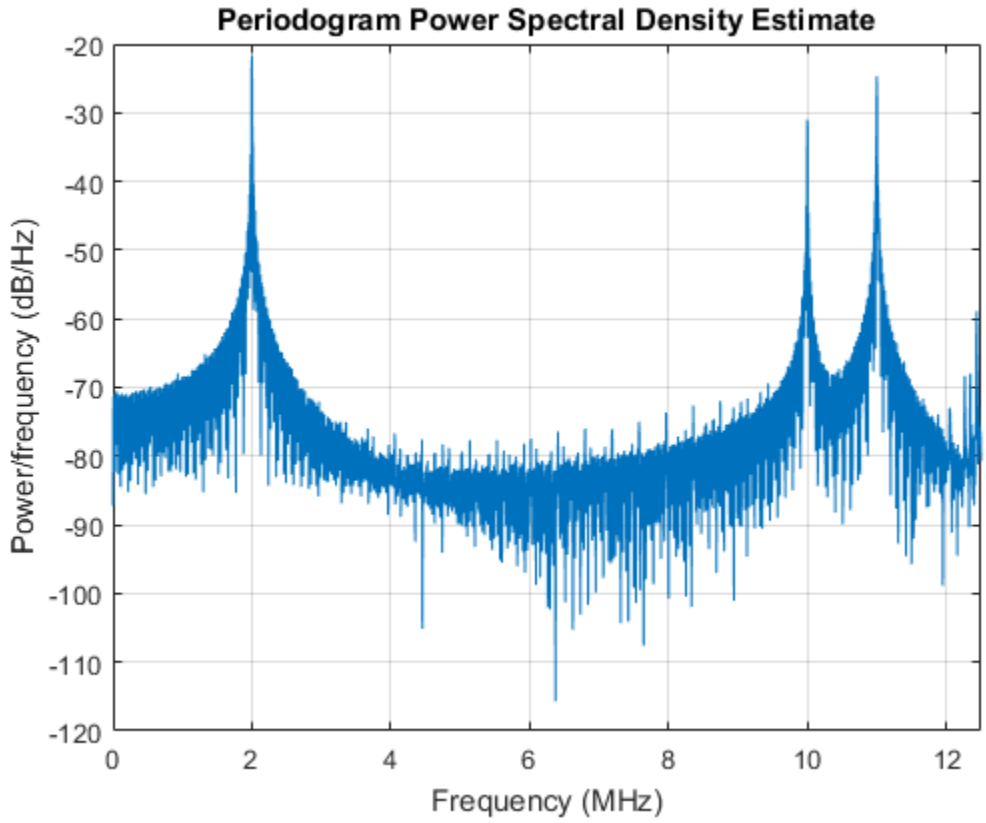
```
plot(t(1:300)*1e6,real(sig(1:300)))
hold on
```

```
plot(t(1:300)*1e6,real(radsig(1:300,1)))
plot(t(1:300)*1e6,real(radsig(1:300,2)))
hold off
xlabel('Time (\mu sec)')
ylabel('Amplitude')
legend('Input signal','Radiate to (30,10)','Radiate to (20,50)')
```



Plot the spectra of the signal that is radiated to (30,10) degrees.

```
periodogram(real(radsig(:,1)),rectwin(size(radsig,1)),4096,fs);
```



Definitions

Subband Frequency Processing

Subband processing decomposes a wideband signal into multiple subbands and applies narrowband processing to the signal in each subband. The signals for all subbands are summed to form the output signal.

When using wideband frequency System objects or blocks, you specify the number of subbands, N_b, in which to decompose the wideband signal. Subband center frequencies and widths are automatically computed from the total bandwidth and number of

subbands. The total frequency band is centered on the carrier or operating frequency, f_c. The overall bandwidth is given by the sample rate, f_s. Frequency subband widths are $\Delta f = f_s/N_B$. The center frequencies of the subbands are

$$f_m = \begin{cases} f_c - \dfrac{f_s}{2} + (m-1)\Delta f, & N_B \text{ even} \\ f_c - \dfrac{(N-1)f_s}{2N} + (m-1)\Delta f, & N_B \text{ odd} \end{cases} \quad ,m = 1,\ldots,N_B$$

Some System objects let you obtain the subband center frequencies as output from the `step` method. The returned subband frequencies are ordered consistent with the ordering of the discrete Fourier transform. Frequencies above the carrier appear first, followed by frequencies below the carrier.

For each subband, the `phased.WidebandRadiator` System object uses the narrowband phased approximation of the time delays across radiating elements in the far field.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

Introduced in R2015b

reset

System object: phased.WidebandRadiator
Package: phased

Reset states of System object

Syntax

```
reset(sWBR)
```

Description

`reset(sWBR)` resets the internal state of the `phased.WidebandRadiator` object, `sWBR`. If the `SeedSource` property applies, and has the value `'Property'`, then this method resets the state of the random number generator.

Input Arguments

`sWBR` — Wideband radiator

System object

Wideband radiator, specified as a System object.

Example: `phased.WidebandRadiator`

Introduced in R2015b

step

System object: phased.WidebandRadiator
Package: phased

Radiate wideband signals

Syntax

```
sigrad = step(sWBR,sig,ang)
sigrad = step(sWBR,sig,ang,laxes)
sigrad = step(sWBR,sig,ang,wts)
sigrad = step(sWBR,sig,ang,steerang)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`sigrad = step(sWBR,sig,ang)` radiates the signal `sig` in the directions specified by `ang`. For each direction, the method computes the radiated signal, `sigrad`, by summing the contributions of each element or subarray.

`sigrad = step(sWBR,sig,ang,laxes)` radiates the signal using the specified the local coordinate system of the radiator, `laxes`. This syntax applies when you set the `EnablePolarization` property to `true`.

`sigrad = step(sWBR,sig,ang,wts)` radiates the signal using `wts` as the weight vector when the `WeightsInputPort` property is `true`.

`sigrad = step(sWBR,sig,ang,steerang)` radiates the signal and uses `steerang` as the subarray steering angle. `steerang` must be a length-2 column vector in the form of `[AzimuthAngle; ElevationAngle]`. This syntax applies when you use a subarray as

the `Sensor` property and set the `SubarraySteering` property of the sensor to `'Phase'` or `'Time'`.

You can combine optional input arguments when you set their enabling properties in the System object during construction. Optional inputs must be listed in the same order as their enabling properties. For example, `sigrad = step(sWBR,sig,laxes,wts, steerang)` is valid when you set both `EnablePolarization` and `WeightsInputPort` to `true` and set the `SubarraySteering` property of the sensor.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`sWBR` — Wideband radiator

System object

Wideband radiator, specified as a phased.WidebandRadiator System object.

Example: `phased.WidebandRadiator`

`sig` — Input signals

M-by-1 complex-valued column vector | *M*-by-*N* complex-valued matrix

Input signals, specified as an *M*-by-1 complex-valued column vector or *M*-by-*N* complex-valued matrix. The quantity *M* is the number of sample values (snapshots) of the signal. If `sig` is a column vector, the same signal is radiated through all elements. If `sig` is a matrix, *N* is the number of sensor elements in the array. For subarrays, *N* is the number of subarrays. Each column of `sig` represents the field radiated by the corresponding element or subarray.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Example: `[[0;1;2;3;4;3;2;1;0],[1;2;3;4;3;2;1;0;0]]`

Data Types: `double`
Complex Number Support: Yes

`ang` — Radiating directions

2-by-L real-valued matrix | 1-by-L real-valued row vector

Radiating directions of the signal, specified as 2-by-L real-valued matrix or 1-by-L real-valued row vector. The quantity L is the number of directions to radiate. If `ang` is a matrix, each column has the form `[azimuth;elevation]`. If `ang` is a row vector, each entry represents the azimuthal direction. The elevation direction is zero degrees. Angle units are in degrees. Angles are defined with respect to the local coordinate system of the array.

When the sensory array is a uniform linear array, `ang` represents the broadside angle.

Data Types: `double`

`laxes` — Local coordinate system axes

`eye(3,3)` (default) | 3-by-3 real-valued orthonormal matrix

Local coordinate system axes, specified as a 3-by-3 real-valued matrix orthonormal matrix. The matrix columns specify the x, y, and z axes of the local coordinate system. Each column takes the form `[x;y;z]` with respect to the global coordinate system. This argument only applies when the `EnablePolarization` property is set to `true`.

Data Types: `double`

`wts` — Weight vector

`ones(N,1)` (default) | N-by-1 complex-valued column vector

Weight vector, specified as an N-by-1 complex-valued column vector. Each weight vector element multiplies the signal at the corresponding element or subarray. N is the number of radiating elements or subarrays. This argument only applies when the `WeightsInputPort` property is `true`.

Data Types: `double`
Complex Number Support: Yes

`steerang` — Subarray steering angle

2-by-1 real-valued column vector

Subarray steering angle, specified as a 2-by-1 real-valued column vector in the form of `[AzimuthAngle; ElevationAngle]`. This argument applies only when the `Sensor`

property refers to a subarray and the `SubarraySteering` property of the sensor is set to `'Phased'` or `'Time'`. Angles are defined with respect to the local coordinate system axes. Angle units are in degrees.

Data Types: `double`

Output Arguments

`sigrad` — Radiated signal

M-by-*L* complex-valued matrix | 1-by-*L* array of `struct` type

Radiated signal, returned as an *M*-by-*L* complex-valued matrix or 1-by-*L* array of `struct` type depending on whether polarization is enabled. The radiated field is the combined far-field output from all elements or subarrays. The quantity *M* is the number of sample values (snapshots) of the signal. The quantity *L* is the number of entries in `ang`.

- If you set `EnablePolarization` to `false`, `sigrad` is an *M*-by-*L* complex-valued matrix.
- If you set `EnablePolarization` is `true`, `sigrad` is a 1-by-*L* array of `struct` type. Each `struct` in the array has three data fields: `sigrad.X`, `sigrad.Y`, `sigrad.Z` which correspond to the *x*, *y*, and *z* components of the electromagnetic field. Electromagnetic field components are defined with respect to the global coordinate system. Each data field is an *M*-by-1 column vector.

Examples

Radiate Wideband Energy from Array

Create a 5-by-5 URA and space the elements one-half wavelength apart. The wavelength corresponds to a design frequency of 300 MHz.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Create 5-by-5 URA Array of Cosine Elements

```
c = physconst('LightSpeed');
```

```
fc = 100e6;
lam = c/fc;
antenna = phased.CosineAntennaElement('CosinePower',[2,2]);
array = phased.URA('Element',antenna,'Size',[5,5],'ElementSpacing',[0.5,0.5]*lam);
```

Create and Radiate Wideband Signal

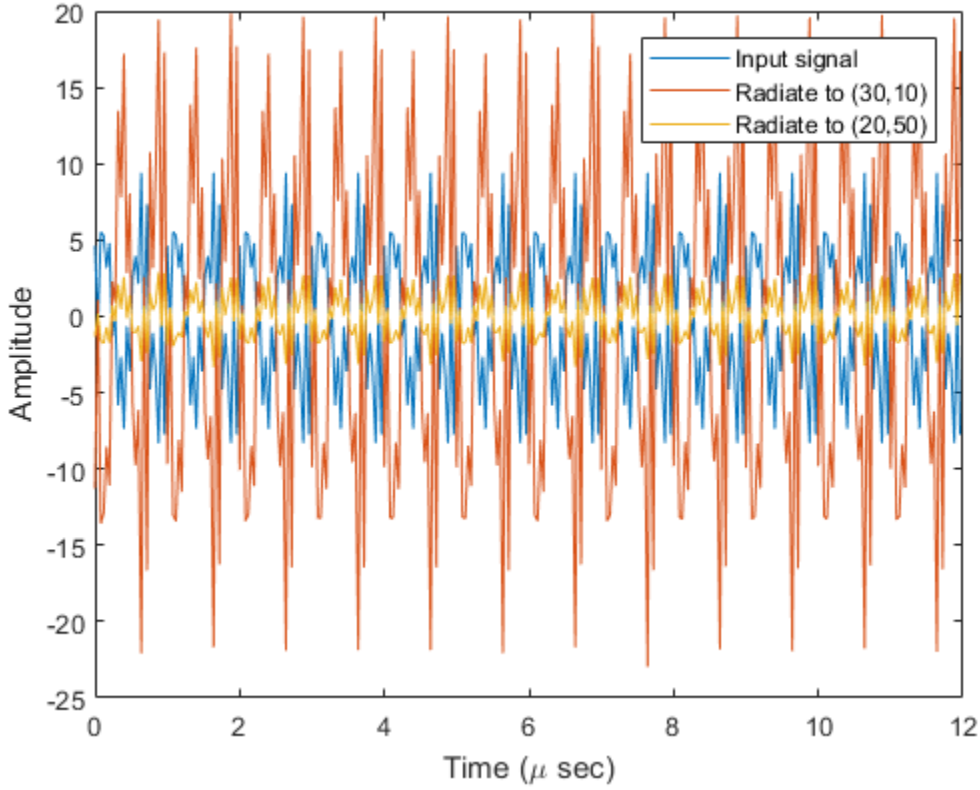
Radiate a wideband signal consisting of three sinusoids at 2, 10 and 11 MHz. Set the sampling rate to 25 MHz. Radiate the fields into two directions: (30,10) degrees azimuth and elevation and (20,50) degrees azimuth and elevation.

```
fs = 25e6;
f1 = 2e6;
f2 = 10e6;
f3 = 11e6;
dt = 1/fs;
Tsig = 100e-6;
t = [0:dt:Tsig];
sig = 5.0*sin(2*pi*f1*t) + 2.0*sin(2*pi*f2*t + pi/10) + 4*sin(2*pi*f3*t + pi/2);
radiatingangles = [30 10; 20 50]';
radiator = phased.WidebandRadiator('Sensor',array,'CarrierFrequency',fc,'SampleRate',fs
radsig = radiator(sig.',radiatingangles);
```

Plot Radiated Signal

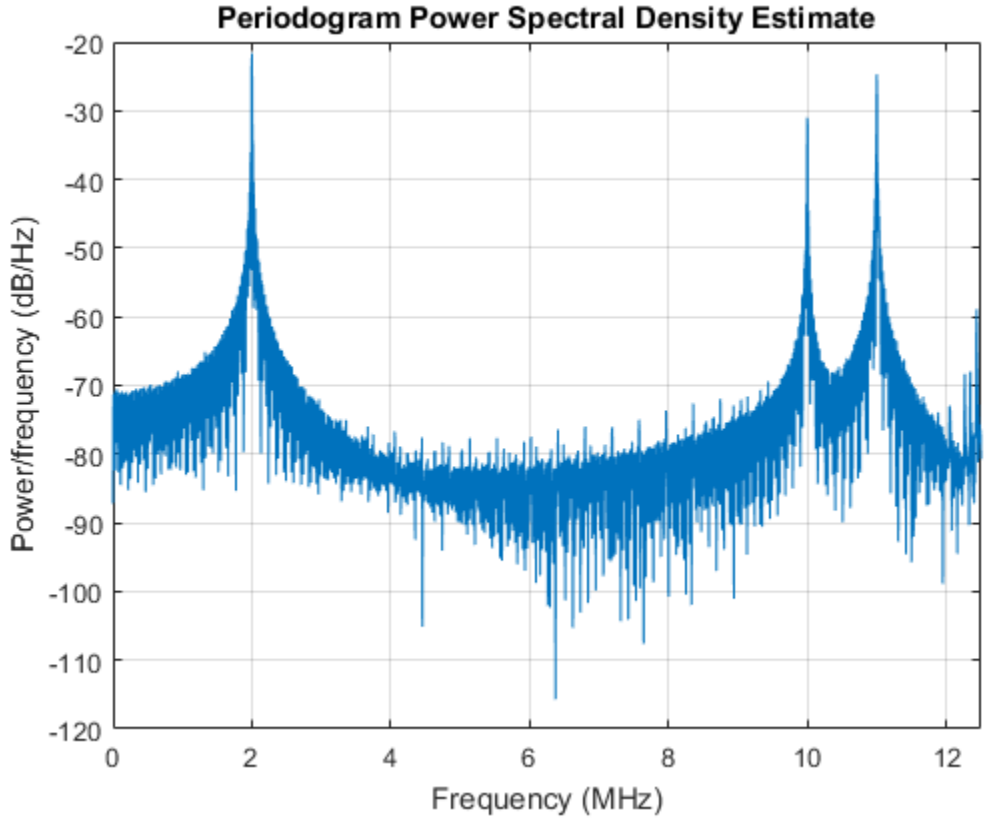
Plot the input signal to the radiator and the radiated signals.

```
plot(t(1:300)*1e6,real(sig(1:300)))
hold on
plot(t(1:300)*1e6,real(radsig(1:300,1)))
plot(t(1:300)*1e6,real(radsig(1:300,2)))
hold off
xlabel('Time (\mu sec)')
ylabel('Amplitude')
legend('Input signal','Radiate to (30,10)','Radiate to (20,50)')
```



Plot the spectra of the signal that is radiated to (30,10) degrees.

```
periodogram(real(radsig(:,1)),rectwin(size(radsig,1)),4096,fs);
```



Radiate Wideband Polarized Fields from Array

Examine the polarized field produced by the wideband radiator from a five-element uniform line array (ULA) composed of short-dipole antenna elements.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Set up the ULA of five short-dipole antennas with polarization enabled. The element spacing is set to 1/2 wavelength of the carrier frequency. Construct the wideband radiator System object™.

```
fc = 100e6;
```

```
c = physconst('LightSpeed');
lam = c/fc;
antenna = phased.ShortDipoleAntennaElement;
array = phased.ULA('Element',antenna,'NumElements',5,'ElementSpacing',lam/2);
% Radiate a signal consisting of the sum of three sine waves. Radiate the
% signal into two different directions.  Radiated angles are azimuth and elevation
% angles defined with respect to a local coordinate system. The local
% coordinate system is defined by 10 degree rotation around the x-axis from
% the global coordinates.
fs = 25e6;
f1 = 2e6;
f2 = 10e6;
f3 = 11e6;
dt = 1/fs;
fc = 100e6;
t = [0:dt:100e-6];
sig = 5.0*sin(2*pi*f1*t) + 2.0*sin(2*pi*f2*t + pi/10) + 4*sin(2*pi*f3*t + pi/2);
radiatingAngle = [30 30; 0 20];
laxes = rotx(10);
radiator = phased.WidebandRadiator('Sensor',array,'SampleRate',fs,...
    'CarrierFrequency',fc,'EnablePolarization',true);
y = radiator(sig.',radiatingAngle,laxes);
```

Plot the first 200 samples of the *y* and *z* components of the polarized field propagating in the `[30,0]` direction.

```
plot(10^6*t(1:200),real(y(1).Y(1:200)))
hold on
plot(10^6*t(1:200),real(y(1).Z(1:200)))
hold off
xlabel('Time (\mu sec)')
ylabel('Amplitude')
legend('Y Polarization','Z Polarization')
```

phased.WidebandTwoRayChannel System object

Package: phased

Wideband two-ray propagation channel

Description

The `phased.WidebandTwoRayChannel` models a wideband two-ray propagation channel. A two-ray propagation channel is the simplest type of multipath channel. You can use a two-ray channel to simulate propagation of signals in a homogeneous, isotropic medium with a single reflecting boundary. This type of medium has two propagation paths: a line-of-sight (direct) propagation path from one point to another and a ray path reflected from the boundary.

You can use this System object for short-range radar and mobile communications applications where the signals propagate along straight paths and the earth is assumed to be flat. You can also use this object for sonar and microphone applications. For acoustic applications, you can choose nonpolarized fields and adjust the propagation speed to be the speed of sound in air or water. You can use `phased.WidebandTwoRayChannel` to model propagation from several points simultaneously.

Although the System object works for all frequencies, the attenuation models for atmospheric gases and rain are valid for electromagnetic signals in the frequency range 1–1000 GHz only. The attenuation model for fog and clouds is valid for 10–1000 GHz. Outside these frequency ranges, the System object uses the nearest valid value.

The `phased.WidebandTwoRayChannel` System object applies range-dependent time delays to the signals, as well as gains or losses, phase shifts, and boundary reflection loss. When either the source or destination is moving, the System object applies Doppler shifts to the signals.

Signals at the channel output can be kept *separate* or be *combined*. If you keep the signals separate, both signals arrive at the destination separately and are not combined. If you choose to combine the signals, the two signals frome the source propagate separately but are coherently summed at the destination into a single quantity. Choose this option when the difference between the sensor or array gains in the directions of the two paths is insignificant.

In contrast to the phased.WidebandFreeSpace and phased.WidebandLOSChannel System objects, this System object does not support two-way propagation.

To compute the propagation delay for specified source and receiver points:

1. Define and set up your two-ray channel. See"Construction" on page 1-1984.
2. Call the `step` method to compute the propagated signal using the properties of the `phased.WidebandTwoRayChannel` System object.

Note: Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`channel = phased.WidebandTwoRayChannel` creates a two-ray propagation channel System object, `channel`.

`channel = phased.WidebandTwoRayChannel(Name,Value)` creates a System object, `channel`, with each specified property `Name` set to the specified `Value`. You can specify additional name and value pair arguments in any order as (`Name1,Value1,...,NameN,ValueN`).

Properties

`PropagationSpeed` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. Units are in m/s. The default value of the speed of light is the value returned by `physconst('LightSpeed')`.

Example: `3e8`

Data Types: `double`

`OperatingFrequency` — Signal carrier frequency

`300e6` (default) | positive real-valued scalar

Signal carrier frequency, specified as a positive real-valued scalar. Units are in Hz.

Example: `1e9`

Data Types: `double`

`SpecifyAtmosphere` — Enable atmospheric attenuation model
`false` (default) | `true`

Option to enable the atmospheric attenuation model, specified as a `false` or `true`. Set this property to `true` to add signal attenuation caused by atmospheric gases, rain, fog, or clouds. Set this property to `false` to ignore atmospheric effects in propagation.

Setting `SpecifyAtmosphere` to `true`, enables the `Temperature`, `DryAirPressure`, `WaterVapourDensity`, `LiquidWaterDensity`, and `RainRate` properties.

Data Types: `logical`

`Temperature` — Ambient temperature
`15` (default) | real-valued scalar

Ambient temperature, specified as a real-valued scalar. Units are in degrees Celsius.

Example: `20.0`

Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

`DryAirPressure` — Atmospheric dry air pressure
`101.325e3` (default) | positive real-valued scalar

Atmospheric dry air pressure, specified as a positive real-valued scalar. Units are in pascals (Pa). The default value of this property corresponds to one standard atmosphere.

Example: `101.0e3`

Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

`WaterVapourDensity` — Atmospheric water vapor density

`7.5` (default) | positive real-valued scalar

Atmospheric water vapor density, specified as a positive real-valued scalar. Units are in g/m^3.

Example: `7.4`

Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

`LiquidWaterDensity` — Liquid water density

`0.0` (default) | nonnegative real-valued scalar

Liquid water density of fog or clouds, specified as a nonnegative real-valued scalar. Units are in g/m^3. Typical values for liquid water density are 0.05 for medium fog and 0.5 for thick fog.

Example: `0.1`

Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

`RainRate` — Rainfall rate

`0.0` (default) | nonnegative scalar

Rainfall rate, specified as a nonnegative scalar. Units are in mm/hr.

Example: `10.0`

Dependencies

To enable this property, set `SpecifyAtmosphere` to `true`.

Data Types: `double`

`SampleRate` — Sample rate of signal

`1e6` (default) | positive scalar

Sample rate of signal, specified as a positive scalar. Units are in Hz. The System object uses this quantity to calculate the propagation delay in units of samples.

Example: `1e6`

Data Types: `double`

`NumSubbands` — Number of processing subbands

`64` (default) | positive integer

Number of processing subbands, specified as a positive integer.

Example: `128`

Data Types: `double`

`EnablePolarization` — Enable polarized fields

`false` (default) | true

Option to enable polarized fields, specified as a logical scalar. Set this property to `true` to enable polarization. Set this property to `false` to ignore polarization.

Data Types: `logical`

`GroundReflectionCoefficient` — Ground reflection coefficient

`-1` (default) | complex-valued scalar | complex-valued 1-by-*N* row vector

Ground reflection coefficient for the field at the reflection point, specified as a complex-valued scalar or a complex-valued 1-by-*N* row vector. Each coefficient has an absolute value less than or equal to one. The quantity *N* is the number of two-ray channels. Units are dimensionless. Use this property to model nonpolarized signals. To model polarized signals, use the `GroundRelativePermittivity` property.

Example: `-0.5`

Dependencies

To enable this property, set `EnablePolarization` to `false`.

Data Types: `double`
Complex Number Support: Yes

`GroundRelativePermittivity` — Ground relative permittivity

`15` (default) | positive real-valued scalar | real-valued 1-by-*N* row vector of positive values

Relative permittivity of the ground at the reflection point, specified as a positive real-valued scalar or a 1-by-*N* real-valued row vector of positive values. The dimension *N* is the number of two-ray channels. Permittivity units are dimensionless. Relative permittivity is defined as the ratio of actual ground permittivity to the permittivity of free space. This property applies when you set the `EnablePolarization` property to `true`. Use this property to model polarized signals. To model nonpolarized signals, use the `GroundReflectionCoefficient` property.

Example: `5`

Dependencies

To enable this property, set `EnablePolarization` to `true`.

Data Types: `double`

`CombinedRaysOutput` — Option to combine two rays at output

`true` (default) | `false`

Option to combine the two rays at channel output, specified as `true` or `false`. When this property is `true`, the object coherently adds the line-of-sight propagated signal and the reflected path signal when forming the output signal. Use this mode when you do not need to include the directional gain of an antenna or array in your simulation.

Data Types: `logical`

`MaximumDistanceSource` — Source of maximum one-way propagation distance

`'Auto'` (default) | `'Property'`

Source of maximum one-way propagation distance, specified as `'Auto'` or `'Property'`. The maximum one-way propagation distance is used to allocate sufficient memory for signal delay computation. When you set this property to `'Auto'`, the System object automatically allocates memory. When you set this property to `'Property'`, you specify the maximum one-way propagation distance using the value of the `MaximumDistance` property.

Data Types: char

MaximumDistance — Maximum one-way propagation distance

10000 (default) | positive real-valued scalar

Maximum one-way propagation distance, specified as a positive real-valued scalar. Units are in meters. Any signal that propagates more than the maximum one-way distance is ignored. The maximum distance must be greater than or equal to the largest position-to-position distance.

Example: 5000

Dependencies

To enable this property, set the MaximumDistanceSource property to 'Property'.

Data Types: double

MaximumNumInputSamplesSource — Source of maximum number of samples

'Auto' (default) | 'Property'

The source of the maximum number of samples of the input signal, specified as 'Auto' or 'Property'. When you set this property to 'Auto', the propagation model automatically allocates enough memory to buffer the input signal. When you set this property to 'Property', you specify the maximum number of samples in the input signal using the MaximumNumInputSamples property. Any input signal longer than that value is truncated.

When you use propagation models in MATLAB Function Block in Simulink with variable-size signals, you must set the MaximumNumInputSamples parameter to 'Property' and set the MaximumNumInputSamples parameter accordingly.

Example: 'Property'

Dependencies

To enable this property, set MaximumDistanceSource to 'Property'.

Data Types: char

`MaximumNumInputSamples` — Maximum number of input signal samples

100 (default) | positive integer

Maximum number of input signal samples, specified as a positive integer. The input signal is the first argument of the `step` method, after the System object itself. The size of the input signal is the number of rows in the input matrix. Any input signal longer than this number is truncated. To process signals completely, ensure that this property value is greater than any maximum input signal length.

The waveform-generating System objects determine the maximum signal size:

- For any waveform, if the waveform `OutputFormat` property is set to `'Samples'`, the maximum signal length is the value specified in the `NumSamples` property.
- For pulse waveforms, if the `OutputFormat` is set to `'Pulses'`, the signal length is the product of the smallest pulse repetition frequency, the number of pulses, and the sample rate.
- For continuous waveforms, if the `OutputFormat` is set to `'Sweeps'`, the signal length is the product of the sweep time, the number of sweeps, and the sample rate.

Example: 2048

Dependencies

To enable this property, set `MaximumNumInputSamplesSource` to `'Property'`.

Data Types: `double`

Methods

reset	Reset states of System object
step	Propagate wideband signal from point to point using two-ray channel model

Common to All System Objects	
`clone`	Create System object with same property values

Common to All System Objects	
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Scalar Wideband Signal Propagating in Two-Ray Channel

This example illustrates the two-ray propagation of a wideband signal, showing how the signals from the line-of-sight path and reflected path arrive at the receiver at different times.

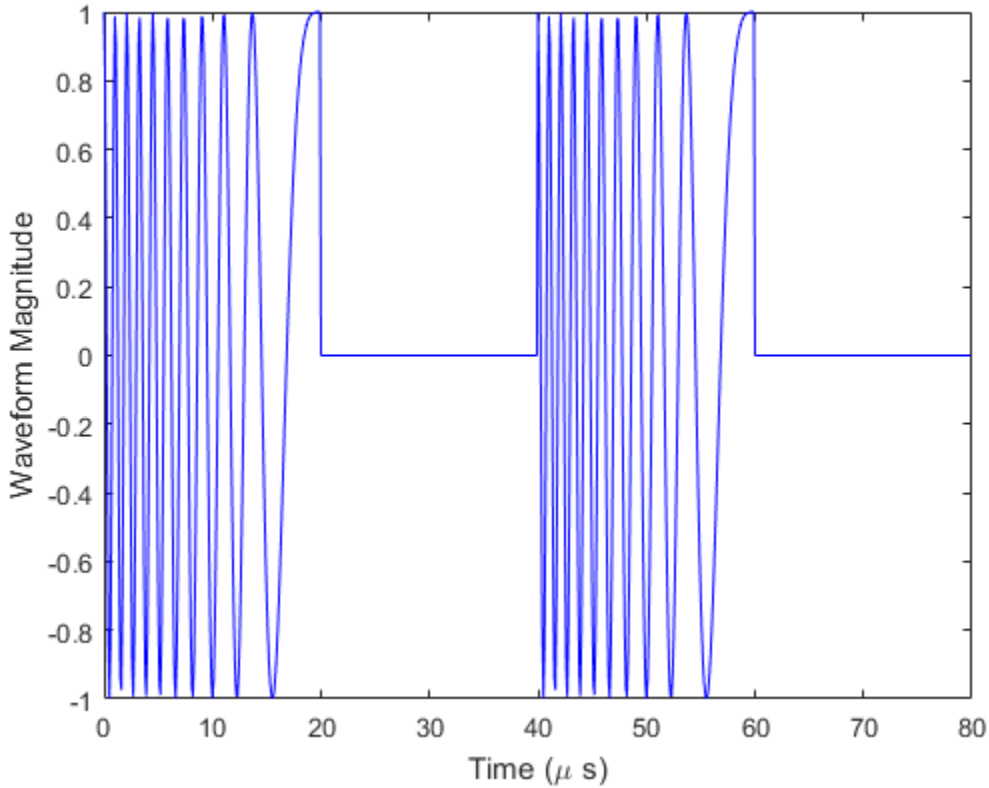
Note: You can replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Create and Plot Transmitted Waveform

Create a nonpolarized electromagnetic field consisting of two linear FM waveform pulses at a carrier frequency of 100 MHz. Assume the pulse width is 20 µs and the sampling rate is 10 MHz. The bandwidth of the pulse is 1 MHz. Assume a 50% duty cycle so that the pulse width is one-half the pulse repetition interval. Create a two-pulse wave train. Set the `GroundReflectionCoefficient` to –0.9 to model strong ground reflectivity. Propagate the field from a stationary source to a stationary receiver. The vertical separation of the source and receiver is approximately 10 km.

```
c = physconst('LightSpeed');
fs = 10e6;
pw = 20e-6;
pri = 2*pw;
PRF = 1/pri;
fc = 100e6;
lambda = c/fc;
bw = 1e6;
waveform = phased.LinearFMWaveform('SampleRate',fs,'PulseWidth',pw,...
    'PRF',PRF,'OutputFormat','Pulses','NumPulses',2,'SweepBandwidth',bw,...
    'SweepDirection','Down','Envelope','Rectangular','SweepInterval',...
    'Positive');
```

```
wav = waveform();
n = size(wav,1);
plot([0:(n-1)]/fs*1e6,real(wav),'b')
xlabel('Time (\mu s)')
ylabel('Waveform Magnitude')
```



Specify the Location of Source and Receiver

Place the source and receiver about 1 km apart horizontally and approximately 5 km apart vertically.

```
pos1 = [0;0;100];
pos2 = [1e3;0;5.0e3];
vel1 = [0;0;0];
```

```
vel2 = [0;0;0];
```

Create a Wideband Two-Ray Channel System Object

Create a two-ray propagation channel System object™ and propagate the signal along both the line-of-sight and reflected ray paths. The same signal is propagated along both paths.

```
channel = phased.WidebandTwoRayChannel('SampleRate',fs,...
    'GroundReflectionCoefficient',-0.9,'OperatingFrequency',fc,...
    'CombinedRaysOutput',false);
prop_signal = channel([wav,wav],pos1,pos2,vel1,vel2);

[rng2,angs] = rangeangle(pos2,pos1,'two-ray');
```

Calculate time delays in μs.

```
tm = rng2/c*1e6;
disp(tm)
```

```
   16.6815   17.3357
```

Display the calculated propagation paths azimuth and elevation angles in degrees.

```
disp(angs)
```

```
         0         0
   78.4654  -78.9063
```

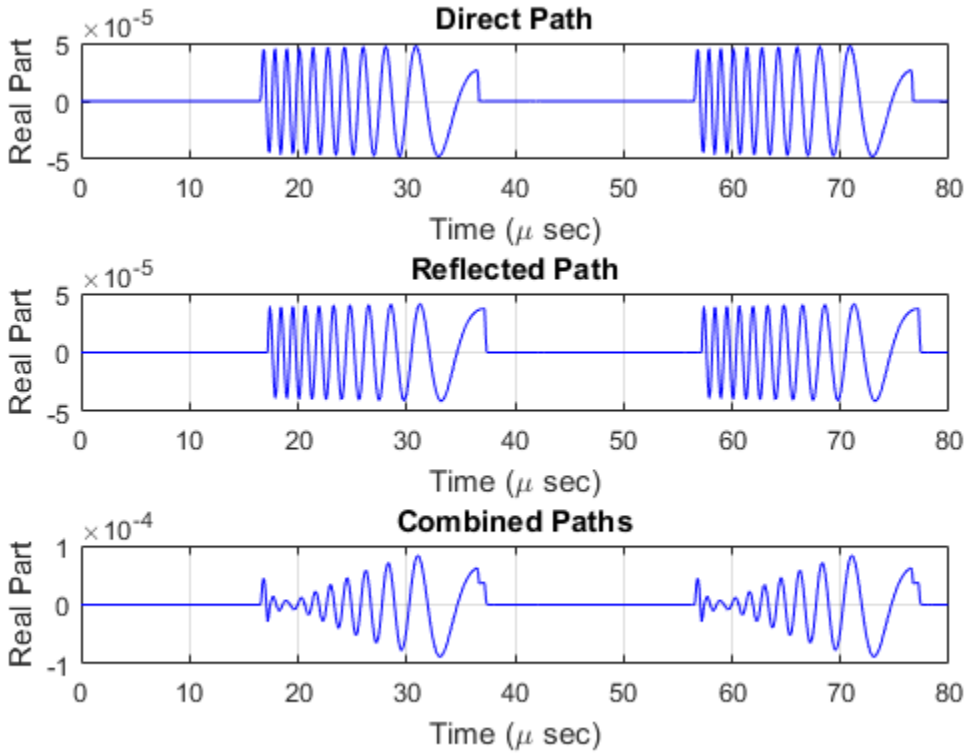
Plot the Propagated Signals

1. Plot the real part of the signal propagated along the line-of-sight path.
2. Plot the real part of the signal propagated along the reflected path.
3. Plot the real part of the coherent sum of the two signals.

```
n = size(prop_signal,1);
delay = [0:(n-1)]/fs*1e6;
subplot(3,1,1)
plot(delay,real([prop_signal(:,1)]),'b')
grid
xlabel('Time (\mu sec)')
ylabel('Real Part')
title('Direct Path')
```

```
subplot(3,1,2)
plot(delay,real([prop_signal(:,2)]),'b')
grid
xlabel('Time (\mu sec)')
ylabel('Real Part')
title('Reflected Path')

subplot(3,1,3)
plot(delay,real([prop_signal(:,1) + prop_signal(:,2)]),'b')
grid
xlabel('Time (\mu sec)')
ylabel('Real Part')
title('Combined Paths')
```



The delay of the reflected path signal agrees with the predicted delay. The magnitude of the coherently combined signal is less than either of the propagated signals. This result indicates that the two signals contain some interference.

Compare Wideband Two-Ray Channel Propagation to Free Space

Calculate the result of propagating a wideband LFM signal in a two-ray environment from a radar 10 meters above the origin *(0,0,10)* to a target at *(3000,2000,2000)* meters. Assume that the radar and target are stationary and that the transmitting antenna is isotropic. Combine the signal from the two paths and compare the signal to a signal propagating in free space. The system operates at 300 MHz. Set the `CombinedRaysOutput` property to `true` to combine the direct path and reflected path signals when forming the output signal.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Create a linear FM waveform.

```
fop = 300.0e6;
fs = 1.0e6;
waveform = phased.LinearFMWaveform();
x = waveform();
```

Specify the target position and velocity.

```
posTx = [0; 0; 10];
posTgt = [3000; 2000; 2000];
velTx = [0;0;0];
velTgt = [0;0;0];
```

Model the free space propagation.

```
fschannel = phased.WidebandFreeSpace('SampleRate',waveform.SampleRate);
y_fs = fschannel(x,posTx,posTgt,velTx,velTgt);
```

Model two-ray propagation from the position of the radar to the target.

```
tworaychannel = phased.WidebandTwoRayChannel('SampleRate',waveform.SampleRate,...
    'CombinedRaysOutput',true);
y_tworay = tworaychannel(x,posTx,posTgt,velTx,velTgt);
```

```
plot(abs([y_tworay y_fs]))
legend('Wideband two-ray (Position 1)','Wideband free space (Position 1)',...
    'Location','best')
xlabel('Samples')
ylabel('Signal Magnitude')
hold on
```

Move the radar by 10 meters horizontally to a second position.

```
posTx = posTx + [10;0;0];
y_fs = fschannel(x,posTx,posTgt,velTx,velTgt);
y_tworay = tworaychannel(x,posTx,posTgt,velTx,velTgt);
plot(abs([y_tworay y_fs]))
legend('Wideband two-ray (Position 1)','Wideband free space (Position 1)',...
```

```
    'Wideband two-ray (Position 2)','Wideband free space (Position 2)',...
    'Location','best')
hold off
```

The free-space propagation losses are the same for both the first and second positions of the radar. The two-ray losses are different due to the interference effect of the two-ray paths.

Wideband Polarized Field Propagation in Two-Ray Channel

Create a polarized electromagnetic field consisting of linear FM waveform pulses. Propagate the field from a stationary source with a crossed-dipole antenna element to a stationary receiver approximately 10 km away. The transmitting antenna is 100 m above

the ground. The receiving antenna is 150 m above the ground. The receiving antenna is also a crossed-dipole. Plot the received signal.

Note: You can replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Set Radar Waveform Parameters

Assume the pulse width is 10 μs and the sampling rate is 10 MHz. The bandwidth of the pulse is 1 MHz. Assume a 50% duty cycle in which the pulse width is one-half the pulse repetition interval. Create a two-pulse wave train. Assume a carrier frequency of 100 MHz.

```
c = physconst('LightSpeed');
fs = 20e6;
pw = 10e-6;
pri = 2*pw;
PRF = 1/pri;
fc = 100e6;
bw = 1e6;
lambda = c/fc;
```

Set Up Required System Objects

Use a `GroundRelativePermittivity` of 10.

```
waveform = phased.LinearFMWaveform('SampleRate',fs,'PulseWidth',pw,...
    'PRF',PRF,'OutputFormat','Pulses','NumPulses',2,'SweepBandwidth',bw,...
    'SweepDirection','Down','Envelope','Rectangular','SweepInterval',...
    'Positive');
antenna = phased.CrossedDipoleAntennaElement(...
    'FrequencyRange',[50,200]*1e6);
radiator = phased.Radiator('Sensor',antenna,'OperatingFrequency',fc,...
    'EnablePolarization',true);
channel = phased.WidebandTwoRayChannel('SampleRate',fs,...
    'OperatingFrequency',fc,'CombinedRaysOutput',false,...
    'EnablePolarization',true,'GroundRelativePermittivity',10);
collector = phased.Collector('Sensor',antenna,'OperatingFrequency',fc,...
    'EnablePolarization',true);
```

Set Up Scene Geometry

Specify transmitter and receiver positions, velocities, and orientations. Place the source and receiver approximately 1000 m apart horizontally and approximately 50 m apart vertically.

```
posTx = [0;100;100];
posRx = [1000;0;150];
velTx = [0;0;0];
velRx = [0;0;0];
laxRx = rotz(180);
laxTx = rotx(1)*eye(3);
```

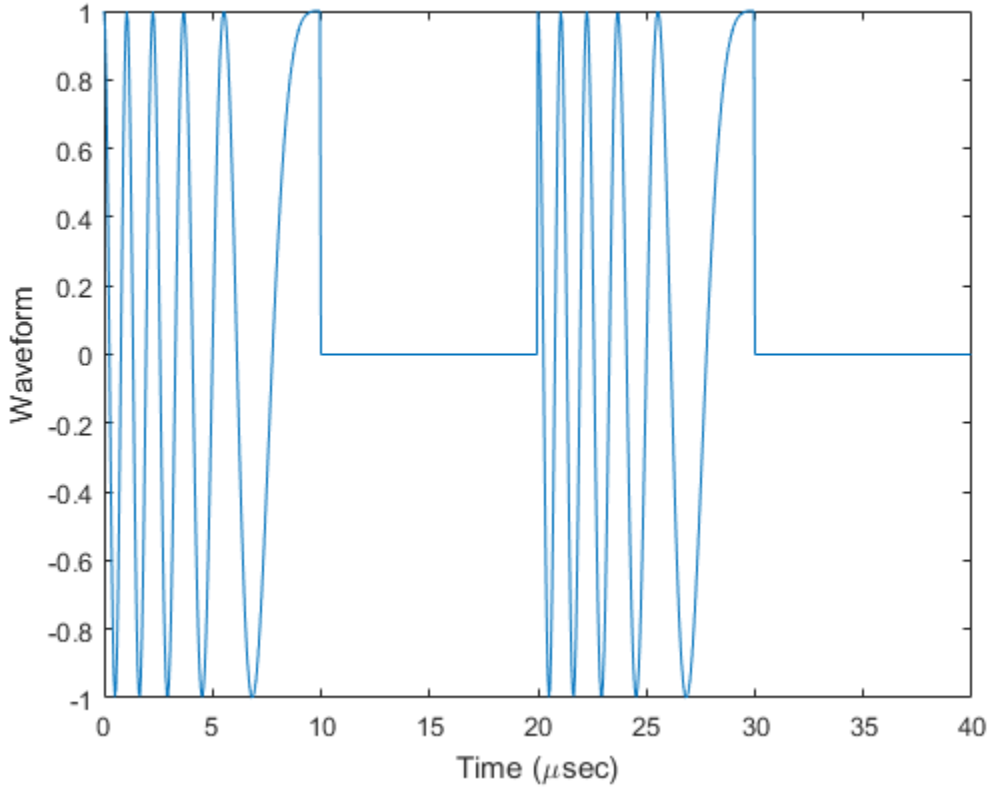
Create and Radiate Signals from Transmitter

Compute the transmission angles for the two rays traveling toward the receiver. These angles are defined with respect to the transmitter local coordinate system. The `phased.Radiator` System object™ uses these angles to apply separate antenna gains to the two signals.

```
[rng,angsTx] = rangeangle(posRx,posTx,laxTx,'two-ray');
wav = waveform();
```

Plot the transmitted waveform.

```
n = size(wav,1);
plot([0:(n-1)]/fs*1000000,real(wav))
xlabel('Time ({\mu}sec)')
ylabel('Waveform')
sig = radiator(wav,angsTx,laxTx);
```



Propagate the signals to the receiver via a two-ray channel.

```
prop_sig = channel(sig,posTx,posRx,velTx,velRx);
```

Receive Propagated Signal

Compute the reception angles for the two rays arriving at the receiver. These angles are defined with respect to the receiver local coordinate system. The `phased.Collector` System object™ uses these angles to apply separate antenna gains to the two signals.

```
[rng1,angsRx] = rangeangle(posTx,posRx,laxRx,'two-ray');
delays = rng1/c*1e6
```

```
delays =

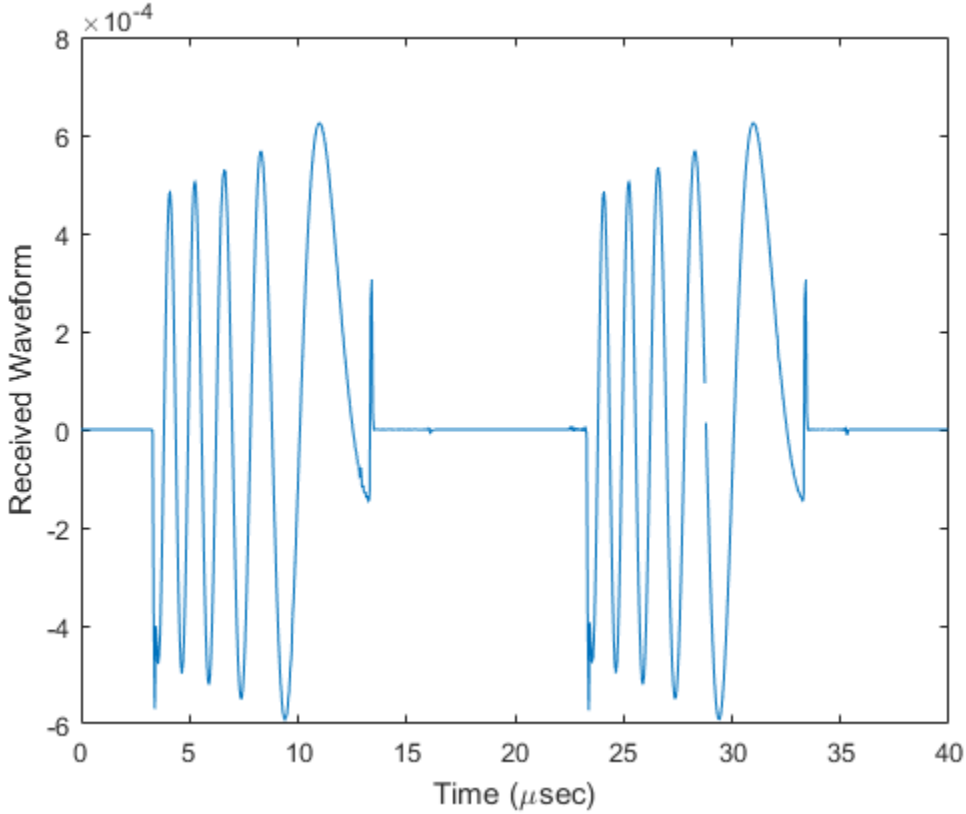
    3.3564    3.4544
```

Collect and combine the received rays.

```
y = collector(prop_sig,angsRx,laxRx);
```

Plot the received waveform.

```
plot([0:(n-1)]/fs*1000000,real(y))
xlabel('Time ({\mu}sec)')
ylabel('Received Waveform')
```



Two-Ray Propagation of Wideband LFM Waveform with Atmospheric Losses

Propagate a wideband linear FM signal in a two-ray channel. The signal bandwidth is 15% of the carrier frequency. Assume there is signal loss caused by atmospheric gases and rain. The signal propagates from a transmitter located at `(0,0,0)` meters in the global coordinate system to a receiver at `(10000,200,30)` meters. Assume that the transmitter and the receiver are stationary and that they both have cosine antenna patterns. Plot the received signal. Set the dry air pressure to 102.0 Pa and the rain rate to 5 mm/hr.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Set Radar Waveform Parameters

```
c = physconst('LightSpeed');
fs = 40e6;
pw = 10e-6;
pri = 2.5*pw;
PRF = 1/pri;
fc = 100e6;
bw = 15e6;
lambda = c/fc;
```

Set Up Radar Scenario

Create the required System objects.

```
waveform = phased.LinearFMWaveform('SampleRate',fs,'PulseWidth',pw,...
    'PRF',PRF,'OutputFormat','Pulses','NumPulses',2,'SweepBandwidth',bw,...
    'SweepDirection','Down','Envelope','Rectangular','SweepInterval',...
    'Positive');
antenna = phased.CosineAntennaElement;
radiator = phased.Radiator('Sensor',antenna);
collector = phased.Collector('Sensor',antenna);
channel = phased.WidebandTwoRayChannel('SampleRate',waveform.SampleRate,...
    'CombinedRaysOutput',false,'GroundReflectionCoefficient',0.95,...
    'SpecifyAtmosphere',true,'Temperature',20,...
    'DryAirPressure',102.5,'RainRate',5.0);
```

Set up the scene geometry. Specify transmitter and receiver positions and velocities. The transmitter and receiver are stationary.

```
posTx = [0;0;0];
posRx = [10000;200;30];
velTx = [0;0;0];
velRx = [0;0;0];
```

Specify the transmitting and receiving radar antenna orientations with respect to the global coordinates. The transmitting antenna points along the positive *x*-direction and the receiving antenna points close to the negative *x*-direction.

```
laxTx = eye(3);
laxRx = rotx(5)*rotz(170);
```

Compute the transmission angles which are the angles at which the two rays traveling toward the receiver leave the transmitter. The `phased.Radiator` System object™ uses

these angles to apply separate antenna gains to the two signals. Because the antenna gains depend on path direction, you must transmit and receive the two rays separately.

```
[~,angTx] = rangeangle(posRx,posTx,laxTx,'two-ray');
```

Create and Radiate Signals from Transmitter

Radiate the signals along the transmission directions.

```
wavfrm = waveform();
wavtrans = radiator(wavfrm,angTx);
```

Propagate the signals to the receiver via a two-ray channel.

```
wavrcv = channel(wavtrans,posTx,posRx,velTx,velRx);
```

Collect Signal at Receiver

Compute the angle at which the two rays traveling from the transmitter arrive at the receiver. The `phased.Collector` System object™ uses these angles to apply separate antenna gains to the two signals.

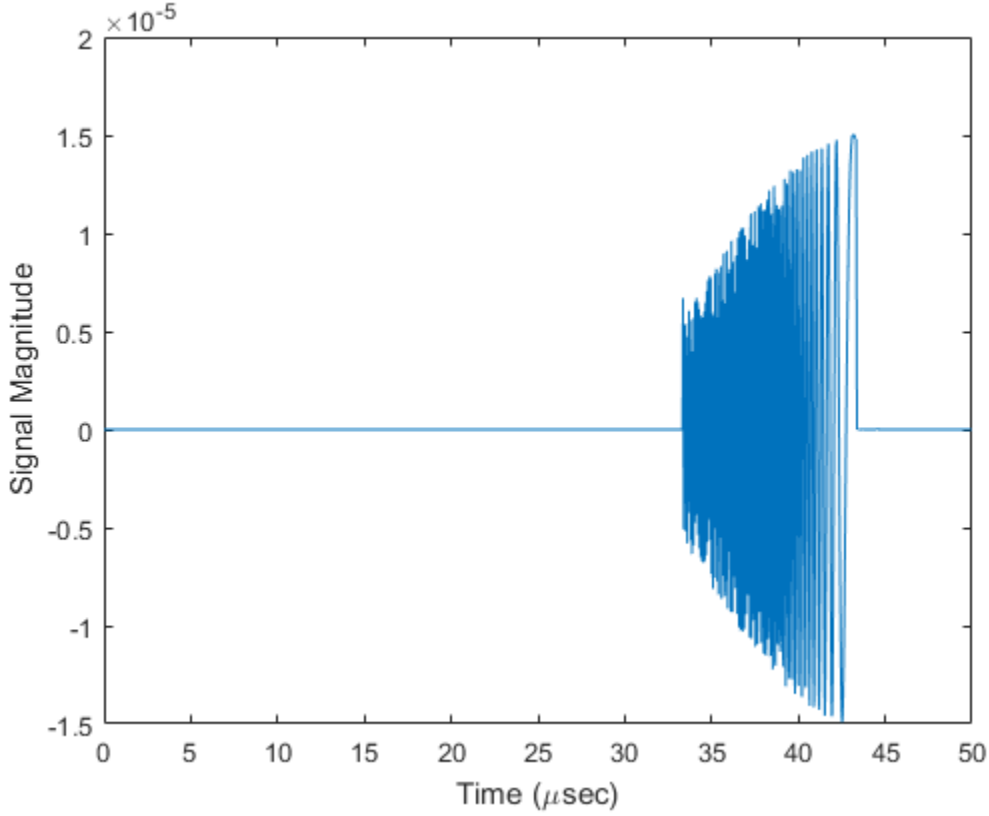
```
[~,angRcv] = rangeangle(posTx,posRx,laxRx,'two-ray');
```

Collect and combine the two received rays.

```
yR = collector(wavrcv,angRcv);
```

Plot Received Signal

```
dt = 1/waveform.SampleRate;
n = size(yR,1);
plot([0:(n-1)]*dt*1e6,real(yR))
xlabel('Time ({\mu}sec)')
ylabel('Signal Magnitude')
```



Definitions

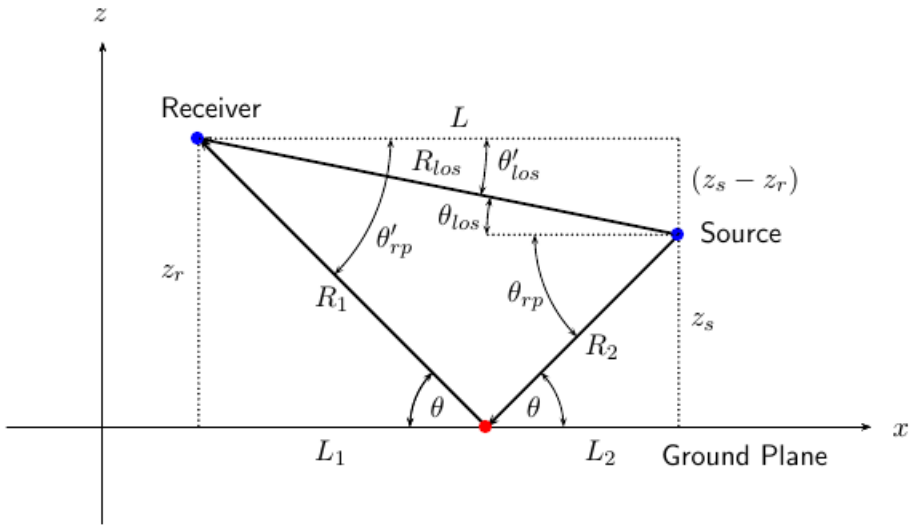
Two-Ray Propagation Paths

A two-ray propagation channel is the next step up in complexity from a free-space channel and is the simplest case of a multipath propagation environment. The free-space channel models a straight-line *line-of-sight* path from point 1 to point 2. In a two-ray channel, the medium is specified as a homogeneous, isotropic medium with a reflecting planar boundary. The boundary is always set at $z = 0$. There are at most two rays propagating from point 1 to point 2. The first ray path propagates along the same line-of-sight path as in the free-space channel (see the phased.FreeSpace System

object). The line-of-sight path is often called the *direct path*. The second ray reflects off the boundary before propagating to point 2. According to the Law of Reflection , the angle of reflection equals the angle of incidence. In short-range simulations such as cellular communications systems and automotive radars, you can assume that the reflecting surface, the ground or ocean surface, is flat.

The phased.TwoRayChannel and phased.WidebandTwoRayChannel System objects model propagation time delay, phase shift, Doppler shift, and loss effects for both paths. For the reflected path, loss effects include reflection loss at the boundary.

The figure illustrates two propagation paths. From the source position, s_s, and the receiver position, s_r, you can compute the arrival angles of both paths, θ'_{los} and θ'_{rp}. The arrival angles are the elevation and azimuth angles of the arriving radiation with respect to a local coordinate system. In this case, the local coordinate system coincides with the global coordinate system. You can also compute the transmitting angles, θ_{los} and θ_{rp}. In the global coordinates, the angle of reflection at the boundary is the same as the angles θ_{rp} and θ'_{rp}. The reflection angle is important to know when you use angle-dependent reflection-loss data. You can determine the reflection angle by using the `rangeangle` function and setting the reference axes to the global coordinate system. The total path length for the line-of-sight path is shown in the figure by R_{los} which is equal to the geometric distance between source and receiver. The total path length for the reflected path is $R_{rp} = R_1 + R_2$. The quantity L is the ground range between source and receiver.



You can easily derive exact formulas for path lengths and angles in terms of the ground range and objects heights in the global coordinate system.

$$\vec{R} = \vec{x}_s - \vec{x}_r$$

$$R_{los} = \left|\vec{R}\right| = \sqrt{\left(z_r - z_s\right)^2 + L^2}$$

$$R_1 = \frac{z_r}{z_r + z_z}\sqrt{\left(z_r + z_s\right)^2 + L^2}$$

$$R_2 = \frac{z_s}{z_s + z_r}\sqrt{\left(z_r + z_s\right)^2 + L^2}$$

$$R_{rp} = R_1 + R_2 = \sqrt{\left(z_r + z_s\right)^2 + L^2}$$

$$\tan\theta_{los} = \frac{\left(z_s - z_r\right)}{L}$$

$$\tan\theta_{rp} = -\frac{\left(z_s + z_r\right)}{L}$$

$$\theta'_{los} = -\theta_{los}$$

$$\theta'_{rp} = \theta_{rp}$$

Two-Ray Attenuation

Attenuation or path loss in the two-ray channel is the product of five components, $L = L_{tworay}\, L_G\, L_g\, L_c\, L_r$, where

- L_{tworay} is the two-ray geometric path attenuation
- L_G is the ground reflection attenuation
- L_g is the atmospheric path attenuation
- L_c is the fog and cloud path attenuation
- L_r is the rain path attenuation

Each component is in magnitude units, not in dB.

Ground Reflection and Propagation Loss

Losses occurs when a signal is reflected from a boundary. You can obtain a simple model of ground reflection loss by representing the electromagnetic field as a scalar field. This approach also works for acoustic and sonar systems. Let E be a scalar free-space electromagnetic field having amplitude E_0 at a reference distance R_0 from a transmitter

(for example, one meter). The propagating free-space field at distance R_{los} from the transmitter is

$$E_{los} = E_0 \left(\frac{R_0}{R_{los}} \right) e^{i\omega(t - R_{los}/c)}$$

for the line-of-sight path. You can express the ground-reflected E-field as

$$E_{rp} = L_G E_0 \left(\frac{R_0}{R_{rp}} \right) e^{i\omega\left(t - R_{rp}/c\right)}$$

where R_{rp} is the reflected path distance. The quantity L_G represents the loss due to reflection at the ground plane. To specify L_G, use the `GroundReflectionCoefficient` property. In general, L_G depends on the incidence angle of the field. If you have empirical information about the angular dependence of L_G, you can use `rangeangle` to compute the incidence angle of the reflected path. The total field at the destination is the sum of the line-of-sight and reflected-path fields.

For electromagnetic waves, a more complicated but more realistic model uses a vector representation of the polarized field. You can decompose the incident electric field into two components. One component, E_p, is parallel to the plane of incidence. The other component, E_s, is perpendicular to the plane of incidence. The ground reflection coefficients for these components differ and can be written in terms of the ground permittivity and incidence angle.

$$G_p = \frac{Z_1 \cos\theta_1 - Z_2 \cos\theta_2}{Z_1 \cos\theta_1 + Z_2 \cos\theta_2} = \frac{\cos\theta_1 - \frac{Z_2}{Z_1}\cos\theta_2}{\cos\theta_1 + \frac{Z_2}{Z_1}\cos\theta_2}$$

$$G_s = \frac{Z_2 \cos\theta_1 - Z_1 \cos\theta_2}{Z_2 \cos\theta_1 + Z_1 \cos\theta_2} = \frac{\cos\theta_2 - \frac{Z_2}{Z_1}\cos\theta_1}{\cos\theta_2 + \frac{Z_2}{Z_1}\cos\theta_1}$$

$$Z_1 = \sqrt{\frac{\mu_1}{\varepsilon_1}}$$

$$Z_2 = \sqrt{\frac{\mu_2}{\varepsilon_2}}$$

where Z is the impedance of the medium. Because the magnetic permeability of the ground is almost identical to that of air or free space, the ratio of impedances depends primarily on the ratio of electric permittivities

$$G_p = \frac{\sqrt{\rho}\cos\theta_1 - \cos\theta_2}{\sqrt{\rho}\cos\theta_1 + \cos\theta_2}$$

$$G_s = \frac{\sqrt{\rho}\cos\theta_2 - \cos\theta_1}{\sqrt{\rho}\cos\theta_2 + \cos\theta_1}$$

where the quantity $\rho = \varepsilon_2/\varepsilon_1$ is the *ground relative permittivity* set by the `GroundRelativePermittivity` property. The angle θ_1 is the incidence angle and the angle θ_2 is the refraction angle at the boundary. You can determine θ_2 using Snell's law of refraction.

After reflection, the full field is reconstructed from the parallel and perpendicular components. The total ground plane attenuation, L_G, is a combination of G_s and G_p.

When the origin and destination are stationary relative to each other, you can write the output `Y` of `step` as $Y(t) = F(t-\tau)/L$. The quantity τ is the signal delay and L is the free-space path loss. The delay τ is given by R/c. R is either the line-of-sight propagation path distance or the reflected path distance, and c is the propagation speed. The path loss

$$L_{tworay} = \frac{(4\pi R)^2}{\lambda^2},$$

where λ is the signal wavelength.

Atmospheric Gas Attenuation Model

This model calculates the attenuation of signals that propagate through atmospheric gases.

Electromagnetic signals attenuate when they propagate through the atmosphere. This effect is due primarily to the absorption resonance lines of oxygen and water vapor, with smaller contributions coming from nitrogen gas. The model also includes a continuous absorption spectrum below 10 GHz. Phased Array System Toolbox uses the ITU model *Recommendation ITU-R P.676-10: Attenuation by atmospheric gases*. The model computes the specific attenuation (attenuation per kilometer) as a function

of temperature, pressure, water vapor density, and signal frequency. The atmospheric gas model is valid for frequencies from 1–1000 GHz and applies to polarized and nonpolarized fields.

The formula for specific attenuation at each frequency is

$$\gamma = \gamma_o(f) + \gamma_w(f) = 0.1820 f N''(f).$$

The quantity $N''()$ is the imaginary part of the complex atmospheric refractivity. It consists of a spectral line component and a continuous component:

$$N''(f) = \sum_i S_i F_i + N_D'(f)$$

The spectral component consists of a sum of discrete spectrum terms composed of a localized frequency bandwidth function, $F(f)_i$, multiplied by a spectral line strength, S_i. For atmospheric oxygen, each spectral line strength is

$$S_i = a_1 \times 10^{-7} \left(\frac{300}{T}\right)^3 \exp\left[a_2 (1 - \left(\frac{300}{T}\right)\right] P.$$

For atmospheric water vapor, each spectral line strength is

$$S_i = b_1 \times 10^{-1} \left(\frac{300}{T}\right)^{3.5} \exp\left[b_2 (1 - \left(\frac{300}{T}\right)\right] W.$$

P is the atmospheric pressure, W is the water vapor density, and T is the ambient temperature.

For each oxygen line, S_i depends on constants a_1 and a_2. Similarly, each water vapor line has constants b_1 and b_2. The ITU documentation cited at the end of this section contains tabulations of these constants.

The localized frequency bandwidth functions $F_i(f)$ are complicated functions of frequency described in the ITU references cited below. The functions depend on empirical model parameters that are also tabulated in the reference.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length, R. Then, the total attenuation is $L_g = R(\gamma_o + \gamma_w)$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

Fog and Cloud Attenuation Model

This model calculates the attenuation of signals that propagate through fog or clouds.

Fog and cloud attenuation are the same atmospheric phenomenon. Phased Array System Toolbox uses the ITU model, *Recommendation ITU-R P.840-6: Attenuation due to clouds and fog*. The model computes the specific attenuation (attenuation per kilometer), of a signal as a function of liquid water density, signal frequency, and temperature. The model applies to polarized and nonpolarized fields. The formula for specific attenuation at each frequency is

$$\gamma_c = K_l(f)M,$$

where M is the liquid water density in gm/m^3. The quantity $K_l(f)$ is the specific attenuation coefficient and depends on frequency. The cloud and fog attenuation model is valid for frequencies 10–1000 GHz. Units for the specific attenuation coefficient are (dB/km)/(g/m^3).

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length R. Total attenuation is $L_c = R\gamma_c$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply narrowband attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

Rainfall Attenuation Model

This model calculates the attenuation of signals that propagate through regions of rainfall.

Electromagnetic signals are attenuate when propagating through a region of rainfall. Rainfall attenuation is computed according to the ITU rainfall model *Recommendation ITU-R P.838-3: Specific attenuation model for rain for use in prediction methods*. The model computes the specific attenuation (attenuation per kilometer) of a signal as a function of rainfall rate, signal frequency, polarization, and path elevation angle. To compute the attenuation, this model uses

$$\gamma_r = kr^{\alpha},$$

where r is the rain rate in mm/hr. The parameter k and exponent α depend on the frequency, the polarization state, and the elevation angle of the signal path. The specific attenuation model is valid for frequencies from 1–1000 GHz.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by a propagation distance, R. Then, total attenuation is $L_r = R\gamma_r$. Instead of using geometric range as the propagation distance, the toolbox uses a modified range. The modified range is the geometric range multiplied by a range factor

$$\frac{1}{1+\frac{R}{R_0}}$$

where

$$R_0 = 35e^{-0.015r}$$

is the effective path length in kilometers (see Seybold, J. *Introduction to RF Propagation*.) When there is no rain, the effective path length is 35 km. When the rain rate is, for example, 10 mm/hr, the effective path length is 30.1 km. At short range, the propagation distance is approximately the geometric range. For longer ranges, the propagation distance asymptotically approaches the effective path length.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

Subband Frequency Processing

Subband processing decomposes a wideband signal into multiple subbands and applies narrowband processing to the signal in each subband. The signals for all subbands are summed to form the output signal.

When using wideband frequency System objects or blocks, you specify the number of subbands, N_b, in which to decompose the wideband signal. Subband center frequencies

and widths are automatically computed from the total bandwidth and number of subbands. The total frequency band is centered on the carrier or operating frequency, f_c. The overall bandwidth is given by the sample rate, f_s. Frequency subband widths are $\Delta f = f_s/N_B$. The center frequencies of the subbands are

$$f_m = \begin{cases} f_c - \dfrac{f_s}{2} + (m-1)\Delta f, & N_B \text{ even} \\ f_c - \dfrac{(N-1)f_s}{2N} + (m-1)\Delta f, & N_B \text{ odd} \end{cases}, m = 1,\ldots,N_B$$

Some System objects let you obtain the subband center frequencies as output from the `step` method. The returned subband frequencies are ordered consistent with the ordering of the discrete Fourier transform. Frequencies above the carrier appear first, followed by frequencies below the carrier.

System Objects

phased.FreeSpace | phased.LOSChannel | phased.TwoRayChannel | phased.WidebandLOSChannel | phased.WidebandFreeSpace | phased.WidebandBackscatterRadarTarget

Introduced in R2016b

reset

System object: phased.WidebandTwoRayChannel
Package: phased

Reset states of System object

Syntax

```
reset(channel)
```

Description

`reset(channel)` resets the internal state of the `phased.WidebandTwoRayChannel` System object, `channel`.

Input Arguments

`channel` — Wideband two-ray channel

`phased.WidebandTwoRayChannel` System object

Wideband two-ray channel, specified as a System object.

Introduced in R2016b

step

System object: phased.WidebandTwoRayChannel
Package: phased

Propagate wideband signal from point to point using two-ray channel model

Syntax

```
prop_sig = step(channel,sig,origin_pos,dest_pos,origin_vel,dest_vel)
```

Description

Note: Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`prop_sig = step(channel,sig,origin_pos,dest_pos,origin_vel,dest_vel)` returns the resulting signal, `prop_sig`, when a wideband signal, `sig`, propagates through a two-ray channel from the `origin_pos` position to the `dest_pos` position. Either the `origin_pos` or `dest_pos` arguments can have multiple points but you cannot specify both as having multiple points. Specify the velocity of the signal origin in `origin_vel` and the velocity of the signal destination in `dest_vel`. The dimensions of `origin_vel` and `dest_vel` must agree with the dimensions of `origin_pos` and `dest_pos`, respectively.

In the two-ray environment, two signal paths connect every signal origin and destination pair. For *N* signal origins (or *N* signal destinations), there are *2N* paths. The signals for each origin-destination pair do not have to be identical. The signals along the two paths for any source-destination pair can have different amplitudes or phases.

The `CombinedRaysOutput` property controls whether the two signals at the destination are kept *separate* or *combined*. *Combined* means that the signals at the source propagate separately along the two paths but are coherently summed at the destination into a single quantity. *Separate*means that the two signals are not summed at the destination.

To use the *combined* option, set `CombinedRaysOutput` to `true`. To use the *separate* option, set `CombinedRaysOutput` to `false`. The *combined* option is convenient when the difference between the sensor or array gains in the directions of the two paths is not significant.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`channel` — Wideband two-ray channel

System object

Wideband two-ray channel, specified as a System object.

Example: `phased.WidebandTwoRayChannel`

`sig` — Wideband signal

M-by-*N* complex-valued matrix | *M*-by-*2N* complex-valued matrix | 1-by-*N* `struct` array containing complex-valued fields | 1-by-*2N* `struct` array containing complex-valued fields

Electromagnetic fields propagated through a two-ray channel can be polarized or nonpolarized. For nonpolarized fields, such as an acoustic field, the propagating signal field, `sig`, is a vector or matrix. When the fields are polarized, `sig` is an array of structures. Every structure element contains an array of electric field vectors in Cartesian form.

- Specify wideband nonpolarized scalar signals as a
  - *M*-by-*N* complex-valued matrix. The same signal is propagated along both the line-of-sight path and the reflected path.
  - *M*-by-*2N* complex-valued matrix. Each adjacent pair of columns represents a different channel. Within each pair, the first column represents the signal

propagated along the line-of-sight path and the second column represents the signal propagated along the reflected path.

- Specify wideband polarized signals as a
  - 1-by-*N* `struct` array containing complex-valued fields. Each `struct` element contains an *M*-by-1 column vector of electromagnetic field components `(sig.X,sig.Y,sig.Z)`. The same signal is propagated along both the line-of-sight path and the reflected path.
  - 1-by-*2N* `struct` array containing complex-valued fields. Each pair of array columns represents a different source-receiver channel. The first column of the pair represents the signal along the line-of-sight path and the second column represents the signal along the reflected path. Each structure element contains an *M*-by-1 column vector of electromagnetic field components `(sig.X,sig.Y,sig.Z)`.

For nonpolarized fields, the quantity *M* is the number of samples of the signal and *N* is the number of two-ray channels. Each channel corresponds to a source-destination pair.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

For polarized fields, the `struct` element contains three *M*-by-1 complex-valued column vectors, `sig.X`, `sig.Y`, and `sig.Z`. These vectors represent the *x*, *y*, and *z* Cartesian components of the polarized signal.

The size of the first dimension of the matrix fields within the `struct` can vary to simulate a changing signal length such as a pulse waveform with variable pulse repetition frequency.

Example: `[1,1;j,1;0.5,0]`

Data Types: `double`
Complex Number Support: Yes

`origin_pos` — Signal origins

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Origin of the signal or signals, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. The quantity *N* is the number of two-ray channels. If `origin_pos` is a column vector, it takes the form `[x;y;z]`. If `origin_pos` is a matrix, each column specifies a different signal origin and has the form `[x;y;z]`. Position units are in meters.

You cannot specify both `origin_pos` and `dest_pos` as matrices. At least one must be a 3-by-1 column vector.

Example: `[1000;100;500]`

Data Types: `double`

`dest_pos` — Signal destinations

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Destination position of the signal or signals, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. The quantity *N* is the number of two-ray channels propagating from or to *N* signal origins. If `dest_pos` is a 3-by-1 column vector, it takes the form `[x;y;z]`. If `dest_pos` is a matrix, each column specifies a different signal destination and takes the form `[x;y;z]` Position units are in meters.

You cannot specify both `origin_pos` and `dest_pos` as matrices. At least one must be a 3-by-1 column vector.

Example: `[0;0;0]`

Data Types: `double`

`origin_vel` — Velocity of signal origin

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Velocity of signal origin, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. The dimensions of `origin_vel` must match the dimensions of `origin_pos`. If `origin_vel` is a column vector, it takes the form `[Vx;Vy;Vz]`. If `origin_vel` is a 3-by-*N* matrix, each column specifies a different origin velocity and has the form `[Vx;Vy;Vz]`. Velocity units are in meters per second.

Example: `[10;0;5]`

Data Types: `double`

`dest_vel` — Velocity of signal destinations

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Velocity of signal destinations, specified as a 3-by-1 real-valued column vector or 3–by-*N* real-valued matrix. The dimensions of `dest_vel` must match the dimensions of `dest_pos`. If `dest_vel` is a column vector, it takes the form `[Vx;Vy;Vz]`. If `dest_vel` is a 3-by-*N* matrix, each column specifies a different destination velocity and has the form `[Vx;Vy;Vz]` Velocity units are in meters per second.

Example: `[0;0;0]`

Data Types: `double`

Output Arguments

`prop_sig` — Propagated signal

M-by-*N* complex-valued matrix | *M*-by-*2N* complex-valued matrix | 1-by-*N* `struct` array containing complex-valued fields | 1-by-*2N* `struct` array containing complex-valued fields

- Wideband nonpolarized scalar signal, returned as an:
  - *M*-by-*N* complex-valued matrix. To return this format, set the `CombinedRaysOutput` property to `true`. Each matrix column contains the coherently combined signals from the line-of-sight path and the reflected path.
  - *M*-by-*2N* complex-valued matrix. To return this format set the `CombinedRaysOutput` property to `false`. Alternate columns of the matrix contain the signals from the line-of-sight path and the reflected path.
- Wideband polarized scalar signal, returned as:
  - 1-by-*N* `struct` array containing complex-valued fields. To return this format, set the `CombinedRaysOutput` property to `true`. Each column of the array contains the coherently combined signals from the line-of-sight path and the reflected path. Each structure element contains the electromagnetic field vector `(prop_sig.X,prop_sig.Y,prop_sig.Z)`.
  - 1-by-*2N* `struct` array containing complex-valued fields. To return this format, set the `CombinedRaysOutput` property to `false`. Alternate columns contains the signals from the line-of-sight path and the reflected path. Each structure element contains the electromagnetic field vector `(prop_sig.X,prop_sig.Y,prop_sig.Z)`.

The output `prop_sig` contains signal samples arriving at the signal destination within the current input time frame. Sometimes it can take longer than the current time frame for the signal to propagate from the origin to the destination, the output may not contain all contributions from the input of the current time frame. In this case, the output does not need to contain all contributions from the input of the current time frame. The remaining output appears in the next call to `step`.

Examples

Scalar Wideband Signal Propagating in Two-Ray Channel

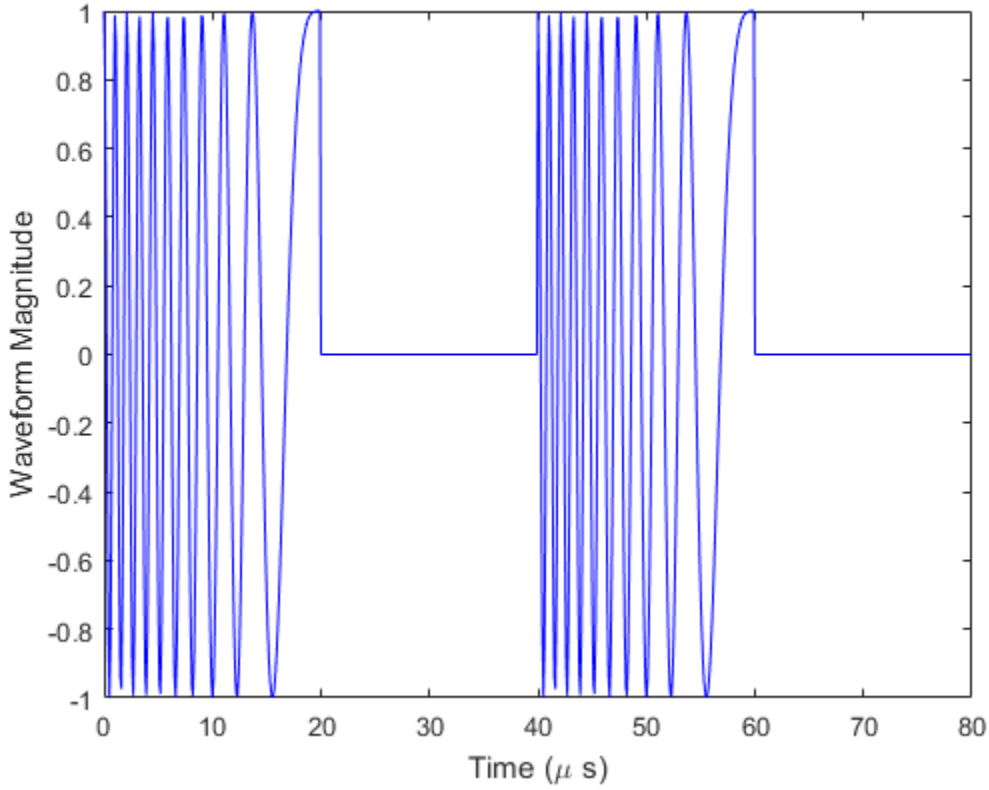
This example illustrates the two-ray propagation of a wideband signal, showing how the signals from the line-of-sight path and reflected path arrive at the receiver at different times.

Note: You can replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Create and Plot Transmitted Waveform

Create a nonpolarized electromagnetic field consisting of two linear FM waveform pulses at a carrier frequency of 100 MHz. Assume the pulse width is 20 µs and the sampling rate is 10 MHz. The bandwidth of the pulse is 1 MHz. Assume a 50% duty cycle so that the pulse width is one-half the pulse repetition interval. Create a two-pulse wave train. Set the `GroundReflectionCoefficient` to –0.9 to model strong ground reflectivity. Propagate the field from a stationary source to a stationary receiver. The vertical separation of the source and receiver is approximately 10 km.

```
c = physconst('LightSpeed');
fs = 10e6;
pw = 20e-6;
pri = 2*pw;
PRF = 1/pri;
fc = 100e6;
lambda = c/fc;
bw = 1e6;
waveform = phased.LinearFMWaveform('SampleRate',fs,'PulseWidth',pw,...
    'PRF',PRF,'OutputFormat','Pulses','NumPulses',2,'SweepBandwidth',bw,...
    'SweepDirection','Down','Envelope','Rectangular','SweepInterval',...
    'Positive');
wav = waveform();
n = size(wav,1);
plot([0:(n-1)]/fs*1e6,real(wav),'b')
xlabel('Time (\mu s)')
ylabel('Waveform Magnitude')
```



Specify the Location of Source and Receiver

Place the source and receiver about 1 km apart horizontally and approximately 5 km apart vertically.

```
pos1 = [0;0;100];
pos2 = [1e3;0;5.0e3];
vel1 = [0;0;0];
vel2 = [0;0;0];
```

Create a Wideband Two-Ray Channel System Object

Create a two-ray propagation channel System object™ and propagate the signal along both the line-of-sight and reflected ray paths. The same signal is propagated along both paths.

```
channel = phased.WidebandTwoRayChannel('SampleRate',fs,...
    'GroundReflectionCoefficient',-0.9,'OperatingFrequency',fc,...
    'CombinedRaysOutput',false);
prop_signal = channel([wav,wav],pos1,pos2,vel1,vel2);

[rng2,angs] = rangeangle(pos2,pos1,'two-ray');
```

Calculate time delays in μs.

```
tm = rng2/c*1e6;
disp(tm)
```

```
   16.6815   17.3357
```

Display the calculated propagation paths azimuth and elevation angles in degrees.

```
disp(angs)
```

```
         0         0
   78.4654  -78.9063
```

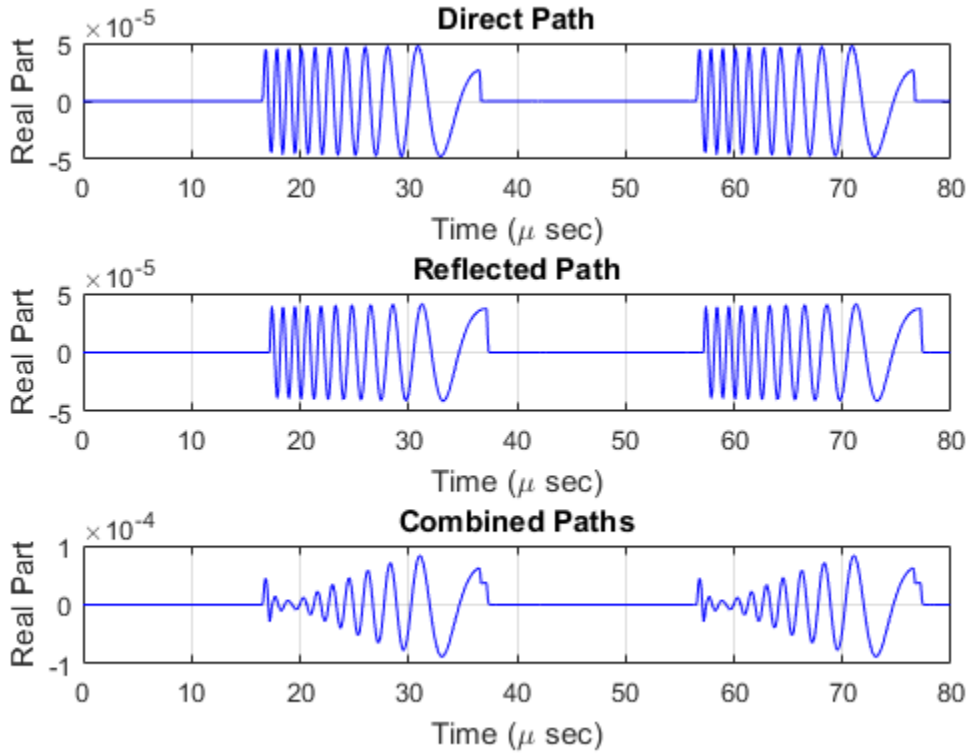
Plot the Propagated Signals

1. Plot the real part of the signal propagated along the line-of-sight path.
2. Plot the real part of the signal propagated along the reflected path.
3. Plot the real part of the coherent sum of the two signals.

```
n = size(prop_signal,1);
delay = [0:(n-1)]/fs*1e6;
subplot(3,1,1)
plot(delay,real([prop_signal(:,1)]),'b')
grid
xlabel('Time (\mu sec)')
ylabel('Real Part')
title('Direct Path')
```

```
subplot(3,1,2)
plot(delay,real([prop_signal(:,2)]),'b')
grid
xlabel('Time (\mu sec)')
ylabel('Real Part')
title('Reflected Path')

subplot(3,1,3)
plot(delay,real([prop_signal(:,1) + prop_signal(:,2)]),'b')
grid
xlabel('Time (\mu sec)')
ylabel('Real Part')
title('Combined Paths')
```



The delay of the reflected path signal agrees with the predicted delay. The magnitude of the coherently combined signal is less than either of the propagated signals. This result indicates that the two signals contain some interference.

Compare Wideband Two-Ray Channel Propagation to Free Space

Calculate the result of propagating a wideband LFM signal in a two-ray environment from a radar 10 meters above the origin *(0,0,10)* to a target at *(3000,2000,2000)* meters. Assume that the radar and target are stationary and that the transmitting antenna is isotropic. Combine the signal from the two paths and compare the signal to a signal propagating in free space. The system operates at 300 MHz. Set the `CombinedRaysOutput` property to `true` to combine the direct path and reflected path signals when forming the output signal.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Create a linear FM waveform.

```
fop = 300.0e6;
fs = 1.0e6;
waveform = phased.LinearFMWaveform();
x = waveform();
```

Specify the target position and velocity.

```
posTx = [0; 0; 10];
posTgt = [3000; 2000; 2000];
velTx = [0;0;0];
velTgt = [0;0;0];
```

Model the free space propagation.

```
fschannel = phased.WidebandFreeSpace('SampleRate',waveform.SampleRate);
y_fs = fschannel(x,posTx,posTgt,velTx,velTgt);
```

Model two-ray propagation from the position of the radar to the target.

```
tworaychannel = phased.WidebandTwoRayChannel('SampleRate',waveform.SampleRate,...
    'CombinedRaysOutput',true);
y_tworay = tworaychannel(x,posTx,posTgt,velTx,velTgt);
plot(abs([y_tworay y_fs]))
legend('Wideband two-ray (Position 1)','Wideband free space (Position 1)',...
    'Location','best')
```

```
xlabel('Samples')
ylabel('Signal Magnitude')
hold on
```

Move the radar by 10 meters horizontally to a second position.

```
posTx = posTx + [10;0;0];
y_fs = fschannel(x,posTx,posTgt,velTx,velTgt);
y_tworay = tworaychannel(x,posTx,posTgt,velTx,velTgt);
plot(abs([y_tworay y_fs]))
legend('Wideband two-ray (Position 1)','Wideband free space (Position 1)',...
    'Wideband two-ray (Position 2)','Wideband free space (Position 2)',...
    'Location','best')
hold off
```

The free-space propagation losses are the same for both the first and second positions of the radar. The two-ray losses are different due to the interference effect of the two-ray paths.

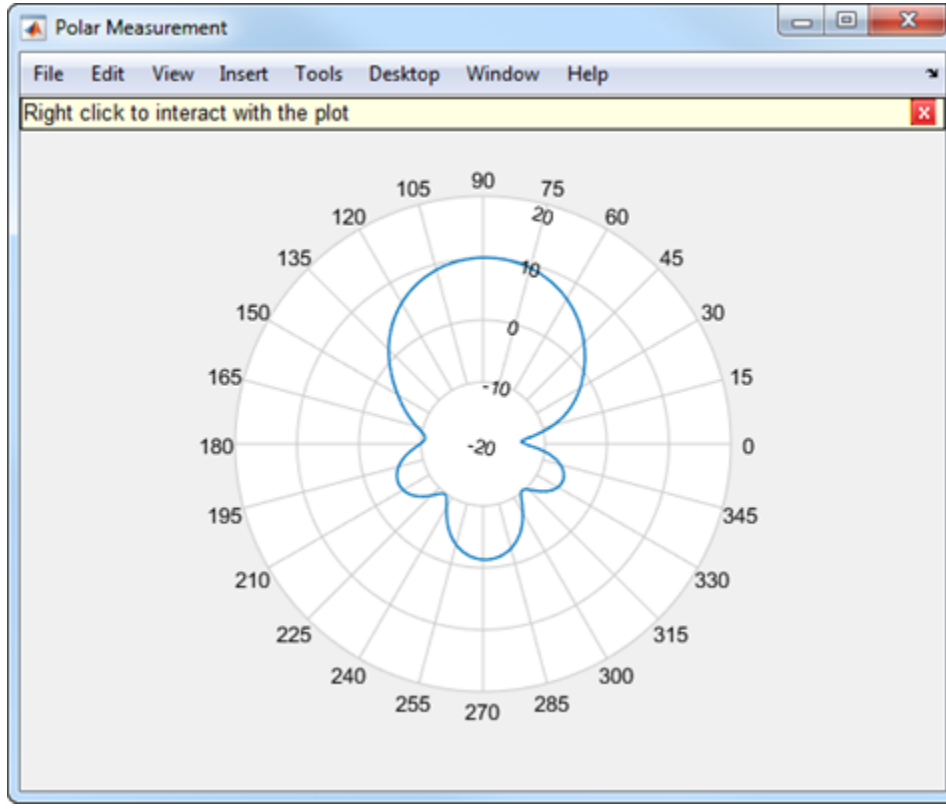
Introduced in R2016b

polarpattern class

Interactive plot of radiation patterns in polar format

Description



`polarpattern` class plots antenna or array radiation patterns in interactive polar format. You can also plot other types of polar data. Use these plots when interactive data visualization or measurement is required. Right-click the **Polar Measurement** window to change the properties, zoom in, or add more data to the plot.

Construction

`polarpattern` plots antenna or array radiation patterns and other types of data in polar format. `polarpattern` plots field value data of radiation patterns for visualization and measurement. Right-click the polar plot to interact.

`polarpattern(data)` creates a polar plot with magnitude values in the vector `d`. In this polar plot, angles are uniformly spaced on the unit circle, starting at `0` degrees.

`polarpattern(angle,magnitude)` creates a polar plot from a set of angle vectors and corresponding magnitudes. You can also create polar plots from multiple sets for angle vectors and corresponding sets of magnitude using the syntax: `polarpattern(angle1, magnitude1, angle2, magnitude2...)`.

`p = polarpattern( ___ )` returns an object handle that you can use to customize the plot or add measurements. You can specify any of the arguments from the previous syntaxes.

`p = polarpattern('gco')` returns an object handle from polar pattern in the current figure.

`polarpattern( ___ ,Name,Value)` creates a polar plot, with additional properties specified by one or more name-value pair arguments. `Name` is the property name and `Value` is the corresponding property value. You can specify several name-value pair arguments in any order as `Name1`, `Value1`, `...`, `NameN`, `ValueN`. Properties not specified retain their default values. To list all the property `Name,Value` pairs, use `details(p)`. To list all the property `Name,Value` pairs, use `details(p)`. You can use the properties to extract any data from the radiation pattern from the polar plot. For example, `p = polarpattern(data,'Peaks',3)` identifies and displays the three highest peaks in the pattern data.

For a list of properties, see PolarPattern Properties.

`polarpattern(ax, ___ )` creates a polar plot using axes handle, `ax` instead of the current axes handle.

Input Arguments

`data` — Antenna or array data

real length-*M* vector | real *M*-by-*N* matrix | real *N*-*D* array | complex vector or matrix

Antenna or array data, specified as one of the following:

- A real length-*M* vector, where *M* contains the magnitude values with angles assumed to be $\frac{(0:M-1)}{M}\times 360^\circ$ degrees.
- A real *M*-by-*N* matrix, where *M* contains the magnitude values and *N* contains the independent data sets. Each column in the matrix has angles taken from the vector $\frac{(0:M-1)}{M}\times 360^\circ$ degrees.
- A real *N*-*D* array, where *N* is the number of dimensions. Arrays with dimensions `2` and greater are independent data sets.
- A complex vector or matrix, where `data` contains Cartesian coordinates (*x*, *y*) of each point. *x* contains the real (`data`) and *y* contains the imaginary (`data`).

When data is in a logarithmic form, such as dB, magnitude values can be negative. In this case,`polarpattern` plots the smallest magnitude values at the origin of the polar plot and largest magnitude values at the maximum radius.

`angle` — Set of angles

vector in degrees

Set of angles, specified as a vector in degrees.

`magnitude` — Set of magnitude values

vector | matrix

Set of magnitude values, specified as a vector or a matrix. For a matrix of magnitude values, each column is an independent set of magnitude values and corresponds to the same set of angles.

Methods

`add`	Add data to existing polar plot
`addCursor`	Add cursor to polar plot angle
`animate`	Replace existing data with new data for animation

`createLabels`	Create legend labels
`findLobes`	Main, back and side lobe data
`replace`	Replace existing data with new data in polar plot
`showPeaksTable`	Show or hide peak marker table
`showSpan`	Show or hide angle span between two markers

Examples

Plot Cosine Pattern in Polar Coordinates

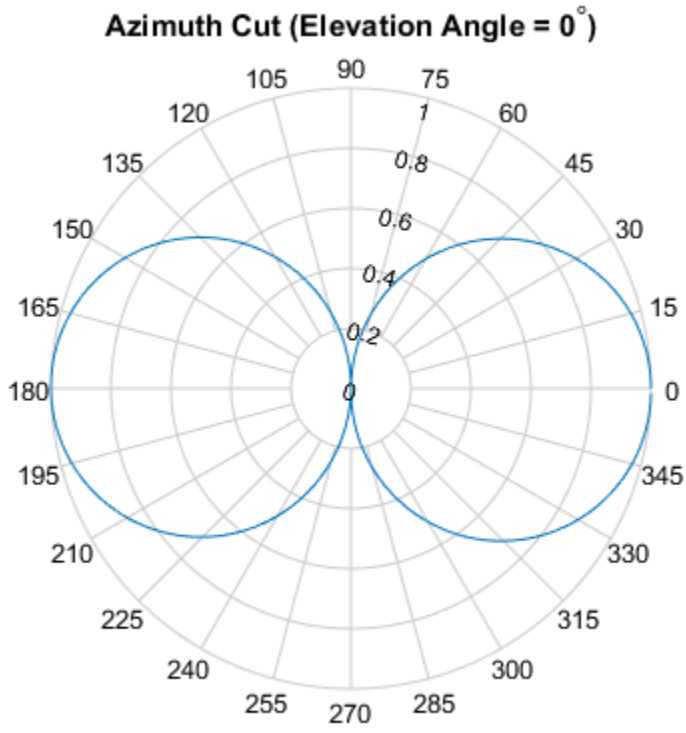
Specify a cosine antenna pattern from 0° to 360° in azimuth at 0° elevation. Then, plot the antenna pattern using `polarpattern`.

Create the pattern.

```
az = [0:360];
p = abs(cosd(az));
```

Plot the polar pattern of the antenna for an azimuth cut at 0° elevation.

```
polarpattern(p,'TitleTopTextInterpreter','tex','TitleTop','Azimuth Cut (Elevation Angle
```



Azimuth Pattern of a 3-by-2 URA

Construct a 3-by-2 rectangular lattice URA. By default, the array consists of isotropic antenna elements. Assume the operating frequency is 1 GHz. Then, plot the antenna pattern using `polarpattern`.

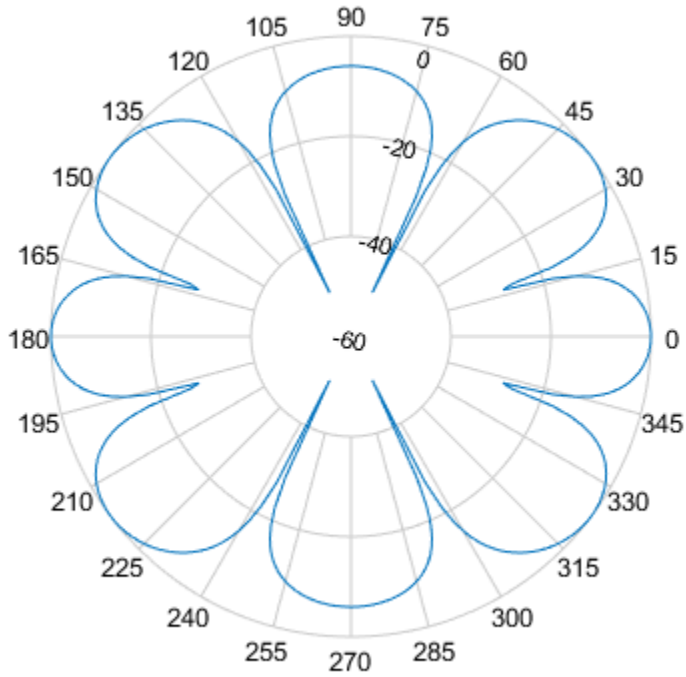
Create the array.

```
array = phased.URA('Size',[3 2]);
fc = 1.0e9;
```

Plot the polar pattern of the array for an elevation cut at 0° azimuth.

```
c = physconst('LightSpeed');
p = pattern(array,fc,[-180:180],0,'PropagationSpeed',c,'CoordinateSystem',...
```

```
    'polar','Type','powerdb','Normalize',true);
polarpattern([-180:180],p);
```



Polar Pattern Display with Title for Short-Dipole Antenna

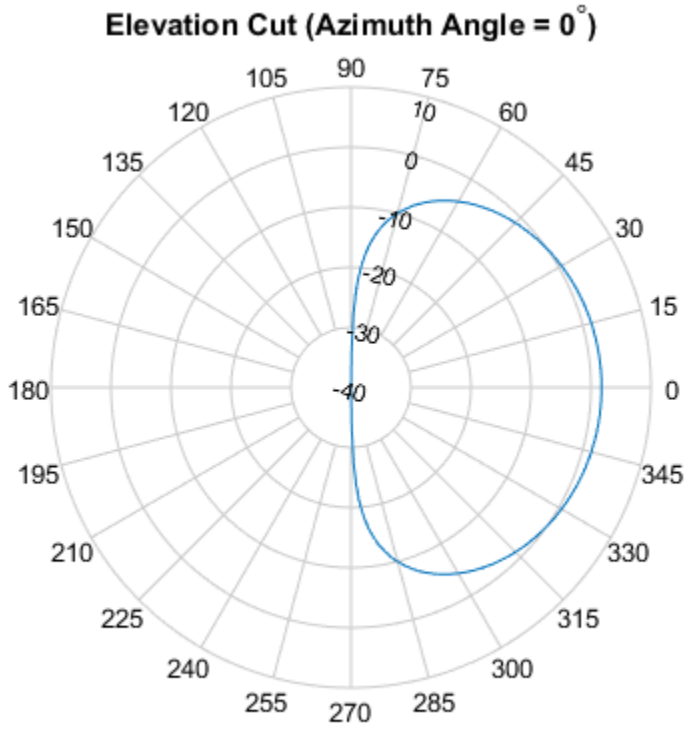
Specify a short-dipole antenna with the dipole oriented along the *z*-axis and operating at 250 MHz. Then, plot the antenna pattern using `polarpattern` and specifying a title.

Create the short-dipole antenna element System object™.

```
antenna = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6,600e6],...
    'AxisDirection','Z');
fc = 250.0e6;
```

Plot the polar pattern of the antenna for an elevation cut at 0° azimuth.

```
v = pattern(antenna,fc,0,-90:90);
polarpattern([-90:90],v,'TitleTopTextInterpreter','tex',...
    'TitleTop','Elevation Cut (Azimuth Angle = 0^{\circ})');
```



Polar Pattern Properties

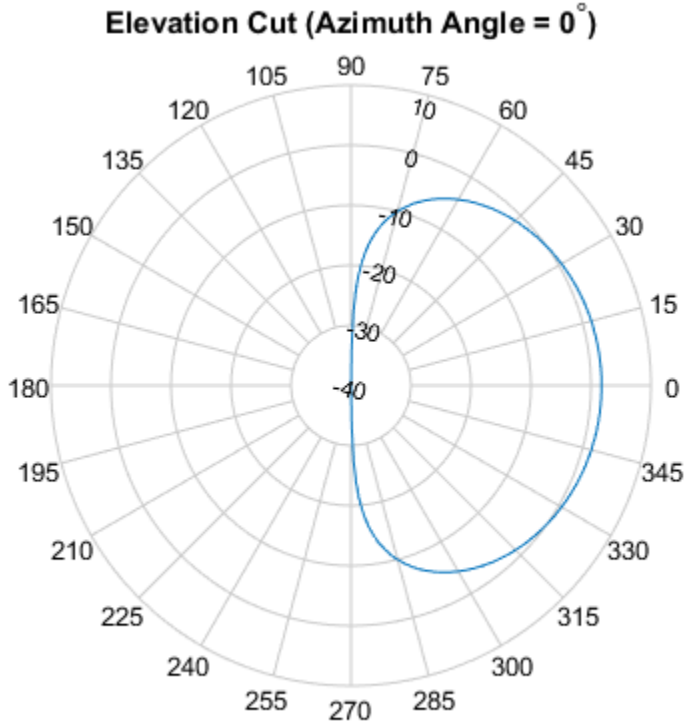
Specify a short-dipole antenna with the dipole oriented along the *z*-axis and operating at 250 MHz. Then, plot the antenna pattern using `polarpattern` and specifying a title.

Create the short-dipole antenna element System object™.

```
antenna = phased.ShortDipoleAntennaElement('FrequencyRange',[100e6,600e6],...
    'AxisDirection','Z');
fc = 250.0e6;
```

Create the polar pattern of the antenna for an elevation cut at 0° azimuth.

```
p = pattern(antenna,fc,0,-90:90);
P = polarpattern([-90:90],p,'TitleTopTextInterpreter','tex',...
    'TitleTop','Elevation Cut (Azimuth Angle = 0^{\circ})');
```



Display the properties of the plot.

```
details(P)
```

```
  internal.polari handle with properties:

Introduced in R2016a

add

Class: polarpattern

Add data to polar plot

Syntax

```
add(p,d)
add(p,angle,magnitude)
```

Description

`add(p,d)` adds new antenna data to the polar plot, `p` based on the real amplitude values, `data`.

`add(p,angle,magnitude)` adds data sets of `angle` vectors and corresponding `magnitude` matrices to polar plot `p`.

Input Arguments

`p` — Polar plot

scalar handle

Polar plot, specified as a scalar handle.

`data` — Antenna or array data

real length-*M* vector | real *M*-by-*N* matrix | real *N*-*D* array | complex vector or matrix

Antenna or array data, specified as one of the following:

- A real length-*M* vector, where *M* contains the magnitude values with angles assumed to be $\frac{(0:M-1)}{M}\times 360^{\circ}$ degrees.

- A real *M*-by-*N* matrix, where *M* contains the magnitude values and *N* contains the independent data sets. Each column in the matrix has angles taken from the vector $\frac{(0:M-1)}{M}\times 360^{\circ}$ degrees. The set of each angle can vary for each column.
- A real *N*-*D* array, where *N* is the number of dimensions. Arrays with dimensions `2` and greater are independent data sets.
- A complex vector or matrix, where `data` contains Cartesian coordinates (*(x,y)* of each point. *x* contains the real part of `data` and *y* contains the imaginary part of `data`.

When data is in a logarithmic form such as dB, magnitude values can be negative. In this case,`polarpattern` plots the lowest magnitude values at the origin of the polar plot and highest magnitude values at the maximum radius.

`angle` — Set of angles
vector in degrees

Set of angles, specified as a vector in degrees.

`magnitude` — Set of magnitude values
vector | matrix

Set of magnitude values, specified as a vector or a matrix. For a matrix of magnitude values, each column is an independent set of magnitude values and corresponds to the same set of angles.

Examples

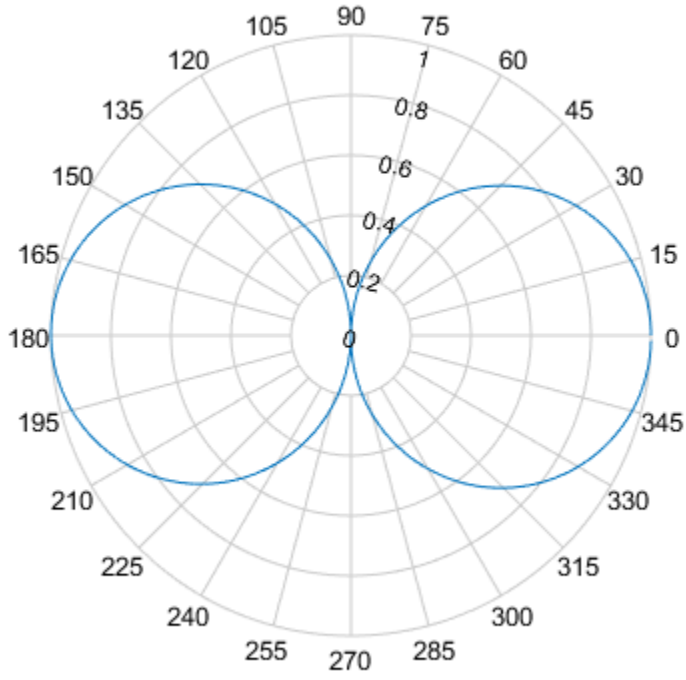
Add Data To Existing Polar Plot

Create a cosine-pattern antenna and plot the pattern from 0° to 360&deg.

```
az = [0:360];
p1 = abs(cosd(az));
```

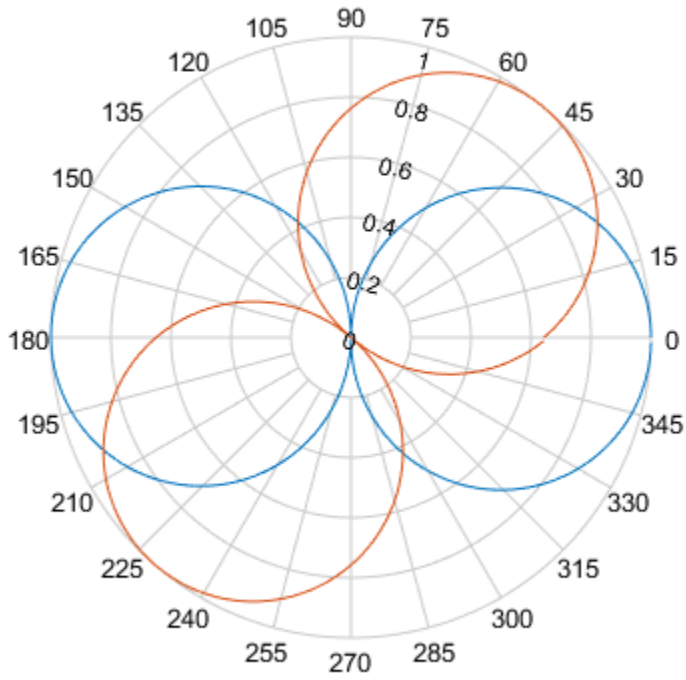
Plot the polar pattern.

```
P = polarpattern(p1);
```



Create a second cosine-pattern antenna rotated by 60°. Add this pattern to the existing pattern.

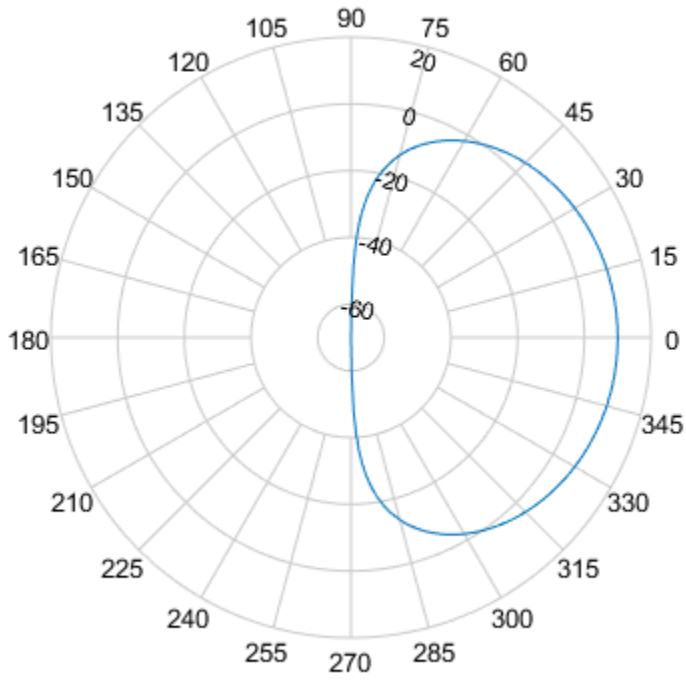
```
p2 = abs(cosd(az - 50));
add(P,p2);
```



Add Second Plot to Polar Pattern

Create a cosine antenna and plot the polar pattern of its directivity at 75 MHz.

```
cosineantenna = phased.CosineAntennaElement('FrequencyRange',[1.0e0 100.0e9],...
    'CosinePower',[2,2]);
p1 = pattern(cosineantenna,75.0e6,[-90:90],0,'Type','Directivity');
P = polarpattern([-90:90],p1);
```



Create an isotropic antenna. Calculate the directivity of this antenna at 75 MHz.

```
isoantenna = phased.IsotropicAntennaElement('FrequencyRange',...
    [1.0e0 100.0e9]);
p2 = pattern(isoantenna,75.0e6,[-180:180],0,'Type','Directivity');
```

Add the directivity plot of the isotropic antenna to the directivity plot of the cosine antenna.

```
add(P,[-180:180],p2);
```

`addCursor` | `animate` | `createLabels` | `findLobes` | `replace` | `showPeaksTable` | `showSpan`

Introduced in R2016a

addCursor

Class: polarpattern

Add cursor to polar plot angle

Syntax

```
addCursor(p,angle)
addCursor(p,angle,index)
id = addCursor( ___ )
```

Description

`addCursor(p,angle)` adds a cursor to the active polar plot, `p`, at the data point closest to the specified `angle`. Angle units are in degrees.

The first cursor added is called `'C1'`, the second `'C2'`, and so on.

`addCursor(p,angle,index)` adds a cursor at a specified data set `index`. `index` can be a vector of indices.

`id = addCursor( ___ )` returns a cell array with one ID for each cursor created. You can specify any of the arguments from the previous syntaxes.

Input Arguments

`p` — Polar plot

scalar handle

Polar plot, specified as a scalar handle.

`angle` — Angle values

scalar in degrees | vector in degrees

Angle values at which the cursor is added, specified as a scalar or a vector in degrees.

`index` — Data set index
scalar | vector

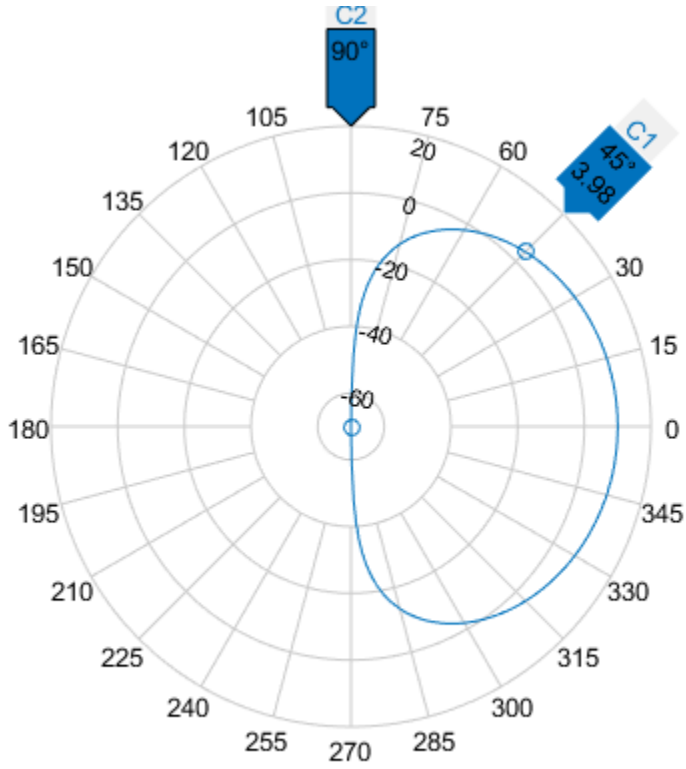
Data set index, specified as a scalar or a vector.

Examples

Add Cursors to Single Polar Pattern Plot

Create a cosine antenna and plot the polar pattern of its directivity at 75 MHz. Then add cursors at two 150° and 270°.

```
cosineantenna = phased.CosineAntennaElement('FrequencyRange',[1.0e0 100.0e9],...
    'CosinePower',[2,2]);
p = pattern(cosineantenna,75.0e6,[-90:90],0,'Type','Directivity');
P = polarpattern([-90:90],p);
addCursor(P,[45 135]);
```

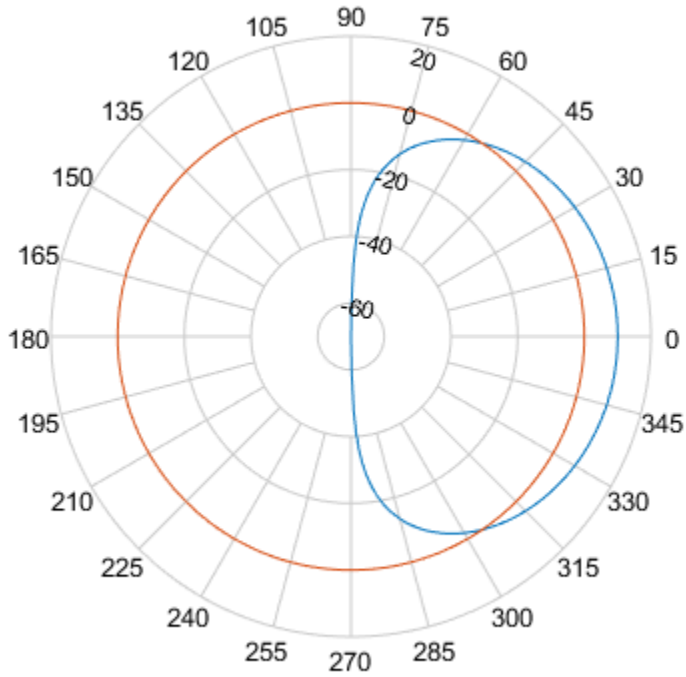


Add Cursors to Multiple Polar Pattern Plots

Create a cosine antenna and plot the polar pattern of its directivity at 75 MHz. Then create an isotropic antenna. Also calculate the directivity of this antenna at 75 MHz. Add the directivity plot of the isotropic antenna to the directivity plot of the cosine antenna. Then add cursors at several points,

```
cosineantenna = phased.CosineAntennaElement('FrequencyRange',[1.0e0 100.0e9],...
    'CosinePower',[2,2]);
p1 = pattern(cosineantenna,75.0e6,[-90:90],0,'Type','Directivity');
P = polarpattern([-90:90],p1);
isoantenna = phased.IsotropicAntennaElement('FrequencyRange',...
    [1.0e0 100.0e9]);
p2 = pattern(isoantenna,75.0e6,[-180:180],0,'Type','Directivity');
```

```
add(P,[-180:180],p2);
```



Add a cursor at approximately 30° to the cosine antenna pattern (designated by index 1) and at 150° and 270° to the isotripic polar pattern (designated by index 2).

```
addCursor(P,[30.5 149.0 314.7],[1 2 1]);
```

`add` | `animate` | `createLabels` | `findLobes` | `replace` | `showPeaksTable` | `showSpan`

Introduced in R2016a

animate

Class: polarpattern

Replace existing data with new data for animation

Syntax

```
animate(p,data)
animate(p,angle,magnitude)
```

Description

`animate(p,data)` removes all the current data from polar plot, `p` and adds new data, based on real amplitude values, `data`.

`animate(p,angle,magnitude)` removes all the current data polar plot, `p` and adds new data sets of angle vectors and corresponding magnitude matrices.

Input Arguments

`p` — Polar plot

scalar handle

Polar plot, specified as a scalar handle.

`data` — Antenna or array data

real length-*M* vector | real *M*-by-*N* matrix | real *N*-*D* array | complex vector or matrix

Antenna or array data, specified as one of the following:

- A real length-*M* vector, where *M* contains the magnitude values with angles assumed to be $\frac{(0:M-1)}{M}\times 360^{\circ}$ degrees.

- A real *M*-by-*N* matrix, where *M* contains the magnitude values and *N* contains the independent data sets. Each column in the matrix has angles taken from the vector $\frac{(0:M-1)}{M}\times 360^{\circ}$ degrees. The set of each angle can vary for each column.
- A real *N*-*D* array, where *N* is the number of dimensions. Arrays with dimensions `2` and greater are independent data sets.
- A complex vector or matrix, where `data` contains Cartesian coordinates (*(x,y)* of each point. *x* contains the real part of `data` and *y* contains the imaginary part of `data`.

When data is in a logarithmic form such as dB, magnitude values can be negative. In this case,`polarpattern` plots the lowest magnitude values at the origin of the polar plot and highest magnitude values at the maximum radius.

`angle` — Set of angles

vector in degrees

Set of angles, specified as a vector in degrees.

`magnitude` — Set of magnitude values

vector | matrix

Set of magnitude values, specified as a vector or a matrix. For a matrix of magnitude values, each column is an independent set of magnitude values and corresponds to the same set of angles.

Examples

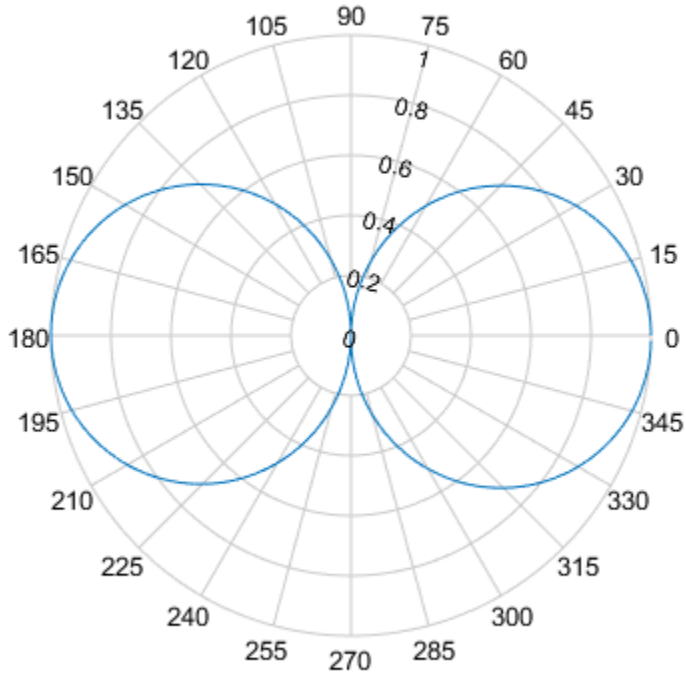
Animate Cosine Pattern Antenna Plot

Create a cosine-pattern antenna and plot the pattern from 0° to 360°.

```
az = [0:360];
p1 = abs(cosd(az));
```

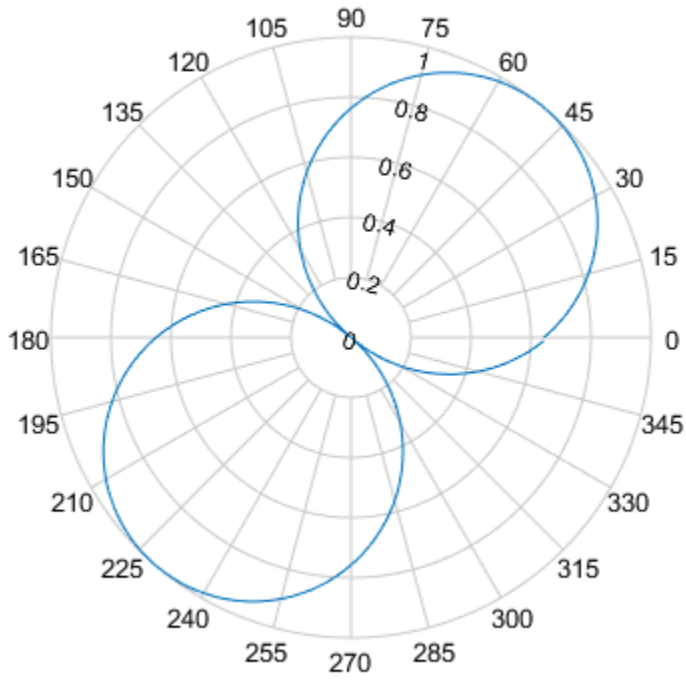
Plot the polar pattern.

```
P = polarpattern(p1);
```



Create a second cosine-pattern antenna rotated by 60°. Animate the pattern by adding this pattern.

```
p2 = abs(cosd(az - 50));
animate(P,p2);
```



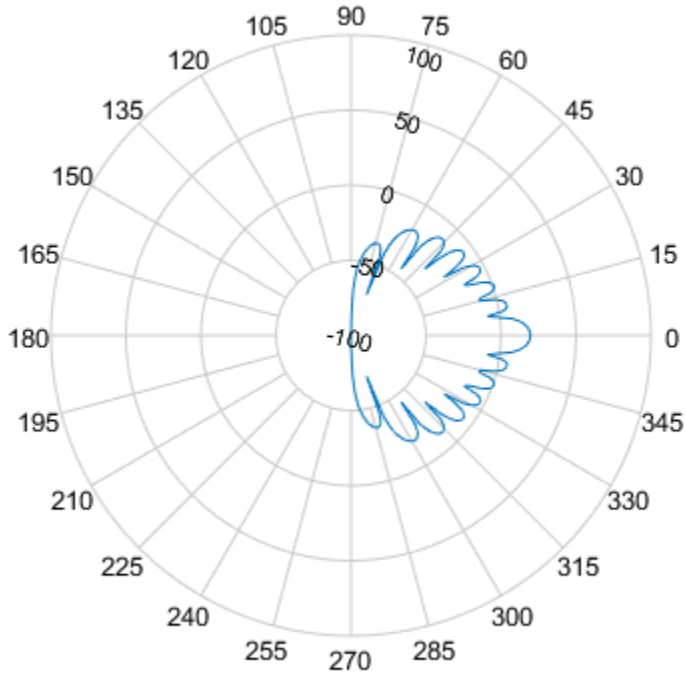
Animate Existing Polar Azimuth Plot Data

Create a 15-element ULA of cosine antennas with elements spaced one-half wavelength apart. Plot the directivity of the array at 20 GHz.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
fc = 20.0e9;
c = physconst('Lightspeed');
lam = c/fc;
angs = [-180:1:180];
antenna = phased.CosineAntennaElement('FrequencyRange',[1.0e9,100.0e9],...
```

```
    'CosinePower',[2.5 2.5]);
array = phased.ULA('Element',antenna,'NumElements',15,'ElementSpacing',lam/2);
a = pattern(array,fc,angs,0);
P = polarpattern(angs,a);
```



Then, steer the array to 45° and, using the `animate` method, replace the existing polar plot with the steered array directivity.

```
steervec = phased.SteeringVector('SensorArray',array,'PropagationSpeed',c,...
    'IncludeElementResponse',true);
sv = steervec(fc,[45;0]);
a1 = pattern(array,fc,angs,0,'Weights',sv);
animate(P,angs,a1);
```

Introduced in R2016a

createLabels

Class: polarpattern

Create legend labels for polar plot

Syntax

```
createLabels(p,format,array)
```

Description

`createLabels(p,format,array)` adds the specified `format` label to each `array` of the polar plot `p`. The labels are stored as a cell array in the `LegendLabels` property of `p`.

Input Arguments

`p` — Polar plot

scalar handle

Polar plot, specified as a scalar handle.

`format` — Format for legend label

cell array

Format for legend label added to the polar plot, specified as a cell array. For more information on legend label format see, `legend`.

Data Types: `char`

`array` — Values to apply to `format`

array

Values to apply to `format` , specified as an array. The values can be an array of angles or array of magnitude.

Examples

Add Legend Label to Polar Plot

Create a polar plot of cosine powers rotated in 30° increments. Generate a legend label for this plot.

```
az = [0:359]';
a1 = abs(cosd(az).^5);
a2 = abs(cosd(az - 30).^5);
a3 = abs(cosd(az - 60).^5);
a4 = abs(cosd(az - 90).^5);
P = polarpattern([a1,a2,a3,a4],'Style','filled');
createLabels(P,'az = %d#deg',0:30:90)
```

`add` | `addCursor` | `animate` | `findLobes` | `replace` | `showPeaksTable` | `showSpan`

Introduced in R2016a

findLobes

Class: polarpattern

Main, back, and side lobe data

Syntax

```
L = findLobes(p)
L = findLobes(p,index)
```

Description

`L = findLobes(p)` returns a structure, `L`, defining the main, back, and side lobes of the antenna or array radiation pattern in the specified polar plot, `p`.

`L = findLobes(p,index)` returns the radiation pattern lobes from the data set specified in `index`.

Input Arguments

`p` — Polar plot

scalar handle

Polar plot, specified as a scalar handle.

`index` — Index of data set

scalar

Index of data set, specified as a scalar.

Examples

Find Lobes of Isotropic Antenna ULA

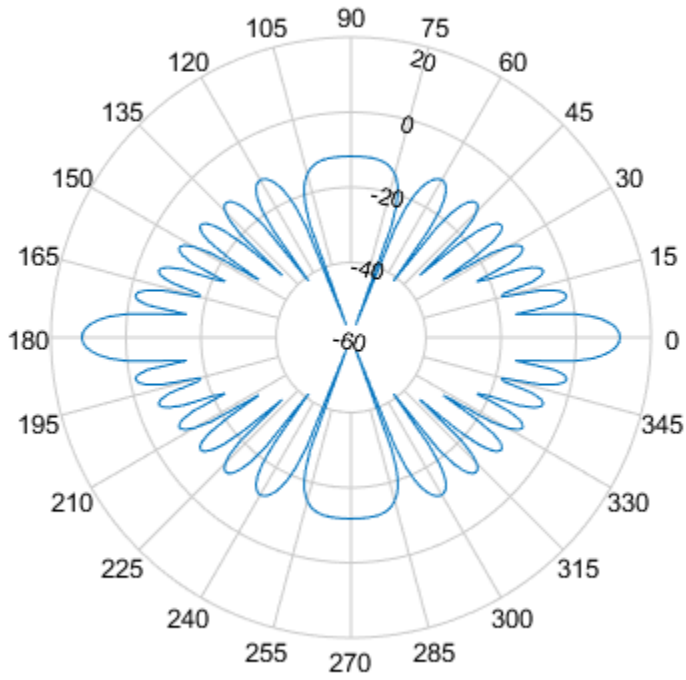
Create a 15-element ULA of isotropic antenna with elements spaced one-half wavelength apart. Plot the directivity of the array at 20 GHz. Then, find the mainlobe, sidelobe, and backlobe directions of the array pattern.

```
fc = 20.0e9;
c = physconst('Lightspeed');
lam = c/fc;
angs = [-180:1:180];
antenna = phased.IsotropicAntennaElement('FrequencyRange',[1.0e9,100.0e9]);
array = phased.ULA('Element',antenna,'NumElements',15,'ElementSpacing',lam/2);
a = pattern(array,fc,angs,0);
P = polarpattern(angs,a);
L = findLobes(P)

L =

  struct with fields:

     mainLobe: [1×1 struct]
     backLobe: [1×1 struct]
    sideLobes: [1×1 struct]
           FB: 0
          SLL: 0
         HPBW: 8.0000
         FNBW: 16.0000
        FBIdx: [181 1]
       SLLIdx: [181 361]
      HPBWIdx: [357 5]
      HPBWAng: [176 -176]
      FNBWIdx: [173 189]
```

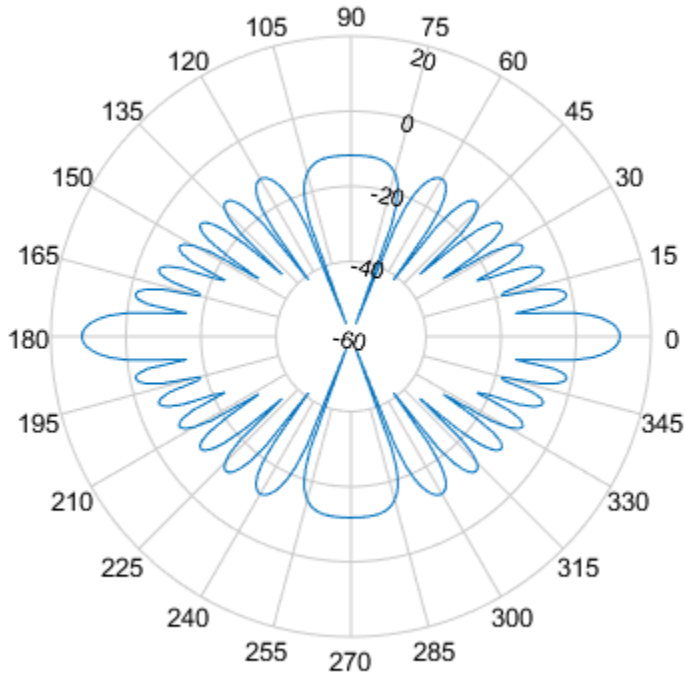


Find Lobes of Steered Isotropic Antenna ULA Patterns

Create a 15-element ULA of isotropic antenna with elements spaced one-half wavelength apart. Plot the directivity of the array at 20 GHz. Then steer the array to 45° azimuth and plot the directivity. Then, find the mainlobe, sidelobe, and backlobe directions of the array pattern.

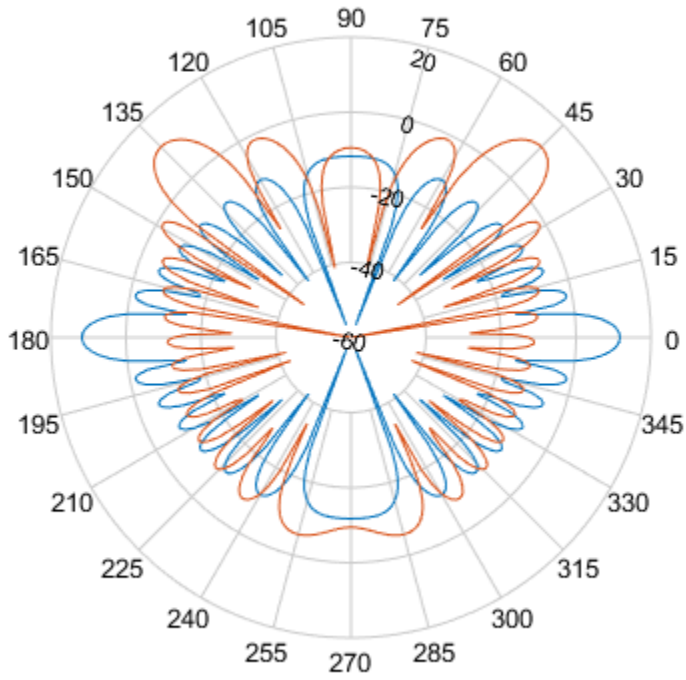
```
fc = 20.0e9;
c = physconst('Lightspeed');
lam = c/fc;
angs = [-180:1:180];
antenna = phased.IsotropicAntennaElement('FrequencyRange',[1.0e9,100.0e9]);
array = phased.ULA('Element',antenna,'NumElements',15,'ElementSpacing',lam/2);
a = pattern(array,fc,angs,0);
```

```
P = polarpattern(angs,a);
```



Steer the array to 45&deg azimuth and add the steered pattern to the polar plot.

```
steervec = phased.SteeringVector('SensorArray',array,'PropagationSpeed',c);
sv = steervec(fc,[45;0]);
a1 = pattern(array,fc,angs,0,'Weights',sv);
add(P,angs,a1);
```



Find the lobes of the steered pattern.

```
L = findLobes(P,2);
L.mainLobe
```

```
ans =

  struct with fields:

        index: 226
    magnitude: 11.7609
        angle: 45
       extent: [216 238]
```

replace

Class: polarpattern

Replace polar plot data with new data

Syntax

```
replace(p,data)
replace(p,angle,magnitude)
```

Description

`replace(p,data)` removes all data from polar plot, `p` and adds new data based on real amplitude values, `data`.

`replace(p,angle,magnitude)` removes all the current data and adds new data sets of angle vectors and corresponding magnitude matrices to the polar plot, `p`.

Input Arguments

`p` — Polar plot

scalar handle

Polar plot, specified as a scalar handle.

`data` — Antenna or array data

real length-*M* vector | real *M*-by-*N* matrix | real *N*-*D* array | complex vector or matrix

Antenna or array data, specified as one of the following:

- A real length-*M* vector, where *M* contains the magnitude values with angles assumed to be $\frac{(0:M-1)}{M}\times 360^{\circ}$ degrees.

- A real *M*-by-*N* matrix, where *M* contains the magnitude values and *N* contains the independent data sets. Each column in the matrix has angles taken from the vector $\frac{(0:M-1)}{M}\times 360^{\circ}$ degrees. The set of each angle can vary for each column.
- A real *N*-*D* array, where *N* is the number of dimensions. Arrays with dimensions `2` and greater are independent data sets.
- A complex vector or matrix, where `data` contains Cartesian coordinates (*(x,y)* of each point. *x* contains the real part of `data` and *y* contains the imaginary part of `data`.

When data is in a logarithmic form such as dB, magnitude values can be negative. In this case,`polarpattern` plots the lowest magnitude values at the origin of the polar plot and highest magnitude values at the maximum radius.

`angle` — Set of angles
vector in degrees

Set of angles, specified as a vector in degrees.

`magnitude` — Set of magnitude values
vector | matrix

Set of magnitude values, specified as a vector or a matrix. For a matrix of magnitude values, each column is an independent set of magnitude values and corresponds to the same set of angles.

Examples

Replace Cosine Polar Plot With Rotated Cosine Polar Plot

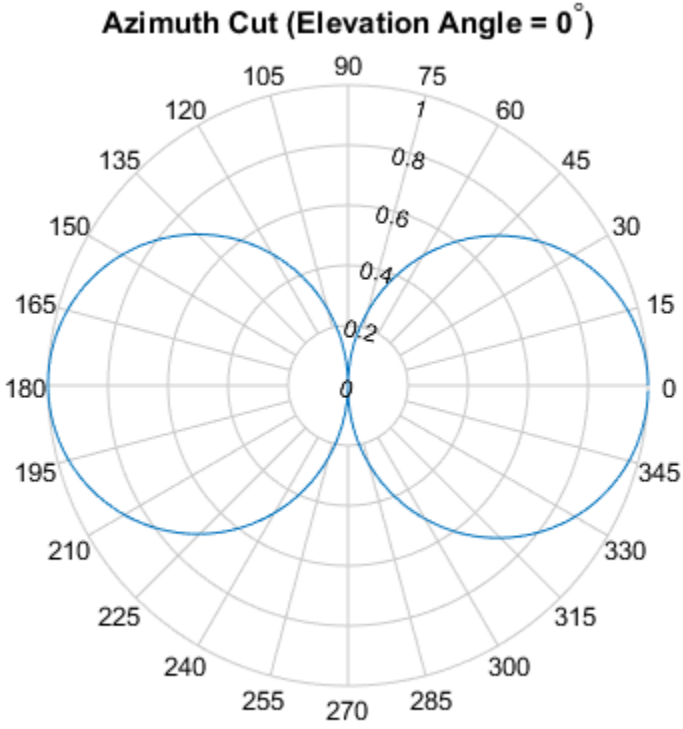
Plot cosine pattern in polar coordinates Specify a cosine antenna pattern from 0° to 360° in azimuth at 0° elevation. Then, plot the antenna pattern using `polarpattern`.

Create the pattern.

```
az = [0:360];
a = abs(cosd(az));
```

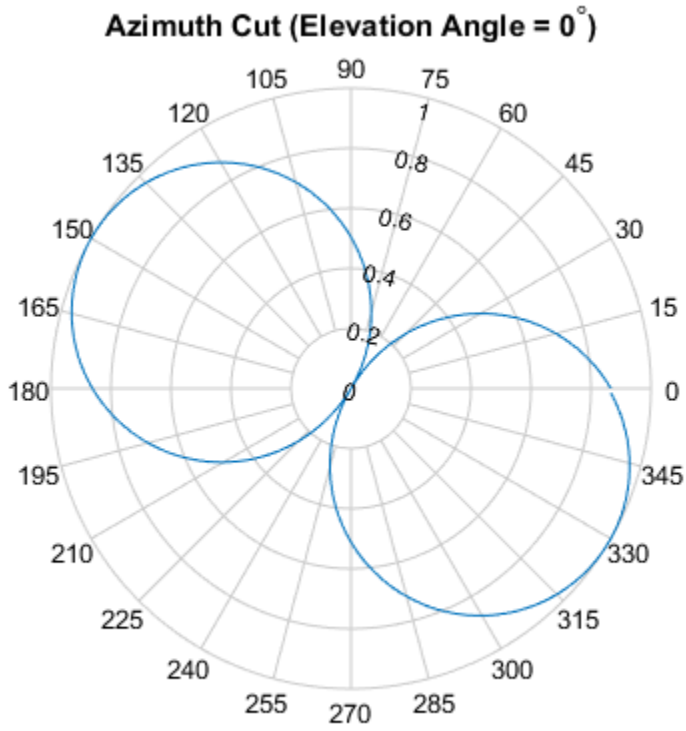
Plot the polar pattern of the antenna for an azimuth cut at 0° elevation.

```
P = polarpattern(a,'TitleTopTextInterpreter','tex','TitleTop','Azimuth Cut (Elevation A
```



Replace this plot with a rotated cosine pattern.

```
a = abs(cosd(az + 30.0));
replace(P,a);
```



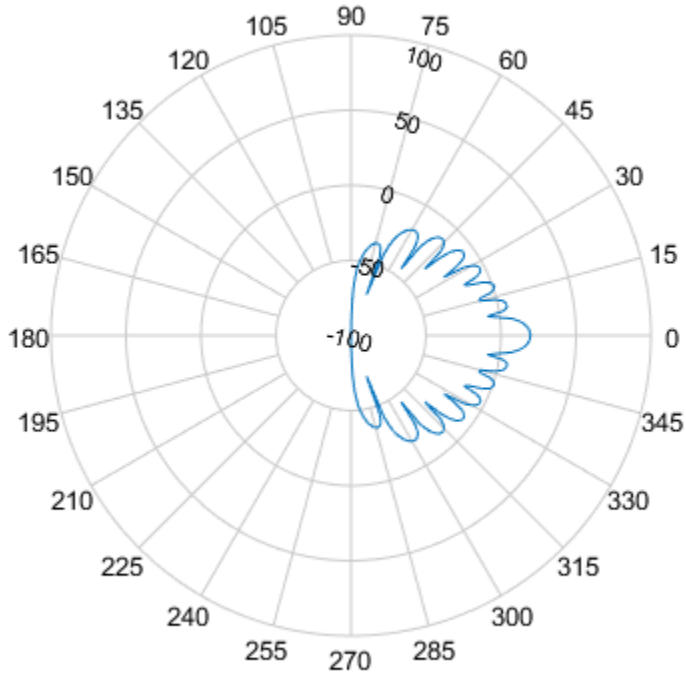
Replace Polar Plot Data with New Angle-Magnitude Data

Create a 15-element ULA of cosine antennas with elements spaced one-half wavelength apart. Plot the directivity of the array at 20 GHz.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
fc = 20.0e9;
c = physconst('Lightspeed');
lam = c/fc;
angs = [-180:1:180];
antenna = phased.CosineAntennaElement('FrequencyRange',[1.0e9,100.0e9],...
```

```
    'CosinePower',[2.5 2.5]);
array = phased.ULA('Element',antenna,'NumElements',15,'ElementSpacing',lam/2);
a = pattern(array,fc,angs,0);
P = polarpattern(angs,a);
```



Then, steer the array to 45° and, using the `replace` method, replace the existing polar plot with the steered array directivity.

```
steervec = phased.SteeringVector('SensorArray',array,'PropagationSpeed',c,...
    'IncludeElementResponse',true);
sv = steervec(fc,[45;0]);
a1 = pattern(array,fc,angs,0,'Weights',sv);
replace(P,angs,a1);
```

`add` | `addCursor` | `animate` | `createLabels` | `findLobes` | `showPeaksTable` | `showSpan`

Introduced in R2016a

showPeaksTable

Class: polarpattern

Show or hide peak marker table

Syntax

```
showPeaksTable(p,vis)
```

Description

`showPeaksTable(p,vis)` shows or hides a table of the peak values. By default, the peak values table is visible.

Input Arguments

p — Polar plot

scalar handle

Polar plot, specified as a scalar handle.

vis — Show or hide peaks table

`0` | `1`

Show or hide peaks table, specified as `0` or `1`.

Examples

Peaks of ULA Array in Polar Pattern

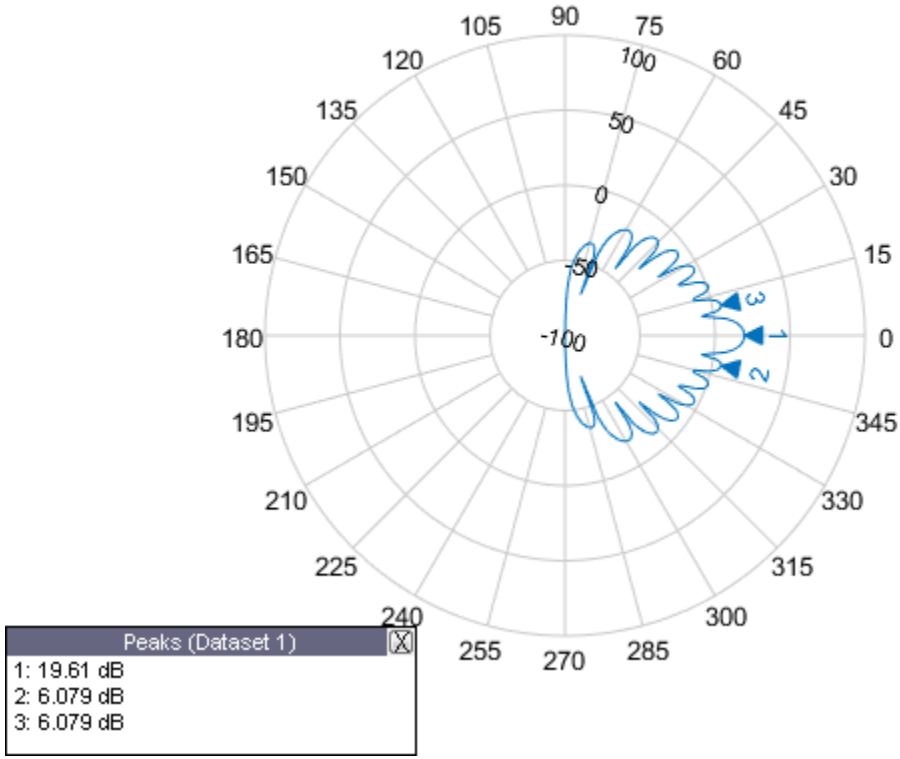
Create a 15-element ULA of cosine antennas with elements spaced one-half wavelength apart. Then, plot the directivity of the array at 20 GHz.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
fc = 20.0e9;
c = physconst('Lightspeed');
lam = c/fc;
angs = [-180:1:180];
antenna = phased.CosineAntennaElement('FrequencyRange',[1.0e9,100.0e9],...
    'CosinePower',[2.5 2.5]);
array = phased.ULA('Element',antenna,'NumElements',15,'ElementSpacing',lam/2);
```

Plot the polar pattern and show three peaks of the antenna. When creating a `polarpattern` plot, if you specify the Peaks property, the peaks table is displayed by default.

```
a = pattern(array,fc,angs,0);
P = polarpattern(angs,a,'Peaks',3);
```



Hide the table. When the peaks table is hidden, the peak markers display the peak values.

```
showPeaksTable(P,0);
```

PolarPattern Properties

Control appearance and behavior of polar plot

Description

Polar pattern properties control the appearance and behavior of the polar pattern object. By changing property values, you can modify certain aspects of the polar plot. To change the default properties use: .

```
p = polarpattern(____,Name,Value)
```

To view all the properties of the polar pattern object use:

```
details(p)
```

Antenna Metrics

`'AntennaMetrics'` — Show antenna metric
`0` (default) | `1`

Show antenna metrics, specified as a comma-separated pair consisting of `'AntennaMetrics'` and `0` or `1`. Antenna metric displays main, back, and side lobes of antenna/array pattern passed as input.

Data Types: `logical`

`'Peaks'` — Maximum number of peaks to compute for each data set
positive integer | vector of integers

Maximum number of peaks to compute for each data set, specified as a comma-separated pair consisting of `'Peaks'` and a positive scalar or vector of integers.

Data Types: `double`

Angle Properties

`'AngleAtTop'` — Angle at top of polar plot
`90` (default) | scalar in degrees

Angle at the top of the polar plot, specified as a comma-separated pair consisting of `'AngleAtTop'` and a scalar in degrees.

Data Types: `double`

`'AngleLim'` — Visible polar angle span

`[0 360]` (default) | 1-by-2 vector of real values

Visible polar angle span, specified as a comma-separated pair consisting of `'AngleLim'` and a 1-by-2 vector of real values.

Data Types: `double`

`'AngleLimVisible'` — Show interactive angle limit cursors

`0` (default) | `1`

Show interactive angle limit cursors, specified as a comma-separated pair consisting of `'AngleLimVisible'` and `0` or `1`.

Data Types: `logical`

`'AngleDirection'` — Direction of increasing angle

`'ccw'` (default) | `'cw'`

Direction of increasing angle, specified as a comma-separated pair consisting of `'AngleDirection'` and `'ccw'` (counterclockwise) or `'cw'` (clockwise).

Data Types: `char`

`'AngleResolution'` — Number of degrees between radial lines

`15` (default) | scalar in degrees

Number of degrees between radial lines depicting angles in the polar plot, specified as a comma-separated pair consisting of `'AngleResolution'` and a scalar in degrees.

Data Types: `double`

`'AngleTickLabelRotation'` — Rotate angle tick labels

`0` (default) | `1`

Rotate angle tick labels, specified as a comma-separated pair consisting of `'AngleTickLabelRotation'` and `0` or `1`.

Data Types: `logical`

'AngleTickLabelVisible' — Show angle tick labels
1 (default) | 0

Show angle tick labels, specified as a comma-separated pair consisting of 'AngleTickLabelVisible' and 0 or 1.

Data Types: logical

'AngleTickLabelFormat' — Format for angle tick labels
360 (default) | 180

Format for angle tick labels, specified as a comma-separated pair consisting of 'AngleTickLabelFormat' and 360 degrees or 180 degrees.

Data Types: double

'AngleFontSizeMultiplier' — Scale factor of angle tick font
1 (default) | numeric value greater than zero

Scale factor of angle tick font, specified as a comma-separated pair consisting of 'AngleFontSizeMultiplier' and a numeric value greater than zero.

Data Types: double

'Span' — Show angle span measurement
0 (default) | 1

Show angle span measurement, specified as a comma-separated pair consisting of 'Span' and 0 or 1.

Data Types: logical

'ZeroAngleLine' — Highlight radial line at zero degrees
0 (default) | 1

Highlight radial line at zero degrees, specified as a comma-separated pair consisting of 'ZeroAngleLine' and 0 or 1.

Data Types: logical

'DisconnectAngleGaps' — Show gaps in line plots with nonuniform angle spacing
1 (default) | 0

Show gaps in line plots with nonuniform angle spacing, specified as a comma-separated pair consisting of 'DisconnectAngleGaps' and 0 or 1.

Data Types: `logical`

Magnitude Properties

`'MagnitudeAxisAngle'` — Angle of magnitude tick label radial line

`75` (default) | real scalar in degrees

Angle of magnitude tick label radial line, specified as a comma-separated pair consisting of `'MagnitudeAxisAngle'` and real scalar in degrees.

Data Types: `double`

`'MagnitudeTick'` — Magnitude ticks

`[0 0.2 0.4 0.6 0.8]` (default) | 1-by-N vector

Magnitude ticks, specified as a comma-separated pair consisting of `'MagnitudeTick'` and a 1-by-N vector, where N is the number of magnitude ticks.

Data Types: `double`

`'MagnitudeTickLabelVisible'` — Show magnitude tick labels

`1` (default) | `0`

Show magnitude tick labels, specified as a comma-separated pair consisting of `'MagnitudeTickLabelVisible'` and `0` or `1`.

Data Types: `logical`

`'MagnitudeLim'` — Minimum and maximum magnitude limits

`[0 1]` (default) | two-element vector of real values

Minimum and maximum magnitude limits, specified as a comma-separated pair consisting of `'MagnitudeLim'` and a two-element vector of real values.

Data Types: `double`

`'MagnitudeLimMode'` — Determine magnitude dynamic range

`'auto'` (default) | `'manual'`

Determine magnitude dynamic range, specified as a comma-separated pair consisting of `'MagnitudeLimMode'` and `'auto'` or `'manual'`.

Data Types: `char`

'MagnitudeAxisAngleMode' — Determine angle for magnitude tick labels

'auto' (default) | 'manual'

Determine angle for magnitude tick labels, specified as a comma-separated pair consisting of 'MagnitudeAxisAngleMode' and 'auto' or 'manual'.

Data Types: char

'MagnitudeTickMode' — Determine magnitude tick locations

'auto' (default) | 'manual'

Determine magnitude tick locations, specified as a comma-separated pair consisting of 'MagnitudeTickMode' and 'auto' or 'manual'.

Data Types: char

'MagnitudeUnits' — Magnitude units

'dB' | 'dBLoss'

Magnitude units, specified as a comma-separated pair consisting of 'MagnitudeUnits' and 'db' or 'dBLoss'.

Data Types: char

'MagnitudeFontSizeMultiplier' — Scale factor of magnitude tick font

0.9000 (default) | numeric value greater than zero

Scale factor of magnitude tick font, specified as a comma-separated pair consisting of 'MagnitudeFontSizeMultiplier' and a numeric value greater than zero.

Data Types: double

Miscellaneous Properties

'NormalizeData' — Normalize each data trace to maximum value

0 (default) | 1

Normalize each data trace to maximum value, specified as a comma-separated pair consisting of 'NormalizeData' and 0 or 1.

Data Types: logical

'ConnectEndpoints' — Connect first and last angles

0 (default) | 1

Connect first and last angles, specified as a comma-separated pair consisting of `'ConnectEndpoints'` and `0` or `1`.

Data Types: `logical`

`'Style'` — Style of polar plot display

`'line'` (default) | `'filled'`

Style of polar plot display, specified as a comma-separated pair consisting of `'Style'` and `'line'` or `'filled'`.

Data Types: `char`

`'TemporaryCursor'` — Create temporary cursor

`0` (default) | `1`

Create a temporary cursor, specified as a comma-separated pair consisting of `'TemporaryCursor'` and `0` or `1`.

Data Types: `logical`

`'ToolTips'` — Show tool tips

`1` (default) | `0`

Show tool tips when you hover over a polar plot element, specified as a comma-separated pair consisting of `'ToolTips'` and `0` or `1`.

Data Types: `logical`

`'ClipData'` — Clip data to outer circle

`0` (default) | `1`

Clip data to outer circle, specified as a comma-separated pair consisting of `'ClipData'` and `0` or `1`.

Data Types: `logical`

`'NextPlot'` — Directive on how to add next plot

`'replace'` (default) | `'new'` | `'add'`

Directive on how to add next plot, specified as a comma-separated pair consisting of `'NextPlot'` and one of the values in the table:

Property Value	Effect
`'new'`	Creates a figure and uses it as the current figure.
`'add'`	Adds new graphics objects without clearing or resetting the current figure.
`'replace'`	Removes all axes objects and resets figure properties to their defaults before adding new graphics objects.

Legend and Title Properties

`'LegendLabels'` — Data tables for legend annotation

character vector | cell array of character vectors

Data tables for legend annotation, specified as a comma-separated pair consisting of `'LegendLabels'` and a character vector or cell array of character vectors.

Data Types: `char`

`'LegendVisible'` — Show legend label

`0` (default) | `1`

Show legend label, specified as a comma-separated pair consisting of `'LegendVisible'` and `0` or `1`.

Data Types: `logical`

`'TitleTop'` — Title to display above the polar plot

character vector

Title to display above the polar plot, specified as a comma-separated pair consisting of `'TitleTop'` and a character vector.

Data Types: `char`

`'TitleBottom'` — Title to display below the polar plot

character vector

Title to display below the polar plot, specified as a comma-separated pair consisting of `'TitleBottom'` and a character vector.

Data Types: `char`

`'TitleTopOffset'` — Offset between top title and angle ticks

`0.1500` (default) | scalar

Offset between top title and angle ticks, specified as a comma-separated pair consisting of `'TitleTopOffset'` and a scalar. The value must be in the range `[-0.5,0.5]`.

Data Types: `double`

`'TitleBottomOffset'` — Offset between bottom title and angle ticks

`0.1500` (default) | scalar

Offset between bottom title and angle ticks, specified as a comma-separated pair consisting of `'TitleBottomOffset'` and a scalar. The value must be in the range `[-0.5,0.5]`.

Data Types: `double`

`'TitleTopFontSizeMultiplier'` — Scale factor of top title font

`1.1000` (default) | numeric value greater than zero

Scale factor of top title font, specified as a comma-separated pair consisting of `'TitleTopFontSizeMultiplier'` and a numeric value greater than zero.

Data Types: `double`

`'TitleBottomFontSizeMultiplier'` — Scale factor of bottom title font

`0.9000` (default) | numeric value greater than zero

Scale factor of bottom title font, specified as a comma-separated pair consisting of `'TitleBottomFontSizeMultiplier'` and a numeric value greater than zero.

Data Types: `double`

`'TitleTopFontWeight'` — Thickness of top title font

`'bold'` (default) | `'normal'`

Thickness of top title font, specified as a comma-separated pair consisting of `'TitleTopFontWeight'` and `'bold'` or `'normal'`.

Data Types: `char`

`'TitleBottomFontWeight'` — Thickness of bottom title font

`'normal'` (default) | `'bold'`

Thickness of bottom title font, specified as a comma-separated pair consisting of `'TitleBottomFontWeight'` and `'bold'` or `'normal'`.

Data Types: `char`

`'TitleTopTextInterpreter'` — Interpretation of top title characters
`'none'` (default) | `'tex'` | `'latex'`

Interpretation of top title characters, specified as a comma-separated pair consisting of `'TitleTopTextInterpreter'` and:

- `'tex'` — Interpret using a subset of TeX markup
- `'latex'` — Interpret using LaTeX markup
- `'none'` — Display literal characters

TeX Markup

By default, MATLAB supports a subset of TeX markup. Use TeX markup to add superscripts and subscripts, modify the text type and color, and include special characters in the text.

This table lists the supported modifiers when the `TickLabelInterpreter` property is set to `'tex'`, which is the default value. Modifiers remain in effect until the end of the text, except for superscripts and subscripts which only modify the next character or the text within the curly braces `{}`.

Modifier	Description	Example
`^{ }`	Superscript	`'text^{superscript}'`
`_{ }`	Subscript	`'text_{subscript}'`
`\bf`	Bold font	`'\bf text'`
`\it`	Italic font	`'\it text'`
`\sl`	Oblique font (rarely available)	`'\sl text'`
`\rm`	Normal font	`'\rm text'`
`\fontname{specifier}`	Set `specifier` as the name of a font family to change the font style. You can use this with other modifiers.	`'\fontname{Courier} text'`

Modifier	Description	Example
`\fontsize{specifier}`	Set `specifier` as a scalar numeric value to change the font size.	`'\fontsize{15} text'`
`\color{specifier}`	Set `specifer` as one of these colors: `red`, `green`, `yellow`, `magenta`, `blue`, `black`, `white`, `gray`, `darkGreen`, `orange`, or `lightBlue`.	`'\color{magenta} text'`
`\color[rgb] {specifier}`	Set `specifier` as a three-element RGB triplet to change the font color.	`'\color[rgb] {0,0.5,0.5} text'`

LaTeX Markup

To use LaTeX markup, set the `TickLabelInterpreter` property to `'latex'`. The displayed text uses the default LaTeX font style. The `FontName`, `FontWeight`, and `FontAngle` properties do not have an effect. To change the font style, use LaTeX markup within the text.

The maximum size of the text that you can use with the LaTeX interpreter is 1200 characters. For multiline text, the maximum size reduces by about 10 characters per line.

For more information about the LaTeX system, see The LaTeX Project website at http://www.latex-project.org/.

Data Types: `char`

`'TitleBottomTextInterpreter'` — Interpretation of bottom title characters

`'none'` (default) | `'tex'` | `'latex'`

Interpretation of bottom title characters, specified as a comma-separated pair consisting of `'TitleBottomTextInterpreter'` and:

- `'tex'` — Interpret using a subset of TeX markup
- `'latex'` — Interpret using LaTeX markup
- `'none'` — Display literal characters

TeX Markup

By default, MATLAB supports a subset of TeX markup. Use TeX markup to add superscripts and subscripts, modify the text type and color, and include special characters in the text.

This table lists the supported modifiers when the `TickLabelInterpreter` property is set to `'tex'`, which is the default value. Modifiers remain in effect until the end of the text, except for superscripts and subscripts which only modify the next character or the text within the curly braces `{}`.

Modifier	Description	Example
`^{ }`	Superscript	`'text^{superscript}'`
`_{ }`	Subscript	`'text_{subscript}'`
`\bf`	Bold font	`'\bf text'`
`\it`	Italic font	`'\it text'`
`\sl`	Oblique font (rarely available)	`'\sl text'`
`\rm`	Normal font	`'\rm text'`
`\fontname{specifier}`	Set `specifier` as the name of a font family to change the font style. You can use this with other modifiers.	`'\fontname{Courier} text'`
`\fontsize{specifier}`	Set `specifier` as a scalar numeric value to change the font size.	`'\fontsize{15} text'`
`\color{specifier}`	Set `specifer` as one of these colors: `red`, `green`, `yellow`, `magenta`, `blue`, `black`, `white`, `gray`, `darkGreen`, `orange`, or `lightBlue`.	`'\color{magenta} text'`
`\color[rgb] {specifier}`	Set `specifier` as a three-element RGB triplet to change the font color.	`'\color[rgb] {0,0.5,0.5} text'`

LaTeX Markup

To use LaTeX markup, set the `TickLabelInterpreter` property to `'latex'`. The displayed text uses the default LaTeX font style. The `FontName`, `FontWeight`, and `FontAngle` properties do not have an effect. To change the font style, use LaTeX markup within the text.

The maximum size of the text that you can use with the LaTeX interpreter is 1200 characters. For multiline text, the maximum size reduces by about 10 characters per line.

For more information about the LaTeX system, see The LaTeX Project website at http://www.latex-project.org/.

Data Types: `char`

Grid Properties

`'GridOverData'` — Draw grid over data plots

`0` (default) | `1`

Draw grid over data plots, specified as a comma-separated pair consisting of `'GridOverData'` and `0` or `1`.

Data Types: `logical`

`'DrawGridToOrigin'` — Draw radial lines within innermost circle

`0` (default) | `1`

Draw radial lines within innermost circle of the polar plot, specified as a comma-separated pair consisting of `'DrawGridToOrigin'` and `0` or `1`.

Data Types: `logical`

`'GridAutoRefinement'` — Increase angle resolution

`0` (default) | `1`

Increase angle resolution in the polar plot, specified as a comma-separated pair consisting of `'GridAutoRefinement'` and `0` or `1`. This property increases angle resolution by doubling the number of radial lines outside each magnitude.

Data Types: `logical`

'GridWidth' — Width of grid lines

0.5000 (default) | positive scalar

Width of grid lines, specified as a comma-separated pair consisting of 'GridWidth' and a positive scalar.

Data Types: double

'GridVisible' — Show grid lines

1 (default) | 0

Show grid lines, including magnitude circles and angle radii, specified as a comma-separated pair consisting of 'GridVisible' and 0 or 1.

Data Types: logical

'GridForeGroundColor' — Color of foreground grid lines

[0.8000 0.8000 0.8000] (default) | 'none' | character vector of color names

Color of foreground grid lines, specified as a comma-separated pair consisting of 'GridForeGroundColor' and an RGB triplet, character vector of color names, or 'none'.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1]; for example, [0.4 0.6 0.7]. This table lists the long and short color name options and the equivalent RGB triplet values.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Data Types: double | char

`'GridBackGroundColor'` — Color of background grid lines

`'w'` (default) | character vector of color names | `'none'`

Color of background grid lines, specified as a comma-separated pair consisting of `'GridBackGroundColor'` and an RGB triplet, character vector of color names, or `'none'`.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`; for example, `[0.4 0.6 0.7]`. This table lists the long and short color name options and the equivalent RGB triplet values.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black'`	`'k'`	`[0 0 0]`

Data Types: `double` | `char`

Marker, Color, Line, and Font Properties

`'Marker'` — Marker symbol

`'none'` (default) | character vector of symbols

Marker symbol, specified as a comma-separated pair consisting of `'Marker'` and either `'none'` or one of the symbols in this table. By default, a line does not have markers. Add markers at selected points along the line by specifying a marker.

Value	Description
`'o'`	Circle
`'+'`	Plus sign

Value	Description
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No markers

'MarkerSize' — Marker size

6 (default) | positive value

Marker size, specified as a comma-separated pair consisting of 'MarkerSize' and a positive value in point units.

Data Types: double

'ColorOrder' — Colors to use for multiline plots

seven predefined colors (default) | three-column matrix of RGB triplets

Colors to use for multiline plots, specified as a comma-separated pair consisting of 'ColorOrder' and a three-column matrix of RGB triplets. Each row of the matrix defines one color in the color order.

Data Types: double

'ColorOrderIndex' — Next color to use in color order

1 (default) | positive integer

Next color to use in color order, specified as a comma-separated pair consisting of 'ColorOrderIndex' and a positive integer. New plots added to the axes use colors based on the current value of the color order index.

Data Types: `double`

`'EdgeColor'` — Color of data lines

`'k'` (default) | RGB triplet vector

Color of data lines, specified as a comma-separated pair consisting of `'EdgeColor'` and a character vector of color names or RGB triplet vector.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`; for example, `[0.4 0.6 0.7]`. This table lists the long and short color name options and the equivalent RGB triplet values.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black'`	`'k'`	`[0 0 0]`

Data Types: `double` | `char`

`'LineStyle'` — Line style of the plot

`'-'` (default) | `'--'` | `':'` | `'-.'` | `'none'`

Line style of the plot, specified as a comma-separated pair consisting of `'LineStyle'` and one of the symbols in the table:

Symbol	Line Style	Resulting Line
`'-'`	Solid line	
`'--'`	Dashed line	
`':'`	Dotted line	

Symbol	Line Style	Resulting Line
`'-.'`	Dash-dotted line	
`'none'`	No line	No line

`'LineWidth'` — Line width of plot
`1` (default) | positive scalar

Line width of the plot, specified as a comma-separated pair consisting of `'LineWidth'` and a positive scalar.

`'FontSize'` — Font size of text in plot
`10` (default) | positive scalar

Font size of text in the plot, specified as a comma-separated pair consisting of `'FontSize'` and a positive scalar.

`'FontSizeAutoMode'` — Set font size
`'auto'` (default) | `'manual'`

Set font size, specified as a comma-separated pair consisting of `'FontSizeAutoMode'` and `'auto'` or `'manual'`.

Data Types: `char`

See Also

showSpan

Class: polarpattern

Show or hide angle span between two markers

Syntax

```
showSpan(p,id1,id2)
showSpan(p,id1,id2,true)
showSpan(p,vis)
showSpan(p)
d = showSpan( ___ )
```

Description

`showSpan(p,id1,id2)` displays the angle span between two angle markers, `id1` and `id2`. The angle span is calculated counterclockwise.

`showSpan(p,id1,id2,true)` automatically reorders the angle markers such that the initial angle span is less than or equal to 180° counterclockwise.

`showSpan(p,vis)` sets angle span visibility by setting `vis` to `true` or `false`.

`showSpan(p)` toggles the angle span display on and off.

`d = showSpan( ___ )` returns angle span details in a structure, `d` using any of the previous syntaxes.

Input Arguments

p — Polar plot

scalar handle

Polar plot, specified as a scalar handle.

`id1,id2` — Cursor or peak marker identifiers

character vector

Cursor or peak marker identifiers, specified as character vector. Adding cursors to the polar plot creates cursor marker identifiers. Adding peaks to the polar plot creates peak marker identifiers.

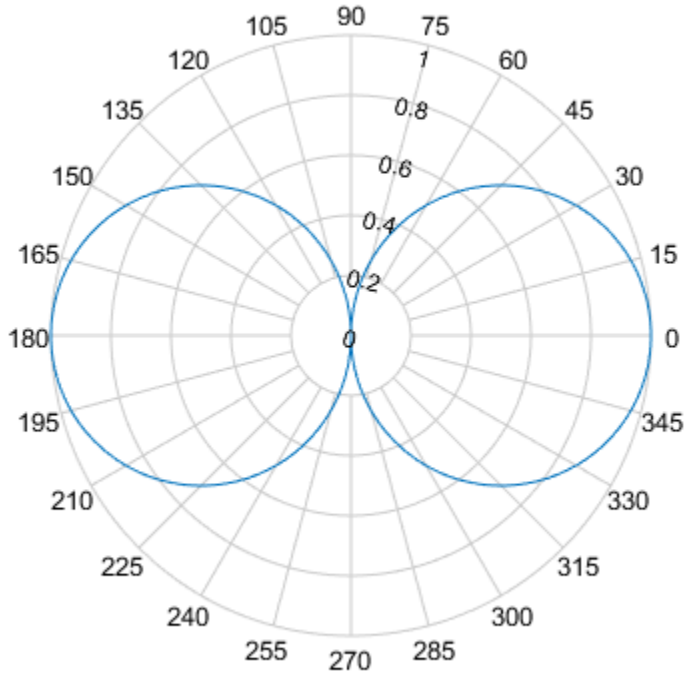
Example: `showspan(p,'C1','C2')`. Displays the angle span between cursors, `C1` and `C2` in polar plot, `p`.

Examples

Show Angle Span for Short-Dipole Antenna

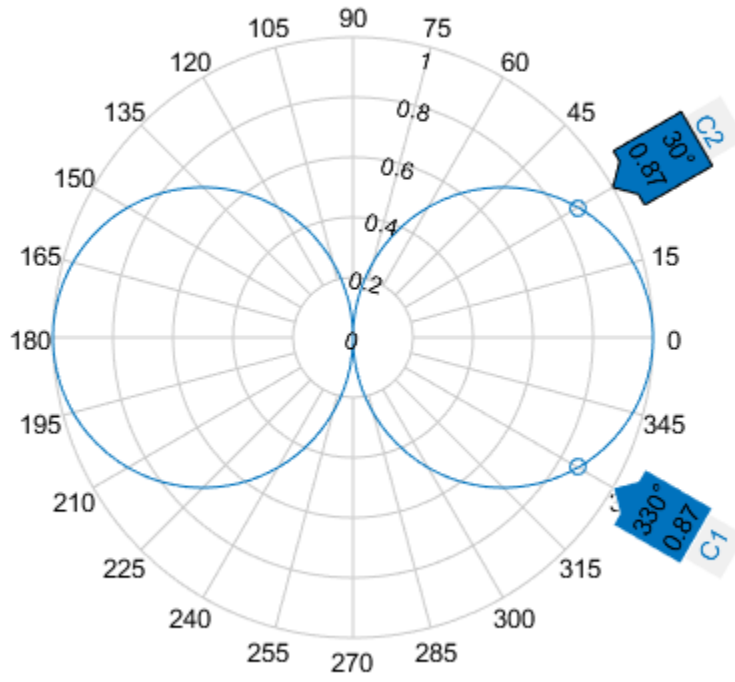
Create a short-dipole antenna element and plot the field values at 250 MHz.

```
antenna = phased.ShortDipoleAntennaElement('FrequencyRange',[100,900]*1e6,...
    'AxisDirection','Y');
angs = [-180:1:180];
fc = 250.0e6;
p = pattern(antenna,250.0e6,angs,0,'CoordinateSystem','polar','Type',...
    'efield','Polarization','H');
P = polarpattern(angs,abs(p));
```



Add cursors to the polar plot at -30° and 30°.

```
addCursor(P,[-30 30]);
```



Show the angle span between the two angles.

```
showSpan(P,'C1','C2');
```

Functions-Alphabetical List

aictest

Dimension of signal subspace

Syntax

```
nsig = aictest(X)
nsig = aictest(X,'fb')
```

Description

`nsig = aictest(X)` estimates the number of signals, `nsig`, present in a *snapshot* of data, `X`, that impinges upon the sensors in an array. The estimator uses the *Akaike Information Criterion test* (AIC). The input argument, `X`, is a complex-valued matrix containing a time sequence of data samples for each sensor. Each row corresponds to a single time sample for all sensors.

`nsig = aictest(X,'fb')` estimates the number of signals. Before estimating, it performs *forward-backward averaging* on the sample covariance matrix constructed from the data snapshot, `X`. This syntax can use any of the input arguments in the previous syntax.

Examples

Estimate the Signal Subspace Dimensions for Two Arriving Signals

Construct a data snapshot for two plane waves arriving at a half-wavelength-spaced uniform line array with 10 elements. The plane waves arrive from 0° and –25° azimuth, both with elevation angles of 0°. Assume the signals arrive in the presence of additive noise that is both temporally and spatially Gaussian white. For each signal, the SNR is 5 dB. Take 300 samples to build a 300-by-10 data snapshot. Then, solve for the number of signals using `aictest`.

```
N = 10;
d = 0.5;
elementPos = (0:N-1)*d;
```

```
angles = [0 -25];
x = sensorsig(elementPos,300,angles,db2pow(-5));
nsig = aictest(x)
```

```
nsig =

     2
```

The result shows that the number of signals is two, as expected.

Estimate the Signal Subspace Dimension using Forward-Backward Smoothing

Construct a data snapshot for two plane waves arriving at a half-wavelength-spaced uniform line array with 10 elements. Two correlated plane waves arrive from 0° and 10° azimuth, both with elevation angles of 0°. Assume that the signals arrive in the presence of additive noise that is both temporally and spatially Gaussian white. For each signal, the SNR is 10 dB. Take 300 samples to build a 300-by-10 data snapshot. Then, solve for the number of signals using `aictest`.

```
N = 10;
d = 0.5;
elementPos = (0:N-1)*d;
angles = [0 10];
ncov = db2pow(-10);
scov = [1 .5]'*[1 .5];
x = sensorsig(elementPos,300,angles,ncov,scov);
Nsig = aictest(x)
```

```
Nsig =

     1
```

This result shows that `aictest` cannot determine the number of signals correctly when the signals are correlated.

Use the forward-backward smoothing option.

```
Nsig = aictest(x,'fb')
```

```
Nsig =
```

2

The addition of forward-backward smoothing yields the correct number of signals.

Input Arguments

X — Data snapshot

complex-valued *K*-by-*N* matrix

Data snapshot, specified as a complex-valued, *K*-by-*N* matrix. A snapshot is a sequence of time-samples taken simultaneous at each sensor. In this matrix, *K* represents the number of time samples of the data, while *N* represents the number of sensor elements.

Example: [–0.1211 + 1.2549i, 0.1415 + 1.6114i, 0.8932 + 0.9765i;]

Data Types: `double`
Complex Number Support: Yes

Output Arguments

nsig — Dimension of signal subspace

non-negative integer

Dimension of signal subspace, returned as a non-negative integer. The dimension of the signal subspace is the number of signals in the data.

Definitions

Estimating the Number of Sources

AIC and MDL tests

Direction finding algorithms such as MUSIC and ESPRIT require knowledge of the number of sources of signals impinging on the array or equivalently, the dimension, *d*, of the signal subspace. The Akaike Information Criterion (AIC) and the Minimum

Description Length (MDL) formulas are two frequently-used estimators for obtaining that dimension. Both estimators assume that, besides the signals, the data contains spatially and temporally white Gaussian random noise. Finding the number of sources is equivalent to finding the multiplicity of the smallest eigenvalues of the sampled spatial covariance matrix. The sample spatial covariance matrix constructed from a data snapshot is used in place of the actual covariance matrix.

A requirement for both estimators is that the dimension of the signal subspace be less than the number of sensors, *N*, and that the number of time samples in the snapshot, *K*, be much greater than *N*.

A variant of each estimator exists when forward-backward averaging is employed to construct the spatial covariance matrix. Forward-backward averaging is useful for the case when some of the sources are highly correlated with each other. In that case, the spatial covariance matrix may be ill conditioned. Forward-backward averaging can only be used for certain types of symmetric arrays, called *centro-symmetric* arrays. Then the forward-backward covariance matrix can be constructed from the sample spatial covariance matrix, *S*, using $S_{FB} = S + JS^*J$ where *J* is the exchange matrix. The exchange matrix maps array elements into their symmetric counterparts. For a line array, it would be the identity matrix flipped from left to right.

All the estimators are based on a cost function

$$L_d(d) = K(N-d)\ln\left\{\frac{\frac{1}{N-d}\sum_{i=d+1}^{N}\lambda_i}{\left\{\prod_{i=d+1}^{N}\lambda_i\right\}^{\frac{1}{N-d}}}\right\}$$

plus an added penalty term. The value λ_i represent the smallest *(N–d)* eigenvalues of the spatial covariance matrix. For each specific estimator, the solution for *d* is given by

- AIC

$$\hat{d}_{AIC} = \underset{d}{\operatorname{argmin}}\{L_d(d) + d(2N-d)\}$$

- AIC for forward-backward averaged covariance matrices

$$\hat{d}_{AIC:\,FB} = \underset{d}{\operatorname{argmin}}\left\{ L_d(d) + \frac{1}{2} d(2N - d + 1) \right\}$$

- MDL

$$\hat{d}_{MDL} = \underset{d}{\operatorname{argmin}}\left\{ L_d(d) + \frac{1}{2} (d(2N - d) + 1) \ln K \right\}$$

- MDL for forward-backward averaged covariance matrices

$$\hat{d}_{MDL\,FB} = \underset{d}{\operatorname{argmin}}\left\{ L_d(d) + \frac{1}{4} d(2N - d + 1) \ln K \right\}$$

albersheim

Required SNR using Albersheim's equation

Syntax

```
SNR = albersheim(prob_Detection,prob_FalseAlarm)
SNR = albersheim(prob_Detection,prob_FalseAlarm,N)
```

Description

`SNR = albersheim(prob_Detection,prob_FalseAlarm)` returns the signal-to-noise ratio in decibels. This value indicates the ratio required to achieve the given probabilities of detection `prob_Detection` and false alarm `prob_FalseAlarm` for a single sample.

`SNR = albersheim(prob_Detection,prob_FalseAlarm,N)` determines the required SNR for the noncoherent integration of `N` samples.

Examples

Compute Required SNR for Probability of Detection

Compute the required SNR of a single pulse to achieve a detection probability of 0.9 as a function of the false alarm probability.

Set the probability of detection to 0.9 and the probabilities of false alarm from .0001 to .01.

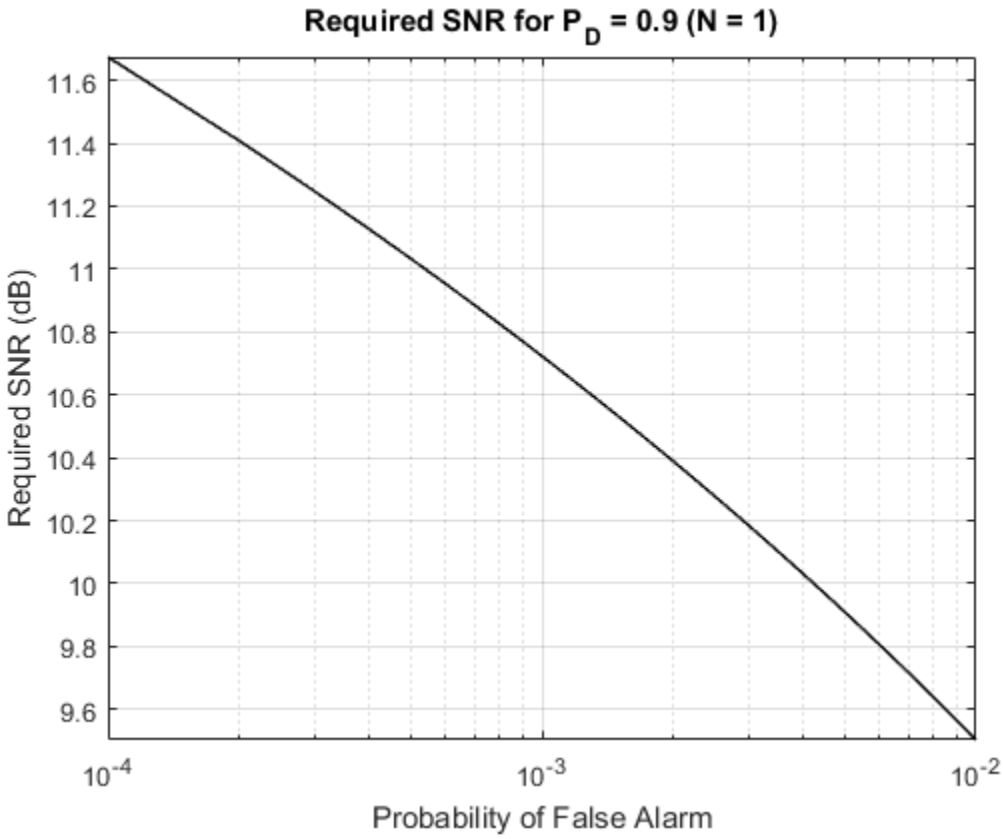
```
Pd=0.9;
Pfa=0.0001:0.0001:.01;
```

Loop the Albersheim equation over all Pfa's.

```
snr = zeros(1,length(Pfa));
for j=1:length(Pfa)
    snr(j) = albersheim(Pd,Pfa(j));
end
```

Plot SNR versus Pfa.

```
semilogx(Pfa,snr,'k','linewidth',1)
grid
axis tight
xlabel('Probability of False Alarm')
ylabel('Required SNR (dB)')
title('Required SNR for P_D = 0.9 (N = 1)')
```



Compute Required SNR for Probability of Detection of 10 Pulses

Compute the required SNR of 10 non-coherently integrated pulse to achieve a detection probability of 0.9 as a function of the false alarm probability.

Set the probability of detection to 0.9 and the probabilities of false alarm from .0001 to .01.

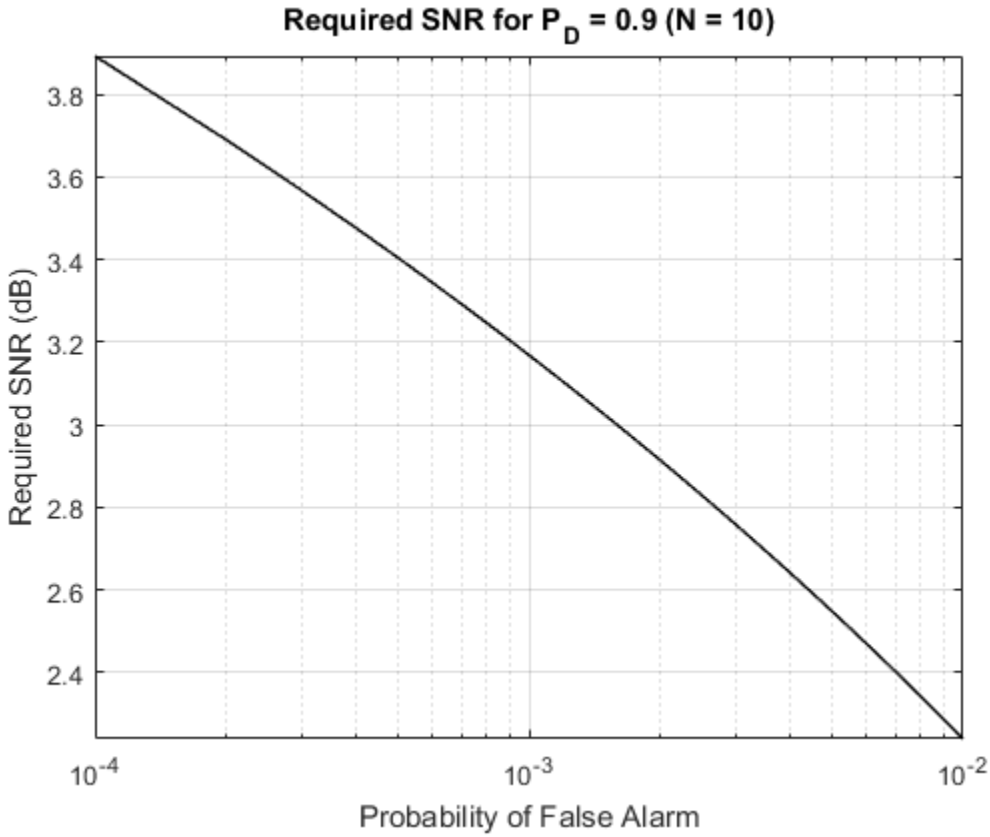
```
Pd=0.9;
Pfa=0.0001:0.0001:.01;
Npulses = 10;
```

Loop over the Albersheim equation over all Pfa's.

```
snr = zeros(1,length(Pfa));
for j=1:length(Pfa)
    snr(j) = albersheim(Pd,Pfa(j),Npulses);
end
```

Plot SNR versus Pfa.

```
semilogx(Pfa,snr,'k','linewidth',1)
grid
axis tight
xlabel('Probability of False Alarm')
ylabel('Required SNR (dB)')
title('Required SNR for P_D = 0.9 (N = 10)')
```



Definitions

Albersheim's Equation

Albersheim's equation uses a closed-form approximation to calculate the SNR. This SNR value is required to achieve the specified detection and false-alarm probabilities for a nonfluctuating target in independent and identically distributed Gaussian noise. The approximation is valid for a linear detector and is extensible to the noncoherent integration of N samples.

Let

$$A = \ln \frac{0.62}{P_{FA}}$$

and

$$B = \ln \frac{P_D}{1 - P_D}$$

where P_{FA} and P_D are the false-alarm and detection probabilities.

Albersheim's equation for the required SNR in decibels is:

$$\text{SNR} = -5 \log_{10} N + [6.2 + 4.54 / \sqrt{N + 0.44}] \log_{10}(A + 0.12AB + 1.7B)$$

where N is the number of noncoherently integrated samples.

Introduced in R2011a

ambgfun

Ambiguity and crossambiguity function

Syntax

```
afmag = ambgfun(x,Fs,PRF)
afmag = ambgfun(x,y,Fs,PRF)
[afmag,delay,doppler] = ambgfun(___)
[afmag,delay,doppler] = ambgfun(___,'Cut','2D')
[afmag,delay] = ambgfun(___,'Cut','Doppler')
[afmag,delay] = ambgfun(___,'Cut','Doppler','CutValue',V)
[afmag,doppler] = ambgfun(___,'Cut','Delay')
[afmag,doppler] = ambgfun(___,'Cut','Delay','CutValue',V)
ambgfun(___)
```

Description

`afmag = ambgfun(x,Fs,PRF)` returns the magnitude of the normalized ambiguity function for the vector `x`. `Fs` is the sampling rate. `PRF` is the pulse repetition rate.

`afmag = ambgfun(x,y,Fs,PRF)` returns the magnitude of the normalized crossambiguity function between the pulse `x` and the pulse `y`.

`[afmag,delay,doppler] = ambgfun(___)` or `[afmag,delay,doppler] = ambgfun(___,'Cut','2D')` returns the time delay vector, `delay`, and the Doppler frequency vector, `doppler`.

`[afmag,delay] = ambgfun(___,'Cut','Doppler')` returns delays from a zero-Doppler cut through the 2-D normalized ambiguity function magnitude.

`[afmag,delay] = ambgfun(___,'Cut','Doppler','CutValue',V)` returns delays from a nonzero Doppler cut through the 2-D normalized ambiguity function magnitude at Doppler value, `V`.

`[afmag,doppler] = ambgfun(___,'Cut','Delay')` returns the Doppler values from zero-delay cut through the 2-D normalized ambiguity function magnitude.

`[afmag,doppler] = ambgfun( ___ ,'Cut','Delay','CutValue',V)` returns the Doppler values from a one-dimensional cut through the 2-D normalized ambiguity function magnitude at a delay value of `V`.

`ambgfun( ___ )`, with no output arguments, plots the ambiguity or crossambiguity function. When `'Cut'` is `'2D'`, the function produces a contour plot of the periodic ambiguity function. When `'Cut'` is `'Delay'` or `'Doppler'`, the function produces a line plot of the periodic ambiguity function cut.

Input Arguments

`x` — Input pulse waveform

complex-valued row or column vector

Input pulse waveform.

`y` — Second input pulse waveform

complex-valued row or column vector

Second input pulse waveform.

`Fs` — Sample rate

real positive scalar

Sampling rate in hertz.

`PRF` — Pulse repetition frequency

real positive scalar

Pulse repetition frequency in hertz.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Cut','Doppler','CutValue',10` specifies that a vector of ambiguity function values be produced at a Doppler shift of 10 Hz.

`'Cut'` — Direction of one-dimensional cut through ambiguity function

`'2D'` (default) | `'Delay'` | `'Doppler'`

Used to generate an ambiguity surface or one-dimensional cut through the ambiguity diagram. The value `'2D'` generates a surface plot of the two-dimensional ambiguity function. The direction of the one-dimensional cut is determined by setting the value of `'Cut'` to `'Delay'` or `'Doppler'`.

The choice of `'Delay'` generates a cut at zero time delay. In this case, the second output argument of `ambgfun`contains the ambiguity function values at Doppler shifted values. You can create a cut at nonzero time delay using the name-value pair `'CutValue'`.

The choice of `'Doppler'` generates a cut at zero Doppler shift. In this case, the second output argument of `ambgfun` contains the ambiguity function values at time-delayed values. You can create cut at nonzero Doppler using the name-value pair `'CutValue'`.

`'CutValue'` — Optional time delay or Doppler shift at which ambiguity function cut is taken

0 (default) | real-valued scalar

When setting the name-value pair `'Cut'` to `'Delay'` or `'Doppler'`, you can set `'CutValue'` to specify a cross-section that may not coincide with either zero time delay or zero Doppler shift. However, `'CutValue'` cannot be used when `'Cut'` is set to `'2D'`.

When `'Cut'` is set to `'Delay'` ,`'CutValue'` is the time delay at which the cut is taken. Time delay units are in seconds.

When `'Cut'` is set to `'Doppler'`, `'CutValue'` is the Doppler shift at which the cut is taken. Doppler units are in hertz.

Example: `'CutValue',10.0`

Data Types: `double`

Output Arguments

`afmag`

Normalized ambiguity or crossambiguity function magnitudes. `afmag` is an *M*-by-*N* matrix where *M* is the number of Doppler frequencies and *N* is the number of time delays.

`delay`

Time delay vector.

`delay` is an *N*-by-1 vector of time delays.

For the ambiguity function, if N_x is the length of signal `x`, then the delay vector consist of $N = 2N_x - 1$ samples in the range, $-(N_x/2) - 1,...,(N_x/2) - 1)$.

For the crossambiguity function, let N_y be the length of the second signal. The time delay vector consists of $N = N_x + N_y - 1$ equally spaced samples. For an even number of delays, the delay sample times are $-(N/2 - 1)/Fs,...,(N/2 - 1))/Fs$. For an odd number of delays, if $N_f = floor(N/2)$, the delay sample times are $-N_f/Fs,...,(N_f - 1)/Fs$.

`doppler`

Doppler frequency vector.

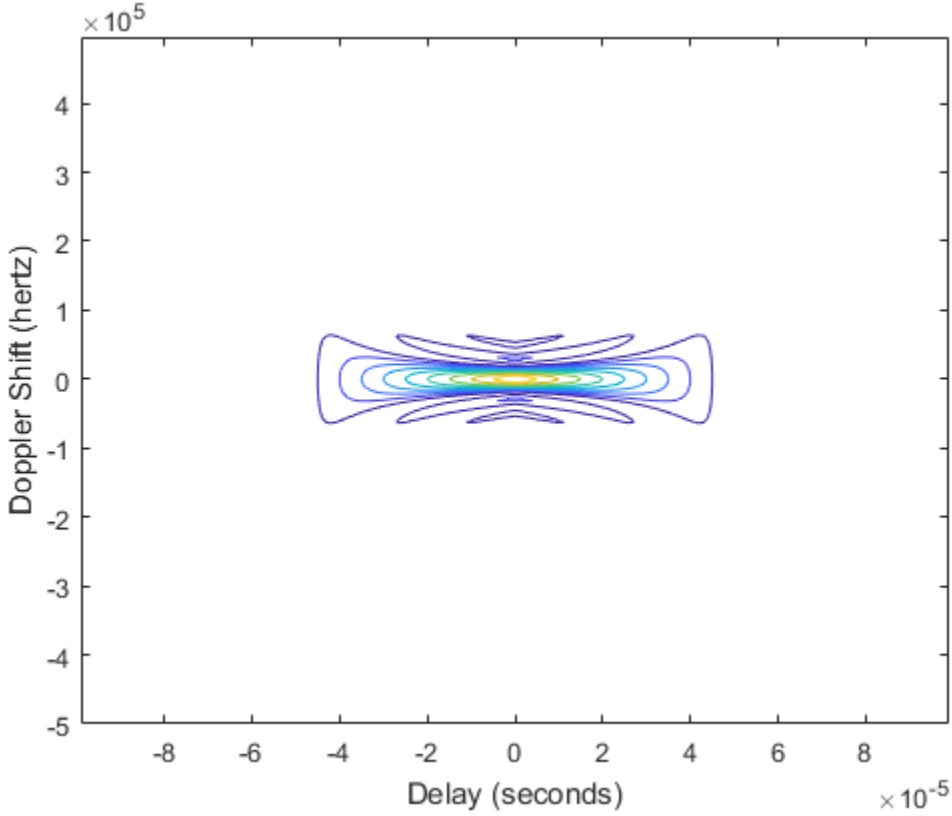
`doppler` is an *M*-by-1 vector of Doppler frequencies. The Doppler frequency vector consists of $M = 2^{ceil(log2\ N)}$ equally-spaced samples. Frequencies are $(-(M/2)F_s,...,(M/2 - 1)F_s)$.

Examples

Plot Ambiguity Function of Rectangular Pulse

Plot the ambiguity function magnitude of a rectangular pulse.

```
waveform = phased.RectangularWaveform;
x = waveform();
PRF = 2e4;
[afmag,delay,doppler] = ambgfun(x,waveform.SampleRate,PRF);
contour(delay,doppler,afmag)
xlabel('Delay (seconds)')
ylabel('Doppler Shift (hertz)')
```

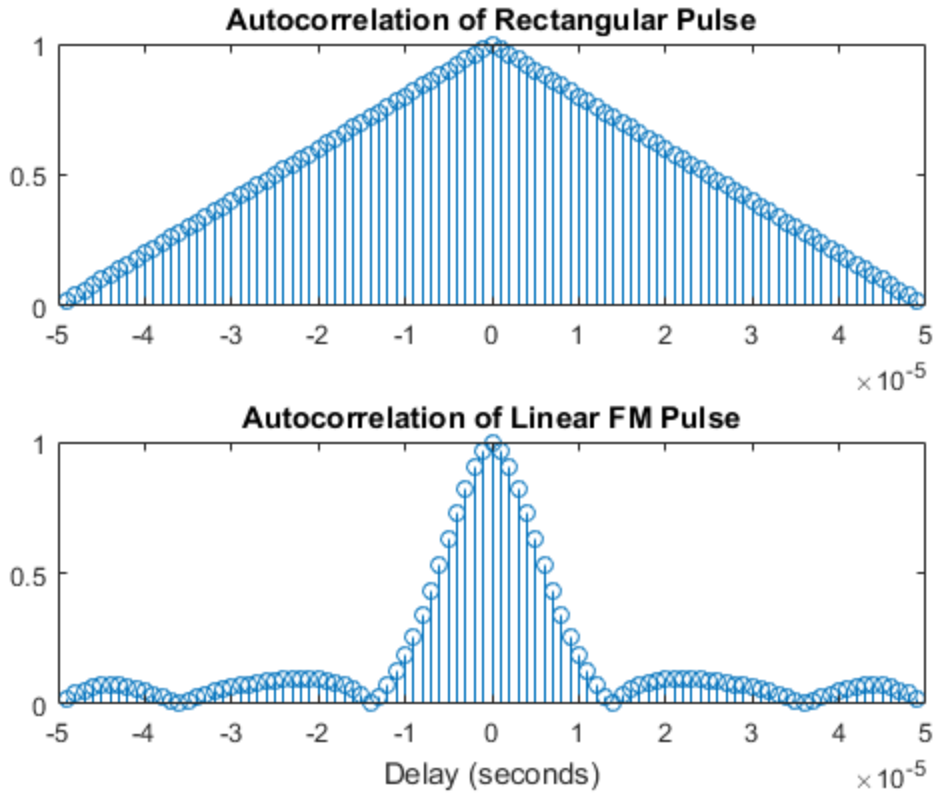


Plot Autocorrelation Sequences of Rectangular and Linear FM Pulses

This example shows how to plot zero-Doppler cuts of the autocorrelation sequences of rectangular and linear FM pulses of equal duration. Note the pulse compression exhibited in the autocorrelation sequence of the linear FM pulse.

```
hrect = phased.RectangularWaveform('PRF',2e4);
hfm = phased.LinearFMWaveform('PRF',2e4);
xrect = step(hrect);
xfm = step(hfm);
[ambrect,delayrect] = ambgfun(xrect,hrect.SampleRate,...,
    hrect.PRF,'Cut','Doppler');
[ambfm,delayfm] = ambgfun(xfm,hfm.SampleRate,...,
    hfm.PRF,'Cut','Doppler');
```

```
figure;
subplot(211);
stem(delayrect,ambrect);
title('Autocorrelation of Rectangular Pulse');
subplot(212);
stem(delayfm,ambfm)
xlabel('Delay (seconds)');
title('Autocorrelation of Linear FM Pulse');
```

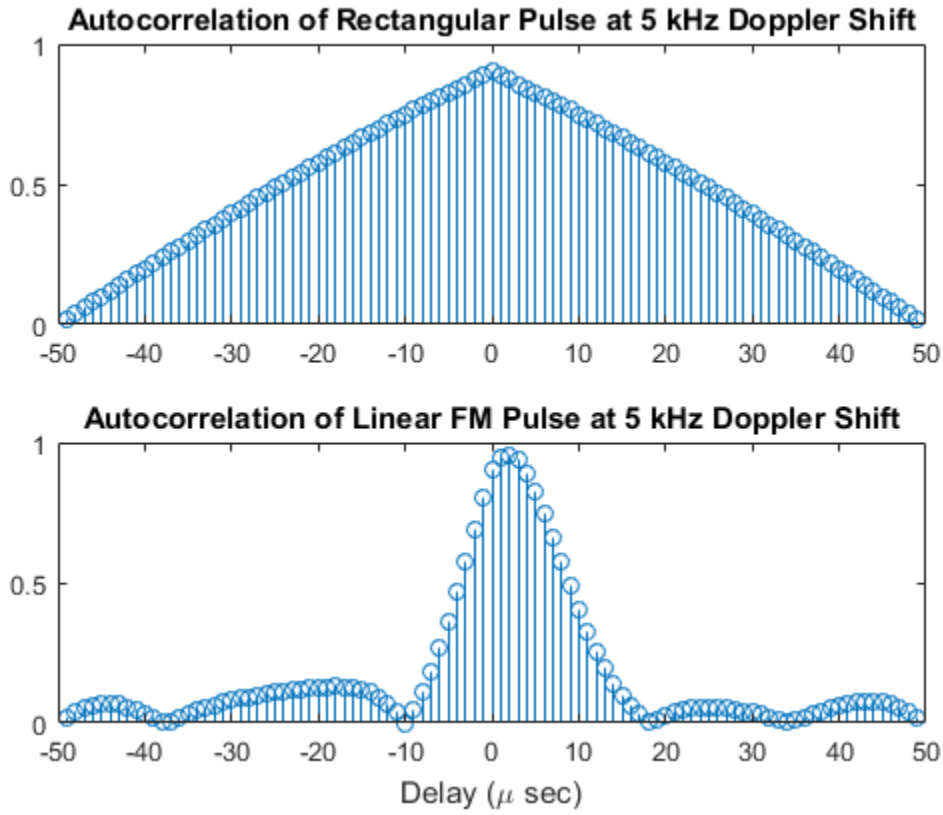


Plot Nonzero-Doppler Cuts of Autocorrelation Sequences

Plot nonzero-Doppler cuts of the autocorrelation sequences of rectangular and linear FM pulses of equal duration. Both cuts are taken at a 5 kHz Doppler shift. Besides the

reduction of the peak value, there is a strong shift in the position of the linear FM peak, evidence of range-doppler coupling.

```
hrect = phased.RectangularWaveform('PRF',2e4);
hfm = phased.LinearFMWaveform('PRF',2e4);
xrect = step(hrect);
xfm = step(hfm);
fd = 5000;
[ambrect,delayrect] = ambgfun(xrect,hrect.SampleRate,...,
    hrect.PRF,'Cut','Doppler','CutValue',fd);
[ambfm,delayfm] = ambgfun(xfm,hfm.SampleRate,...,
    hfm.PRF,'Cut','Doppler','CutValue',fd);
figure;
subplot(211);
stem(delayrect*10^6,ambrect);
title('Autocorrelation of Rectangular Pulse at 5 kHz Doppler Shift');
subplot(212);
stem(delayfm*10^6,ambfm)
xlabel('Delay (\mu sec)');
title('Autocorrelation of Linear FM Pulse at 5 kHz Doppler Shift');
```



Plot Crossambiguity Function

Plot the crossambiguity function between an LFM pulse and a delayed replica. Compare the crossambiguity function with the original ambiguity function. Set the sampling rate to 100 Hz, the pulse width to 0.5 sec, and the pulse repetition frequency to 1 Hz. The delay or lag is 10 samples equal to 100 ms. The bandwidth of the LFM signal is 10 Hz.

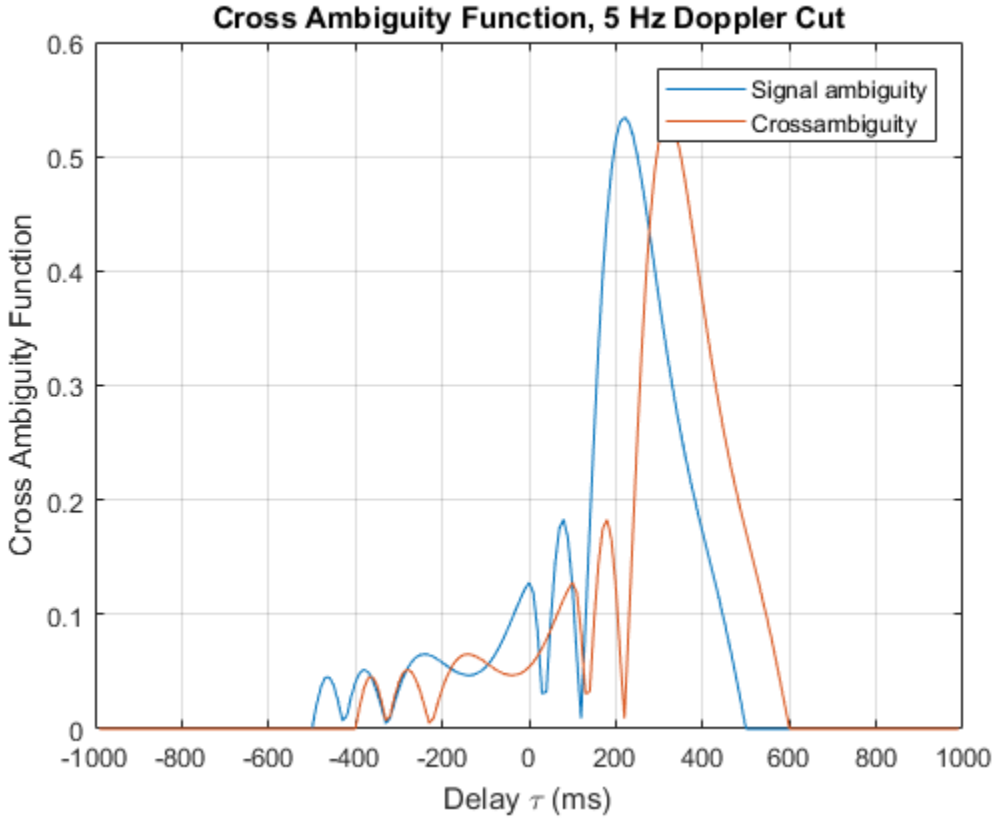
```
fs = 100.0;
bw1 = 10.0;
prf = 1;
nsamp = fs/prf;
pw = 0.5;
nlag = 10;
```

Create the original waveform and its delayed replica.

```
waveform1 = phased.LinearFMWaveform('SampleRate',fs,'PulseWidth',1,...
    'SweepBandwidth',bw1,'SweepDirection','Up','PulseWidth',pw,'PRF',prf);
wav1 = waveform1();
wav2 = [zeros(nlag,1);wav1(1:(end-nlag))];
```

Plot the ambiguity and crossambiguity functions.

```
ambgfun(wav1,fs,prf,'Cut','Doppler','CutVal',5)
hold on
ambgfun(wav1,wav2,fs,[prf,prf],'Cut','Doppler','CutVal',5)
legend('Signal ambiguity', 'Crossambiguity')
hold off
```



Definitions

Normalized Ambiguity Function

The normalized ambiguity function is

$$A(t,f_d) = \frac{1}{E_x} \left| \int_{-\infty}^{\infty} x(u) e^{j2\pi f_d u} x^*(u-t)\, du \right|$$

$$E_x = \int_{-\infty}^{\infty} x(u) x^*(u)\, du$$

where E_x is the squared norm of the signal, *x(t)*, *t* is the time delay, and f_d is the Doppler shift. The asterisk (*) denotes the complex conjugate. The ambiguity function describes the effects of time delays and Doppler shifts on the output of a matched filter.

The magnitude of the ambiguity function achieves maximum value at (0,0). At this point, there is perfect correspondence between the received waveform and the matched filter. The maximum value of the normalized ambiguity function is one.

The magnitude of the ambiguity function at zero time delay and Doppler shift, $|A(0,0)|$, is the matched filter output when the received waveform exhibits the time delay and Doppler shift for which the matched filter is designed. Nonzero values of the time delay and Doppler shift variables indicate that the received waveform exhibits mismatches in time delay and Doppler shift from the matched filter.

The crossambiguity function between two different signals is

$$A(t,f_d) = \frac{1}{\sqrt{E_x E_y}} \left| \int_{-\infty}^{\infty} x(u) e^{j2\pi f_d u} y^*(u-t)\, du \right|$$

$$E_x = \int_{-\infty}^{\infty} x(u) x^*(u)\, du$$

$$E_x = \int_{-\infty}^{\infty} y(u) y^*(u)\, du$$

The peak of the crossambiguity function is not necessarily unity.

aperture2gain

Convert effective aperture to gain

Syntax

```
G = aperture2gain(A,lambda)
```

Description

`G = aperture2gain(A,lambda)` returns the antenna gain in decibels corresponding to an effective aperture of `A` square meters for an incident electromagnetic wave with wavelength `lambda` meters. `A` can be a scalar or vector. If `A` is a vector, `G` is a vector of the same size as `A`. The elements of `G` represent the gains for the corresponding elements of `A`. `lambda` must be a scalar.

Input Arguments

`A`

Antenna effective aperture in square meters. The effective aperture describes how much energy is captured from an incident electromagnetic plane wave. The argument describes the functional area of the antenna and is not equivalent to the actual physical area. For a fixed wavelength, the antenna gain is proportional to the effective aperture. `A` can be a scalar or vector. If `A` is a vector, each element of `A` is the effective aperture of a single antenna.

`lambda`

Wavelength of the incident electromagnetic wave. The wavelength of an electromagnetic wave is the ratio of the wave propagation speed to the frequency. For a fixed effective aperture, the antenna gain is inversely proportional to the square of the wavelength. `lambda` must be a scalar.

Output Arguments

G

Antenna gain in decibels. G is a scalar or a vector. If G is a vector, each element of G is the gain corresponding to effective aperture of the same element in A.

Examples

Compute Antenna Gain

An antenna has an effective aperture of 3 square meters. Find the antenna gain when used to capture an electromagnetic wave with a wavelength of 10 cm.

```
g = aperture2gain(3,0.1)
```

```
g =

   35.7633
```

Definitions

Gain and Effective Aperture

The relationship between the gain, G, and effective aperture of an antenna, A_e is:

$$G = \frac{4\pi}{\lambda^2} A_e$$

where λ is the wavelength of the incident electromagnetic wave. The gain expressed in decibels is:

$$10\log_{10}(G)$$

`gain2aperture`

Introduced in R2011a

az2broadside

Convert azimuth and elevation angle to broadside angle

Syntax

```
bsang = az2broadside(az)
bsang = az2broadside(az,el)
```

Description

`bsang = az2broadside(az)` returns the broadside angle `bsang` corresponding to the azimuth angle, `az`, and zero elevation angle. All angles are in the local coordinate system.

`bsang = az2broadside(az,el)` in addition, specifies the elevation angle, `el`.

Examples

Convert Azimuth Angle to Broadside Angle

Return the broadside angle corresponding to 45° azimuth and 0° elevation.

```
bsang = az2broadside(45)
```

```
bsang =

   45.0000
```

Convert Azimuth and Elevation to Broadside Angle

Return the broadside angle corresponding to 45° azimuth and 45° elevation.

```
bsang = az2broadside(45,45)
```

```
bsang =

   30.0000
```

Convert Multiple Azimuth and Elevation Angles to Broadside Angles

Return broadside angles for 10 azimuth-elevation pairs.

```
az = (75:5:120)';
el = (45:5:90)';
bsang = az2broadside(az,el);
```

Input Arguments

`az` — Azimuth angle

scalar | vector

Azimuth angle, specified as a scalar or vector. The azimuth angle must be within *[–180 ,180]*. Units are in degrees.

Example: `[35;20;-10]`

`el` — Elevation angle

`0` (default) | scalar | vector

Elevation angle, specified as a scalar or vector. The elevation angle must be within *[–90 ,90]*. The dimension of `el` must match the dimensions of `az`. Units are in degrees.

Example: `[5;2;-1]`

Output Arguments

`bsang` — Broadside angle

scalar | vector

Broadside angle, returned as a scalar or vector. The dimension of `bsang` are the same as the dimensions of `az`. Units are in degrees.

Definitions

Broadside Angle

Broadside angles are useful in describing the response pattern of a uniform linear array (ULA).

For the definition of the broadside angle and how to convert between azimuth and elevation, and broadside angle see “Broadside Angles”. For definitions of the azimuth and elevation angles, see “Azimuth and Elevation Angles”.

`azel2phitheta` | `azel2uv` | `broadside2az`

Introduced in R2011a

azel2phitheta

Convert angles from azimuth/elevation form to phi/theta form

Syntax

```
PhiTheta = azel2phitheta(AzEl)
```

Description

`PhiTheta = azel2phitheta(AzEl)` converts the azimuth/elevation angle pairs to their corresponding phi/theta angle pairs.

Examples

Convert Azimuth-Elevation Pair

Find the corresponding φ/θ representation for 30° azimuth and 0° elevation.

```
PhiTheta = azel2phitheta([30; 0])
```

```
PhiTheta =

         0
   30.0000
```

Input Arguments

`AzEl` — Azimuth/elevation angle pairs

two-row matrix

Azimuth and elevation angles, specified as a two-row matrix. Each column of the matrix represents an angle in degrees, in the form [azimuth; elevation].

Data Types: `double`

Output Arguments

`PhiTheta` — Phi/theta angle pairs
two-row matrix

Phi and theta angles, returned as a two-row matrix. Each column of the matrix represents an angle in degrees, in the form [phi; theta]. The matrix dimensions of `PhiTheta` are the same as those of `AzEl`.

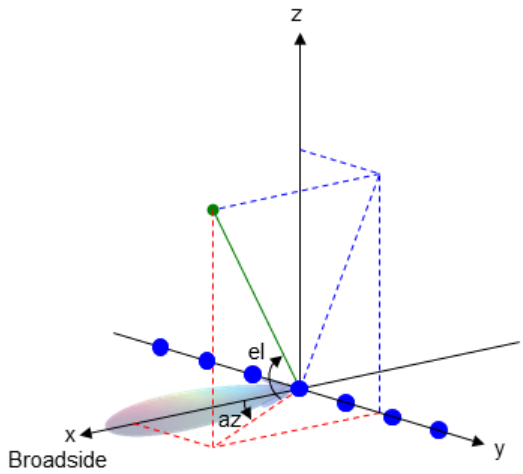
Definitions

Azimuth Angle, Elevation Angle

The *azimuth angle* of a vector is the angle between the x-axis and the orthogonal projection of the vector onto the xy plane. The angle is positive in going from the x axis toward the y axis. Azimuth angles lie between –180 and 180 degrees. The *elevation angle* is the angle between the vector and its orthogonal projection onto the xy-plane. The angle is positive when going toward the positive z-axis from the xy plane. These definitions assume the boresight direction is the positive x-axis.

Note: The elevation angle is sometimes defined in the literature as the angle a vector makes with the positive z-axis. The MATLAB and Phased Array System Toolbox products do not use this definition.

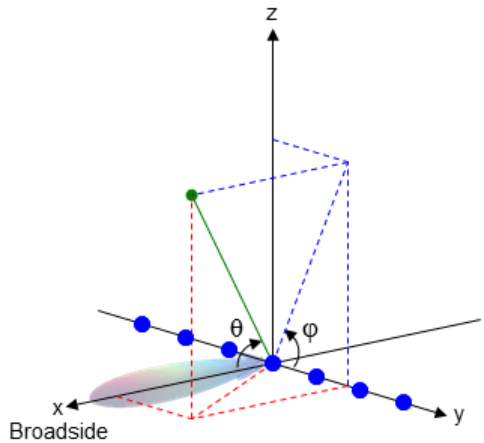
This figure illustrates the azimuth angle and elevation angle for a vector that appears as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue circles.



Phi Angle, Theta Angle

The φ angle is the angle from the positive *y*-axis toward the positive *z*-axis, to the vector's orthogonal projection onto the *yz* plane. The φ angle is between 0 and 360 degrees. The θ angle is the angle from the *x*-axis toward the *yz* plane, to the vector itself. The θ angle is between 0 and 180 degrees.

The figure illustrates φ and θ for a vector that appears as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue circles.



The coordinate transformations between φ/θ and *az*/*el* are described by the following equations

$$\sin(\text{el}) = \sin\phi\sin\theta$$
$$\tan(\text{az}) = \cos\phi\tan\theta$$

$$\cos\theta = \cos(\text{el})\cos(\text{az})$$
$$\tan\phi = \tan(\text{el}) / \sin(\text{az})$$

Extended Capabilities

phitheta2azel

Topics

"Spherical Coordinates"

Introduced in R2012a

azel2phithetapat

Convert radiation pattern from azimuth/elevation to phi/theta form

Syntax

```
pat_phitheta = azel2phithetapat(pat_azel,az,el)
pat_phitheta = azel2phithetapat(pat_azel,az,el,phi,theta)
[pat_phitheta,phi,theta] = azel2phithetapat( ___ )
```

Description

`pat_phitheta = azel2phithetapat(pat_azel,az,el)` expresses the antenna radiation pattern `pat_azel` in φ/θ angle coordinates instead of azimuth/elevation angle coordinates. `pat_azel` samples the pattern at azimuth angles in `az` and elevation angles in `el`. The `pat_phitheta` matrix covers φ values from 0 to 180 degrees and θ values from 0 to 360 degrees. `pat_phitheta` is uniformly sampled with a step size of 1 for φ and θ. The function interpolates to estimate the response of the antenna at a given direction.

`pat_phitheta = azel2phithetapat(pat_azel,az,el,phi,theta)` uses vectors `phi` and `theta` to specify the grid at which to sample `pat_phitheta`. To avoid interpolation errors, `phi` should cover the range [0, 180], and `theta` should cover the range [0, 360].

`[pat_phitheta,phi,theta] = azel2phithetapat( ___ )` returns vectors containing the φ and θ angles at which `pat_phitheta` samples the pattern, using any of the input arguments in the previous syntaxes.

Examples

Convert Radiation Pattern to Phi-Theta

Convert a radiation pattern to φ/θ form, with the φ and θ angles spaced 1 degree apart.

Define the pattern in terms of azimuth and elevation.

```
az = -180:180;
el = -90:90;
pat_azel = mag2db(repmat(cosd(el)',1,numel(az)));
```

Convert the pattern to φ/θ space.

```
pat_phitheta = azel2phithetapat(pat_azel,az,el);
```

Plot Converted Radiation Pattern

Plot the result of converting a radiation pattern to ϕ/θ space with the ϕ and θ angles spaced 1 degree apart.

The radiation pattern is the cosine of the elevation.

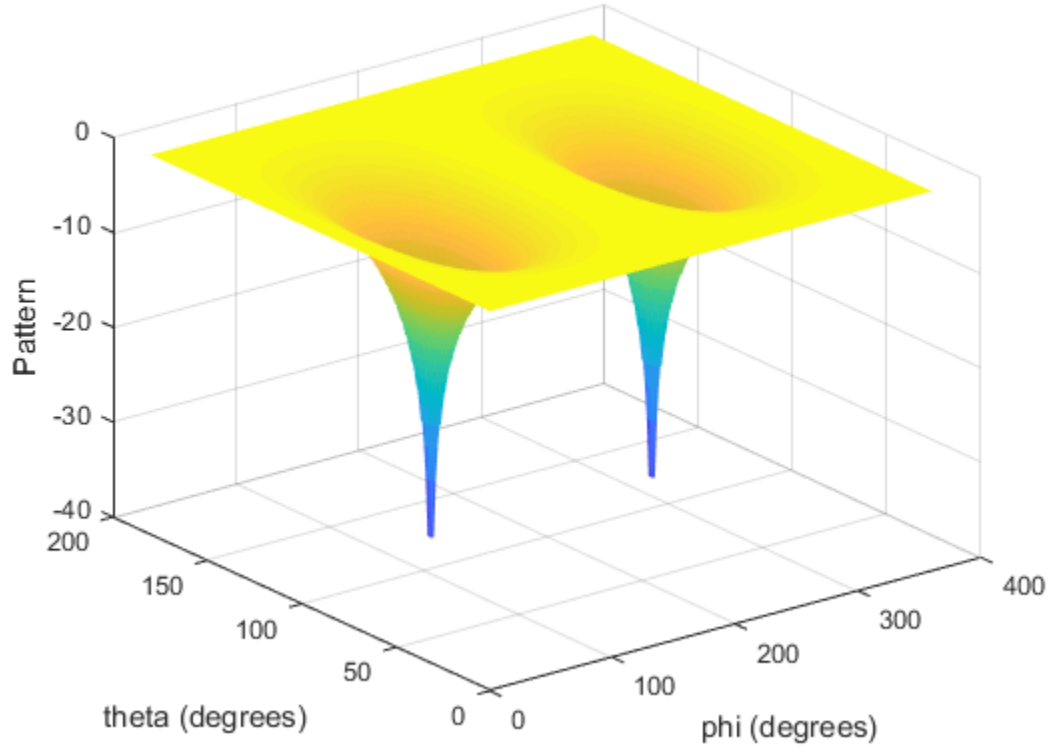
```
az = -180:180;
el = -90:90;
pat_azel = repmat(cosd(el)',1,numel(az));
```

Convert the pattern to ϕ/θ space. Use the returned ϕ and θ angles for plotting.

```
[pat_phitheta,phi,theta] = azel2phithetapat(pat_azel,az,el);
```

Plot the result.

```
H = surf(phi,theta,mag2db(pat_phitheta));
H.LineStyle = 'none';
xlabel('phi (degrees)');
ylabel('theta (degrees)');
zlabel('Pattern');
```



Convert Radiation Pattern For Specific Phi/Theta Values

Convert a radiation pattern to ϕ/θ space with ϕ and θ angles spaced 5 degrees apart.

The radiation pattern is the cosine of the elevation.

```
az = -180:180;
el = -90:90;
pat_azel = repmat(cosd(el)',1,numel(az));
```

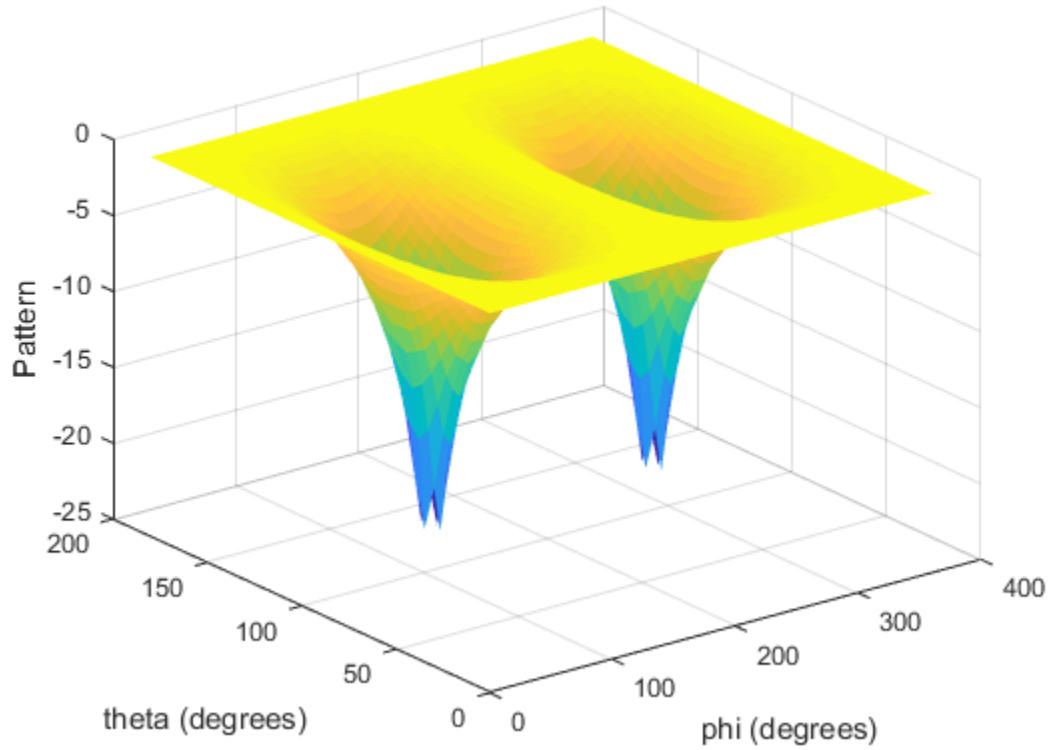
Define the set of ϕ and θ angles at which to sample the pattern. Then, convert the pattern.

```
phi = 0:5:360;
```

```
theta = 0:5:180;
pat_phitheta = azel2phithetapat(pat_azel,az,el,phi,theta);
```

Plot the result.

```
H = surf(phi,theta,mag2db(pat_phitheta));
H.LineStyle = 'none';
xlabel('phi (degrees)');
ylabel('theta (degrees)');
zlabel('Pattern');
```



Input Arguments

`pat_azel` — Antenna radiation pattern in azimuth/elevation form

Q-by-P matrix

Antenna radiation pattern in azimuth/elevation form, specified as a Q-by-P matrix. `pat_azel` samples the 3-D magnitude pattern in decibels, in terms of azimuth and elevation angles. P is the length of the `az` vector, and Q is the length of the `el` vector.

Data Types: `double`

`az` — Azimuth angles
vector of length P

Azimuth angles at which `pat_azel` samples the pattern, specified as a vector of length P. Each azimuth angle is in degrees, between –180 and 180.

Data Types: `double`

`el` — Elevation angles
vector of length Q

Elevation angles at which `pat_azel` samples the pattern, specified as a vector of length Q. Each elevation angle is in degrees, between –90 and 90.

Data Types: `double`

`phi` — Phi angles
`[0:360]` (default) | vector of length L

Phi angles at which `pat_phitheta` samples the pattern, specified as a vector of length L. Each φ angle is in degrees, between 0 and 360.

Data Types: `double`

`theta` — Theta angles
`[0:180]` (default) | vector of length M

Theta angles at which `pat_phitheta` samples the pattern, specified as a vector of length M. Each θ angle is in degrees, between 0 and 180.

Data Types: `double`

Output Arguments

`pat_phitheta` — Antenna radiation pattern in phi/theta form
M-by-L matrix

Antenna radiation pattern in phi/theta form, returned as an M-by-L matrix. `pat_phitheta` samples the 3-D magnitude pattern in decibels, in terms of φ and θ angles. L is the length of the `phi` vector, and M is the length of the `theta` vector.

`phi` — Phi angles
vector of length L

Phi angles at which `pat_phitheta` samples the pattern, returned as a vector of length L. Angles are expressed in degrees.

`theta` — Theta angles
vector of length M

Theta angles at which `pat_phitheta` samples the pattern, returned as a vector of length M. Angles are expressed in degrees.

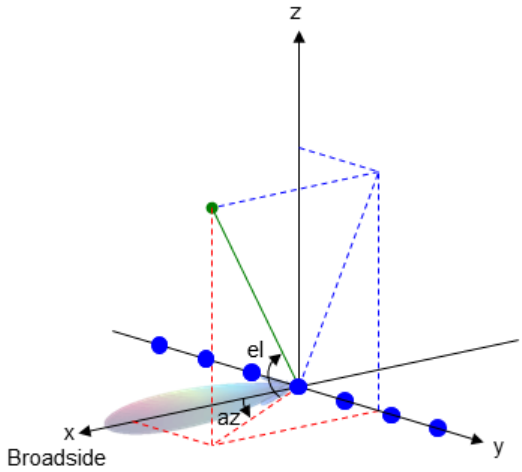
Definitions

Azimuth Angle, Elevation Angle

The *azimuth angle* of a vector is the angle between the *x*-axis and the orthogonal projection of the vector onto the *xy* plane. The angle is positive in going from the *x* axis toward the *y* axis. Azimuth angles lie between –180 and 180 degrees. The *elevation angle* is the angle between the vector and its orthogonal projection onto the *xy*-plane. The angle is positive when going toward the positive *z*-axis from the *xy* plane. These definitions assume the boresight direction is the positive *x*-axis.

Note: The elevation angle is sometimes defined in the literature as the angle a vector makes with the positive *z*-axis. The MATLAB and Phased Array System Toolbox products do not use this definition.

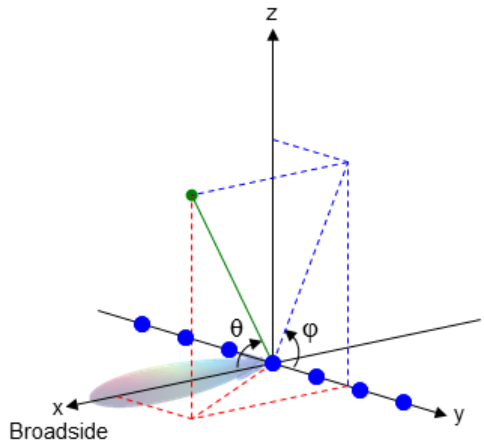
This figure illustrates the azimuth angle and elevation angle for a vector that appears as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue circles.



Phi Angle, Theta Angle

The φ angle is the angle from the positive *y*-axis toward the positive *z*-axis, to the vector's orthogonal projection onto the *yz* plane. The φ angle is between 0 and 360 degrees. The θ angle is the angle from the *x*-axis toward the *yz* plane, to the vector itself. The θ angle is between 0 and 180 degrees.

The figure illustrates φ and θ for a vector that appears as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue circles.



The coordinate transformations between φ/θ and *az*/*el* are described by the following equations

$$\sin(\mathrm{el}) = \sin\phi\sin\theta$$
$$\tan(\mathrm{az}) = \cos\phi\tan\theta$$

$$\cos\theta = \cos(\mathrm{el})\cos(\mathrm{az})$$
$$\tan\phi = \tan(\mathrm{el}) / \sin(\mathrm{az})$$

Topics

"Spherical Coordinates"

Introduced in R2012a

azel2uv

Convert azimuth/elevation angles to u/v coordinates

Syntax

```
UV = azel2uv(AzEl)
```

Description

`UV = azel2uv(AzEl)` converts the azimuth/elevation angle pairs to their corresponding coordinates in *u*/*v* space.

Examples

Conversion of Azimuth and Elevation to UV

Find the corresponding *uv* representation for 30° azimuth and 0° elevation.

```
uv = azel2uv([30;0])
```

```
uv =

    0.5000
         0
```

Input Arguments

`AzEl` — Azimuth/elevation angle pairs

two-row matrix

Azimuth and elevation angles, specified as a two-row matrix. Each column of the matrix represents an angle in degrees, in the form [azimuth; elevation].

Data Types: `double`

Output Arguments

UV — Angle in u/v space

two-row matrix

Angle in *u*/*v* space, returned as a two-row matrix. Each column of the matrix represents an angle in the form [*u*; *v*]. The matrix dimensions of `UV` are the same as those of `AzEl`.

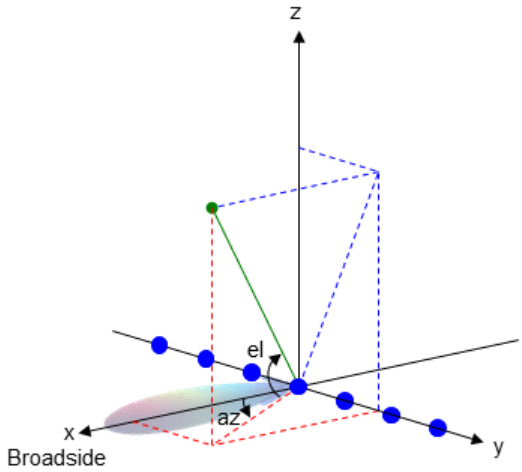
Definitions

Azimuth Angle, Elevation Angle

The *azimuth angle* of a vector is the angle between the *x*-axis and the orthogonal projection of the vector onto the *xy* plane. The angle is positive in going from the *x* axis toward the *y* axis. Azimuth angles lie between –180 and 180 degrees. The *elevation angle* is the angle between the vector and its orthogonal projection onto the *xy*-plane. The angle is positive when going toward the positive *z*-axis from the *xy* plane. These definitions assume the boresight direction is the positive *x*-axis.

Note: The elevation angle is sometimes defined in the literature as the angle a vector makes with the positive *z*-axis. The MATLAB and Phased Array System Toolbox products do not use this definition.

This figure illustrates the azimuth angle and elevation angle for a vector that appears as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue circles.



U/V Space

The u/v coordinates for the positive hemisphere $x \geq 0$ can be derived from the phi and theta angles.

The relation between these two coordinates systems is

$$u = \sin\theta\cos\phi$$
$$v = \sin\theta\sin\phi$$

In these expressions, φ and θ are the phi and theta angles, respectively.

In terms of azimuth and elevation, the u and v coordinates are

$$u = \cos el \sin az$$
$$v = \sin el$$

The values of u and v satisfy the inequalities

$$-1 \leq u \leq 1$$
$$-1 \leq v \leq 1$$
$$u^2 + v^2 \leq 1$$

Conversely, the phi and theta angles can be written in terms of u and v using

$$\tan\phi = u / v$$
$$\sin\theta = \sqrt{u^2 + v^2}$$

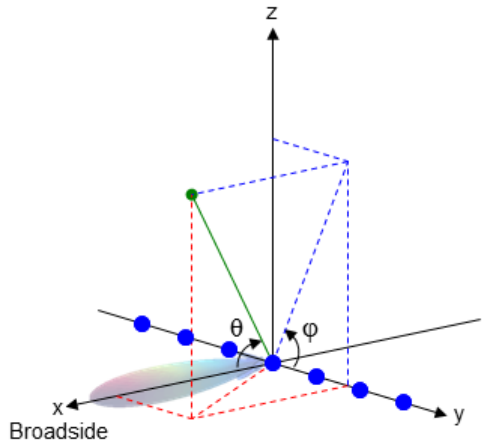
The azimuth and elevation angles can also be written in terms of u and v

$$\sin el = v$$
$$\tan az = \frac{u}{\sqrt{1 - u^2 - v^2}}$$

Phi Angle, Theta Angle

The φ angle is the angle from the positive y-axis toward the positive z-axis, to the vector's orthogonal projection onto the yz plane. The φ angle is between 0 and 360 degrees. The θ angle is the angle from the x-axis toward the yz plane, to the vector itself. The θ angle is between 0 and 180 degrees.

The figure illustrates φ and θ for a vector that appears as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue circles.



The coordinate transformations between φ/θ and *az*/*el* are described by the following equations

$$\sin(\mathrm{el}) = \sin\phi\sin\theta$$
$$\tan(\mathrm{az}) = \cos\phi\tan\theta$$

$$\cos\theta = \cos(\mathrm{el})\cos(\mathrm{az})$$
$$\tan\phi = \tan(\mathrm{el}) / \sin(\mathrm{az})$$

`uv2azel`

Topics

"Spherical Coordinates"

Introduced in R2012a

azel2uvpat

Convert radiation pattern from azimuth/elevation form to u/v form

Syntax

```
pat_uv = azel2uvpat(pat_azel,az,el)
pat_uv = azel2uvpat(pat_azel,az,el,u,v)
[pat_uv,u,v] = azel2uvpat( ___ )
```

Description

`pat_uv = azel2uvpat(pat_azel,az,el)` expresses the antenna radiation pattern `pat_azel` in u/v space coordinates instead of azimuth/elevation angle coordinates. `pat_azel` samples the pattern at azimuth angles in `az` and elevation angles in `el`. The `pat_uv` matrix uses a default grid that covers u values from –1 to 1 and v values from –1 to 1. In this grid, `pat_uv` is uniformly sampled with a step size of 0.01 for u and v. The function interpolates to estimate the response of the antenna at a given direction. Values in `pat_uv` are NaN for u and v values outside the unit circle because u and v are undefined outside the unit circle.

`pat_uv = azel2uvpat(pat_azel,az,el,u,v)` uses vectors `u` and `v` to specify the grid at which to sample `pat_uv`. To avoid interpolation errors, `u` should cover the range [–1, 1] and `v` should cover the range [–1, 1].

`[pat_uv,u,v] = azel2uvpat( ___ )` returns vectors containing the u and v coordinates at which `pat_uv` samples the pattern, using any of the input arguments in the previous syntaxes.

Examples

Convert Radiation Pattern to UV Space

Convert a radiation pattern to u-v space, with the u and v coordinates spaced by 0.01.

Define the pattern in terms of azimuth and elevation.

```
az = -90:90;
el = -90:90;
pat_azel = mag2db(repmat(cosd(el)',1,numel(az)));
```

Convert the pattern to u-v space.

```
pat_uv = azel2uvpat(pat_azel,az,el);
```

Plot Converted Radiation Pattern

Plot the result of converting a radiation pattern to u/v space with the u and v coordinates spaced by 0.01.

The radiation pattern is the cosine of the elevation angle.

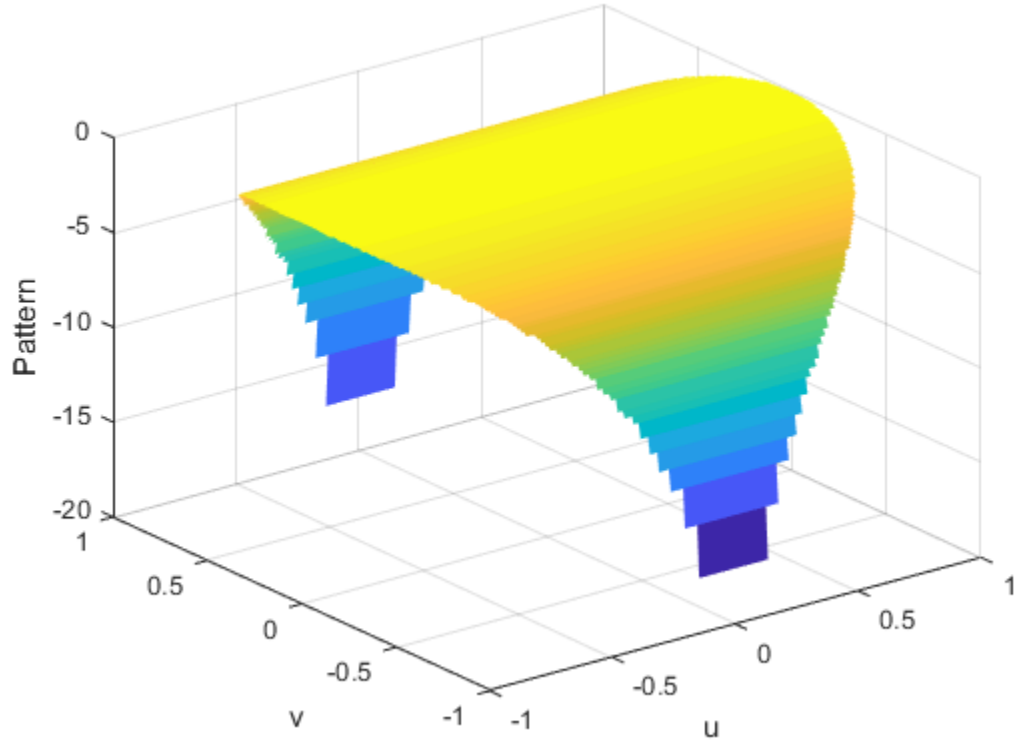
```
az = -90:90;
el = -90:90;
pat_azel = repmat(cosd(el)',1,numel(az));
```

Convert the pattern to u/v space. Use the u and v coordinates for plotting.

```
[pat_uv,u,v] = azel2uvpat(pat_azel,az,el);
```

Plot the result.

```
H = surf(u,v,mag2db(pat_uv));
H.LineStyle = 'none';
xlabel('u');
ylabel('v');
zlabel('Pattern');
```



Convert Radiation Pattern For Specific U/V Values

Convert a radiation pattern to u/v form, with the u and v coordinates spaced by 0.05.

The radiation pattern is cosine of the elevation angle.

```
az = -90:90;
el = -90:90;
pat_azel = repmat(cosd(el)',1,numel(az));
```

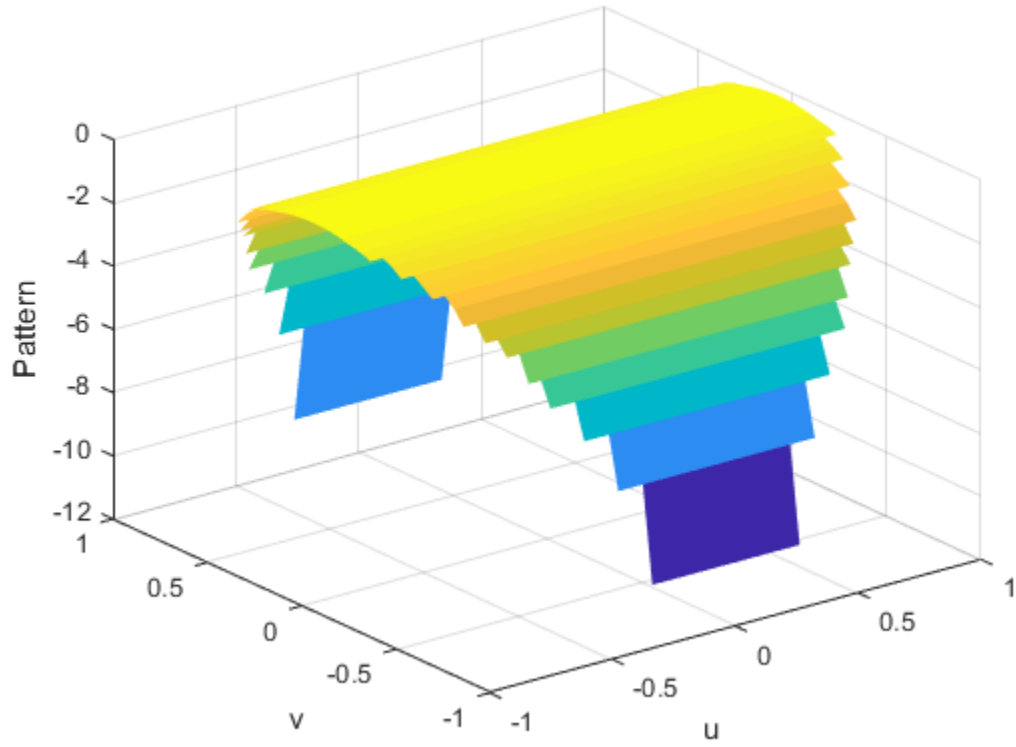
Define the set of u and v coordinates at which to sample the pattern. Then, convert the pattern.

```
u = -1:0.05:1;
```

```
v = -1:0.05:1;
pat_uv = azel2uvpat(pat_azel,az,el,u,v);
```

Plot the result.

```
H = surf(u,v,mag2db(pat_uv));
H.LineStyle = 'none';
xlabel('u');
ylabel('v');
zlabel('Pattern');
```



Input Arguments

`pat_azel` — Antenna radiation pattern in azimuth/elevation form

Q-by-P matrix

Antenna radiation pattern in azimuth/elevation form, specified as a Q-by-P matrix. `pat_azel` samples the 3-D magnitude pattern in decibels, in terms of azimuth and elevation angles. P is the length of the `az` vector, and Q is the length of the `el` vector.

Data Types: `double`

az — Azimuth angles

vector of length P

Azimuth angles at which `pat_azel` samples the pattern, specified as a vector of length P. Each azimuth angle is in degrees, between –90 and 90. Such azimuth angles are in the hemisphere for which *u* and *v* are defined.

Data Types: `double`

el — Elevation angles

vector of length Q

Elevation angles at which `pat_azel` samples the pattern, specified as a vector of length Q. Each elevation angle is in degrees, between –90 and 90.

Data Types: `double`

u — *u* coordinates

`[-1:0.01:1]` (default) | vector of length L

u coordinates at which `pat_uv` samples the pattern, specified as a vector of length L. Each *u* coordinate is between –1 and 1.

Data Types: `double`

v — *v* coordinates

`[-1:0.01:1]` (default) | vector of length M

v coordinates at which `pat_uv` samples the pattern, specified as a vector of length M. Each *v* coordinate is between –1 and 1.

Data Types: `double`

Output Arguments

pat_uv — Antenna radiation pattern in *u*/*v* form

M-by-L matrix

Antenna radiation pattern in *u*/*v* form, returned as an M-by-L matrix. `pat_uv` samples the 3-D magnitude pattern in decibels, in terms of *u* and *v* coordinates. L is the length of the `u` vector, and M is the length of the `v` vector. Values in `pat_uv` are NaN for *u* and *v* values outside the unit circle because *u* and *v* are undefined outside the unit circle.

u — *u* coordinates
vector of length L

u coordinates at which `pat_uv` samples the pattern, returned as a vector of length L.

v — *v* coordinates
vector of length M

v coordinates at which `pat_uv` samples the pattern, returned as a vector of length M.

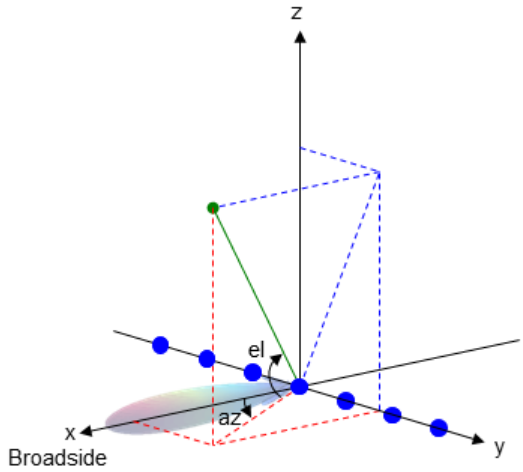
Definitions

Azimuth Angle, Elevation Angle

The *azimuth angle* of a vector is the angle between the *x*-axis and the orthogonal projection of the vector onto the *xy* plane. The angle is positive in going from the *x* axis toward the *y* axis. Azimuth angles lie between –180 and 180 degrees. The *elevation angle* is the angle between the vector and its orthogonal projection onto the *xy*-plane. The angle is positive when going toward the positive *z*-axis from the *xy* plane. These definitions assume the boresight direction is the positive *x*-axis.

Note: The elevation angle is sometimes defined in the literature as the angle a vector makes with the positive *z*-axis. The MATLAB and Phased Array System Toolbox products do not use this definition.

This figure illustrates the azimuth angle and elevation angle for a vector that appears as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue circles.



U/V Space

The u and v coordinates are the direction cosines of a vector with respect to the y-axis and z-axis, respectively.

The u/v coordinates for the hemisphere $x \geq 0$ are derived from the phi and theta angles by:

$$u = \sin\theta\cos\phi$$
$$v = \sin\theta\sin\phi$$

In these expressions, φ and θ are the phi and theta angles, respectively.

In terms of azimuth and elevation, the u and v coordinates are

$$u = \cos el \sin az$$
$$v = \sin el$$

The values of u and v satisfy the inequalities

$$-1 \leq u \leq 1$$
$$-1 \leq v \leq 1$$
$$u^2 + v^2 \leq 1$$

Conversely, the phi and theta angles can be written in terms of u and v using

$$\tan\phi = u / v$$
$$\sin\theta = \sqrt{u^2 + v^2}$$

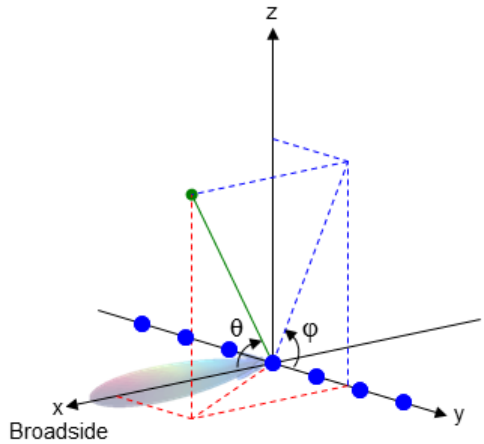
The azimuth and elevation angles can also be written in terms of u and v

$$\sin el = v$$
$$\tan az = \frac{u}{\sqrt{1 - u^2 - v^2}}$$

Phi Angle, Theta Angle

The φ angle is the angle from the positive y-axis toward the positive z-axis, to the vector's orthogonal projection onto the yz plane. The φ angle is between 0 and 360 degrees. The θ angle is the angle from the x-axis toward the yz plane, to the vector itself. The θ angle is between 0 and 180 degrees.

The figure illustrates φ and θ for a vector that appears as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue circles.



The coordinate transformations between φ/θ and *az*/*el* are described by the following equations

$$\sin(\text{el}) = \sin\phi\sin\theta$$
$$\tan(\text{az}) = \cos\phi\tan\theta$$

$$\cos\theta = \cos(\text{el})\cos(\text{az})$$
$$\tan\phi = \tan(\text{el}) / \sin(\text{az})$$

Topics

"Spherical Coordinates"

Introduced in R2012a

azelaxes

Spherical basis vectors in 3-by-3 matrix form

Syntax

```
A = azelaxes(az,el)
```

Description

`A = azelaxes(az,el)` returns a 3-by-3 matrix containing the components of the basis $(\mathbf{e}_R, \mathbf{e}_{az}, \mathbf{e}_{el})$ at each point on the unit sphere specified by azimuth, `az`, and elevation, `el`. The columns of `A` contain the components of basis vectors in the order of radial, azimuthal and elevation directions.

Examples

Compute Spherical Basis Vectors

At the point located at 45° azimuth, 45° elevation, compute the 3-by-3 matrix containing the components of the spherical basis.

```
A = azelaxes(45,45)
```

```
A =

    0.5000   -0.7071   -0.5000
    0.5000    0.7071   -0.5000
    0.7071         0    0.7071
```

The first column of A contains the radial basis vector `[0.5000; 0.5000; 0.7071]`. The second and third columns are the azimuth and elevation basis vectors, respectively.

Input Arguments

az — Azimuth angle

scalar in range [–180,180]

Azimuth angle specified as a scalar in the closed range [–180,180]. Angle units are in degrees. To define the azimuth angle of a point on a sphere, construct a vector from the origin to the point. The azimuth angle is the angle in the *xy*-plane from the positive *x*-axis to the vector's orthogonal projection into the *xy*-plane. As examples, zero azimuth angle and zero elevation angle specify a point on the *x*-axis while an azimuth angle of 90° and an elevation angle of zero specify a point on the *y*-axis.

Example: `45`

Data Types: `double`

el — Elevation angle

scalar in range [–90,90]

Elevation angle specified as a scalar in the closed range [–90,90]. Angle units are in degrees. To define the elevation of a point on the sphere, construct a vector from the origin to the point. The elevation angle is the angle from its orthogonal projection into the *xy*-plane to the vector itself. As examples, zero elevation angle defines the equator of the sphere and ±90° elevation define the north and south poles, respectively.

Example: `30`

Data Types: `double`

Output Arguments

A — Spherical basis vectors

3-by-3 matrix

Spherical basis vectors returned as a 3-by-3 matrix. The columns contain the unit vectors in the radial, azimuthal, and elevation directions, respectively. Symbolically we can write the matrix as

$(\mathbf{e}_R, \mathbf{e}_{az}, \mathbf{e}_{el})$

where each component represents a column vector.

Definitions

Spherical basis

Spherical basis vectors are a local set of basis vectors which point along the radial and angular directions at any point in space.

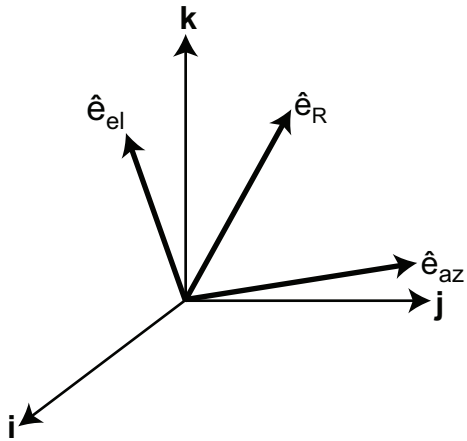
The spherical basis vectors $(\mathbf{e}_R, \mathbf{e}_{az}, \mathbf{e}_{el})$ at the point *(az,el)* can be expressed in terms of the Cartesian unit vectors by

$$\begin{aligned}
\hat{\mathbf{e}}_{\mathbf{R}} &= \cos(el)\cos(az)\hat{\mathbf{i}} + \cos(el)\sin(az)\hat{\mathbf{j}} + \sin(el)\hat{\mathbf{k}} \\
\hat{\mathbf{e}}_{\mathbf{az}} &= -\sin(az)\hat{\mathbf{i}} + \cos(az)\hat{\mathbf{j}} \\
\hat{\mathbf{e}}_{\mathbf{el}} &= -\sin(el)\cos(az)\hat{\mathbf{i}} - \sin(el)\sin(az)\hat{\mathbf{j}} + \cos(el)\hat{\mathbf{k}}
\end{aligned} .$$

This set of basis vectors can be derived from the local Cartesian basis by two consecutive rotations: first by rotating the Cartesian vectors around the *y*-axis by the negative elevation angle, *-el*, followed by a rotation around the *z*-axis by the azimuth angle, *az*. Symbolically, we can write

$$\begin{aligned}
\hat{\mathbf{e}}_{\mathbf{R}} &= R_z(az)R_y(-el)\begin{bmatrix}1\\0\\0\end{bmatrix} \\
\hat{\mathbf{e}}_{\mathbf{az}} &= R_z(az)R_y(-el)\begin{bmatrix}0\\1\\0\end{bmatrix} \\
\hat{\mathbf{e}}_{\mathbf{el}} &= R_z(az)R_y(-el)\begin{bmatrix}0\\0\\1\end{bmatrix}
\end{aligned}$$

The following figure shows the relationship between the spherical basis and the local Cartesian unit vectors.



Algorithms

MATLAB computes the matrix A from the equations

```
A = [cosd(el)*cosd(az), -sind(az), -sind(el)*cosd(az); ...
  cosd(el)*sind(az),  cosd(az), -sind(el)*sind(az); ...
  sind(el),           0,         cosd(el)];
```

Extended Capabilities

Introduced in R2013a

beat2range

Convert beat frequency to range

Syntax

```
r = beat2range(fb,slope)
r = beat2range(fb,slope,c)
```

Description

`r = beat2range(fb,slope)` converts the beat frequency of a dechirped linear FMCW signal to its corresponding range. `slope` is the slope of the FMCW sweep.

`r = beat2range(fb,slope,c)` specifies the signal propagation speed.

Examples

Range of Target in FMCW Radar System

Assume that an FMCW waveform sweeps a band of 3 MHz in 2 ms. The dechirped target return has a beat frequency of 1 kHz. Compute the target range.

```
slope = 30e6/(2e-3);
fb = 1e3;
r = beat2range(fb,slope)
```

```
r =

    9.9931
```

- Automotive Adaptive Cruise Control Using FMCW Technology

Input Arguments

`fb` — Beat frequency of dechirped signal

M-by-1 vector | M-by-2 matrix

Beat frequency of dechirped signal, specified as an M-by-1 vector or M-by-2 matrix in hertz. If the FMCW signal performs an upsweep or downsweep, `fb` is a vector of beat frequencies.

If the FMCW signal has a triangular sweep, `fb` is an M-by-2 matrix in which each row represents a pair of beat frequencies. Each row has the form `[UpSweepBeatFrequency,DownSweepBeatFrequency]`.

Data Types: `double`

`slope` — Sweep slope

nonzero scalar

Slope of FMCW sweep, specified as a nonzero scalar in hertz per second. If the FMCW signal has a triangular sweep, `slope` is the sweep slope of the up-sweep half. In this case, `slope` must be positive and the down-sweep half is assumed to have a slope of `-slope`.

Data Types: `double`

`c` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as a positive scalar in meters per second.

Data Types: `double`

Output Arguments

`r` — Range

M-by-1 column vector

Range, returned as an M-by-1 column vector in meters. Each row of `r` is the range corresponding to the beat frequency in a row of `fb`.

Definitions

Beat Frequency

For an upsweep or downsweep FMCW signal, the beat frequency is $F_t - F_r$. In this expression, F_t is the transmitted signal's carrier frequency, and F_r is the received signal's carrier frequency.

For an FMCW signal with triangular sweep, the upsweep and downsweep have separate beat frequencies.

Algorithms

If `fb` is a vector, the function computes `c*fb/(2*slope)`.

If `fb` is an M-by-2 matrix with a row `[UpSweepBeatFrequency,DownSweepBeatFrequency]`, the corresponding row in `r` is `c*((UpSweepBeatFrequency - DownSweepBeatFrequency)/2)/(2*slope)`.

billingsleyicm

Billingsley's intrinsic clutter motion (ICM) model

Syntax

```
P = billingsleyicm(fd,fc,wspeed)
P = billingsleyicm(fd,fc,wspeed,c)
```

Description

`P = billingsleyicm(fd,fc,wspeed)` calculates the clutter Doppler spectrum shape, `P`, due to intrinsic clutter motion (ICM) at Doppler frequencies specified in `fd`. ICM arises when wind blows on vegetation or other clutter sources. This function uses Billingsley's model in the calculation. `fc` is the operating frequency of the system. `wspeed` is the wind speed.

`P = billingsleyicm(fd,fc,wspeed,c)` specifies the propagation speed `c` in meters per second.

Input Arguments

`fd`

Doppler frequencies in hertz. This value can be a scalar or a vector.

`fc`

Operating frequency of the system in hertz

`wspeed`

Wind speed in meters per second

`c`

Propagation speed in meters per second

Default: Speed of light

Output Arguments

P

Shape of the clutter Doppler spectrum due to intrinsic clutter motion. The vector size of `P` is the same as that of `fd`.

Examples

Compute Billingsley Doppler Spectrum

Calculate and plot the Doppler spectrum shape predicted by the Billingsley ICM model. Assume the PRF is 2 kHz, the operating frequency is 1 GHz, and the wind speed is 5 m/s.

```
v = -3:0.1:3;
fc = 1e9;
wspeed = 5;
c = physconst('LightSpeed');
fd = 2*v/(c/fc);
p = billingsleyicm(fd,fc,wspeed);
plot(fd,pow2db(p))
xlabel('Doppler frequency (Hz)')
ylabel('P (dB)')
```

blakechart

Range-angle-height (Blake) chart

Syntax

```
blakechart(vcp,vcpangles)
blakechart(vcp,vcpangles,rmax,hmax)
blakechart(___,'Name','Value')
```

Description

`blakechart(vcp,vcpangles)` creates a range-angle-height plot (also called a Blake chart) for a narrowband radar antenna. This chart shows the maximum radar range as a function of target elevation. In addition, the Blake chart displays lines of constant range and lines of constant height. The input consist of the vertical coverage pattern, `vcp`, and vertical coverage pattern angles, `vcpangles`, produced by `radarvcd`.

`blakechart(vcp,vcpangles,rmax,hmax)`, in addition, specifies the maximum range and height of the Blake chart. You can specify range and height units separately in the Name-Value pairs, `RangeUnit` and `HeightUnit`. This syntax can use any of the input arguments in the previous syntax.

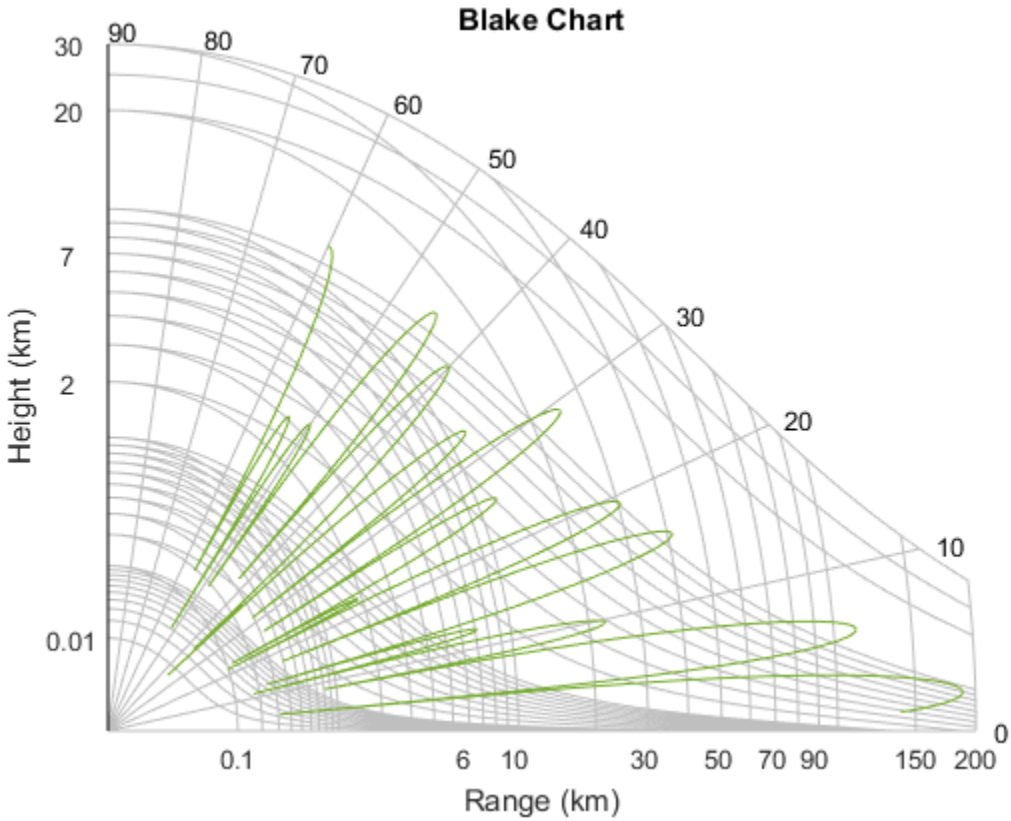
`blakechart(___,'Name','Value')` allows you to specify additional input parameters in the form of Name-Value pairs. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`). This syntax can use any of the input arguments in the previous syntaxes.

Examples

Display Vertical Coverage Diagram

Display the vertical coverage diagram of an antenna transmitting at 100 MHz and placed 20 meters above the ground. Set the free-space range to 100 km. Use default plotting parameters.

```
freq = 100e6;
ant_height = 20;
rng_fs = 100;
[vcp, vcpangles] = radarvcd(freq,rng_fs,ant_height);
blakechart(vcp, vcpangles);
```

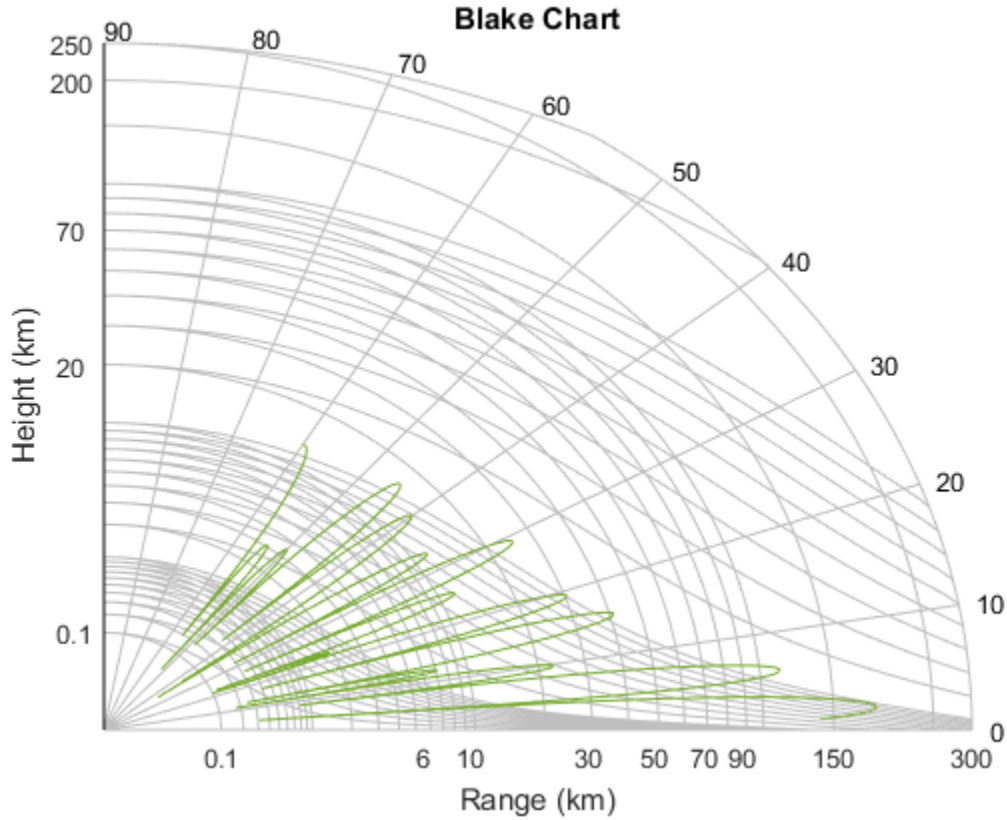


Display Vertical Coverage Diagram Specifying Maximum Range and Height

Display the vertical coverage diagram of an antenna transmitting at 100 MHz and placed 20 meters above the ground. Set the free-space range to 100 km. Set the maximum plotting range to 300 km and the maximum plotting height to 250 km.

```
freq = 100e6;
ant_height = 20;
```

```
rng_fs = 100;
[vcp, vcpangles] = radarvcd(freq,rng_fs,ant_height);
rmax = 300;
hmax = 250;
blakechart(vcp,vcpangles,rmax,hmax);
```



Display Vertical Coverage Diagram of Sinc Pattern Antenna

Plot the range-height-angle curve of a radar having a sinc-function antenna pattern.

Specify antenna pattern

Specify the antenna pattern as a sinc function.

```
pat_angles = linspace(-90,90,361)';
pat_u = 1.39157/sind(90/2)*sind(pat_angles);
pat = sinc(pat_u/pi);
```

Specify radar and environment parameters

Set the transmitting frequency to 100 MHz, the free-space range to 100 km, the antenna tilt angle to 0 degrees, and place the antenna 20 meters above the ground. Assume a surface roughness of one meter.

```
freq = 100e6;
ant_height = 10;
rng_fs = 100;
tilt_ang = 0;
surf_roughness = 1;
```

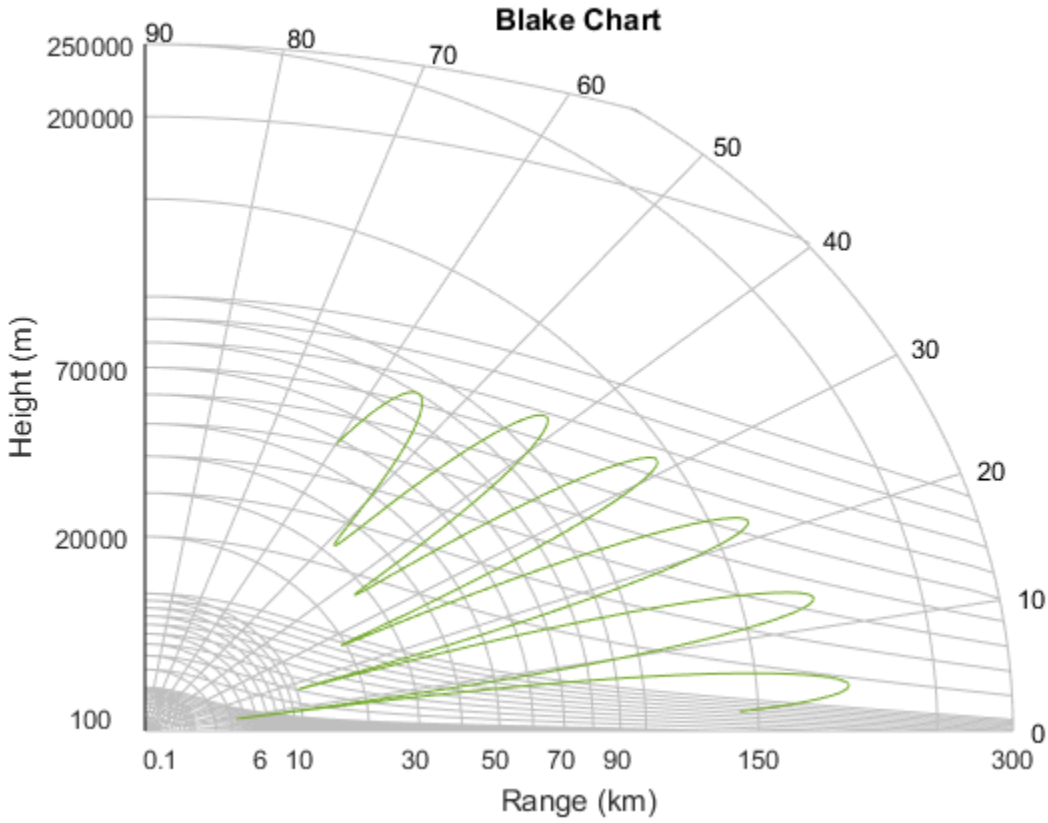
Create radar range-height-angle data

```
[vcp, vcpangles] = radarvcd(freq,rng_fs,ant_height,...
    'RangeUnit','km','HeightUnit','m',...
    'AntennaPattern',pat,...
    'PatternAngles',pat_angles,'TiltAngle',tilt_ang,...
    'SurfaceRoughness',surf_roughness);
```

Plot radar range-height-angle data

Set the maximum plotting range to 300 km and the maximum plotting height to 250,000 m. Choose the range units as kilometers, `'km'`, and the height units as meters, `'m'`. Set the range and height axes scale powers to 1/2.

```
rmax = 300;
hmax = 250e3;
blakechart(vcp, vcpangles, rmax, hmax, 'RangeUnit','km',...
    'ScalePower',1/2,'HeightUnit','m');
```



Input Arguments

`vcp` — Vertical coverage pattern

real-valued vector

Vertical coverage pattern specified as a *K*-by-1 column vector. The vertical coverage pattern is the actual maximum range of the radar. Each entry of the vertical coverage pattern corresponds to one of the angles specified in `vcpangles`. Values are expressed in kilometers unless you change the unit of measure using the `'RangeUnit'` Name-Value pair.

Example: [282.3831; 291.0502; 299.4252]

Data Types: `double`

`vcpangles` — Vertical coverage pattern angles

real-valued vector

Vertical coverage pattern angles specified as a *K*-by-1 column vector. The set of angles range from –90° to 90°.

Example: [2.1480; 2.2340; 2.3199]

Data Types: `double`

`rmax` — Maximum range of plot

real-valued scalar

Maximum range of plot specified as a real-valued scalar. Range units are specified by the `RangeUnit` Name-Value pair.

Example: 200

Data Types: `double`

`hmax` — Maximum height of plot

real-valued scalar

Maximum height of plot specified as a real-valued scalar. Height units are specified by the `HeightUnit` Name-Value pair.

Example: 100000

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: 'RangeUnit','m'

`'RangeUnit'` — Radar range units

`'km'` (default) | `'nmi'` | `'mi'` | `'ft'` | `'m'`

Range units denoting nautical miles, miles, kilometers, feet or meters. This Name-Value pair specifies the units for the vertical coverage pattern input argument, `vcp`, and the maximum range input argument, `rmax`.

Example: `'mi'`

Data Types: `char`

`'HeightUnit'` — Height units
`'km'` (default) | `'nmi'` | `'mi'` | `'ft'` | `'m'`

Height units specified as one of `'nmi' | 'mi' | 'km' | 'ft' |'m'` denoting nautical miles, miles, kilometers, feet or meters. This Name-Value pair specifies the units for the maximum height, `hmax`.

Example: `'m'`

Data Types: `char`

`'ScalePower'` — Scale power
0.25 (default) | real-valued scalar

Scale power, specified as a scalar between 0 and 1. This parameter specifies the range and height axis scale power.

Example: 0.5

Data Types: `double`

`'SurfaceRefractivity'` — Surface refractivity
313 (default) | real-valued scalar

Surface refractivity, specified as a non-negative real-valued scalar. The surface refractivity is a parameter of the "CRPL Exponential Reference Atmosphere Model" on page 2-81 used in this function.

Example: 314

Data Types: `double`

`'RefractionExponent'` — Refraction exponent
0.143859 (default) | real-valued scalar

Refraction exponent specified as a non-negative, real-valued scalar. The refraction exponent is a parameter of the "CRPL Exponential Reference Atmosphere Model" on page 2-81 used in this function.

Example: 0.15

Data Types: `double`

Definitions

CRPL Exponential Reference Atmosphere Model

The `blakechart` function uses the CRPL Exponential Reference Atmosphere to model refraction effects. The index of refraction is a function of height

$$n(h) = 1.0 + \left(N_s \times 10^{-6} \right) e^{-R_{exp} h}$$

where N_s is the atmospheric refractivity value (in units of 10^{-6}) at the surface of the earth, R_{exp} is a decay constant, and h is the height above the surface in kilometers. The default value of N_s is 313 and can be modified using the `'SurfaceRefractivity'` Name-Value pair. The default value of R_{exp} is 0.143859 and can be modified using the `'RefractionExponent'` Name-Value pair.

Introduced in R2013a

broadside2az

Convert broadside angle to azimuth angle

Syntax

```
az = broadside2az(bsang)
az = broadside2az(bsang,el), in addition, specifies the elevation
angle
```

Description

`az = broadside2az(bsang)` returns the azimuth angle, `az`, corresponding to the broadside angle `bsang` for zero elevation angle. All angles are in degrees and in the local coordinate system.

`az = broadside2az(bsang,el), in addition, specifies the elevation angle`, `el`.

Examples

Convert Broadside Angle to Azimuth Angle at Zero Elevation

Return the azimuth angle corresponding to a broadside angle of 45° at 0° elevation.

```
az = broadside2az(45.0)
```

```
az =

   45.0000
```

Convert Broadside Angle to Azimuth Angle

Return the azimuth angle corresponding to a broadside angle of 45° and an elevation angle of 20°.

```
az = broadside2az(45,20)
```

```
az =

   48.8063
```

Convert Multiple Broadside Angles to Azimuth Angles

Return azimuth angles for 10 pairs of broadside angle and elevation angle.

```
BSang = (45:5:90)';
el = (45:-5:0)';
az = broadside2az(BSang,el);
```

Input Arguments

`bsang` — Broadside angle

scalar | vector

Broadside angle, specified as a scalar or vector. The dimension of `bsang` must match the dimensions of `az`. Units are in degrees.

`el` — Elevation angle

0 (default) | scalar | vector

Elevation angle, specified as a scalar or vector. The elevation angle must be within *[–90 ,90]*. The dimension of `el` must match the dimensions of `bsang`. Units are in degrees.

Example: `[5;2;-1]`

Output Arguments

`az` — Azimuth angle

scalar | vector

Azimuth angle, returned as a scalar or vector. The azimuth angles are defined within *[–180 ,180]*. The dimensions of `az` match the dimensions of `bsang`. Units are in degrees.

Example: `[35;20;-10]`

Definitions

Broadside Angle

Broadside angles are useful in describing the response pattern of a uniform linear array (ULA).

For the definition of the broadside angle and how to convert between azimuth and elevation, and broadside angle see “Broadside Angles”. For definitions of the azimuth and elevation angles, see “Azimuth and Elevation Angles”.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

Does not support variable-size inputs.

Introduced in R2011a

bw2range

Convert bandwidth to range resolution

Syntax

```
rngres = bw2range(bw)
rngres = range2bw(bw,c)
```

Description

`rngres = bw2range(bw)` returns the range resolution of a signal corresponding to its bandwidth. Range resolution gives you the minimum range difference needed to distinguish two targets. The function applies to two-way propagation, as in a monostatic radar system.

`rngres = range2bw(bw,c)` specifies the signal propagation speed, `c`.

Examples

Compute Range Resolution from Bandwidth

Assume you have a monostatic radar system that uses a rectangular waveform. Calculate the range resolution obtained using a bandwith of 20 MHz.

```
bw = 20e6;
rngres = bw2range(bw)
```

```
rngres =

    7.4948
```

Compute Sonar Range Resolution from Bandwidth

Calculate the range resolution of a two-way sonar system that uses a rectangular waveform. The signal bandwith is 2 kHz. The speed of sound is 1520 m/s.

```
bw = 2e3;
```

```
c = 1520.0;
rngres = bw2range(bw,c)
```

```
rngres =

    0.3800
```

- Automotive Adaptive Cruise Control Using FMCW Technology

Input Arguments

bw — Signal bandwidth

positive scalar | MATLAB array of positive real values

Signal bandwidth, specified as any array of array of positive real values. Units are in hertz.

c — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as a positive scalar. The default value is the output of `physconst('LightSpeed')`. Units are in meters per second.

Data Types: `double`

Output Arguments

rngres — Target range resolution

positive scalar | MATLAB array of positive real values

Target range resolution, returned as a scalar or MATLAB array of positive real numbers. The dimensions of `rngres` are the same as those of `bw`. Units are in meters.

Data Types: `double`

Tips

- This function assumes two-way propagation. For one-way propagation, you can find the required range resolution by multiplying the output of this function by 2.

Algorithms

The function computes range resolution from `rngres = c/(2*bw)`.

cart2sphvec

Convert vector from Cartesian components to spherical representation

Syntax

```
vs = cart2sphvec(vr,az,el)
```

Description

`vs = cart2sphvec(vr,az,el)` converts the components of a vector or set of vectors, `vr`, from their representation in a local Cartesian coordinate system to a *spherical basis representation* contained in `vs`. A spherical basis representation is the set of components of a vector projected into a basis given by $(\mathbf{e}_{az}, \mathbf{e}_{el}, \mathbf{e}_R)$. The orientation of a spherical basis depends upon its location on the sphere as determined by azimuth, `az`, and elevation, `el`.

Examples

Spherical Representation of Unit Z-Vector

Start with a vector in Cartesian coordinates pointing along the *z*-direction and located at 45° azimuth, 45° elevation. Compute its components with respect to the spherical basis at that point.

```
vr = [0;0;1];
vs = cart2sphvec(vr,45,45)
```

```
vs =

         0
    0.7071
    0.7071
```

Input Arguments

`vr` — Vector in Cartesian basis representation

3-by-1 column vector | 3-by-N matrix

Vector in Cartesian basis representation specified as a 3-by-1 column vector or 3-by-N matrix. Each column of `vr` contains the three components of a vector in the right-handed Cartesian basis *x,y,x*.

Example: `[4.0; -3.5; 6.3]`

Data Types: `double`
Complex Number Support: Yes

`az` — Azimuth angle

scalar in range [–180,180]

Azimuth angle specified as a scalar in the closed range [–180,180]. Angle units are in degrees. To define the azimuth angle of a point on a sphere, construct a vector from the origin to the point. The azimuth angle is the angle in the *xy*-plane from the positive *x*-axis to the vector's orthogonal projection into the *xy*-plane. As examples, zero azimuth angle and zero elevation angle specify a point on the *x*-axis while an azimuth angle of 90° and an elevation angle of zero specify a point on the *y*-axis.

Example: `45`

Data Types: `double`

`el` — Elevation angle

scalar in range [–90,90]

Elevation angle specified as a scalar in the closed range [–90,90]. Angle units are in degrees. To define the elevation of a point on the sphere, construct a vector from the origin to the point. The elevation angle is the angle from its orthogonal projection into the *xy*-plane to the vector itself. As examples, zero elevation angle defines the equator of the sphere and ±90° elevation define the north and south poles, respectively.

Example: `30`

Data Types: `double`

Output Arguments

`vs` — Vector in spherical basis

3-by-1 column vector | 3-by-N matrix

Spherical representation of a vector returned as a 3-by-1 column vector or 3-by-N matrix having the same dimensions as `vs`. Each column of `vs` contains the three components of the vector in the right-handed $(\mathbf{e}_{az}, \mathbf{e}_{el}, \mathbf{e}_R)$ basis.

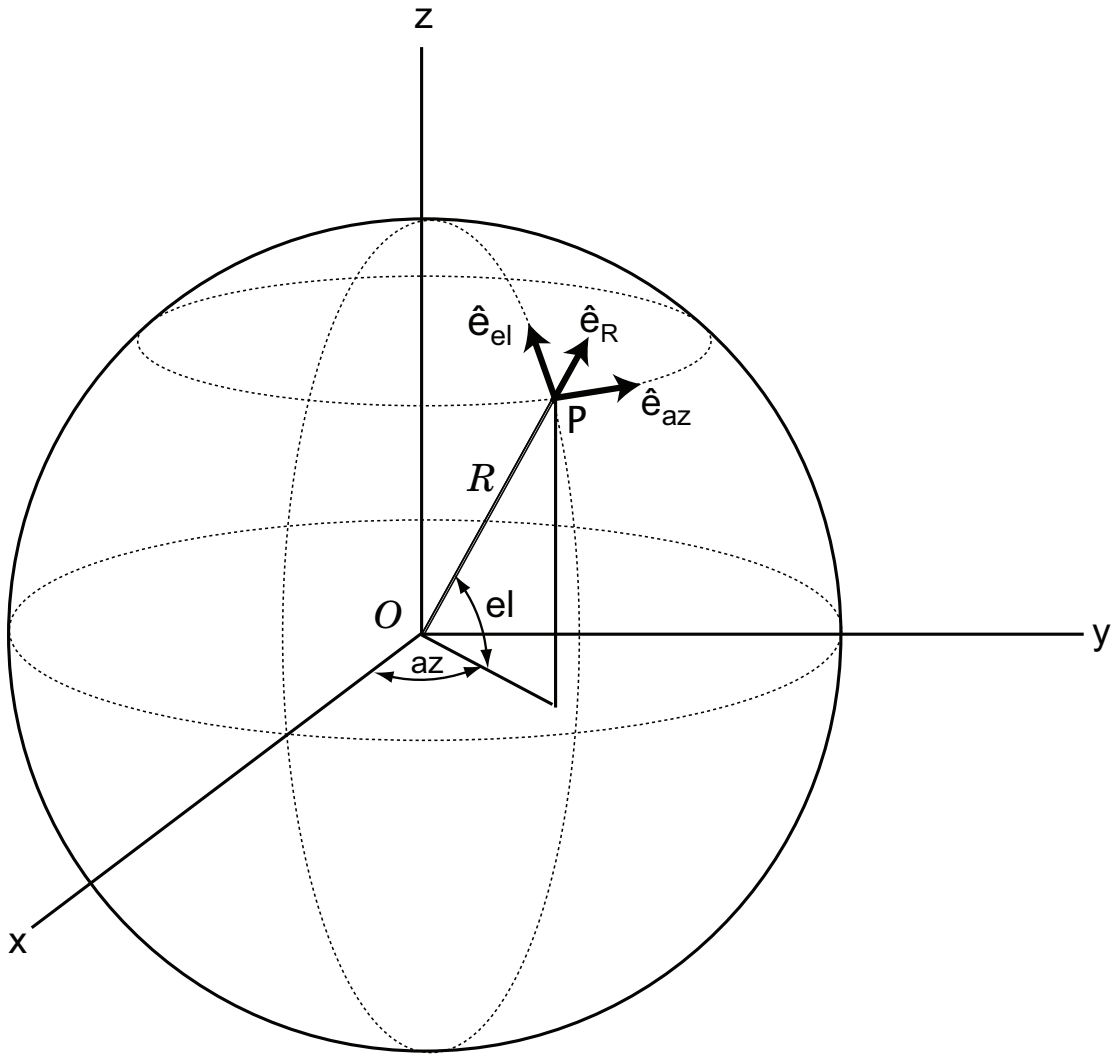
Definitions

Spherical basis representation of vectors

Spherical basis vectors are a local set of basis vectors which point along the radial and angular directions at any point in space.

The spherical basis is a set of three mutually orthogonal unit vectors $(\mathbf{e}_{az}, \mathbf{e}_{el}, \mathbf{e}_R)$ defined at a point on the sphere. The first unit vector points along lines of azimuth at constant radius and elevation. The second points along the lines of elevation at constant azimuth and radius. Both are tangent to the surface of the sphere. The third unit vector points radially outward.

The orientation of the basis changes from point to point on the sphere but is independent of R so as you move out along the radius, the basis orientation stays the same. The following figure illustrates the orientation of the spherical basis vectors as a function of azimuth and elevation:



For any point on the sphere specified by *az* and *el*, the basis vectors are given by:

$$\begin{aligned}\hat{\mathbf{e}}_{\mathbf{az}} &= -\sin(az)\hat{\mathbf{i}} + \cos(az)\hat{\mathbf{j}} \\ \hat{\mathbf{e}}_{\mathbf{el}} &= -\sin(el)\cos(az)\hat{\mathbf{i}} - \sin(el)\sin(az)\hat{\mathbf{j}} + \cos(el)\hat{\mathbf{k}} \\ \hat{\mathbf{e}}_{\mathbf{R}} &= \cos(el)\cos(az)\hat{\mathbf{i}} + \cos(el)\sin(az)\hat{\mathbf{j}} + \sin(el)\hat{\mathbf{k}} \quad .\end{aligned}$$

Any vector can be written in terms of components in this basis as $\mathbf{v} = v_{az}\hat{\mathbf{e}}_{\mathbf{az}} + v_{el}\hat{\mathbf{e}}_{\mathbf{el}} + v_R\hat{\mathbf{e}}_{\mathbf{R}}$. The transformations between spherical basis components and Cartesian components take the form

$$\begin{bmatrix} v_x \\ v_y \\ v_z \end{bmatrix} = \begin{bmatrix} -\sin(az) & -\sin(el)\cos(az) & \cos(el)\cos(az) \\ \cos(az) & -\sin(el)\sin(az) & \cos(el)\sin(az) \\ 0 & \cos(el) & \sin(el) \end{bmatrix} \begin{bmatrix} v_{az} \\ v_{el} \\ v_R \end{bmatrix}$$

.

and

$$\begin{bmatrix} v_{az} \\ v_{el} \\ v_R \end{bmatrix} = \begin{bmatrix} -\sin(az) & \cos(az) & 0 \\ -\sin(el)\cos(az) & -\sin(el)\sin(az) & \cos(el) \\ \cos(el)\cos(az) & \cos(el)\sin(az) & \sin(el) \end{bmatrix} \begin{bmatrix} v_x \\ v_y \\ v_z \end{bmatrix}.$$

cbfweights

Conventional beamformer weights

Syntax

```
wt = cbfweights(pos,ang)
wt = cbfweights(pos,ang,nqbits)
```

Description

`wt = cbfweights(pos,ang)` returns narrowband conventional beamformer weights. When applied to the elements of a sensor array, these weights steer the response of the array to a specified arrival direction or set of directions. The `pos` argument specifies the sensor positions in the array. The `ang` argument specifies the azimuth and elevation angles of the desired response directions. The output weights, `wt`, are returned as an *N*-by-*M* matrix. In this matrix, *N* represents the number of sensors in the array while *M* represents the number of arrival directions. Each column of `wt` contains the weights for the corresponding direction specified in the `ang`. The argument `wt` is equivalent to the output of the function `steervec` divided by *N*. All elements in the sensor array are assumed to be isotropic.

`wt = cbfweights(pos,ang,nqbits)` returns quantized narrowband conventional beamformer weights when the number of phase-shifter bits is set to `nqbits`.

Examples

Conventional Weights for Two Beamformer Directions

Specify a line array of five elements spaced 10 cm apart. Compute the weights for two directions: 30° azimuth, 0° elevation, and 45° azimuth, 0° elevation. Assume the array is tuned to plane waves having a frequency of 1 GHz.

```
elementPos = (0:.1:.4);
c = physconst('LightSpeed');
fc = 1e9;
lambda = c/fc;
ang = [30 45];
```

```
wt = cbfweights(elementPos/lambda,ang)
```

```
wt =

   0.2000 + 0.0000i   0.2000 + 0.0000i
   0.0999 + 0.1733i   0.0177 + 0.1992i
  -0.1003 + 0.1731i  -0.1969 + 0.0353i
  -0.2000 - 0.0004i  -0.0527 - 0.1929i
  -0.0995 - 0.1735i   0.1875 - 0.0696i
```

Quantized Weights for Two Beamformer Directions

Specify a line array of five elements spaced 10 cm apart. Compute the weights for two directions: 30° azimuth, 0° elevation, and 45° azimuth, 0° elevation. Assume the array is tuned to plane waves having a frequency of 1 GHz. Assume the weights are quantized to six bits.

```
elementPos = (0:.1:.4);
c = physconst('LightSpeed');
fc = 1e9;
lambda = c/fc;
ang = [30 45];
nqbits = 6;
wt = cbfweights(elementPos/lambda,ang,nqbits)
```

```
wt =

   0.2000 + 0.0000i   0.2000 + 0.0000i
   0.0943 + 0.1764i   0.0196 + 0.1990i
  -0.0943 + 0.1764i  -0.1962 + 0.0390i
  -0.2000 + 0.0000i  -0.0581 - 0.1914i
  -0.0943 - 0.1764i   0.1848 - 0.0765i
```

Input Arguments

`pos` — Positions of array sensor elements

1-by-*N* real-valued vector | 2-by-*N* real-valued matrix | 3-by-*N* real-valued matrix

Positions of the elements of a sensor array specified as a 1-by-*N* vector, a 2-by-*N* matrix, or a 3-by-*N* matrix. In this vector or matrix, *N* represents the number of elements of the

array. Each column of `pos` represents the coordinates of an element. You define sensor position units in term of signal wavelength. If `pos` is a 1-by-*N* vector, then it represents the *y*-coordinate of the sensor elements of a line array. The *x* and *z*-coordinates are assumed to be zero. When `pos` is a 2-by-*N* matrix, it represents the *(y,z)*-coordinates of the sensor elements of a planar array. This array is assumed to lie in the *yz*-plane. The *x*-coordinates are assumed to be zero. When `pos` is a 3-by-*N* matrix, then the array has arbitrary shape.

Example: `[0,0,0; 0.1,0.4,0.3;1,1,1]`

Data Types: `double`

`ang` — Beamforming directions

1-by-*M* real-valued vector | 2-by-*M* real-valued matrix

Beamforming directions specified as a 1-by-*M* vector or a 2-by-*M* matrix. In this vector or matrix, *M* represents the number of incoming signals. If `ang` is a 2-by-*M* matrix, each column specifies the direction in azimuth and elevation of the beamforming direction as `[az;el]`. Angular units are specified in degrees. The azimuth angle must lie between –180° and 180° and the elevation angle must lie between –90° and 90°. The azimuth angle is the angle between the *x*-axis and the projection of the beamforming direction vector onto the *xy* plane. The angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the beamforming direction vector and *xy*-plane. It is positive when measured towards the positive *z* axis. If `ang` is a 1-by-*M* vector, then it represents a set of azimuth angles with the elevation angles assumed to be zero.

Example: `[45;10]`

Data Types: `double`

`nqbits` — Number of phase shifter quantization bits

0 (default) | non-negative integer

Number of bits used to quantize the phase shift in beamformer or steering vector weights, specified as a non-negative integer. A value of zero indicates that no quantization is performed.

Example: `5`

Output Arguments

`wt` — Beamformer weights

N-by-*M* complex-valued matrix

Beamformer weights returned as an *N*-by-*M* complex-valued matrix. In this matrix, *N* represents the number of sensor elements of the array while *M* represents the number of beamforming directions. Each column of `wt` corresponds to a beamforming direction specified in `ang`.

Introduced in R2013a

circpol2pol

Convert circular component representation of field to linear component representation

Syntax

```
fv = circpol2pol(cfv)
```

Description

`fv = circpol2pol(cfv)` converts the circular polarization components of the field or fields contained in `cfv` to their linear polarization components contained in `fv`. Any polarized field can be expressed as a linear combination of horizontal and vertical components.

Examples

Convert Circular to Linear Polarization

Convert a horizontally polarized field, originally expressed in circular polarization components, into linear polarization components.

```
cfv = [1;1];
fv = circpol2pol(cfv)
```

```
fv =

    1.4142
         0
```

The vertical component of the output is zero for horizontally polarized fields.

Convert Circular Polarization Ratio to Linear Polarization Ratio

Create a right circularly polarized field. Compute the circular polarization ratio and convert to a linear polarization ratio equivalent. Note that the input circular polarization ratio is `Inf`.

```
cfv = [0;1];
q = cfv(2)/cfv(1);
p = circpol2pol(q)

p =

   0.0000 - 1.0000i
```

Input Arguments

`cfv` — Field vector in circular polarization representation

1-by-*N* complex-valued row vector or 2-by-*N* complex-valued matrix

Field vector in its circular polarization representation specified as a 1-by-*N* complex row vector or a 2-by-*N* complex matrix. If `cfv` is a matrix, each column represents a field in the form of `[El;Er]`, where `El` and `Er` are the left and right circular polarization components of the field. If `cfv` is a row vector, each column in `cfv` represents the polarization ratio, `Er/El`. For a row vector, the value `Inf` can designate the case when the ratio is computed for `El = 0`.

Example: [1;-1]

Data Types: `double`
Complex Number Support: Yes

Output Arguments

`fv` — Field vector in linear polarization representation or Jones vector

1-by-*N* complex-valued row vector or 2-by-*N* complex-valued matrix

Field vector in linear polarization representation or Jones vector returned as a 1-by-*N* complex-valued row vector or 2-by-*N* complex-valued matrix. `fv` has the same dimensions as `cfv`. If `cfv` is a matrix, each column of `fv` contains the horizontal and vertical linear polarization components of the field in the form, `[Eh;Ev]`. If `cfv` is a row vector, each entry in `fv` contains the linear polarization ratio, defined as `Ev/Eh`.

dechirp

Perform dechirp operation on FMCW signal

Syntax

```
y = dechirp(x,xref)
```

Description

`y = dechirp(x,xref)` mixes the incoming signal, `x`, with the reference signal, `xref`. The signals can be complex baseband signals. In an FMCW radar system, `x` is the received signal and `xref` is the transmitted signal.

Examples

Dechirp FMCW Signal

Dechirp a delayed FMCW signal, and plot the spectrum before and after dechirping.

Create an FMCW signal.

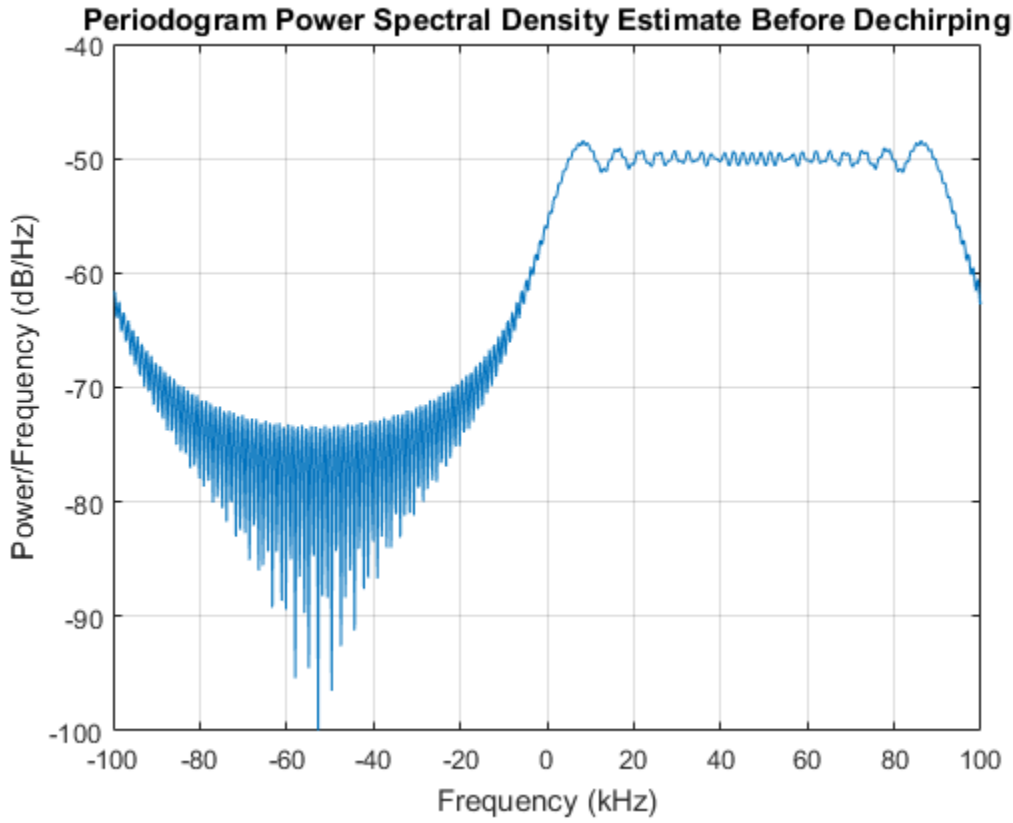
```
Fs = 2e5; Tm = 0.001;
hwav = phased.FMCWWaveform('SampleRate',Fs,'SweepTime',Tm);
xref = step(hwav);
```

Dechirp a delayed copy of the signal.

```
x = [zeros(10,1); xref(1:end-10)];
y = dechirp(x,xref);
```

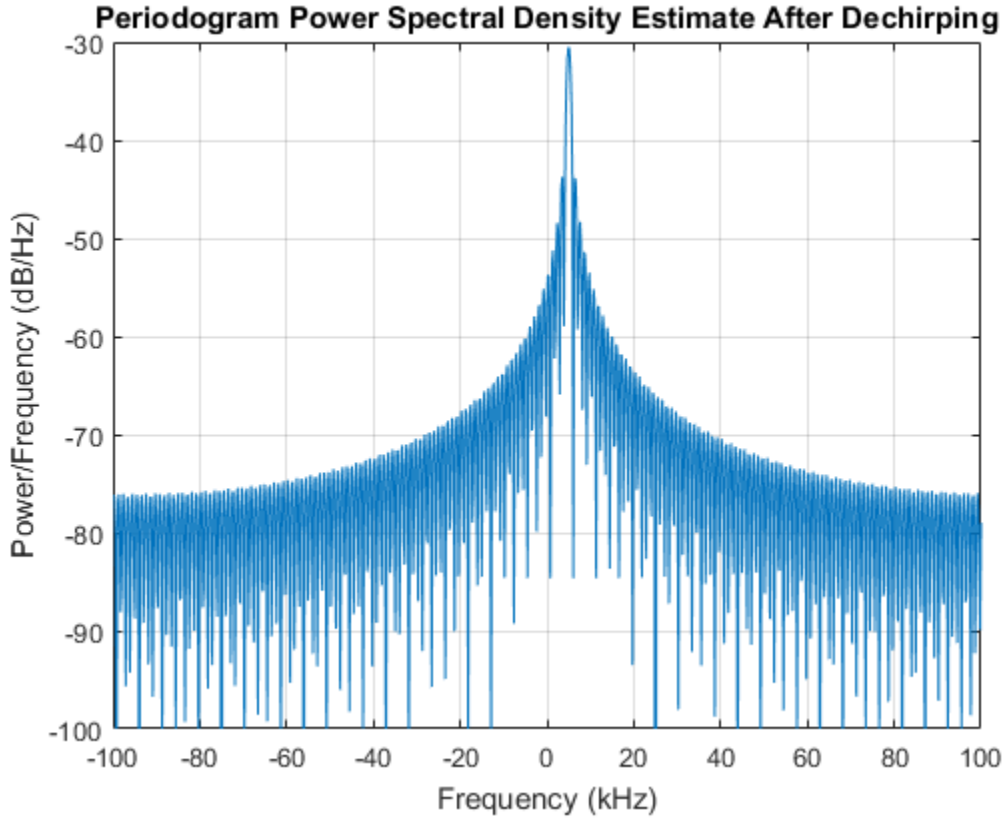
Plot the spectrum before dechirping.

```
[Pxx,F] = periodogram(x,[],1024,Fs,'centered');
plot(F/1000,10*log10(Pxx)); grid;
xlabel('Frequency (kHz)');
ylabel('Power/Frequency (dB/Hz)');
title('Periodogram Power Spectral Density Estimate Before Dechirping');
```



Plot the spectrum after dechirping.

```
[Pyy,F] = periodogram(y,[],1024,Fs,'centered');
plot(F/1000,10*log10(Pyy));
xlabel('Frequency (kHz)');
ylabel('Power/Frequency (dB/Hz)');
ylim([-100 -30]); grid
title('Periodogram Power Spectral Density Estimate After Dechirping');
```



- Automotive Adaptive Cruise Control Using FMCW Technology

Input Arguments

x — Incoming signal

M-by-N matrix

Incoming signal, specified as an M-by-N matrix. Each column of `x` is an independent signal and is individually mixed with `xref`.

Data Types: `double`
Complex Number Support: Yes

`xref` — Reference signal

M-by-1 vector

Reference signal, specified as an M-by-1 vector.

Data Types: `double`
Complex Number Support: Yes

Output Arguments

`y` — Dechirped signal

M-by-N matrix

Dechirped signal, returned as an M-by-N matrix. Each column is the mixer output for the corresponding column of `x`.

Algorithms

For column vectors `x` and `xref`, the mix operation is defined as `xref .* conj(x)`.

If `x` has multiple columns, the mix operation applies the preceding expression to each column of `x` independently.

The mix operation negates the Doppler shift embedded in `x`, because of the order of `xref` and `x`.

The mixing order affects the sign of the imaginary part of `y`. There is no consistent convention in the literature about the mixing order. This function and the `beat2range` function use the same convention. If your program processes the output of `dechirp` in other ways, take the mixing order into account.

delayseq

Delay or advance sequence

Syntax

```
shifted_data = delayseq(data,DELAY)
shifted_data = delayseq(data,DELAY,Fs)
```

Description

`shifted_data = delayseq(data,DELAY)` delays or advances the input `data` by `DELAY` samples. Negative values of `DELAY` advance `data`, while positive values delay `data`. Noninteger values of `DELAY` represent fractional delays or advances. In this case, the function interpolates. How the `delayseq` function operates on the columns of `data` depends on the dimensions of `data` and `DELAY`:

- If `DELAY` is a scalar, the function applies that shift to each column of `data`.
- If `DELAY` is a vector whose length equals the number of columns of `data`, the function shifts each column by the corresponding vector entry.
- If `DELAY` is a vector and `data` has one column, the function shifts `data` by each entry in `DELAY` independently. The number of columns in `shifted_data` is the vector length of `DELAY`. The *k*th column of `shifted_data` is the result of shifting `data` by `DELAY(k)`.

`shifted_data = delayseq(data,DELAY,Fs)` specifies `DELAY` in seconds. `Fs` is the sampling frequency of `data`. If `DELAY` is not divisible by the reciprocal of the sampling frequency, `delayseq` interpolates to implement a fractional delay or advance of `data`.

Input Arguments

`data`

Vector or matrix of real or complex data.

`DELAY`

Amount by which to delay or advance the input. If you specify the optional `Fs` argument, `DELAY` is in seconds; otherwise, `DELAY` is in samples.

`Fs`

Sampling frequency of the data in hertz. If you specify this argument, the function assumes `DELAY` is in seconds.

Default: 1

Output Arguments

`shifted_data`

Result of delaying or advancing the data. `shifted_data` has the same number of rows as `data`, with appropriate truncations or zero padding.

Examples

Delay Signal by Integral Number of Samples

Delay a cosine signal an integral number of samples.

```
fs = 1.0e4;
t = 0:1/fs:0.005;
signal = cos(2*pi*1000*t)';
```

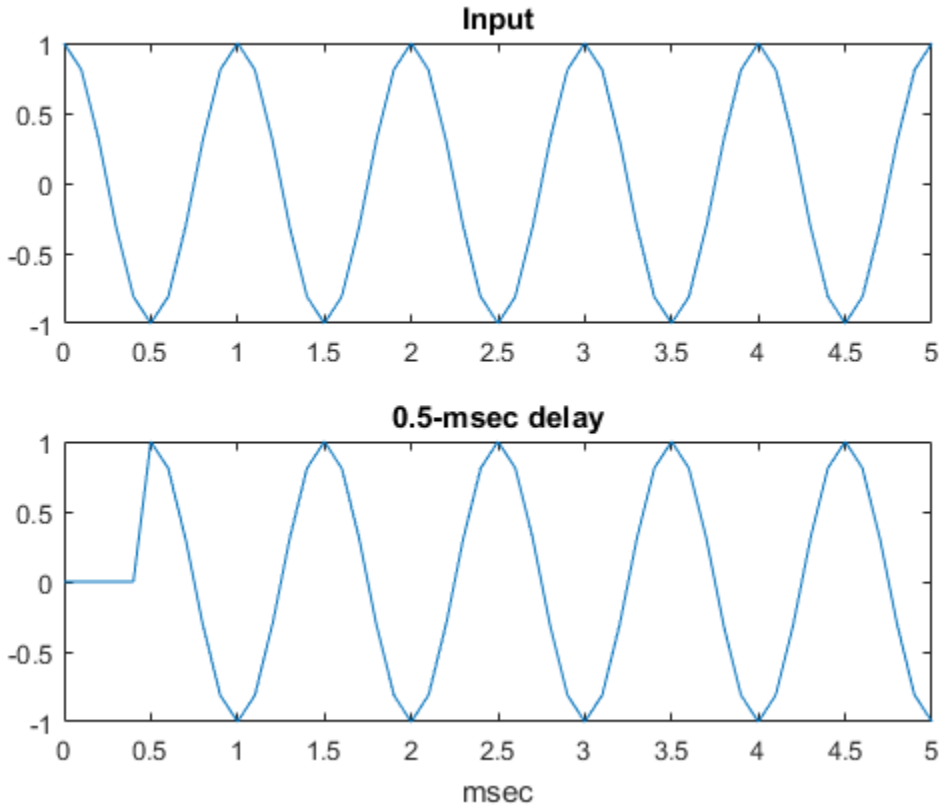
Set the delay to 0.5 ms or 5 samples.

```
shifted_signal = delayseq(signal,0.5e-3,fs);
```

Plot the original and delayed signals.

```
subplot(2,1,1)
plot(t.*1000,signal)
title('Input')
subplot(2,1,2)
```

```
plot(t.*1000,shifted_signal)
title('0.5-msec delay')
xlabel('msec')
```



Delay Signal by Fractional Number of Samples

Delay a cosine signal a fractional number of samples.

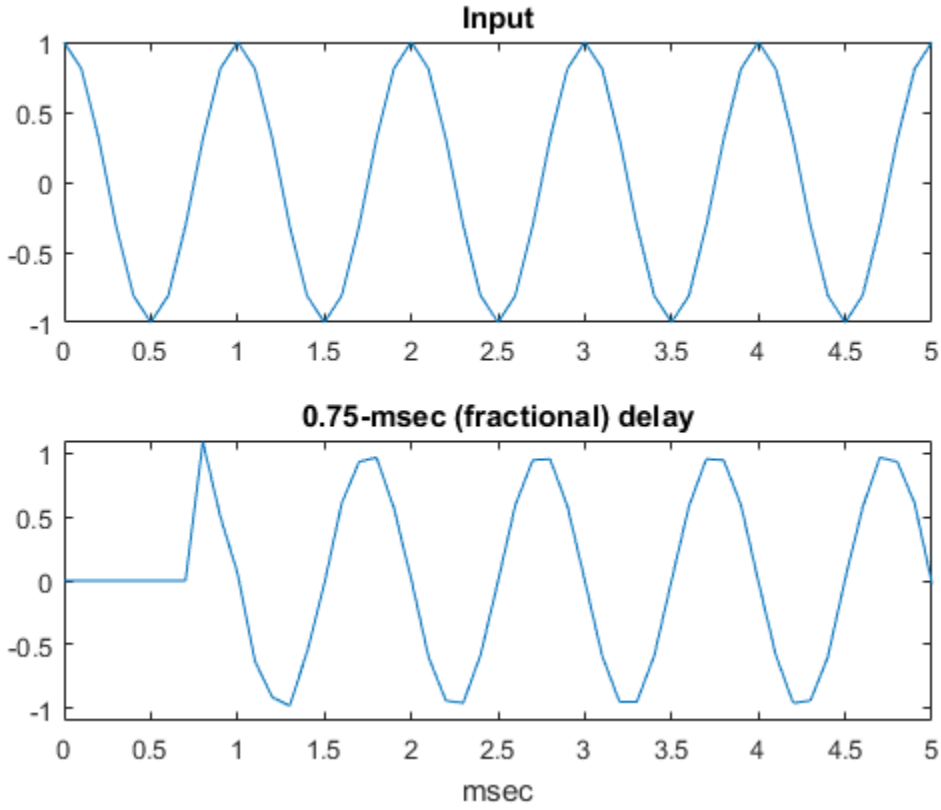
```
fs = 1e4;
t = 0:1/fs:0.005;
signal = cos(2*pi*1000*t)';
```

Set the delay to 0.75 ms or 7.5 samples.

```
shifted_signal = delayseq(signal,0.75e-3,fs);
```

Plot the original and delayed signals.

```
subplot(2,1,1)
plot(t.*1000,signal)
title('Input')
subplot(2,1,2)
plot(t.*1000,shifted_signal)
title('0.75-msec (fractional) delay')
axis([0 5 -1.1 1.1])
xlabel('msec')
```



Tthe values of the shifted signal differ from the input signal because of the interpolation resulting from the fractional delay.

depressionang

Depression angle of surface target

Syntax

```
depAng = depressionang(H,R)
depAng = depressionang(H,R,MODEL)
depAng = depressionang(H,R,MODEL,Re)
```

Description

`depAng = depressionang(H,R)` returns the depression angle from the horizontal at an altitude of `H` meters to surface targets. The sensor is `H` meters above the surface. `R` is the range from the sensor to the surface targets. The computation assumes a curved earth model with an effective earth radius of approximately 4/3 times the actual earth radius.

`depAng = depressionang(H,R,MODEL)` specifies the earth model used to compute the depression angle. `MODEL` is either `'Flat'` or `'Curved'`.

`depAng = depressionang(H,R,MODEL,Re)` specifies the effective earth radius. Effective earth radius applies to a curved earth model. When `MODEL` is `'Flat'`, the function ignores `Re`.

Input Arguments

H

Height of the sensor above the surface, in meters. This argument can be a scalar or a vector. If both `H` and `R` are nonscalar, they must have the same dimensions.

R

Distance in meters from the sensor to the surface target. This argument can be a scalar or a vector. If both `H` and `R` are nonscalar, they must have the same dimensions. `R` must be between `H` and the horizon range determined by `H`.

MODEL

Earth model, as one of | 'Curved' | 'Flat' |.

Default: 'Curved'

Re

Effective earth radius in meters. This argument requires a positive scalar value.

Default: effearthradius, which is approximately 4/3 times the actual earth radius

Output Arguments

depAng

Depression angle, in degrees, from the horizontal at the sensor altitude toward surface targets R meters from the sensor. The dimensions of depAng are the larger of size(H) and size(R).

Examples

Compute Depression Angle

Calculate the depression angle for a ground clutter patch that is 1.0 km away from a sensor. The sensor is located on a platform 300 m above the ground.

```
depang = depressionang(300,1000)
```

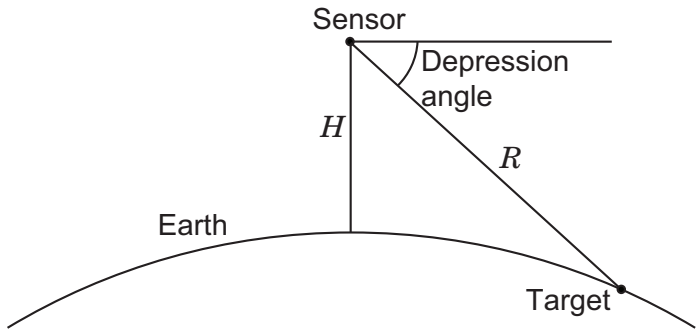
```
depang =

   17.4608
```

Definitions

Depression Angle

The depression angle is the angle between a horizontal line containing the sensor and the line from the sensor to a surface target.



For the curved earth model with an effective earth radius of R_e, the depression angle is:

$$\sin^{-1}\left(\frac{H^2 + 2HR_e + R^2}{2R(H + R_e)}\right)$$

For the flat earth model, the depression angle is:

$$\sin^{-1}\left(\frac{H}{R}\right)$$

diagbfweights

Diagonalize MIMO channel

Syntax

```
[wp,wc] = diagbfweights(chanmat)
[wp,wc,P] = diagbfweights(chanmat)
[wp,wc,P,G] = diagbfweights(chanmat)
[wp,wc,P,G,C] = diagbfweights(chanmat)
[ ___ ] = diagbfweights(chanmat,Pt)
[ ___ ] = diagbfweights(chanmat,Pt Pn)
[ ___ ] = diagbfweights(chanmat,Pt Pn,powdistoption)
```

Description

`[wp,wc] = diagbfweights(chanmat)` returns precoding weights, `wp`, and combining weights, `wc`, for the channel response matrix, `chanmat`. Together, these weights diagonalize the channel into subchannels so that the matrix `wp*chanmat*wc` is diagonal.

`[wp,wc,P] = diagbfweights(chanmat)` also returns the distributed power, `P`, for each element of the transmitting array.

`[wp,wc,P,G] = diagbfweights(chanmat)` also returns the subcarrier gains, `G`.

`[wp,wc,P,G,C] = diagbfweights(chanmat)` also returns the channel capacity sum, `C`.

`[ ___ ] = diagbfweights(chanmat,Pt)` also specifies total transmit power, `Pt`, and returned values any of the previous output argument combinations.

`[ ___ ] = diagbfweights(chanmat,Pt Pn)` also specifies the noise power per transmitting antenna, `Pn`.

`[ ___ ] = diagbfweights(chanmat,Pt Pn,powdistoption)` also specifies the noise distribution, `powdistoption`, across all transmitting antennas.

Examples

Compute and Diagonalize Channel Matrix

Compute the channel matrix for a 4-by-4 transmitting URA array and a 5-by-5 receiving URA array. Assume that three scatterers are randomly located located within a specified angular range. The element spacings for both arrays is one-half wavelength. The receive array is 500 wavelengths away from the transmitting array along the *x*-axis. Constrain the angular span for the transmitting and receiving arrays. Diagonalize the channel matrix to compute the precoding and combining weights.

Specify the 4-by-4 transmitting array. Element spacing is in units of wavelength.

```
Nt = 4;
sp = 0.5;
ygridtx = (0:Nt-1)*sp - (Nt-1)/2*sp;
zgridtx = (0:Nt-1)*sp - (Nt-1)/2*sp;
[ytx,ztx] = meshgrid(ygridtx,zgridtx);
txpos = [zeros(1,Nt*Nt);ytx(:).';ztx(:).'];
```

Specify the 5-by-5 receiving array. Element spacing is in units of wavelength.

```
Nr = 5;
sp = 0.5;
ygridrx = (0:Nr-1)*sp - (Nr-1)/2*sp;
zgridrx = (0:Nr-1)*sp - (Nr-1)/2*sp;
[yrx,zrx] = meshgrid(ygridrx,zgridrx);
rxpos = [500*ones(1,Nr*Nr);yrx(:).';zrx(:).'];
```

Set the angular limits for transmitting and receiving.

- The azimuth angle limits for the transmitter are −45° to +45°.
- The azimuth angle limits for the receiver are −75° to +50°.
- The elevation angle limits for the transmitter are −12° to +12°.
- The elevation angle limits for the receiver are −30° to +30°.

```
angrange = [-45 45 -75 50; -12 12 -30 30];
```

Specify three scatterers and create the channel matrix.

```
numscat = 3;
chmat = scatteringchanmtx(txpos,rxpos,numscat,angrange);
```

Diagonalize the channel matrix.

```
[wp,wc] = diagbfweights(chmat);
z = wp*chmat*wc;
```

Show the first four diagonal elements.

```
z(1:4,1:4)
```

```
ans =

  23.3713 - 0.0000i   0.0000 + 0.0000i   0.0000 + 0.0000i   0.0000 - 0.0000i
   0.0000 - 0.0000i  10.7803 + 0.0000i   0.0000 - 0.0000i   0.0000 + 0.0000i
  -0.0000 - 0.0000i   0.0000 - 0.0000i   1.0566 + 0.0000i   0.0000 + 0.0000i
  -0.0000 - 0.0000i  -0.0000 + 0.0000i  -0.0000 + 0.0000i  -0.0000 - 0.0000i
```

Distributed Power of Diagonalized Channel Matrix

Compute the channel matrix for a 4-by-4 transmitting URA array and a 5-by-5 receiving URA array. Assume that three scatterers are randomly located within a specified angular range. The element spacings for both arrays is one-half wavelength. The receive array is 500 wavelengths away along the *x*-axis. Diagonalize the channel matrix to compute the precoding and combining weights and the distributed power.

Specify the 4-by-4 transmitting array. Element spacing is in units of wavelength.

```
Nt = 4;
sp = 0.5;
ygridtx = (0:Nt-1)*sp - (Nt-1)/2*sp;
zgridtx = (0:Nt-1)*sp - (Nt-1)/2*sp;
[ytx,ztx] = meshgrid(ygridtx,zgridtx);
txpos = [zeros(1,Nt*Nt);ytx(:).';ztx(:).'];
```

Specify the 5-by-5 receiving array. Element spacing is in units of wavelength.

```
Nr = 5;
sp = 0.5;
ygridrx = (0:Nr-1)*sp - (Nr-1)/2*sp;
zgridrx = (0:Nr-1)*sp - (Nr-1)/2*sp;
[yrx,zrx] = meshgrid(ygridrx,zgridrx);
rxpos = [500*ones(1,Nr*Nr);yrx(:).';zrx(:).'];
```

Set the angular limits for transmitting and receiving.

- The azimuth angle limits for the transmitter are −45° to +45°.
- The azimuth angle limits for the receiver are −75° to +50°.
- The elevation angle limits for the transmitter are −12° to +12°.
- The elevation angle limits for the receiver are −30° to +30°.

```
angrange = [-45 45 -75 50; -12 12 -30 30];
```

Specify three scatterers and create the channel matrix.

```
numscat = 3;
chmat = scatteringchanmtx(txpos,rxpos,numscat,angrange);
```

Diagonalize the channel matrix and return the distributed power.

```
[wp,wc,P] = diagbfweights(chmat);
disp(P.')

Subchannel Gains of Diagonalized Channel Matrix

Compute the channel matrix for an 11-element transmitting ULA array and a 7-element receiving ULA array. Assume that there are five randomly located scatterers. The element spacings for both arrays is one-half wavelength. The receive array is 500 wavelengths away from the transmit array along the *x*-axis. Diagonalize the channel matrix to compute the precoding and combining weights, the distributed power, and the subchannel gains.

Specify the 11-element transmitting ULA array. Element spacing is in units of wavelength.

```
Nt = 11;
sp = 0.5;
txpos = (0:Nt-1)*sp - (Nt-1)/2*sp;
```

Specify the 7-element receiving ULA array. Element spacing is in units of wavelength.

```
Nr = 7;
sp = 0.5;
rxpos = (0:Nr-1)*sp - (Nr-1)/2*sp;
numscat = 5;
chmat = scatteringchanmtx(txpos,rxpos,numscat);
```

Diagonalize the channel matrix and return the subchannel gains.

```
[wp,wc,P,G] = diagbfweights(chmat);
disp(G.')
```

Channel Capacity Sum of Diagonalized Channel Matrix

Compute the channel matrix for an 11-element transmitting ULA array and a 7-element receiving ULA array. Assume that there are five randomly located scatterers. The element spacings for both arrays is one-half wavelength. The receive array is 500 wavelengths away from the transmitting array along the *x*-axis. Create a channel matrix with two subcarriers. Diagonalize the channel matrix to compute the precoding and combining weights, the distributed power, the subchannel gains, and the channel capacity sum.

Specify the 11-element transmitting ULA array. Element spacing is in units of wavelength.

```
Nt = 11;
sp = 0.5;
txpos = (0:Nt-1)*sp - (Nt-1)/2*sp;
```

Specify the 7-element receiving ULA array. Element spacing is in units of wavelength.

```
Nr = 7;
sp = 0.5;
rxpos = (0:Nr-1)*sp - (Nr-1)/2*sp;
numscat = 5;
```

Create two subcarriers.

```
chmat1 = scatteringchanmtx(txpos,rxpos,numscat);
chmat2 = scatteringchanmtx(txpos,rxpos,numscat);
chmat(1,:,:) = chmat1;
chmat(2,:,:) = chmat2;
```

Diagonalize the channel matrix and return the subchannel gains.

```
[wp,wc,P,G,C] = diagbfweights(chmat);
disp(C.')
```

```
    9.5466    9.3605
```

Diagonalize Channel Matrix with Specified Power

Compute the channel matrix for an 11-element transmitting ULA array and a 7-element receiving ULA array. Specify the total transmitted power at 1000. Assume that there are five randomly located scatterers. The element spacings for both arrays is one-half wavelength. The receive array is 500 wavelengths away from the transmitting array along the *x*-axis. Create a channel matrix with two subcarriers. Diagonalize the channel matrix to compute the precoding and combining weights, the distributed power, the subchannel gains, and the channel capacity sum.

Specify the 11-element transmitting ULA array. Element spacing is in units of wavelength.

```
Nt = 11;
sp = 0.5;
txpos = (0:Nt-1)*sp - (Nt-1)/2*sp;
```

Specify the 7-element receiving ULA array. Element spacing is in units of wavelength.

```
Nr = 7;
sp = 0.5;

Diagonalize Channel Matrix with Specified Noise Power

Compute the channel matrix for an 11-element transmitting ULA array and a 7-element receiving ULA array. Specify the total transmitted power at 1000 and the transmitting antenna noise power at 100. Assume that there are five randomly located scatterers. The element spacings for both arrays is one-half wavelength. The receive array is 500 wavelengths away from the transmit array along the *x*-axis. Create a channel matrix with two subcarriers. Diagonalize the channel matrix to compute the precoding and combining weights, the distributed power, subchannel gains, and channel capacity sum.

Specify the 11-element transmitting ULA array. Element spacing is in units of wavelength.

```
Nt = 11;
sp = 0.5;
txpos = (0:Nt-1)*sp - (Nt-1)/2*sp;

Diagonalize Channel Matrix Using Waterfill Power Distribution

Compute the channel matrix for an 11-element transmitting ULA array and a 7-element receiving ULA array. Specify the total transmitted power at 1000 and the transmitting antenna noise power at 100. Specify the transmitted power distribution as `'Waterfill'`. Assume that there are five randomly located scatterers. The element spacing for both arrays is one-half wavelength. The receive array is 500 wavelengths away from the transmitting array along the *x*-axis. Create a channel matrix with two subcarriers. Diagonalize the channel matrix to compute the precoding and combining weights, the distributed power, the subchannel gains, and the channel capacity sum.

Specify the 11-element transmitting ULA array. Element spacing is in units of wavelength.

```
Nt = 11;
sp = 0.5;
txpos = (0:Nt-1)*sp - (Nt-1)/2*sp;
```

Specify the 7-element receiving ULA array. Element spacing is in units of wavelength.

```
Nr = 7;
sp = 0.5;
rxpos = (0:Nr-1)*sp - (Nr-1)/2*sp;
numscat = 5;
```

Create two subcarriers.

Input Arguments

`chanmat` — Channel response matrix

N_t-by-N_r complex-valued matrix | L-by-N_t-by-N_r complex-valued MATLAB array

Channel response matrix, specified as an N_t-by-N_r complex-valued matrix or an L-by-N_t-by-N_r complex-valued MATLAB array.

- N_t is the number of elements in the transmitting array.
- N_r is the number of elements in the receiving array.
- L is the number of subcarriers.

When `chanmat` is a MATLAB array containing subcarriers, each subcarrier is decomposed independently into subchannels.

Data Types: `double`
Complex Number Support: Yes

`Pt` — Total transmit power

1 (default) | positive scalar | L-element vector of positive values

Total transmit power, specified as a positive scalar or an L-element vector of positive values. `Pt` has the same units as the total distributed power, `P`.

Data Types: `double`

`Pn` — Noise power

1 (default) | positive scalar

Noise power in each receiving antenna, specified as a positive scalar. `Pn` has the same units as the total transmit power, `Pt`.

Data Types: `double`

`powdistoption` — Power distribution option

`'Uniform'` (default) | `'Waterfill'`

Power distribution option, specified as `'Uniform'` or `'Waterfill'`. When `powdistoption` is `'Uniform'`, the transmit power is evenly distributed across all N_t channels. If `powdistoption` is `'Waterfill'`, the transmit power is distributed across the N_t channels using a waterfill algorithm.

Data Types: `char`

Output Arguments

`wp` — Precoding weights

N_t-by-N_t complex-valued matrix | L-by-N_t-by-N_t complex-valued MATLAB array

Precoding weights, returned as an N_t-by-N_t complex-valued matrix or an L-by-N_t-by-N_t complex-valued MATLAB array. Units are dimensionless.

Data Types: `double`
Complex Number Support: Yes

wc — Combining weights

N_r-by-N_r complex-valued matrix | L-by-N_r-by-N_r complex-valued MATLAB array

Combining weights, returned as an N_r-by-N_r complex-valued matrix or an L-by-N_r-by-N_r complex-valued MATLAB array. Units are dimensionless.

Data Types: `double`
Complex Number Support: Yes

P — Distributed power

1-by-N_t real-valued row vector | L-by-N_t real-valued matrix

Distributed power, returned as a vector or matrix.

- When `chanmat` is an N_t-by-N_r real-valued matrix, `P` is a 1-by-N_t real-valued row vector.
- When `chanmat` is an L-by-N_t-by-N_r real-valued MATLAB array, `P` is an L-by-N_t real-valued matrix.

Power units are linear.

Data Types: `double`

G — Subchannel gains

1-by-N_g complex-valued row vector | L-by-N_g complex-valued matrix

Subchannel gains, returned as a vector or matrix.

- When `chanmat` is an N_t-by-N_r complex-valued matrix, `G` is a 1-by-N_g complex-valued row vector.
- When `chanmat` is an L-by-N_t-by-N_r complex-valued MATLAB array, `G` is an L-by-N_g complex-valued matrix.

N_g is the smaller of N_t and N_r.

Gain units are linear.

Data Types: `double`
Complex Number Support: Yes

C — Channel capacity sum for each subcarrier

scalar | L-by-1 vector

Channel capacity sum for each subcarrier, returned as a scalar or vector.

- When `chanmat` is an N_t-by-N_r complex-valued matrix, `C` is a scalar.
- When `chanmat` is an L-by-N_t-by-N_r complex-valued MATLAB array, `C` is an L-by-1 vector.

Capacity units are in bps/Hz.

Data Types: `double`
Complex Number Support: Yes

dop2speed

Convert Doppler shift to speed

Syntax

```
radvel = dop2speed(Doppler_shift,wavelength)
```

Description

`radvel = dop2speed(Doppler_shift,wavelength)` returns the radial velocity in meters per second. This value corresponds to the one-way Doppler shift, `Doppler_shift`, for the wavelength, `wavelength`, in meters.

Examples

Calculate Speed of Car

Calculate the radial velocity of an automobile based on the Doppler shift of a continuous-wave radar. The radar carrier frequency is 24.15 GHz. Assume a doppler shift of 2.880 kHz.

```
f0 = 24.15e9;
lambda = physconst('LightSpeed')/f0;
dopshift = 2.880e3;
radvel = dop2speed(dopshift,lambda)
```

```
radvel =

   35.7516
```

The radial velocity is approximately 35.75 meters per second or 80 miles/hour.

Definitions

Doppler-Radial Velocity Relation

The radial velocity of a source relative to a receiver can be computed from the one-way Doppler shift:

$$V_{s,r} = \Delta f \lambda$$

where $V_{s,r}$ denotes the radial velocity of the source relative to the receiver, Δf is the Doppler shift in hertz, and λ is the carrier frequency wavelength in meters.

`dopsteeringvec` | `speed2dop`

Introduced in R2011a

dopsteeringvec

Doppler steering vector

Syntax

```
DSTV = dopsteeringvec(dopplerfreq,numpulses)
DSTV = dopsteeringvec(dopplerfreq,numpulses,PRF)
```

Description

`DSTV = dopsteeringvec(dopplerfreq,numpulses)` returns the N-by-1 temporal (time-domain) Doppler steering vector for a target at a normalized Doppler frequency of `dopplerfreq` in hertz. The pulse repetition frequency is assumed to be 1 Hz.

`DSTV = dopsteeringvec(dopplerfreq,numpulses,PRF)` specifies the pulse repetition frequency, `PRF`.

Input Arguments

`dopplerfreq`

The Doppler frequency in hertz. The normalized Doppler frequency is the Doppler frequency divided by the pulse repetition frequency.

`numpulses`

The number of pulses. The time-domain Doppler steering vector consists of `numpulses` samples taken at intervals of `1/PRF` (slow-time samples).

`PRF`

Pulse repetition frequency in hertz. The time-domain Doppler steering vector consists of `numpulses` samples taken at intervals of `1/PRF` (slow-time samples). The normalized Doppler frequency is the Doppler frequency divided by the pulse repetition frequency.

Output Arguments

DSTV

Temporal (time-domain) Doppler steering vector. DSTV is an N-by-1 column vector where N is the number of pulses, numpulses.

Examples

Compute Steering Vector for Doppler Shift

Calculate the steering vector corresponding to a Doppler frequency of 200 Hz. Assume there are 10 pulses and the PRF is 1 kHz.

```
dstv = dopsteeringvec(200,10,1000)
```

```
dstv =

   1.0000 + 0.0000i
   0.3090 + 0.9511i
  -0.8090 + 0.5878i
  -0.8090 - 0.5878i
   0.3090 - 0.9511i
   1.0000 - 0.0000i
   0.3090 + 0.9511i
  -0.8090 + 0.5878i
  -0.8090 - 0.5878i
   0.3090 - 0.9511i
```

Definitions

Temporal Doppler Steering Vector

The temporal (time-domain) steering vector corresponding to a point scatterer is:

$$e^{j2\pi f_d T_p n}$$

where *n=0,1,2, ..., N-1* are slow-time samples (one sample from each pulse), f_d is the Doppler frequency, and T_p is the pulse repetition interval. The product of the Doppler frequency and the pulse repetition interval is the normalized Doppler frequency.

effearthradius

Effective earth radius

Syntax

```
Re = effearthradius
Re = effearthradius(RGradient)
```

Description

`Re = effearthradius` returns the effective radius of spherical earth in meters. The calculation uses a refractivity gradient of `-39e-9`. As a result, `Re` is approximately 4/3 of the actual earth radius.

`Re = effearthradius(RGradient)` specifies the refractivity gradient.

Input Arguments

`RGradient`

Refractivity gradient in units of 1/meter. This value must be a nonpositive scalar.

Default: `-39e-9`

Output Arguments

`Re`

Effective earth radius in meters.

Definitions

Effective Earth Radius

The *effective earth radius* is a scaling of the actual earth radius. The scale factor is:

$$\frac{1}{1+r\cdot \texttt{RGradient}}$$

where r is the actual earth radius in meters and `RGradient` is the refractivity gradient. The refractivity gradient, which depends on the altitude, is the rate of change of refraction index with altitude. The *refraction index* for a given altitude is the ratio between the free-space propagation speed and the propagation speed in the air band at that altitude.

The most commonly used scale factor is 4/3. This value corresponds to a refractivity gradient of $-39\times10^{-9}\ \mathrm{m}^{-1}$.

`depressionang` | `horizonrange`

Introduced in R2011b

espritdoa

Direction of arrival using TLS ESPRIT

Syntax

```
ang = espritdoa(R,nsig)
ang = espritdoa( ___ ,Name,Value)
```

Description

`ang = espritdoa(R,nsig)` estimates the directions of arrival, `ang`, of a set of plane waves received on a uniform line array (ULA). The estimation employs the *TLS ESPRIT*, the total least-squares ESPRIT, algorithm. The input arguments are the estimated spatial covariance matrix between sensor elements, `R`, and the number of arriving signals, `nsig`. In this syntax, sensor elements are spaced one-half wavelength apart.

`ang = espritdoa( ___ ,Name,Value)` estimates the directions of arrival with additional options specified by one or more `Name,Value` pair arguments. This syntax can use any of the input arguments in the previous syntax.

Examples

Three Signals Arriving at Half-Wavelength-Spaced ULA

Assume a half-wavelength spaced uniform line array with 10 elements. Three plane waves arrive from the 0°, –25°, and 30° azimuth directions. Elevation angles are 0°. The noise is spatially and temporally white. The SNR for each signal is 5 dB. Find the arrival angles.

```
N = 10;
d = 0.5;
elementPos = (0:N-1)*d;
angles = [0 -25 30];
Nsig = 3;
R = sensorcov(elementPos,angles,db2pow(-5));
doa = espritdoa(R,Nsig)
```

```
doa =

   30.0000    0.0000  -25.0000
```

The `espritdoa` function returns the correct angles.

Three Signals Arriving at 0.4-Wavelength-Spaced ULA

Assume a uniform line array with 10 elements. The element spacing is 0.4 wavelength. Three plane waves arrive from the 0°, –25°, and 30° azimuth directions. Elevation angles are 0°. The noise is spatially and temporally white. The SNR for each signal is 5 dB. Find the arrival angles.

```
N = 10;
d = 0.4;
elementPos = (0:N-1)*d;
angles = [0 -25 30];
Nsig = 3;
R = sensorcov(elementPos,angles,db2pow(-5));
doa = espritdoa(R,Nsig,'ElementSpacing',d)
```

```
doa =

  -25.0000   -0.0000   30.0000
```

`espritdoa` returns the correct angles.

Input Arguments

`R` — Spatial covariance matrix

complex-valued positive-definite *N*-by-*N* matrix.

Spatial covariance matrix, specified as a complex-valued, positive-definite, *N*-by-*N* matrix. In this matrix, *N* represents the number of elements in the ULA array. If `R` is not Hermitian, a Hermitian matrix is formed by averaging the matrix and its conjugate transpose, `(R+R')/2`.

Example: [4.3162, –0.2777 – 0.2337i; –0.2777 + 0.2337i , 4.3162]

Data Types: `double`
Complex Number Support: Yes

`nsig` — Number of arriving signals

positive integer

Number of arriving signals, specified as a positive integer.

Example: 3

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: 'ElementSpacing', 0.45

`'ElementSpacing'` — ULA element spacing

0.5 (default) | real-valued positive scalar

ULA element spacing, specified as a real-valued, positive scalar. Position units are measured in terms of signal wavelength.

Example: 0.4

Data Types: `double`

`'RowWeighting'` — Row weights

1 (default) | real-valued positive scalar

Row weights specified as a real-valued positive scalar. These weights are applied to the selection matrices which determine the ESPRIT subarrays. A larger value is generally better but the value must be less than or equal to $(N_s–1)/2$, where N_s is the number of subarray elements. The number of subarray elements is $N_s = N–1$. The value of N is the number of ULA elements, as specified by the dimensions of the spatial covariance matrix, `R`. A detailed discussion of selection matrices and row weighting can be found in Van Trees [1], p. 1178.

Example: 5

Data Types: `double`

Output Arguments

`ang` — Directions of arrival angles

real-valued 1-by-*M* row vector

Directions of arrival angle returned as a real-valued, 1-by-*M* vector. The dimension *M* is the number of arriving signals specified in the argument, `nsig`. This angle is the broadside angle. Angle units are degrees and angle values lie between –90° and 90°.

fogpl

RF signal attenuation due to fog and clouds

Syntax

```
L = fogpl(R,freq,T,den)
```

Description

`L = fogpl(R,freq,T,den)` returns attenuation, `L`, when signals propagate in fog or clouds. `R` represents the signal path length. `freq` represents the signal carrier frequency, `T` is the ambient temperature, and `den` specifies the liquid water density in the fog or cloud.

The `fogpl` function applies the International Telecommunication Union (ITU) cloud and fog attenuation model to calculate path loss of signals propagating through clouds and fog [1]. Fog and clouds are the same atmospheric phenomenon, differing only by height above ground. Both environments are parameterized by their liquid water density. Other model parameters include signal frequency and temperature. This function applies when the signal path is contained entirely in a uniform fog or cloud environment. The liquid water density does not vary along the signal path. The attenuation model applies only for frequencies at 10–1000 GHz.

Examples

Attenuation in Cumulus Clouds

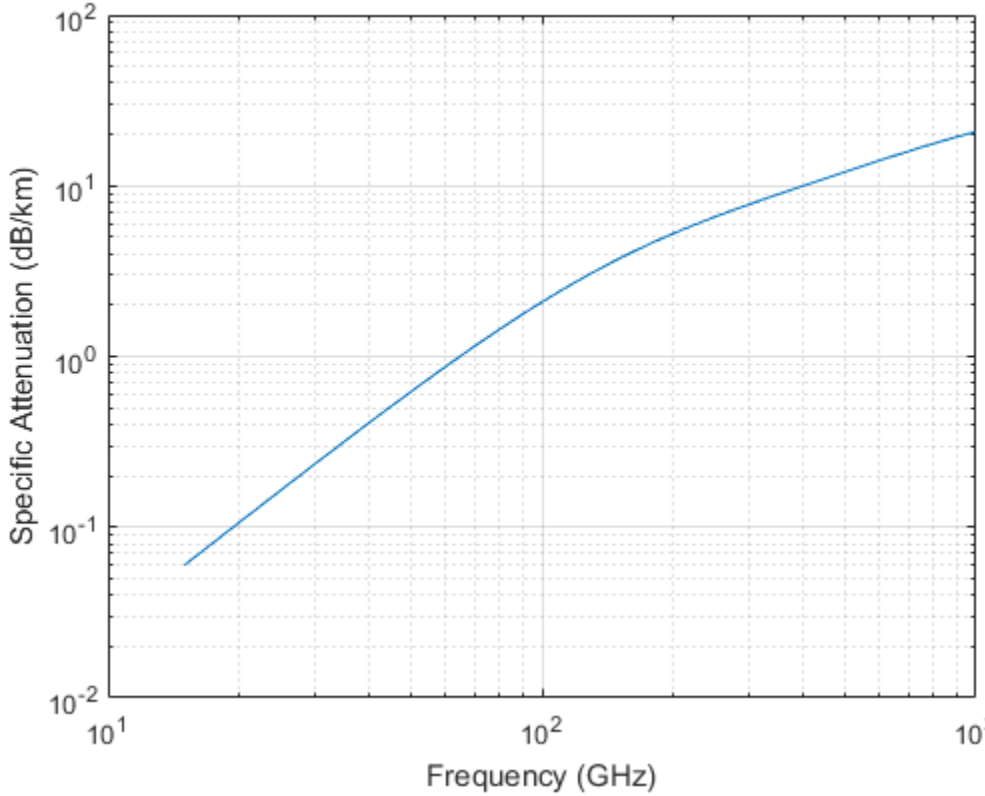
Compute the attenuation of signals propagating through a cloud that is 1 km long at 1000 meters altitude. Compute the attenuation for frequencies from 15 to 1000 GHz.

A typical value for the cloud liquid water density is 0.5 g/m^3. Assume the atmospheric temperature at 1000 meters is 20°C.

```
R = 1000.0;
freq = [15:5:1000]*1e9;
T = 20.0;
lwd = 0.5;
L = fogpl(R,freq,T,lwd);
```

Plot the specific attenuation as a function of frequency. Specific attenuation is the attenuation or loss per kilometer.

```
loglog(freq/1e9,L)
grid
xlabel('Frequency (GHz)')
ylabel('Specific Attenuation (dB/km)')
```



Input Arguments

R — Signal path length

positive real-valued scalar | *M*-by-1 nonnegative real-valued vector | 1-by-*M* nonnegative real-valued vector

Signal path length, specified as a scalar or as an *M*-by-1 or 1-by-*M* vector of nonnegative real-values. Total attenuation is the specific attenuation multiplied by the path length. Units are meters.

Example: `[1300.0,1400.0]`

`freq` — Signal frequency

positive real-valued scalar | *N*-by-1 nonnegative real-valued column vector | 1-by-*N* nonnegative real-valued row vector

Signal frequency, specified as a positive real-valued scalar or as an *N*-by-1 nonnegative real-valued vector or 1-by-*N* nonnegative real-valued vector. Frequencies must lie in the range 10–1000 GHz.

Example: `[14.0e9,15.0e9]`

`T` — Ambient temperature

real-valued scalar

Ambient temperature in fog or cloud, specified as a real-valued scalar. Units are in degrees Celsius.

Example: `-10.0`

`den` — Liquid water density

nonnegative real-valued scalar

Liquid water density, specified as a nonnegative real-valued scalar. Units are g/m^3. Typical values for liquid water density in fog range from approximately 0.05 g/m^3 for medium fog to approximately 0.5 g/m^3 for thick fog. For medium fog, visibility is about 50 meters. For heavy fog, visibility is about 300 meters. Cumulus cloud liquid water density is typically 0.5 g/m^3.

Example: `0.01`

Output Arguments

`L` — Signal attenuation

real-valued *M*-by-*N* matrix

Signal attenuation, returned as a real-valued *M*-by-*N* matrix. Each matrix row represents a different path where *M* is the number of paths. Each column represents a different frequency where *N* is the number of frequencies. Units are in dB.

Definitions

Fog and Cloud Attenuation Model

This model calculates the attenuation of signals that propagate through fog or clouds.

Fog and cloud attenuation are the same atmospheric phenomenon. Phased Array System Toolbox uses the ITU model, *Recommendation ITU-R P.840-6: Attenuation due to clouds and fog*. The model computes the specific attenuation (attenuation per kilometer), of a signal as a function of liquid water density, signal frequency, and temperature. The model applies to polarized and nonpolarized fields. The formula for specific attenuation at each frequency is

$$\gamma_c = K_l(f)M,$$

where M is the liquid water density in gm/m^3. The quantity $K_l(f)$ is the specific attenuation coefficient and depends on frequency. The cloud and fog attenuation model is valid for frequencies 10–1000 GHz. Units for the specific attenuation coefficient are (dB/km)/(g/m^3).

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length R. Total attenuation is $L_c = R\gamma_c$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply narrowband attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

`fspl` | `gaspl` | LOSChannel | `rainpl` | WidebandLOSChannel

Introduced in R2016a

fspl

Free space path loss

Syntax

```
L = fspl(R,lambda)
```

Description

`L = fspl(R,lambda)` returns the free space path loss in decibels for a waveform with wavelength `lambda` propagated over a distance of `R` meters. The minimum value of `L` is zero, indicating no path loss.

Input Arguments

`R`

real-valued 1-by-*M* or *M*-by-1 vector

Propagation distance of signal. Units are in meters.

`lambda`

real-valued 1-by-*N* or *N*-by-1 vector

The wavelength is the speed of propagation divided by the signal frequency. Wavelength units are meters.

Output Arguments

`L`

Path loss in decibels. *M*-by-*N* nonnegative matrix. A value of zero signifies no path loss. When `lambda` is a scalar, `L` has the same dimensions as `R`.

Examples

Calculate Free-Space Path Loss

Calculate the free-space path loss (in dB) of a 10 GHz radar signal over a distance of 10 km.

```
fc = 10.0e9;
lambda = physconst('LightSpeed')/fc;
R = 10e3;
L = fspl(R,lambda)
```

```
L =

  132.4478
```

Definitions

Free Space Path Loss

The free-space path loss, L, in decibels is:

$$L = 20\log_{10}\left(\frac{4\pi R}{\lambda}\right)$$

This formula assumes that the target is in the far-field of the transmitting element or array. In the near-field, the free-space path loss formula is not valid and can result in a loss smaller than 0 dB, equivalent to a signal gain. For this reason, the loss is set to 0 dB for range values $R \le \lambda/4\pi$.

gain2aperture

Convert gain to effective aperture

Syntax

```
A = gain2aperture(G,lambda)
```

Description

`A = gain2aperture(G,lambda)` returns the effective aperture in square meters corresponding to a gain of `G` decibels for an incident electromagnetic wave with wavelength `lambda` meters. `G` can be a scalar or vector. If `G` is a vector, `A` is a vector of the same size as `G`. The elements of `A` represent the effective apertures for the corresponding elements of `G`. `lambda` must be a scalar.

Input Arguments

`G`

Antenna gain in decibels. `G` is a scalar or a vector. If `G` is a vector, each element of `G` is the gain in decibels of a single antenna.

`lambda`

Wavelength of the incident electromagnetic wave. The wavelength of an electromagnetic wave is the ratio of the wave propagation speed to the frequency. For a fixed effective aperture, the antenna gain is inversely proportional to the square of the wavelength. `lambda` must be a scalar.

Output Arguments

`A`

Antenna effective aperture in square meters. The effective aperture describes how much energy is captured from an incident electromagnetic plane wave. The argument describes

the functional area of the antenna and is not equivalent to the actual physical area. For a fixed wavelength, the antenna gain is proportional to the effective aperture. `A` can be a scalar or vector. If `A` is a vector, each element of `A` is the effective aperture of the corresponding gain in `G`.

Examples

Compute Effective Aperture

An antenna has a gain of 3 dB. Calculate the antenna's effective aperture when used to capture an electromagnetic wave with a wavelength of 10 cm.

```
a = gain2aperture(3,0.1)
```

```
a =

    0.0016
```

Definitions

Gain and Effective Aperture

The relationship between the gain, *G*, in decibels of an antenna and the antenna's effective aperture is:

$$A_e = 10^{G/10}\frac{\lambda^2}{4\pi}$$

where λ is the wavelength of the incident electromagnetic wave.

`aperture2gain`

Introduced in R2011a

gaspl

RF signal attenuation due to atmospheric gases

Syntax

```
L = gaspl(range,freq,T,P,den)
```

Description

`L = gaspl(range,freq,T,P,den)` returns the attenuation, `L`, when signals propagate through the atmosphere. `range` represents the signal path length, and `freq` represents the signal carrier frequency. `T` represents the ambient temperature, `P` represents the atmospheric pressure, and `den` represents the atmospheric water vapor density.

The `gaspl` function applies the International Telecommunication Union (ITU) atmospheric gas attenuation model [1] to calculate path loss for signals primarily due to oxygen and water vapor. The model computes attenuation as a function of ambient temperature, pressure, water vapor density, and signal frequency. The function requires that the signal path is contained entirely in a uniform environment. Atmospheric parameters do not vary along the signal path. The attenuation model applies only for frequencies at 1–1000 GHz.

Examples

Atmospheric Gas Attenuation Spectrum

Compute the attenuation spectrum from 1–1000 GHz for an atmospheric pressure of 101.300 kPa and a temperature of 15°C. Plot the spectrum for a water vapor density of 7.5 g/m^3 and then plot the spectrum for dry air (zero water vapor density).

Set the attenuation frequencies.

```
freq = [1:1000]*1e9;
```

Assume a 1 km path distance.

```
R = 1000.0;
```

Compute the attenuation for air containing water vapor.

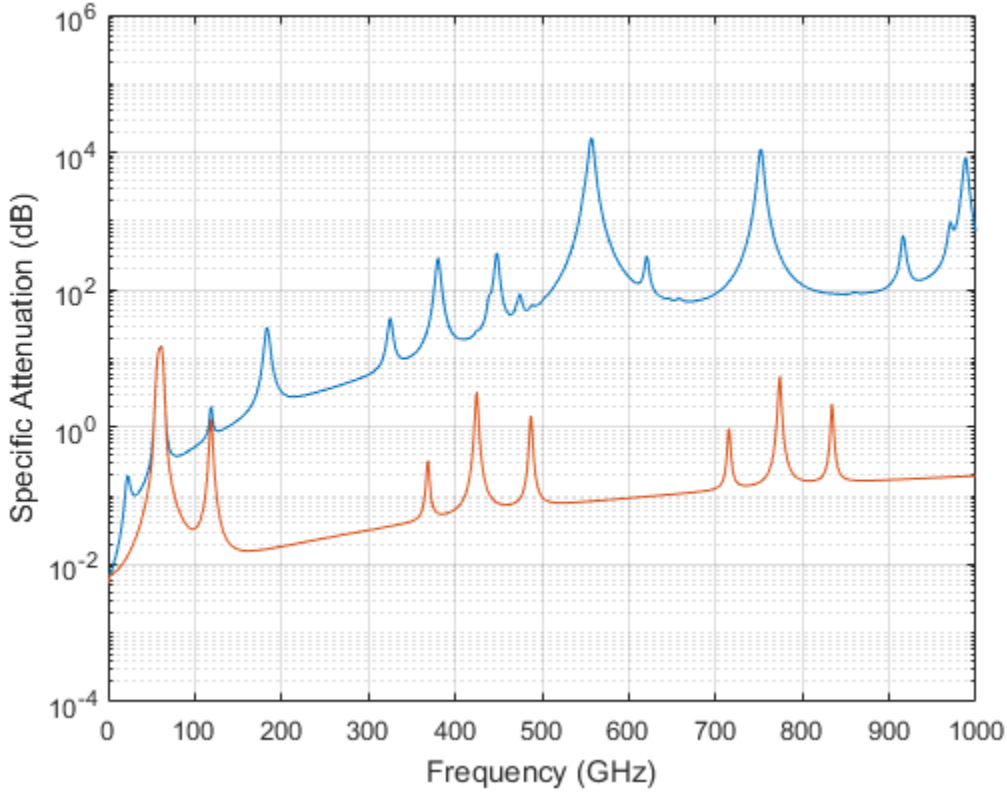
```
T = 15;
P = 101300.0;
W = 7.5;
L = gaspl(R,freq,T,P,W);
```

Compute the attenuation for dry air.

```
L0 = gaspl(R,freq,T,P,0.0);
```

Plot the attenuations.

```
semilogy(freq/1e9,L)
hold on
semilogy(freq/1e9,L0)
grid
xlabel('Frequency (GHz)')
ylabel('Specific Attenuation (dB)')
hold off
```



Plot Attenuation Due to Atmospheric Gases and Free Space

First, plot the specific attenuation of atmospheric gases for frequencies from 1 GHz to 1000 GHz. Assume a sea-level dry air pressure of 101.325e5 kPa and a water vapor density of 7.5 g/m^3. The air temperature is 20 Celsius. Specific attenuation is defined as dB loss per kilometer. Then, plot the actual attenuation at 10 GHz for a span of ranges.

Plot Specific Atmospheric Gas Attenuation

Set the atmosphere temperature, pressure, water vapor density.

```
T = 20.0;
Patm = 101.325e3;
```

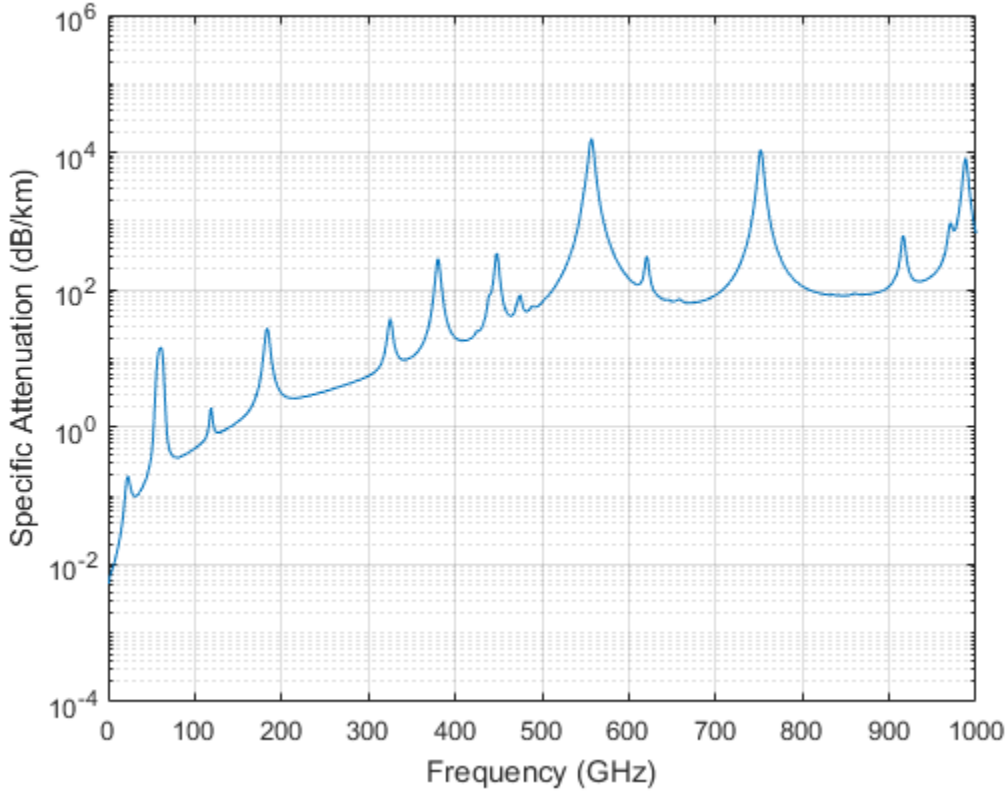
```
rho_wv = 7.5;
```

Set the propagation distance, speed of light, and frequencies.

```
km = 1000.0;
c = physconst('LightSpeed');
freqs = [1:1000]*1e9;
```

Compute and plot the atmospheric gas loss.

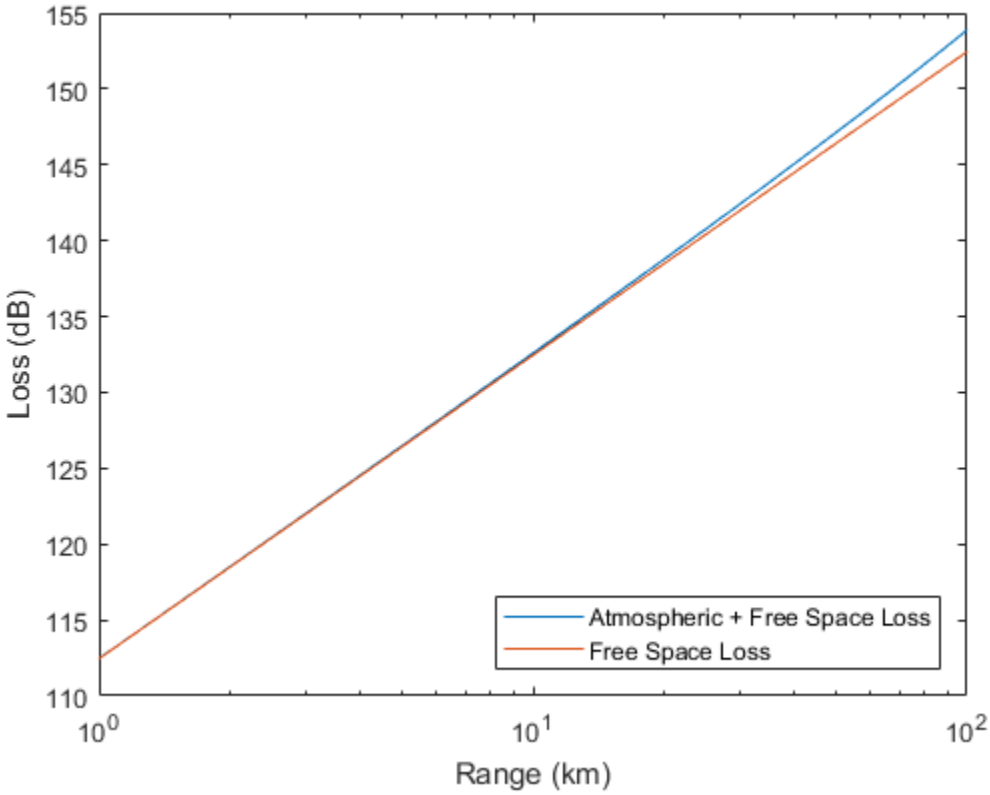
```
loss = gaspl(km,freqs,T,Patm,rho_wv);
semilogy(freqs/1e9,loss)
grid on
xlabel('Frequency (GHz)')
ylabel('Specific Attenuation (dB/km)')
```



Plot Actual Atmospheric and Free Space Attenuation

Compute both free space loss and atmospheric gas loss at 10 GHz for ranges from 1–100 km. The frequency corresponds to an *X*-band radar. Then, plot the free space loss and the total (atmospheric + free space) loss.

```
ranges = [1:100]*1000;
freq_xband = 10e9;
loss_gas = gaspl(ranges,freq_xband,T,Patm,rho_wv);
lambda = c/freq_xband;
loss_fsp = fspl(ranges,lambda);
semilogx(ranges/1000,loss_gas + loss_fsp.',ranges/1000,loss_fsp)
legend('Atmospheric + Free Space Loss','Free Space Loss','Location','SouthEast')
xlabel('Range (km)')
ylabel('Loss (dB)')
```



Input Arguments

`range` — Signal path length

nonnegative real-valued scalar | *M*-by-1 nonnegative real-valued column vector | 1-by-*M* nonnegative real-valued row vector

Signal path length used to compute attenuation, specified as a nonnegative real-valued scalar or vector. You can specify multiple path lengths simultaneously. Units are in meters.

Example: `[13000.0,14000.0]`

`freq` — Signal frequency

positive real-valued scalar | *N*-by-1 nonnegative real-valued column vector | 1-by-*N* nonnegative real-valued row vector

Signal frequency, specified as a positive real-valued scalar, or as an *N*-by-1 nonnegative real-valued vector or 1-by-*N* nonnegative real-valued vector. You can specify multiple frequencies simultaneously. Frequencies must lie in the range 1–1000 GHz. Units are in hertz.

Example: `[1.4e9,2.0e9]`

`T` — Ambient temperature

real-valued scalar

Ambient temperature, specified as a real-valued scalar. Units are in degrees Celsius.

Example: `-10.0`

`P` — Ambient pressure

positive real-valued scalar

Ambient pressure, specified as a positive real-valued scalar. Units are in Pascals. One standard atmosphere at sea level is 101.325 kPa.

Example: `101300.0`

`den` — Water vapor density

nonnegative real-valued scalar

Water vapor density or absolute humidity, specified as a nonnegative real-valued scalar. Units are g/m^3. The maximum water vapor density of air at 30° C is approximately 30.0 g/m^3. The maximum water vapor density of air at 0°C is approximately 5.0 g/m^3.

Example: `4.0`

Output Arguments

`L` — Signal attenuation

real-valued *M*-by-*N* matrix

Signal attenuation, returned as a real-valued *M*-by-*N* matrix. Each matrix row represents a different path where *M* is the number of paths. Each column represents a different frequency where *N* is the number of frequencies. Units are in dB.

Definitions

Atmospheric Gas Attenuation Model

This model calculates the attenuation of signals that propagate through atmospheric gases.

Electromagnetic signals attenuate when they propagate through the atmosphere. This effect is due primarily to the absorption resonance lines of oxygen and water vapor, with smaller contributions coming from nitrogen gas. The model also includes a continuous absorption spectrum below 10 GHz. Phased Array System Toolbox uses the ITU model *Recommendation ITU-R P.676-10: Attenuation by atmospheric gases*. The model computes the specific attenuation (attenuation per kilometer) as a function of temperature, pressure, water vapor density, and signal frequency. The atmospheric gas model is valid for frequencies from 1–1000 GHz and applies to polarized and nonpolarized fields.

The formula for specific attenuation at each frequency is

$$\gamma = \gamma_o(f) + \gamma_w(f) = 0.1820 f N''(f).$$

The quantity $N''()$ is the imaginary part of the complex atmospheric refractivity. It consists of a spectral line component and a continuous component:

$$N''(f) = \sum_i S_i F_i + N_D''(f)$$

The spectral component consists of a sum of discrete spectrum terms composed of a localized frequency bandwidth function, $F(f)_i$, multiplied by a spectral line strength, S_i. For atmospheric oxygen, each spectral line strength is

$$S_i = a_1 \times 10^{-7} \left(\frac{300}{T}\right)^3 \exp\left[a_2 \left(1 - \left(\frac{300}{T}\right)\right)\right] P.$$

For atmospheric water vapor, each spectral line strength is

$$S_i = b_1 \times 10^{-1}\left(\frac{300}{T}\right)^{3.5} \exp\left[b_2\left(1-\left(\frac{300}{T}\right)\right)\right] W.$$

P is the atmospheric pressure, W is the water vapor density, and T is the ambient temperature.

For each oxygen line, S_i depends on constants a_1 and a_2. Similarly, each water vapor line has constants b_1 and b_2. The ITU documentation cited at the end of this section contains tabulations of these constants.

The localized frequency bandwidth functions $F_i(f)$ are complicated functions of frequency described in the ITU references cited below. The functions depend on empirical model parameters that are also tabulated in the reference.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length, R. Then, the total attenuation is $L_g = R(\gamma_o + \gamma_w)$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

`fogpl` | `fspl` | LOSChannel | `rainpl` | WidebandLOSChannel

Introduced in R2016a

gccphat

Generalized cross-correlation

Syntax

```
tau = gccphat(sig,refsig)
tau = gccphat(sig,refsig,fs)
[tau,R,lag] = gccphat( ___ )

[ ___ ] = gccphat(sig)
[ ___ ] = gccphat(sig,fs)
```

Description

`tau = gccphat(sig,refsig)` computes the time delay, `tau`, between the signal, `sig`, and a reference signal, `refsig`. Both `sig` and `refsig` can have multiple channels. The function assumes that the signal and reference signal come from a single source. To estimate the delay, `gccphat` finds the location of the peak of the cross-correlation between `sig` and `refsig`. The cross-correlation is computed using the generalized cross-correlation phase transform (GCC-PHAT) algorithm. Time delays are multiples of the sample interval corresponding to the default sampling frequency of one hertz.

`tau = gccphat(sig,refsig,fs)`, specifies the sampling frequency of the signal. Time delays are multiples of the sample interval corresponding to the sampling frequency. All input signals should have the same sample rate.

`[tau,R,lag] = gccphat( ___ )` returns, in addition, the cross-correlation values and correlation time lags, using any of the arguments from previous syntaxes. The lags are multiples of the sampling interval. The number of cross-correlation channels equals the number of channels in `sig`.

`[ ___ ] = gccphat(sig)` or `[ ___ ] = gccphat(sig,fs)` returns the estimated delays and cross correlations between all pairs of channels in `sig`. If `sig` has M columns, the resulting `tau` and `R` have M^2 columns. In these syntaxes, no reference signal input is used. The first M columns of `tau` and `R` contain the delays and cross correlations that use

the first channel as the reference. The second *M* columns contain the delays and cross-correlations that use the second channel as the reference, and so on.

Examples

Cross-Correlation Between Two Signals and Reference Signal

Load a gong sound signal. First, use the gong signal as a reference signal. Then, duplicate the signal twice, introducing time delays of 5 and 25 seconds. Leave the sampling rate to its default of one hertz. Use `gccphat` to estimate the time delays between the delayed signals and the reference signal.

```
load gong;
refsig = y;
delay1 = 5;
delay2 = 25;
sig1 = delayseq(refsig,delay1);
sig2 = delayseq(refsig,delay2);
tau_est = gccphat([sig1,sig2],refsig)
```

```
tau_est =

     5    25
```

Cross-Correlation Between Signal and Reference Signal

Load a gong sound signal. Use the gong signal as a reference signal. Then, duplicate the signal, introducing a time delays of 5 milliseconds. Use the sampling rate of 8192 Hz. Use `gccphat` to estimate the time delay between the delayed signal and the reference signal.

```
load gong;
delay = 0.005;
refsig = y;
sig = delayseq(refsig,delay,Fs);
tau_est = gccphat(sig,refsig,Fs)
```

```
tau_est =

    0.0050
```

Plot Cross-Correlation of Three Signals with Reference Signal

Load a musical sound signal with a sample rate is 8192 hertz. Then, duplicate the signal three times and introduce time delays between the signals. Estimate the time delays between the delayed signals and the reference signals. Plot the correlation values.

```
load handel;
dt = 1/Fs;
refsig = y;
```

Create three delayed versions of the signal.

```
delay1 = -5.2*dt;
delay2 = 10.3*dt;
delay3 = 7*dt;
sig1 = delayseq(refsig,delay1,Fs);
sig2 = delayseq(refsig,delay2,Fs);
sig3 = delayseq(refsig,delay3,Fs);
```

Cross-correlate the delayed signals with the reference signal.

```
[tau_est,R,lags] = gccphat([sig1,sig2,sig3],refsig,Fs);
```

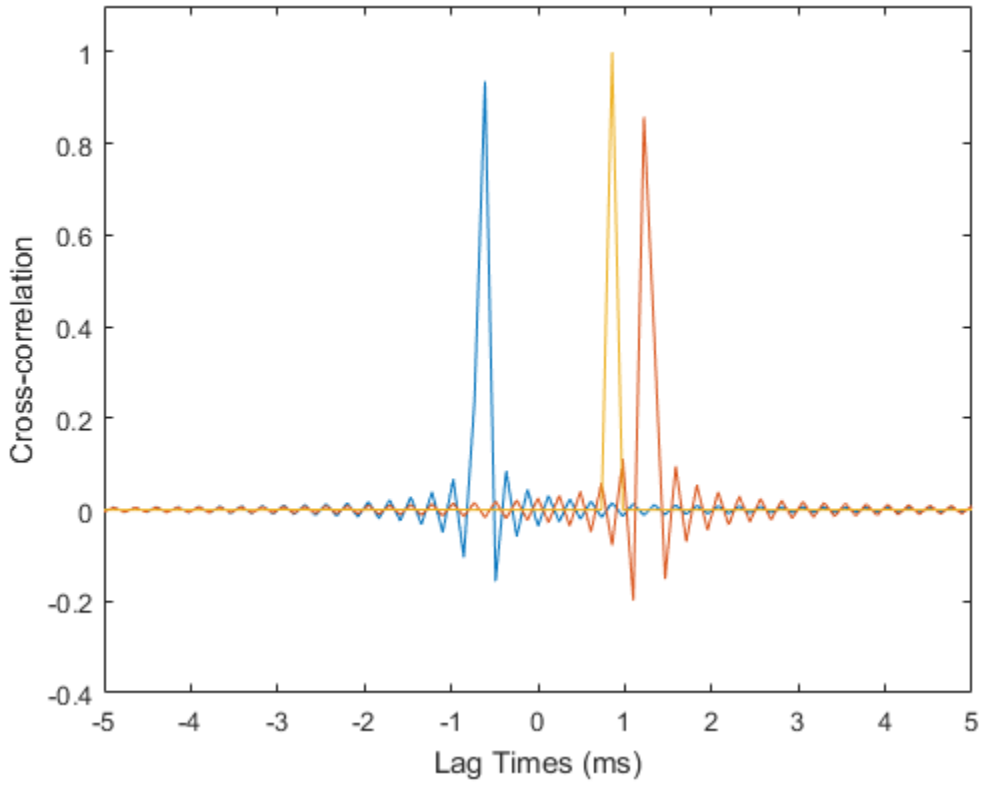
The `gccphat` functions estimates the delay to the nearest sample interval.

```
disp(tau_est*Fs)
```

```
    -5    10     7
```

Plot the correlation functions.

```
plot(1000*lags,real(R(:,1)))
xlabel('Lag Times (ms)')
ylabel('Cross-correlation')
axis([-5,5,-.4,1.1])
hold on
plot(1000*lags,real(R(:,2)))
plot(1000*lags,real(R(:,3)))
hold off
```



Plot Cross-Correlation of Several Signals

Load a musical sound signal with a sample rate is 8192 hertz. Then, duplicate the signal two times and introduce time delays between the two signals and the reference signal. Estimate the time delays and plot the cross-correlation function between all pairs of signals.

```
load handel;
dt = 1/Fs;
refsig = y;
```

Create three delayed versions of the signal.

```
delay1 = -5.7*dt;
```

```
delay2 = 10.2*dt;
sig1 = delayseq(refsig,delay1,Fs);
sig2 = delayseq(refsig,delay2,Fs);
```

Cross-correlate all signals with the other signal.

```
[tau_est,R,lags] = gccphat([refsig,sig1,sig2],Fs);
```

Show the time delays in units of sample interval. The algorithm estimates time delays quantized to the nearest sample interval. Cross-correlation of three signals produce 9 possible time delays, one for each possible signal pair.

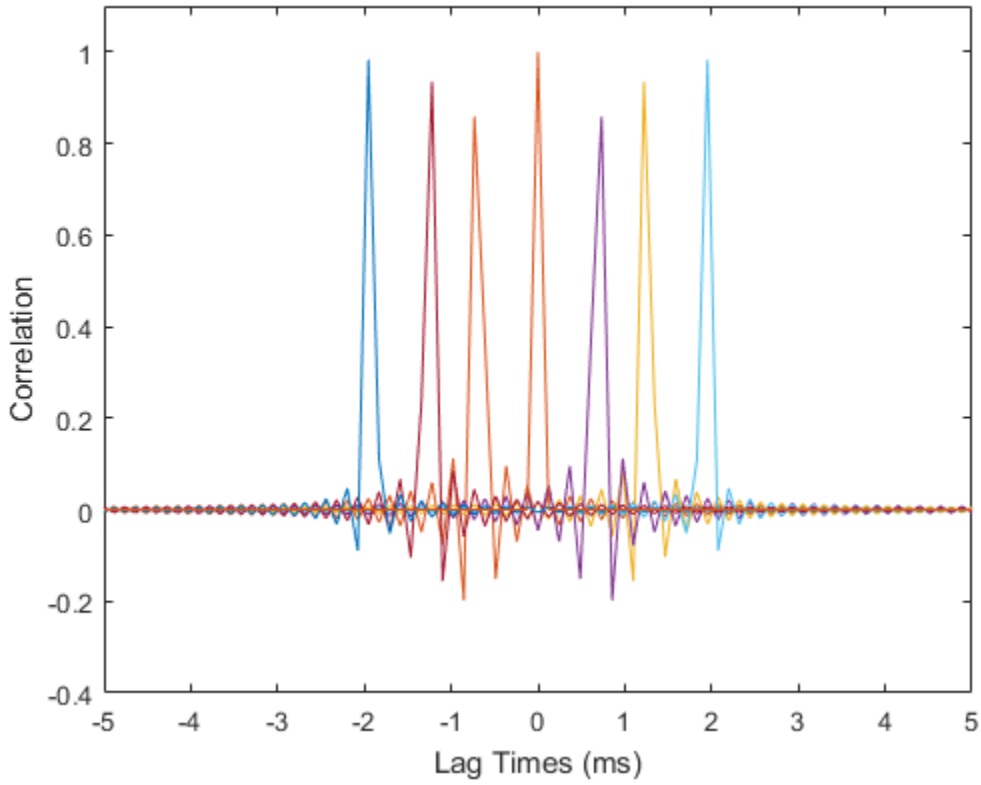
```
disp(tau_est*Fs)
```

```
     0    -6    10     6     0    16   -10   -16     0
```

A signal correlated with itself gives zero lag.

Plot the correlation functions.

```
for n=1:9
    plot(1000*lags,real(R(:,n)))
    if n==1
        hold on
        xlabel('Lag Times (ms)')
        ylabel('Correlation')
        axis([-5,5,-.4,1.1])
    end
end
hold off
```



Input Arguments

`sig` — Sensor signals

N-by-1 complex-valued column vector | *N*-by-*M* complex-valued matrix

Sensor signals, specified as an *N*-by-1 column vector or an *N*-by-*M* matrix. *N* is the number of time samples and *M* is the number of channels. If `sig` is a matrix, each column is a different channel.

Example: `[0,1,2,3,2,1,0]`

Data Types: `double`

Complex Number Support: Yes

`refsig` — Reference sensor signals

N-by-1 complex-valued column vector | *N*-by-*M* complex-valued matrix

Reference signals, specified as an *N*-by-1 complex-valued column vector or an *N*-by-*M* complex-valued matrix. If `refsig` is a column vector, then all channels in `sig` use `refsig` as the reference signal when computing the cross-correlation.

If `refsig` is a matrix, then the size of `refsig` must match the size of `sig`. The `gccphat` function computes the cross-correlation between corresponding channels in `sig` and `refsig`. The signals can come from different sources.

Example: `[1,2,3,2,1,0,0]`

Data Types: `double`
Complex Number Support: Yes

`fs` — Signal sample rate

1 (default) | positive real-valued scalar

Signal sample rate, specified as a positive real-valued scalar. All signals should have the same sample rate. Sample rate units are in hertz.

Example: 8000

Data Types: `double`
Complex Number Support: Yes

Output Arguments

`tau` — Time delay

1-by-*K* real-valued row vector

Time delay, returned as a 1-by-*K* real-valued row vector. The value of *K* depends upon the input argument syntax.

- When a reference signal, `refsig`, is used, the value of *K* equals the column dimension of `sig`, *M*. Each entry in `tau` specifies the estimated delay for the corresponding signal pairs in `sig` and `refsig`.
- When no reference signal is used, the value of *K* equals the square of the column dimension of `sig`, M^2. Each entry in `tau` specifies the estimated delay for the corresponding signal pairs in `sig`.

Units are seconds.

`R` — Cross-correlation between signals
(2*N*+1)-by-*K* complex-valued matrix

Cross-correlation between signals at different sensors, returned as a (2*N*+1)-by-*K* complex-valued matrix.

- When a reference signal, `refsig`, is used, the value of *K* equals the column dimension of `sig`, *M*. Each column is the cross-correlation between the corresponding signal pairs in `sig` and `refsig`.
- When no reference signal is used, the value of *K* equals the square of the column dimension of `sig`, M^2. Each column is the cross-correlation between the corresponding signal pairs in `sig`.

`lag` — Cross-correlation lag times
(2*N*+1) real-valued column vector

Correlation lag times, returned as a *(2N+1)* real-valued column vector. Each row of `lag` contains the lag time for the corresponding row of `R`. Lag values are constrained to be multiples of the sampling interval. Lag units are in seconds.

Definitions

Generalized Cross-Correlation

You can use generalized cross-correlation to estimate the time difference of arrival of a signal at two different sensors.

A model of a signal emitted by a source and received at two sensors is given by:

$$r_1(t) = s(t) + n_1(t)$$
$$r_2(t) = s(t - D) + n_2(t)$$

where *D* is the time difference of arrival (*TDOA*), or time lag, of the signal at one sensor with respect to the arrival time at a second sensor. You can estimate the time delay by finding the time lag that maximizes the cross-correlation between the two signals.

From the TDOA, you can estimate the broadside arrival angle of the plane wave with respect to the line connecting the two sensors. For two sensors separated by distance L, the broadside arrival angle, "Broadside Angles", is related to the time lag by

$$\sin\beta = \frac{c\tau}{L}$$

where c is the propagation speed in the medium.

A common method of estimating time delay is to compute the cross-correlation between signals received at two sensors. To identify the time delay, locate the peak in the cross-correlation. When the signal-to-noise ratio (SNR) is large, the correlation peak, τ, corresponds to the actual time delay D.

$$R(\tau) = E\{r_1(t)r_2(t+\tau)\}$$
$$D = \arg\max_{\tau} R(\tau)$$

When the correlation function is more sharply peaked, performance improves. You can sharpen a cross correlation peak using a weighting function that whitens the input signals. This technique is called *generalized cross-correlation*(GCC). One particular weighting function normalizes the signal spectral density by the spectrum magnitude, leading to the *generalized cross-correlation phase transform* method (*GCC-PHAT*).

$$S(f) = \int_{-\infty}^{\infty} R(\tau)e^{-i2\pi f\tau}d\tau$$
$$\tilde{R}(\tau) = \int_{-\infty}^{\infty} \frac{S(f)}{|S(f)|}e^{+i2\pi f\tau}df$$
$$\tilde{D} = \arg\max_{\tau} \tilde{R}(\tau)$$

If you use just two sensor pairs, you can only estimate the broadside angle of arrival. However, if you use multiple pairs of non-collinear sensors, for example, in a URA, you can estimate the arrival azimuth and elevation angles of the plane wave using least-square estimation. For N sensors, you can write the delay time τ_{kj} of a signal arriving at the k^{th} sensor with respect to the j^{th} sensor by

$$c\tau_{kj} = -\left(\vec{x}_k - \vec{x}_j\right)\cdot\vec{u}$$
$$\vec{u} = \cos\alpha\sin\theta i + \sin\alpha\sin\theta j + \cos\theta k$$

where u is the unit propagation vector of the plane wave. The angles α and θ are the azimuth and elevation angles of the propagation vector. All angles and vectors are defined with respect to the local axes. You can solve the first equation using least-squares to yield the three components of the unit propagation vector. Then, you can solve the second equation for the azimuth and elevation angles.

global2localcoord

Convert global to local coordinates

Syntax

```
lclCoord = global2localcoord(gCoord, OPTION)
gCoord = global2localcoord( ___ ,localOrigin)
gCoord = global2localcoord( ___ ,localAxes)
```

Description

`lclCoord = global2localcoord(gCoord, OPTION)` returns the local coordinate `lclCoord` corresponding to the global coordinate `gCoord`. `OPTION` determines the type of global-to-local coordinate transformation.

`gCoord = global2localcoord( ___ ,localOrigin)` specifies the origin of the local coordinate system.

`gCoord = global2localcoord( ___ ,localAxes)` specifies the axes of the local coordinate system.

Input Arguments

`gCoord`

Global coordinates in rectangular or spherical coordinate form. `gCoord` is a 3-by-1 vector or 3-by-N matrix. Each column represents a global coordinate.

If the coordinates are in rectangular form, the column represents (*X*,*Y*,*Z*) in meters.

If the coordinates are in spherical form, the column represents (*az*,*el*,*r*). *az* is the azimuth angle in degrees, *el* is the elevation angle in degrees, and *r* is the radius in meters.

The origin of the global coordinate system is at [0; 0; 0]. That system's axes are the standard unit basis vectors in three-dimensional space, [1; 0; 0], [0; 1; 0], and [0; 0; 1].

`OPTION`

Type of coordinate transformation. Valid types are

OPTION	Transformation
`'rr'`	Global rectangular to local rectangular
`'rs'`	Global rectangular to local spherical
`'sr'`	Global spherical to local rectangular
`'ss'`	Global spherical to local spherical

`localOrigin`

Origin of local coordinate system. `localOrigin` is a 3-by-1 column vector containing the rectangular coordinate of the local coordinate system origin with respect to the global coordinate system.

Default: `[0; 0; 0]`

`localAxes`

Axes of local coordinate system. `localAxes` is a 3-by-3 matrix with the columns specifying the local X, Y, and Z axes in rectangular form with respect to the global coordinate system.

Default: `[1 0 0;0 1 0;0 0 1]`

Output Arguments

`lclCoord`

Local coordinates in rectangular or spherical coordinate form.

Examples

Convert Global Coordinates to Local Coordinates

Convert global rectangular coordinates, *(0,1,0)*, to local rectangular coordinates. The local coordinate origin is *(1,1,1)*.

```
lclCoord = global2localcoord([0;1;0],'rr',[1;1;1])
```

```
lclCoord =

    -1
     0
    -1
```

Convert global spherical coordinates to local rectangular coordinates.

```
lclCoord = global2localcoord([45;45;50],'sr',[50;50;50])
```

```
lclCoord =

  -25.0000
  -25.0000
  -14.6447
```

Definitions

Azimuth Angle, Elevation Angle

The *azimuth angle* of a vector is the angle between the x-axis and the orthogonal projection of the vector onto the xy plane. The angle is positive in going from the x axis toward the y axis. Azimuth angles lie between –180 and 180 degrees. The *elevation angle* is the angle between the vector and its orthogonal projection onto the xy-plane. The angle is positive when going toward the positive z-axis from the xy plane. These definitions assume the boresight direction is the positive x-axis.

Note: The elevation angle is sometimes defined in the literature as the angle a vector makes with the positive z-axis. The MATLAB and Phased Array System Toolbox products do not use this definition.

This figure illustrates the azimuth angle and elevation angle for a vector that appears as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue circles.

grazingang

Grazing angle of surface target

Syntax

```
grazAng = grazingang(H,R)
grazAng = grazingang(H,R,MODEL)
grazAng = grazingang(H,R,MODEL,Re)
```

Description

`grazAng = grazingang(H,R)` returns the grazing angle for a sensor `H` meters above the surface, to surface targets `R` meters away. The computation assumes a curved earth model with an effective earth radius of approximately 4/3 times the actual earth radius.

`grazAng = grazingang(H,R,MODEL)` specifies the earth model used to compute the grazing angle. `MODEL` is either `'Flat'` or `'Curved'`.

`grazAng = grazingang(H,R,MODEL,Re)` specifies the effective earth radius. Effective earth radius applies to a curved earth model. When `MODEL` is `'Flat'`, the function ignores `Re`.

Input Arguments

`H`

Height of the sensor above the surface, in meters. This argument can be a scalar or a vector. If both `H` and `R` are nonscalar, they must have the same dimensions.

`R`

Distance in meters from the sensor to the surface target. This argument can be a scalar or a vector. If both `H` and `R` are nonscalar, they must have the same dimensions. `R` must be between `H` and the horizon range determined by `H`.

`MODEL`

Earth model, as one of `| 'Curved' | 'Flat' |`.

Default: `'Curved'`

`Re`

Effective earth radius in meters. This argument requires a positive scalar value.

Default: `effearthradius`, which is approximately 4/3 times the actual earth radius

Output Arguments

`grazAng`

Grazing angle, in degrees. The size of `grazAng` is the larger of `size(H)` and `size(R)`.

Examples

Compute Grazing Angle

Determine the grazing angle (in degrees) of a path to a ground target located 1.0 km from a sensor. The sensor is mounted on a platform that is 300 m above the ground.

```
grazAng = grazingang(300,1.0e3)
```

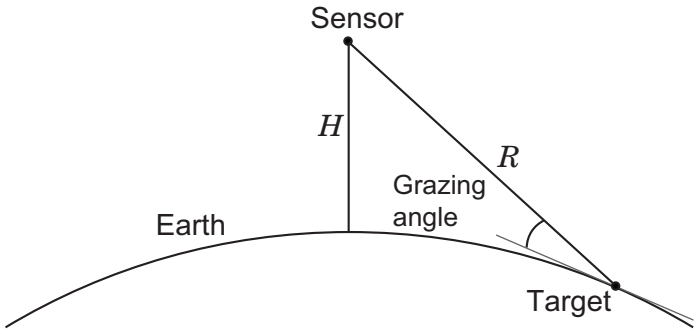
```
grazAng =

   17.4544
```

Definitions

Grazing Angle

The grazing angle is the angle between a line from the sensor to a surface target, and a tangent to the earth at the site of that target.



For the curved earth model with an effective earth radius of R_e, the grazing angle is:

$$\sin^{-1}\left(\frac{H^2 + 2HR_e - R^2}{2RR_e}\right)$$

For the flat earth model, the grazing angle is:

$$\sin^{-1}\left(\frac{H}{R}\right)$$

`depressionang` | `horizonrange`

Introduced in R2011b

horizonrange

Horizon range

Syntax

```
Rh = horizonrange(H)
Rh = horizonrange(H,Re)
```

Description

`Rh = horizonrange(H)` returns the horizon range of a radar system `H` meters above the surface. The computation uses an effective earth radius of approximately 4/3 times the actual earth radius.

`Rh = horizonrange(H,Re)` specifies the effective earth radius.

Input Arguments

`H`

Height of radar system above surface, in meters. This argument can be a scalar or a vector.

`Re`

Effective earth radius in meters. This argument must be a positive scalar.

Default: `effearthradius`, which is approximately 4/3 times the actual earth radius

Output Arguments

`Rh`

Horizon range in meters of radar system at altitude `H`.

Examples

Compute Range to Horizon

Determine the range to horizon for an antenna that is 30 m high.

```
Rh = horizonrange(30)
```

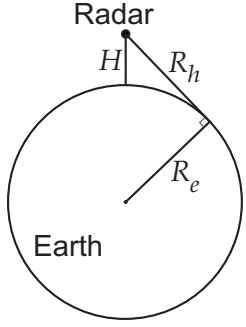
```
Rh =

   2.2553e+04
```

Definitions

Horizon Range

The *horizon range* of a radar system is the distance from the radar system to the earth along a tangent. Beyond the horizon range, the radar system detects no return from the surface through a direct path.



The value of the horizon range is:

$$\sqrt{2R_eH + H^2}$$

where R_e is the effective earth radius and H is the altitude of the radar system.

Introduced in R2011b

lcmvweights

Narrowband linearly constrained minimum variance (LCMV) beamformer weights

Syntax

```
wt = lcmvweights(constr,resp,cov)
```

Description

`wt = lcmvweights(constr,resp,cov)` returns narrowband linearly-constrained minimum variance (LCMV) beamformer weights, `wt`, for a phased array. When applied to the elements of the array, these weights steer the response of the array toward a specific arrival direction or set of directions. LCMV beamforming requires that the beamformer response to signals from a direction of interest are passed with specified gain and phase delay. However, power from interfering signals and noise from all other directions is minimized. Additional constraints may be imposed to specifically nullify output power coming from known directions. The constraints are contained in the matrix, `constr`. Each column of `constr` represents a separate constraint vector. The desired response to each constraint is contained in the response vector, `resp`. The argument `cov` is the sensor spatial covariance matrix. All elements in the sensor array are assumed to be isotropic.

Examples

LCMV Beamformer with Nulls at -40 and 20 degrees

Construct a 10-element half-wavelength-spaced line array. Then, compute the LCMV weights for a desired arrival direction of 0 degrees azimuth. Impose three direction constraints : a null at -40 degrees, a unit desired response in the arrival direction 0 degrees, and another null at 20 degrees. The sensor spatial covariance matrix includes two signals arriving from -60 and 60 degrees and -10 dB isotropic white noise.

```
N = 10;
d = 0.5;
elementPos = (0:N-1)*d;
sv = steervec(elementPos,[-40 0 20]);
resp = [0 1 0]';
```

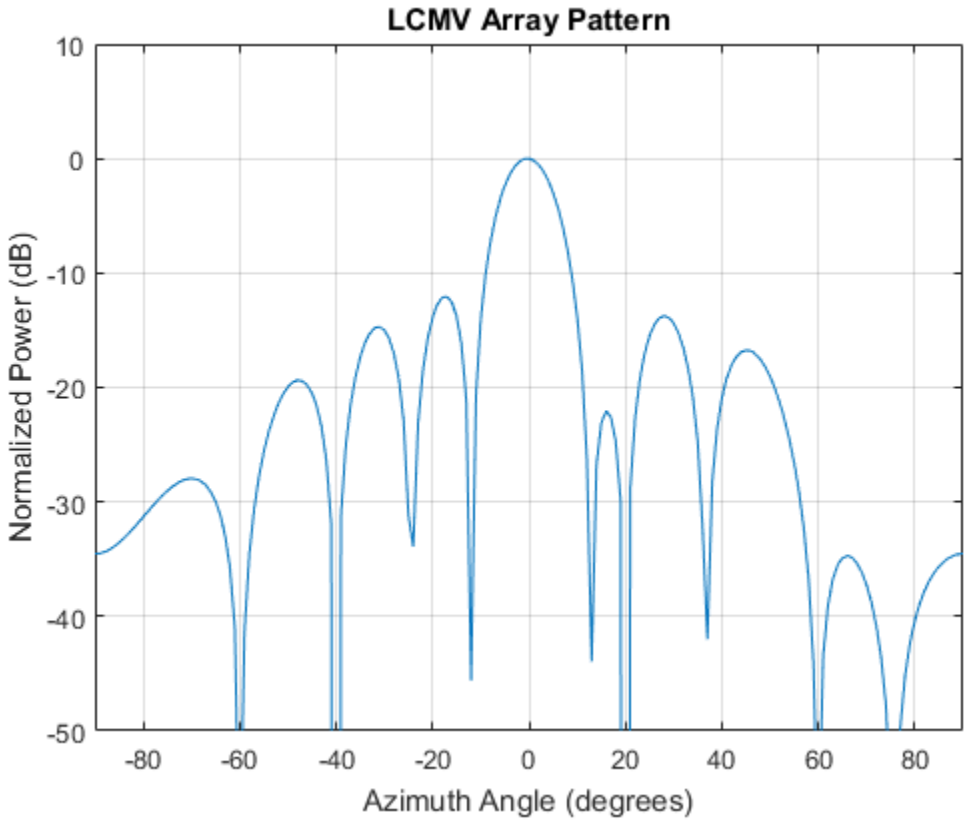
```
Sn  = sensorcov(elementPos,[-60 60],db2pow(-10));
```

Compute the beamformer weights.

```
w = lcmvweights(sv,resp,Sn);
```

Plot the array pattern for the computed weights.

```
vv = steervec(elementPos,[-90:90]);
plot([-90:90],mag2db(abs(w'*vv)))
grid on
axis([-90,90,-50,10]);
xlabel('Azimuth Angle (degrees)');
ylabel('Normalized Power (dB)');
title('LCMV Array Pattern');
```



The above figure shows that maximum gain is attained at 0 degrees as expected. In addition, the constraints impose nulls at -40 and 20 degrees and these can be seen in the plot. The nulls at -60 and 60 degrees arise from the fundamental property of the LCMV beamformer of suppressing the power contained in the two plane waves that contributed to the sensor spatial covariance matrix.

Input Arguments

`constr` — Constraint matrix

N-by-*K* complex-valued matrix

Constraint matrix specified as a complex-valued, *N*-by-*K*, complex-valued matrix. In this matrix *N* represents the number of elements in the sensor array while *K* represents the number of constraints. Each column of the matrix specifies a constraint on the beamformer weights. The number of *K* must be less than or equal to *N*.

Example: [0, 0, 0; .1, .2, .3; 0,0,0]

Data Types: `double`
Complex Number Support: Yes

`resp` — Desired response

K-by-1 complex-valued column vector.

Desired response specified as complex-valued, *K*-by-1 column vector where *K* is the number of constraints. The value of each element in the vector is the desired response to the constraint specified in the corresponding column of `constr`.

Example: [45;0]

Data Types: `double`
Complex Number Support: Yes

`cov` — Sensor spatial covariance matrix

N-by-*N* complex-valued matrix

Sensor spatial covariance matrix specified as a complex-valued, *N*-by-*N* matrix. In this matrix, *N* represents the number of sensor elements. The covariance matrix consists of the variances of the element data and the covariance between sensor elements. It contains contributions from all incoming signals and noise.

Example: [45;0]

Data Types: `double`
Complex Number Support: Yes

Output Arguments

`wt` — Beamformer weights

N-by-1 complex-valued vector

Beamformer weights returned as an *N*-by-1, complex-valued vector. In this vector, *N* represents the number of elements in the array.

Definitions

Linear-Constrained Minimum Variance Beamformers

The LCMV beamformer computes weights that minimize the total output power of an array but that are subject to some constraints (see Van Trees [1], p. 527). In order to steer the response of the array to a particular arrival direction, weights are chosen to produce unit gain when applied to the steering vector for that direction. This requirement can be thought of as a constraint on the weights. Additional constraints may be applied to nullify the array response to signals from other arrival directions such as those containing noise sources. Let $(az_1,el_1),(az_2,el_2),\ldots,(az_K,el_K)$ be the set of directions for which a constraint is to be imposed. Each direction has a corresponding steering vector, $\mathbf{c}_k$, and the response of the array to that steering vector is given by $\mathbf{c}_k^H\mathbf{w}$. The transpose conjugate of a vector is denoted by the superscript symbol *H*. A constraint is imposed when a desired response is required when the beamformer weights act on a steering vector, $\mathbf{c}_k$,

$$\mathbf{c}_k^H\mathbf{w} = r_k$$

This response could be specified as unity to allow the array to pass through the signal from a certain direction. It could be zero to nullify the response from that direction. All the constraints can be collected into a single matrix, *C*, and all the response into a single column vector, $\mathbf{R}$. This allows the constraints to be represented together in matrix form

$$C^H\mathbf{w} = \mathbf{R}$$

The LCMV beamformer chooses weights to minimize the total output power

$$P = \mathbf{w}^H S \mathbf{w}$$

subject to the above constraints. S denotes the sensor spatial covariance matrix. The solution to the power minimization is

$$\mathbf{w} = S^{-1}C^H \left(CS^{-1}C^H\right)^{-1} \mathbf{R}$$

and its derivation can be found in [2].

local2globalcoord

Convert local to global coordinates

Syntax

```
gCoord = local2globalcoord(lclCoord,OPTION)
gCoord = local2globalcoord( ___ ,localOrigin)
gCoord = local2globalcoord( ___ ,localAxes)
```

Description

`gCoord = local2globalcoord(lclCoord,OPTION)` returns the global coordinate `gCoord` corresponding to the local coordinate `lclCoord`. `OPTION` determines the type of local-to-global coordinate transformation.

`gCoord = local2globalcoord( ___ ,localOrigin)` specifies the origin of the local coordinate system.

`gCoord = local2globalcoord( ___ ,localAxes)` specifies the axes of the local coordinate system.

Input Arguments

`lclCoord`

Local coordinates in rectangular or spherical coordinate form. `lclCoord` is a 3-by-1 vector or 3-by-N matrix. Each column represents a local coordinate.

If the coordinates are in rectangular form, the column represents (*X*,*Y*,*Z*) in meters.

If the coordinates are in spherical form, the column represents (*az*,*el*,*r*). *az* is the azimuth angle in degrees, *el* is the elevation angle in degrees, and *r* is the radius in meters.

`OPTION`

Types of coordinate transformations. Valid values are

OPTION	Transformation
`'rr'`	Local rectangular to global rectangular
`'rs'`	Local rectangular to global spherical
`'sr'`	Local spherical to global rectangular
`'ss'`	Local spherical to global spherical

`localOrigin`

Origin of local coordinate system. `localOrigin` is a 3-by-1 column vector containing the rectangular coordinate of the local coordinate system origin with respect to the global coordinate system.

Default: `[0; 0; 0]`

`localAxes`

Axes of local coordinate system. `localAxes` is a 3-by-3 matrix with the columns specifying the local X, Y, and Z axes in rectangular form with respect to the global coordinate system.

Default: `[1 0 0;0 1 0;0 0 1]`

Output Arguments

`gCoord`

Global coordinates in rectangular or spherical coordinate form. The origin of the global coordinate system is at [0; 0; 0]. That system's axes are the standard unit basis vectors in three-dimensional space, [1; 0; 0], [0; 1; 0], and [0; 0; 1].

Examples

Convert Local Rectangular Coordinates to Global Rectangular Coordinates

Convert from local rectangular coordinates to global rectangular coordinates. The local coordinate origin is a *(1,1,1)*

```
globalcoord = local2globalcoord([0;1;0], 'rr',[1;1;1])
```

```
globalcoord =

     1
     2
     1
```

Convert Local Spherical Coordinates to Global Rectangular Coordinates

Convert local spherical coordinate to global rectangular coordinate.

```
globalcoord = local2globalcoord([30;45;4],'sr')
```

```
globalcoord =

    2.4495
    1.4142
    2.8284
```

Definitions

Azimuth Angle, Elevation Angle

The *azimuth angle* of a vector is the angle between the x-axis and the orthogonal projection of the vector onto the xy plane. The angle is positive in going from the x axis toward the y axis. Azimuth angles lie between –180 and 180 degrees. The *elevation angle* is the angle between the vector and its orthogonal projection onto the xy-plane. The angle is positive when going toward the positive z-axis from the xy plane. These definitions assume the boresight direction is the positive x-axis.

Note: The elevation angle is sometimes defined in the literature as the angle a vector makes with the positive z-axis. The MATLAB and Phased Array System Toolbox products do not use this definition.

This figure illustrates the azimuth angle and elevation angle for a vector that appears as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue circles.

mdltest

Dimension of signal subspace

Syntax

```
nsig = mdltest(X)
nsig = mdltest(X,'fb')
```

Description

`nsig = mdltest(X)` estimates the number of signals, `nsig`, present in a *snapshot* of data, `X`, that impinges upon the sensors in an array. The estimator uses the *Minimum Description Length* (MDL) test. The input argument, `X`, is a complex-valued matrix containing a time sequence of data samples for each sensor. Each row corresponds to a single time sample for all sensors.

`nsig = mdltest(X,'fb')` estimates the number of signals. Before estimating, it performs *forward-backward averaging* on the sample covariance matrix constructed from the data snapshot, `X`. This syntax can use any of the input arguments in the previous syntax.

Examples

Estimate the Signal Subspace Dimensions for Two Arriving Signals

Construct a data snapshot of two plane waves arriving at a half-wavelength-spaced uniform line array having 10 elements. The plane waves arrive from 0° and –25° azimuth, both with elevation angles of 0°. Assume the signals arrive in the presence of additive noise that is both temporally and spatially Gaussian white. For each signal, the SNR is 5 dB. Take 300 samples to build a 300-by-10 data snapshot. Then, solve for the number of signals using `mdltest`.

```
N = 10;
d = 0.5;
elementPos = (0:N-1)*d;
```

```
angles = [0 -25];
x = sensorsig(elementPos,300,angles,db2pow(-5));
Nsig = mdltest(x)

Nsig =

     2
```

The result shows that the number of signals is two, as expected.

Estimate the Signal Subspace Dimensions Using Forward-Backward Averaging

Construct a data snapshot for two plane waves arriving at a half-wavelength-spaced uniform line array with 10 elements. Correlated plane waves arrive from 0° and 10° azimuth, both with elevation angles of 0°. Assume the signals arrive in the presence of additive noise that is both temporally and spatially Gaussian white noise. For each signal, the SNR is 10 dB. Take 300 samples to build a 300-by-10 data snapshot. Then, solve for the number of signals using `mdltest`.

```
N = 10;
d = 0.5;
elementPos = (0:N-1)*d;
angles = [0 10];
ncov = db2pow(-10);
scov = [1 .5]'*[1 .5];
x = sensorsig(elementPos,300,angles,ncov,scov);
Nsig = mdltest(x)

Nsig =

     1
```

This result shows that `mdltest` cannot determine the number of signals correctly when the signals are correlated.

Now, try the forward-backward smoothing option.

```
Nsig = mdltest(x,'fb')

Nsig =
```

2

The addition of forward-backward smoothing yields the correct number of signals.

Input Arguments

X — Data snapshot

complex-valued *K*-by-*N* matrix

Data snapshot, specified as a complex-valued, *K*-by-*N* matrix. A snapshot is a sequence of time-samples taken simultaneous at each sensor. In this matrix, *K* represents the number of time samples of the data, while *N* represents the number of sensor elements.

Example: [–0.1211 + 1.2549i, 0.1415 + 1.6114i, 0.8932 + 0.9765i;]

Data Types: `double`
Complex Number Support: Yes

Output Arguments

nsig — Dimension of signal subspace

non-negative integer

Dimension of signal subspace, returned as a non-negative integer. The dimension of the signal subspace is the number of signals in the data.

Definitions

Estimating the Number of Sources

AIC and MDL tests

Direction finding algorithms such as MUSIC and ESPRIT require knowledge of the number of sources of signals impinging on the array or equivalently, the dimension, *d*, of the signal subspace. The Akaike Information Criterion (AIC) and the Minimum

Description Length (MDL) formulas are two frequently-used estimators for obtaining that dimension. Both estimators assume that, besides the signals, the data contains spatially and temporally white Gaussian random noise. Finding the number of sources is equivalent to finding the multiplicity of the smallest eigenvalues of the sampled spatial covariance matrix. The sample spatial covariance matrix constructed from a data snapshot is used in place of the actual covariance matrix.

A requirement for both estimators is that the dimension of the signal subspace be less than the number of sensors, *N*, and that the number of time samples in the snapshot, *K*, be much greater than *N*.

A variant of each estimator exists when forward-backward averaging is employed to construct the spatial covariance matrix. Forward-backward averaging is useful for the case when some of the sources are highly correlated with each other. In that case, the spatial covariance matrix may be ill conditioned. Forward-backward averaging can only be used for certain types of symmetric arrays, called *centro-symmetric* arrays. Then the forward-backward covariance matrix can be constructed from the sample spatial covariance matrix, *S*, using $S_{FB} = S + JS^*J$ where *J* is the exchange matrix. The exchange matrix maps array elements into their symmetric counterparts. For a line array, it would be the identity matrix flipped from left to right.

All the estimators are based on a cost function

$$L_d(d) = K(N-d)\ln\left\{\frac{\frac{1}{N-d}\sum_{i=d+1}^{N}\lambda_i}{\left\{\prod_{i=d+1}^{N}\lambda_i\right\}^{\frac{1}{N-d}}}\right\}$$

plus an added penalty term. The value λ_i represent the smallest *(N–d)* eigenvalues of the spatial covariance matrix. For each specific estimator, the solution for *d* is given by

- AIC

$$\hat{d}_{AIC} = \underset{d}{\operatorname{argmin}}\{L_d(d) + d(2N-d)\}$$

- AIC for forward-backward averaged covariance matrices

$$\hat{d}_{AIC:\,FB} = \underset{d}{\operatorname{argmin}}\left\{ L_d(d) + \frac{1}{2} d(2N - d + 1) \right\}$$

- MDL

$$\hat{d}_{MDL} = \underset{d}{\operatorname{argmin}}\left\{ L_d(d) + \frac{1}{2} (d(2N - d) + 1) \ln K \right\}$$

- MDL for forward-backward averaged covariance matrices

$$\hat{d}_{MDL\,FB} = \underset{d}{\operatorname{argmin}}\left\{ L_d(d) + \frac{1}{4} d(2N - d + 1) \ln K \right\}$$

mvdrweights

Minimum variance distortionless response (MVDR) beamformer weights

Syntax

```
wt = mvdrweights(pos,ang,cov)
wt = mvdrweights(pos,ang,nqbits)
```

Description

`wt = mvdrweights(pos,ang,cov)` returns narrowband minimum variance distortionless response (MVDR) beamformer weights for a phased array. When applied to the elements of an array, the weights steer the response of a sensor array in a specific arrival direction or set of directions. The `pos` argument specifies the sensor positions of the array. The `ang` argument specifies the azimuth and elevation angles of the desired response directions. `cov` is the sensor spatial covariance matrix between sensor elements. The output argument, `wt`, is a matrix contains the beamformer weights for each sensor and each direction. Each column of `wt` contains the weights for the corresponding direction specified in `ang`. All elements in the sensor array are assumed to be isotropic.

`wt = mvdrweights(pos,ang,nqbits)` returns quantized narrowband MVDR beamformer weights when the number of phase shifter bits is set to `nqbits`.

Examples

MVDR Beamformer with Arrival Directions of 30 and 45 Degrees

Construct a 10-element, half-wavelength-spaced line array. Choose two arrival directions of interest - one at 30° azimuth and the other at 45° azimuth. Assume both directions are at 0° elevation. Compute the MVDR beamformer weights for each direction. Specify a sensor spatial covariance matrix that contains signals arriving from -60° and 60° and noise at -10 dB.

Set up the array and sensor spatial covariance matrix.

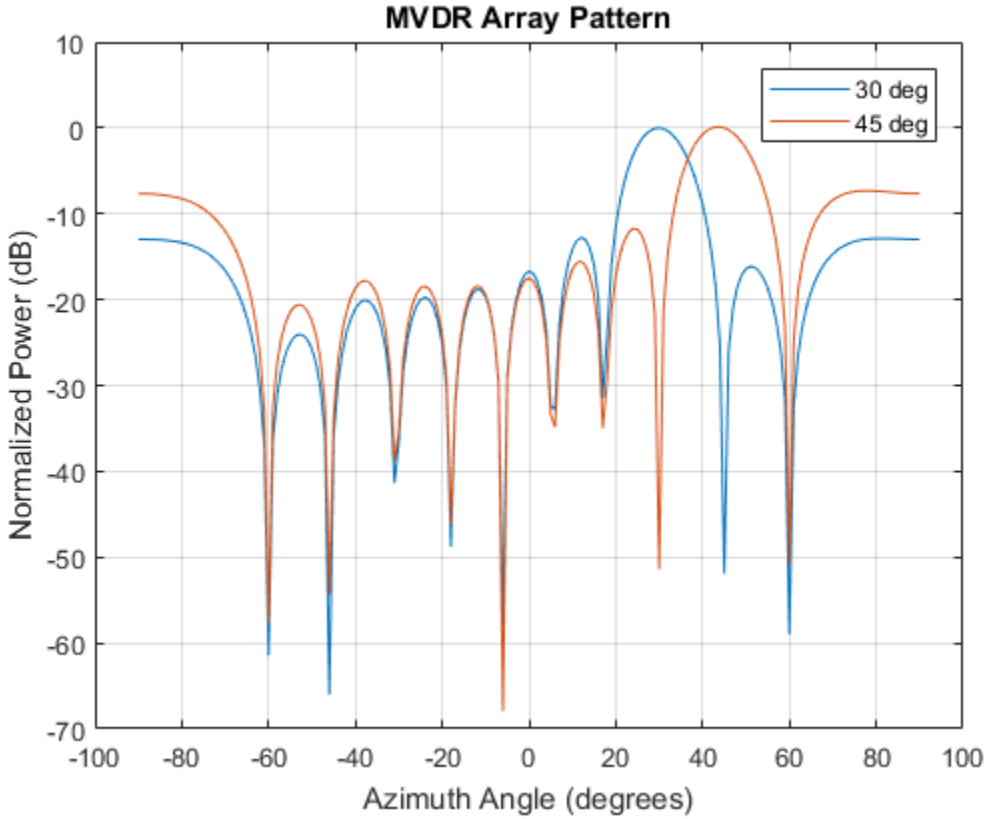
```
N = 10;
d = 0.5;
elementPos = (0:N-1)*d;
Sn  = sensorcov(elementPos,[-60 60],db2pow(-10));
```

Solve for the MVDR beamformer weights.

```
w = mvdrweights(elementPos,[30 45],Sn);
```

Plot the two MVDR array patterns.

```
plotangl = -90:90;
vv = steervec(elementPos,plotangl);
plot(plotangl,mag2db(abs(w'*vv)))
grid on
xlabel('Azimuth Angle (degrees)');
ylabel('Normalized Power (dB)');
legend('30 deg','45 deg');
title('MVDR Array Pattern')
```



The figure shows plots for each beamformer direction. One plot has the expected maximum gain at 30 degrees and the other at 45 degrees. The nulls at -60 and 60 degrees arise from the fundamental property of the MVDR beamformer of suppressing power in all directions except for the arrival direction.

Quantized Weights in MVDR Beamformer

Construct a 10-element, half-wavelength-spaced line array. Choose the arrival direction of interest to be 18.5° azimuth and 10° elevation. Compute the MVDR beamformer weights and then compute the weights for 3-bit quantization. Specify a sensor spatial covariance matrix that contains signals arriving from -60° and 60° and noise at -10 dB.

Set up the array and the sensor spatial covariance matrix.

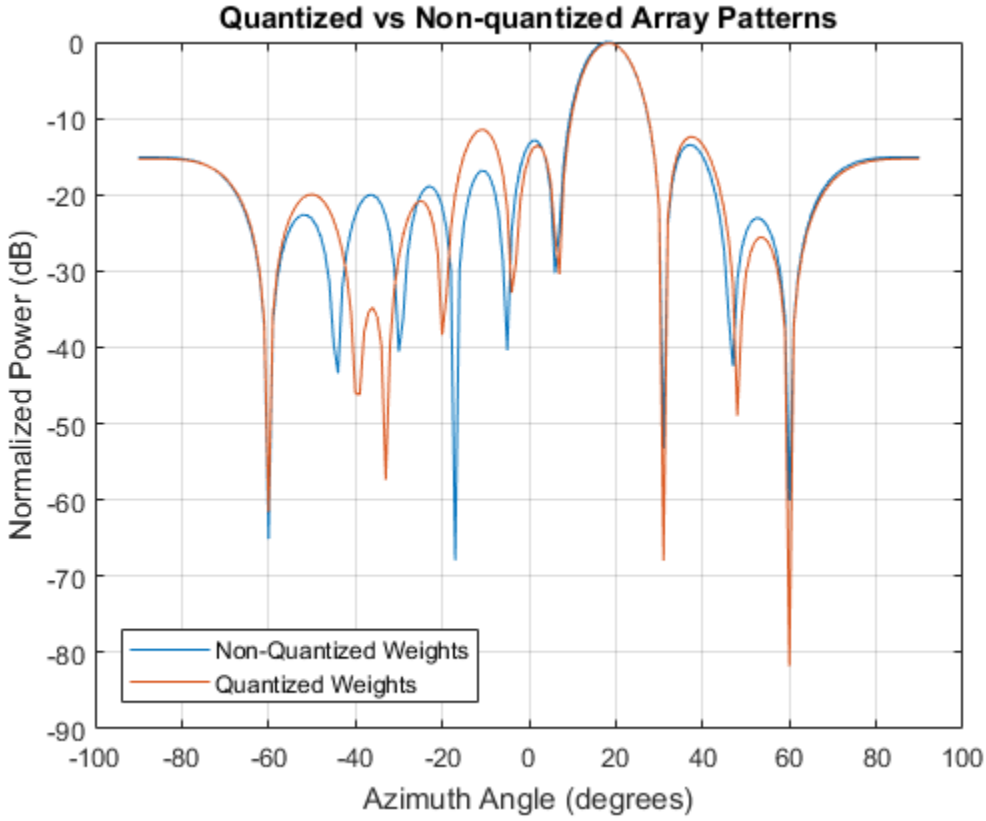
```
N = 10;
d = 0.5;
elementPos = (0:N-1)*d;
SN  = sensorcov(elementPos,[-60 60],db2pow(-10));
```

Solve for the MVDR beamformer weights with and without quantization.

```
w = mvdrweights(elementPos,[18.5;10],SN);
wq = mvdrweights(elementPos,[18.5;10],SN,3);
```

Plot both MVDR array patterns.

```
plotangl = -90:90;
vv = steervec(elementPos,plotangl);
plot(plotangl,mag2db(abs(w'*vv)))
hold on
plot(plotangl,mag2db(abs(wq'*vv)))
grid on
xlabel('Azimuth Angle (degrees)')
ylabel('Normalized Power (dB)')
legend('Non-Quantized Weights','Quantized Weights','Location','SouthWest');
title('Quantized vs Non-quantized Array Patterns')
hold off
```



Input Arguments

pos — Positions of array sensor elements

1-by-*N* real-valued vector | 2-by-*N* real-valued matrix | 3-by-*N* real-valued matrix

Positions of the elements of a sensor array specified as a 1-by-*N* vector, a 2-by-*N* matrix, or a 3-by-*N* matrix. In this vector or matrix, *N* represents the number of elements of the array. Each column of `pos` represents the coordinates of an element. You define sensor position units in term of signal wavelength. If `pos` is a 1-by-*N* vector, then it represents the *y*-coordinate of the sensor elements of a line array. The *x* and *z*-coordinates are assumed to be zero. When `pos` is a 2-by-*N* matrix, it represents the *(y,z)*-coordinates of

the sensor elements of a planar array. This array is assumed to lie in the *yz*-plane. The *x*-coordinates are assumed to be zero. When `pos` is a 3-by-*N* matrix, then the array has arbitrary shape.

Example: `[0,0,0; 0.1,0.4,0.3;1,1,1]`

Data Types: `double`

`ang` — Beamforming directions

1-by-*M* real-valued vector | 2-by-*M* real-valued matrix

Beamforming directions specified as a 1-by-*M* vector or a 2-by-*M* matrix. In this vector or matrix, *M* represents the number of incoming signals. If `ang` is a 2-by-*M* matrix, each column specifies the direction in azimuth and elevation of the beamforming direction as `[az;el]`. Angular units are specified in degrees. The azimuth angle must lie between –180° and 180° and the elevation angle must lie between –90° and 90°. The azimuth angle is the angle between the *x*-axis and the projection of the beamforming direction vector onto the *xy* plane. The angle is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the beamforming direction vector and *xy*-plane. It is positive when measured towards the positive *z* axis. If `ang` is a 1-by-*M* vector, then it represents a set of azimuth angles with the elevation angles assumed to be zero.

Example: `[45;10]`

Data Types: `double`

`cov` — Sensor spatial covariance matrix

N-by-*N* complex-valued matrix

Sensor spatial covariance matrix specified as an *N*-by-*N*, complex-valued matrix. In this matrix, *N* represents the number of sensor elements.

Example: `[5,0.1;0.1,2]`

Data Types: `double`
Complex Number Support: Yes

`nqbits` — Number of phase shifter quantization bits

0 (default) | non-negative integer

Number of bits used to quantize the phase shift in beamformer or steering vector weights, specified as a non-negative integer. A value of zero indicates that no quantization is performed.

Example: `5`

Output Arguments

`wt` — Beamformer weights
N-by-*M* complex-valued matrix

Beamformer weights returned as a complex-valued, *N*-by-*M* matrix. In this matrix, *N* represents the number of sensor elements of the array while *M* represents the number of beamforming directions. Each column of `wt` corresponds to a beamforming direction specified in `ang`.

Definitions

Minimum Variance Distortionless Response

MVDR beamformer weights minimize the total array output power while setting the gain in the desired response direction to unity (see Van Trees [1], p. 442). MVDR weights are given by

$$\mathbf{w} = \frac{S^{-1}|\mathbf{v_0}}{\mathbf{v_0}^H S^{-1}\mathbf{v_0}}$$

where $\mathbf{v}_0$ is the steering vector corresponding to the desired response direction. S is the spatial covariance matrix. The covariance matrix consists of the variances of the element data and the covariances of the data between the sensor elements. The covariance contains contributions from all incoming signals and noise.

Introduced in R2013a

musicdoa

Estimate arrival directions of signals using MUSIC

Syntax

```
doas = musicdoa(covmat,nsig)
[doas,spec,specang] = musicdoa(covmat,nsig)
[ ___ ] = musicdoa(covmat,nsig, ___ ,'ScanAngles',scanangle)
[ ___ ] = musicdoa(covmat,nsig, ___ ,'ElementSpacing',dist)
```

Description

`doas = musicdoa(covmat,nsig)` uses the *MUSIC* algorithm to estimate the directions of arrival, `doas`, of `nsig` plane waves received on a uniform linear array (ULA). The argument `covmat` is a positive-definite Hermitian matrix representing the sensor covariance matrix. Detected sources appear as peaks in the spatial spectrum. The argument `nsig` is the number of arriving signals. Sensor elements are spaced one-half wavelength apart in units of wavelengths. The function forces exact conjugate symmetry of `covmat` by averaging the covariance matrix with its conjugate transpose.

`[doas,spec,specang] = musicdoa(covmat,nsig)` also returns the spatial spectrum, `spec`, and the `nsig` angles of the spectrum peaks, `specang`.

`[ ___ ] = musicdoa(covmat,nsig, ___ ,'ScanAngles',scanangle)` specifies the grid of broadside angles to search for spectrum peaks.

`[ ___ ] = musicdoa(covmat,nsig, ___ ,'ElementSpacing',dist)` specifies the spacing between array elements.

Examples

Estimate DOA of Multiple Signals Using MUSIC

Calculate the directions of arrival of 3 uncorrelated signals arriving at an 11-element ULA with half-wavelength spacing. Assume the signals are coming from the broadside angles of 0°, –12°, and 85°. The noise at each element is Gaussian white noise and is uncorrelated between elements. The SNR is 5 dB.

Specify the number of ULA elements and the element spacing (in wavelengths).

```
nelem = 11;
d = 0.5;
snr = 5.0;
elementPos = (0:nelem-1)*d;
```

Specify the number of signals and their broadside arrival angles.

```
nsig = 3;
angles = [0.0 -12.0 85.0];
```

Create the sensor covariance matrix.

```
covmat = sensorcov(elementPos,angles,db2pow(-snr));
```

Estimate the broadside arrival angles.

```
doas = musicdoa(covmat,nsig)
```

```
doas =

   -12     0    85
```

The estimated angles match the specified angles.

Display MUSIC Spectrum of Multiple Signals

Calculate the directions of arrival of 3 uncorrelated signals arriving at an 11-element ULA with half-wavelength spacing. Assume the signals are coming from the broadside angles of 0°, –12°, and 85°. The noise at each element is Gaussian white noise and is uncorrelated between elements. The SNR is 2 dB.

Specify the number of ULA elements and the element spacing (in wavelengths).

```
nelem = 11;
d = 0.5;
snr = 2.0;
elementPos = (0:nelem-1)*d;
```

Specify the number of signals and their broadside arrival angles.

```
nsig = 3;
angles = [0.0 -12.0 85.0];
```

Create the sensor covariance matrix.

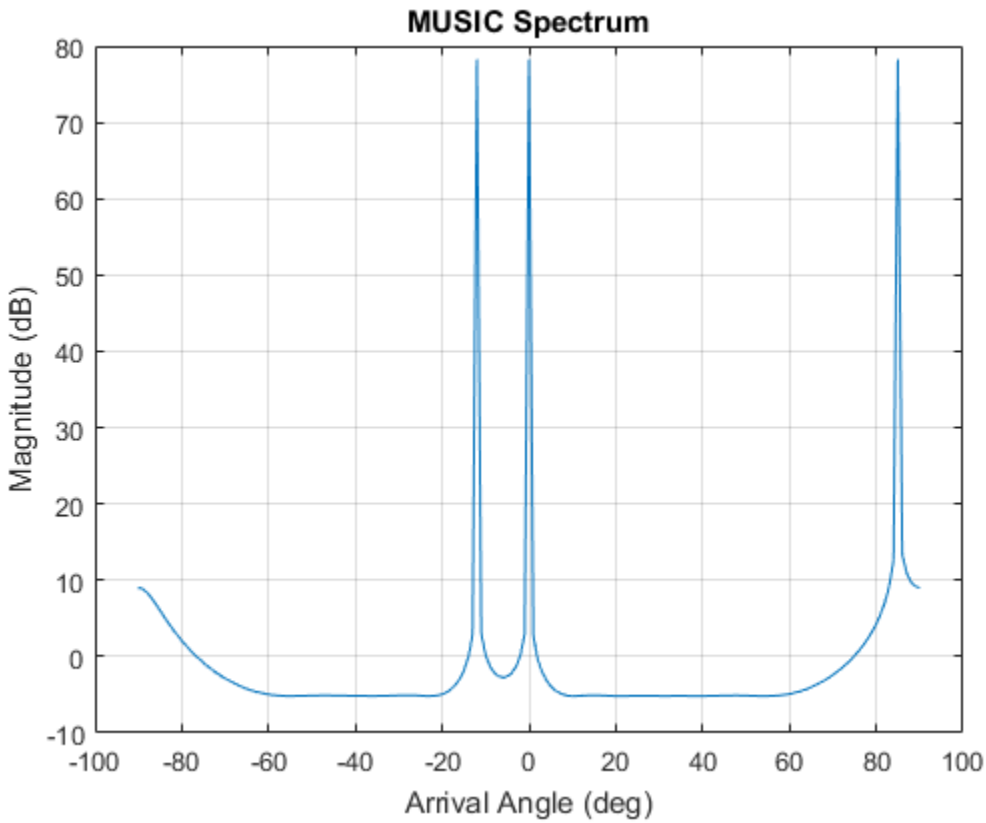
```
covmat = sensorcov(elementPos,angles,db2pow(-snr));
```

Compute the MUSIC spectrum and estimate the broadside arrival angles.

```
[doas,spec,specang] = musicdoa(covmat,nsig);
```

Plot the MUSIC spectrum.

```
plot(specang,10*log10(spec))
xlabel('Arrival Angle (deg)')
ylabel('Magnitude (dB)')
title('MUSIC Spectrum')
grid
```



The estimated angles match the specified angles.

Display MUSIC Spectrum Over Specified Direction Span

Calculate the directions of arrival of 4 uncorrelated signals arriving at an 11-element ULA. The element spacing is 0.5 wavelengths. Assume the signals are coming from the broadside angles of –60.2°, –20.7°, 0.5°, and 84.8°. The noise at each element is Gaussian white noise and is uncorrelated between elements. The SNR is 0 dB.

Specify the number of ULA elements and the element spacing (in wavelengths).

```
nelem = 11;
d = 0.5;
snr = 5.0;
elementPos = (0:nelem-1)*d;
```

Specify the number of signals and their broadside arrival angles.

```
nsig = 4;
angles = [-60.2 -20.7 0.5 84.8];
```

Create the sensor covariance matrix.

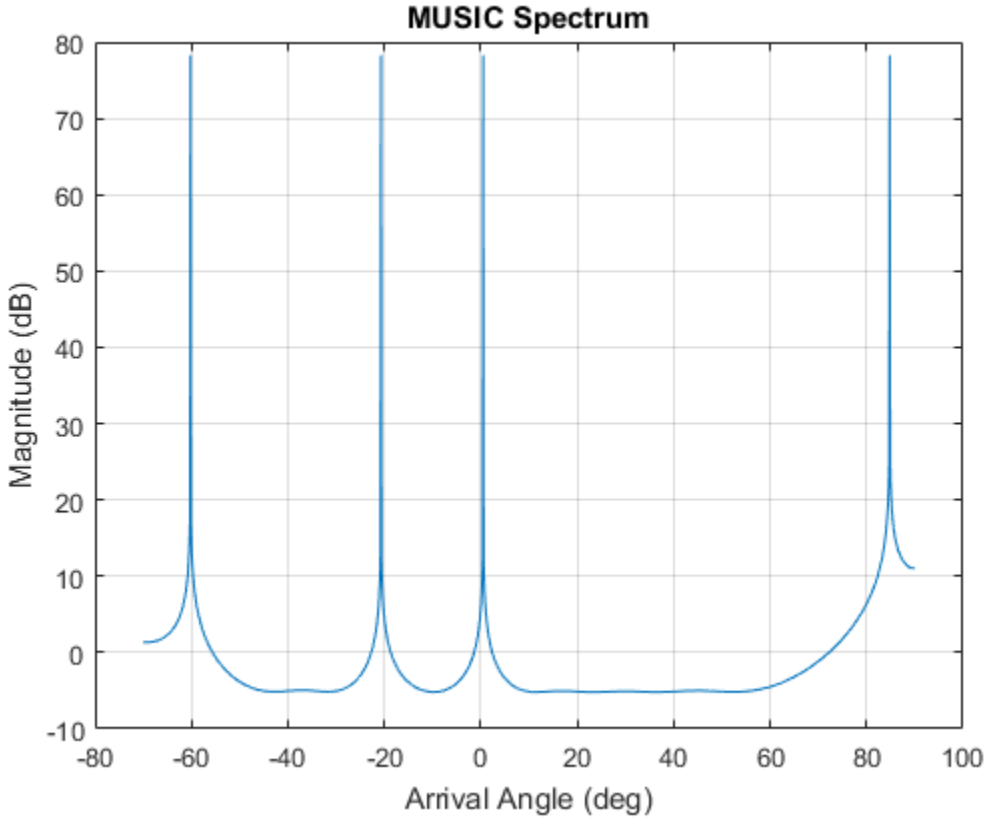
```
covmat = sensorcov(elementPos,angles,db2pow(-snr));
```

Compute the MUSIC spectrum and estimate the broadside arrival angles in the range from -70° to 90° in 0.1° increments.

```
[doas,spec,specang] = musicdoa(covmat,nsig,'ScanAngles',[-70:.1:90]);
```

Plot the MUSIC spectrum.

```
plot(specang,10*log10(spec))
xlabel('Arrival Angle (deg)')
ylabel('Magnitude (dB)')
title('MUSIC Spectrum')
grid
```



```
disp(doas)
```

```
   84.8000    0.5000  -60.2000  -20.7000
```

The estimated angles match the specified angles.

Display MUSIC Spectrum with Specified Element Spacing

Calculate the directions of arrival of 4 uncorrelated signals arriving at an 11-element ULA. The element spacing is 0.4 wavelengths spacing. Assume the signals are coming from the broadside angles of –60°, –20°, 0°, and 85°. The noise at each element is Gaussian white noise and is uncorrelated between elements. The SNR is 0 dB.

Specify the number of ULA elements and the element spacing (in wavelengths).

```
nelem = 11;
d = 0.4;
snr = 0.0;
elementPos = (0:nelem-1)*d;
```

Specify the number of signals and their broadside arrival angles.

```
nsig = 4;
angles = [-60.0 -20.0 0.0 85.0];
```

Create the sensor covariance matrix.

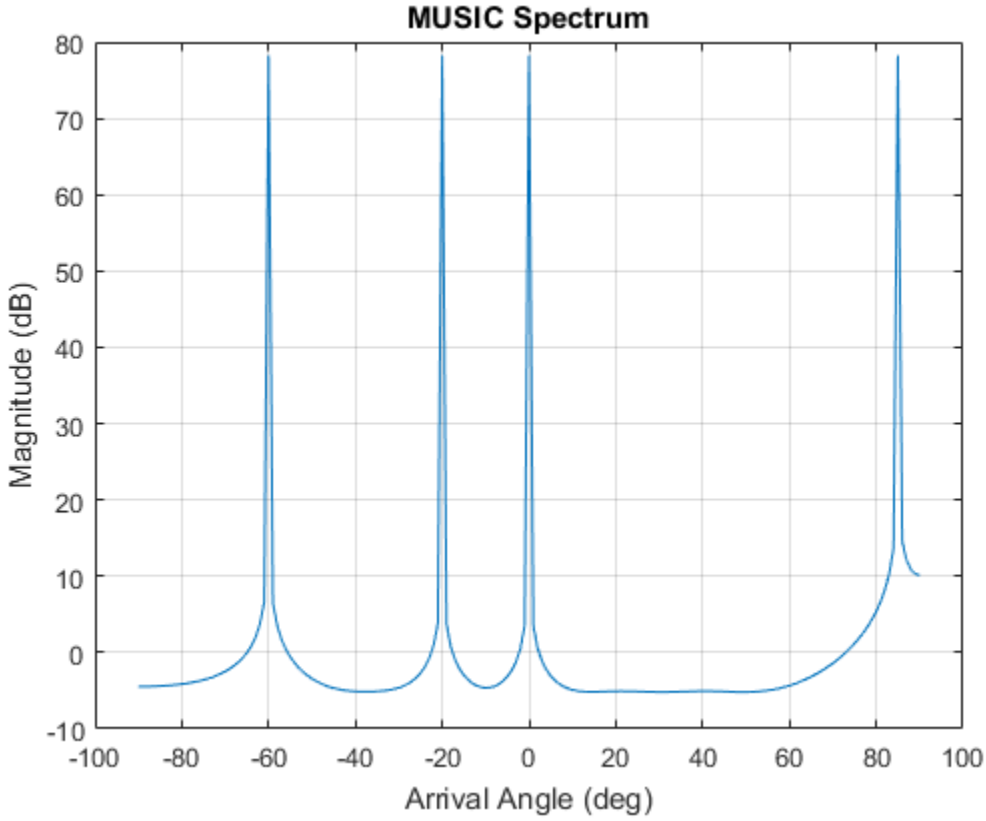
```
covmat = sensorcov(elementPos,angles,db2pow(-snr));
```

Compute the MUSIC spectrum and estimate the broadside arrival angles.

```
[doas,spec,specang] = musicdoa(covmat,nsig,'ElementSpacing',d);
```

Plot the MUSIC spectrum.

```
plot(specang,10*log10(spec))
xlabel('Arrival Angle (deg)')
ylabel('Magnitude (dB)')
title('MUSIC Spectrum')
grid
```



The estimated angles match the specified angles.

Input Arguments

`covmat` — Sensor covariance matrix

(default) | positive-definite complex-valued *M*-by-*M* matrix

Sensor covariance matrix, specified as a complex-valued, positive-definite *M*-by-*M* matrix. The quantity *M* is the number of elements in the ULA array. The function forces Hermiticity property by averaging the matrix and its conjugate transpose.

Data Types: `double`

Complex Number Support: Yes

`nsig` — Number of arriving signals

positive integer

Number of arriving signals, specified as a positive integer. The number of signals must be smaller than the number of elements in the ULA array.

Example: `2`

Data Types: `double`

`scanangle` — Broadside search angles

`[-90:90]` (default) | real-valued vector

Broadside search angles, specified as a real-valued vector. Angles must lie in the range (–90°,90°) and must be in increasing order.

Example: `[-40:0.5:50]`

Data Types: `double`

`dist` — Distance between array elements

`0.5` (default) | real-valued positive scalar

Distance between array elements, specified as a real-valued positive scalar.

Example: `0.45`

Data Types: `double`

Output Arguments

`doas` — Directions of arrival angles

real-valued vector

Directions of arrival angle, returned as a real-valued 1-by-*D* vector, where *D* is the number of arriving signals specified in `nsig`. Angle units are in degrees. Angle values lie in the range specified by `scanangle`.

`spec` — Spatial spectrum

positive real-valued vector

Spatial spectrum, returned as a positive real-valued vector. The dimension of `spec` equals the dimension of `scanangle`.

`specang` — Broadside angles of spectrum peaks
real-valued vector

Broadside angle of spectrum, returned as a real-valued vector. The dimension of `specang` equals the dimension of `scanangle`.

noisepow

Receiver noise power

Syntax

```
NPOWER = noisepow(NBW,NF,REFTEMP)
```

Description

`NPOWER = noisepow(NBW,NF,REFTEMP)` returns the noise power, `NPOWER`, in watts for a receiver. This receiver has a noise bandwidth `NBW` in hertz, noise figure `NF` in decibels, and reference temperature `REFTEMP` in degrees kelvin.

Input Arguments

`NBW`

The noise bandwidth of the receiver in hertz. For a superheterodyne receiver, the noise bandwidth is approximately equal to the bandwidth of the intermediate frequency stages [1].

`NF`

Noise figure. The noise figure is a dimensionless quantity that indicates how much a receiver deviates from an ideal receiver in terms of internal noise. An ideal receiver only produces the expected thermal noise power for a given noise bandwidth and temperature. A noise figure of 1 indicates that the noise power of a receiver equals the noise power of an ideal receiver. Because an actual receiver cannot exhibit a noise power value less than an ideal receiver, the noise figure is always greater than or equal to one.

`REFTEMP`

Reference temperature in degrees kelvin. The temperature of the receiver. Typical values range from 290–300 degrees kelvin.

Output Arguments

NPOWER

Noise power in watts. The internal noise power contribution of the receiver to the signal-to-noise ratio.

Examples

Compute Receiver Noise Power with Specified Temperature

Calculate the noise power of a receiver having a noise bandwidth of 10 kHz, a noise figure of 1 dB, and a reference temperature of 300 K.

```
npower = noisepow(10e3,1,300)
```

```
npower =

npwgnthresh

Detection SNR threshold for signal in white Gaussian noise

Syntax

```
snrthresh = npwgnthresh(pfa)
snrthresh = npwgnthresh(pfa,numpulses)
snrthresh = npwgnthresh(pfa,numpulses,dettype)
snrthresh = npwgnthresh(pfa,numpulses,dettype,outscale)
```

Description

`snrthresh = npwgnthresh(pfa)` calculates the SNR threshold in decibels for detecting a deterministic signal in white Gaussian noise. The detection uses the Neyman-Pearson (NP) decision rule to achieve a specified probability of false alarm, `pfa`. This function uses a square-law detector.

Note: The output of `npwgnthresh` determines the detection threshold required to achieve a particular Pfa. The threshold increases when pulse integration is used in the receiver. This threshold is not the single sample SNR that is used as an input to `rocsnr` or as the output of `rocpfa`, `albersheim`, and `shnidman`. For any fixed Pfa, you can decrease the single sample SNR required to achieve a particular Pd when pulse integration is used in the receiver. See "Signal Detection in White Gaussian Noise" and "Signal Detection Using Multiple Samples" for examples of how to use `npwgnthresh` in a detection system.

`snrthresh = npwgnthresh(pfa,numpulses)` specifies `numpulses` as the number of pulses used in the pulse integration.

`snrthresh = npwgnthresh(pfa,numpulses,dettype)` specifies `dettype` as the type of detection. A square law detector is used in noncoherent detection.

`snrthresh = npwgnthresh(pfa,numpulses,dettype,outscale)` specifies the output scale.

Input Arguments

pfa

Probability of false alarm.

numpulses

Number of pulses used in the integration.

Default: 1

dettype

Detection type.

Specifies the type of pulse integration used in the NP decision rule. Valid choices for `dettype` are `'coherent'`, `'noncoherent'`, and `'real'`. `'coherent'` uses magnitude and phase information of complex-valued samples. `'noncoherent'` uses squared magnitudes. `'real'` uses real-valued samples.

Default: `'noncoherent'`

outscale

Output scale.

Specifies the scale of the output value as one of `'db'` or `'linear'`. When `outscale` is set to `'linear'`, the returned threshold represents amplitude.

Default: `'db'`

Output Arguments

snrthresh

Detection threshold expressed in signal-to-noise ratio in decibels or linear if `outscale` is set to `'linear'`. The relationship between the linear threshold and the threshold in dB is

$$T_{dB} = 20\log_{10} T_{lin}$$

Examples

Compute detection threshold from Pfa

Calculate the detection threshold that achieves a probability of false alarm (pfa) of 0.01. Assume a single pulse with a `real` detection type. Then, verify that this threshold produces a pfa of approximately 0.01. Do this by constructing 10000 real white gaussian noise (wgn) samples and computing the fraction of samples exceeding the threshold.

Compute the threshold from pfa. The detection threshold is expressed as a signal-to-noise ratio in db.

```
pfa = 0.01;
numpulses = 1;
snrthreshold = npwgnthresh(pfa,numpulses,'real')
```

```
snrthreshold =

    7.3335
```

Compute fraction of simulated noise samples exceeding the threshold. The noise has unit power with 10000 samples.

```
noisepower = 1;
Ntrial = 10000;
noise = sqrt(noisepower)*randn(1,Ntrial);
```

Express the threshold in amplitude units.

```
threshold = sqrt(noisepower*db2pow(snrthreshold));
calculated_Pfa = sum(noise>threshold)/Ntrial
```

```
calculated_Pfa =

    0.0107
```

Detection Threshold Versus Number of Pulses

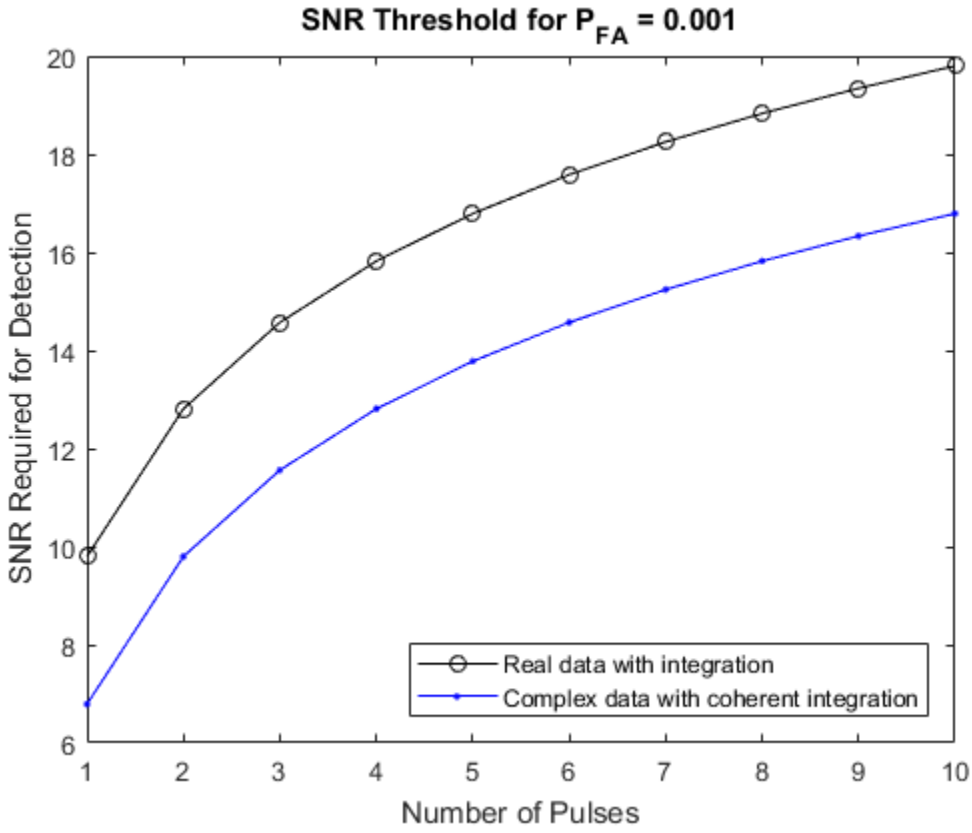
Plot the SNR detection threshold against the number of pulses, for real and complex noise. In each case, the SNR detection threshold is set for a probability of false alarm (pfa) of 0.001.

Compute detection threshold for 1 to 10 pulses of real and complex noise.

```
Npulses = 10;
snrcoh = zeros(1,Npulses);
snrreal = zeros(1,Npulses);
Pfa = 1e-3;
for num = 1:Npulses
    snrreal(num) = npwgnthresh(Pfa,num,'real');
    snrcoh(num)  = npwgnthresh(Pfa,num,'coherent');
end
```

Plot the detection thresholds against number of pulses.

```
plot(snrreal,'ko-')
hold on
plot(snrcoh,'b.-')
legend('Real data with integration',...
    'Complex data with coherent integration',...
    'location','southeast')
xlabel('Number of Pulses')
ylabel('SNR Required for Detection')
title('SNR Threshold for P_F_A = 0.001')
hold off
```



Linear detection threshold versus number of pulses

Plot the linear detection threshold against the number of pulses, for real and complex data. In each case, the threshold is set for a probability of false alarm of 0.001.

Compute detection threshold for 1 to 10 pulses of real and complex noise.

```
Npulses = 10;
snrcoh = zeros(1,Npulses); % preallocate space
snrreal = zeros(1,Npulses);
Pfa = 1e-3;
for num = 1:Npulses
    snrreal(num) = npwgnthresh(Pfa,num,'real','linear');
    snrcoh(num)  = npwgnthresh(Pfa,num,'coherent','linear');
```

```
end
```

Plot the detection thresholds against number of pulses.

```
plot(snrreal,'ko-')
hold on
plot(snrcoh,'b.-')
legend('Real data with integration',...
    'Complex data with coherent integration',...
    'location','southeast');
xlabel('Number of Pulses')
ylabel('Detection Threshold')
str = sprintf('Linear Detection Threshold for P_F_A = %4.3f',Pfa);
title(str)
hold off
```

Definitions

Detection in Real-Valued White Gaussian Noise

This function is designed for the detection of a nonzero mean in a sequence of Gaussian random variables. The function assumes that the random variables are independent and identically distributed, with zero mean. The linear detection threshold λ for an NP detector is

$$\frac{\lambda}{\sigma} = \sqrt{2N}\,\mathrm{erfc}^{-1}(2P_{fa})$$

This threshold can also be expressed as a signal-to-noise ratio in decibels

$$10\log_{10}\left(\frac{\lambda^2}{\sigma^2}\right) = 10\log_{10}\left(2N\left(\mathrm{erfc}^{-1}(2P_{fa})\right)^2\right)$$

In these equations

- σ^2 is the variance of the white Gaussian noise sequence
- N is the number of samples
- $erfc^{-1}$ is the inverse of the complementary error function
- P_{fa} is the probability of false alarm

Note: For probabilities of false alarm greater than or equal to 1/2, the formula for detection threshold as SNR is invalid because erfc^{-1} is less than or equal to zero for values of its argument greater than or equal to one. In that case, use the linear output of the function invoked by setting `outscale` to `'linear'`.

Detection in Complex-Valued White Gaussian Noise (Coherent Samples)

The NP detector for complex-valued signals is similar to that discussed in "Detection in Real-Valued White Gaussian Noise" on page 2-225. In addition, the function makes these assumptions:

- The variance of the complex-valued Gaussian random variable is divided equally among the real and imaginary parts.
- The real and imaginary parts are uncorrelated.

Under these assumptions, the linear detection threshold for an NP detector is

$$\frac{\lambda}{\sigma} = \sqrt{N}\,\mathrm{erfc}^{-1}(2P_{fa})$$

and expressed as a signal-to-noise ratio in decibels is:

$$10\log_{10}\left(\frac{\lambda^2}{\sigma^2}\right) = 10\log_{10}\left(N\left(\text{erfc}^{-1}(2P_{fa})\right)^2\right)$$

Note: For probabilities of false alarm greater than or equal to 1/2, the formula for detection threshold as SNR is invalid since erfc^{-1} is less than or equal to zero for values of its argument greater than or equal to one. In that case, use the linear output of the function invoked by setting `outscale` to `'linear'`.

Detection of Noncoherent Samples in White Gaussian Noise

For noncoherent samples in white Gaussian noise, detection of a nonzero mean leads to a square-law detector. For a detailed derivation, see [2], pp. 324–329.

The linear detection threshold for the noncoherent NP detector is:

$$\frac{\lambda}{\sigma} = \sqrt{P^{-1}(N, 1-P_{fa})}$$

The threshold expressed as a signal-to-noise ratio in decibels is:

$$10\log_{10}\left(\frac{\lambda^2}{\sigma^2}\right) = 10\log_{10} P^{-1}(N, 1-P_{fa})$$

where $P^{-1}(x, y)$ is the inverse of the lower incomplete gamma function, P_{fa} is the probability of false alarm, and N is the number of pulses.

pambgfun

Periodic ambiguity function

Syntax

```
pafmag = pambgfun(X,fs)
[pafmag,delay,doppler] = pambgfun(X,fs)
[pafmag,delay,doppler] = pambgfun(X,fs,P)

[pafmag,delay] = pambgfun(___,'Cut','Doppler')
[pafmag,delay] = pambgfun(___,'Cut','Doppler','CutValue',V)
[pafmag,doppler] = pambgfun(___,'Cut','Delay')
[pafmag,doppler] = pambgfun(___,'Cut','Delay','CutValue',V)
[pafmag,delay,doppler] = pambgfun(___,'Cut','2D')

pambgfun(___)
```

Description

`pafmag = pambgfun(X,fs)` returns the magnitude of the normalized periodic ambiguity function (PAF) for one period of the periodic signal `X`. `fs` is the sampling rate.

`[pafmag,delay,doppler] = pambgfun(X,fs)` also returns the time delay vector, `delay`, and the Doppler shift vector, `doppler`. The delay vector is along the zero Doppler cut of the PAF. The Doppler shift vector is along the zero delay cut.

`[pafmag,delay,doppler] = pambgfun(X,fs,P)` returns the magnitude of the normalized PAF for `P` periods of the periodic signal `X`.

`[pafmag,delay] = pambgfun(___,'Cut','Doppler')` returns the PAF, `pafmag`, along a zero Doppler cut. The `delay` argument contains the time delay vector corresponding to the columns of `pafmag`.

`[pafmag,delay] = pambgfun(___,'Cut','Doppler','CutValue',V)` returns the PAF, `pafmag`, along a nonzero Doppler cut specified by `V`. The `delay` argument contains the time delay vector corresponding to the columns of `pafmag`.

`[pafmag,doppler] = pambgfun( ___ ,'Cut','Delay')` returns the PAF, `pafmag`, along the zero delay cut. The `doppler` argument contains the Doppler shift vector corresponding to the rows of `pafmag`.

`[pafmag,doppler] = pambgfun( ___ ,'Cut','Delay','CutValue',V)` returns the PAF, `pafmag`, along a nonzero delay cut specified by `V`. The `doppler` argument contains the Doppler shift vector corresponding to the rows of `pafmag`.

`[pafmag,delay,doppler] = pambgfun( ___ ,'Cut','2D')` returns the PAF, `pafmag`, for all delays and Doppler shifts. The `doppler` argument contains the Doppler shift vector corresponding to the rows of `pafmag`. The `delay` argument contains the time delay vector corresponding to the columns of `pafmag`. You cannot use `'CutValue'` when `'Cut'` is set to `'2D'`.

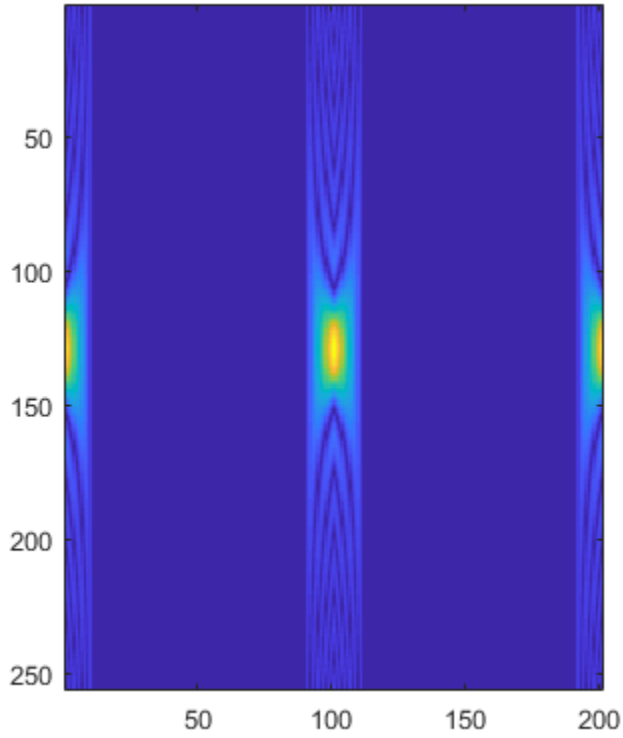
`pambgfun( ___ )` with no output arguments plots the PAF. When `'Cut'` is `'2D'`, the function produces a contour plot of the PAF function. When `'Cut'` is `'Delay'` or `'Doppler'`, the function produces a line plot of the PAF cut.

Examples

Periodic Ambiguity Function for Rectangular Waveform

Plot the PAF function of a rectangular pulse waveform for one period. Assume the pulse repetition frequency (PRF) is 10.0 kHz and that the sampling frequency is a multiple of the PRF.

```
PRF = 10.0e3;
fs = 101*PRF;
waveform = phased.RectangularWaveform('SampleRate',fs,'PulseWidth',1e-5, ...
    'NumPulses',1,'PRF',PRF);
wav = waveform();
pamf = pambgfun(wav,fs);
imagesc(pamf)
axis equal
axis tight
```



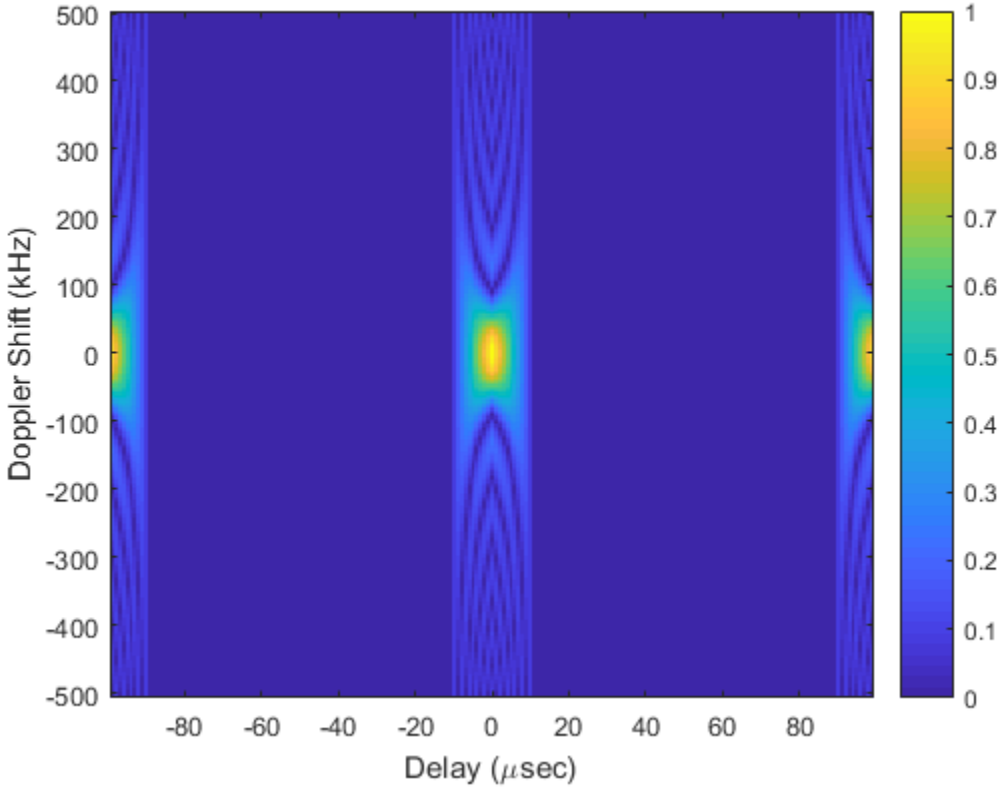
Periodic Ambiguity Function with Delay and Doppler Output

Plot the periodic ambiguity function of a rectangular pulse waveform for one period. Assume the pulse repetition frequency (PRF) is 10.0 kHz and that the sampling frequency is a multiple of the PRF. Return the Doppler and delay values from the `pambgfun` function.

```
PRF = 10.0e3;
fs = 101*PRF;
waveform = phased.RectangularWaveform('SampleRate',fs,'PulseWidth',1e-5, ...
    'NumPulses',1,'PRF',PRF);
wav = waveform();
[pamf,delays,doppler] = pambgfun(wav,fs);
```

Plot the periodic ambiguity function.

```
imagesc(delays*1e6,doppler/1000,pamf)
axis xy
xlabel('Delay (\musec)')
ylabel('Doppler Shift (kHz)')
colorbar
```



Zero Delay Cut of Periodic Ambiguity Function

Plot a cut at zero delay for the periodic ambiguity function of a rectangular pulse waveform for five periods. Assume the pulse repetition frequency is 10.0 kHz and that the sampling frequency is a multiple of the PRF. Return the Doppler and delay values from the function.

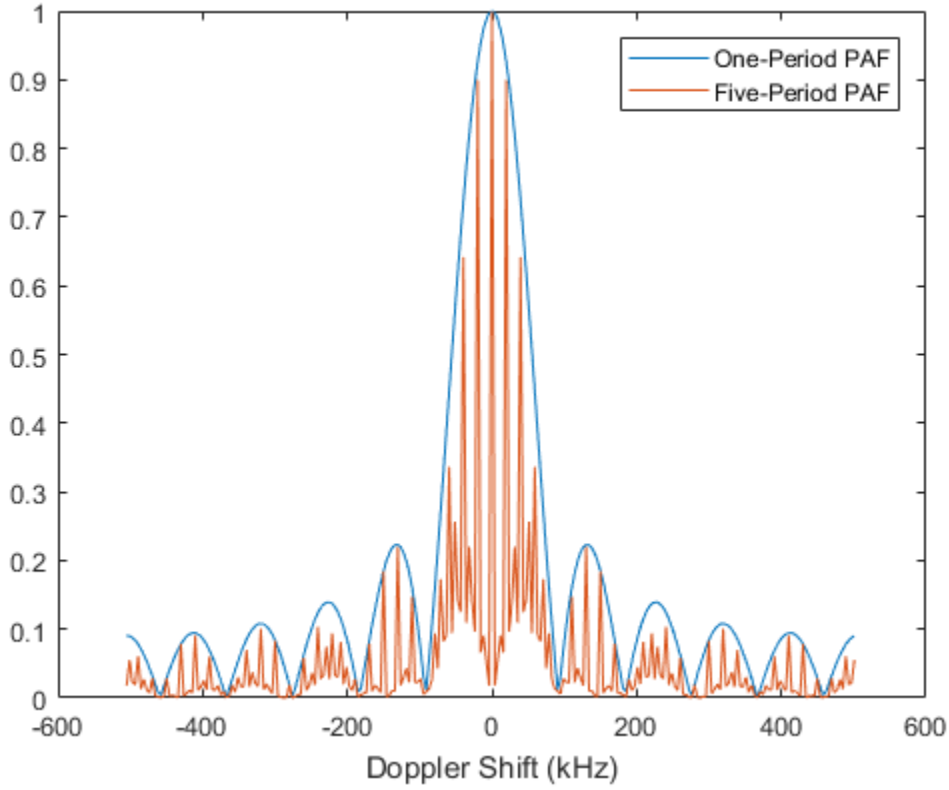
```
PRF = 10.0e3;
fs = 101*PRF;
waveform = phased.RectangularWaveform('SampleRate',fs,'PulseWidth',1e-5, ...
    'NumPulses',1,'PRF',PRF);
wav = waveform();
```

Find the periodic ambiguity functions along a zero delay cut for one and for five periods.

```
[pamf,delays,doppler] = pambgfun(wav,fs,1);
f1 = pamf(:,101);
[pamf,delays,doppler] = pambgfun(wav,fs,5);
f2 = pamf(:,101);
```

Plot the periodic ambiguity functions.

```
plot(doppler/1000,f1)
hold on
plot(doppler/1000,f2)
xlabel('Doppler Shift (kHz)')
legend('One-Period PAF','Five-Period PAF')
```



Zero Doppler Cut of LFM Periodic Ambiguity Function

Plot the zero Doppler cut for the five-period periodic ambiguity function of a linear FM pulse waveform. Assume the pulse repetition frequency (PRF) is 10.0 kHz and that the sampling frequency is a multiple of the PRF. Return the Doppler and delay values from the `pambgfun` function.

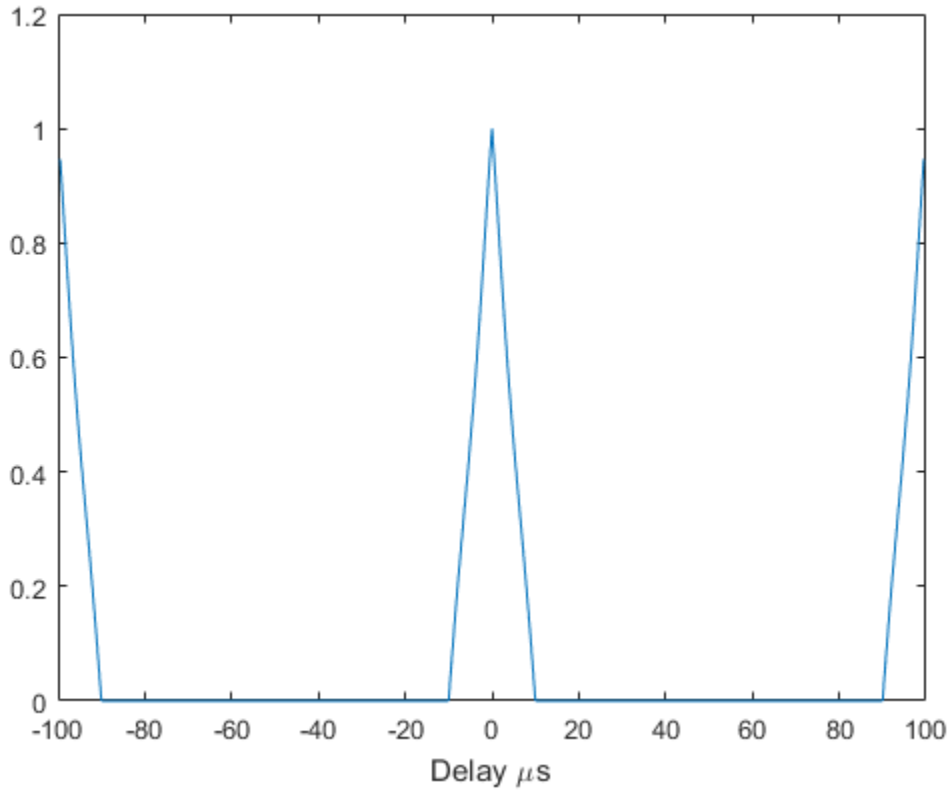
```
PRF = 10.0e3;
fs = 200*PRF;
waveform = phased.LinearFMWaveform('SampleRate',fs,'PulseWidth',1e-5, ...
    'NumPulses',1,'PRF',PRF);
wav = waveform();
```

Find the five-period periodic ambiguity function along a zero Doppler cut.

```
[pamf,delays] = pambgfun(wav,fs,5,'Cut','Doppler');
```

Plot the periodic ambiguity functions.

```
plot(delays*1.0e6,pamf)
xlabel('Delay \mus')
```



Non-Zero Doppler Cut of LFM Periodic Ambiguity Function

Plot a non-zero Doppler cut for the 5-period periodic ambiguity function of a linear FM pulse waveform by explicitly specifying the cut value. Assume the pulse repetition frequency is 10.0e3 Hz and that the sampling frequency is a multiple of the PRF. Return the doppler and delay values from the function.

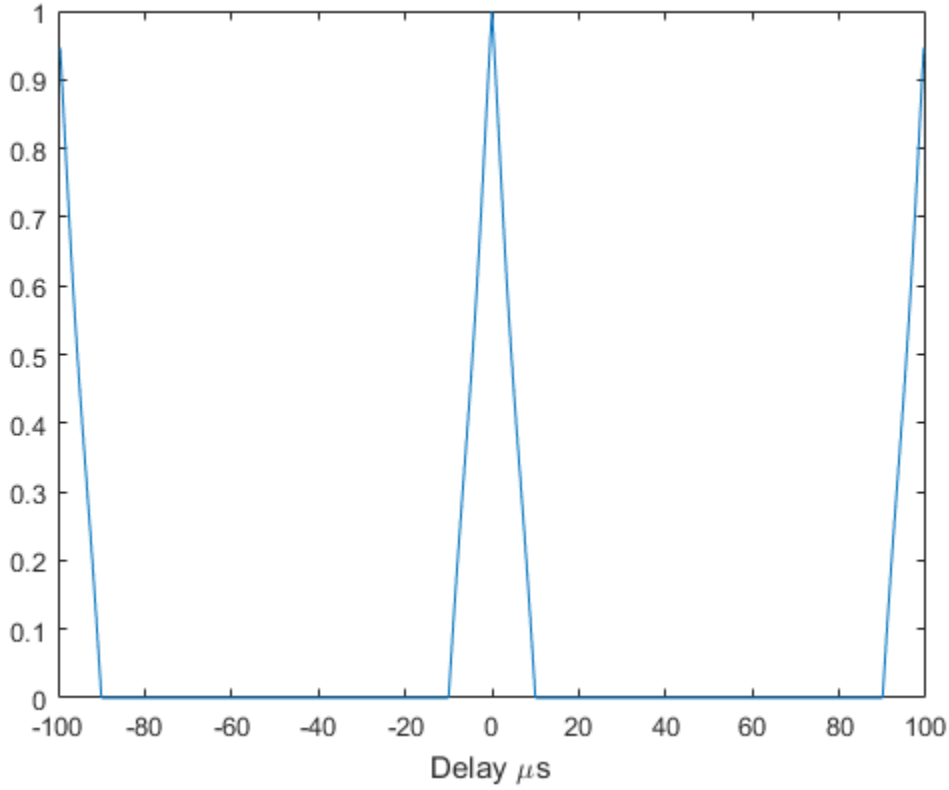
```
PRF = 10.0e3;
fs = 200*PRF;
waveform = phased.LinearFMWaveform('SampleRate',fs,'PulseWidth',1e-5,...
    'NumPulses',1,'PRF',PRF);
wav = waveform();
```

Find the 5-period periodic ambiguity function along a non-zero Doppler cut.

```
dopval = 20.0;
[pamf,delays] = pambgfun(wav,fs,5,'Cut','Doppler','CutValue',dopval);
```

Plot the periodic ambiguity functions.

```
plot(delays*1.0e6,pamf)
xlabel('Delay \mus')
```



Zero Delay Cut of FMCW Periodic Ambiguity Function

Plot a zero delay cut for the three-period periodic ambiguity function of an FMCW waveform. Assume a sweep bandwidth of 100 kHz with a sampling frequency of 1 MHz. Return and plot the Doppler shift values.

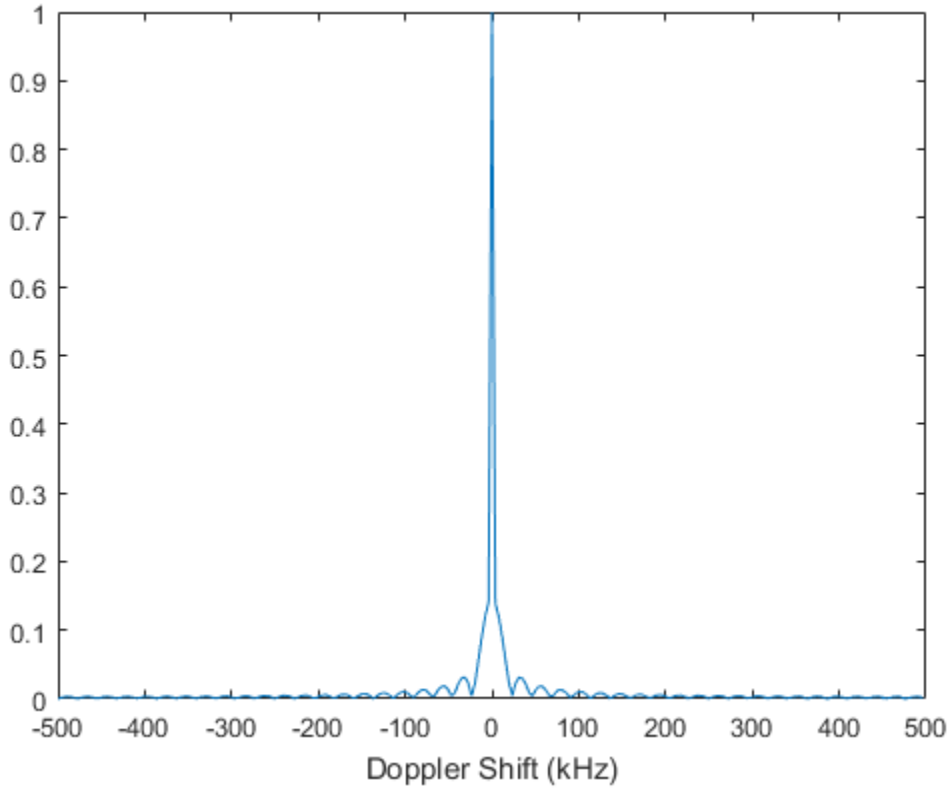
```
fs = 1.0e6;
waveform = phased.FMCWWaveform('SweepBandwidth',100.0e3,'SampleRate',fs, ...
    'OutputFormat','Sweeps','NumSweeps',1);
wav = waveform();
```

Find the three-period periodic ambiguity function along a zero delay cut.

```
[pamf,doppler] = pambgfun(wav,fs,3,'Cut','Delay');
```

Plot the zero delay cut of tje periodic ambiguity function.

```
plot(doppler/1.0e3,pamf)
xlabel('Doppler Shift (kHz)')
```



Nonzero Delay Cut of FMCW Periodic Ambiguity Function

Plot a non-zero delay cut of -20 µs for the three-period periodic ambiguity function of an FMCW waveform. Assume a sweep bandwidth of 100 kHz with a sampling frequency of 1 MHz. Return and plot the Doppler shift values.

```
fs = 1.0e6;
waveform = phased.FMCWWaveform('SweepBandwidth',100.0e3,'SampleRate',fs, ...
```

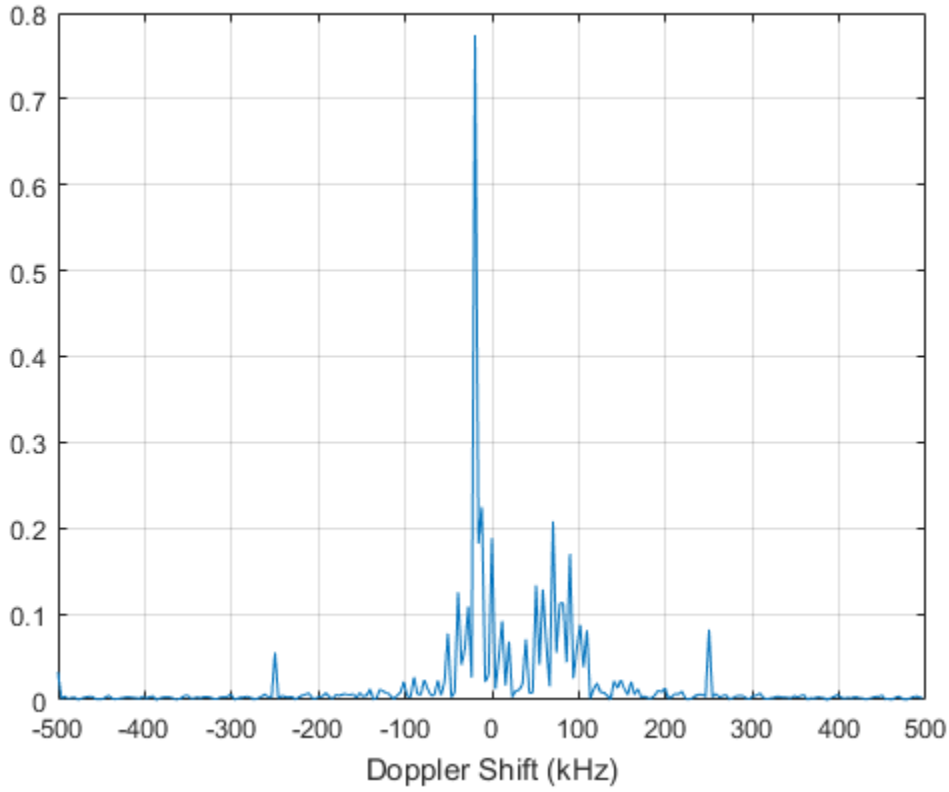
```
    'OutputFormat','Sweeps','NumSweeps',1,'SweepTime',100e-6);
wav = waveform();
```

Find the three-period periodic ambiguity function along a nonzero Delay cut.

```
delayval = -20.0e-6;
[pamf,doppler] = pambgfun(wav,fs,3,'Cut','Delay','CutValue',delayval);
```

Plot the nonzero delay cut of the periodic ambiguity function.

```
plot(doppler/1.0e3,pamf)
grid
xlabel('Doppler Shift (kHz)')
```



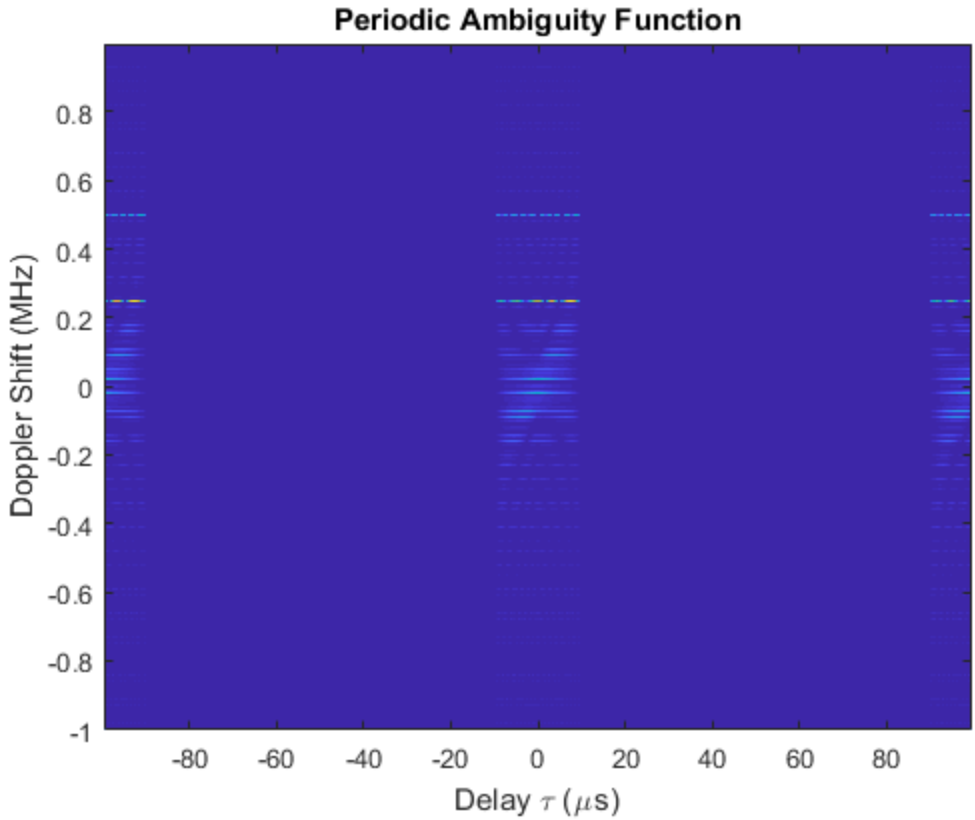
Linear FM Periodic Ambiguity Diagram Image

Display an image of the 9-period periodic ambiguity function for a linear FM pulse waveform. Assume the pulse repetition frequency is 10.0e3 Hz and that the sampling frequency is a multiple of the PRF.

```
PRF = 10.0e3;
fs = 200*PRF;
waveform = phased.LinearFMWaveform('SampleRate',fs,'PulseWidth',1e-5,...
    'NumPulses',1,'PRF',PRF);
wav = waveform();
```

Compute and display the 9-period periodic ambiguity function for all delays and frequencies.

```
[pamf,delays,doppler] = pambgfun(wav,fs,9,'Cut','2D');
imagesc(delays*1e6,doppler/1e6,pamf)
title('Periodic Ambiguity Function')
xlabel('Delay \tau ({\mu}s)')
ylabel('Doppler Shift (MHz)')
axis xy
```



Linear FM Periodic Ambiguity Diagram

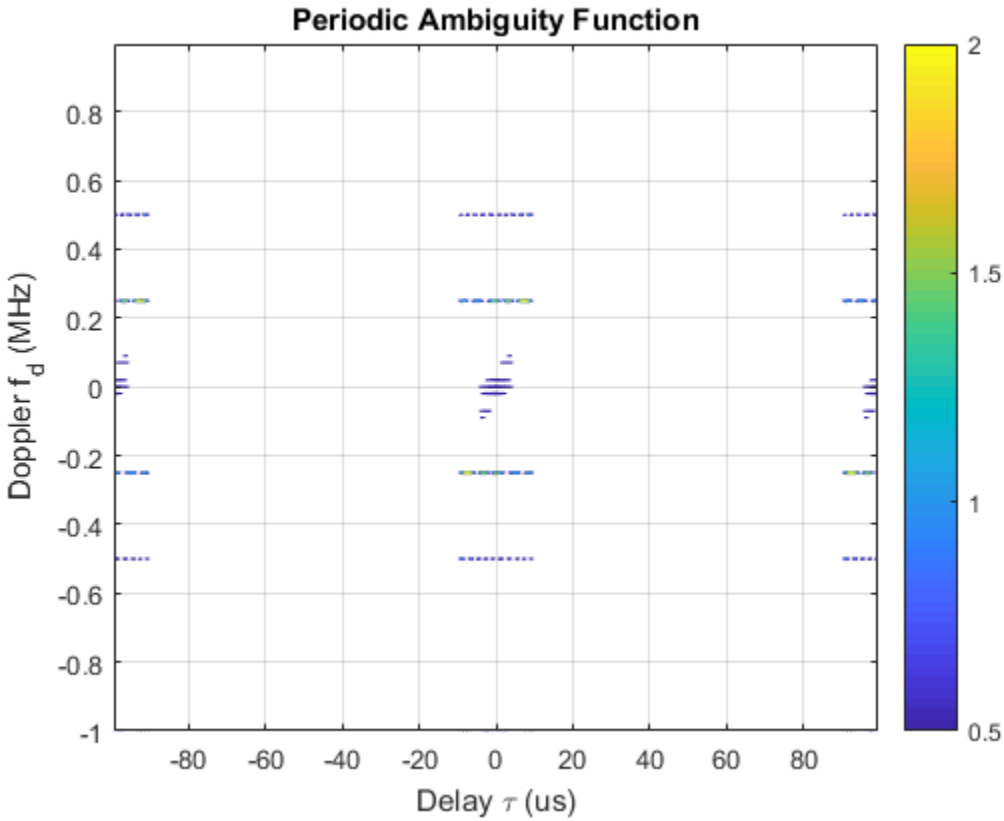
Plot the seven-period periodic ambiguity function of a linear FM pulse waveform. Assume the pulse repetition frequency (PRF) is 10.0 kHz and that the sampling frequency is a multiple of the PRF.

```
PRF = 10.0e3;
```

```
fs = 200*PRF;
waveform = phased.LinearFMWaveform('SampleRate',fs,'PulseWidth',1e-5, ...
    'NumPulses',1,'PRF',PRF);
wav = waveform();
```

Find the periodic ambiguity function.

```
pambgfun(wav,fs,7,'Cut','2D')
```



Input Arguments

X — Input pulse waveform

complex-valued vector

Input pulse waveform, specified as a complex-valued vector.

Example: `[0,.1,.3,.4,.3,.1.0]`

Data Types: `double`
Complex Number Support: Yes

`fs` — Sampling frequency

positive scalar

Sampling frequency, specified as a positive scalar. Units are in hertz.

Example: `3e3`

Data Types: `double`

`P` — Number of periods

1 (default) | positive integer

Number of periods, specified as a positive integer.

Example: `5`

Data Types: `double`

`V` — Optional time delay or Doppler shift at which ambiguity function cut is taken

0 (default) | real-valued scalar

When you set `'Cut'` to `'Delay'` or `'Doppler'`, use `V` to specify a nonzero cut value. You cannot use `V` when you set `'Cut'` to `'2D'`.

When `'Cut'` is set to `'Delay'`, `V` is the time delay at which the cut is taken. Time delay units are in seconds.

When `'Cut'` is set to `'Doppler'`, `V` is the Doppler frequency shift at which the cut is taken. Doppler units are in hertz.

Example: `10.0`

Data Types: `double`

Output Arguments

`pafmag` — Normalized PAF function magnitude

real-valued *M*-by-*N* matrix | real-valued *M*-element column vector | real-valued *N*-element row vector

Normalized PAF function magnitude, returned as a vector or a matrix of nonnegative real values. The dimensions of `pafmag` depend on the value of `'Cut'`.

`'Cut'`	`pafmag`dimensions
`'2D'`	*M*-by-*N* matrix.
`'Delay'`	*M*-element column vector.
`'Doppler'`	*N*-element row vector.

M is the number of Doppler frequencies and *N* is the number of time delays.

`delay` — Time delay vector

real-valued *N*-element vector

Time delay vector, returned as an *N*-by-1 vector. If *N* is the length of signal `X`, then the delay vector consist of $2N - 1$ samples in the range, $-(N/2) - 1,\ldots,(N/2) - 1)$.

`doppler` — Doppler shift vector

real-valued *M* vector

Doppler shift vector, returned as an *M*-by-1 vector of Doppler frequencies. The Doppler frequency vector consists of $M = 2^{ceil(log2\ N)}$ equally-spaced samples. Frequencies are $(-(M/2)F_s,\ldots,(M/2-1)F_s)$.

Definitions

Periodic Ambiguity Function

The periodic ambiguity function (PAF) is an extension of the ordinary ambiguity function to periodic waveforms.

Use this function analyze the response of a correlation receiver to a time-delayed or Doppler-shifted narrowband periodic waveform. Narrowband periodic signals consist of CW tones modulated by a periodic complex envelope. These types of signals are commonly used in radar systems to form transmitted pulse trains.

A time periodic waveform has the property *y(t + T) = y(t)*, where *T* is the period. The PAF function for an *N*-period waveform is defined as

$$A_{NT}(\tau,\nu) = \frac{1}{NT}\int_0^{NT} y(t+\frac{\tau}{2})y^*(t-\frac{\tau}{2})e^{i2\pi\nu t}dt$$

Taking advantage of the periodicity, you can rewrite the function as

$$A_{NT}(\tau,\nu) = \frac{1}{NT}\sum_{n=1}^{N} e^{i2\pi\nu(n-1)T}\int_0^{T} u(t+\frac{\tau}{2})u^*(t-\frac{\tau}{2})e^{i2\pi\nu s}ds$$

The last term on the right side is the one-period PAF function, $A_T(\tau,\nu)$. The first term on the right side is due to Doppler only. The Doppler term is proportional to the periodic *sinc()* function and you can rewrite the periodic ambiguity function as

$$A_{NT}(\tau,\nu) = \frac{\sin 2\pi\nu NT}{N\sin 2\pi\nu T}e^{i2\pi\nu(N-1)T}A_T(\tau,\nu)$$

The Doppler term improves the Doppler resolution by a factor of *1/NT*.

The one-period PAF function is not the same as the ordinary ambiguity because the integration limits are different.

phitheta2azel

Convert angles from phi/theta form to azimuth/elevation form

Syntax

```
AzEl = phitheta2azel(PhiTheta)
```

Description

`AzEl = phitheta2azel(PhiTheta)` converts the phi/theta angle pairs to their corresponding azimuth/elevation angle pairs.

Examples

Convert Phi and Theta to Azimuth and Elevation

Find the azimuth and elevation representation for $\varphi = 30°$ and $\theta = 0°$.

```
azel = phitheta2azel([30;0]);
```

Input Arguments

`PhiTheta` — Phi/theta angle pairs

two-row matrix

Phi and theta angles, specified as a two-row matrix. Each column of the matrix represents an angle in degrees, in the form [phi; theta].

Data Types: `double`

Output Arguments

`AzEl` — Azimuth/elevation angle pairs

two-row matrix

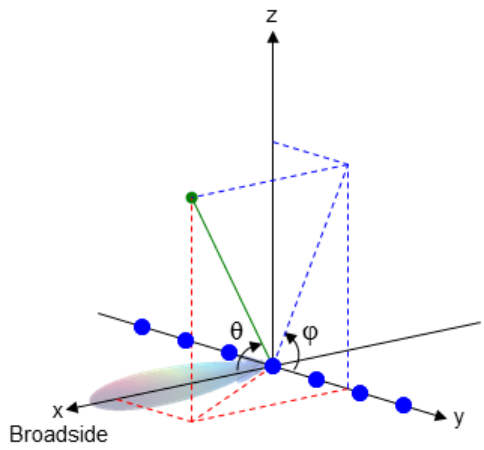
Azimuth and elevation angles, returned as a two-row matrix. Each column of the matrix represents an angle in degrees, in the form [azimuth; elevation]. The matrix dimensions of `AzEl` are the same as those of `PhiTheta`.

Definitions

Phi Angle, Theta Angle

The φ angle is the angle from the positive *y*-axis toward the positive *z*-axis, to the vector's orthogonal projection onto the *yz* plane. The φ angle is between 0 and 360 degrees. The θ angle is the angle from the *x*-axis toward the *yz* plane, to the vector itself. The θ angle is between 0 and 180 degrees.

The figure illustrates φ and θ for a vector that appears as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue circles.



The coordinate transformations between φ/θ and *az*/*el* are described by the following equations

$$\sin(\text{el}) = \sin\phi\sin\theta$$
$$\tan(\text{az}) = \cos\phi\tan\theta$$

$$\cos\theta = \cos(\text{el})\cos(\text{az})$$
$$\tan\phi = \tan(\text{el}) / \sin(\text{az})$$

Azimuth Angle, Elevation Angle

The *azimuth angle* of a vector is the angle between the *x*-axis and the orthogonal projection of the vector onto the *xy* plane. The angle is positive in going from the *x* axis toward the *y* axis. Azimuth angles lie between –180 and 180 degrees. The *elevation angle* is the angle between the vector and its orthogonal projection onto the *xy*-plane. The angle is positive when going toward the positive *z*-axis from the *xy* plane. These definitions assume the boresight direction is the positive *x*-axis.

Note: The elevation angle is sometimes defined in the literature as the angle a vector makes with the positive *z*-axis. The MATLAB and Phased Array System Toolbox products do not use this definition.

This figure illustrates the azimuth angle and elevation angle for a vector that appears as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue circles.

`azel2phitheta`

Topics

"Spherical Coordinates"

Introduced in R2012a

phitheta2azelpat

Convert radiation pattern from phi/theta form to azimuth/elevation form

Syntax

```
pat_azel = phitheta2azelpat(pat_phitheta,phi,theta)
pat_azel = phitheta2azelpat(pat_phitheta,phi,theta,az,el)
[pat_azel,az,el] = phitheta2azelpat( ___ )
```

Description

`pat_azel = phitheta2azelpat(pat_phitheta,phi,theta)` expresses the antenna radiation pattern `pat_phitheta` in azimuth/elevation angle coordinates instead of φ/θ angle coordinates. `pat_phitheta` samples the pattern at φ angles in `phi` and θ angles in `theta`. The `pat_azel` matrix uses a default grid that covers azimuth values from –90 to 90 degrees and elevation values from –90 to 90 degrees. In this grid, `pat_azel` is uniformly sampled with a step size of 1 for azimuth and elevation. The function interpolates to estimate the response of the antenna at a given direction.

`pat_azel = phitheta2azelpat(pat_phitheta,phi,theta,az,el)` uses vectors `az` and `el` to specify the grid at which to sample `pat_azel`. To avoid interpolation errors, `az` should cover the range [–180, 180] and `el` should cover the range [–90, 90].

`[pat_azel,az,el] = phitheta2azelpat( ___ )` returns vectors containing the azimuth and elevation angles at which `pat_azel` samples the pattern, using any of the input arguments in the previous syntaxes.

Examples

Convert Radiation Pattern to Azimuth and Elevation

Convert a radiation pattern to azimuth/elevation form, with the azimuth and elevation angles spaced 1° apart.

Define the pattern in terms of φ and θ.

```
phi = 0:360;
theta = 0:180;
pat_phitheta = mag2db(repmat(cosd(theta)',1,numel(phi)));
```

Convert the pattern to azimuth/elevation space.

```
pat_azel = phitheta2azelpat(pat_phitheta,phi,theta);
```

Plot Converted Radiation Pattern

Convert a radiation pattern from theta/phi coordinates to azimuth/elevation coordinates, with azimuth and elevation angles spaced 1° apart.

Define the pattern in terms of phi, ϕ, and theta, θ, coordinates.

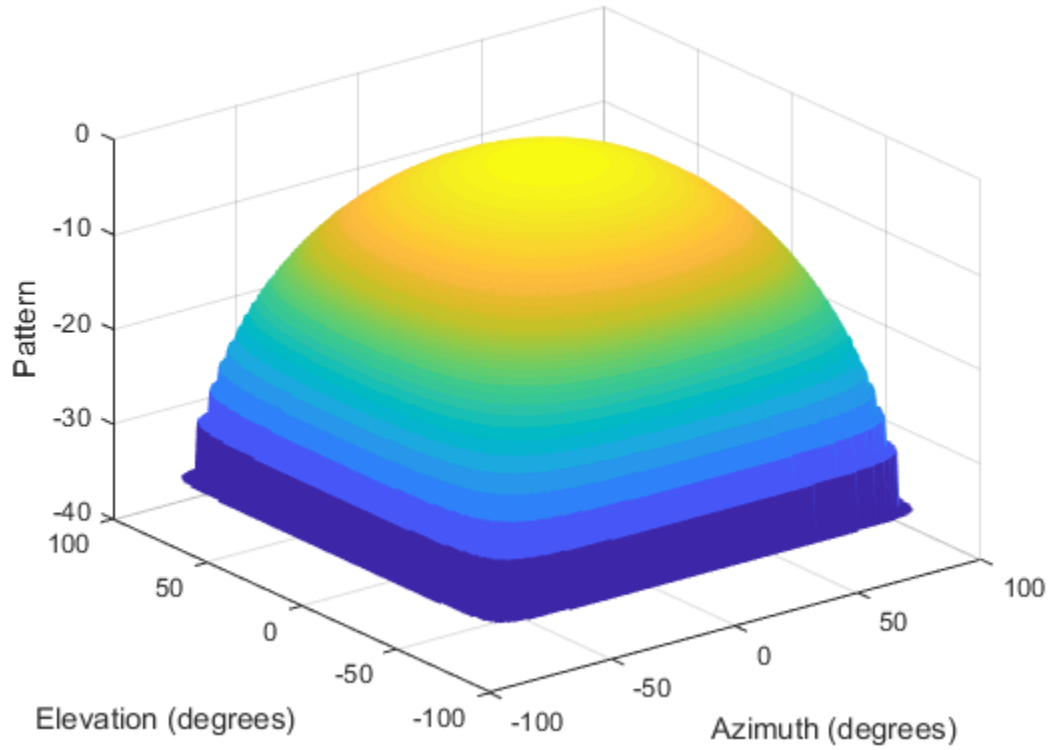
```
phi = 0:360;
theta = 0:180;
pat_phitheta = mag2db(repmat(cosd(theta)',1,numel(phi)));
```

Convert the pattern to azimuth/elevation coordinates. Get the azimuth and elevation angles for use in plotting.

```
[pat_azel,az,el] = phitheta2azelpat(pat_phitheta,phi,theta);
```

Plot the radiation pattern.

```
H = surf(az,el,pat_azel);
H.LineStyle = 'none';
xlabel('Azimuth (degrees)');
ylabel('Elevation (degrees)');
zlabel('Pattern');
```



Convert Radiation Pattern For Specific Azimuth/Elevation Values

Convert a radiation pattern from phi/theta coordinates to azimuth/elevation coordinates, with the azimuth and elevation angles spaced 5° apart.

Define the pattern in terms of phi and theta.

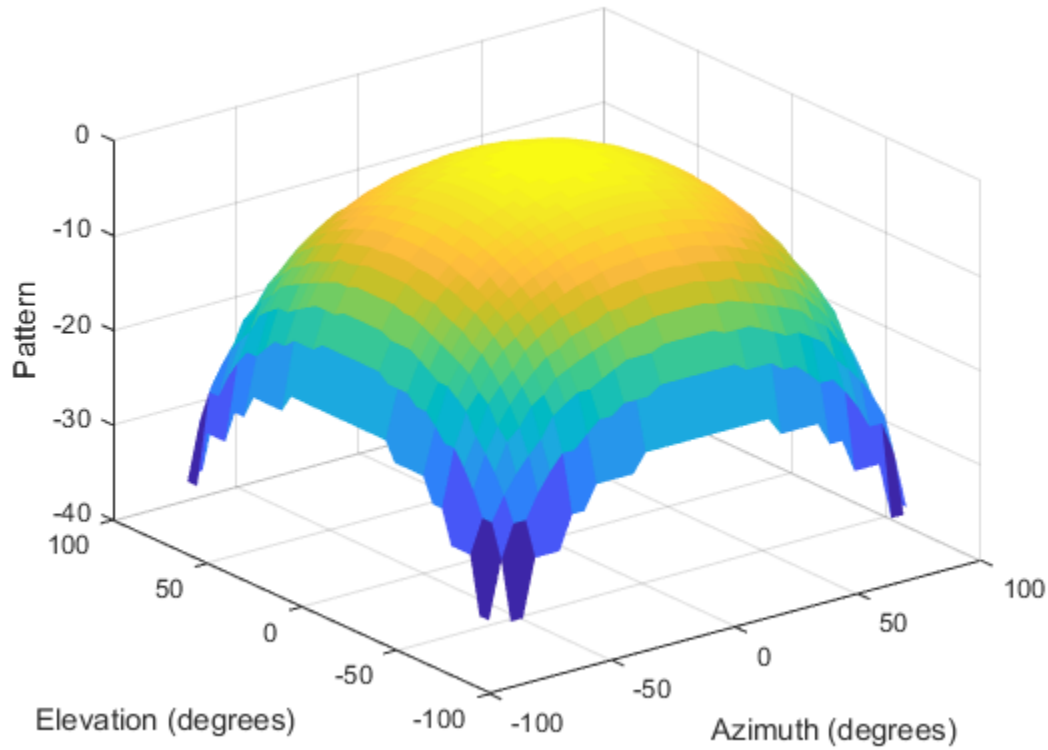
```
phi = 0:360;
theta = 0:180;
pat_phitheta = mag2db(repmat(cosd(theta)',1,numel(phi)));
```

Define the set of azimuth and elevation angles at which to sample the pattern. Then, convert the pattern.

```
az = -180:5:180;
el = -90:5:90;
pat_azel = phitheta2azelpat(pat_phitheta,phi,theta,az,el);
```

Plot the radiation pattern.

```
H = surf(az,el,pat_azel);
H.LineStyle = 'none';
xlabel('Azimuth (degrees)');
ylabel('Elevation (degrees)');
zlabel('Pattern');
```



- Antenna Array Analysis with Custom Radiation Pattern

Input Arguments

`pat_phitheta` — Antenna radiation pattern in phi/theta form

Q-by-P matrix

Antenna radiation pattern in phi/theta form, specified as a Q-by-P matrix. `pat_phitheta` samples the 3-D magnitude pattern in decibels, in terms of φ and θ angles. P is the length of the `phi` vector, and Q is the length of the `theta` vector.

Data Types: `double`

`phi` — Phi angles

vector of length P

Phi angles at which `pat_phitheta` samples the pattern, specified as a vector of length P. Each φ angle is in degrees, between 0 and 360.

Data Types: `double`

`theta` — Theta angles

vector of length Q

Theta angles at which `pat_phitheta` samples the pattern, specified as a vector of length Q. Each θ angle is in degrees, between 0 and 180.

Data Types: `double`

`az` — Azimuth angles

`[-180:180]` (default) | vector of length L

Azimuth angles at which `pat_azel` samples the pattern, specified as a vector of length L. Each azimuth angle is in degrees, between –180 and 180.

Data Types: `double`

`el` — Elevation angles

`[-90:90]` (default) | vector of length M

Elevation angles at which `pat_azel` samples the pattern, specified as a vector of length M. Each elevation angle is in degrees, between –90 and 90.

Data Types: `double`

Output Arguments

`pat_azel` — Antenna radiation pattern in azimuth/elevation form
M-by-L matrix

Antenna radiation pattern in azimuth/elevation form, returned as an M-by-L matrix. `pat_azel` samples the 3-D magnitude pattern in decibels, in terms of azimuth and elevation angles. L is the length of the `az` vector, and M is the length of the `el` vector.

`az` — Azimuth angles
vector of length L

Azimuth angles at which `pat_azel` samples the pattern, returned as a vector of length L. Angles are expressed in degrees.

`el` — Elevation angles
vector of length M

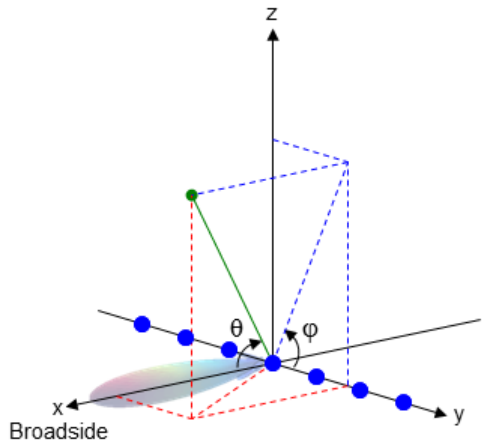
Elevation angles at which `pat_azel` samples the pattern, returned as a vector of length M. Angles are expressed in degrees.

Definitions

Phi Angle, Theta Angle

The φ angle is the angle from the positive *y*-axis toward the positive *z*-axis, to the vector's orthogonal projection onto the *yz* plane. The φ angle is between 0 and 360 degrees. The θ angle is the angle from the *x*-axis toward the *yz* plane, to the vector itself. The θ angle is between 0 and 180 degrees.

The figure illustrates φ and θ for a vector that appears as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue circles.



The coordinate transformations between φ/θ and *az*/*el* are described by the following equations

$$\sin(\text{el}) = \sin\phi\sin\theta$$
$$\tan(\text{az}) = \cos\phi\tan\theta$$

$$\cos\theta = \cos(\text{el})\cos(\text{az})$$
$$\tan\phi = \tan(\text{el}) / \sin(\text{az})$$

Azimuth Angle, Elevation Angle

The *azimuth angle* of a vector is the angle between the *x*-axis and the orthogonal projection of the vector onto the *xy* plane. The angle is positive in going from the *x* axis toward the *y* axis. Azimuth angles lie between –180 and 180 degrees. The *elevation angle* is the angle between the vector and its orthogonal projection onto the *xy*-plane. The angle is positive when going toward the positive *z*-axis from the *xy* plane. These definitions assume the boresight direction is the positive *x*-axis.

Note: The elevation angle is sometimes defined in the literature as the angle a vector makes with the positive *z*-axis. The MATLAB and Phased Array System Toolbox products do not use this definition.

This figure illustrates the azimuth angle and elevation angle for a vector that appears as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue circles.

phitheta2uv

Convert phi/theta angles to u/v coordinates

Syntax

```
UV = phitheta2uv(PhiTheta)
```

Description

`UV = phitheta2uv(PhiTheta)` converts the phi/theta angle pairs to their corresponding *u*/*v* space coordinates.

Examples

Conversion of Phi-Theta Pair

Find the corresponding *u*-*v* representation for φ = 30° and θ = 0°.

```
uv = phitheta2uv([30; 0])
```

```
uv =

     0
     0
```

Input Arguments

`PhiTheta` — Phi/theta angle pairs

two-row matrix

Phi and theta angles, specified as a two-row matrix. Each column of the matrix represents an angle in degrees, in the form [phi; theta].

Data Types: `double`

Output Arguments

UV — Angle in u/v space

two-row matrix

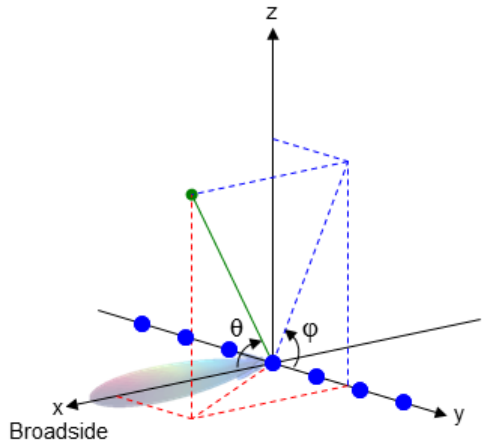
Angle in *u*/*v* space, returned as a two-row matrix. Each column of the matrix represents an angle in the form [*u*; *v*]. The matrix dimensions of `UV` are the same as those of `PhiTheta`.

Definitions

Phi Angle, Theta Angle

The φ angle is the angle from the positive *y*-axis toward the positive *z*-axis, to the vector's orthogonal projection onto the *yz* plane. The φ angle is between 0 and 360 degrees. The θ angle is the angle from the *x*-axis toward the *yz* plane, to the vector itself. The θ angle is between 0 and 180 degrees.

The figure illustrates φ and θ for a vector that appears as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue circles.



The coordinate transformations between φ/θ and *az*/*el* are described by the following equations

$$\sin(\mathrm{el}) = \sin\phi\sin\theta$$
$$\tan(\mathrm{az}) = \cos\phi\tan\theta$$

$$\cos\theta = \cos(\mathrm{el})\cos(\mathrm{az})$$
$$\tan\phi = \tan(\mathrm{el}) / \sin(\mathrm{az})$$

U/V Space

The u/v coordinates for the hemisphere $x \geq 0$ are derived from the phi and theta angles.

The relations are

$$u = \sin\theta\cos\phi$$
$$v = \sin\theta\sin\phi$$

In these expressions, φ and θ are the phi and theta angles, respectively.

In terms of azimuth and elevation, the u and v coordinates are

$$u = \cos el \sin az$$
$$v = \sin el$$

The values of u and v satisfy the inequalities

$$-1 \leq u \leq 1$$
$$-1 \leq v \leq 1$$
$$u^2 + v^2 \leq 1$$

Conversely, the phi and theta angles can be written in terms of u and v using

$$\tan\phi = u / v$$
$$\sin\theta = \sqrt{u^2 + v^2}$$

The azimuth and elevation angles can also be written in terms of u and v

$$\sin el = v$$

$$\tan az = \frac{u}{\sqrt{1-u^2-v^2}}$$

"Spherical Coordinates"

Introduced in R2012a

phitheta2uvpat

Convert radiation pattern from phi/theta form to u/v form

Syntax

```
pat_uv = phitheta2uvpat(pat_phitheta,phi,theta)
pat_uv = phitheta2uvpat(pat_phitheta,phi,theta,u,v)
[pat_uv,u,v] = phitheta2uvpat( ___ )
```

Description

`pat_uv = phitheta2uvpat(pat_phitheta,phi,theta)` expresses the antenna radiation pattern `pat_phitheta` in u/v space coordinates instead of φ/θ angle coordinates. `pat_phitheta` samples the pattern at φ angles in `phi` and θ angles in `theta`. The `pat_uv` matrix uses a default grid that covers u values from –1 to 1 and v values from –1 to 1. In this grid, `pat_uv` is uniformly sampled with a step size of 0.01 for u and v. The function interpolates to estimate the response of the antenna at a given direction. Values in `pat_uv` are NaN for u and v values outside the unit circle because u and v are undefined outside the unit circle.

`pat_uv = phitheta2uvpat(pat_phitheta,phi,theta,u,v)` uses vectors `u` and `v` to specify the grid at which to sample `pat_uv`. To avoid interpolation errors, `u` should cover the range [–1, 1] and `v` should cover the range [–1, 1].

`[pat_uv,u,v] = phitheta2uvpat( ___ )` returns vectors containing the u and v coordinates at which `pat_uv` samples the pattern, using any of the input arguments in the previous syntaxes.

Examples

Conversion of Radiation Pattern

Convert a radiation pattern to u-v form, with the u and v coordinates spaced by 0.01.

Define the pattern in terms of φ and θ.

```
phi = 0:360;
theta = 0:90;
pat_phitheta = mag2db(repmat(cosd(theta)',1,numel(phi)));
```

Convert the pattern to u-v form.

```
pat_uv = phitheta2uvpat(pat_phitheta,phi,theta);
```

Convert and Plot Radiation Pattern

Convert a radiation pattern to $u - v$ coordinates, with the u and v coordinates spaced by 0.01.

Define the pattern in terms of ϕ and θ.

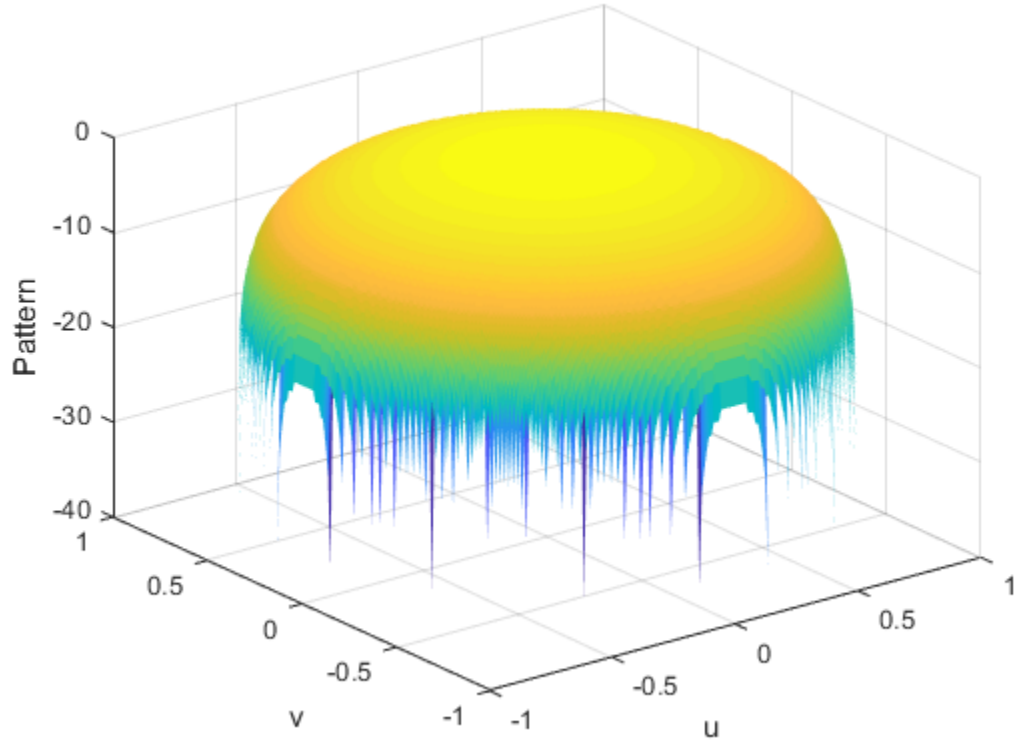
```
phi = 0:360;
theta = 0:90;
pat_phitheta = mag2db(repmat(cosd(theta)',1,numel(phi)));
```

Convert the pattern to $u - v$ coordinates. Store the u and v coordinates for use in plotting.

```
[pat_uv,u,v] = phitheta2uvpat(pat_phitheta,phi,theta);
```

Plot the result.

```
H = surf(u,v,pat_uv);
H.LineStyle = 'none';
xlabel('u');
ylabel('v');
zlabel('Pattern');
```



Convert Radiation Pattern For Specific U/V Values

Convert a radiation pattern to $u - v$ coordinates, with the u and v coordinates spaced by 0.05.

Define the pattern in terms of ϕ and θ.

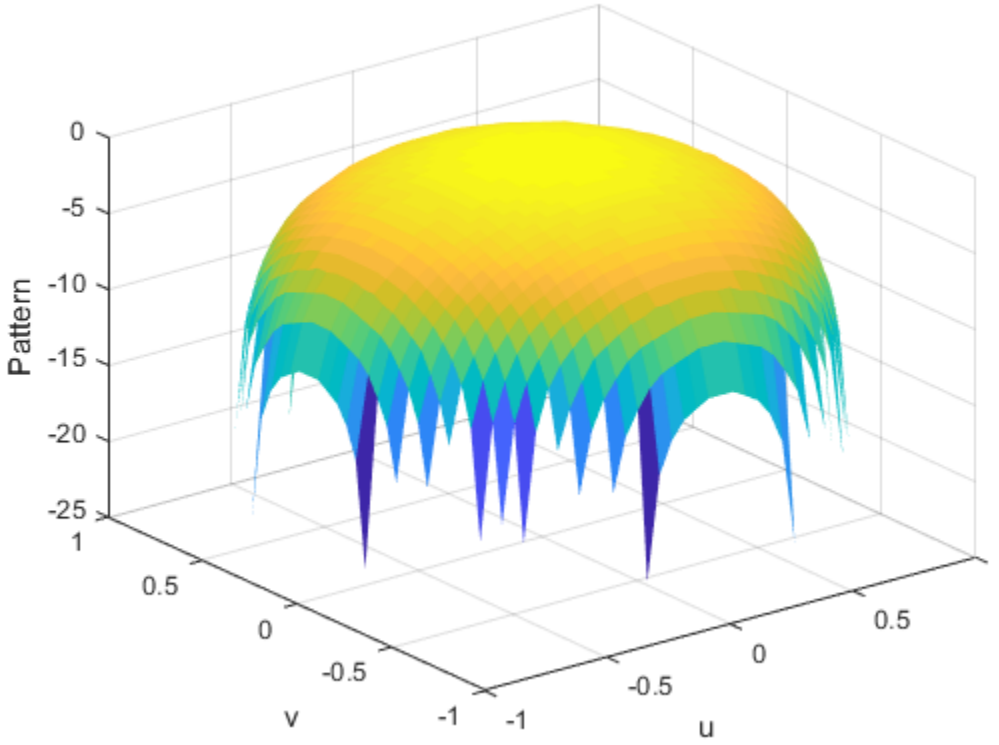
```
phi = 0:360;
theta = 0:90;
pat_phitheta = mag2db(repmat(cosd(theta)',1,numel(phi)));
```

Define the set of u and v coordinates at which to sample the pattern. Then, convert the pattern.

```
u = -1:0.05:1;
v = -1:0.05:1;
pat_uv = phitheta2uvpat(pat_phitheta,phi,theta,u,v);
```

Plot the result.

```
H = surf(u,v,pat_uv);
H.LineStyle = 'none';
xlabel('u');
ylabel('v');
zlabel('Pattern');
```



Input Arguments

`pat_phitheta` — Antenna radiation pattern in phi/theta form

Q-by-P matrix

Antenna radiation pattern in phi/theta form, specified as a Q-by-P matrix. `pat_phitheta` samples the 3-D magnitude pattern in decibels, in terms of φ and θ angles. P is the length of the `phi` vector, and Q is the length of the `theta` vector.

Data Types: `double`

`phi` — Phi angles
vector of length P

Phi angles at which `pat_phitheta` samples the pattern, specified as a vector of length P. Each φ angle is in degrees, between 0 and 180.

Data Types: `double`

`theta` — Theta angles
vector of length Q

Theta angles at which `pat_phitheta` samples the pattern, specified as a vector of length Q. Each θ angle is in degrees, between 0 and 90. Such angles are in the hemisphere for which *u* and *v* are defined.

Data Types: `double`

`u` — *u* coordinates
`[-1:0.01:1]` (default) | vector of length L

u coordinates at which `pat_uv` samples the pattern, specified as a vector of length L. Each *u* coordinate is between –1 and 1.

Data Types: `double`

`v` — *v* coordinates
`[-1:0.01:1]` (default) | vector of length M

v coordinates at which `pat_uv` samples the pattern, specified as a vector of length M. Each *v* coordinate is between –1 and 1.

Data Types: `double`

Output Arguments

`pat_uv` — Antenna radiation pattern in *u*/*v* form
M-by-L matrix

Antenna radiation pattern in *u*/*v* form, returned as an M-by-L matrix. `pat_uv` samples the 3-D magnitude pattern in decibels, in terms of *u* and *v* coordinates. L is the length of the `u` vector, and M is the length of the `v` vector. Values in `pat_uv` are NaN for *u* and *v* values outside the unit circle because *u* and *v* are undefined outside the unit circle.

u — *u* coordinates
vector of length L

u coordinates at which `pat_uv` samples the pattern, returned as a vector of length L.

v — *v* coordinates
vector of length M

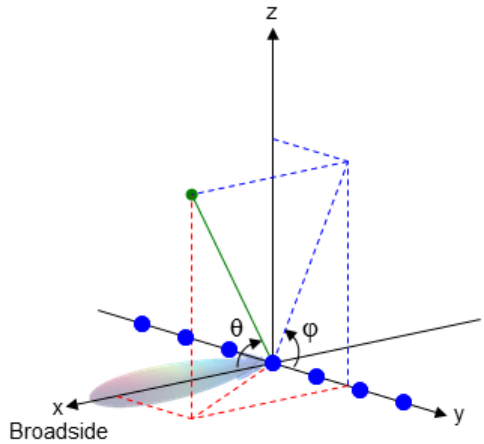
v coordinates at which `pat_uv` samples the pattern, returned as a vector of length M.

Definitions

Phi Angle, Theta Angle

The φ angle is the angle from the positive *y*-axis toward the positive *z*-axis, to the vector's orthogonal projection onto the *yz* plane. The φ angle is between 0 and 360 degrees. The θ angle is the angle from the *x*-axis toward the *yz* plane, to the vector itself. The θ angle is between 0 and 180 degrees.

The figure illustrates φ and θ for a vector that appears as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue circles.



The coordinate transformations between φ/θ and *az*/*el* are described by the following equations

$$\sin(\text{el}) = \sin\phi\sin\theta$$
$$\tan(\text{az}) = \cos\phi\tan\theta$$

$$\cos\theta = \cos(\text{el})\cos(\text{az})$$
$$\tan\phi = \tan(\text{el}) / \sin(\text{az})$$

U/V Space

The *u* and *v* coordinates are the direction cosines of a vector with respect to the *y*-axis and *z*-axis, respectively.

The *u*/*v* coordinates for the hemisphere $x \geq 0$ are derived from the phi and theta angles, as follows:

$$u = \sin\theta\cos\phi$$
$$v = \sin\theta\sin\phi$$

In these expressions, φ and θ are the phi and theta angles, respectively.

In terms of azimuth and elevation, the *u* and *v* coordinates are

$$u = \cos el\sin az$$
$$v = \sin el$$

The values of *u* and *v* satisfy the inequalities

$$-1 \leq u \leq 1$$
$$-1 \leq v \leq 1$$
$$u^2 + v^2 \leq 1$$

Conversely, the phi and theta angles can be written in terms of *u* and *v* using

$$\tan\phi = u / v$$
$$\sin\theta = \sqrt{u^2 + v^2}$$

The azimuth and elevation angles can also be written in terms of u and v

$$\sin el = v$$

$$\tan az = \frac{u}{\sqrt{1-u^2-v^2}}$$

physconst

Physical constants

Syntax

```
Const = physconst(Name)
```

Description

`Const = physconst(Name)` returns the constant specified in the `Name` argument. Valid values are `'LightSpeed'`, `'Boltzmann'`, or `'EarthRadius'`. Values are in SI units.

Input Arguments

`Name`

Character vector that indicates which physical constant the function returns. Values are not case sensitive.

Output Arguments

`Const`

Value of physical constant specified in the input argument `Name`.

Examples

Convert Frequency to Wavelength

Determine the wavelength of a 1 Ghz electromagnetic wave.

```
freq = 1e9;
lambda = physconst('LightSpeed')/freq
```

```
lambda =
```

```
    0.2998
```

Thermal Noise Power

Approximate the thermal noise power per unit bandwidth in the I and Q channels of a receiver.

Specify the receiver temperature and Boltzmann constant.

```
T = 290;
k = physconst('Boltzmann');
```

Compute the noise power per unit bandwidth, split evenly between the in-phase and quadrature channels.

```
Noise_power = 10*log10(k*T/2);
```

Definitions

Physical Constants

This table lists the supported constants and their values in SI units.

Constant	Description	Value
`'LightSpeed'`	Speed of light in vacuum	299,792,458 m/s. Most commonly denoted by c.
`'Boltzmann'`	Boltzmann constant relating energy to temperature	1.38×10^{-23} J/K. Most commonly denoted by k.
`'EarthRadius'`	Mean radius of the Earth	6,371,000 m

pilotcalib

Array calibration using pilot sources

Syntax

```
estpos = pilotcalib(nompos,x,pilotang)
[estpos,esttaper] = pilotcalib(nompos,x,pilotang)
[estpos,esttaper] = pilotcalib(nompos,x,pilotang,nomtaper)
[estpos,esttaper] = pilotcalib(nompos,x,pilotang,nomtaper,uncerts)
```

Description

`estpos = pilotcalib(nompos,x,pilotang)` returns the estimated element positions, `estpos`, of a sensor array. The argument `nompos` represents the relative nominal positions of the sensor array before calibration. The nominal position is relative to the first element of the array. The argument `x` represents the signals received by the array coming from the pilot sources. The argument `pilotang` contains the known directions of each of the pilot sources. Three or more pilot sources are required in this case.

`[estpos,esttaper] = pilotcalib(nompos,x,pilotang)` also returns the estimated array taper, `esttaper`. Each element of `esttaper` contains the estimated taper value of the corresponding array element. In this case, the prior nominal taper is one for each element. Four or more pilot sources are required in this case.

`[estpos,esttaper] = pilotcalib(nompos,x,pilotang,nomtaper)` specifies `nomtaper` as the nominal taper of the array. Four or more pilot sources are required in this case.

`[estpos,esttaper] = pilotcalib(nompos,x,pilotang,nomtaper,uncerts)` specifies `uncerts` as the configuration settings to use for calibrating array uncertainties. Configuration settings determine which parameters to estimate.

Examples

Estimate ULA Element Positions Using Pilot Calibration

Construct a 7-element ULA array of isotropic antenna elements spaced one-half wavelength apart. Assume the array is geometrically perturbed in three dimensions. Perform pilot calibration on the array using 4 pilot sources at azimuth and elevation angles of (-60,0), (10,-40), (40,0), and (120,45) degrees. For the calibration process, pilot signals have an SNR of 30 dB. Each pilot signal containes 10,000 samples. Assume the signals have a frequency of 600 MHz.

Set up the ULA with nominal parameters

```
fc = 600e6;
c = physconst('LightSpeed');
lam = c/fc;
d = 0.5*lam;
sIso = phased.IsotropicAntennaElement('FrequencyRange',[100,900]*1e6);
Nelem = 7;
NominalTaper = ones(1,Nelem);
sULA = phased.ULA('Element',sIso,'NumElements',Nelem,'ElementSpacing',d,...
    'Taper',NominalTaper);
```

Create the pilot signals

Randomly perturb the element positions with a gaussian distribution having 0.1 wavelength standard deviation. Do not perturb the position of the first element or the tapers.

```
posstd = 0.1;
rng default
NominalElementPositions = getElementPosition(sULA)/lam;
ReferenceElement = NominalElementPositions(:,1);
PositionPert = [zeros(3,1),posstd*randn(3,Nelem-1)];
ActualElementPositions = NominalElementPositions + PositionPert;
ActualTaper = NominalTaper;
```

Generate the signals using the actual positions and tapers.

```
Nsamp  = 10000;
ncov = 0.001;
PilotAng = [-60,10,40,120; 0,-40,0,45];
Npilot = size(PilotAng,2);
for n = 1:Npilot
```

```
    X(:,:,n) = sensorsig(ActualElementPositions,...
        Nsamp,PilotAng(:,n),ncov,'Taper',ActualTaper.');
end
```

Perform the pilot calibration

```
estpos = pilotcalib(NominalElementPositions - ReferenceElement*ones(1,Nelem),...
    X,PilotAng);
```

Add back the position of the reference sensor

```
estpos = estpos + NominalElementPositions(:,1)*ones(1,Nelem);
```

Examine the root mean squared (RMS) error of the calibrated parameters

Compute the RMS value of the initial position error.

```
numpos = 3*Nelem;
initposRMSE = sqrt(sum(PositionPert(:).^2)/numpos);
```

Compute the RMS value of the calibrated position error.

```
solvposErr = ActualElementPositions - estpos;
solvposRMSE = sqrt(sum(solvposErr(:).^2)/(numpos));
```

Compare the calibrated RMS position error to the initial position RMS error. The calibration reduces the RMS position error.

```
disp(solvposRMSE/initposRMSE)
```

```
   2.3493e-04
```

Estimate ULA Element Position and Taper Errors Using Pilot Calibration

Construct a 7-element ULA array of isotropic antenna elements spaced one-half wavelength apart. Assume the array is geometrically perturbed in three dimensions. Perform pilot calibration on the array using 4 pilot sources at azimuth and elevation angles of (-60,0), (10,80), (40,-40), and (-80,0) degrees. For the calibration process, pilot signals have an SNR of 30 dB. Each pilot signal containes 10,000 samples. Assume the signals have a frequency of 600 MHz.

Set up the ULA with nominal parameters

```
fc = 600e6;
```

```
c = physconst('LightSpeed');
lam = c/fc;
d = 0.5*lam;
sIso = phased.IsotropicAntennaElement('FrequencyRange',[100,900]*1e6);
Nelem = 7;
NominalTaper = ones(1,Nelem);
sULA = phased.ULA('Element',sIso,'NumElements',Nelem,'ElementSpacing',d,...
    'Taper',NominalTaper);
```

Create the pilot signals

Randomly perturb the element positions using a Gaussian distribution that has a standard deviation of 0.1 wavelength. Do not perturb the position of the first element.

```
posstd = 0.1;
rng default
NominalElementPositions = getElementPosition(sULA)/lam;
ReferenceElement = NominalElementPositions(:,1);
PositionPert = [zeros(3,1),posstd*randn(3,Nelem-1)];
ActualElementPositions = NominalElementPositions + PositionPert;
```

Perturb the taper in magnitude and phase. Do not perturb the first taper.

```
tapermagstd = 0.15;
taperphasestd = 0.15;
tapermagpert = tapermagstd*[0; randn(Nelem-1,1)];
ActualTaper = NominalTaper' + tapermagpert;
taperphasepert = taperphasestd*[0;randn(Nelem-1,1)];
ActualTaper = ActualTaper.*exp(1i*taperphasepert);
```

Generate the signals using the perturbed positions, tapers and four pilot sources.

```
Nsamp  = 10000;
ncov = 0.001;
PilotAng = [-60,10,40,-80; 10,80,-40,0];
Npilot = size(PilotAng,2);
for n = 1:Npilot
    X(:,:,n) = sensorsig(ActualElementPositions,Nsamp,...,
        PilotAng(:,n),ncov,'Taper',ActualTaper);
end
```

Perform the pilot calibration

```
[estpos,esttaper] = pilotcalib(...
    NominalElementPositions - ReferenceElement*ones(1,Nelem),...
```

```
    X,PilotAng);
```

Add back the position of the reference sensor

```
estpos = estpos + NominalElementPositions(:,1)*ones(1,Nelem);
```

Examine the root mean square (RMS) error of the calibrated parameters

Compute the RMS values of the initial taper perturbations.

```
tapermagpertRMSE = sqrt(tapermagpert'*tapermagpert/Nelem);
taperphasepertRMSE = sqrt(taperphasepert'*taperphasepert/Nelem);
```

Compute the RMS value of the calibrated taper magnitude error.

```
diff = abs(ActualTaper) - abs(esttaper);
diff2 = diff'*diff;
tapermagsolvRMSE = sqrt(diff2/Nelem);
```

Compare the calibrated RMS magnitude error to the initial RMS magnitude error. The calibration reduces the RMS magnitude error.

```
disp(tapermagsolvRMSE/tapermagpertRMSE)
```

```
   6.7715e-04
```

Compute the RMS value of the calibrated taper phase error.

```
diff = unwrap(angle(ActualTaper) - angle(esttaper));
diff2 = diff'*diff;
tapersolvphaseRMSE = sqrt(diff2/Nelem);
```

Compare the calibrated RMS phase error to the initial RMS phase error. The calibration reduces the RMS phase error.

```
disp(tapersolvphaseRMSE/taperphasepertRMSE)

% Compute the RMS value of the initial position error.
numpos = 3*Nelem;
initposRMSE = sqrt(sum(PositionPert(:).^2)/numpos);
```

```
    0.0021
```

Compute the RMS value of the calibrated position error.

```
solvposErr = ActualElementPositions - estpos;
solvposRMSE = sqrt(sum(solvposErr(:).^2)/(numpos));
```

Compare the calibrated RMS position error to the initial position RMS error. The calibration reduces the RMS position error.

```
disp(solvposRMSE/initposRMSE)
```

```

```

Estimate URA Element Position Errors Using Pilot Calibration

Construct a 9-element URA of isotropic antenna elements spaced one-half wavelength apart. Assume the array has been geometrically perturbed in all directions except for the first element. Perform pilot calibration on the array using 5 pilot sources at azimuth and elevation angles of (-60,0), (10,-40), (40,0), (120,45), and (170,50) degrees. For the calibration process, pilot signals have an SNR of 30 dB. Each pilot signal containes 10,000 samples. Assume the signals have a frequency of 600 MHz.

Create the array

For convenience, use a `phased.URA` System object™ to set the nominal position and taper values.

```
fc = 300e6;
c = physconst('LightSpeed');
lam = c/fc;
d = 0.5*lam;
sIso = phased.IsotropicAntennaElement('FrequencyRange',[100,900]*1e6);
sURA = phased.URA('Element',sIso,'Size',[3,3],...
    'ElementSpacing',d,'Taper',ones(3,3));
Nelem = getNumElements(sURA);
taper = getTaper(sURA);
```

Create the pilot signals

Randomly perturb the element positions using a Gaussian distribution that has a standard deviation of 0.1 wavelength. Do not perturb the position of the first element.

```
posstd = 0.1;
rng default
NominalElementPositions = getElementPosition(sURA)/lam;
ReferenceElement = NominalElementPositions(:,1);
```

```
PositionPert = [zeros(3,1),posstd*randn(3,Nelem-1)];
ActualElementPositions = NominalElementPositions + PositionPert;
```

Perturb the taper in magnitude and phase. Do not perturb the first taper.

```
NominalTaper = getTaper(sURA);
tapermagstd = 0.1;
taperphasestd = 0.1;
tapermagpert = tapermagstd*[0; randn(Nelem-1,1)];
ActualTaper = NominalTaper + tapermagpert;
taperphasepert = taperphasestd*[0;randn(Nelem-1,1)];
ActualTaper = ActualTaper.*exp(1i*taperphasepert);
```

Generate the pilot signals using the perturbed positions and tapers.

```
Nsamp  = 10000;
ncov = 0.001;
PilotAng = [-60,10,40,120,170; 0,-40,0,45,50];
Npilot = size(PilotAng,2);
for n = 1:Npilot
    X(:,:,n) = sensorsig(ActualElementPositions,Nsamp,...
        PilotAng(:,n),ncov,'Taper',ActualTaper);
end
```

Perform the pilot calibration

```
[estpos,esttaper] = pilotcalib(NominalElementPositions - ReferenceElement*ones(1,Nelem)
    X,PilotAng,NominalTaper);
```

Add back the position of the reference sensor.

```
estpos = estpos + NominalElementPositions(:,1)*ones(1,Nelem);
```

Examine the root mean square (RMS) error of the calibrated parameters

Compute the RMS values of the initial taper perturbations to compare with the RMS values of the calibrated parameters.

```
tapermagpertRMSE = sqrt(tapermagpert'*tapermagpert/Nelem);
taperphasepertRMSE = sqrt(taperphasepert'*taperphasepert/Nelem);
```

Compute the RMS value of the calibrated taper magnitude error.

```
diff = abs(ActualTaper) - abs(esttaper);
diff2 = diff'*diff;
tapermagsolvRMSE = sqrt(diff2/Nelem);
```

Compare the calibrated RMS magnitude error to the initial RMS error. The calibration reduces the RMS magnitude error.

```
disp(tapermagsolvRMSE/tapermagpertRMSE)
```

```
    0.0014
```

Compute the RMS value of the calibrated taper phase error.

```
diff = unwrap(angle(ActualTaper) - angle(esttaper));
diff2 = diff'*diff;
tapersolvphaseRMSE = sqrt(diff2/Nelem);
```

Compare the calibrated RMS phase error to the initial RMS error. The calibration reduces the RMS phase error.

```
disp(tapersolvphaseRMSE/taperphasepertRMSE)
```

```
    0.0015
```

Compute the RMS value of the initial position error.

```
numpos = 3*Nelem;
initposRMSE = sqrt(sum(PositionPert(:).^2)/numpos);
```

Compute the RMS value of the calibrated position error.

```
solvposErr = ActualElementPositions - estpos;
solvposRMSE = sqrt(sum(solvposErr(:).^2)/(numpos));
```

Compare the calibrated RMS position error to initial position RMS error. The calibration reduces the RMS position error.

```
disp(solvposRMSE/initposRMSE)
```

```
   7.1582e-04
```

Estimate Selected ULA Parameters Using Pilot Calibration

Construct a 6-element ULA of isotropic antenna elements that are spaced one-half wavelength apart. Assume the array has been geometrically perturbed in the *x*-*y* plane and contains an unknown taper error. Perform pilot calibration on the array using four pilot sources at azimuth and elevation angles of (-60,0), (10,-40), (40,0), and (120,45)

degrees. For the calibration process, pilot signals have an SNR of 30 dB. Each pilot signal containes 10,000 samples. Assume the signals have a frequency of 600 MHz.

Set up the ULA with nominal parameters

```
fc = 600e6;
c = physconst('LightSpeed');
lam = c/fc;
d = 0.5*lam;
sIso = phased.IsotropicAntennaElement('FrequencyRange',[100,900]*1e6);
Nelem = 6;
NominalTaper = ones(1,Nelem);
sULA = phased.ULA('Element',sIso,'NumElements',Nelem,'ElementSpacing',d,...
    'Taper',NominalTaper);
```

Create the pilot signals

Randomly perturb the element positions using a Gaussian distribution that has a standard deviation of 0.13 wavelength. Do not perturb the position of the first element.

```
posstd = 0.13;
rng default
NominalElementPositions = getElementPosition(sULA)/lam;
ReferenceElement = NominalElementPositions(:,1);
PositionPert = [zeros(3,1),posstd*randn(3,Nelem-1)];
ActualElementPositions = NominalElementPositions + PositionPert;
```

Perturb the taper in magnitude and phase. Do not perturb the first taper.

```
tapermagstd = 0.15;
taperphasestd = 0.15;
tapermagpert = tapermagstd*[0; randn(Nelem-1,1)];
ActualTaper = NominalTaper' + tapermagpert;
taperphasepert = taperphasestd*[0;randn(Nelem-1,1)];
ActualTaper = ActualTaper.*exp(1i*taperphasepert);
```

Generate the signals using the perturbed positions and tapers.

```
Nsamp  = 10000;
ncov = 0.001;
PilotAng = [-60,10,40,120; 0,-40,0,45];
Npilot = size(PilotAng,2);
for n = 1:Npilot
    X(:,:,n) = sensorsig(ActualElementPositions,Nsamp,...
        PilotAng(:,n),ncov,'Taper',ActualTaper);
end
```

Perform the pilot calibration

Turn off estimation of taper weights.

```
[estpos,esttaper] = pilotcalib(NominalElementPositions - ReferenceElement*ones(1,Nelem)
    X,PilotAng,NominalTaper.',[1,1,1,0]');
```

Add back the position of the reference sensor

```
estpos = estpos + NominalElementPositions(:,1)*ones(1,Nelem);
```

Examine the root mean square (RMS) error of the calibrated parameters

Compute the RMS values of the initial taper perturbations to compare with the RMS values of the calibrated parameters.

```
tapermagpertRMSE = sqrt(tapermagpert'*tapermagpert/Nelem);
taperphasepertRMSE = sqrt(taperphasepert'*taperphasepert/Nelem);
```

Compute the RMS value of the calibrated taper magnitude error.

```
diff = abs(ActualTaper) - abs(esttaper);
diff2 = diff'*diff;
tapermagsolvRMSE = sqrt(diff2/Nelem);
```

Compare the calibrated RMS magnitude error to the initial RMS error. The calibration reduces the RMS magnitude error.

```
disp(tapermagsolvRMSE/tapermagpertRMSE)
```

```
    1.0000
```

Compute the RMS value of the calibrated taper phase error

```
diff = unwrap(angle(ActualTaper) - angle(esttaper));
diff2 = diff'*diff;
tapersolvphaseRMSE = sqrt(diff2/Nelem);
```

Compare the calibrated RMS phase error to the initial RMS error. The calibration reduces the RMS phase error.

```
disp(tapersolvphaseRMSE/taperphasepertRMSE)
```

```
     1
```

Compute the RMS value of the initial position error.

```
numpos = 3*Nelem;
initposRMSE = sqrt(sum(PositionPert(:).^2)/numpos);
```

Compute the RMS value of the calibrated position error.

```
solvposErr = ActualElementPositions - estpos;
solvposRMSE = sqrt(sum(solvposErr(:).^2)/(numpos));
```

Compare the calibrated RMS position error to initial position RMS error. The calibration reduces the RMS position error.

```
disp(solvposRMSE/initposRMSE)
```

```
    0.1502
```

Input Arguments

`nompos` — Nominal relative element positions

real-valued 3-by-*N* matrix

Nominal relative element positions, specified as a real-valued 3-by-*N* matrix. The dimension *N* is the number of elements in the sensor array. Elements positions are relative to the first element of the array and are specified in units of signal wavelength. Each column of `nompos` represents the `[x;y;z]` coordinates of the corresponding element. The nominal position of all sensors must be within one-half of a wavelength of their actual positions for successful calibration.

Example:

Data Types: `double`

`x` — Pilot signals

complex-valued *L*-by-*N*-by-*M* matrix

Pilot signals, specified as a complex-valued *L*-by-*N*-by-*M* matrix. The argument `x` represents the signals received by the array when pilot sources are transmitting. The dimension *L* is the number of snapshots of each pilot source signal. The dimension *N* is the number of array elements. The dimension *M* is the number of pilot sources.

Example:

Data Types: `double`
Complex Number Support: Yes

`pilotang` — Pilot angles

real-valued 2-by-*M* matrix

Pilot angles, specified as a real-valued 2-by-*M* matrix. The dimension *M* is the number of pilot sources. Each column contains the direction of the pilot source in the form `[azimuth; elevation]`. Angle units are in degrees. The azimuth angle must lie between -180° and 180° and the elevation angle must lie between -90° and 90°. The azimuth angle is measured from the *x*-axis to the projection of the source direction into the *xy* plane, positive toward the *y*-axis. The elevation angle is defined as the angle from the *xy* plane to the source direction, positive toward the *z*-axis. Calibration source directions must span sufficiently diverse azimuth and elevation angles.

Example:

Data Types: `double`

`nomtaper` — Nominal taper

1 (default) | complex-valued *N*-by-1 column vector

Nominal taper of array elements, specified as a complex-valued *N*-by-1 column vector. The dimension *N* is the number of array elements. Each component represents the nominal taper of the corresponding element.

Example:

Data Types: `double`
Complex Number Support: Yes

`uncerts` — Uncertainty estimation configuration

`[1,1,1,1]` (default) | 1-by-4 vector of ones and zeros

Uncertainty estimation configuration, specified as a 1-by-4 vector consisting of `0`'s and `1`'s. The vector `uncerts` determines which uncertainties to estimated. The vector takes the form of `[xflag; yflag; zflag; taperflag]`. Set `xflag`, `yflag`, or `zflag` to `1` to estimate uncertainties in the *x*, *y*, or *z* axes. Set `taperflag` to `1` to estimate uncertainties in the taper. The number of pilot sources must greater than or equal to the number of `1`'s in the vector.

For example, set `uncerts` to `[0;1;1;1]` to estimate uncertainties in the *y* and *z* element position components and the taper simultaneously.

Example:

Data Types: `double`

Output Arguments

`estpos` — Estimated positions

real-valued 3-by-*N* matrix

Estimated element positions, returned as a real-valued 3-by-*N* matrix. Units are in signal wavelength. The dimension *N* is the number of array elements. Each column of `estpos` represents the `[x;y;z]` coordinates of the corresponding element.

`esttaper` — Estimated taper

complex-valued *N*-by-1 column vector

Estimated taper values, returned as a complex-valued *N*-by-1 column vector. The dimension *N* is the number of array elements. Each element of `esttaper` represents the taper of the corresponding sensor element.

Pilot Calibration Requirements

This algorithm requires that the pilot sources be independent narrowband plane-wave signals incoming from the far field region of the array. In addition, signals must not exhibit multipath propagation effects or coherence. All elements in the sensor array are assumed to be isotropic.

The algorithm calibrates relative positions of the array sensors with respect to the first sensor. To use the algorithm, first subtract the position of the first element from each element, then pass the relative array into the function as the nominal position argument to produced the calibrated relative positions. Finally, add back the first element position to all the relative positions to create the fully calibrated array.

pol2circpol

Convert linear component representation of field to circular component representation

Syntax

```
cfv = pol2circpol(fv)
```

Description

`cfv = pol2circpol(fv)` converts the linear polarization components of the field or fields contained in `fv` to their equivalent circular polarization components in `cfv`. The expression of a field in terms of a two-row vector of linear polarization components is called the *Jones vector formalism*.

Examples

Convert Linear To Circular Polarization Components

Express a 45° linear polarized field in terms of right-circular and left-circular components.

```
fv = [2;2]
cfv = pol2circpol(fv)
```

```
fv =

     2
     2

cfv =

   1.4142 - 1.4142i
   1.4142 + 1.4142i
```

Convert Linear Polarization Components to Circular Polarization Components

Specify two input fields `[1+1i;-1+1i]` and `[1;1]` in the same matrix. The first field is a linear representation of a left-circularly polarized field and the second is a linearly polarized field.

```
fv=[1+1i 1;-1+1i 1]
cfv = pol2circpol(fv)
```

```
fv =

   1.0000 + 1.0000i   1.0000 + 0.0000i
  -1.0000 + 1.0000i   1.0000 + 0.0000i

cfv =

   1.4142 + 1.4142i   0.7071 - 0.7071i
   0.0000 + 0.0000i   0.7071 + 0.7071i
```

Input Arguments

`fv` — Field vector in linear component representation

1-by-*N* complex-valued row vector or a 2-by-*N* complex-valued matrix

Field vector in its linear component representation specified as a 1-by-*N* complex row vector or a 2-by-*N* complex matrix. If `fv` is a matrix, each column in `fv` represents a field in the form of `[Eh;Ev]`, where `Eh` and `Ev` are the field's horizontal and vertical polarization components. If `fv` is a vector, each entry in `fv` is assumed to contain the polarization ratio, `Ev/Eh`. For a row vector, the value `Inf` designates the case when the ratio is computed for a field with `Eh = 0`.

Example: `[1;-i]`

Example: `2 + pi/3*i`

Data Types: `double`
Complex Number Support: Yes

Output Arguments

`cfv` — Field vector in circular component representation
1-by-*N* complex-valued row vector or 2-by-*N* complex-valued matrix

Field vector in circular component representation returned as a 1-by-*N* complex-valued row vector or 2-by-*N*complex-valued matrix. `cfv` has the same dimensions as `fv`. If `fv` is a matrix, each column of `cfv` contains the circular polarization components, `[El;Er]`, of the field where `El` and `Er` are the left-circular and right-circular polarization components. If `fv` is a row vector, then `cfv` is also a row vector and each entry in `cfv` contains the circular polarization ratio, defined as `Er/El`.

`circpol2pol` | `polellip` | `polratio` | `stokes`

Introduced in R2013a

polellip

Parameters of ellipse traced out by tip of a polarized field vector

Syntax

```
tau = polellip(fv)
[tau,epsilon] = polellip(fv)
[tau,epsilon,ar] = polellip(fv)
[tau,epsilon,ar,rs] = polellip(fv)

polellip(fv)
```

Description

`tau = polellip(fv)` returns the tilt angle, in degrees, of the polarization ellipse of a field or set of fields specified in `fv`. `fv` contains the linear polarization components of a field in either one of two forms: (1) each column represents a field in the form of `[Eh;Ev]`, where `Eh` and `Ev` are the field's horizontal and vertical linear polarization components or (2) each column contains the polarization ratio, `Ev/Eh`. The expression of a field in terms of a two-row vector of linear polarization components is called the *Jones vector formalism*.

`[tau,epsilon] = polellip(fv)` returns, in addition, a row vector, `epsilon`, containing the ellipticity angle (in degrees) of the polarization ellipses. The ellipticity angle is the angle determined by the ratio of the length of the semi-minor axis to semi-major axis and lies in the range `[-45°,45°]`. This syntax can use any of the input arguments in the previous syntax.

`[tau,epsilon,ar] = polellip(fv)` returns, in addition, a row vector, `ar`, containing the axial ratios of the polarization ellipses. The axial ratio is defined as the ratio of the lengths of the semi-major axis of the ellipse to the semi-minor axis. This syntax can use any of the input arguments in the previous syntaxes.

`[tau,epsilon,ar,rs] = polellip(fv)` returns, in addition, a cell array of character vectors, `rs`, containing the rotation senses of the polarization ellipses. Each

entry in the array is one of `'Linear'`, `'Left Circular'`, `'Right Circular'`, `'Left Elliptical'` or `'Right Elliptical'`. This syntax can use any of the input arguments in the previous syntaxes.

`polellip(fv)` plots the polarization ellipse of the field specified in `fv`. This syntax requires that `fv` have only one column. Unlike the returned arguments, the size of the drawn ellipse depends upon the magnitude of `fv`.

Examples

Tilt Angle for Linearly Polarized Field

Create an input field that is linearly polarized by setting both the horizontal and vertical components to have the same phase. Then, compute the tilt angle.

```
fv = [2;1];
tau = polellip(fv)
```

```
tau =

   26.5651
```

For linear polarization, `tau` is computed using `tau = atan(fv(2)/fv(1))*180/pi`.

Tilt Angle and Ellipticity for Elliptically Polarized Field

Start with an elliptically polarized input field (the horizontal and vertical components differ in magnitude and in phase). Choose the phase difference to be 90°.

```
fv = [3*exp(-i*pi/2);1];
[tau,epsilon] = polellip(fv)
```

```
tau =

   1.3156e-15

epsilon =
```

```
   18.4349
```

The tilt vanishes because of the 90° phase difference between the horizontal and vertical components of the field.

Tilt Angle, Ellipticity and Axial Ratio for Elliptically Polarized Field

Start with an elliptically polarized input field (the horizontal and vertical components differ in magnitude and in phase). Choose the phase difference to be 60°.

```
fv = [2*exp(-i*pi/3);1];
[tau,epsilon,ar] = polellip(fv)

tau =

   16.8450

epsilon =

   21.9269

ar =

   -2.4842
```

The nonzero tilt occurs because of the 60° phase difference. The negative value of the axial ratio indicates left elliptical polarization.

Tilt Angle, Ellipticity, Axial Ratio and Rotation Sense for Elliptically Polarized Field

Start with an elliptically polarized input field (the horizontal and vertical components differ in magnitude and in phase). Choose the phase difference to be 60°.

```
fv = [2*exp(-i*pi/3);1];
[tau,epsilon,ar,rs] = polellip(fv)
```

```
tau =

   16.8450

epsilon =

   21.9269

ar =

   -2.4842

rs =

  cell

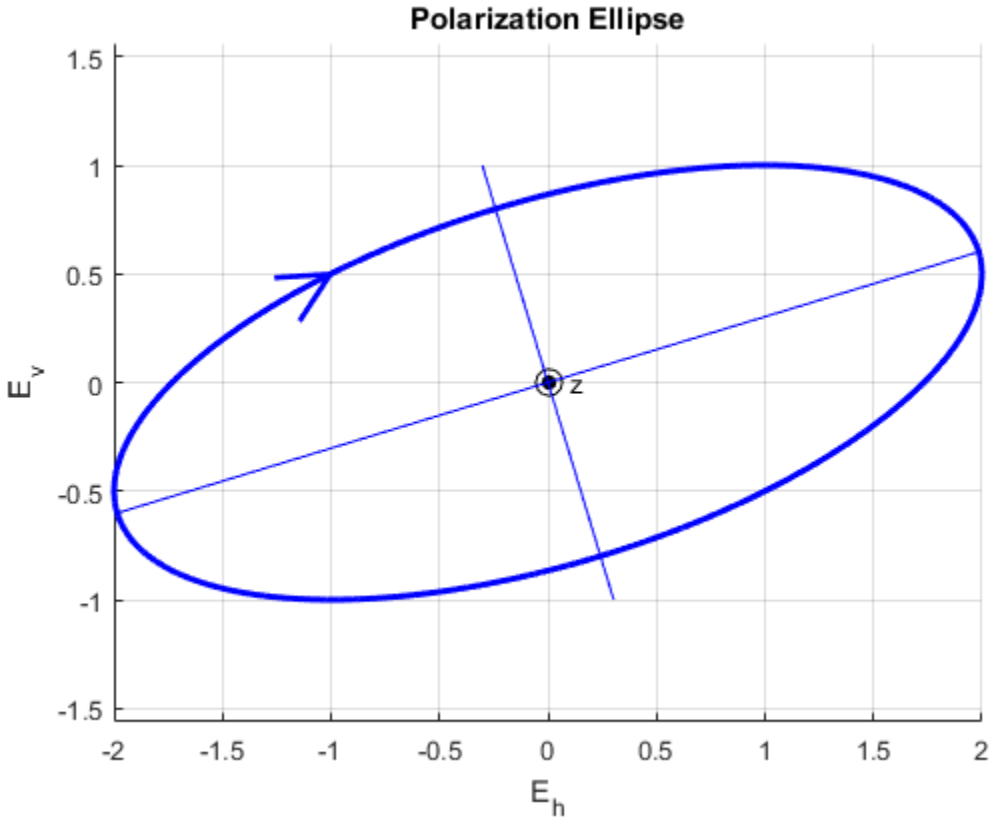
    'Left Elliptical'
```

A nonzero tilt occurs because of the 60° phase difference. The rotation sense is `'Left Elliptical'` indicating that the tip of the field vector is moving clockwise when looking towards the source of the field.

Polarization Ellipse

Draw the figure of an elliptically polarized field. Begin with an elliptically polarized input field (the horizontal and vertical components differ in magnitude and in phase) and choose the phase difference to be 60 degrees.

```
fv = [2*exp(-i*pi/3);1];
polellip(fv)
```



The rotation sense is `'Left Elliptical'` as shown by the direction of the arrow on the ellipse. The filled circle at the origin indicates that the observer is looking towards the source of the field.

Input Argument

`fv` — Field vector in linear component representation

1-by-*N* complex-valued row vector or 2-by-*N* complex-valued matrix

Field vector in linear component representation specified as a 1-by-*N* complex-valued row vector or 2-by-*N* complex-valued matrix. Each column contains an instance of a

field specification. If `fv` is a matrix, each column in `fv` represents a field in the form of `[Eh;Ev]`, where `Eh` and `Ev` are the field's linear horizontal and vertical polarization components. If `fv` is a row vector, then the row contains the ratio of the vertical to horizontal components of the field `Ev/Eh`. For a row vector, the value `Inf` is allowed to designate the case when the ratio is computed for `Eh = 0`. `Eh` and `Ev` cannot both be set to zero.

Example: `[1;-i]`

Example: `2 + pi/3*i`

Data Types: `double`
Complex Number Support: Yes

Output Arguments

`tau` — Tilt angle of polarization ellipse

1-by-*N* real-valued row vector

Tilt angle of polarization ellipse returned as a 1-by-*N* real-valued row vector. Each entry in `tau` contains the tilt angle of the polarization ellipse associated with each column of the field `fv`. The tilt angle is the angle between the semi-major axis of the ellipse and the horizontal axis (i.e. *x*axis) and lies in the range `[-90,90]°`.

`epsilon` — Ellipticity angle of the polarization ellipse

1-by-*N* real-valued row vector

Ellipticity angle of the polarization ellipse returned as 1-by-*N* real-valued row vector. Each entry in `epsilon` contains the ellipticity angle of the polarization ellipse associated with each column of the field `fv`. The ellipticity angle describes the shape of the ellipse and lies in the range `[-45°,45°]`.

`ar` — Axial ratio of the polarization ellipse

1-by-*N* real-valued row vector

Axial ratio of the polarization ellipse returned as a 1-by-*N* real-valued row vector. Each entry in `ar` contains the axial ratio of the polarization ellipse associated with each column of the field `fv`. The axial ratio is the signed ratio of the major-axis length to the minor-axis length of the polarization ellipse. Its absolute value is always greater than or equal to one. The sign of `ar` carries the rotational sense of the vector – a negative sign denotes left-handed rotation and a positive sign denotes right-handed rotation.

`rs` — Rotation sense of the polarization ellipse

1-by-*N* cell array of character vectors

Rotation sense of the polarization ellipse returned as a 1-by-*N* cell array of character vectors. Each entry in `rs` contains the rotation sense of the polarization ellipse associated with each column of the field `fv`. The rotation sense can be one of `'Linear'`, `'Left Circular'`, `'Right Circular'`, `'Left Elliptical'` or `'Right Elliptical'`.

Introduced in R2013a

polloss

Polarization loss

Syntax

```
rho = polloss(fv_tr,fv_rcv)
rho = polloss(fv_tr,fv_rcv,pos_rcv)
rho = polloss(fv_tr,fv_rcv,pos_rcv,axes_rcv)
rho = polloss(fv_tr,fv_rcv,pos_rcv,axes_rcv,pos_tr)
rho = polloss(fv_tr,fv_rcv,pos_rcv,axes_rcv,pos_tr,axes_tr)
```

Description

`rho = polloss(fv_tr,fv_rcv)` returns the loss, in decibels, because of mismatch between the polarization of a transmitted field, `fv_tr`, and the polarization of the receiving antenna, `fv_rcv`. The field vector lies in a plane orthogonal to the direction of propagation from the transmitter to the receiver. The transmitted field is represented as a 2-by-1 column vector `[Eh;Ev]`. In this vector, `Eh` and `Ev` are the field's horizontal and vertical linear polarization components with respect to the transmitter's local coordinate system. The receiving antenna's polarization is specified by a 2-by-1 column vector, `fv_rcv`. You can also specify this polarization in the form of `[Eh;Ev]` with respect to the receiving antenna's local coordinate system. In this syntax, both local coordinate axes align with the global coordinate system.

`rho = polloss(fv_tr,fv_rcv,pos_rcv)` specifies, in addition, the position of the receiver. The receiver is defined as a 3-by-1 column vector, `[x;y;z]`, with respect to the global coordinate system (position units are in meters). This syntax can use any of the input arguments in the previous syntax.

`rho = polloss(fv_tr,fv_rcv,pos_rcv,axes_rcv)` specifies, in addition, the orthonormal axes, `axes_rcv`. These axes define the receiver's local coordinate system as a 3-by-3 matrix. The first column gives the *x*-axis of the local system with respect to the global coordinate system. The second and third columns give the *y* and *z* axes, respectively. This syntax can use any of the input arguments in the previous syntaxes.

`rho = polloss(fv_tr,fv_rcv,pos_rcv,axes_rcv,pos_tr)` specifies, in addition, the position of the transmitter as a 3-by-1 column vector, `[x;y;z]`, with respect to the

global coordinate system (position units are in meters). This syntax can use any of the input arguments in the previous syntaxes.

`rho = polloss(fv_tr,fv_rcv,pos_rcv,axes_rcv,pos_tr,axes_tr)` specifies, in addition, the orthonormal axes, `axes_tr`. These axes define the transmitter's local coordinate system as a 3-by-3 matrix. The first column gives the *x*-axis of the local system with respect to the global coordinate system. The second and third columns give the *y* and *z* axes, respectively. This syntax can use any of the input arguments in the previous syntaxes.

Examples

Mismatch Between 45° Polarized Field and Horizontally Polarized Receiver

Begin with a 45° polarized transmitted field and a receiver that is horizontally polarized. By default, the transmitter and receiver local axes coincide with the global coordinate system. Compute the polarization loss in dB.

```
fv_tr = [1;1];
fv_rcv = [1;0];
rho = polloss(fv_tr,fv_rcv)
```

```
rho =

    3.0103
```

The loss is 3 dB as expected because only half the power of the field matches to the receive antenna polarization.

Polarization Loss Unaffected by Receiver Position

Begin with identical transmitter and receiver polarizations. Place the receiver at a position 100 meters along the *y*-axis. The transmitter is at the origin (its default position) and both local coordinate axes coincide with the global coordinate system (by default). First, compute the polarization loss. Then, move the receiver 100 meters along the_x_-axis, and compute the polarization loss again.

```
fv_tr = [1;0];
fv_rcv = [1;0];
pos_rcv = [0;100;0];
```

```
rho(1) = polloss(fv_tr,fv_rcv,pos_rcv);
pos_rcv = [100;100;0];
rho(2) = polloss(fv_tr,fv_rcv,pos_rcv)
```

```
rho =

     0     0
```

No polarization loss occurs at either position. The spherical basis vectors of each antenna are parallel to other antenna and the polarization vectors are the same.

Loss Due to Receiver Axes Rotation

Start with identical transmitter and receiver polarizations. Put the receiver at a position 100 meters along the *y*-axis. The transmitter is at the origin (default) and both local coordinate axes coincide with the global coordinate system (default). Compute the loss, and then rotate the receiver 30° around the *y*-axis. This rotation changes the azimuth and elevation of the transmitter with respect to the receiver and, therefore, the direction of polarization.

```
fv_tr = [1;0];
fv_rcv = [1;0];
pos_rcv = [0;100;0];
ax_rcv = azelaxes(0,0);
rho(1) = polloss(fv_tr,fv_rcv,pos_rcv,ax_rcv);
ax_rcv = roty(30)*ax_rcv;
rho(2) = polloss(fv_tr,fv_rcv,pos_rcv,ax_rcv)
```

```
rho =

         0    1.2494
```

The receiver polarization vector remains unchanged. However, rotating the local coordinate system changes the direction of the field of the receiving antenna polarization with respect to global coordinates. This change results in a 1.2 dB loss.

Polarization Loss Unaffected by Transmitter Position

Start with identical transmitter and receiver polarizations. Put the receiver at a position 100 meters along the_y_-axis. The transmitter is at the origin (default) and both local coordinate axes coincide with the global coordinate system (default). First, compute the

polarization loss. Then, move the transmitter 100 meters along the *x*-axis and 100 meters along the *y*-axis, and compute the polarization loss again.

```
fv_tr = [1;0];
fv_rcv = [1;0];
pos_rcv = [0;100;0];
ax_rcv = azelaxes(0,0);
pos_tr = [0;0;0];
rho(1) = polloss(fv_tr,fv_rcv,pos_rcv,ax_rcv,pos_tr);
pos_tr = [100;100;0];
rho(2) = polloss(fv_tr,fv_rcv,pos_rcv,ax_rcv,pos_tr)
```

```
rho =

     0     0
```

There is no polarization loss at either position because the spherical basis vectors of each antenna are parallel to their counterparts and the polarization vectors are the same.

Plot Polarization Loss as Receiving Antenna Rotates

Specifying identical transmitter and receiver polarizations, plot the loss as the local receiving antenna axes rotate around the x-axis.

```
fv_tr = [1;0];
fv_rcv = [1;0];
```

The position of the transmitting antenna is at the origin and its local axes align with the global coordinate system. The position of the receiving antenna is 100 meters along the global x-axis. However, its local x-axis points towards the transmitting antenna.

```
pos_tr = [0;0;0];
axes_tr = azelaxes(0,0);
pos_rcv = [100;0;0];
axes_rcv0 = rotz(180)*azelaxes(0,0);
```

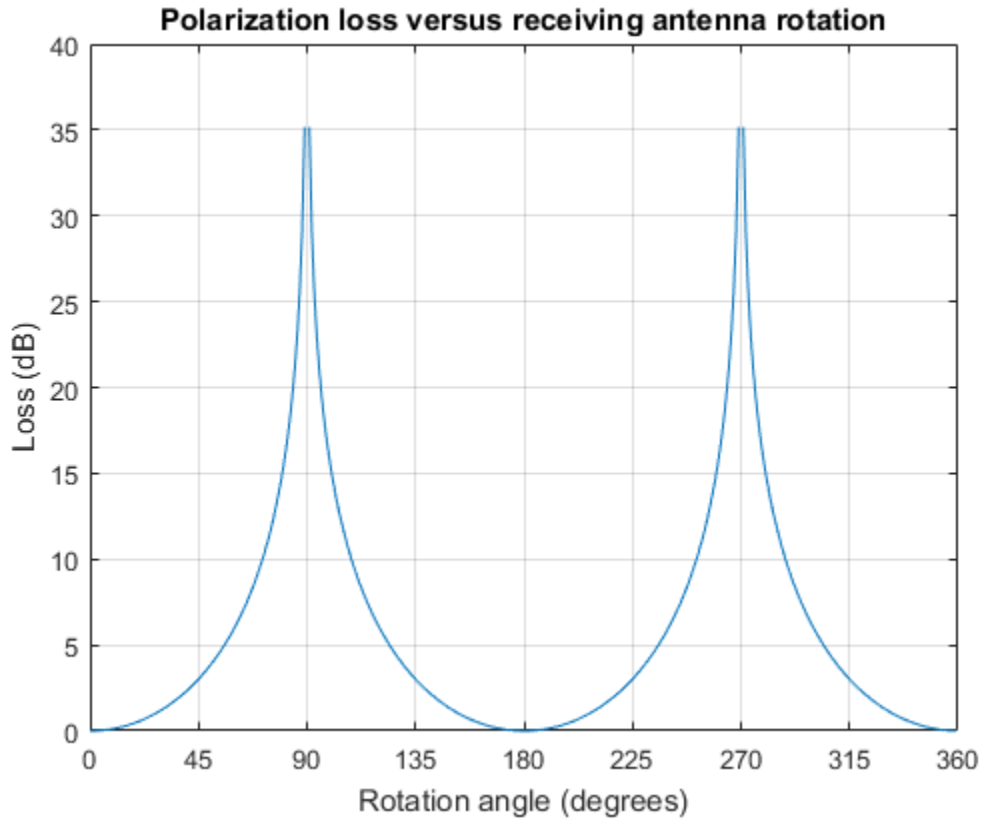
Rotate the receiving antenna around its local x-axis in one-degree increments. Compute the loss for each angle.

```
angles = [0:1:359];
n = size(angles,2);
rho = zeros(1,n); % Initialize space
for k = 1:n
    axes_rcv = rotx(angles(k))*axes_rcv0;
```

```
    rho(k) = polloss(fv_tr,fv_rcv,pos_tr,axes_tr,...
        pos_rcv,axes_rcv);
end
```

Plot the polarization loss.

```
hp = plot(angles,rho);
hax = hp.Parent;
hax.XLim = [0,360];
xticks = (0:(n-1))*45;
hax.XTick = xticks;
grid;
title('Polarization loss versus receiving antenna rotation')
xlabel('Rotation angle (degrees)');
ylabel('Loss (dB)');
```



The angle-loss plot shows nulls (`Inf` dB) at 90 degrees and 270 degrees where the polarizations are orthogonal.

Input Arguments

`fv_tr` — Transmitted field vector in linear component representation

2-by-1 complex-valued column vector

The transmitted field vector in linear component representation specified as a 2-by-1, complex-valued column vector `[Eh;Ev]`. In this vector, `Eh` and `Ev` are the field's horizontal and vertical linear components.

Example: [1;1]

Data Types: `double`
Complex Number Support: Yes

`fv_rcv` — Receiver polarization vector in linear component representation

2-by-1 complex-valued column vector

Receiver polarization vector in linear component representation specified as a 2-by-1, complex-valued column vector `[Eh;Ev]`. In this vector, `Eh` and `Ev` are the polarization vector's horizontal and vertical linear components.

Example: [0;1]

Data Types: `double`
Complex Number Support: Yes

`pos_rcv` — Receiving antenna position

[0;0;0] (default) | 3-by-1 real-valued column vector

Receiving antenna position specified as a 3-by-1, real-valued column vector. The components of `pos_rcv` are specified in the global coordinate system as `[x;y;z]`.

Example: [1000;0;0]

Data Types: `double`

`axes_rcv` — Receiving antenna local coordinate axes

3-by-3 identity matrix (default) | 3-by-3 real-valued matrix

Receiving antenna local coordinate axes specified as a 3-by-3, real-valued matrix. Each column is a unit vector specifying the local coordinate system's orthonormal x, y, and z

axes, respectively, with respect to the global coordinate system. Each column is written in `[x;y;z]` form. If `axes_rcv` is specified as the identity matrix, the local coordinate system is aligned with the global coordinate system.

Example: [1, 0, 0; 0, 1, 0; 0, 0 ,1]

Data Types: `double`

`pos_tr` — Transmitter position

[0;0;0] (default) | 3-by-1 real-valued column vector

Transmitter position specified as a 3-by-1, real-valued column vector. The components of `pos_tr` are specified in the global coordinate system as `[x;y;z]`.

Example: [0;0;0]

Data Types: `double`

`axes_tr` — Transmitting antenna local coordinate axes

3-by-3 identity matrix (default) | 3-by-3 real-valued matrix

Transmitting antenna local coordinate axes specified as a 3-by-3, real-valued matrix. Each column is a unit vector specifying the local coordinate system's orthonormal *x*, *y*, and *z* axes, respectively, with respect to the global coordinate system. Each column is written in `[x;y;z]` form. If `axes_tr` is the identity matrix, the local coordinate system is aligned with the global coordinate system.

Example: [1, 0, 0; 0, 1, 0; 0, 0 ,1]

Data Types: `double`

Output Arguments

`rho` — Polarization loss

scalar

Polarization loss returned as scalar in decibel units. The polarization loss is the projection of the normalized transmitted field vector into the normalized receiving antenna polarization vector. Its value lies between zero and unity. When converted into dB, (and a sign changed to show loss as positive) its value lies between 0 and `-Inf`.

Definitions

Polarization Loss Due to Field and Receiver Mismatch

Loss occurs when a receiver is not matched to the polarization of an incident electromagnetic field.

In the case of the polarization of a field emitted by a transmitting antenna, first, look at the far zone of the transmitting antenna, as shown in the following figure. At this location—which is the location of the receiving antenna—the electromagnetic field is orthogonal to the direction from transmitter to receiver.

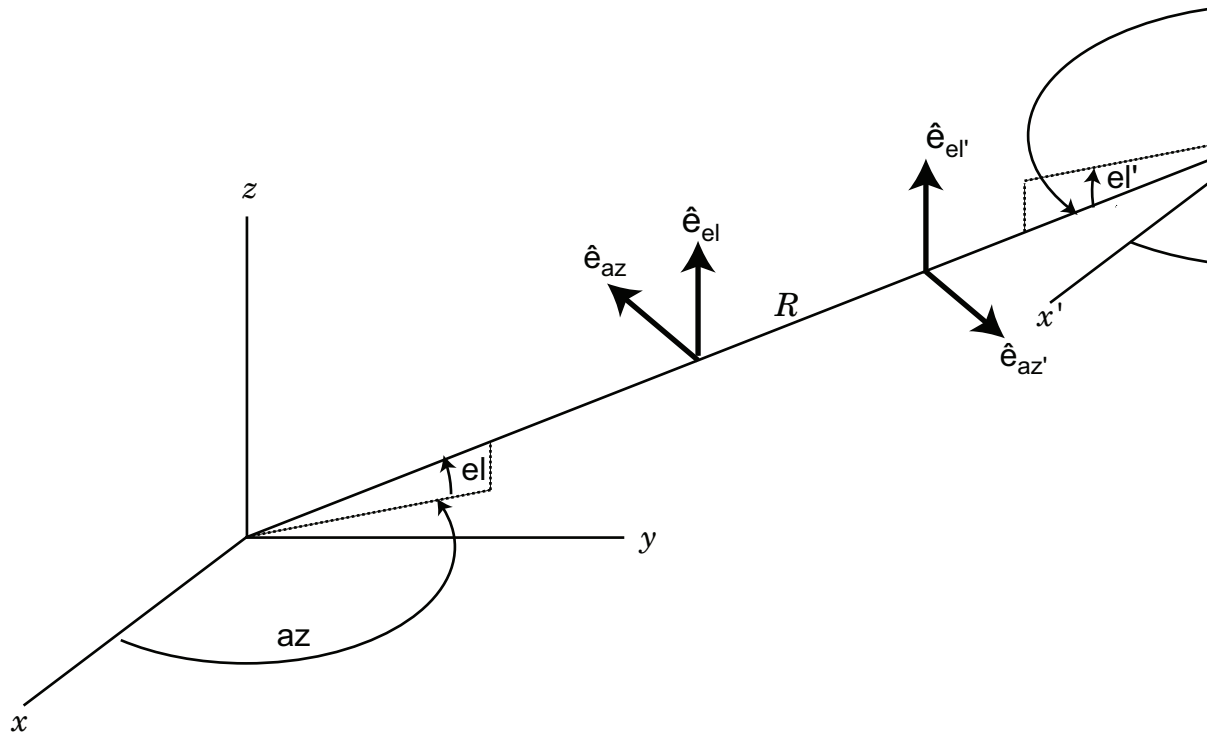
You can represent the transmitted electromagnetic field, `fv_tr`, by the components of a vector with respect to a spherical basis of the transmitter's local coordinate system. The orientation of this basis depends on its direction from the origin. The direction is specified by the azimuth and elevation of the receiving antenna with respect to the transmitter's local coordinate system. Then, the transmitter's polarization, in terms of the spherical basis vectors of the transmitter's local coordinate system, is

$$\mathbf{E} = E_H \hat{\mathbf{e}}_{az} + E_V \hat{\mathbf{e}}_{el} = E_m \mathbf{P}_i$$

In the same manner, the receiver's polarization vector, `fv_rcv`, is defined with respect to a spherical basis in the receiver's local coordinate system. Now, the azimuth and elevation specify the transmitter's position with respect to the receiver's local coordinate system. You can write the receiving antennas polarization in terms of the spherical basis vectors of the receiver's local coordinate system:

$$\mathbf{P} = P_H \hat{\mathbf{e}}'_{az} + P_V \hat{\mathbf{e}}'_{el}$$

This figure shows the construction of the different transmitter and receiver local coordinate systems. It also shows the spherical basis vectors with which to write the field components.



The polarization loss is the projection (or dot product) of the normalized transmitted field vector onto the normalized receiver polarization vector. Notice that the loss occurs because of the mismatch in direction of the two vectors not in their magnitudes. Because the vectors are defined in different coordinate systems, they must be converted to the global coordinate system in order to form the projection. The polarization loss is defined by:

$$\rho = \frac{|\mathbf{E}_i \cdot \mathbf{P}|^2}{|\mathbf{E}_i|^2 |\mathbf{P}|^2}$$

Introduced in R2013a

polratio

Ratio of vertical to horizontal linear polarization components of a field

Syntax

```
p = polratio(fv)
```

Description

`p = polratio(fv)` returns the ratio of the vertical to horizontal component of the field or set of fields contained in `fv`.

Each column of `fv` contains the linear polarization components of a field in the form `[Eh;Ev]`, where `Eh` and `Ev` are the field's linear horizontal and vertical polarization components. The expression of a field in terms of a two-row vector of linear polarization components is called the *Jones vector formalism*. The argument `fv` can refer to either the electric or magnetic part of an electromagnetic wave.

Each entry in `p` contains the ratio `Ev/Eh` of the components of `fv`.

Examples

Polarization Ratio for 45° Linearly Polarized Field

Determine the polarization ratio for a linearly polarized field (when the horizontal and vertical components of a field have the same phase).

```
fv = [2;2];
p = polratio(fv)
```

```
p =

     1
```

The polarization ratio is real. Because the components have equal amplitudes, the polarization ratio is unity.

Polarization Ratios for Two Fields

Compute the polarization ratios for two fields. The first field is *(2;i)* and the second is *(i;1)*.

```
fv = [2,1i;1i,1];
p = polratio(fv)
```

```
p =

   0.0000 + 0.5000i   0.0000 - 1.0000i
```

Polarization Ratio for Vertically Polarized Field

Determine the polarization ratio for a vertically polarized field (the horizontal component of the field vanishes).

```
fv = [0;2];
p = polratio(fv)
```

```
p =

   Inf
```

The polarization ratio is infinite as expected from the definition,_Ev/Eh_.

Input Arguments

`fv` — Field vector in linear component representation

2-by-*N* complex-valued matrix

Field vector in linear component representation specified as a 2-by-*N* complex-valued matrix. Each column of `fv` contains an instance of a field specified by `[Eh;Ev]`, where `Eh` and `Ev` are the field's linear horizontal and vertical polarization components. Two rows of the same column cannot both be zero.

Example: [2 , i; i, 1]

Data Types: `double`
Complex Number Support: Yes

Output Arguments

p — Polarization ratio

1-by-*N* complex-valued row vector

Polarization ratio returned as a 1-by-*N* complex-valued row vector. `p` contains the ratio of the components of the second row of `fv` to the first row, `Ev/Eh`.

`circpol2pol` | `pol2circpol` | `polellip` | `stokes`

Introduced in R2013a

polsignature

Copolarization and cross-polarization signatures

Syntax

```
resp = polsignature(rcsmat)
resp = polsignature(rcsmat,type)
resp = polsignature(rcsmat,type,epsilon)
resp = polsignature(rcsmat,type,epsilon,tau)

polsignature( ___ )
```

Description

`resp = polsignature(rcsmat)` returns the normalized radar cross-section copolarization (*co-pol*) signature, `resp` (in square meters), determined from the scattering cross section matrix, `rcsmat` of an object. The signature is a function of the transmitting antenna polarization, specified by the ellipticity angle and the tilt angle of the polarization ellipse. In this syntax case, the ellipticity angle takes the values `[-45:45]` and the tilt angle takes the values `[-90:90]`. The output `resp` is a 181-by-91 matrix whose elements correspond to the signature at each ellipticity angle-tilt angle pair.

`resp = polsignature(rcsmat,type)`, in addition, specifies the polarization signature type as one of `'c'|'x'`, where `'c'` creates the copolarization signature and `'x'` creates the cross-polarization (*cross-pol*) signature. The default value of this parameter is `'c'`. The output `resp` is a 181-by-91 matrix whose elements correspond to the signature at each ellipticity angle-tilt angle pair. This syntax can use the input arguments in the previous syntax.

`resp = polsignature(rcsmat,type,epsilon)`, in addition, specifies the transmit antenna polarization's ellipticity angle (in degrees) as a length-M vector. The angle `epsilon` must lie between –45° and 45°. The argument `resp` is a 181-by-M matrix whose elements correspond to the signature at each ellipticity angle-tilt angle pair. This syntax can use any of the input arguments in the previous syntaxes.

`resp = polsignature(rcsmat,type,epsilon,tau)`, in addition, specifies the tilt angle of the polarization ellipse of the transmitted wave (in degrees) as a length-*N* vector. The angle `tau` must be between –90° and 90°. The signature, `resp`, is represented as a function of the transmitting antenna polarization. The transmitting antenna polarization is characterized by the ellipticity angle, `epsilon`, and the tilt angle, `tau`. The argument `resp` is a *N*-by-*M* matrix whose elements correspond to the signature at each ellipticity angle-tilt angle pair. This syntax can use any of the input arguments in the previous syntaxes.

`polsignature( ___ )` plots a three dimensional surface using any of the syntax forms specified above.

Examples

Copolarization Signature of a Dihedral

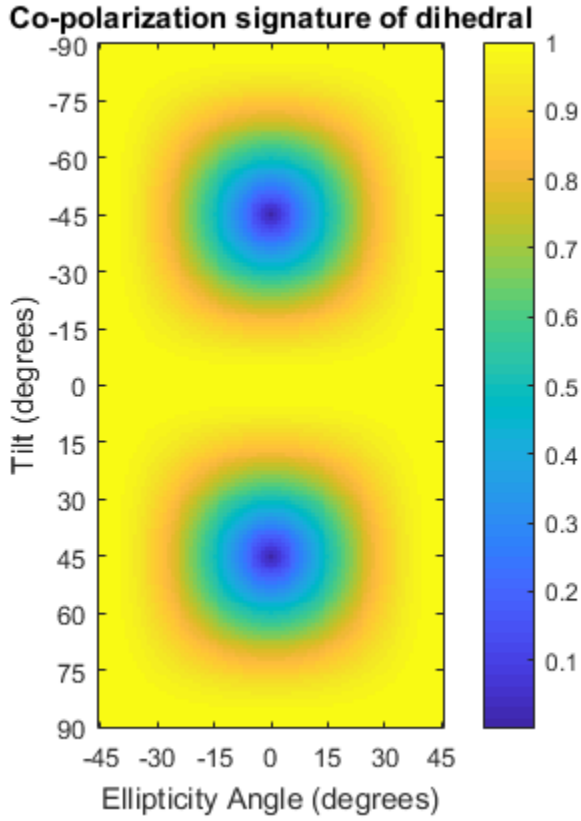
Calculate and plot the copolarization response to the scattering cross-section matrix, `rscmat`, of a dihedral object. Specify the ellipticity angle values as `[-45:45]` and the tilt angle values as `[-90:90]`. Display the response matrix as an image.

Calculate the copolarization response.

```
rscmat = [-1,0;0,1];
resp = polsignature(rscmat);
```

Plot the copolarization response.

```
el = [-45:45];
tilt = [-90:90];
imagesc(el,tilt,resp);
ylabel('Tilt (degrees)');
xlabel('Ellipticity Angle (degrees)')
axis image
ax = gca;
ax.XTick = [-45:15:45];
ax.YTick = [-90:15:90];
title('Co-polarization signature of dihedral');
colorbar;
```



Cross-Polarization Signature of a Dihedral

Calculate and plot the cross-polarization response to the scattering cross-section matrix, `rscmat`, of a dihedral object. Specify the ellipticity angle values as [-45:45] and the tilt angle values as [-90:90]. Display the response matrix as an image.

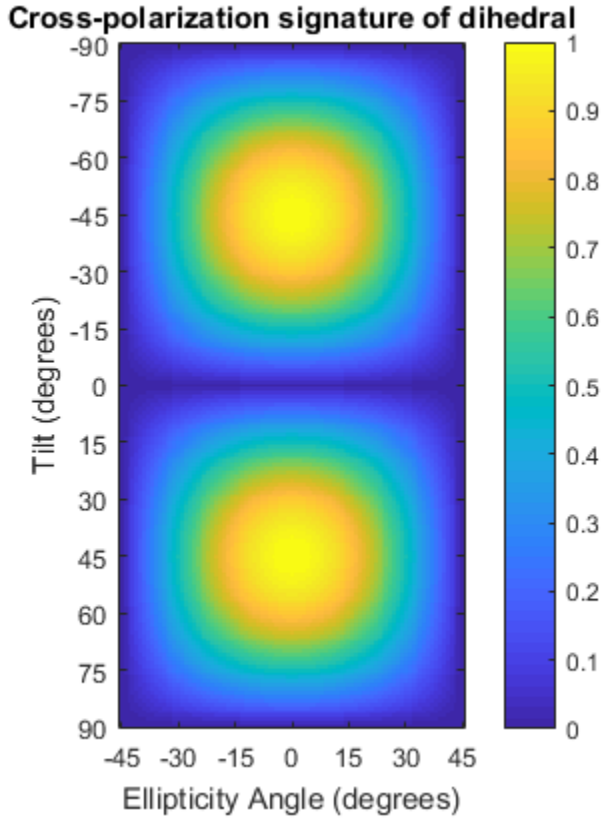
Calculate the cross-polarization response. To do this, set the `type` argument to `'x'`.

```
rscmat = [-1,0;0,1];
resp = polsignature(rscmat,'x');
```

Plot the cross-polarization response.

```
el = [-45:45];
tilt = [-90:90];
```

```
imagesc(el,tilt,resp);
ylabel('Tilt (degrees)');
xlabel('Ellipticity Angle (degrees)');
axis image
ax = gca;
ax.XTick = [-45:15:45];
ax.YTick = [-90:15:90];
title('Cross-polarization signature of dihedral');
colorbar;
```

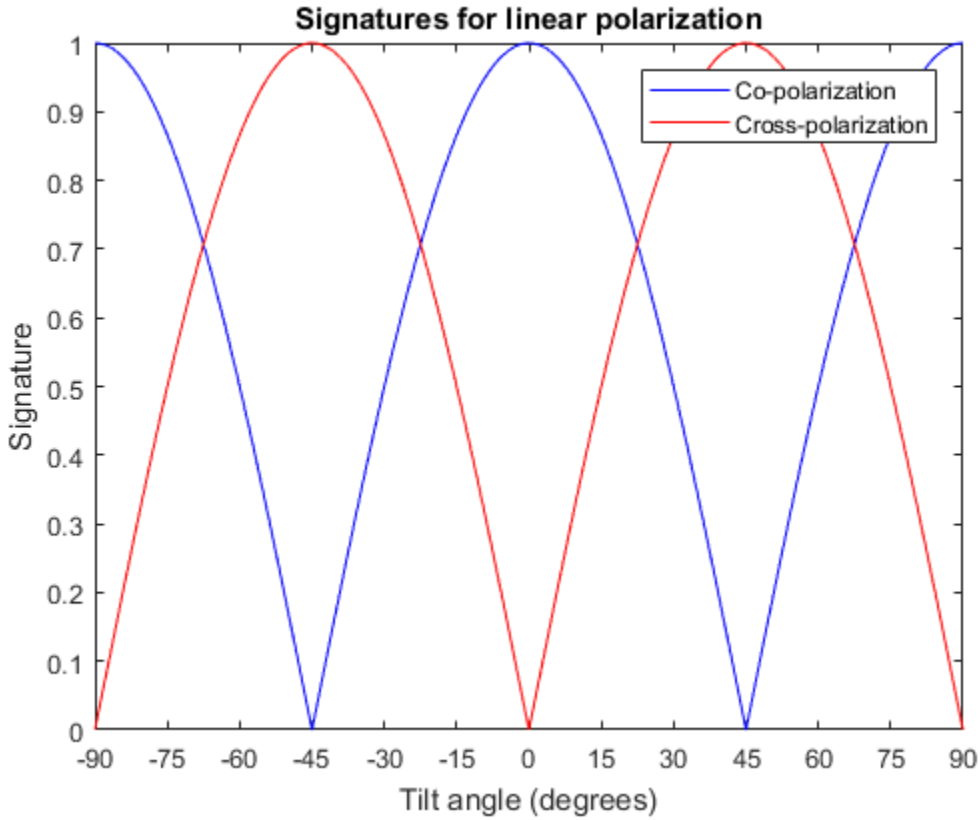


Signatures for Linear Polarization with Varied Tilt Angles

Set the ellipticity angle to zero, and vary the tilt angle from -90 to +90 degrees to generate all possible linear polarization directions. Then, plot both the copolarization and cross-polarization signatures.

```
rscmat = [-1,0;0,1];
el = [0];
respc = polsignature(rscmat,'c',el);
respx = polsignature(rscmat,'x',el);
tilt = [-90:90];
plot(tilt,respc,'b',tilt,respx,'r')
ax = gca;
ax.XLim = [-90,90];
```

```
ax.XTick = [-90:15:90];
legend('Co-polarization','Cross-polarization')
title('Signatures for linear polarization')
xlabel('Tilt angle (degrees)')
ylabel('Signature')
```



Copolarization Signature of Dihedral for Left and Right Circular Polarizations

This example shows how to obtain numerical values for the polarization signatures of a dihedral target for left and right circular polarized incident waves.

Specify the radar cross-section matrix of a dihedral

```
rscmat = [-1,0;0,1];
```

Specify a left circularly polarized wave and obtain its tilt angle and ellipticity.

```
fv = 1/sqrt(2)*[1;1i];
[tilt_lcp,el_lcp] = polellip(fv);
disp([tilt_lcp,el_lcp])
```

```
    45    45
```

Specify a right circularly polarized wave by complex conjugation of a left circulary polarized wave. Obtain its tilt angle and ellipticity.

```
[tilt_rcp,el_rcp] = polellip(conj(fv));
disp([tilt_rcp,el_rcp])
```

```
    45   -45
```

Both tilt angles are 45 degrees. Compute the copolarization and cross-polarization signatures for the two waves.

```
el = [el_lcp, el_rcp];
tilt = tilt_rcp;
respc = polsignature(rscmat,'c',el,tilt);
respx = polsignature(rscmat,'x',el,tilt);
disp(respc)
disp(respx)
```

```
     1     1

     1     1
```

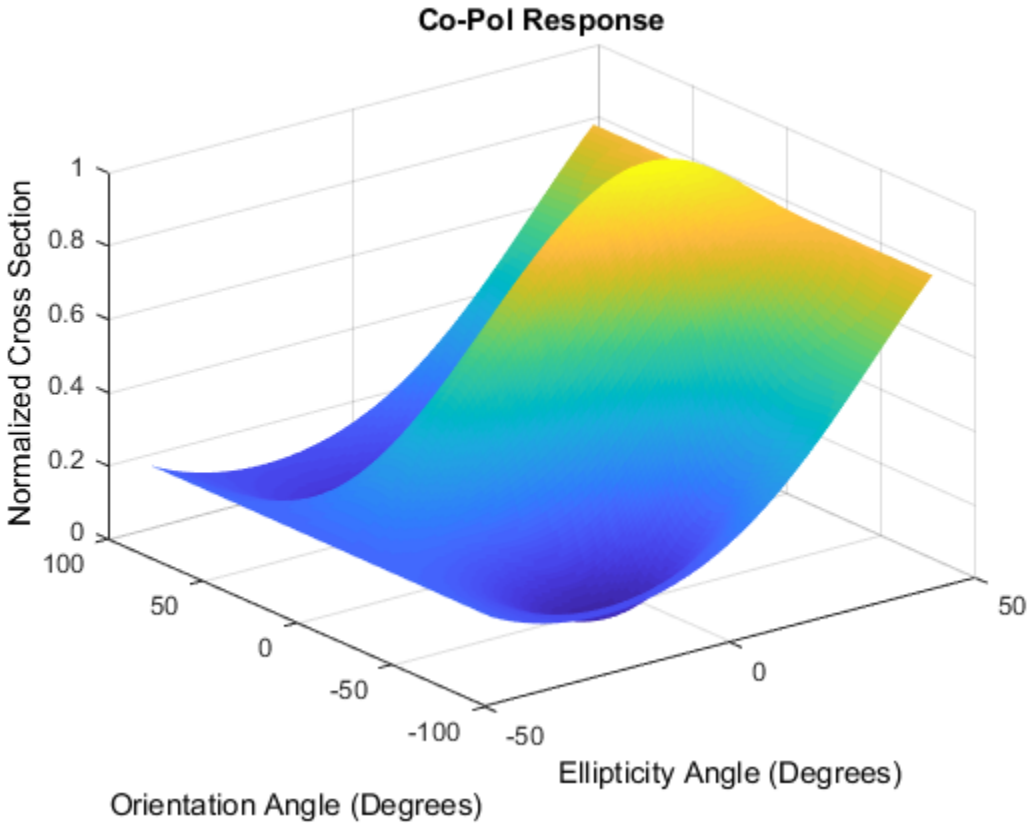
Surface Plot of Copolarization Signature of General Target

Use a general RCSM matrix to create a 3-D surface plot.

```
rscmat = [1i*2,0.5; 0.5, -1i];
el = [-45:45];
tilt = [-90:90];
```

With no output arguments, `polsignature` automatically creates a surface plot.

```
polsignature(rscmat,'c',el,tilt);
```



Input Arguments

`rcsmat` — Radar cross-section scattering matrix

2-by-2 complex-valued matrix

Radar cross-section scattering matrix (*RCSM*) of an object specified as a 2-by-2, complex-valued matrix. The radar cross-section scattering matrix describes the polarization of a scattered wave as a function of the polarization of an incident wave upon a target. The response to an incident wave can be construct from the individual responses to the incident field's horizontal and vertical polarization components. These components are taken with respect to the transmit antenna or array local coordinate system. The

scattered wave can be decomposed into horizontal and vertical polarization components with respect to the receive antenna or array local coordinate system. The matrix *RCSM* contains four components `[rcs_hh rcs_hv;rcs_vh rcs_vv]` where each component is the radar cross section defined by the polarization of the transmit and receive antennas.

- `rcs_hh` – Horizontal response due to horizontal transmit polarization component
- `rcs_hv` – Horizontal response due to vertical transmit polarization component
- `rcs_vh` – Vertical response due to horizontal transmit polarization component
- `rcs_vv` – Vertical response due to vertical transmit polarization component

In the monostatic radar case, when the wave is backscattered, the RCSM matrix is symmetric.

Example: `[-1,1i;1i,1]`

Data Types: `double`
Complex Number Support: Yes

`type` — Polarization signature type

`'c'` (default) | single character `'c'|'x'`

Polarization signature type of the scattered wave specified by a single character: `'c'` denoting the copolarized signature or `'x'` denoting the cross-polarized signature.

Example: `'x'`

Data Types: `char`

`epsilon` — Ellipticity angle of the polarization ellipse of the transmitted wave

`[-45:45]` (default) | scalar or 1-by-*M* real-valued row vector

Ellipticity angle of the polarization ellipse of the transmitted wave specified as a length-*M* vector. Units are degrees. The ellipticity angle describes the shape of the ellipse. By definition, the tangent of the ellipticity angle is the signed ratio of the semiminor axis to semimajor axis of the polarization ellipse. Since the absolute value of this ratio cannot exceed unity, the ellipticity angle lies between ±45°.

Example: `[-45:0.5:45]`

Data Types: `double`

`tau` — Tilt angle of the polarization ellipse of the transmitted wave

`[-90:90]` (default) | scalar or 1-by-*N* real-valued row vector.

Tilt angle of the polarization ellipse of the transmitted wave specified as a length-N vector. Units are degrees. The tilt angle is defined as the angle between the semimajor axis of the ellipse and the x-axis. Because the ellipse is symmetrical, an ellipse with a tilt angle of 100° is the same ellipse as one with a tilt angle of –80°. Therefore, the tilt angle need only be specified between ±90°.

Example: `[-30:2:30]`

Data Types: `double`

Output Arguments

`resp` — Normalized magnitude response

scalar or N-by-M real-valued matrix.

Normalized magnitude response returned as a scalar or N-by-M, real-valued matrix having values between 0 and 1. `resp` returns a value for each ellipticity-tilt angle pair.

Definitions

Scattering Cross-Section Matrix

Scattering cross-section matrix determines response of an object to incident polarized electromagnetic field.

When a polarized plane wave is incident on an object, the amplitude and polarization of the scattered wave may change with respect to the incident wave polarization. The polarization may depend upon the direction from which the scattered wave is observed. The exact way that the polarization changes depends upon the properties of the scattering object. The quantity describing the response of an object to the incident field is called the scattering cross-section matrix, S. The scattering matrix can be measured as follows: when a unit amplitude horizontally polarized wave is scattered, both a horizontal and vertical scattered component are produced. Call these two components S_{HH} and S_{VH}. These are complex numbers containing the amplitude and phase changes from the incident wave. Similarly, when a unit amplitude vertically polarized wave is scattered, the horizontal and vertical scattered component produced are S_{HV} and S_{VV}. Because any incident field can be decomposed into horizontal and vertical components, stack these quantities into a matrix and write the scattered field in terms of the incident field

$$\begin{bmatrix} E_H^{(sc)} \\ E_V^{(sc)} \end{bmatrix} = \begin{bmatrix} S_{HH} & S_{VH} \\ S_{HV} & S_{VV} \end{bmatrix} \begin{bmatrix} E_H^{(inc)} \\ E_V^{(inc)} \end{bmatrix} = S \begin{bmatrix} E_H^{(inc)} \\ E_V^{(inc)} \end{bmatrix}$$

The scattering cross section matrix depends upon the angles that the incident and scattered fields make with the object. When the incident field is backscattered to the transmitting antenna, the scattering matrix is symmetric.

Polarization Signature

Polarization signature for visualizing scattering cross-section matrix.

To understand how the scattered wave depends upon the polarization of the incident wave, an examination of all possible scattered field polarizations for each incident polarization is required. Because this amount of data is difficult to visualize, you can look at two particular scattered polarizations:

- Choose one polarization that has the same polarization as the incident field (copolarization)
- Choose a second one that is orthogonal to the polarization of the incident field (cross-polarization)

Both the incident and orthogonal polarization states can be specified in terms of the tilt angle-ellipticity angle pair (τ,ε). From the incident field tilt and ellipticity angles, the unit incident polarization vector can be expressed as

$$\begin{bmatrix} E_H^{(inc)} \\ E_V^{(inc)} \end{bmatrix} = \begin{bmatrix} \cos\tau & -\sin\tau \\ \sin\tau & \cos\tau \end{bmatrix} \begin{bmatrix} \cos\varepsilon \\ j\sin\varepsilon \end{bmatrix}$$

while the orthogonal polarization vector is

$$\begin{bmatrix} E_H^{(inc)\perp} \\ E_V^{(inc)\perp} \end{bmatrix} = \begin{bmatrix} -\sin\tau & -\cos\tau \\ \cos\tau & -\sin\tau \end{bmatrix} \begin{bmatrix} \cos\varepsilon \\ -j\sin\varepsilon \end{bmatrix}$$

To form the copolarization signature, use the RCSM matrix, S, to compute:

$$P^{(co)} = \begin{bmatrix} E_H^{(inc)} & E_V^{(inc)} \end{bmatrix}^* S \begin{bmatrix} E_H^{(inc)} \\ E_V^{(inc)} \end{bmatrix}$$

where `[ ]*` denotes complex conjugation. For the cross-polarization signature, compute

$$P^{(cross)} = \begin{bmatrix} E_H^{(inc)\perp} & E_V^{(inc)\perp} \end{bmatrix}^* S \begin{bmatrix} E_H^{(inc)} \\ E_V^{(inc)} \end{bmatrix}$$

The output of this function is the absolute value of each signature normalized by its maximum value.

Introduced in R2013a

pulsint

Pulse integration

Syntax

```
Y = pulsint(X)
Y = pulsint(X,METHOD)
```

Description

`Y = pulsint(X)` performs video (noncoherent) integration of the pulses in `X` and returns the integrated output in `Y`. Each column of `X` is one pulse.

`Y = pulsint(X,METHOD)` performs pulse integration using the specified method. `METHOD` is `'coherent'` or `'noncoherent'`.

Input Arguments

X

Pulse input data. Each column of `X` is one pulse.

METHOD

Pulse integration method. `METHOD` is the method used to integrate the pulses in the columns of `X`. Valid values of `METHOD` are `'coherent'` and `'noncoherent'`. The values are not case sensitive.

Default: `'noncoherent'`

Output Arguments

Y

Integrated pulse. `Y` is an N-by-1 column vector where N is the number of rows in the input `X`.

Examples

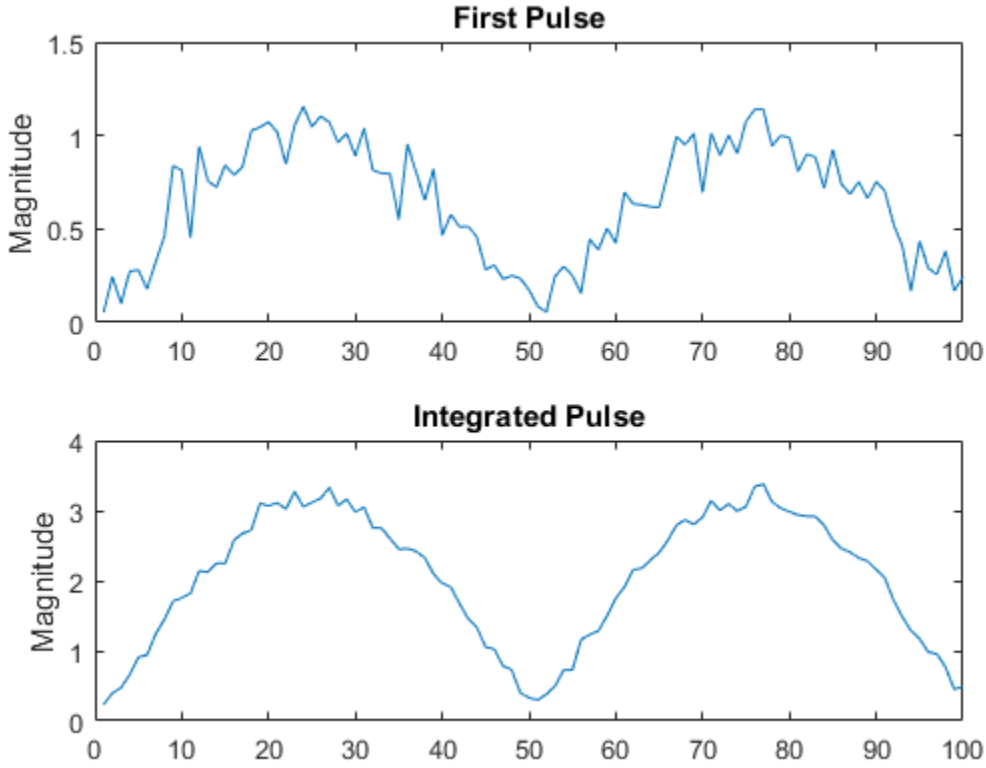
Noncoherent Integration of Pulses

Noncoherently integrate 10 pulses of a sinusoid with added gaussian white noise.

```
npulse = 10;
x = repmat(sin(2*pi*(0:99)'/100),1,npulse) + 0.1*randn(100,npulse);
y = pulsint(x);
```

Plot a single pulse and then the integrated pulses.

```
subplot(2,1,1)
plot(abs(x(:,1)))
ylabel('Magnitude')
title('First Pulse')
subplot(2,1,2)
plot(abs(y))
ylabel('Magnitude')
title('Integrated Pulse')
```



Definitions

Coherent Integration

Let X_{ij} denote the *(i,j)*-th entry of an M-by-N matrix of pulses X.

The coherent integration of the pulses in X is:

$$Y_i = \sum_{j=1}^{N} X_{ij}$$

Noncoherent (video) Integration

Let X_{ij} denote the *(i,j)*-th entry of an M-by-N matrix of pulses X.

The noncoherent (video) integration of the pulses in X is:

$$Y_i = \sqrt{\sum_{j=1}^{N} |X_{ij}|^2}$$

radarEquationCalculator

Radar equation calculator

Description

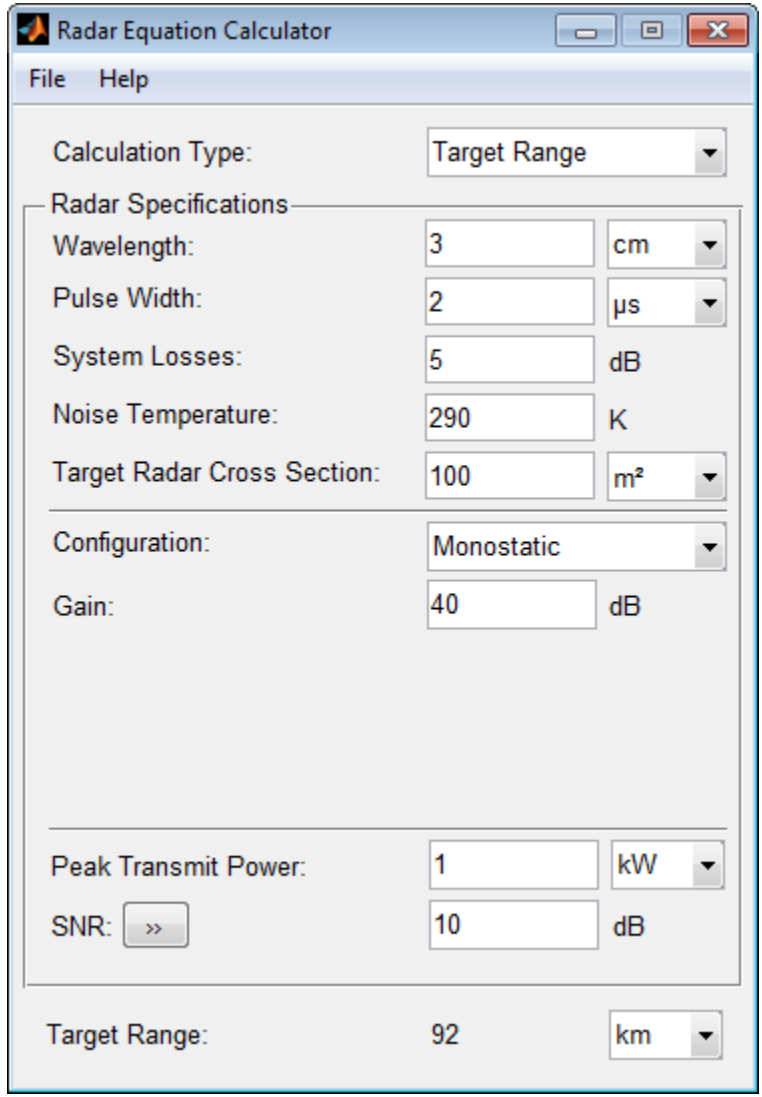
The **Radar Equation Calculator** app is a tool for solving the basic radar equation for monostatic or bistatic radar systems. The radar equation relates target range, transmitted power and received signal SNR. Using this app, you can solve for any one of these three quantities. If you know the transmit power of your radar and the desired received SNR, you can solve for the maximum target range. If you know the target range and desired received SNR, you can compute how much power you need to transmit. Finally, if you know the range and transmit power, you can calculate the received SNR value.

After you choose the type of solution, set other parameters to build a complete model. The principal parameters to specify are target cross-section, wavelength, antenna gains, noise temperature, and overall system losses.

Examples

Maximum Detection Range of a Monostatic Radar

Compute the maximum detection range of a 10 GHz, 1 kW, monostatic radar with a 40 dB antenna gain and a detection threshold of 10 dB. From the **Calculation Type** drop-down list, choose **Target Range** as the solution and choose **Configuration** as `monostatic`. Enter 40 dB for the antenna **Gain**, and set the **Wavelength** to 3 cm. Set the **SNR** detection threshold parameter to 10 dB. Assuming the target is a large airplane, set the **Target Radar Cross Section** value to 100 m^2. Next, specify the **Peak Transmit Power** as 1 kW and the **Pulse Width** as 2 μs. Finally, assume a total of 5 dB **System Losses**.



The maximum target detection range is 92 km.

Maximum Detection Range of a Monostatic Radar Using Multiple Pulses

Continue with the results from the previous example. Use multiple pulses to reduce the transmitted power while maintaining the same maximum target range. Clicking

on the arrows to the right of the **SNR** label opens the **Detection Specifications for SNR** menu. There, set the **Probability of Detection** to 0.95, the **Probability of False Alarm** to 10^{-6}, and the **Number of Pulses** to 4. Then, reduce the **Peak Transmit Power** to 0.75 kW. Assume a nonfluctuating target model, i.e., the **Swerling Case Number** is 0.

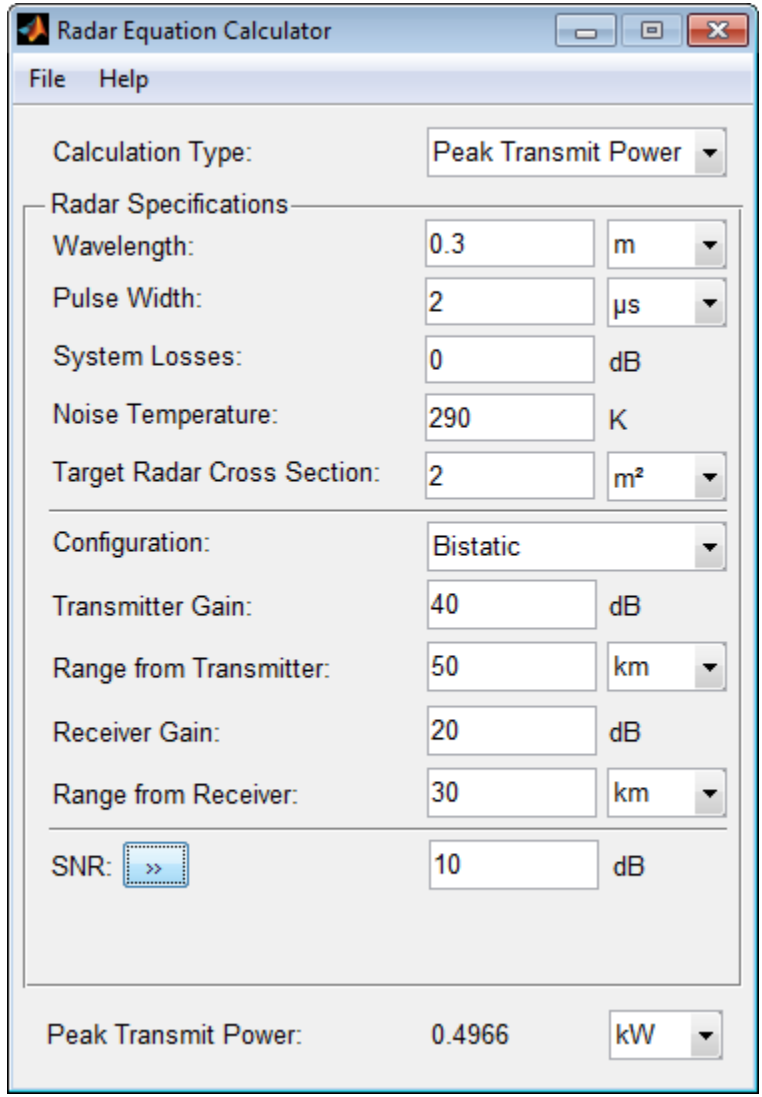
Required Transmit Power for a Bistatic Radar

Compute the required peak transmit power of a 10 GHz, bistatic X-band radar for a 80 km total bistatic range, and 10 dB received SNR. The system has a 40 dB transmitter gain and a 20 dB receiver gain. The required receiver SNR is 10 dB. From the **Calculation Type** drop-down list, choose **Peak Transmit Power** as the solution type and choose **Configuration** as `bistatic`. From the system specifications, set **Transmitter Gain** to 40 dB and **Receiver Gain** to 20 dB. Set the **SNR** detection threshold to 10 dB and the **Wavelength** to 0.3 m. Assume the target is a fighter aircraft having a **Target Radar Cross Section** value of 2 m^2. Choose **Range from Transmitter** as 50 km, and **Range from Receiver** as 30 km. Finally, set the **Pulse Width** to 2 μs and the **System Losses** to 0 dB.



The required Peak Transmit Power is about 0.5 kW.

Receiver SNR for a Monostatic Radar

Compute the received SNR for a monostatic radar with 1 kW peak transmit power with a target at a range of 2 km. Assume a 2 GHz radar frequency and 20 dB antenna gain. From the **Calculation Type** drop-down list, choose **SNR** as the solution type and set the **Configuration** as `monostatic`. Set the **Gain** to 20, the **Peak Transmit Power** to 1 kW, and the **Target Range** to 2000 m. Set the **Wavelength** to 15 cm.

Find the received SNR of a small boat having a **Target Radar Cross Section** value of 0.5 m^2. The **Pulse Width** is 1 μs and **System Losses** are 0 dB.

"Radar Equation Theory"

Introduced in R2013a

radareqpow

Peak power estimate from radar equation

Syntax

```
Pt = radareqpow(lambda,tgtrng,SNR,Tau)
Pt = radareqpow(...,Name,Value)
```

Description

`Pt = radareqpow(lambda,tgtrng,SNR,Tau)` estimates the peak transmit power required for a radar operating at a wavelength of `lambda` meters to achieve the specified signal-to-noise ratio `SNR` in decibels for a target at a range of `tgtrng` meters. The target has a nonfluctuating radar cross section (RCS) of 1 square meter.

`Pt = radareqpow(...,Name,Value)` estimates the required peak transmit power with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`lambda`

Wavelength of radar operating frequency (in meters). The wavelength is the ratio of the wave propagation speed to frequency. For electromagnetic waves, the speed of propagation is the speed of light. Denoting the speed of light by *c* and the frequency (in hertz) of the wave by *f*, the equation for wavelength is:

$$\lambda = \frac{c}{f}$$

`tgtrng`

Target range in meters. When the transmitter and receiver are colocated (monostatic radar), `tgtrng` is a real-valued positive scalar. When the transmitter and receiver are not colocated (bistatic radar), `tgtrng` is a 1-by-2 row vector with real-valued positive

elements. The first element is the target range from the transmitter, and the second element is the target range from the receiver.

`SNR`

The minimum output signal-to-noise ratio at the receiver in decibels.

`Tau`

Single pulse duration in seconds.

Name-Value Pair Arguments

`'Gain'`

Transmitter and receiver gain in decibels (dB). When the transmitter and receiver are colocated (monostatic radar), `Gain` is a real-valued scalar. The transmit and receive gains are equal. When the transmitter and receiver are not colocated (bistatic radar), `Gain` is a 1-by-2 row vector with real-valued elements. The first element is the transmitter gain and the second element is the receiver gain.

Default: 20

`'Loss'`

System loss in decibels (dB). `Loss` represents a general loss factor that comprises losses incurred in the system components and in the propagation to and from the target.

Default: 0

`'RCS'`

Radar cross section in square meters. The target RCS is nonfluctuating.

Default: 1

`'Ts'`

System noise temperature in kelvin. The system noise temperature is the product of the system temperature and the noise figure.

Default: 290 kelvin

Output Arguments

`Pt`

Transmitter peak power in watts.

Examples

Compute Required Transmit Power

Estimate the required peak transmit power required to achieve a minimum SNR of 6 dB for a target at a range of 50 km. The target has a nonfluctuating RCS of 1 m^2. The radar operating frequency is 1 GHz. The pulse duration is 1 μs.

```
fc = 1.0e9;
lambda = physconst('LightSpeed')/fc;
tgtrng = 50e3;
tau = 1e-6;
SNR = 6;
Pt = radareqpow(lambda,tgtrng,SNR,tau)
```

```
Pt =

   2.1996e+05
```

Compute Required Transmit Power at Specified System Temperature

Estimate the required peak transmit power required to achieve a minimum SNR of 10 dB for a target with an RCS of 0.5 m^2 at a range of 50 km. The radar operating frequency is 10 GHz. The pulse duration is 1 μs. Assume a transmit and receive gain of 30 dB and an overall loss factor of 3 dB. The system temperature is 300 K.

```
fc = 10.0e9;
lambda = physconst('LightSpeed')/fc;
Pt = radareqpow(lambda,50e3,10,1e-6,'RCS',0.5,...
    'Gain',30,'Ts',300,'Loss',3)
```

```
Pt =
```

```
   2.2809e+06
```

Compute Required Transmit Power for Bistatic Radar

Estimate the required peak transmit power for a bistatic radar to achieve a minimum SNR of 6 dB for a target with an RCS of 1 m^2. The target is 50 km from the transmitter and 75 km from the receiver. The radar operating frequency is 10 GHz and the pulse duration is 10 μs. The transmitter and receiver gains are 40 dB and 20 dB, respectively.

```
fc = 10.0e9;
lambda = physconst('LightSpeed')/fc;
SNR = 6;
tau = 10e-6;
TxRng = 50e3;
RvRng = 75e3;
TxRvRng =[TxRng RvRng];
TxGain = 40;
RvGain = 20;
Gain = [TxGain RvGain];
Pt = radareqpow(lambda,TxRvRng,SNR,tau,'Gain',Gain)
```

```
Pt =

   4.9492e+04
```

Definitions

Point Target Radar Range Equation

The point target radar range equation estimates the power at the input to the receiver for a target of a given radar cross section at a specified range. The model is deterministic and assumes isotropic radiators. The equation for the power at the input to the receiver is

$$P_r = \frac{P_t G_t G_r \lambda^2 \sigma}{(4\pi)^3 R_t^2 R_r^2 L}$$

where the terms in the equation are:

- P_t — Peak transmit power in watts
- G_t — Transmitter gain in decibels
- G_r — Receiver gain in decibels. If the radar is monostatic, the transmitter and receiver gains are identical.
- λ — Radar operating frequency wavelength in meters
- σ — Target's nonfluctuating radar cross section in square meters
- L — General loss factor in decibels that accounts for both system and propagation loss
- R_t — Range from the transmitter to the target
- R_r — Range from the receiver to the target. If the radar is monostatic, the transmitter and receiver ranges are identical.

Terms expressed in decibels such as the loss and gain factors enter the equation in the form $10^{x/10}$ where x denotes the variable. For example, the default loss factor of 0 dB results in a loss term of $10^{0/10}=1$.

Receiver Output Noise Power

The equation for the power at the input to the receiver represents the *signal* term in the signal-to-noise ratio. To model the noise term, assume the thermal noise in the receiver has a white noise power spectral density (PSD) given by:

$$P(f) = kT$$

where k is the Boltzmann constant and T is the effective noise temperature. The receiver acts as a filter to shape the white noise PSD. Assume that the magnitude squared receiver frequency response approximates a rectangular filter with bandwidth equal to the reciprocal of the pulse duration, $1/\tau$. The total noise power at the output of the receiver is:

$$N = \frac{kTF_n}{\tau}$$

where F_n is the receiver *noise factor*.

The product of the effective noise temperature and the receiver noise factor is referred to as the *system temperature* and is denoted by T_s, so that $T_s=TF_n$.

Receiver Output SNR

Using the equation for the received signal power in "Point Target Radar Range Equation" on page 2-347 and the output noise power in "Receiver Output Noise Power" on page 2-348, the receiver output SNR is:

$$\frac{P_r}{N}=\frac{P_t\tau G_t G_r\lambda^2\sigma}{(4\pi)^3 kT_s R_t^2 R_r^2 L}$$

Solving for the peak transmit power

$$P_t=\frac{P_r(4\pi)^3 kT_s R_t^2 R_r^2 L}{N\tau G_t G_r\lambda^2\sigma}$$

Introduced in R2011a

radareqrng

Maximum theoretical range estimate

Syntax

```
maxrng = radareqrng(lambda,SNR,Pt,Tau)
maxrng = radareqrng(...,Name,Value)
```

Description

`maxrng = radareqrng(lambda,SNR,Pt,Tau)` estimates the theoretical maximum detectable range `maxrng` for a radar operating with a wavelength of `lambda` meters with a pulse duration of `Tau` seconds. The signal-to-noise ratio is `SNR` decibels, and the peak transmit power is `Pt` watts.

`maxrng = radareqrng(...,Name,Value)` estimates the theoretical maximum detectable range with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`lambda`

Wavelength of radar operating frequency (in meters). The wavelength is the ratio of the wave propagation speed to frequency. For electromagnetic waves, the speed of propagation is the speed of light. Denoting the speed of light by *c* and the frequency (in hertz) of the wave by *f*, the equation for wavelength is:

$$\lambda = \frac{c}{f}$$

`Pt`

Transmitter peak power in watts.

`SNR`

The minimum output signal-to-noise ratio at the receiver in decibels.

`Tau`

Single pulse duration in seconds.

Name-Value Pair Arguments

`'Gain'`

Transmitter and receiver gain in decibels (dB). When the transmitter and receiver are colocated (monostatic radar), `Gain` is a real-valued scalar. The transmit and receive gains are equal. When the transmitter and receiver are not colocated (bistatic radar), `Gain` is a 1-by-2 row vector with real-valued elements. The first element is the transmitter gain, and the second element is the receiver gain.

Default: 20

`'Loss'`

System loss in decibels (dB). `Loss` represents a general loss factor that comprises losses incurred in the system components and in the propagation to and from the target.

Default: 0

`'RCS'`

Radar cross section in square meters. The target RCS is nonfluctuating.

Default: 1

`'Ts'`

System noise temperature in kelvins. The system noise temperature is the product of the system temperature and the noise figure.

Default: 290 kelvin

`'unitstr'`

Units of the estimated maximum theoretical range. `unitstr` takes one of the following values

- `'km'` kilometers
- `'m'` meters
- `'nmi'` nautical miles (U.S.)

Default: `'m'`

Output Arguments

`maxrng`

The estimated theoretical maximum detectable range. The units of `maxrng` depends on the value of `unitstr`. By default `maxrng` is in meters. For bistatic radars, `maxrng` is the geometric mean of the range from the transmitter to the target and the receiver to the target.

Examples

Estimate Maximum Detectable Range

Estimate the theoretical maximum detectable range for a monostatic radar operating at 10 GHz using a pulse duration of 10 µs. Assume the output SNR of the receiver is 6 dB.

```
lambda = physconst('LightSpeed')/10e9;
SNR = 6;
tau = 10e-6;
Pt = 1e6;
maxrng = radareqrng(lambda,SNR,Pt,tau)
```

```
maxrng =

   4.1057e+04
```

Estimate Maximum Detectable Range With Target RCS

Estimate the theoretical maximum detectable range for a monostatic radar operating at 10 GHz using a pulse duration of 10 µs. The target RCS is 0.1 m^2. Assume the output SNR of the receiver is 6 dB. The transmitter-receiver gain is 40 dB. Assume a loss factor of 3 dB.

```
lambda = physconst('LightSpeed')/10e9;
SNR = 6;
tau = 10e-6;
Pt = 1e6;
RCS = 0.1;
Gain = 40;
Loss = 3;
maxrng2 = radareqrng(lambda,SNR,Pt,tau,'Gain',Gain,...
    'RCS',RCS,'Loss',Loss)
```

```
maxrng2 =

   1.9426e+05
```

Definitions

Point Target Radar Range Equation

The point target radar range equation estimates the power at the input to the receiver for a target of a given radar cross section at a specified range. The model is deterministic and assumes isotropic radiators. The equation for the power at the input to the receiver is

$$P_r = \frac{P_t G_t G_r \lambda^2 \sigma}{(4\pi)^3 R_t^2 R_r^2 L}$$

where the terms in the equation are:

- P_t — Peak transmit power in watts
- G_t — Transmitter gain in decibels
- G_r — Receiver gain in decibels. If the radar is monostatic, the transmitter and receiver gains are identical.
- λ — Radar operating frequency wavelength in meters
- σ — Target's nonfluctuating radar cross section in square meters
- L — General loss factor in decibels that accounts for both system and propagation loss

- R_t — Range from the transmitter to the target
- R_r — Range from the receiver to the target. If the radar is monostatic, the transmitter and receiver ranges are identical.

Terms expressed in decibels, such as the loss and gain factors, enter the equation in the form $10^{x/10}$ where x denotes the variable. For example, the default loss factor of 0 dB results in a loss term of $10^{0/10}=1$.

Receiver Output Noise Power

The equation for the power at the input to the receiver represents the *signal* term in the signal-to-noise ratio. To model the noise term, assume the thermal noise in the receiver has a white noise power spectral density (PSD) given by:

$$P(f) = kT$$

where k is the Boltzmann constant and T is the effective noise temperature. The receiver acts as a filter to shape the white noise PSD. Assume that the magnitude squared receiver frequency response approximates a rectangular filter with bandwidth equal to the reciprocal of the pulse duration, $1/\tau$. The total noise power at the output of the receiver is:

$$N = \frac{kTF_n}{\tau}$$

where F_n is the receiver *noise factor*.

The product of the effective noise temperature and the receiver noise factor is referred to as the *system temperature*. This value is denoted by T_s, so that $T_s=TF_n$.

Receiver Output SNR

The receiver output SNR is:

$$\frac{P_r}{N} = \frac{P_t \tau G_t G_r \lambda^2 \sigma}{(4\pi)^3 k T_s R_t^2 R_r^2 L}$$

You can derive this expression using the following equations:

- Received signal power in “Point Target Radar Range Equation” on page 2-354
- Output noise power in “Receiver Output Noise Power” on page 2-355

Theoretical Maximum Detectable Range

For monostatic radars, the range from the target to the transmitter and receiver is identical. Denoting this range by R, you can express this relationship as $R^4 = R_t^2 R_r^2$.

Solving for R

$$R = \left(\frac{NP_t\tau G_t G_r \lambda^2 \sigma}{P_r (4\pi)^3 k T_s L}\right)^{1/4}$$

For bistatic radars, the theoretical maximum detectable range is the geometric mean of the ranges from the target to the transmitter and receiver:

$$\sqrt{R_t R_r} = \left(\frac{NP_t\tau G_t G_r \lambda^2 \sigma}{P_r (4\pi)^3 k T_s L}\right)^{1/4}$$

Introduced in R2011a

radareqsnr

SNR estimate from radar equation

Syntax

```
SNR = radareqsnr(lambda,tgtrng,Pt,tau)
SNR = radareqsnr(...,Name,Value)
```

Description

`SNR = radareqsnr(lambda,tgtrng,Pt,tau)` estimates the output signal-to-noise ratio (SNR) at the receiver based on the wavelength `lambda` in meters, the range `tgtrng` in meters, the peak transmit power `Pt` in watts, and the pulse width `tau` in seconds.

`SNR = radareqsnr(...,Name,Value)` estimates the output SNR at the receiver with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`lambda`

Wavelength of radar operating frequency in meters. The wavelength is the ratio of the wave propagation speed to frequency. For electromagnetic waves, the speed of propagation is the speed of light. Denoting the speed of light by *c* and the frequency in hertz of the wave by *f*, the equation for wavelength is:

$$\lambda = \frac{c}{f}$$

`tgtrng`

Target range in meters. When the transmitter and receiver are colocated (monostatic radar), `tgtrng` is a real-valued positive scalar. When the transmitter and receiver are

not colocated (bistatic radar), `tgtrng` is a 1-by-2 row vector with real-valued positive elements. The first element is the target range from the transmitter, and the second element is the target range from the receiver.

`Pt`

Transmitter peak power in watts.

`tau`

Single pulse duration in seconds.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Gain'`

Transmitter and receiver gain in decibels (dB). When the transmitter and receiver are colocated (monostatic radar), `Gain` is a real-valued scalar. The transmit and receive gains are equal. When the transmitter and receiver are not colocated (bistatic radar), `Gain` is a 1-by-2 row vector with real-valued elements. The first element is the transmitter gain, and the second element is the receiver gain.

Default: 20

`'Loss'`

System loss in decibels (dB). `Loss` represents a general loss factor that comprises losses incurred in the system components and in the propagation to and from the target.

Default: 0

`'RCS'`

Target radar cross section in square meters. The target RCS is nonfluctuating.

Default: 1

'Ts'

System noise temperature in kelvin. The system noise temperature is the product of the effective noise temperature and the noise figure.

Default: 290 kelvin

Output Arguments

SNR

The estimated output signal-to-noise ratio at the receiver in decibels. SNR is $10\log_{10}(P_r/N)$. The ratio P_r/N is defined in "Receiver Output SNR" on page 2-363.

Examples

Compute SNR Using Radar Equation

Estimate the output SNR for a target with an RCS of 1 m^2 at a range of 50 km. The system is a monostatic radar operating at 1 GHz with a peak transmit power of 1 MW and pulse width of 0.2 μs. The transmitter and receiver gain is 20 dB. The system temperature has the default value of 290 K.

```
fc = 1.0e9;
lambda = physconst('LightSpeed')/fc;
tgtrng = 50e3;
Pt = 1e6;
tau = 0.2e-6;
snr = radareqsnr(lambda,tgtrng,Pt,tau)
```

```
snr =

    5.5868
```

Compute SNR with Specified System Temperature

Estimate the output SNR for a target with an RCS of 0.5 m^2 at 100 km. The system is a monostatic radar operating at 10 GHz with a peak transmit power of 1 MW and pulse

width of 1 μs. The transmitter and receiver gain is 40 dB. The system temperature is 300 K and the loss factor is 3 dB.

```
fc = 10.0;
T = 300.0;
lambda = physconst('LightSpeed')/10e9;
snr = radareqsnr(lambda,100e3,1e6,1e-6,'RCS',0.5,...
    'Gain',40,'Ts',T,'Loss',3)
```

```
snr =

   14.3778
```

Compute SNR for Bistatic Radar

Estimate the output SNR for a target with an RCS of 1 m^2. The radar is bistatic. The target is located 50 km from the transmitter and 75 km from the receiver. The radar operating frequency is 10.0 GHz. The transmitter has a peak transmit power of 1 MW with a gain of 40 dB. The pulse width is 1 μs. The receiver gain is 20 dB.

```
fc = 10.0e9;
lambda = physconst('LightSpeed')/fc;
tau = 1e-6;
Pt = 1e6;
txrvRng =[50e3 75e3];
Gain = [40 20];
snr = radareqsnr(lambda,txrvRng,Pt,tau,'Gain',Gain)
```

```
snr =

    9.0547
```

Definitions

Point Target Radar Range Equation

The point target radar range equation estimates the power at the input to the receiver for a target of a given radar cross section at a specified range. The model is deterministic

and assumes isotropic radiators. The equation for the power at the input to the receiver is

$$P_r = \frac{P_t G_t G_r \lambda^2 \sigma}{(4\pi)^3 R_t^2 R_r^2 L}$$

where the terms in the equation are:

- P_t — Peak transmit power in watts
- G_t — Transmitter gain in decibels
- G_r — Receiver gain in decibels. If the radar is monostatic, the transmitter and receiver gains are identical.
- λ — Radar operating frequency wavelength in meters
- σ — Nonfluctuating target radar cross section in square meters
- L — General loss factor in decibels that accounts for both system and propagation losses
- R_t — Range from the transmitter to the target in meters
- R_r — Range from the receiver to the target in meters. If the radar is monostatic, the transmitter and receiver ranges are identical.

Terms expressed in decibels such as the loss and gain factors enter the equation in the form $10^{x/10}$ where x denotes the variable value in decibels. For example, the default loss factor of 0 dB results in a loss term equal to one in the equation ($10^{0/10}$).

Receiver Output Noise Power

The equation for the power at the input to the receiver represents the signal term in the signal-to-noise ratio. To model the noise term, assume the thermal noise in the receiver has a white noise power spectral density (PSD) given by:

$$P(f) = kT$$

where k is the Boltzmann constant and T is the effective noise temperature. The receiver acts as a filter to shape the white noise PSD. Assume that the magnitude squared receiver frequency response approximates a rectangular filter with bandwidth equal to the reciprocal of the pulse duration, $1/\tau$. The total noise power at the output of the receiver is:

$$N = \frac{kTF_n}{\tau}$$

where F_n is the receiver *noise factor*.

The product of the effective noise temperature and the receiver noise factor is referred to as the *system temperature* and is denoted by T_s, so that $T_s = TF_n$.

Receiver Output SNR

The receiver output SNR is:

$$\frac{P_r}{N} = \frac{P_t \tau G_t G_r \lambda^2 \sigma}{(4\pi)^3 k T_s R_t^2 R_r^2 L}$$

You can derive this expression using the following equations:

- Received signal power in "Point Target Radar Range Equation" on page 2-361
- Output noise power in "Receiver Output Noise Power" on page 2-362

radarvcd

Vertical coverage diagram

Syntax

```
[vcp,vcpangles] = radarvcd(freq,rfs,anht)
[vcp,vcpangles] = radarvcd( ___ ,Name,Value)

radarvcd( ___ )
```

Description

`[vcp,vcpangles] = radarvcd(freq,rfs,anht)` calculates the vertical coverage pattern of a narrowband radar antenna. The "Vertical Coverage Pattern" on page 2-373 is the radar's range, `vcp`, as a function of elevation angle, `vcpangles`. The vertical coverage pattern depends upon three parameters. These parameters are the radar's maximum free-space detection range, `rfs`, the radar frequency, `freq`, and the antenna height, `anht`.

`[vcp,vcpangles] = radarvcd( ___ ,Name,Value)` allows you to specify additional input parameters as Name-Value pairs. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`). This syntax can use any of the input arguments in the previous syntax.

`radarvcd( ___ )` displays the vertical coverage diagram for a radar system. The plot is the locus of points ofmaximum radar range as a function of target elevation. This plot is also known as the *Blake chart*. To create this chart, `radarvcd` invokes the function `blakechart` using default parameters. To produce a Blake chart with different parameters, first call `radarvcd` to obtain `vcp` and `vcpangles`. Then, call `blakechart` with user-specified parameters. This syntax can use any of the input arguments in the previous syntaxes.

Examples

Plot Vertical Coverage Pattern Using Default Parameters

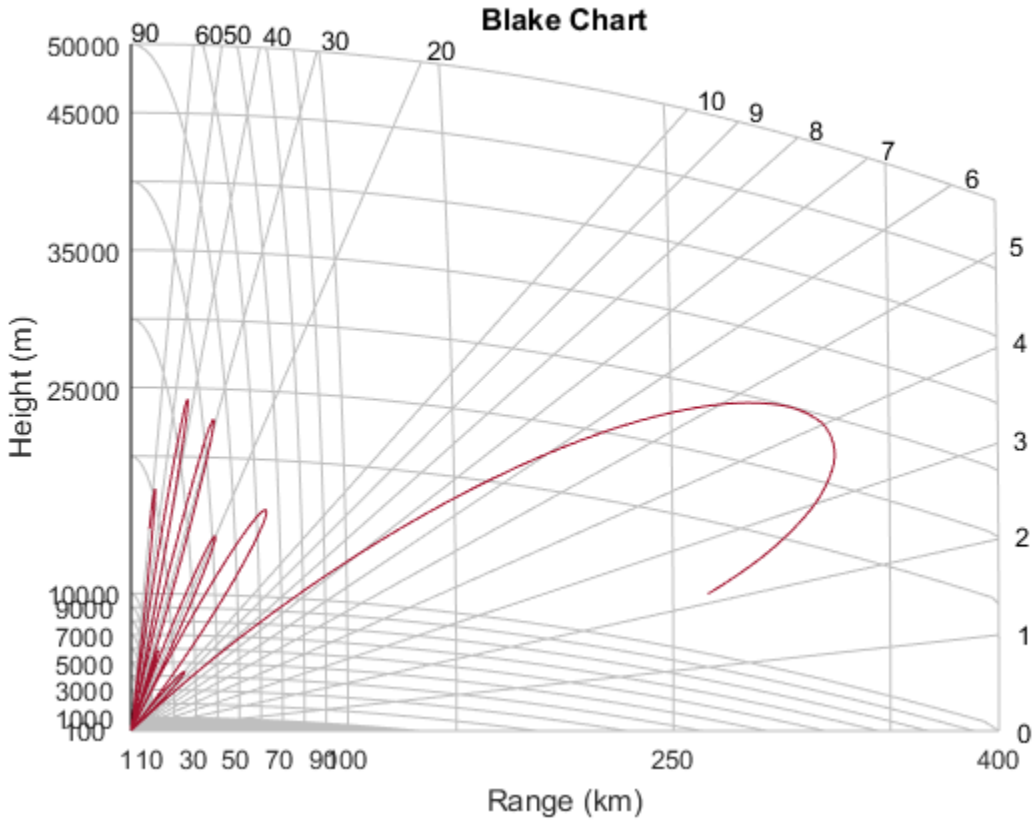
Set the frequency to 100 MHz, the antenna height to 10 m, and the free-space range to 200 km. The antenna pattern, surface roughness, antenna tilt angle, and field polarization assume their default values as specified in the `AntennaPattern`, `SurfaceRoughness`, `TiltAngle`, and `Polarization` properties.

Obtain an array of vertical coverage pattern values and angles.

```
freq = 100e6;
ant_height = 10;
rng_fs = 200;
[vcp,vcpangles] = radarvcd(freq,rng_fs,ant_height);
```

To see the vertical coverage pattern, omit the output arguments.

```
freq = 100e6;
ant_height = 10;
rng_fs = 200;
radarvcd(freq,rng_fs,ant_height);
```



Vertical Coverage Pattern with Specified Antenna Pattern

Set the frequency to 100 MHz, the antenna height to 10 m, and the free-space range to 200 km. The antenna pattern is a sinc function with 45° half-power width. The surface roughness is set to 1 m. The antenna tilt angle is set to 0°, and the field polarization is horizontal.

```
pat_angles = linspace(-90,90,361)';
pat_u = 1.39157/sind(45/2)*sind(pat_angles);
pat = sinc(pat_u/pi);
freq = 100e6;
ant_height = 10;
rng_fs = 200;
tilt_ang = 0;
```

```
[vcp,vcpangles] = radarvcd(freq,rng_fs,ant_height,...
    'RangeUnit','km','HeightUnit','m',...
    'AntennaPattern',pat,...
    'PatternAngles',pat_angles,...
    'TiltAngle',tilt_ang,'SurfaceRoughness',1);
```

Plot Vertical Coverage Diagram For User-Specified Antenna

Plot the range-height-angle curve (Blake Chart) for a radar with a user-specified antenna pattern.

Define a sinc-function antenna pattern with a half-power beamwidth of 90 degrees.

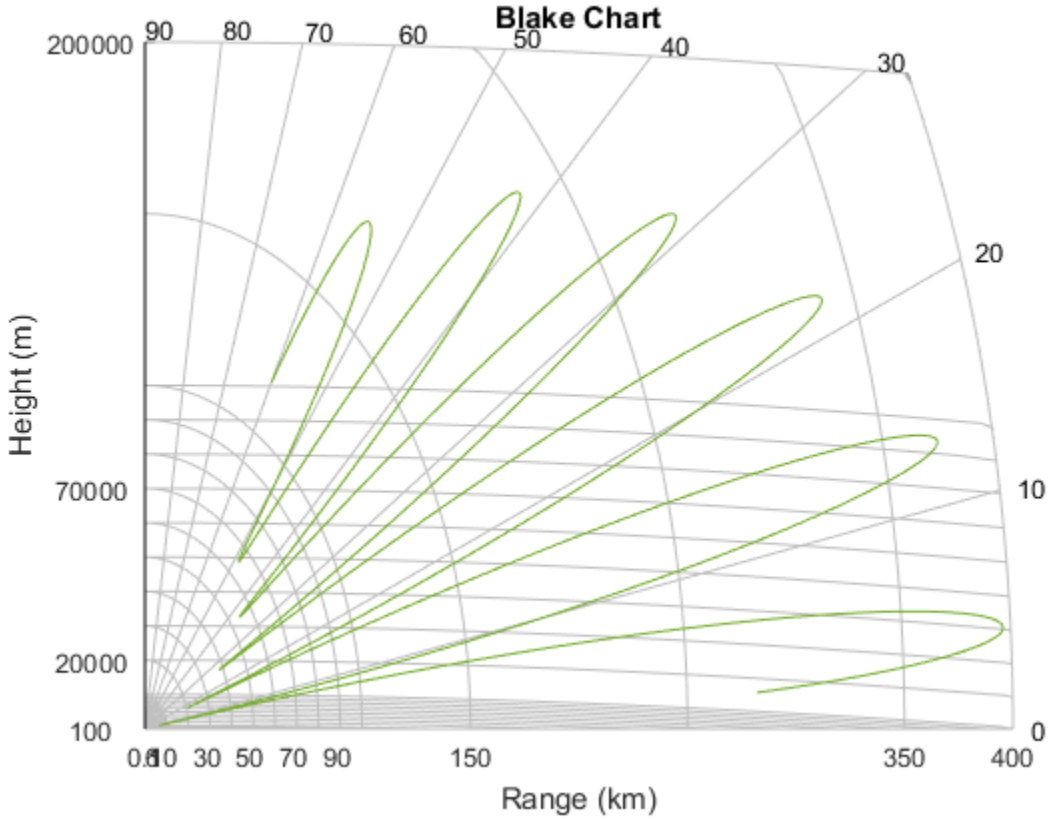
```
pat_angles = linspace(-90,90,361)';
pat_u = 1.39157/sind(90/2)*sind(pat_angles);
pat = sinc(pat_u/pi);
```

Specify a radar that transmits at 100 MHz. The free-space range is 200 km, the antenna height is 10 meters, the antenna tilt angle is zero degrees, and the surface roughness is one meter.

```
freq = 100e6;
ant_height = 10;
rng_fs = 200;
tilt_ang = 0;
surf_roughness = 1;
```

Create the radar range-height-angle plot.

```
radarvcd(freq,rng_fs,ant_height,...
    'RangeUnit','km','HeightUnit','m',...
    'AntennaPattern',pat,...
    'PatternAngles',pat_angles,...
    'TiltAngle',tilt_ang,...
    'SurfaceRoughness',surf_roughness);
```



Input Arguments

`freq` — Radar frequency

real-valued scalar less than 10 GHz

Radar frequency specified as a real-valued scalar less than 10 GHz (10e9).

Example: 100e6

Data Types: `double`

`rfs` — Free-space range

real-valued scalar

Free-space range specified as a real-valued scalar. Range units are set by the `RangeUnit` Name-Value pair.

Example: 100e3

Data Types: `double`

`anht` — Radar antenna height

real-valued scalar

Radar antenna height specified as a real-valued scalar. Height units are set by the `HeightUnit` Name-Value pair.

Example: 10

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: 'HeightUnit', k'm'

`'RangeUnit'` — Radar range units

`'km'` (default) | `'nmi'` | `'mi'` | `'ft'` | `'m'`

Radar range units denoting kilometers, nautical miles, miles, feet or meters. This name-value pair specifies the units for the free-space range argument, `rfs`, and the output vertical coverage pattern, `vcp`.

Example: `'mi'`

Data Types: `char`

`'HeightUnit'` — Antenna height units

`'m'` (default) | `'nmi'` | `'mi'` | `'km'` | `'ft'`

Antenna height units denoting meters, nautical miles, miles, kilometers, or feet. This name-value pair specifies the units for the antenna height, `anht`, and the `'SurfaceRoughness'` name-value pair.

Example: `'m'`

Data Types: `char`

`'Polarization'` — Transmitted wave polarization

`'H'` (default) | `'H'` | `'V'`

Transmitted wave polarization specified as `'H'` for horizontal polarization and `'V'` for vertical polarization.

Example: `'V'`

Data Types: `char`

`'SurfaceDielectric'` — Dielectric constant of reflecting surface

frequency dependent model (default) | complex-valued scalar

Dielectric constant of reflecting surface specified as complex-valued scalar. When omitted, the dielectric constant is taken from a frequency-dependent seawater dielectric model derived in Blake[1].

Example: 70

Data Types: `double`

`'SurfaceRoughness'` — Surface roughness

0 (default) | real-valued scalar

Surface roughness specified as a non-negative real scalar. Surface roughness is a measure of the height variation of the reflecting surface. The roughness is modeled as a sinusoid wave with crest-to-trough height given by this value. A value of 0 indicates a smooth surface. The units for surface roughness height is specified by the value of the `'HeightUnit'` Name-Value pair.

Example: 2

Data Types: `double`

`'AntennaPattern'` — Antenna elevation pattern

real-valued *N*-by-1 column vector

Antenna elevation pattern, specified as a real-valued *N*-by-1 column vector. Values for `'AntennaPattern'` must be specified together with values for `'PatternAngles'`.

Example: `cosd([–90:90])`

Data Types: `double`

`'PatternAngles'` — Antenna pattern elevation angles

real-valued *N*-by-1 column vector

Antenna pattern elevation angles specified as a real-valued *N*-by-1 column vector. The size of the vector specified by `'PatternAngles'` must be the same as that specified by `'AntennaPattern'`. Angle units are expressed in degrees and must lie between –90° and 90°. In general, to properly compute the coverage, the antenna pattern should fill the whole range from –90° to 90°.

Example: `[-90:90]`

Data Types: `double`

`'TiltAngle'` — Antenna tilt angle

real-valued scalar

Antenna tilt angle specified as a real-valued scalar. The tilt angle is the elevation angle of the antenna with respect to the surface. Angle units are expressed in degrees.

Example: 10

Data Types: `double`

`'MaxElevation'` — Maximum elevation angle

real-valued scalar

Maximum elevation angle, specified as a real-valued scalar. The maximum elevation angle is the largest angle for which the vertical coverage pattern is calculated. Angle units are expressed in degrees.

Example: 70

Data Types: `double`

Output Arguments

`vcp` — Vertical coverage pattern

real-valued vector

Vertical coverage pattern returned as a real-valued, *K*-by-1 column vector. The vertical coverage pattern is the actual maximum range of the radar. Each entry of the vertical coverage pattern corresponds to one of the angles returned in `vcpangles`.

`vcpangles` — Vertical coverage pattern angles
real-valued vector

Vertical coverage pattern angles returned as a *K*-by-1 column vector. The angles range from –90° to 90°.

Definitions

Vertical Coverage Pattern

The maximum detection range of a radar antenna can differ, depending on placement. Suppose you place a radar antenna near a reflecting surface, such as the earth's land or sea surface and computed maximum detection range. If you then move the same radar antenna to free space far from any boundaries, a different maximum detection range would result. This is an effect of multi-path interference that occurs when waves, reflected from the surface, constructively add to or nullify the direct path signal from the radar to a target. Multipath interference gives rise to a series of lobes in the vertical plane. The vertical coverage pattern is the plot of the actual maximum detection range of the radar versus target elevation and depends upon the maximum free-space detection range and target elevation angle. See Blake [1].

radarWaveformAnalyzer

Radar waveform analyzer

Description

The **Radar Waveform Analyzer** app is a tool for exploring the properties of various kinds of signals often used in radar and sonar systems. The app lets you determine the basic performance characteristics of the following waveforms:

- Rectangular
- Linear FM
- Stepped FM
- Phase-coded
- FMCW

Each waveform has a set of parameters that are unique to its kind. After you select a signal, the signal parameters menu changes so you can quickly modify the signal. Parameters you can set include the duration, pulse-repetition frequency, number of pulse, bandwidth and sample rate. Changing the propagation speed lets you display properties of sound waves in air and water, or electromagnetic waves. After you enter all the information for a signal of interest, the app displays basic characteristics such as range resolution, Doppler resolution, maximum and minimum range and maximum Doppler.

The **Radar Waveform Analyzer** app lets you produce a variety of plots and images. These are plots of the waveform's

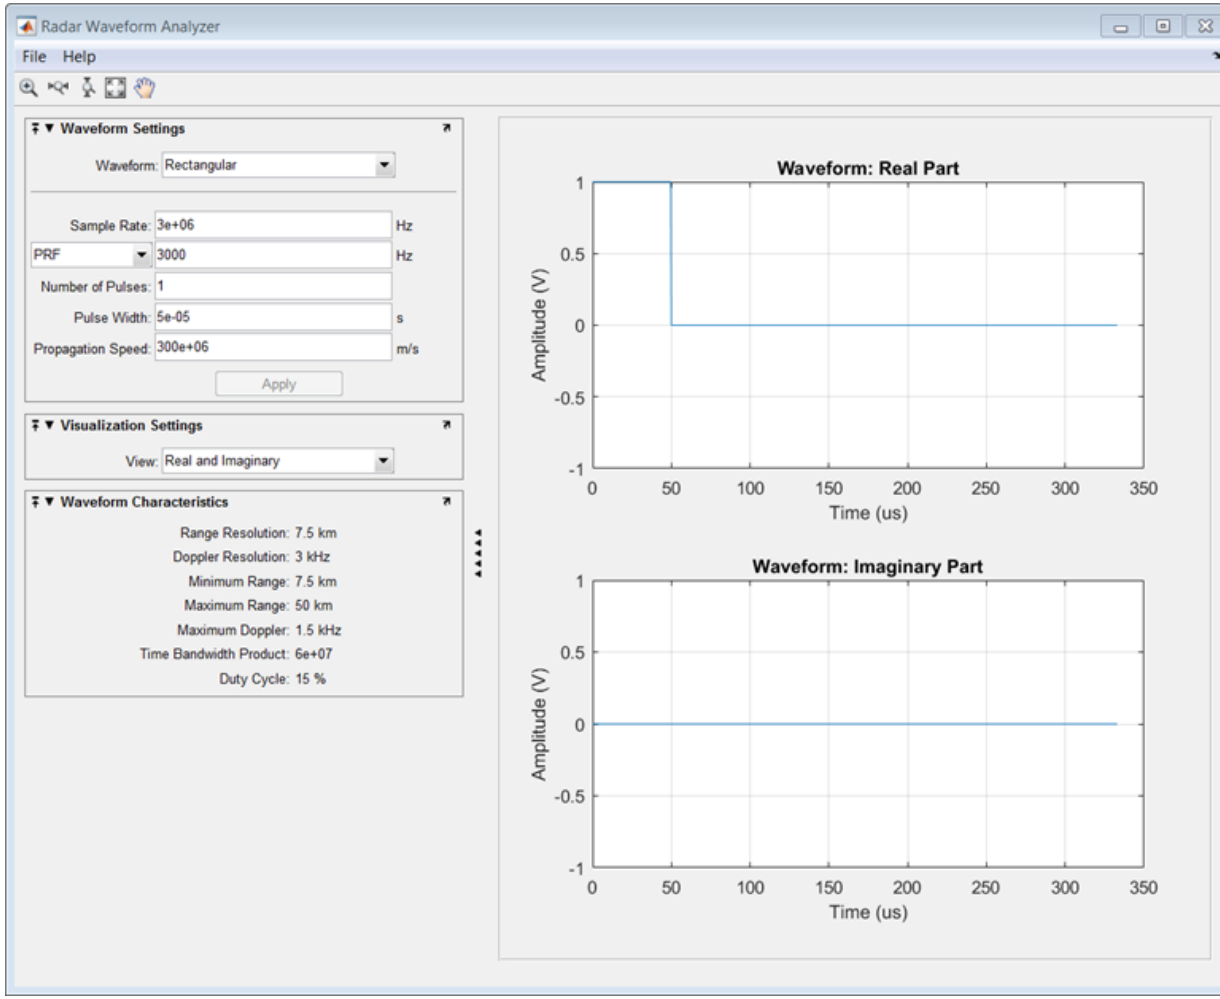
- Real and imaginary components
- Magnitude and phase
- Spectrum
- Spectrogram
- Representations of the ambiguity function
    - Contour
    - Surface

  - Delay cut
  - Doppler cut
- Autocorrelation function

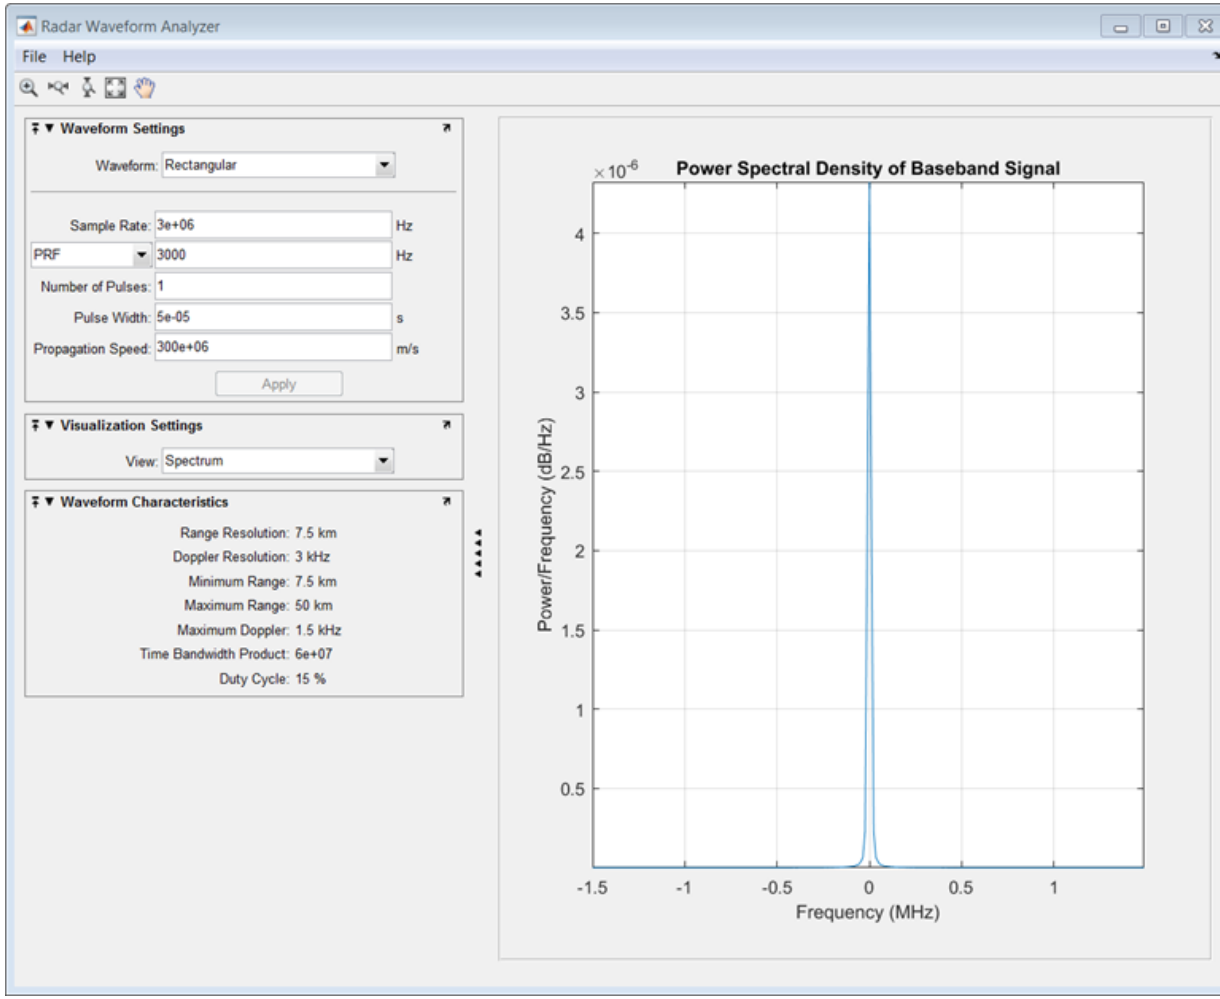
Examples

Rectangular Waveform

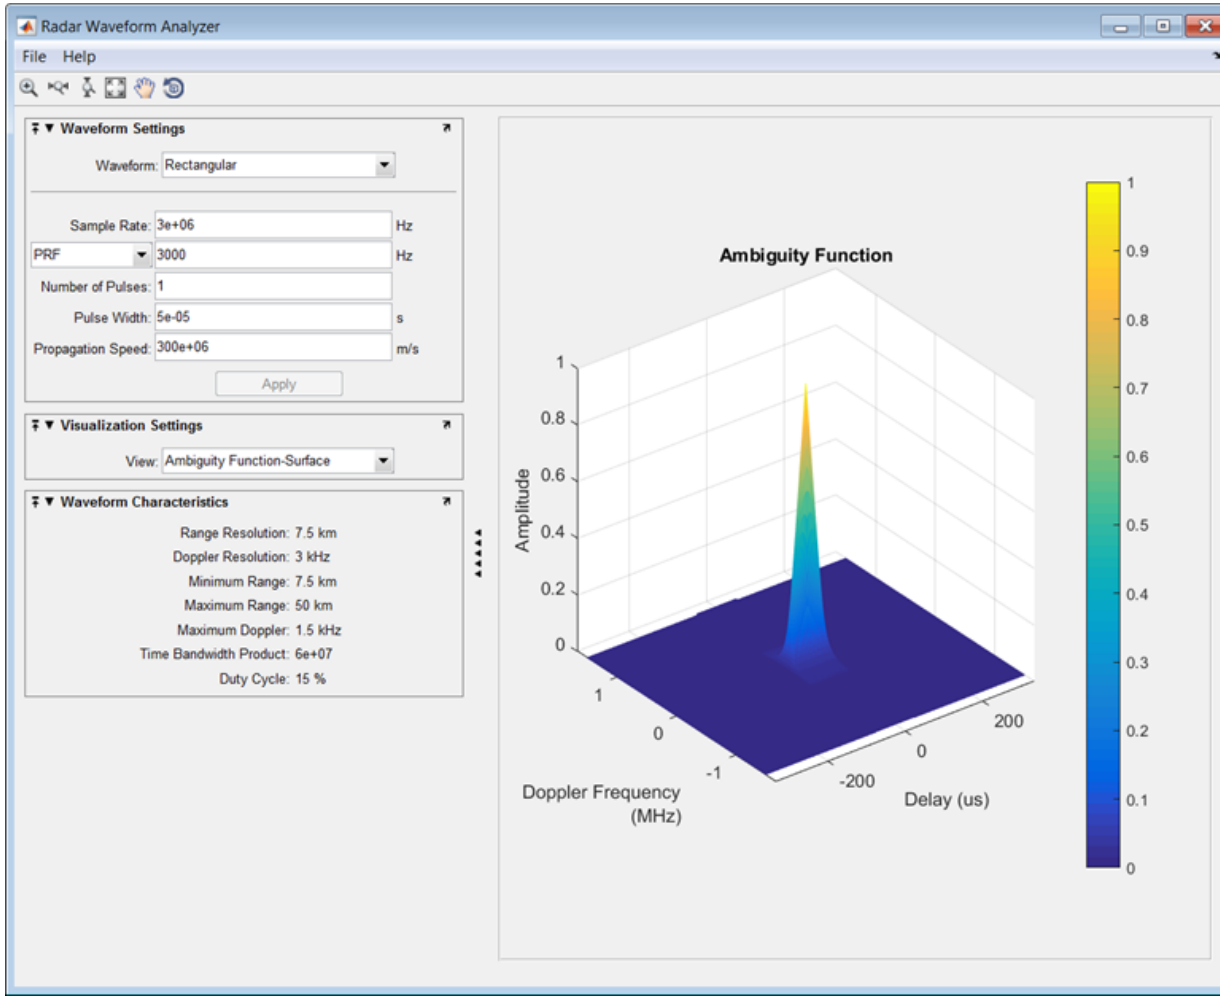
Assume a rectangular waveform. Set the **Waveform Type** to `Rectangular`. An ideal rectangular waveform jumps instantaneously to a finite value and stays there for some duration. Assume the radar is designed for a maximum range of 50 km. With this assumption, the propagation time for a signal to go to that range and return is 333 µs. This means you must allow 333 µs between pulses, equivalent to a maximum pulse repetition frequency (**PRF)**) of 3000 Hz. Set the **Pulse Width** to 50 µs. With these values, the app displays a 7.5 km range resolution. The resolution of a rectangular pulse is roughly 1/2 the pulse-width multiplied by the speed of light, which is entered here in the **Propagation Speed** field as 300e6 m/s. The Doppler resolution is approximately the width of the Fourier transform of the pulse. The same analysis can be used for sonar if you assume a much smaller speed of propagation, 1500 m/s. The following figure shows the real and imaginary parts of the waveform. This is the default view on the **View** drop-down list.



Next, you can view the signal spectrum. To do so, select `spectrum` from the **View** drop-down menu.



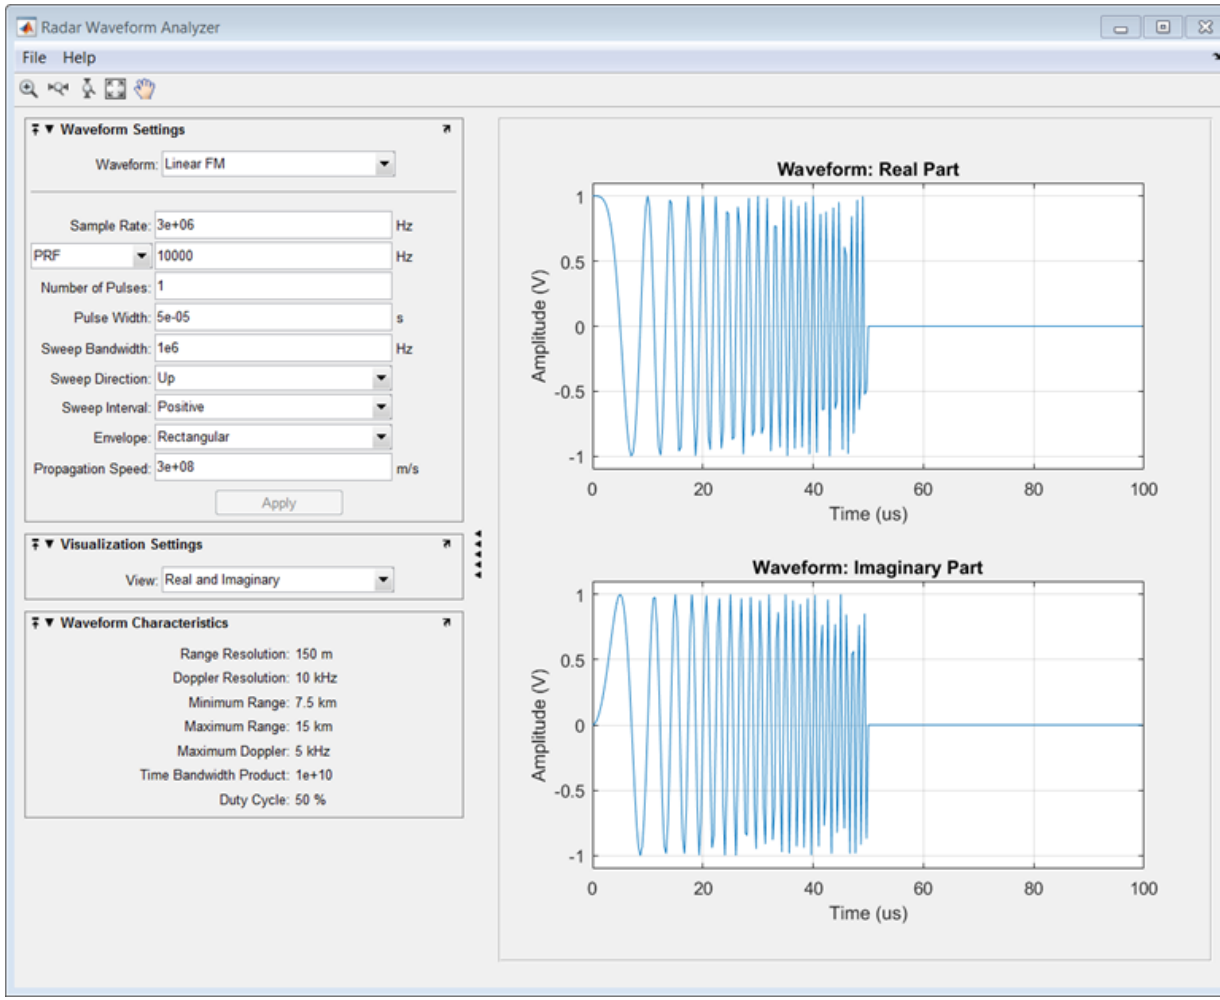
Finally, you can display the joint range-Doppler resolution by selecting `Ambigity-Function Surface` from the **View** pull-down menu.



Linear FM Waveform

In the previous example, the range resolution of the rectangular pulse was poor, at 7.5 km. You can improve the range resolution by choosing a signal with a larger bandwidth. A good choice is a linear FM pulse. Do this by setting the **Waveform Type** to `Linear FM`. This pulse has a variable frequency which can either increase or decrease as a linear function of time. Choose the **Sweep Direction** as `Up`, and the **Sweep Bandwidth** as

1 MHz. You can see that keeping the same pulse width as before improves the range resolution to 150 m, as shown in the following figure.



Finally, examine the ambiguity function which shows a trade-off. While the range resolution is better, the Doppler resolution is worse than that of a rectangular waveform.

radialspeed

Relative radial speed

Syntax

```
Rspeed = radialspeed(Pos,V)
Rspeed = radialspeed(Pos,V,RefPos)
Rspeed = radialspeed(Pos,V,RefPos,RefV)
```

Description

`Rspeed = radialspeed(Pos,V)` returns the radial speed of the given platforms relative to a reference platform. The platforms have positions `Pos` and velocities `V`. The reference platform is stationary and is located at the origin.

`Rspeed = radialspeed(Pos,V,RefPos)` specifies the position of the reference platform.

`Rspeed = radialspeed(Pos,V,RefPos,RefV)` specifies the velocity of the reference platform.

Input Arguments

`Pos`

Positions of platforms, specified as a 3-by-N matrix. Each column specifies a position in the form [*x*; *y*; *z*], in meters.

`V`

Velocities of platforms, specified as a 3-by-N matrix. Each column specifies a velocity in the form [*x*; *y*; *z*], in meters per second.

`RefPos`

Position of reference platform, specified as a 3-by-1 vector. The vector has the form [*x*; *y*; *z*], in meters.

Default: `[0; 0; 0]`

`RefV`

Velocity of reference platform, specified as a 3-by-1 vector. The vector has the form [*x*; *y*; *z*], in meters per second.

Default: `[0; 0; 0]`

Output Arguments

`Rspeed`

Radial speed in meters per second, as an N-by-1 vector. Each number in the vector represents the radial speed of the corresponding platform. Positive numbers indicate that the platform is approaching the reference platform. Negative numbers indicate that the platform is moving away from the reference platform.

Examples

Radial Speed of Target Relative to Stationary Platform

Calculate the radial speed of a target relative to a stationary platform. Assume the target is located at *(20,20,0)* meters in cartesian coordinates and is moving with velocity *(10,10,0)* meters per second. The reference platform is located at *(1,1,0)*.

```
rspeed = radialspeed([20; 20; 0],[10; 10; 0],[1; 1; 0])
```

```
rspeed =

  -14.1421
```

Negative radial speed indicates that the target is receding from the platform.

rainpl

RF signal attenuation due to rainfall

Syntax

```
L = rainpl(range,freq,rainrate)
L = rainpl(range,freq,rainrate,elev)
L = rainpl(range,freq,rainrate,elev,tau)
```

Description

`L = rainpl(range,freq,rainrate)` returns the signal attenuation, `L`, due to rainfall. In this syntax, attenuation is a function of signal path length, `range`, signal frequency, `freq`, and rain rate, `rainrate`. The path elevation angle and polarization tilt angles are assumed to zero.

The `rainpl` function applies the International Telecommunication Union (ITU) rainfall attenuation model to calculate path loss of signals propagating in a region of rainfall [1]. The function applies when the signal path is contained entirely in a uniform rainfall environment. Rain rate does not vary along the signal path. The attenuation model applies only for frequencies at 1–1000 GHz.

`L = rainpl(range,freq,rainrate,elev)` specifies the elevation angle, `elev`, of the propagation path.

`L = rainpl(range,freq,rainrate,elev,tau)` specifies the polarization tilt angle, `tau`, of the signal.

Examples

Signal Attenuation Due to Rainfall

Compute the signal attenuation due to rainfall for a 20 GHz signal over a distance of 10 km in light and heavy rain.

Propagate the signal in a light rainfall of 1 mm/hr.

```
rr = 1.0;
L = rainpl(10000,20.0e9,rr)
```

```
L =

    0.7104
```

Propagate the signal in a heavy rainfall of 10 mm/hr.

```
rr = 10.0;
L = rainpl(10000,20.0e9,rr)
```

```
L =

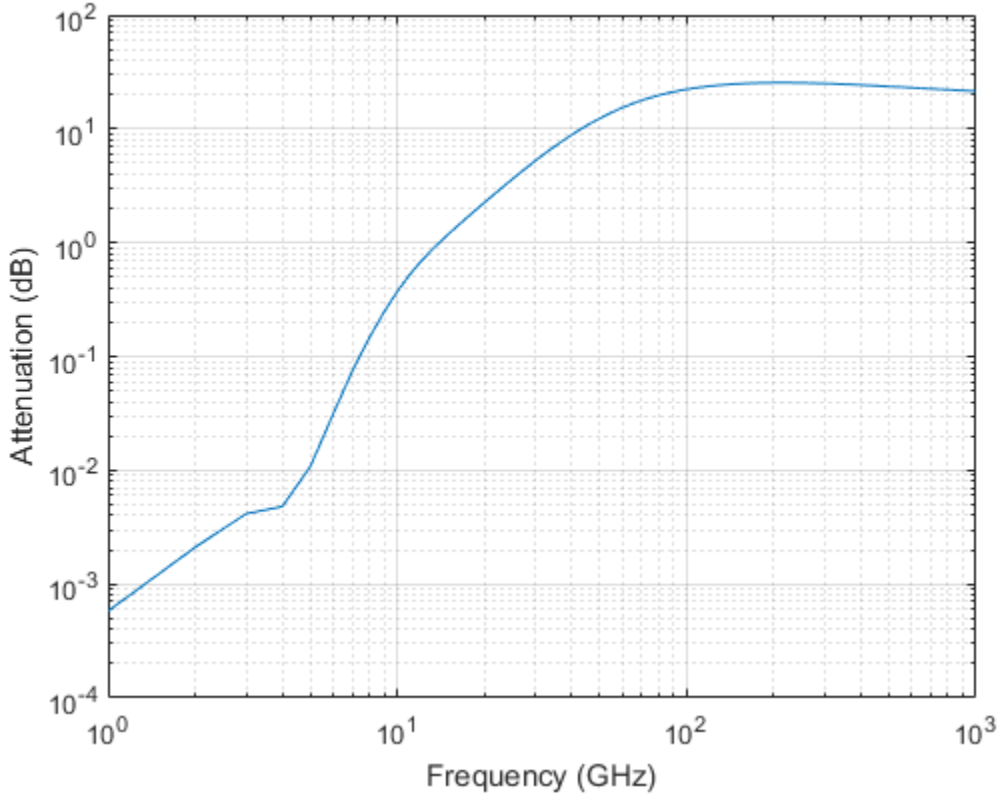
    7.8413
```

Signal Attenuation Due to Rainfall as Function of Frequency

Plot the signal attenuation due to moderate rainfall for signals in the frequency range 1–1000 GHz. The path distance is 10 km.

Set the rain rate value for moderate rainfall to 3 mm/hr.

```
rr = 3.0;
freq = [1:1000]*1e9;
L = rainpl(10000,freq,rr);
loglog(freq/1e9,L)
grid
xlabel('Frequency (GHz)')
ylabel('Attenuation (dB)')
```



Signal Attenuation Due to Rainfall as Function of Elevation Angle

Compute the signal attenuation due to heavy rain as a function of elevation angle. Elevation angles vary from 0°–90°. Assume a path distance of 100 km and a signal frequency of 100 GHz.

Set the rain rate to 10 mm/hr.

```
rr = 10.0;
```

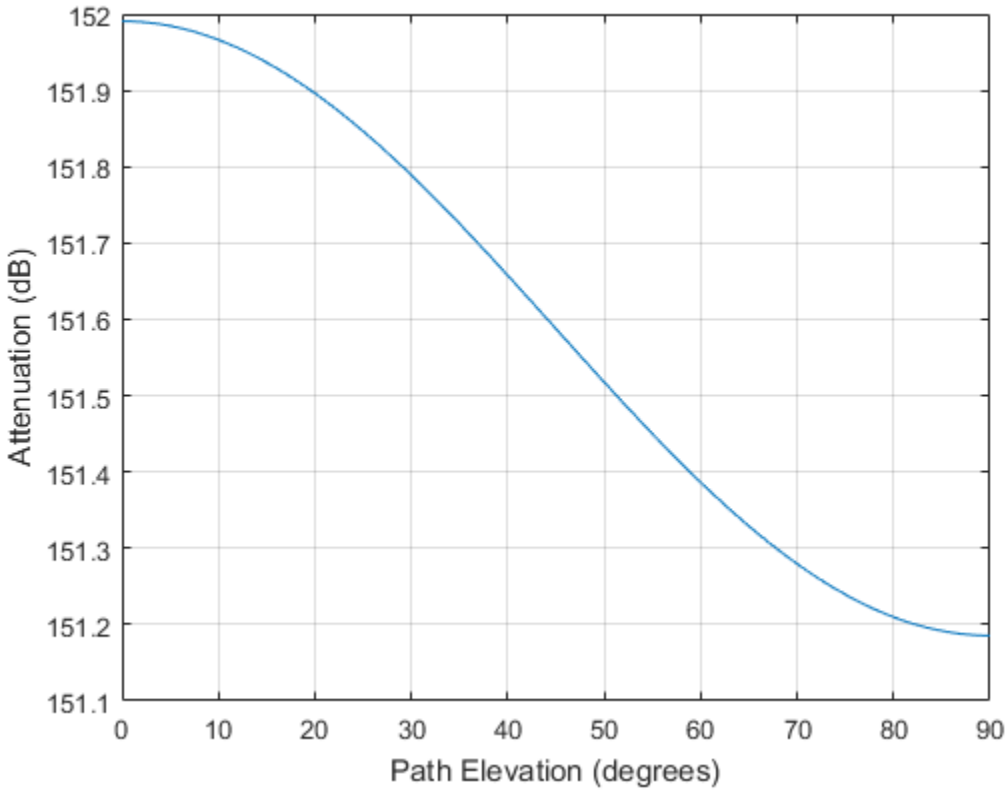
Set the elevation angles, frequency, range.

```
elev = [0:1:90];
freq = 100.0e9;
```

```
rng = 100000.0*ones(size(elev));
```

Compute and plot the loss.

```
L = rainpl(rng,freq,rr,elev);
plot(elev,L)
grid
xlabel('Path Elevation (degrees)')
ylabel('Attenuation (dB)')
```



Signal Attenuation Due to Rainfall as Function of Polarization

Compute the signal attenuation due to heavy rainfall as a function of the polarization tilt angle. Assume a path distance of 100 km, a signal frequency of 100 GHz signal,

and a path elevation angle of 0°. Set the rainfall rate to 10 mm/hour. Plot the signal attenuation versus polarization tilt angle.

Set the polarization tilt angle to vary from –90 to 90°.

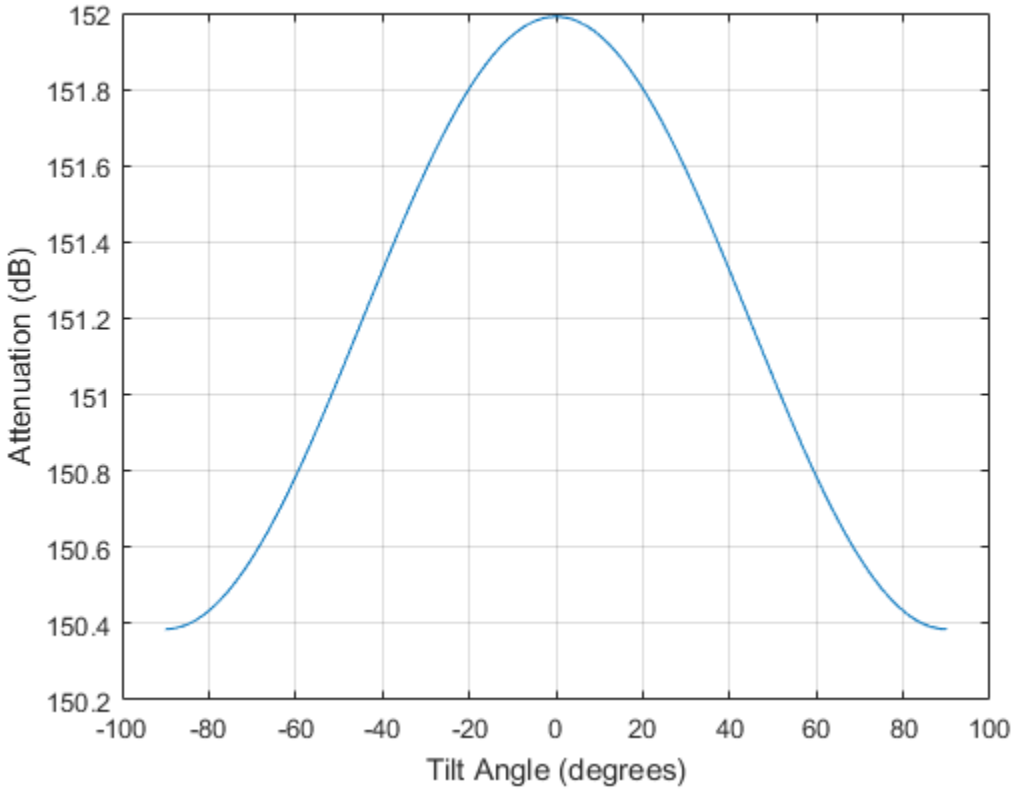
```
tau = [-90:90];
```

Set the elevation angle, frequency, path distance, and rain rate.

```
elev = 0;
freq = 100.0e9;
rng = 100e3*ones(size(tau));
rr = 10.0;
```

Compute and plot the attenuation.

```
L = rainpl(rng,freq,rr,elev,tau);
plot(tau,L)
grid
xlabel('Tilt Angle (degrees)')
ylabel('Attenuation (dB)')
```



Input Arguments

`range` — Signal path length

nonnegative real-valued scalar | nonnegative real-valued *M*-by-1 column vector | nonnegative real-valued 1-by-*M* row vector

Signal path length, specified as a nonnegative real-valued scalar, or as a *M*-by-1 or 1-by-*M* vector. Units are in meters.

Example: `[13000.0,14000.0]`

`freq` — Signal frequency

positive real-valued scalar | nonnegative real-valued *N*-by-1 column vector | nonnegative real-valued 1-by-*N* row vector

Signal frequency, specified as a positive real-valued scalar, or as a nonnegative *N*-by-1 or 1-by-*N* vector. Frequencies must lie in the range 1–1000 GHz.

Example: `[1400.0e6,2.0e9]`

`rainrate` — Rain rate

nonnegative real-valued scalar

Rain rate, specified as a nonnegative real-valued scalar. Units are in mm/hr.

Example: `1.5`

`elev` — Signal path elevation angle

0.0 (default) | real-valued scalar | real-valued *M*-by-1 column vector | real-valued 1-by-*M* row vector

Signal path elevation angle, specified as a real-valued scalar, or as an *M*-by-1 or 1-by-*M* vector. Units are in degrees between –90° and 90°. If `elev` is a scalar, all propagation paths have the same elevation angle. If `elev` is a vector, its length must match the dimension of `range` and each element in `elev` corresponds to a propagation range in `range`.

Example: `[0,45]`

`tau` — Tilt angle of polarization ellipse

0.0 (default) | real-valued scalar | real-valued *M*-by-1 column vector | real-valued 1-by-*M* row vector

Tilt angle of the signal polarization ellipse, specified as a real-valued scalar, or as an *M*-by-1 or 1-by- *M* vector. Units are in degrees between –90° and 90°. If `tau` is a scalar, all signals have the same tilt angle. If `tau` is a vector, its length must match the dimension of `range`. In that case, each element in `tau` corresponds to a propagation path in `range`.

The tilt angle is defined as the angle between the semimajor axis of the polarization ellipse and the *x*-axis. Because the ellipse is symmetrical, a tilt angle of 100° corresponds to the same polarization state as a tilt angle of -80°. Thus, the tilt angle need only be specified between ±90°.

Example: `[45,30]`

Output Arguments

L — Signal attenuation

real-valued *M*-by-*N* matrix

Signal attenuation, returned as a real-valued *M*-by-*N* matrix. Each matrix row represents a different path where *M* is the number of paths. Each column represents a different frequency where *N* is the number of frequencies. Units are in dB.

Definitions

Rainfall Attenuation Model

This model calculates the attenuation of signals that propagate through regions of rainfall.

Electromagnetic signals are attenuate when propagating through a region of rainfall. Rainfall attenuation is computed according to the ITU rainfall model *Recommendation ITU-R P.838-3: Specific attenuation model for rain for use in prediction methods*. The model computes the specific attenuation (attenuation per kilometer) of a signal as a function of rainfall rate, signal frequency, polarization, and path elevation angle. To compute the attenuation, this model uses

$$\gamma_r = kr^{\alpha},$$

where r is the rain rate in mm/hr. The parameter k and exponent α depend on the frequency, the polarization state, and the elevation angle of the signal path. The specific attenuation model is valid for frequencies from 1–1000 GHz.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by a propagation distance, R. Then, total attenuation is $L_r = R\gamma_r$. Instead of using geometric range as the propagation distance, the toolbox uses a modified range. The modified range is the geometric range multiplied by a range factor

$$\frac{1}{1+\frac{R}{R_0}}$$

where

$$R_0 = 35e^{-0.015r}$$

is the effective path length in kilometers (see Seybold, J. *Introduction to RF Propagation*.) When there is no rain, the effective path length is 35 km. When the rain rate is, for example, 10 mm/hr, the effective path length is 30.1 km. At short range, the propagation distance is approximately the geometric range. For longer ranges, the propagation distance asymptotically approaches the effective path length.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

range2beat

Convert range to beat frequency

Syntax

```
fb = range2beat(r,slope)
fb = range2beat(r,slope,c)
```

Description

`fb = range2beat(r,slope)` converts the range of a dechirped linear FMCW signal to the corresponding beat frequency. `slope` is the slope of the FMCW sweep.

`fb = range2beat(r,slope,c)` specifies the signal propagation speed.

Examples

Maximum Beat Frequency in FMCW Radar System

Calculate the maximum beat frequency in MhZ for the received signal of an upsweep FMCW waveform. The waveform sweeps a 300 MHz band in 1 ms. Assume that the waveform can detect a stationary target as far as 18 km.

```
slope = 300e6/1e-3;
r = 18e3;
fb = range2beat(r,slope)/1e6
```

```
fb =

   36.0249
```

- Automotive Adaptive Cruise Control Using FMCW Technology

Input Arguments

`r` — Range
array of nonnegative numbers

Range, specified as an array of nonnegative numbers in meters.

Data Types: `double`

`slope` — Sweep slope
nonzero scalar

Slope of FMCW sweep, specified as a nonzero scalar in hertz per second.

Data Types: `double`

`c` — Signal propagation speed
speed of light (default) | positive scalar

Signal propagation speed, specified as a positive scalar in meters per second.

Data Types: `double`

Output Arguments

`fb` — Beat frequency of dechirped signal
array of nonnegative numbers

Beat frequency of dechirped signal, returned as an array of nonnegative numbers in hertz. Each entry in `fb` is the beat frequency corresponding to the corresponding range in `r`. The dimensions of `fb` match the dimensions of `r`.

Data Types: `double`

Definitions

Beat Frequency

For an up-sweep or down-sweep FMCW signal, the beat frequency is $F_t - F_r$. In this expression, F_t is the transmitted signal's carrier frequency, and F_r is the received signal's carrier frequency.

For an FMCW signal with triangular sweep, the upsweep and downsweep have separate beat frequencies.

Algorithms

The function computes `2*r*slope/c`.

range2bw

Convert range resolution to required bandwidth

Syntax

```
bw = range2bw(rngres)
bw = range2bw(rngres,c)
```

Description

`bw = range2bw(rngres)` returns the bandwidth needed to distinguish two targets separated by a given range. Such capability is often referred to as *range resolution*. The propagation is assumed to be two-way, as in a monostatic radar system.

`bw = range2bw(rngres,c)` specifies the signal propagation speed.

Examples

Pulse Width for Specified Range Resolution

Assume you have a monostatic radar system that uses a rectangular waveform. Calculate the required pulse bandwidth in MHz of the waveform so that the system can achieve a range resolution of 10 m.

```
rngres = 10;
c = physconst('LightSpeed');
bw = range2bw(rngres,c)/1e6;
```

The required bandwidth is approximately 15 MHz.

- Automotive Adaptive Cruise Control Using FMCW Technology

Input Arguments

`rngres` — Target range resolution

positive scalar | MATLAB array of positive real values

Target range resolution in meters, specified as a scalar or a MATLAB array of positive real values.

Data Types: `double`

c — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as a positive scalar. Units are in meters per second.

Data Types: `double`

Output Arguments

bw — Required bandwidth

positive scalar | MATLAB array of positive real values

Required bandwidth in hertz, returned as a MATLAB array of positive real values. The dimensions of `bw` are the same as those of `rngres`.

Tips

- This function assumes two-way propagation. For one-way propagation, you can find the required bandwidth by multiplying the output of this function by 2.

Algorithms

The function computes `c/(2*rngres)`.

range2time

Convert propagation distance to propagation time

Syntax

```
t = range2time(r)
t = range2time(r,c)
```

Description

`t = range2time(r)` returns the time a signal takes to propagate a given distance. The propagation is assumed to be two-way, as in a monostatic radar system.

`t = range2time(r,c)` specifies the signal propagation speed.

Examples

PRF for Specified Unambiguous Range

Calculate the required PRF in Hertz for a monostatic radar system so that it can have a maximum unambiguous range of 15 km.

```
r = 15.0e3;
prf = 1/range2time(r)
```

```
prf =

   9.9931e+03
```

- Automotive Adaptive Cruise Control Using FMCW Technology

Input Arguments

r — Signal range

array of nonnegative numbers

Signal range in meters, specified as an array of nonnegative numbers.

Data Types: `double`

`c` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as a positive scalar in meters per second.

Data Types: `double`

Output Arguments

`t` — Propagation time

array of nonnegative numbers

Propagation time in seconds, returned as an array of nonnegative numbers. The dimensions of `t`are the same as those of `r`.

Algorithms

The function computes `2*r/c`.

rangeangle

Range and angle calculation

Syntax

```
[rng,ang] = rangeangle(pos)
[rng,ang] = rangeangle(pos,refpos)
[rng,ang] = rangeangle(pos,refpos,refaxes)
[rng,ang] = rangeangle(___,model)
```

Description

The function `rangeangle` determines the propagation path length and path direction of a signal from any point to a reference point. The function supports two propagation models — the *free space* model and the *two-ray* model. The *free space* model is a single line-of-sight path from a point to a reference point. The *two-ray* multipath model generates two paths. The first path follows the free-space path. The second path is a reflected path off a boundary plane at $z = 0$. Path directions are defined with respect to either the global coordinate system at the reference point or a local coordinate system at the reference point. Distances and angles at the reference point do not depend upon which direction the signal is travelling along the path. Path lengths are independent of the coordinate system.

`[rng,ang] = rangeangle(pos)` returns the propagation path length, `rng`, and direction, `ang`, of a signal path from one point or set of points, `pos`, to the reference point. In this syntax, the reference point coincides with the global coordinate system origin. Directions are specified by azimuth and elevation angles with respect to the global coordinate system. Signals follow a line-of-sight path from the source to the origin. The line-of-sight path corresponds to the geometric straight line between the points.

`[rng,ang] = rangeangle(pos,refpos)`, in addition, specifies a reference point, `refpos`. Directions are specified by azimuth and elevation with respect to a global coordinate system at the reference point.

`[rng,ang] = rangeangle(pos,refpos,refaxes)` in addition, specifies the reference axes, `refaxes`. Path angles are defined by azimuth and elevation with respect to a local coordinate system with its origin at `refpos` and axes defined by `refaxes`.

`[rng,ang] = rangeangle( ___ ,model)`, in addition, specifies a propagation model. When `model` is set to `'freespace'`, the signal propagates along a line-of-sight path from source point to reception point. When `model` is set to `'two-ray'`, the signal propagates along two paths from source point to reception point. The first path is the line-of-sight path. The second path is the reflecting path. In this case, the function returns the distances and angles for two paths for each source point.

Input Arguments

`pos`

Point position, specified as a 3-by-*N* real-valued matrix of rectangular coordinates where each column takes the form `[x;y;z]`. Each column in `pos` represents the coordinates of one position. Position units are meters.

`refpos`

Reference position, specified as a real-valued 3-by-1 vector of rectangular coordinates in the form `[x;y;z]`. The reference position is the origin of the local coordinate system. Ranges and angles to the columns of `pos` are measured with respect to `refpos`. Position units are meters.

Default: `[0;0;0]`

`refaxes`

Local coordinate system axes, specified as a real-valued 3-by-3 matrix whose columns define the axes of the local coordinate system with origin at `refpos`. Each column in `refaxes` specifies the direction of an axis for the local coordinate system in rectangular coordinates `[x;y;z]`.

Default: `[1 0 0;0 1 0;0 0 1]`

`model`

Propagation model, taking the value `'freespace'` or `'two-ray'`. Choosing `'freespace'` invokes the free space propagation model. Choosing `'two-ray'` invokes the two-ray propagation model.

Default: `'freespace'`

Output Arguments

`rng`

Propagation distance, returned as a 1-by-*M* vector of ranges from the source to the positions defined by the corresponding columns in `pos`. When `model` is set to `'freespace'`, *M* = *N*. When `model` is set to `'two-ray'`, *M* = *2N*. Alternate columns of `ang` refer to the line-of-sight path and reflected path, respectively. Position units are meters.

`ang`

Azimuth and elevation angles, returned as a 2-by-*M* matrix whose columns are angles in the form `[azimuth;elevation]`. Each column corresponds to the positions specified in `pos`. When `model` is set to `'freespace'`, *M* = *N*. When `model` is set to `'two-ray'`, *M* = *2N*. Alternate columns of `ang` refer to the line-of-sight path and reflected path, respectively. Angle units are in degrees.

Examples

Range and Angle Computation

Compute the range and angle of a target located at *(1000,2000,50)* meters from the origin.

```
TargetLoc = [1000;2000;50];
[tgtrng,tgtang] = rangeangle(TargetLoc)
```

```
tgtrng =

   2.2366e+03

tgtang =

   63.4349
    1.2810
```

Range and Angle With Respect to Local Origin

Compute the range and angle of a target located at *(1000,2000,50)* meters with respect to a local origin at *(100,100,10)* meters.

```
TargetLoc = [1000;2000;50];
Origin = [100;100;10];
[tgtrng,tgtang] = rangeangle(TargetLoc,Origin)
```

```
tgtrng =

   2.1028e+03

tgtang =

   64.6538
    1.0900
```

Range and Angle With Respect to Local Coordinates

Compute the range and angle of a target located at *(1000,2000,50)* meters but with respect to a local origin at *(100,100,10)* meters. Choose a local coordinate axes rotated around the z-axis by 45 degrees from the global coordinate axes.

```
TargetLoc = [1000;2000;50];
Origin = [100;100;10];
refaxes = [1/sqrt(2) 1/sqrt(2) 0; 1/sqrt(2) -1/sqrt(2) 0; 0 0 1];
[tgtrng,tgtang] = rangeangle(TargetLoc,Origin,refaxes)
```

```
tgtrng =

   2.1028e+03

tgtang =

  -19.6538
    1.0900
```

Two-Ray Range and Angle

Compute the two-ray propagation distances and arrival angles of rays from a source located at *(1000,1000,500)* meters from the origin. The receiver is located at *(100,100,200)* meters from the origin.

```
sourceLoc = [1000;1000;500];
receiverLoc = [100;100;200];
[sourcerngs,sourceangs] = rangeangle(sourceLoc,receiverLoc,'two-ray')
```

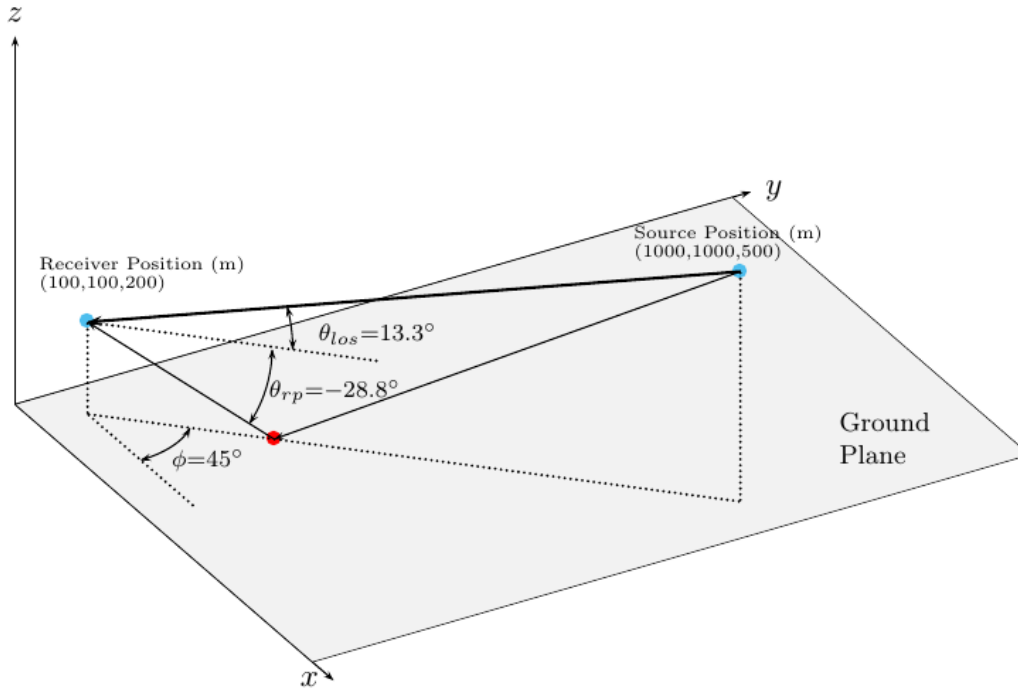
```
sourcerngs =

   1.0e+03 *

    1.3077    1.4526

sourceangs =

   45.0000   45.0000
   13.2627  -28.8096
```



Find the range and angle of the same target with the same origin but with respect to a local coordinate axes. The local coordinate axes are rotated around the z-axis by 45 degrees from the global coordinate axes.

```
refaxes = rotz(45);
[sourcerngs,sourceangs] = rangeangle(sourceLoc,receiverLoc,refaxes,'two-ray')
```

```
sourcerngs =

   1.0e+03 *
```

```
    1.3077    1.4526

sourceangs =

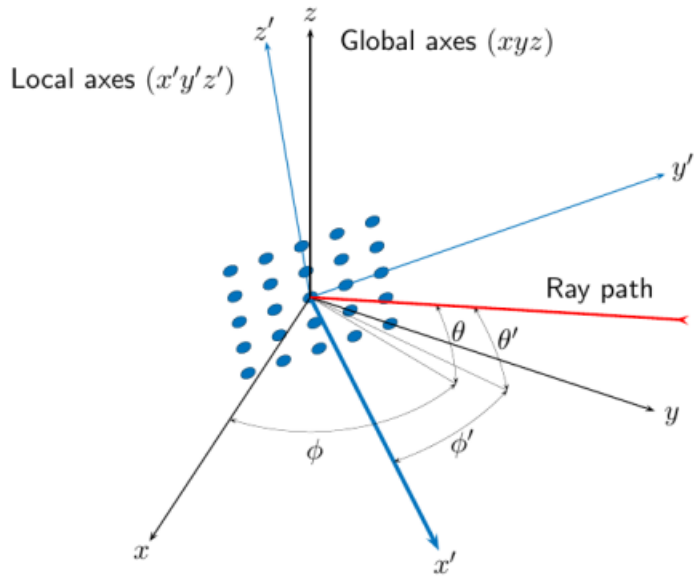
         0         0
   13.2627  -28.8096
```

- "Global and Local Coordinate Systems"

Propagation Models

Angles in Local and Global Coordinate Systems

The `rangeangle` function returns the path distance and path angles in either the global or local coordinate systems. Every antenna or microphone element and array has a gain pattern that is expressed in local angular coordinates of azimuth and elevation. As the element or array moves or rotates, the gain pattern is carried with it. To determine the strength of a signal's transmission or reception, you must know the angle that the signal path makes with respect to the local angular coordinates of the element or array. By default, the `rangeangle` function determines the angle a signal path makes with respect to global coordinates. If you add the `refaxes` argument, you can compute the angles with respect to local coordinates. As an illustration, the figure below shows a 5-by-5 uniform rectangular array (URA) rotated from the global coordinates *(xyz)* using `refaxes`. The *x′* axis of the local coordinate system *(x′y′z′)* is aligned with the main axis of the array and moves as the array moves. The path length is independent of orientation. The global coordinate system defines the azimuth and elevations angles (φ,θ) and the local coordinate system defines the azimuth and elevations angles (φ',θ').



Local and Global Coordinate Axes

Free Space Propagation Model

The free-space signal propagation model states that a signal propagating from one point to another in a homogeneous, isotropic medium travels in a straight line, called the *line-of-sight* or *direct path*. The straight line is defined by the geometric vector from the radiation source to the destination. Similar assumptions are made for sonar but the term *isovelocity* channel is usually used in place of free space.

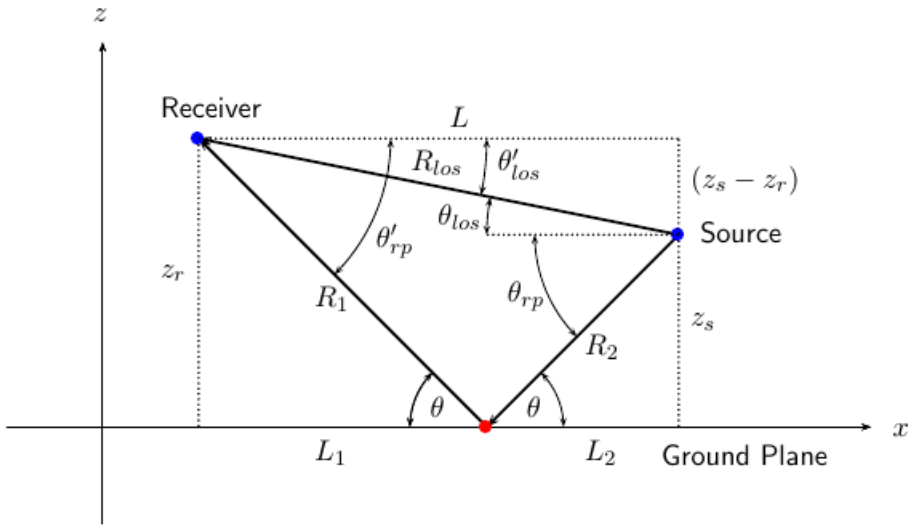
Two-ray Propagation Model

A two-ray propagation channel is the next step up in complexity from a free-space channel and is the simplest case of a multipath propagation environment. The free-space channel models a straight-line *line-of-sight* path from point 1 to point 2. In a two-ray channel, the medium is specified as a homogeneous, isotropic medium with

a reflecting planar boundary. The boundary is always set at $z = 0$. There are at most two rays propagating from point 1 to point 2. The first ray path propagates along the same line-of-sight path as in the free-space channel (see the phased.FreeSpace System object). The line-of-sight path is often called the *direct path*. The second ray reflects off the boundary before propagating to point 2. According to the Law of Reflection , the angle of reflection equals the angle of incidence. In short-range simulations such as cellular communications systems and automotive radars, you can assume that the reflecting surface, the ground or ocean surface, is flat.

The phased.TwoRayChannel and phased.WidebandTwoRayChannel System objects model propagation time delay, phase shift, Doppler shift, and loss effects for both paths. For the reflected path, loss effects include reflection loss at the boundary.

The figure illustrates two propagation paths. From the source position, s_s, and the receiver position, s_r, you can compute the arrival angles of both paths, θ'_{los} and θ'_{rp}. The arrival angles are the elevation and azimuth angles of the arriving radiation with respect to a local coordinate system. In this case, the local coordinate system coincides with the global coordinate system. You can also compute the transmitting angles, θ_{los} and θ_{rp}. In the global coordinates, the angle of reflection at the boundary is the same as the angles θ_{rp} and θ'_{rp}. The reflection angle is important to know when you use angle-dependent reflection-loss data. You can determine the reflection angle by using the `rangeangle` function and setting the reference axes to the global coordinate system. The total path length for the line-of-sight path is shown in the figure by R_{los} which is equal to the geometric distance between source and receiver. The total path length for the reflected path is $R_{rp} = R_1 + R_2$. The quantity L is the ground range between source and receiver.



You can easily derive exact formulas for path lengths and angles in terms of the ground range and objects heights in the global coordinate system.

$$\vec{R} = \vec{x}_s - \vec{x}_r$$

$$R_{los} = \left|\vec{R}\right| = \sqrt{\left(z_r - z_s\right)^2 + L^2}$$

$$R_1 = \frac{z_r}{z_r + z_z}\sqrt{\left(z_r + z_s\right)^2 + L^2}$$

$$R_2 = \frac{z_s}{z_s + z_r}\sqrt{\left(z_r + z_s\right)^2 + L^2}$$

$$R_{rp} = R_1 + R_2 = \sqrt{\left(z_r + z_s\right)^2 + L^2}$$

$$\tan\theta_{los} = \frac{\left(z_s - z_r\right)}{L}$$

$$\tan\theta_{rp} = -\frac{\left(z_s + z_r\right)}{L}$$

$$\theta'_{los} = -\theta_{los}$$

$$\theta'_{rp} = \theta_{rp}$$

rdcoupling

Range Doppler coupling

Syntax

```
dr = rdcoupling(fd,slope)
dr = rdcoupling(fd,slope,c)
```

Description

`dr = rdcoupling(fd,slope)` returns the range offset due to the Doppler shift in a linear frequency modulated signal. For example, the signal can be a linear FM pulse or an FMCW signal. `slope` is the slope of the linear frequency modulation.

`dr = rdcoupling(fd,slope,c)` specifies the signal propagation speed.

Examples

Target Range After Correcting for Doppler Shift

Calculate the true range of the target for an FMCW waveform that sweeps a band of 30 MHz in 2 ms. The dechirped target echo has a beat frequency of 1 kHz. The processing of the target return indicates a Doppler shift of 100 Hz.

```
slope = 30e6/2e-3;
fb = 1e3;
fd = 100;
r = beat2range(fb,slope) - rdcoupling(fd,slope)
```

```
r =

   10.9924
```

- Automotive Adaptive Cruise Control Using FMCW Technology

Input Arguments

`fd` — Doppler shift

array of real numbers

Doppler shift, specified as an array of real numbers.

Data Types: `double`

`slope` — Slope of linear frequency modulation

nonzero scalar

Slope of linear frequency modulation, specified as a nonzero scalar in hertz per second.

Data Types: `double`

`c` — Signal propagation speed

speed of light (default) | positive scalar

Signal propagation speed, specified as a positive scalar in meters per second.

Data Types: `double`

Output Arguments

`dr` — Range offset due to Doppler shift

real scalar

Range offset due to Doppler shift, returned as an array of real numbers. The dimensions of `dr` match the dimensions of `fd`.

Definitions

Range Offset

The *range offset* is the difference between the estimated range and the true range. The difference arises from coupling between the range and Doppler shift.

Algorithms

The function computes `-c*fd/(2*slope)`.

rocpfa

Receiver operating characteristic curves by false-alarm probability

Syntax

```
[Pd,SNR] = rocpfa(Pfa)
[Pd,SNR] = rocpfa(Pfa,Name,Value)
rocpfa(...)
```

Description

`[Pd,SNR] = rocpfa(Pfa)` returns the single-pulse detection probabilities, `Pd`, and required SNR values, `SNR`, for the false-alarm probabilities in the row or column vector `Pfa`. By default, for each false-alarm probability, the detection probabilities are computed for 101 equally spaced SNR values between 0 and 20 dB. The ROC curve is constructed assuming a single pulse in coherent receiver with a nonfluctuating target.

`[Pd,SNR] = rocpfa(Pfa,Name,Value)` returns detection probabilities and SNR values with additional options specified by one or more `Name,Value` pair arguments.

`rocpfa(...)` plots the ROC curves.

Input Arguments

`Pfa`

False-alarm probabilities in a row or column vector.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'MaxSNR'`

Maximum SNR to include in the ROC calculation.

Default: 20

`'MinSNR'`

Minimum SNR to include in the ROC calculation.

Default: 0

`'NumPoints'`

Number of SNR values to use when calculating the ROC curves. The actual values are equally spaced between `MinSNR` and `MaxSNR`.

Default: 101

`'NumPulses'`

Number of pulses to integrate when calculating the ROC curves. A value of 1 indicates no pulse integration.

Default: 1

`'SignalType'`

This property specifies the type of received signal or, equivalently, the probability density functions (PDF) used to compute the ROC. Valid values are: `'Real'`, `'NonfluctuatingCoherent'`, `'NonfluctuatingNoncoherent'`, `'Swerling1'`, `'Swerling2'`, `'Swerling3'`, and `'Swerling4'`. Values are not case sensitive.

The `'NonfluctuatingCoherent'` signal type assumes that the noise in the received signal is a complex-valued, Gaussian random variable. This variable has independent zero-mean real and imaginary parts each with variance $\sigma^2/2$ under the null hypothesis. In the case of a single pulse in a coherent receiver with complex white Gaussian noise, the probability of detection, P_D, for a given false-alarm probability, P_{FA} is:

$$P_D = \frac{1}{2}\text{erfc}(\text{erfc}^{-1}(2P_{FA}) - \sqrt{\chi})$$

where `erfc` and $\texttt{erfc}^{-1}$ are the complementary error function and that function's inverse, and χ is the SNR not expressed in decibels.

For details about the other supported signal types, see [1].

Default: `'NonfluctuatingCoherent'`

Output Arguments

Pd

Detection probabilities corresponding to the false-alarm probabilities. For each false-alarm probability in `Pfa`, `Pd` contains one column of detection probabilities.

SNR

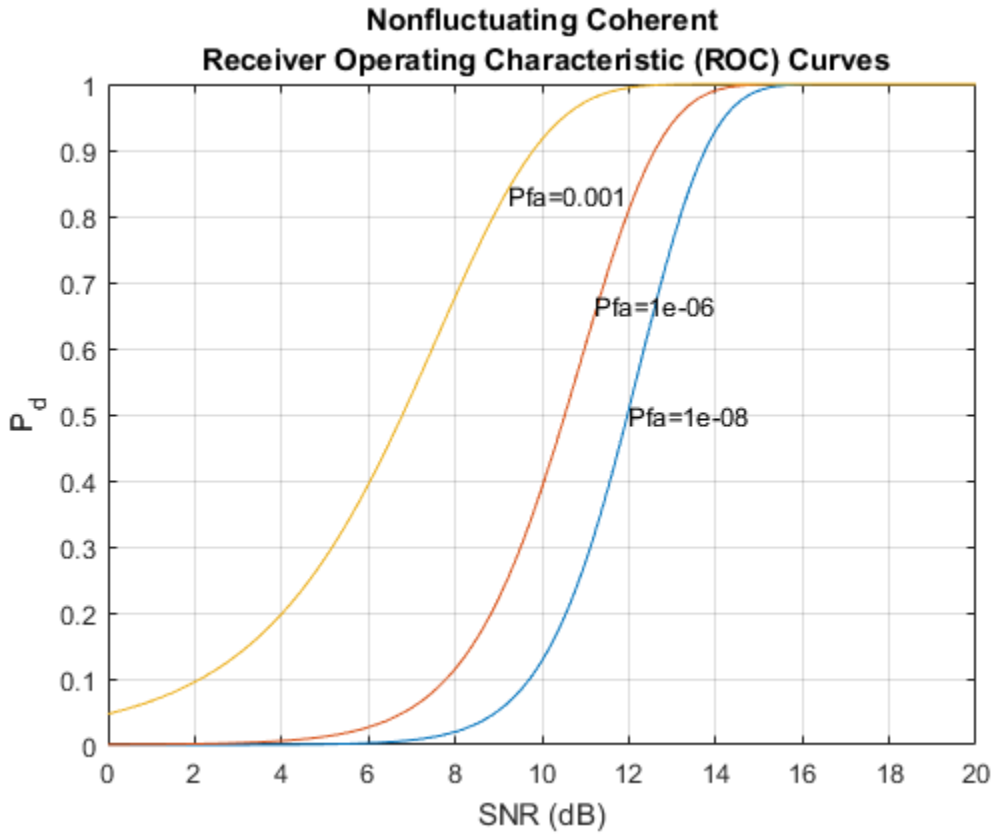
Signal-to-noise ratios in a column vector. By default, the SNR values are 101 equally spaced values between 0 and 20. To change the range of SNR values, use the optional `MinSNR` or `MaxSNR` input argument. To change the number of SNR values, use the optional `NumPoints` input argument.

Examples

Plot ROC Curves For Different PFAs

Plot ROC curves for false-alarm probabilities of 1e-8, 1e-6, and 1e-3, assuming no pulse integration.

```
Pfa = [1e-8 1e-6 1e-3];
rocpfa(Pfa,'SignalType','NonfluctuatingCoherent')
```



References

Introduced in R2011a

rocsnr

Receiver operating characteristic curves by SNR

Syntax

```
[Pd,Pfa] = rocsnr(SNRdB)
[Pd,Pfa] = rocsnr(SNRdB,Name,Value)
rocsnr(...)
```

Description

`[Pd,Pfa] = rocsnr(SNRdB)` returns the single-pulse detection probabilities, `Pd`, and false-alarm probabilities, `Pfa`, for the SNRs in the vector `SNRdB`. By default, for each SNR, the detection probabilities are computed for 101 false-alarm probabilities between 1e–10 and 1. The false-alarm probabilities are logarithmically equally spaced. The ROC curve is constructed assuming a coherent receiver with a nonfluctuating target.

`[Pd,Pfa] = rocsnr(SNRdB,Name,Value)` returns detection probabilities and false-alarm probabilities with additional options specified by one or more `Name,Value` pair arguments.

`rocsnr(...)` plots the ROC curves.

Input Arguments

`SNRdB`

Signal-to-noise ratios in decibels, in a row or column vector.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'MaxPfa'`

Maximum false-alarm probability to include in the ROC calculation.

Default: `1`

`'MinPfa'`

Minimum false-alarm probability to include in the ROC calculation.

Default: `1e-10`

`'NumPoints'`

Number of false-alarm probabilities to use when calculating the ROC curves. The actual probability values are logarithmically equally spaced between `MinPfa` and `MaxPfa`.

Default: `101`

`'NumPulses'`

Number of pulses to integrate when calculating the ROC curves. A value of `1` indicates no pulse integration.

Default: `1`

`'SignalType'`

This property specifies the type of received signal or, equivalently, the probability density functions (PDF) used to compute the ROC. Valid values are: `'Real'`, `'NonfluctuatingCoherent'`, `'NonfluctuatingNoncoherent'`, `'Swerling1'`, `'Swerling2'`, `'Swerling3'`, and `'Swerling4'`. Values are not case sensitive.

The `'NonfluctuatingCoherent'` signal type assumes that the noise in the received signal is a complex-valued, Gaussian random variable. This variable has independent zero-mean real and imaginary parts each with variance $\sigma^2/2$ under the null hypothesis. In the case of a single pulse in a coherent receiver with complex white Gaussian noise, the probability of detection, P_D, for a given false-alarm probability, P_{FA} is:

$$P_D = \frac{1}{2}\text{erfc}(\text{erfc}^{-1}(2P_{FA}) - \sqrt{\chi})$$

where `erfc` and `erfc`$^{-1}$ are the complementary error function and that function's inverse, and χ is the SNR not expressed in decibels.

For details about the other supported signal types, see [1].

Default: `'NonfluctuatingCoherent'`

Output Arguments

`Pd`

Detection probabilities corresponding to the false-alarm probabilities. For each SNR in `SNRdB`, `Pd` contains one column of detection probabilities.

`Pfa`

False-alarm probabilities in a column vector. By default, the false-alarm probabilities are 101 logarithmically equally spaced values between 1e–10 and 1. To change the range of probabilities, use the optional `MinPfa` or `MaxPfa` input argument. To change the number of probabilities, use the optional `NumPoints` input argument.

Examples

ROC Curves for Different SNRs

Plot ROC curves for different SNR's for a single pulse.

```
SNRdB = [3 6 9 12];
[Pd,Pfa] = rocsnr(SNRdB,'SignalType','NonfluctuatingCoherent');
semilogx(Pfa,Pd)
grid on
xlabel('P_{fa}')
ylabel('P_d')
legend('SNR 3 dB','SNR 6 dB','SNR 9 dB','SNR 12 dB',  'location','northwest')
title('Receiver Operating Characteristic (ROC) Curves')
```

`npwgnthresh` | `rocpfa` | `shnidman`

Introduced in R2011a

rootmusicdoa

Direction of arrival using Root MUSIC

Syntax

```
ang = rootmusicdoa(R,nsig)
ang = rootmusicdoa( ___ ,'Name','Value')
```

Description

`ang = rootmusicdoa(R,nsig)` estimates the directions of arrival, `ang`, of a set of plane waves received on a uniform line array (ULA). The estimation uses the *root MUSIC* algorithm. The input arguments are the estimated spatial covariance matrix between sensor elements, `R`, and the number of arriving signals, `nsig`. In this syntax, sensor elements are spaced one-half wavelength apart.

`ang = rootmusicdoa( ___ ,'Name','Value')` allows you to specify additional input parameters in the form of Name-Value pairs. This syntax can use any of the input arguments in the previous syntax.

Examples

Three Signals Arriving at Half-Wavelength-Spaced ULA

Assume a half-wavelength spaced uniform line array with 10 elements. Three plane waves arrive from the 0°, –25°, and 30° azimuth directions. Elevation angles are 0°. The noise is spatially and temporally white Gaussian noise.

Set the SNR for each signal to 5 dB. Find the arrival angles.

```
N = 10;
d = 0.5;
elementPos = (0:N-1)*d;
angles = [0 -25 30];
Nsig = 3;
R = sensorcov(elementPos,angles,db2pow(-5));
doa = rootmusicdoa(R,Nsig)
```

```
doa =

    0.0000  -25.0000   30.0000
```

These angles agree with the known input angles.

Three Signals Arriving at 0.4-Wavelength-Spaced ULA

Assume a uniform line array 10 elements, as in the previous example. But now the element spacing is smaller than one-half wavelength. Three plane waves arrive from the 0°, –25°, and 30° azimuth directions. Elevation angles are 0°. The noise is spatially and temporally white Gaussian noise. The SNR for each signal is 5 dB.

Set element spacing to 0.4 wavelengths using the `ElementSpacing` name-value pair. Then, find the arrival angles.

```
N = 10;
d = 0.4;
elementPos = (0:N-1)*d;
angles = [0 -25 30];
Nsig = 3;
R = sensorcov(elementPos,angles,db2pow(-5));
doa = rootmusicdoa(R,Nsig,'ElementSpacing',d)
```

```
doa =

    0.0000  -25.0000   30.0000
```

The solution agrees with the known angles.

Input Arguments

`R` — Spatial covariance matrix

complex-valued positive-definite *N*-by-*N* matrix

Spatial covariance matrix, specified as a complex-valued, positive-definite, *N*-by-*N* matrix. In this matrix, *N* represents the number of elements in the ULA array. If `R` is not Hermitian, a Hermitian matrix is formed by averaging the matrix and its conjugate transpose, `(R+R')/2`.

Example: [4.3162, –0.2777 –0.2337i; –0.2777 + 0.2337i , 4.3162]

Data Types: `double`
Complex Number Support: Yes

`nsig` — Number of arriving signals

positive integer

Number of arriving signals, specified as a positive integer. The number of signals must be smaller than the number of elements in the ULA array.

Example: 2

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: 'ElementSpacing', 0.4

`'ElementSpacing'` — ULA element spacing

0.5 (default) | real-valued positive scalar

ULA element spacing, specified as a real-valued, positive scalar. Position units are measured in terms of signal wavelength.

Example: 0.4

Data Types: `double`

Output Arguments

`ang` — Directions of arrival angles

real-valued 1-by-*M* row vector

Directions of arrival angle, returned as a real-valued, 1-by-*M* vector. The dimension *M* is the number of arriving signals specified in the argument `nsig`. Angle units are degrees and angle values lie between –90° and 90°.

rotx

Rotation matrix for rotations around x-axis

Syntax

```
R = rotx(ang)
```

Description

`R = rotx(ang)` creates a 3-by-3 matrix used to rotated a 3-by-1 vector or 3-by-N matrix of vectors around the x-axis by `ang` degrees. When acting on a matrix, each column of the matrix represents a different vector. For the rotation matrix `R` and vector `v`, the rotated vector is given by `R*v`.

Examples

Rotation Matrix for 30° Rotation

Construct the matrix for a rotation of a vector around the x-axis by 30°. Then let the matrix operate on a vector.

```
R = rotx(30)
x = [2;-2;4];
y = R*x
```

```
R =

    1.0000         0         0
         0    0.8660   -0.5000
         0    0.5000    0.8660

y =

    2.0000
   -3.7321
```

```
    2.4641
```

Under a rotation around the *x*-axis, the x-component of a vector is invariant.

Input Arguments

ang — Rotation angle

real-valued scalar

Rotation angle specified as a real-valued scalar. The rotation angle is positive if the rotation is in the counter-clockwise direction when viewed by an observer looking along the x-axis towards the origin. Angle units are in degrees.

Example: 30.0

Data Types: `double`

Output Arguments

R — Rotation matrix

real-valued orthogonal matrix

3-by-3 rotation matrix returned as

$$R_x(\alpha) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos\alpha & -\sin\alpha \\ 0 & \sin\alpha & \cos\alpha \end{bmatrix}$$

for a rotation angle α.

Definitions

Rotation Matrices

Rotation matrices are used to rotate a vector into a new direction.

In transforming vectors in three-dimensional space, rotation matrices are often encountered. Rotation matrices are used in two senses: they can be used to rotate a vector into a new position or they can be used to rotate a coordinate basis (or coordinate system) into a new one. In this case, the vector is left alone but its components in the new basis will be different from those in the original basis. In Euclidean space, there are three basic rotations: one each around the x, y and z axes. Each rotation is specified by an angle of rotation. The rotation angle is defined to be positive for a rotation that is counterclockwise when viewed by an observer looking along the rotation axis towards the origin. Any arbitrary rotation can be composed of a combination of these three *(Euler's rotation theorem)*. For example, one can rotated a vector using a sequence of three rotations: $\mathbf{v}' = A\mathbf{v} = R_z(\gamma)R_y(\beta)R_x(\alpha)\mathbf{v}$.

The rotation matrices that rotate a vector around the x, y, and z-axes are given by:

- Counterclockwise rotation around x-axis

$$R_x(\alpha) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos\alpha & -\sin\alpha \\ 0 & \sin\alpha & \cos\alpha \end{bmatrix}$$

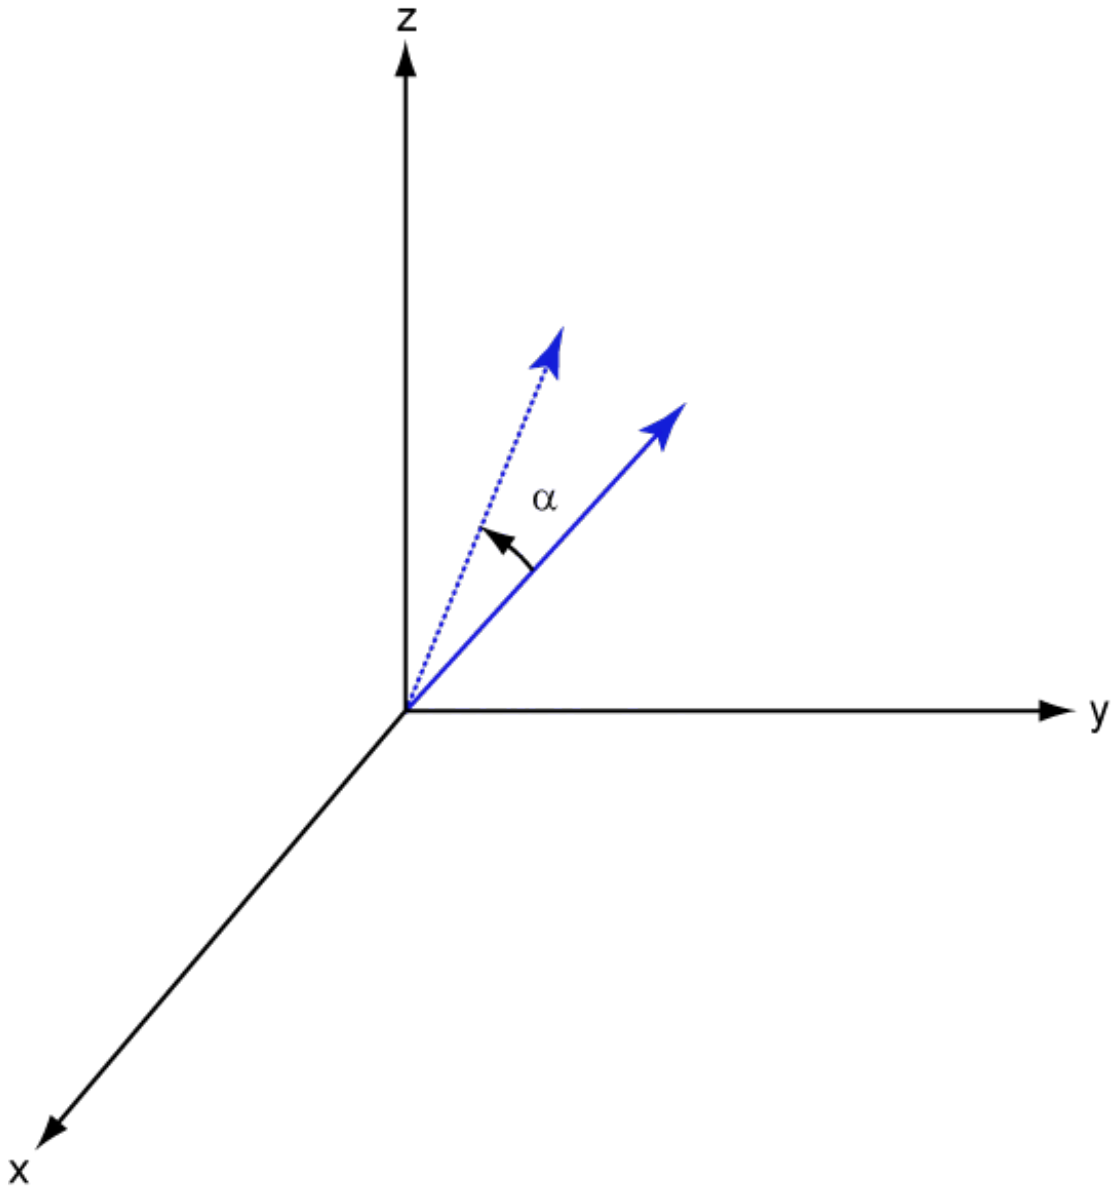
- Counterclockwise rotation around y-axis

$$R_y(\beta) = \begin{bmatrix} \cos\beta & 0 & \sin\beta \\ 0 & 1 & 0 \\ -\sin\beta & 0 & \cos\beta \end{bmatrix}$$

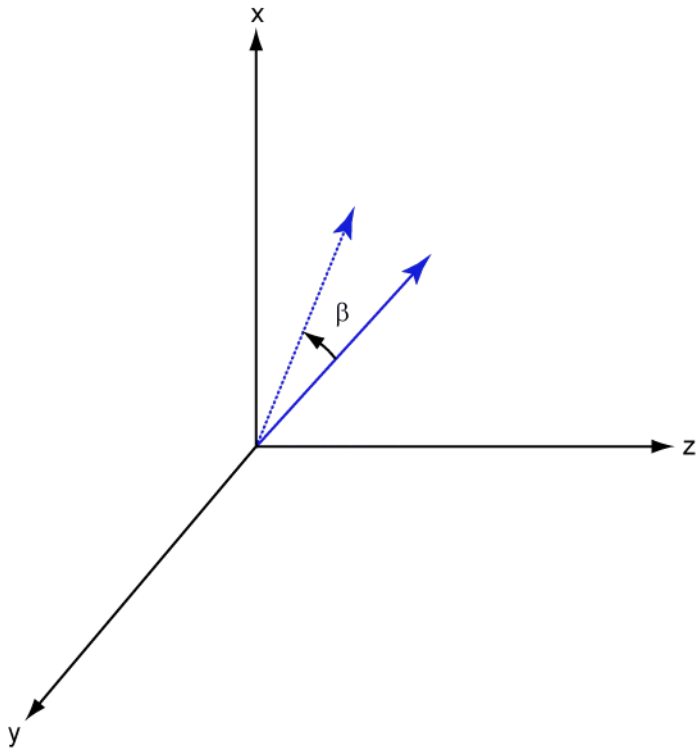
- Counterclockwise rotation around z-axis

$$R_z(\gamma) = \begin{bmatrix} \cos\gamma & -\sin\gamma & 0 \\ \sin\gamma & \cos\gamma & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

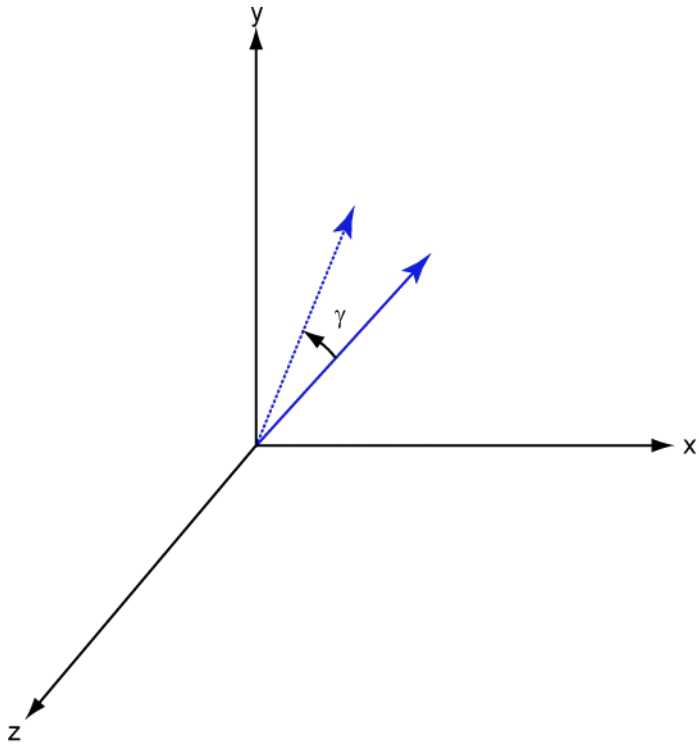
The following three figures show what positive rotations look like for each rotation axis:



z
α
y
x



x
β
z
y



For any rotation, there is an inverse rotation satisfying $A^{-1}A = 1$. For example, the inverse of the x-axis rotation matrix is obtained by changing the sign of the angle:

$$R_x^{-1}(\alpha) = R_x(-\alpha) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos\alpha & \sin\alpha \\ 0 & -\sin\alpha & \cos\alpha \end{bmatrix} = R_x'(\alpha)$$

This example illustrates a basic property: the inverse rotation matrix equals the transpose of the original. Rotation matrices satisfy *A'A = 1*, and consequently *det(A) = 1*. Under rotations, vector lengths are preserved as well as the angles between vectors.

We can think of rotations in another way. Consider the original set of basis vectors, $\mathbf{i},\mathbf{j},\mathbf{k}$, and rotate them all using the rotation matrix *A*. This produces a new set of basis vectors $\mathbf{i}',\mathbf{j}',\mathbf{k}'$ related to the original by:

$$\begin{aligned}\mathbf{i}' &= A\mathbf{i}\\ \mathbf{j}' &= A\mathbf{j}\\ \mathbf{k}' &= A\mathbf{k}\end{aligned}$$

The new basis vectors can be written as linear combinations of the old ones and involve the transpose:

$$\begin{bmatrix}\mathbf{i}'\\ \mathbf{j}'\\ \mathbf{k}'\end{bmatrix} = A'\begin{bmatrix}\mathbf{i}\\ \mathbf{j}\\ \mathbf{k}\end{bmatrix}$$

Now any vector can be written as a linear combination of either set of basis vectors:

$$\mathbf{v} = v_x\mathbf{i} + v_y\mathbf{j} + v_z\mathbf{k} = v'_x\mathbf{i}' + v'_y\mathbf{j}' + v'_z\mathbf{k}'$$

Using some algebraic manipulation, one can derive the transformation of components for a fixed vector when the basis (or coordinate system) rotates

$$\begin{bmatrix}v'_x\\ v'_y\\ v'_z\end{bmatrix} = A^{-1}\begin{bmatrix}v_x\\ v_y\\ v_z\end{bmatrix} = A'\begin{bmatrix}v_x\\ v_y\\ v_z\end{bmatrix}$$

Thus the change in components of a vector when the coordinate system rotates involves the transpose of the rotation matrix. The next figure illustrates how a vector stays fixed as the coordinate system rotates around the x-axis. The figure after shows how this can be interpreted as a rotation *of the vector* in the opposite direction.

for a rotation angle γ.

Definitions

Rotation Matrices

Rotation matrices are used to rotate a vector into a new direction.

In transforming vectors in three-dimensional space, rotation matrices are often encountered. Rotation matrices are used in two senses: they can be used to rotate a vector into a new position or they can be used to rotate a coordinate basis (or coordinate system) into a new one. In this case, the vector is left alone but its components in the new basis will be different from those in the original basis. In Euclidean space, there are three basic rotations: one each around the x, y and z axes. Each rotation is specified by an angle of rotation. The rotation angle is defined to be positive for a rotation that is counterclockwise when viewed by an observer looking along the rotation axis towards the origin. Any arbitrary rotation can be composed of a combination of these three *(Euler's rotation theorem)*. For example, one can rotated a vector using a sequence of three rotations: $\mathbf{v}' = A\mathbf{v} = R_z(\gamma)R_y(\beta)R_x(\alpha)\mathbf{v}$.

The rotation matrices that rotate a vector around the x, y, and z-axes are given by:

- Counterclockwise rotation around x-axis

$$R_x(\alpha) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos\alpha & -\sin\alpha \\ 0 & \sin\alpha & \cos\alpha \end{bmatrix}$$

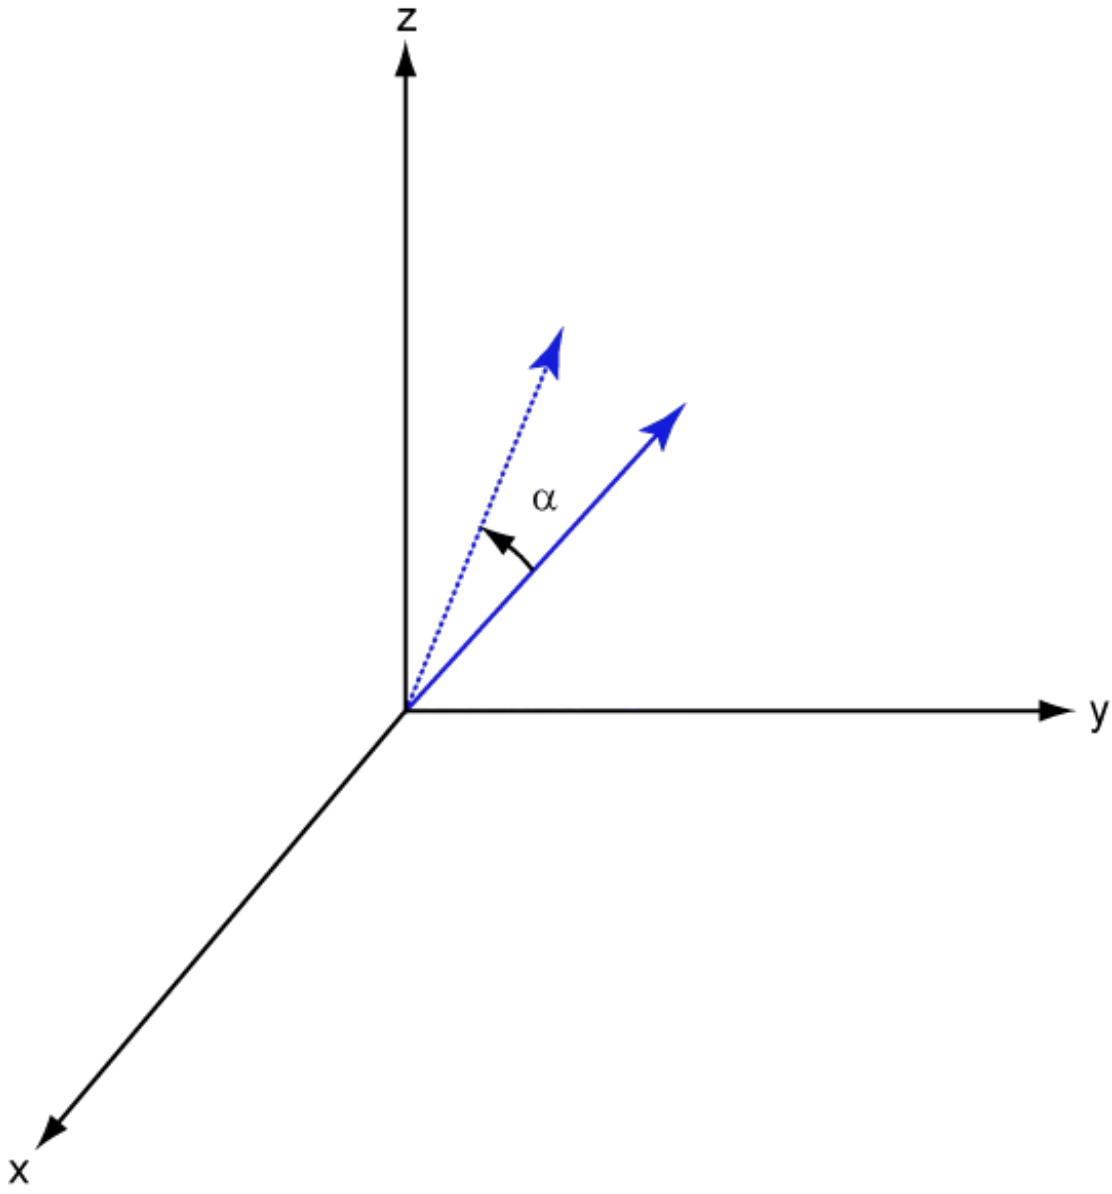
- Counterclockwise rotation around y-axis

$$R_y(\beta) = \begin{bmatrix} \cos\beta & 0 & \sin\beta \\ 0 & 1 & 0 \\ -\sin\beta & 0 & \cos\beta \end{bmatrix}$$

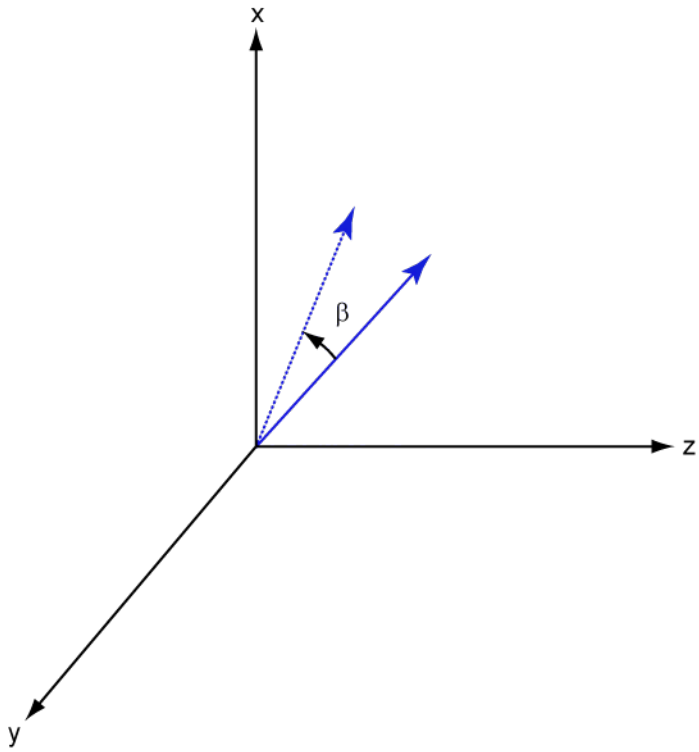
- Counterclockwise rotation around z-axis

$$R_z(\gamma) = \begin{bmatrix} \cos\gamma & -\sin\gamma & 0 \\ \sin\gamma & \cos\gamma & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

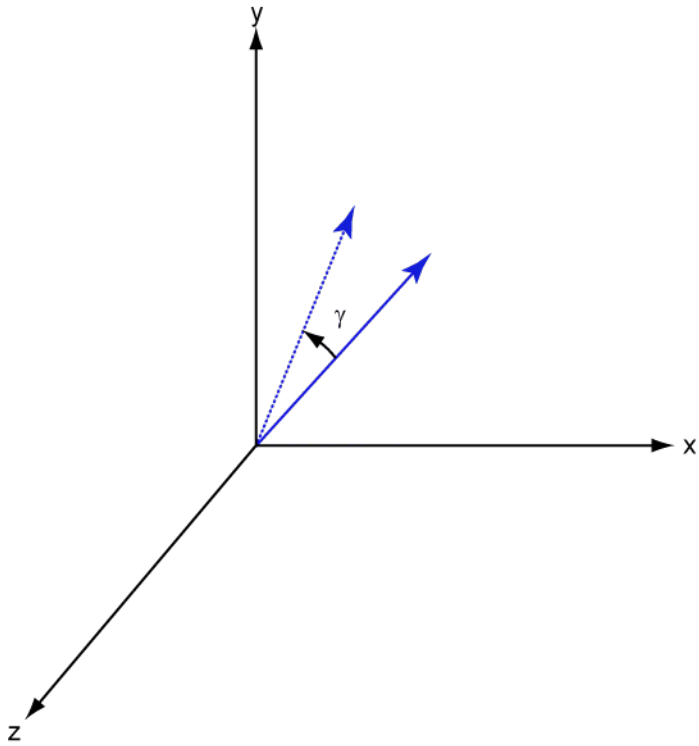
The following three figures show what positive rotations look like for each rotation axis:



z
α
y
x



x
β
z
y



For any rotation, there is an inverse rotation satisfying $A^{-1}A = 1$. For example, the inverse of the x-axis rotation matrix is obtained by changing the sign of the angle:

$$R_x^{-1}(\alpha) = R_x(-\alpha) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos\alpha & \sin\alpha \\ 0 & -\sin\alpha & \cos\alpha \end{bmatrix} = R_x'(\alpha)$$

This example illustrates a basic property: the inverse rotation matrix equals the transpose of the original. Rotation matrices satisfy *A'A = 1*, and consequently *det(A) = 1*. Under rotations, vector lengths are preserved as well as the angles between vectors.

We can think of rotations in another way. Consider the original set of basis vectors, $\mathbf{i},\mathbf{j},\mathbf{k}$, and rotate them all using the rotation matrix *A*. This produces a new set of basis vectors $\mathbf{i}',\mathbf{j}',\mathbf{k}'$ related to the original by:

$$\begin{aligned}\mathbf{i}' &= A\mathbf{i}\\ \mathbf{j}' &= A\mathbf{j}\\ \mathbf{k}' &= A\mathbf{k}\end{aligned}$$

The new basis vectors can be written as linear combinations of the old ones and involve the transpose:

$$\begin{bmatrix}\mathbf{i}'\\ \mathbf{j}'\\ \mathbf{k}'\end{bmatrix} = A'\begin{bmatrix}\mathbf{i}\\ \mathbf{j}\\ \mathbf{k}\end{bmatrix}$$

Now any vector can be written as a linear combination of either set of basis vectors:

$$\mathbf{v} = v_x\mathbf{i} + v_y\mathbf{j} + v_z\mathbf{k} = v'_x\mathbf{i}' + v'_y\mathbf{j}' + v'_z\mathbf{k}'$$

Using some algebraic manipulation, one can derive the transformation of components for a fixed vector when the basis (or coordinate system) rotates

$$\begin{bmatrix}v'_x\\ v'_y\\ v'_z\end{bmatrix} = A^{-1}\begin{bmatrix}v_x\\ v_y\\ v_z\end{bmatrix} = A'\begin{bmatrix}v_x\\ v_y\\ v_z\end{bmatrix}$$

Thus the change in components of a vector when the coordinate system rotates involves the transpose of the rotation matrix. The next figure illustrates how a vector stays fixed as the coordinate system rotates around the x-axis. The figure after shows how this can be interpreted as a rotation *of the vector* in the opposite direction.

Introduced in R2013a

sensorArrayAnalyzer

Sensor array analyzer

Description

You use the **Sensor Array Analyzer** app to construct and analyze common sensor array configurations. These configurations range from 1-D to 3-D arrays of antennas and microphones. You can use this app to generate the directivity of the following arrays.

Uniform Linear Array (ULA)	Uniform Rectangular Array (URA)
Uniform Circular Array	Uniform Hexagonal Array
Circular Plane Array	Concentric Array
Spherical Array	Cylindrical Array
Arbitrary Geometry	

Each array type has different sets of parameters for its specification. After you select an array type, you can modify the array parameters. The parameters you can set include the type of antenna or microphone elements, the number and spacing of elements, and any array *tapering* (also called *shading*). You can enter the element spacing in meters or units of wavelength. After you enter all the information for your array, the app then displays basic performance characteristics, such as array directivity and array dimensions.

These are the types of elements available to populate an array.

Isotropic Antenna

Cosine Antenna

Omnidirectional Microphone

Cardioid Microphone

Custom Antenna

The **Sensor Array Analyzer** app lets you produce a variety of plots and images. These are types of plots available.

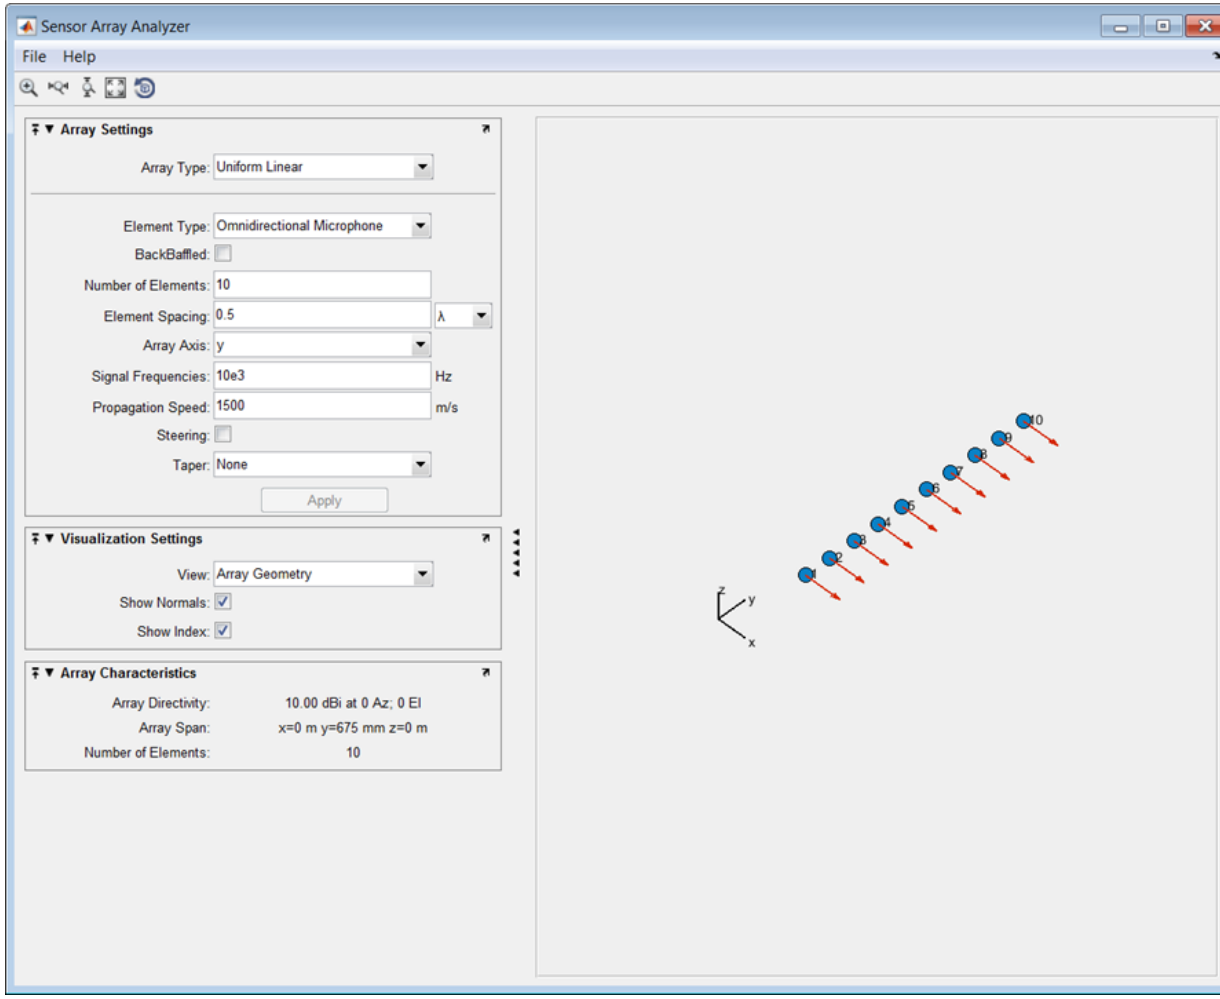
Plot type	
Array Geometry	
2D Array Directivity	
3D Array Directivity	
Grating Lobes	Available for the Uniform Linear Array, the Uniform Rectangular Array, the Uniform Hexagonal Array, and the Circular Planar Array.

Examples

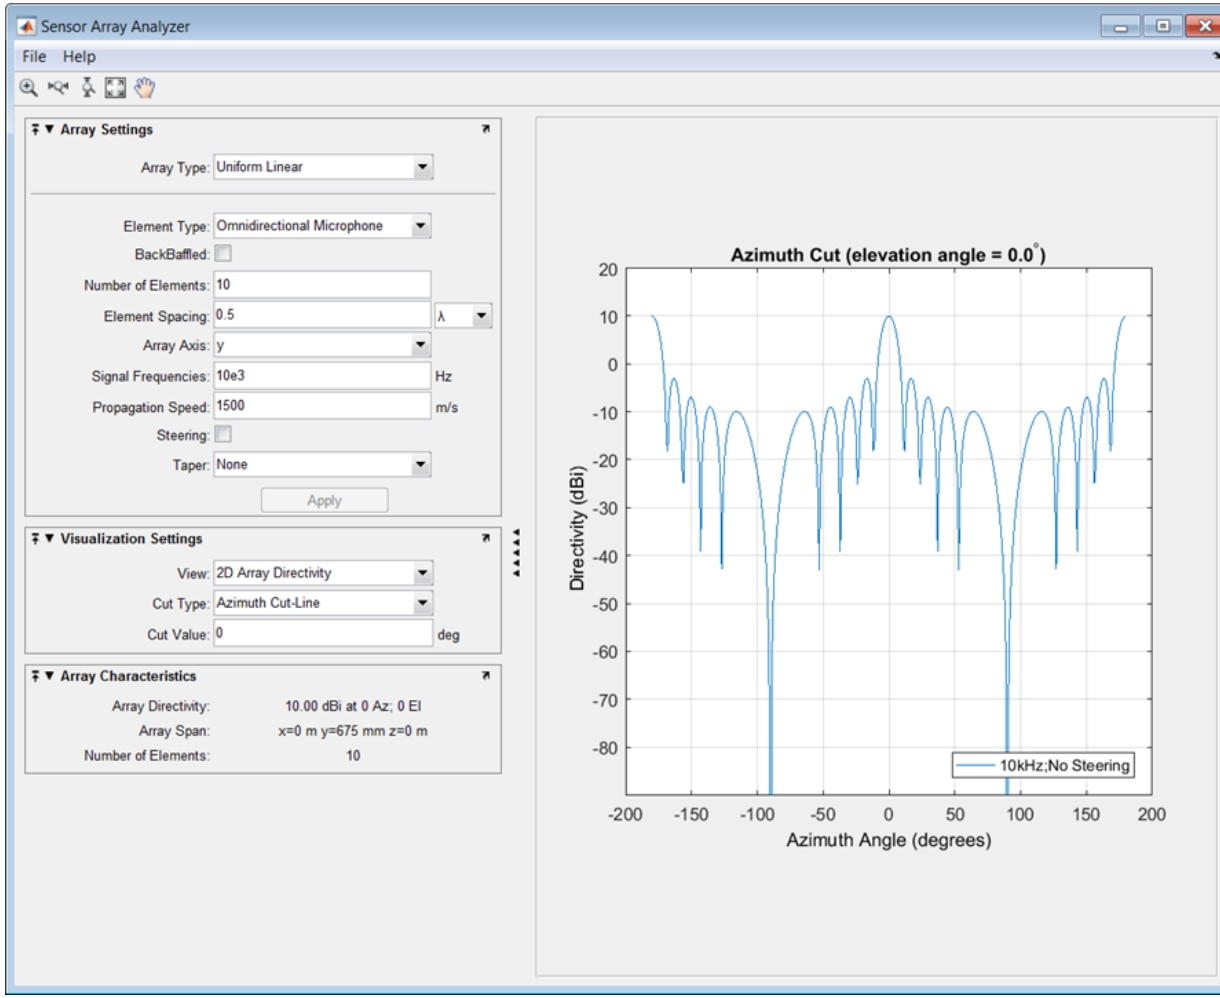
Uniform Linear Array

Start with 10-element uniform linear array (ULA) in a sonar application with omnidirectional microphones. A uniform linear array has its sensor elements equally-spaced spaced along a single line. Set the **Array Type** to `Uniform Linear` and the **Element Type** to `Omnidirectional Microphone`. Design the array to find the arrival direction of a 10 kHz signal by setting **Signal Frequencies** to `10000` and the **Element Spacing** to 0.5 wavelengths. In water, for example, you can set the signal **Propagation Speed** to equal the speed of sound in water, `1500` m/s.

Then, in the **View** dropdown menu, choose the `Array Geometry` option to draw the shape of the array.



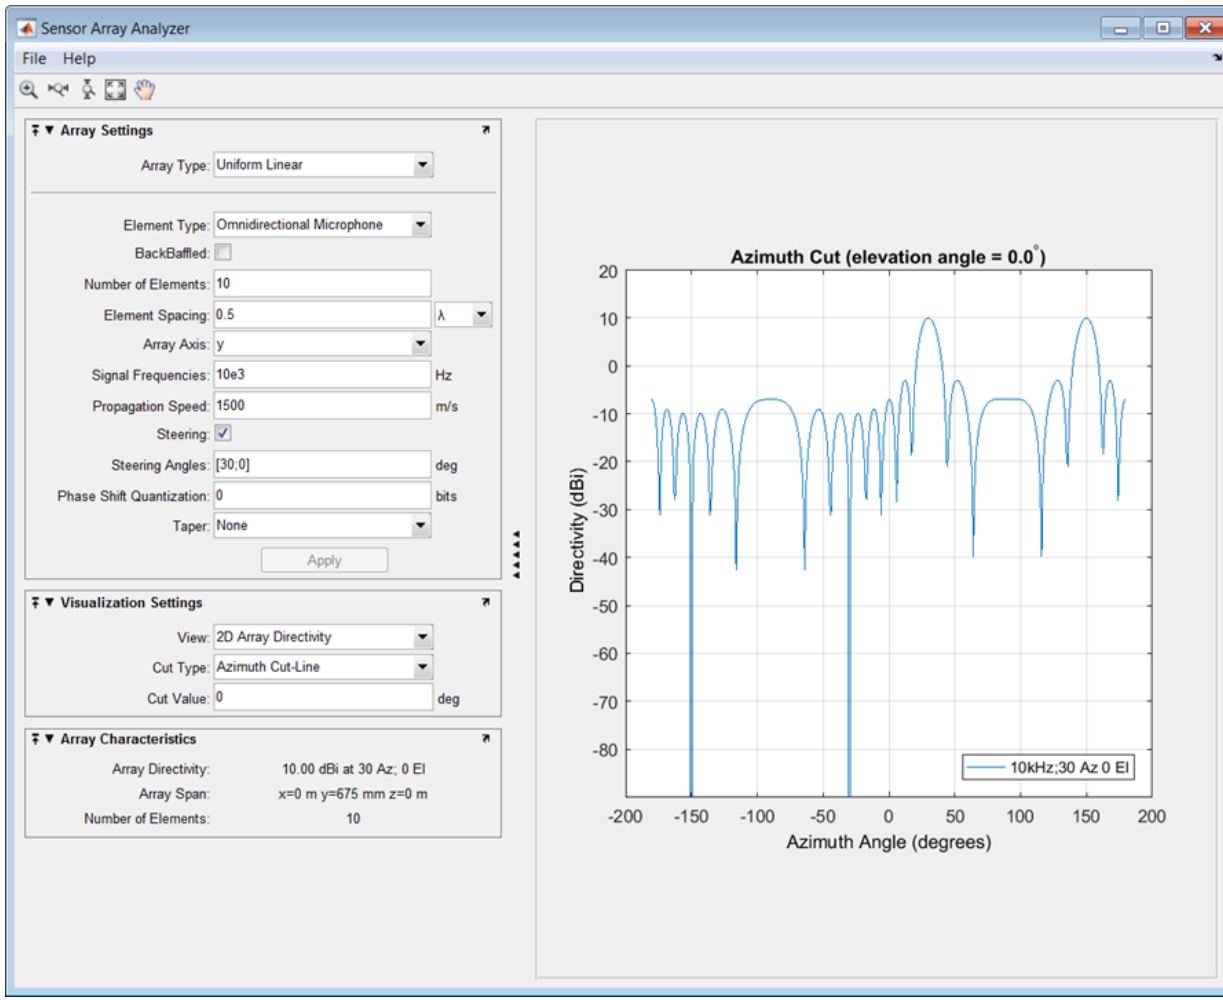
Next, examine the directivity of the array. To do so, select `2D Array Directivity` in the **View** drop-down list. The 2-D array directivity is shown below.



You can see the mainlobe of the array directivity function (also called the main beam) at 0° and another mainlobe at ±180°. Two mainlobes appear because of the cylindrical symmetry of the ULA array.

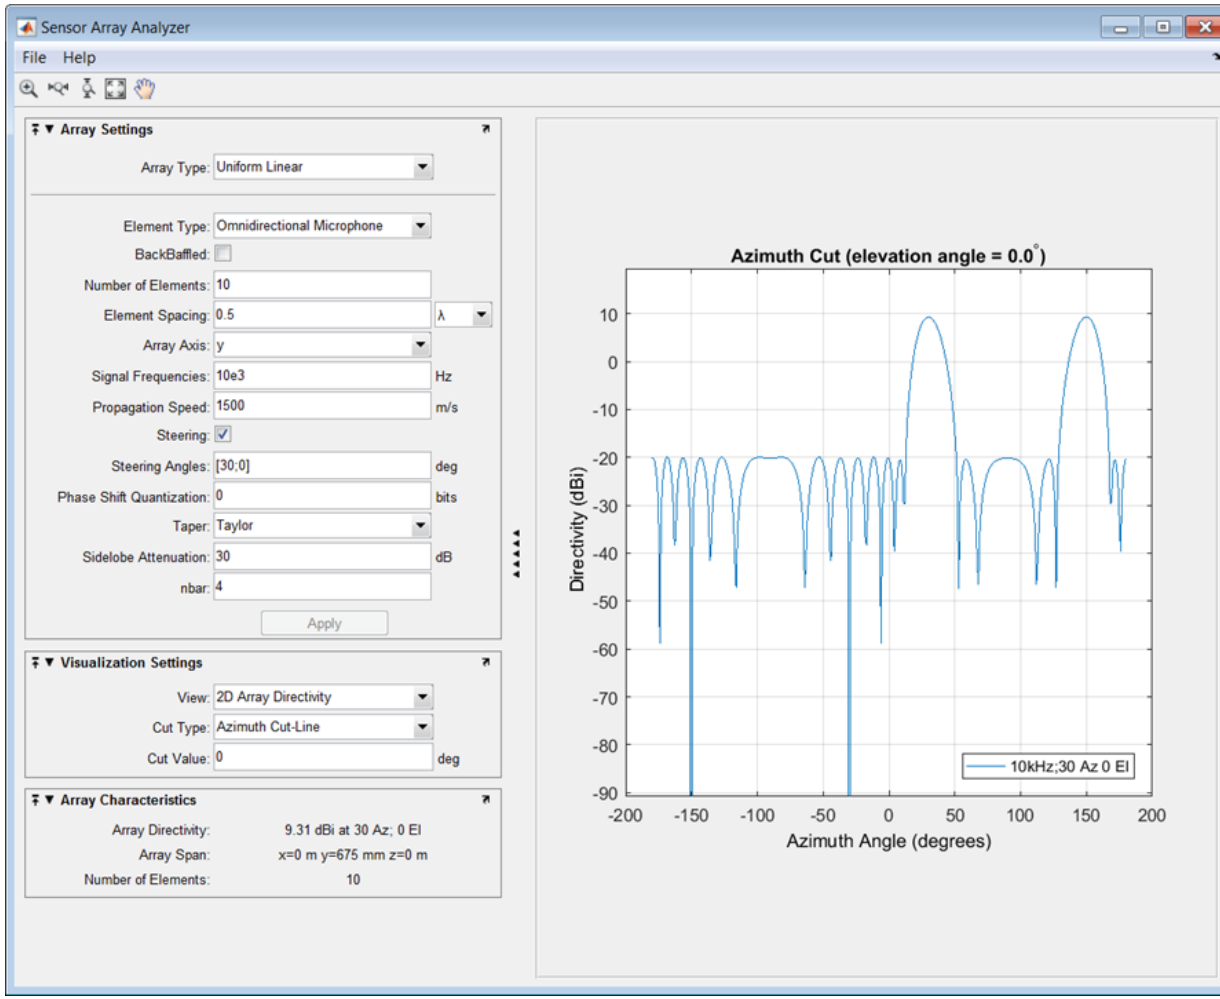
A beamscanner works by successively pointing the array mainlobe in a sequence of different directions. Setting the **Steering** option to `On` lets you steer the mainlobe in the direction specified by the **Steering Angles** option. In this case, set the steering angle to `[30;0]` to point the mainlobe to 30° in azimuth and 0° elevation. In the next figure, you

can see two mainlobes, one at 30° as expected, and another at 150°. Again, two mainlobes appear because of the cylindrical symmetry of the array.



A disadvantage of the ULA is its large side lobes. An examination of the array directivity shows two side lobes close to each mainlobe, each down by about only 13 dB. A strong sidelobe inhibits the ability of the array to detect a weaker signal in the presence of a larger nearby signal. By using array tapering, you can reduce the side lobes. Use the **Taper** option to specify the array taper as a `Taylor` window with **Sidelobe**

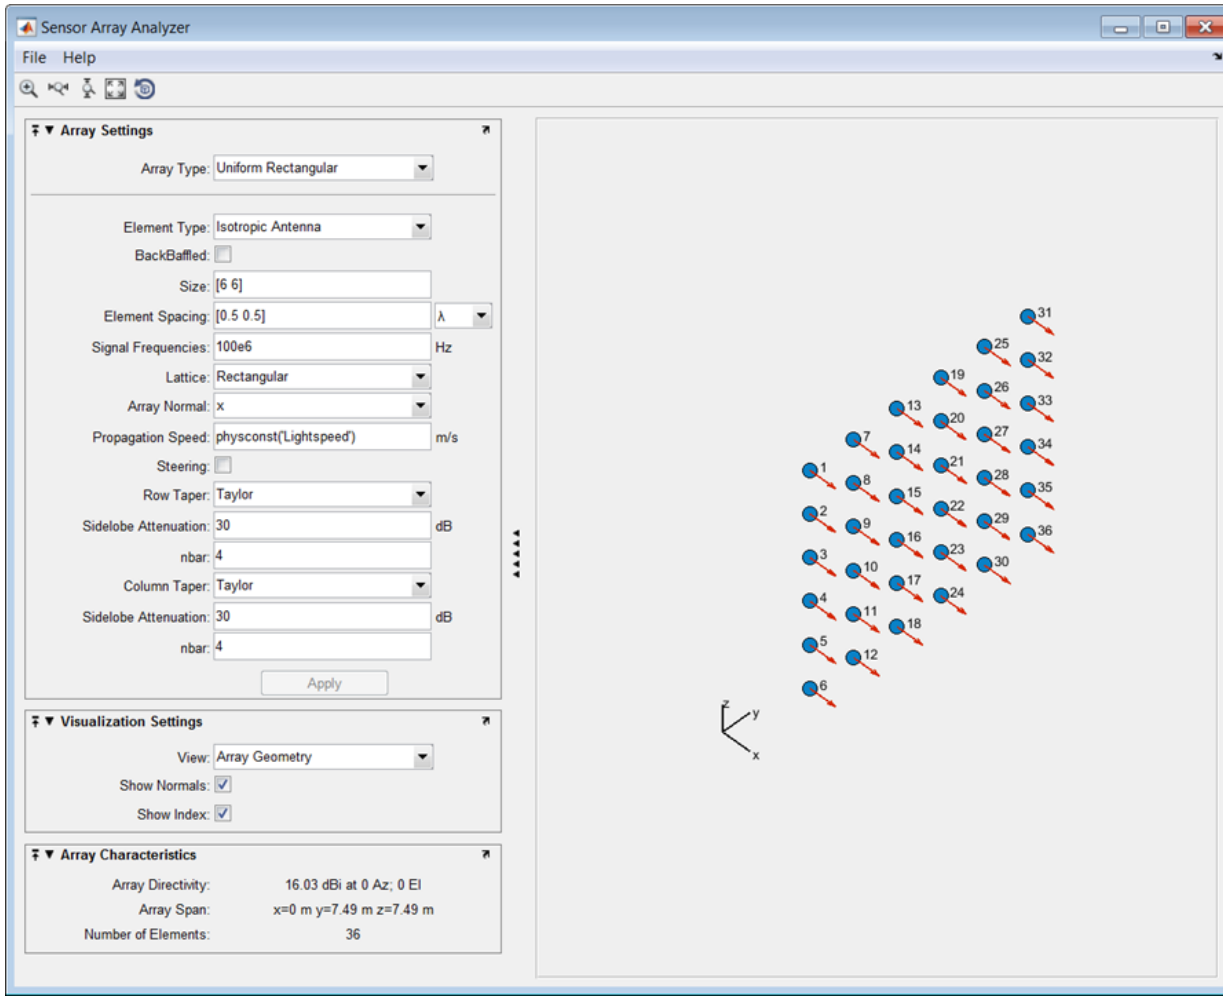
Attenuation set to 30 dB. The next figure shows how the Taylor window reduces all side lobes to –30 dB—but at the expense of broadening the mainlobe.



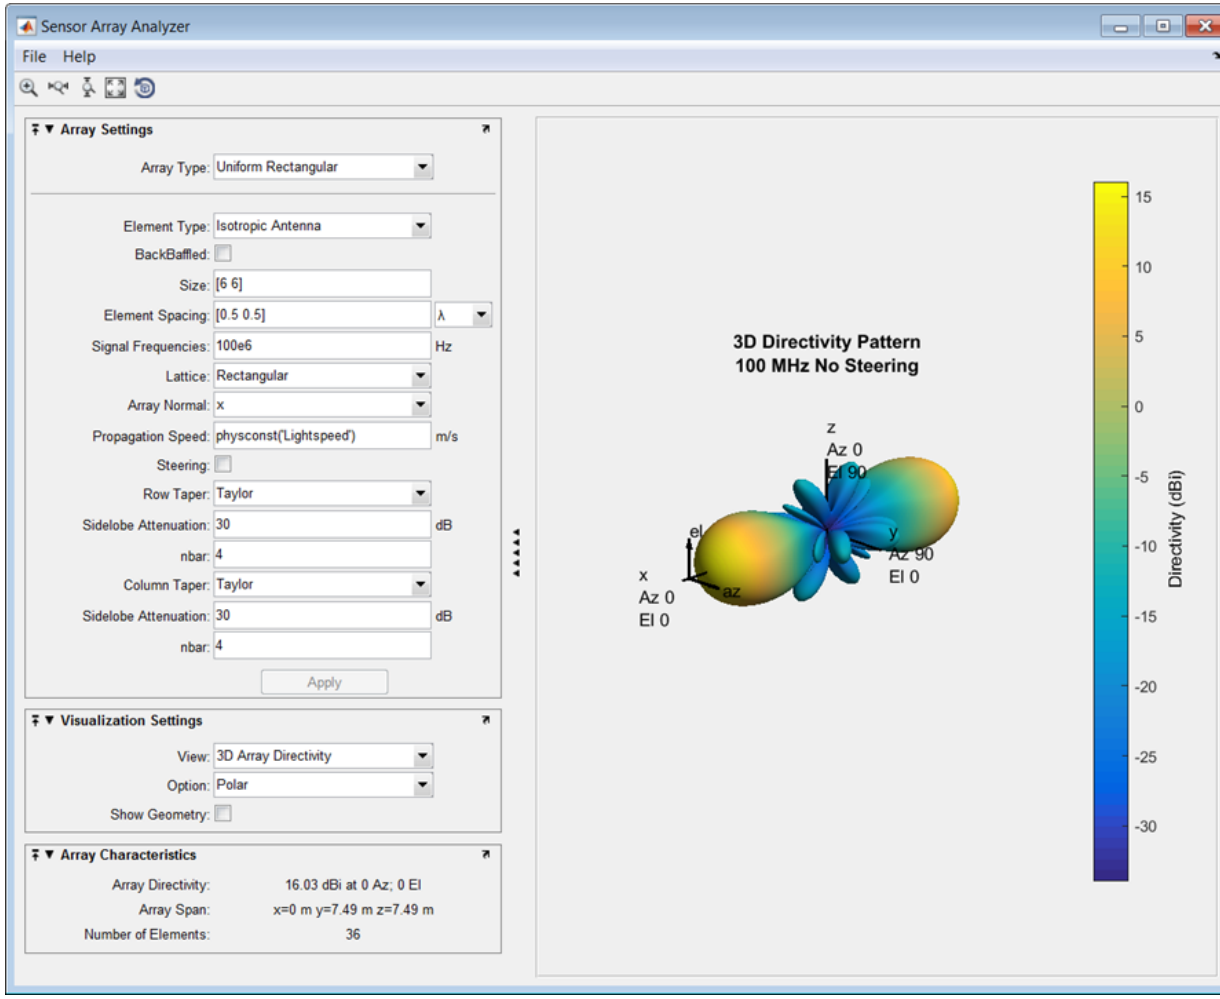
Uniform Rectangular Array

Construct a 6-by-6 uniform rectangular array (URA) designed to detect and localize a 100 MHz signal. Set the **Array Type** to `Uniform Rectangular`, the **Element Type** to `Isotropic Antenna`, and the **Size** to `[6 6]`. Design the array to find the arrival

direction of a 100 MHz signal by setting **Signal Frequencies** to `100e+6` and the row and column **Element Spacing** to 0.5 wavelength. Set both the **Row Taper** and **Column Taper** to a `Taylor` window. The shape of the array is shown in the figure below.



Finally, display the 3-D array directivity by setting the **View** option to `3D Array Directivity`, as shown in the following figure:

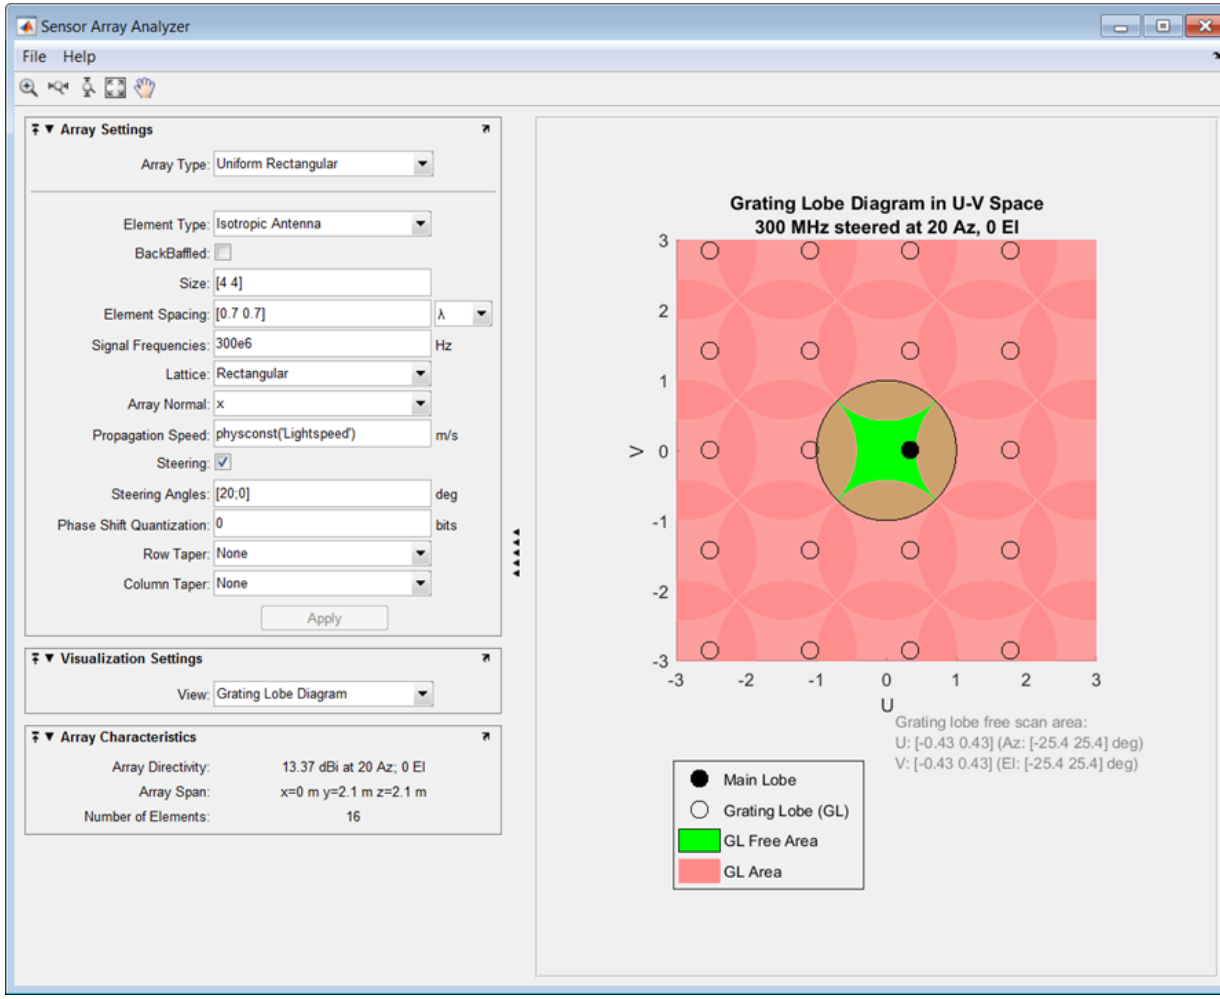


A significant performance criterion for any array is its array directivity. You can use the app to examine the effects of tapering on array directivity. Without tapering, the array directivity for this URA is 17.2 dB. With tapering, the array directivity loses 1 dB to yield 16.0 dB.

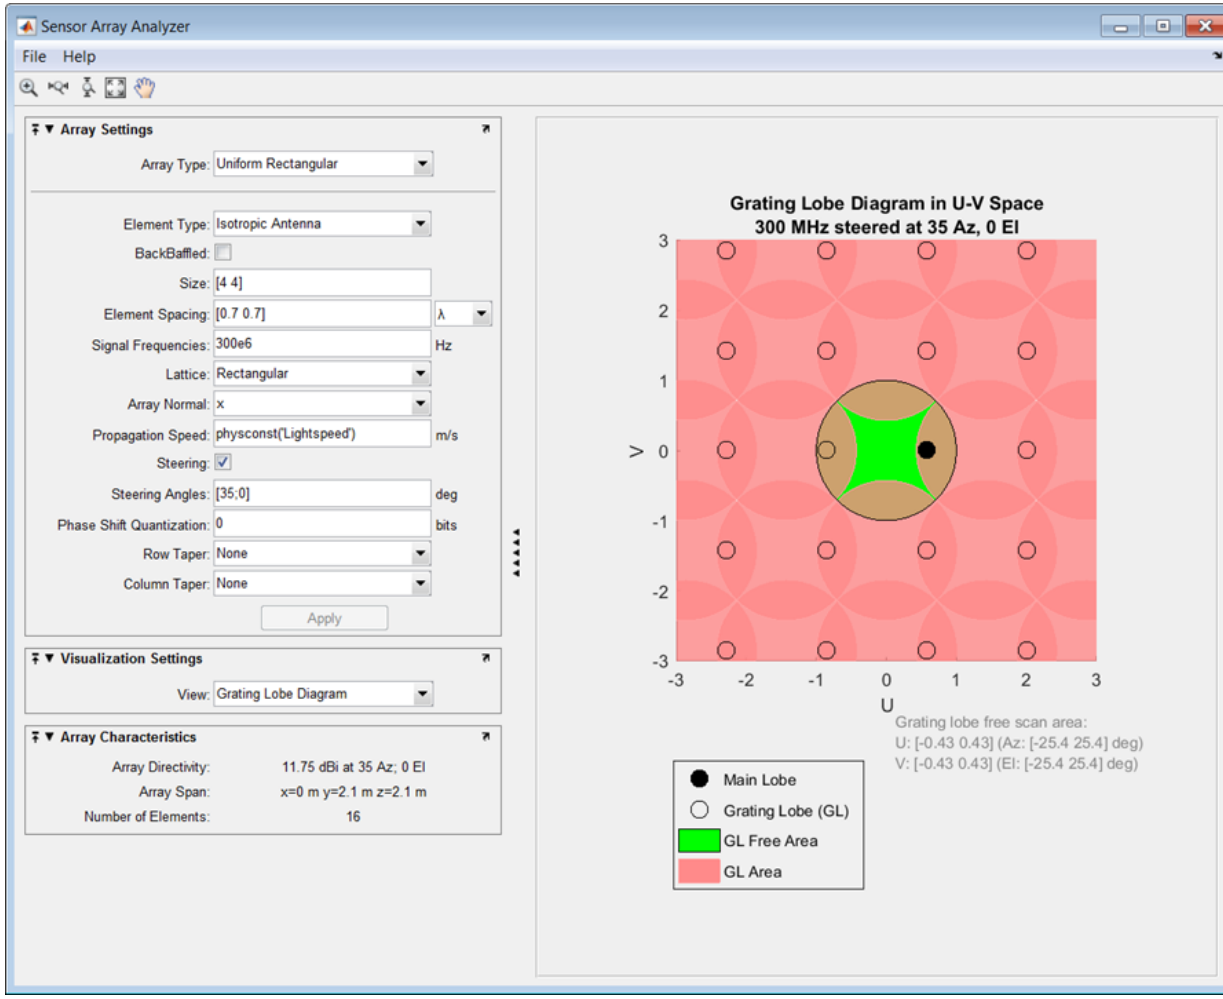
Grating Lobes for a Rectangular Array

Show the grating lobe diagram of a 4-by-4 uniform rectangular array (URA) designed to detect and localize a 300 MHz signal. Set the **Array Type** to `Uniform Rectangular`, the **Element Type** to `Isotropic Antenna`, and the array **Size** to `[4 4]`. Set the **Signal Frequencies** to `300e+6`. By setting the row and column **Element Spacing** to 0.7 wavelengths, you create a spatially undersampled array.

This figure shows the grating lobe diagram produced when you beamform the array towards the angle [20,0]. The mainlobe is designated by the small black-filled circle. The multiple grating lobes are designated by the small unfilled black circles. The larger black circle is called the physical region, for which $u^2 + v^2 \leq 1$. The mainlobe always lies in the physical region. The grating lobes may or may not lie in the physical region. Any grating lobe in the physical region leads to an ambiguity in the direction of the incoming wave. The green region shows where the mainlobe can be pointed without any grating lobes appearing in the physical region. If the mainlobe is set to point outside the green region, a grating lobe moves into the physical region.

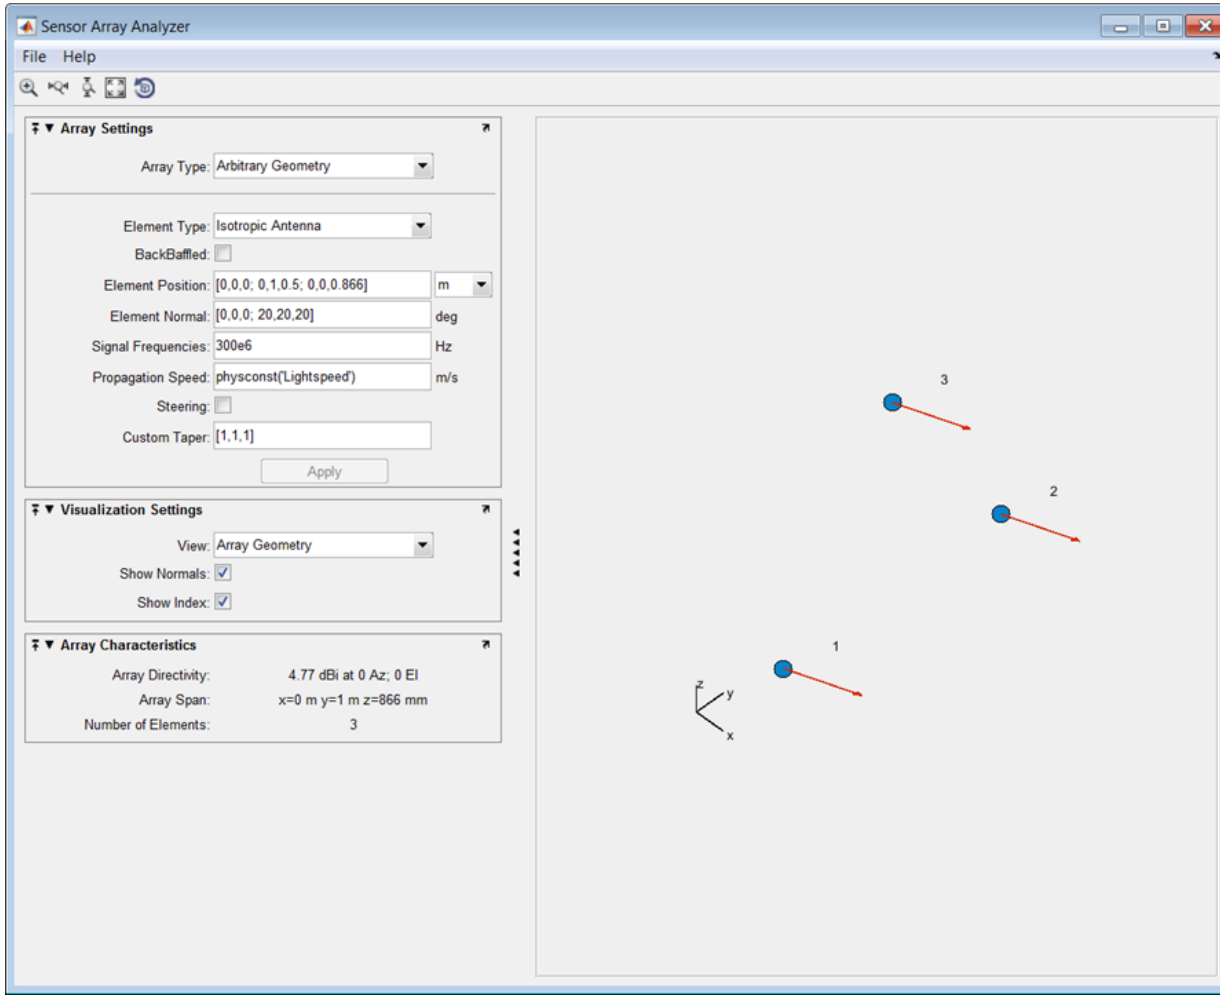


The next figure shows what happens when the pointing direction lies outside the green region. In this case, one grating lobe moves into the physical region.

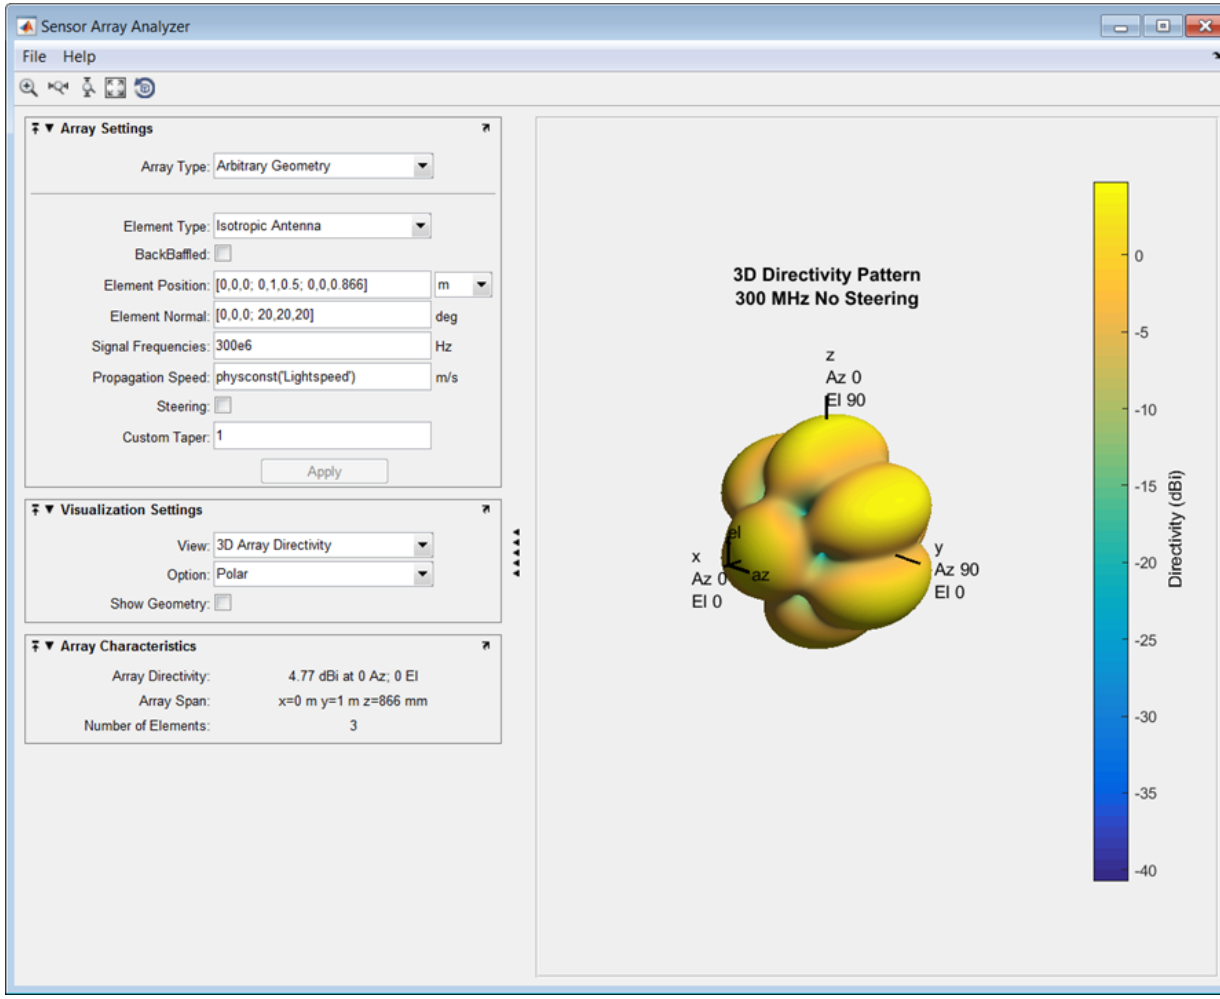


Specify Arbitrary Array Geometry

You can specify an array which has an arbitrary placement of sensors. This simple example shows how to construct a triangular array of three isotropic antenna elements. The elements are placed at `[0,0,0]'`, `[0,1,0.5]'`, and `[0,0,0.866]'`. All elements have the same normal direction `[0,20]`, pointing to 0° in azimuth and 20° in elevation.



Plot the 3-D array directivity in polar coordinates.



Specify Arbitrary Array Geometry Using Variables

Specify an array which has an arbitrary placement of sensors but, in this case, create MATLAB variables or arrays at the command line and use them in the appropriate `sensorArrayAnalyzer` fields. This simple example shows the how to construct a triangular array of three isotropic antenna elements. At the command line, create an element position array, `pos`, an element normal array, `nrm`, and a taper value array, `tpr`.

```
pos = [0,0,0;0,1,0.5;0,0,0.866];
nrm = [0,0,0;20,20,20];
tpr = [1,1,1];
```

Then, enter these variables in the appropriate `sensorArrayAnalyzer` fields.

Introduced in R2013a

sensorcov

Sensor spatial covariance matrix

Syntax

```
xcov = sensorcov(pos,ang)
xcov = sensorcov(pos,ang,ncov)
xcov = sensorcov(pos,ang,ncov,scov)
```

Description

`xcov = sensorcov(pos,ang)` returns the sensor spatial covariance matrix, `xcov`, for narrowband plane wave signals arriving at a sensor array. The sensor array is defined by the sensor positions specified in the `pos` argument. The signal arrival directions are specified by azimuth and elevation angles in the `ang` argument. In this syntax, the noise power is assumed to be zero at all sensors, and the signal power is assumed to be unity for all signals.

`xcov = sensorcov(pos,ang,ncov)` specifies, in addition, the spatial noise covariance matrix, `ncov`. This value represents the noise power on each sensor as well as the correlation of the noise between sensors. In this syntax, the signal power is assumed to be unity for all signals. This syntax can use any of the input arguments in the previous syntax.

`xcov = sensorcov(pos,ang,ncov,scov)` specifies, in addition, the signal covariance matrix, `scov`, which represents the power in each signal and the correlation between signals. This syntax can use any of the input arguments in the previous syntaxes.

Examples

Covariance Matrix for Two Signals without Noise

Create a covariance matrix for a 3-element, half-wavelength-spaced uniform line array. Use the default syntax, which assumes no noise power and unit signal power.

```
N = 3;
```

```
d = 0.5;
elementPos = (0:N-1)*d;
xcov = sensorcov(elementPos,[30 60])

xcov =

   2.0000 + 0.0000i  -0.9127 - 1.4086i  -0.3339 + 0.7458i
  -0.9127 + 1.4086i   2.0000 + 0.0000i  -0.9127 - 1.4086i
  -0.3339 - 0.7458i  -0.9127 + 1.4086i   2.0000 + 0.0000i
```

The diagonal terms of the matrix represent the sum of the two signal powers.

Covariance Matrix for Two Independent Signals with 10 dB SNR

Create a spatial covariance matrix for a 3-element, half-wavelength-spaced uniform line array. Assume there are two incoming signals with unit power and there is additive noise with –10 dB power.

```
N = 3;
d = 0.5;
elementPos = (0:N-1)*d;
xcov = sensorcov(elementPos,[30 35],db2pow(-10))

xcov =

   2.1000 + 0.0000i  -0.2291 - 1.9734i  -1.8950 + 0.4460i
  -0.2291 + 1.9734i   2.1000 + 0.0000i  -0.2291 - 1.9734i
  -1.8950 - 0.4460i  -0.2291 + 1.9734i   2.1000 + 0.0000i
```

The diagonal terms represent the two signal powers plus noise power at each sensor.

Covariance Matrix for Two Correlated Signals with 10 dB SNR

Compute the covariance matrix for a 3-element half-wavelength spaced line array when there is some correlation between two signals. The correlation can model, for example, multipath propagation caused by reflection from a surface. Assume an additive noise power value of –10 dB.

```
N = 3;
d = 0.5;
elementPos = (0:N-1)*d;
```

```
scov = [1, 0.8; 0.8, 1];
xcov = sensorcov(elementPos,[30 35],db2pow(-10),scov)

xcov =

   3.7000 + 0.0000i  -0.4124 - 3.5521i  -3.4111 + 0.8028i
  -0.4124 + 3.5521i   3.6574 + 0.0000i  -0.4026 - 3.4682i
  -3.4111 - 0.8028i  -0.4026 + 3.4682i   3.5321 + 0.0000i
```

Input Arguments

pos — Positions of array sensor elements

1-by-*N* real-valued vector | 2-by-*N* real-valued matrix | 3-by-*N* real-valued matrix

Positions of the elements of a sensor array specified as a 1-by-*N* vector, a 2-by-*N* matrix, or a 3-by-*N* matrix. In this vector or matrix, *N* represents the number of elements of the array. Each column of `pos` represents the coordinates of an element. You define sensor position units in term of signal wavelength. If `pos` is a 1-by-*N* vector, then it represents the *y*-coordinate of the sensor elements of a line array. The *x* and *z*-coordinates are assumed to be zero. When `pos` is a 2-by-*N* matrix, it represents the *(y,z)*-coordinates of the sensor elements of a planar array. This array is assumed to lie in the *yz*-plane. The *x*-coordinates are assumed to be zero. When `pos` is a 3-by-*N* matrix, then the array has arbitrary shape.

Example: `[0,0,0; 0.1,0.4,0.3;1,1,1]`

Data Types: `double`

ang — Arrival directions of incoming signals

1-by-*M* real-valued vector | 2-by-*M* real-valued matrix

Arrival directions of incoming signals specified as a 1-by-*M* vector or a 2-by-*M* matrix, where *M* is the number of incoming signals. If `ang` is a 2-by-*M* matrix, each column specifies the direction in azimuth and elevation of the incoming signal `[az;el]`. Angular units are specified in degrees. The azimuth angle must lie between –180° and 180° and the elevation angle must lie between –90° and 90°. The azimuth angle is the angle between the *x*-axis and the projection of the arrival direction vector onto the *xy* plane. It is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the arrival direction vector and *xy*-plane. It is positive when measured

towards the *z* axis. If `ang` is a 1-by-*M* vector, then it represents a set of azimuth angles with the elevation angles assumed to be zero.

Example: [45;0]

Data Types: `double`

`ncov` — Noise spatial covariance matrix

0 (default) | non-negative real-valued scalar | *1*-by-*N* non-negative real-valued vector | *N*-by-*N* positive definite, complex-valued matrix

Noise spatial covariance matrix specified as a non-negative, real-valued scalar, a non-negative, 1-by-*N* real-valued vector or an *N*-by-*N*, positive definite, complex-valued matrix. In this argument, *N* is the number of sensor elements. Using a non-negative scalar results in a noise spatial covariance matrix that has identical white noise power values (in watts) along its diagonal and has off-diagonal values of zero. Using a non-negative real-valued vector results in a noise spatial covariance that has diagonal values corresponding to the entries in `ncov` and has off-diagonal entries of zero. The diagonal entries represent the independent white noise power values (in watts) in each sensor. If `ncov` is *N*-by-*N* matrix, this value represents the full noise spatial covariance matrix between all sensor elements.

Example: [1,1,4,6]

Data Types: `double`
Complex Number Support: Yes

`scov` — Signal covariance matrix

1 (default) | non-negative real-valued scalar | *1*-by-*M* non-negative real-valued vector | *N*-by-*M* positive semidefinite, complex-valued matrix

Signal covariance matrix specified as a non-negative, real-valued scalar, a *1*-by-*M* non-negative, real-valued vector or an *M*-by-*M* positive semidefinite, matrix representing the covariance matrix between *M* signals. The number of signals is specified in `ang`. If `scov` is a nonnegative scalar, it assigns the same power (in watts) to all incoming signals which are assumed to be uncorrelated. If `scov` is a 1-by-*M* vector, it assigns the separate power values (in watts) to each incoming signal which are also assumed to be uncorrelated. If `scov` is an *M*-by-*M* matrix, then it represents the full covariance matrix between all incoming signals.

Example: [1 0 ; 0 2]

Data Types: `double`
Complex Number Support: Yes

Output Arguments

`xcov` — Sensor spatial covariance matrix
complex-valued *N*-by-*N* matrix

Sensor spatial covariance matrix returned as a complex-valued, *N*-by-*N* matrix. In this matrix, *N* represents the number of sensor elements of the array.

`cbfweights` | `lcmvweights` | `mvdrweights` | phased.SteeringVector | `sensorsig` | `steervec`

Introduced in R2013a

sensorsig

Simulate received signal at sensor array

Syntax

```
x = sensorsig(pos,ns,ang)
x = sensorsig(pos,ns,ang,ncov)
x = sensorsig(pos,ns,ang,ncov,scov)
x = sensorsig(pos,ns,ang,ncov,scov,'Taper',taper)
[x,rt] = sensorsig( ___ )
[x,rt,r] = sensorsig( ___ )
```

Description

`x = sensorsig(pos,ns,ang)` simulates the received narrowband plane wave signals at a sensor array. `pos` represents the positions of the array elements, each of which is assumed to be isotropic. `ns` indicates the number of snapshots of the simulated signal. `ang` represents the incoming directions of each plane wave signal. The plane wave signals are assumed to be constant-modulus signals with random phases.

`x = sensorsig(pos,ns,ang,ncov)` describes the noise across all sensor elements. `ncov` specifies the noise power or covariance matrix. The noise is a Gaussian distributed signal.

`x = sensorsig(pos,ns,ang,ncov,scov)` specifies the power or covariance matrix for the incoming signals.

`x = sensorsig(pos,ns,ang,ncov,scov,'Taper',taper)` specifies the array taper as a comma-separated pair consisting of `'Taper'` and a scalar or column vector.

`[x,rt] = sensorsig( ___ )` also returns the theoretical covariance matrix of the received signal, using any of the input arguments in the previous syntaxes.

`[x,rt,r] = sensorsig( ___ )` also returns the sample covariance matrix of the received signal.

Examples

Received Signal and Direction-of-Arrival Estimation

Simulate the received signal at an array, and use the data to estimate the arrival directions.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

Create an 8-element uniform linear array whose elements are spaced half a wavelength apart.

```
fc = 3e8;
c = 3e8;
lambda = c/fc;
array = phased.ULA(8,lambda/2);
```

Simulate 100 snapshots of the received signal at the array. Assume there are two signals, coming from azimuth 30° and 60°, respectively. The noise is white across all array elements, and the SNR is 10 dB.

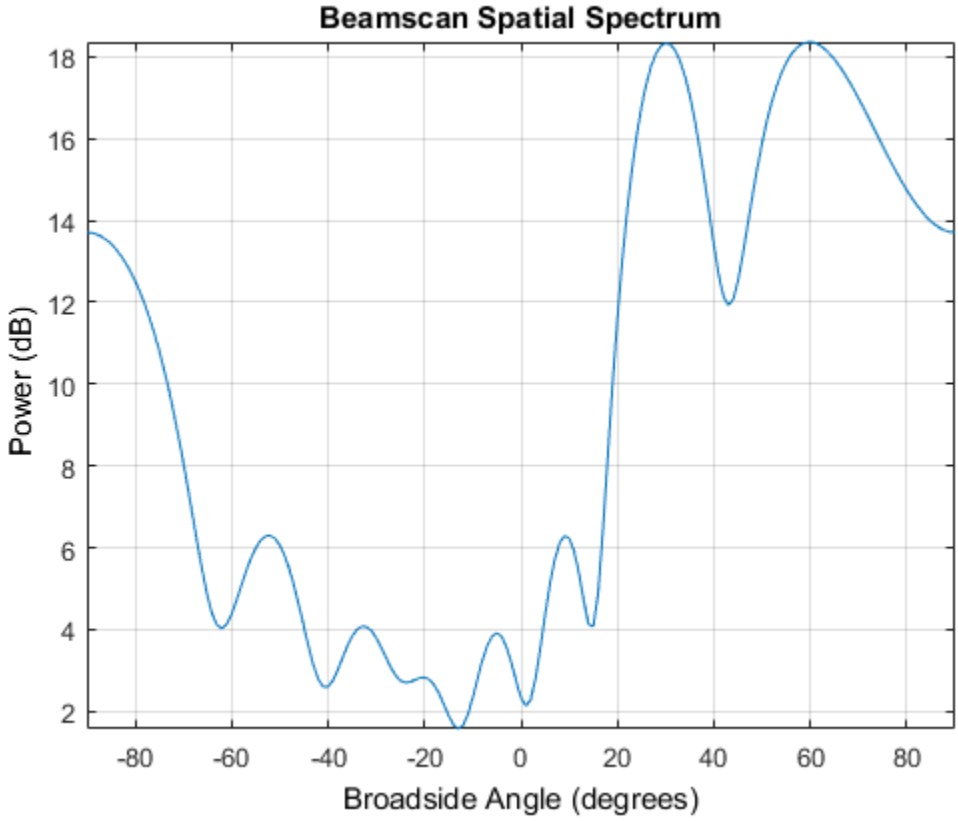
```
x = sensorsig(getElementPosition(array)/lambda,...
   100,[30 60],db2pow(-10));
```

Use a beamscan spatial spectrum estimator to estimate the arrival directions, based on the simulated data.

```
estimator = phased.BeamscanEstimator('SensorArray',array,...
   'PropagationSpeed',c,'OperatingFrequency',fc,...
   'DOAOutputPort',true,'NumSignals',2);
[~,ang_est] = estimator(x);
```

Plot the spatial spectrum resulting from the estimation process.

```
plotSpectrum(estimator)
```



The plot shows peaks at 30° and 60°.

Signals With Different Power Levels

Simulate receiving two uncorrelated incoming signals that have different power levels. A vector named `scov` stores the power levels.

Create an 8-element uniform linear array whose elements are spaced half a wavelength apart.

```
fc = 3e8;
c = 3e8;
lambda = c/fc;
```

```
ha = phased.ULA(8,lambda/2);
```

Simulate 100 snapshots of the received signal at the array. Assume that one incoming signal originates from 30 degrees azimuth and has a power of 3 W. A second incoming signal originates from 60 degrees azimuth and has a power of 1 W. The two signals are not correlated with each other. The noise is white across all array elements, and the SNR is 10 dB.

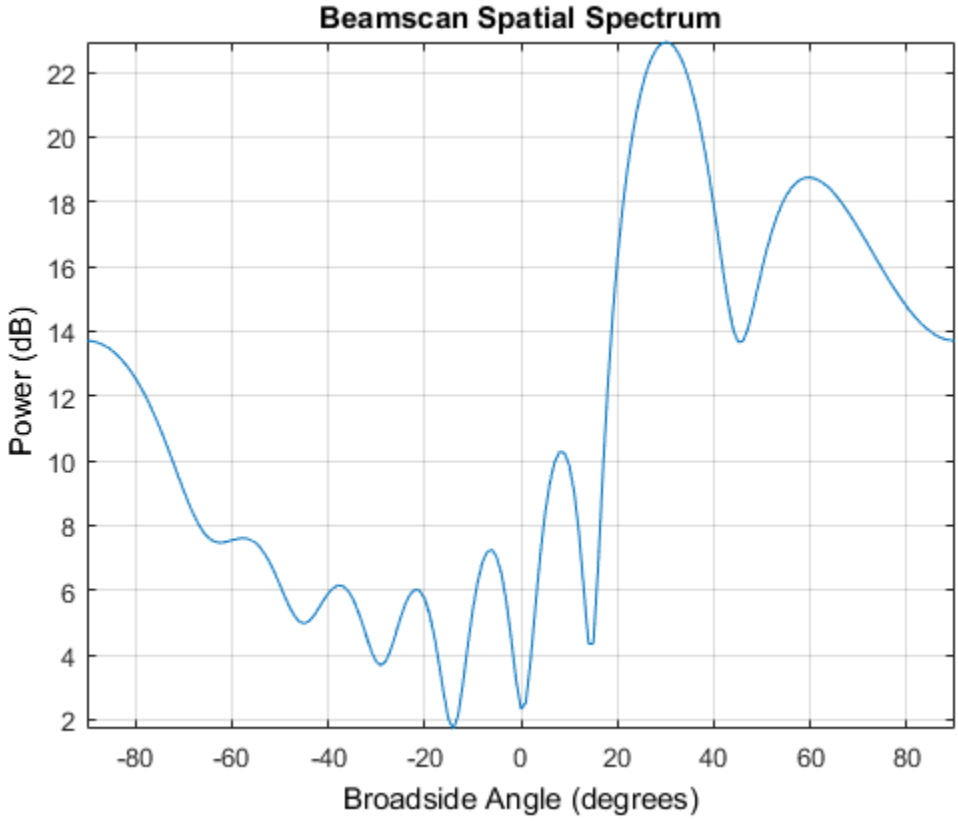
```
ang = [30 60];
scov = [3 1];
x = sensorsig(getElementPosition(ha)/lambda,...
   100,ang,db2pow(-10),scov);
```

Use a beamscan spatial spectrum estimator to estimate the arrival directions, based on the simulated data.

```
hdoa = phased.BeamscanEstimator('SensorArray',ha,...
   'PropagationSpeed',c,'OperatingFrequency',fc,...
   'DOAOutputPort',true,'NumSignals',2);
[~,ang_est] = step(hdoa,x);
```

Plot the spatial spectrum resulting from the estimation process.

```
plotSpectrum(hdoa);
```



The plot shows a high peak at 30 degrees and a lower peak at 60 degrees.

Reception of Correlated Signals

Simulate the reception of three signals, two of which are correlated.

Create a signal covariance matrix in which the first and third of three signals are correlated with each other.

```
scov = [1 0 0.6;...
        0 2 0;...
        0.6 0 1];
```

Simulate receiving 100 snapshots of three incoming signals from 30°, 40°, and 60° azimuth, respectively. The array that receives the signals is an 8-element uniform linear array whose elements are spaced one-half wavelength apart. The noise is white across all array elements, and the SNR is 10 dB.

```
pos = (0:7)*0.5;
ns = 100;
ang = [30 40 60];
ncov = db2pow(-10);
x = sensorsig(pos,ns,ang,ncov,scov);
```

Theoretical and Empirical Covariance of Received Signal

Simulate receiving a signal at a URA. Compare the signal theoretical covariance with its sample covariance.

Create a 2-by-2 uniform rectangular array having elements spaced 1/4-wavelength apart.

```
pos = 0.25 * [0 0 0 0; -1 1 -1 1; -1 -1 1 1];
```

Define the noise power independently for each of the four array elements. Each entry in `ncov` is the noise power of an array element. This element position is the corresponding column in `pos`. Assume the noise is uncorrelated across elements.

```
ncov = db2pow([-9 -10 -10 -11]);
```

Simulate 100 snapshots of the received signal at the array, and store the theoretical and empirical covariance matrices. Assume that one incoming signal originates from 30° azimuth and 10° elevation. A second incoming signal originates from 50° azimuth and 0° elevation. The signals have a power of 1 W and are uncorrelated.

```
ns = 100;
ang1 = [30; 10];
ang2 = [50; 0];
ang = [ang1, ang2];
rng default
[x,rt,r] = sensorsig(pos,ns,ang,ncov);
```

View the magnitudes of the theoretical covariance and sample covariance.

```
abs(rt)
abs(r)

ans =
```

```
    2.1259    1.8181    1.9261    1.9754
    1.8181    2.1000    1.5263    1.9261
    1.9261    1.5263    2.1000    1.8181
    1.9754    1.9261    1.8181    2.0794

ans =

    2.2107    1.7961    2.0205    1.9813
    1.7961    1.9858    1.5163    1.8384
    2.0205    1.5163    2.1762    1.8072
    1.9813    1.8384    1.8072    2.0000
```

Correlation of Noise Between Sensors

Simulate receiving a signal at a ULA, where the noise between different sensors is correlated.

Create a 4-element uniform linear array whose elements are spaced one-half wavelength apart.

```
pos = 0.5 * (0:3);
```

Define the noise covariance matrix. The value in the (*k*,_j_) position in the `ncov` matrix is the covariance between the *k* and *j* array elements listed in array.

```
ncov = 0.1 * [1 0.1 0 0; 0.1 1 0.1 0; 0 0.1 1 0.1; 0 0 0.1 1];
```

Simulate 100 snapshots of the received signal at the array. Assume that one incoming signal originates from 60° azimuth.

```
ns = 100;
ang = 60;
[x,rt,r] = sensorsig(pos,ns,ang,ncov);
```

View the theoretical and sample covariance matrices for the received signal.

```
rt,r

rt =

   1.1000 + 0.0000i  -0.9027 - 0.4086i   0.6661 + 0.7458i  -0.3033 - 0.9529i
```

```
  -0.9027 + 0.4086i   1.1000 + 0.0000i  -0.9027 - 0.4086i   0.6661 + 0.7458i
   0.6661 - 0.7458i  -0.9027 + 0.4086i   1.1000 + 0.0000i  -0.9027 - 0.4086i
  -0.3033 + 0.9529i   0.6661 - 0.7458i  -0.9027 + 0.4086i   1.1000 + 0.0000i

r =

   1.1059 + 0.0000i  -0.8681 - 0.4116i   0.6550 + 0.7017i  -0.3151 - 0.9363i
  -0.8681 + 0.4116i   1.0037 + 0.0000i  -0.8458 - 0.3456i   0.6578 + 0.6750i
   0.6550 - 0.7017i  -0.8458 + 0.3456i   1.0260 + 0.0000i  -0.8775 - 0.3753i
  -0.3151 + 0.9363i   0.6578 - 0.6750i  -0.8775 + 0.3753i   1.0606 + 0.0000i
```

Input Arguments

pos — Positions of elements in sensor array

1-by-N vector | 2-by-N matrix | 3-by-N matrix

Positions of elements in sensor array, specified as an N-column vector or matrix. The values in the matrix are in units of signal wavelength. For example, `[0 1 2]` describes three elements that are spaced one signal wavelength apart. N is the number of elements in the array.

Dimensions of `pos`:

- For a linear array along the y axis, specify the y coordinates of the elements in a 1-by-N vector.
- For a planar array in the yz plane, specify the y and z coordinates of the elements in columns of a 2-by-N matrix.
- For an array of arbitrary shape, specify the x, y, and z coordinates of the elements in columns of a 3-by-N matrix.

Data Types: `double`

ns — Number of snapshots of simulated signal

positive integer scalar

Number of snapshots of simulated signal, specified as a positive integer scalar. The function returns this number of samples per array element.

Data Types: `double`

ang — Directions of incoming plane wave signals

1-by-M vector | 2-by-M matrix

Directions of incoming plane wave signals, specified as an M-column vector or matrix in degrees. M is the number of incoming signals.

Dimensions of `ang`:

- If `ang` is a 2-by-M matrix, each column specifies a direction. Each column is in the form `[azimuth; elevation]`. The azimuth angle must be between –180 and 180 degrees, inclusive. The elevation angle must be between –90 and 90 degrees, inclusive.
- If `ang` is a 1-by-M vector, each entry specifies an azimuth angle. In this case, the corresponding elevation angle is assumed to be 0.

Data Types: `double`

ncov — Noise characteristics

0 (default) | nonnegative scalar | 1-by-N vector of positive numbers | N-by-N positive definite matrix

Noise characteristics, specified as a nonnegative scalar, 1-by-N vector of positive numbers, or N-by-N positive definite matrix.

Dimensions of `ncov`:

- If `ncov` is a scalar, it represents the noise power of the white noise across all receiving sensor elements, in watts. In particular, a value of `0` indicates that there is no noise.
- If `ncov` is a 1-by-N vector, each entry represents the noise power of one of the sensor elements, in watts. The noise is uncorrelated across sensors.
- If `ncov` is an N-by-N matrix, it represents the covariance matrix for the noise across all sensor elements.

Data Types: `double`

scov — Incoming signal characteristics

1 (default) | positive scalar | 1-by-M vector of positive numbers | M-by-M positive semidefinite matrix

Incoming signal characteristics, specified as a positive scalar, 1-by-M vector of positive numbers, or M-by-M positive semidefinite matrix.

Dimensions of `scov`:

- If `scov` is a scalar, it represents the power of all incoming signals, in watts. In this case, all incoming signals are uncorrelated and share the same power level.
- If `scov` is a 1-by-M vector, each entry represents the power of one of the incoming signals, in watts. In this case, all incoming signals are uncorrelated with each other.
- If `scov` is an M-by-M matrix, it represents the covariance matrix for all incoming signals. The matrix describes the correlation among the incoming signals. In this case, `scov` can be real or complex.

Data Types: `double`

`taper` — Array element taper

1 (default) | scalar | *N*-by-1 column vector

Array element taper, specified as a scalar or complex-valued *N*-by-1 column vector. The dimension *N* is the number of array elements. If `taper` is a scalar, all elements in the array use the same value. If `taper` is a vector, each entry specifies the taper applied to the corresponding array element.

Data Types: `double`
Complex Number Support: Yes

Output Arguments

`x` — Received signal

complex `ns`-by-N matrix

Received signal at sensor array, returned as a complex `ns`-by-N matrix. Each column represents the received signal at the corresponding element of the array. Each row represents a snapshot.

`rt` — Theoretical covariance matrix

complex N-by-N matrix

Theoretical covariance matrix of the received signal, returned as a complex N-by-N matrix.

`r` — Sample covariance matrix

complex N-by-N matrix

Sample covariance matrix of the received signal, returned as a complex N-by-N matrix. N is the number of array elements. The function derives this matrix from `x`.

Note: If you specify this output argument, consider making `ns` greater than or equal to N. Otherwise, `r` is rank deficient.

Definitions

Azimuth Angle, Elevation Angle

The *azimuth angle* of a vector is the angle between the *x*-axis and the orthogonal projection of the vector onto the *xy* plane. The angle is positive in going from the *x* axis toward the *y* axis. Azimuth angles lie between –180 and 180 degrees. The *elevation angle* is the angle between the vector and its orthogonal projection onto the *xy*-plane. The angle is positive when going toward the positive *z*-axis from the *xy* plane. These definitions assume the boresight direction is the positive *x*-axis.

Note: The elevation angle is sometimes defined in the literature as the angle a vector makes with the positive *z*-axis. The MATLAB and Phased Array System Toolbox products do not use this definition.

This figure illustrates the azimuth angle and elevation angle for a vector that appears as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue circles.

phased.SteeringVector

Introduced in R2012b

shnidman

Required SNR using Shnidman's equation

Syntax

```
SNR = shnidman(Prob_Detect,Prob_FA)
SNR = shnidman(Prob_Detect,Prob_FA,N)
SNR = shnidman(Prob_Detect,Prob_FA,N, Swerling_Num)
```

Description

`SNR = shnidman(Prob_Detect,Prob_FA)` returns the required signal-to-noise ratio in decibels for the specified detection and false-alarm probabilities using Shnidman's equation. The SNR is determined for a single pulse and a Swerling case number of 0, a nonfluctuating target.

`SNR = shnidman(Prob_Detect,Prob_FA,N)` returns the required SNR for a nonfluctuating target based on the noncoherent integration of `N` pulses.

`SNR = shnidman(Prob_Detect,Prob_FA,N, Swerling_Num)` returns the required SNR for the Swerling case number `Swerling_Num`.

Examples

Compute Single-Pulse SNR

Find and compare the required single-pulse SNR for Swerling cases I and III. The Swerling case I has no dominant scatterer while the Swerling case III has a dominant scatterer.

Specify the false-alarm and detection probabilities.

```
pfa = 1e-6:1e-5:.001;
Pd = 0.9;
```

Allocate arrays for plotting.

```
SNR_Sw1 = zeros(1,length(pfa));
SNR_Sw3 = zeros(1,length(pfa));
```

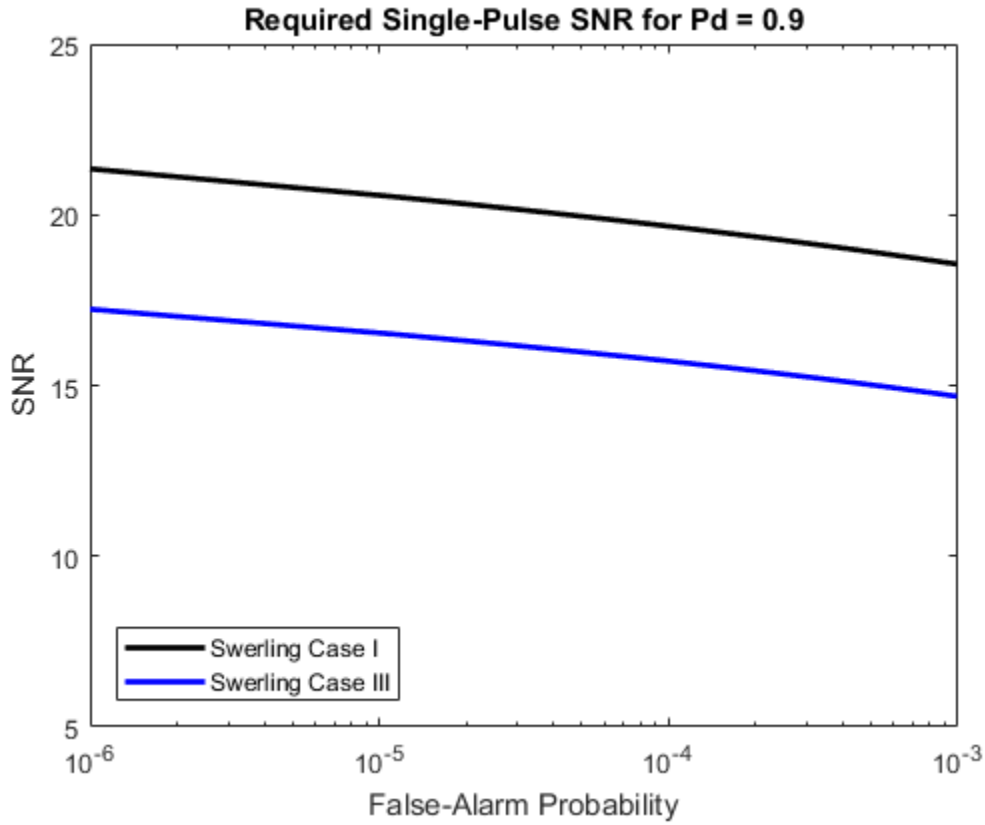
Loop over PFA's for both scatterer cases.

```
for j=1:length(pfa)

    SNR_Sw1(j) = shnidman(Pd,pfa(j),1,1);
    SNR_Sw3(j) = shnidman(Pd,pfa(j),1,3);
end
```

Plot the SNR vs PFA.

```
semilogx(pfa,SNR_Sw1,'k','linewidth',2)
hold on
semilogx(pfa,SNR_Sw3,'b','linewidth',2)
axis([1e-6 1e-3 5 25])
xlabel('False-Alarm Probability')
ylabel('SNR')
title('Required Single-Pulse SNR for Pd = 0.9')
legend('Swerling Case I','Swerling Case III',...
    'Location','SouthWest')
```



The presence of a dominant scatterer reduces the required SNR for the specified detection and false-alarm probabilities.

Definitions

Shnidman's Equation

Shnidman's equation is a series of equations that yield an estimate of the SNR required for a specified false-alarm and detection probability. Like Albersheim's equation, Shnidman's equation is applicable to a single pulse or the noncoherent integration of *N* pulses. Unlike Albersheim's equation, Shnidman's equation holds for square-law

detectors and is applicable to fluctuating targets. An important parameter in Shnidman's equation is the Swerling case number.

Swerling Case Number

The Swerling case numbers characterize the detection problem for fluctuating pulses in terms of:

- A decorrelation model for the received pulses
- The distribution of scatterers affecting the probability density function (PDF) of the target radar cross section (RCS).

The Swerling case numbers consider all combinations of two decorrelation models (scan-to-scan; pulse-to-pulse) and two RCS PDFs (based on the presence or absence of a dominant scatterer).

Swerling Case Number	Description
0 (alternatively designated as 5)	Nonfluctuating pulses.
I	Scan-to-scan decorrelation. Rayleigh/ exponential PDF–A number of randomly distributed scatterers with no dominant scatterer.
II	Pulse-to-pulse decorrelation. Rayleigh/ exponential PDF– A number of randomly distributed scatterers with no dominant scatterer.
III	Scan-to-scan decorrelation. Chi-square PDF with 4 degrees of freedom. A number of scatterers with one dominant.
IV	Pulse-to-pulse decorrelation. Chi-square PDF with 4 degrees of freedom. A number of scatterers with one dominant.

scatteringchanmtx

Scattering channel matrix

Syntax

```
chmat = scatteringchanmtx(txarraypos,rxarraypos,numscat)
chmat = scatteringchanmtx(txarraypos,rxarraypos,numscat,angrange)
chmat = scatteringchanmtx(txarraypos,rxarraypos,txang,rxang,G)
```

Description

`chmat = scatteringchanmtx(txarraypos,rxarraypos,numscat)` returns the channel matrix, `chmat`, for a MIMO channel consisting of a transmitting array, a receiver array, and multiple scatterers. The transmitting array is located at `txarraypos` and the receiving array at `rxarraypos`. `numscat` is the number of point scatterers.

The function generates `numscat` random transmission directions and `numscat` random receiving directions. The channel matrix describes multipath propagation through the `numscat` paths. By assumption, all paths arrive at the receiving array simultaneously implying that the channel is frequency flat. Flat frequency means that the spectrum of the signal is not changed. Path gains are derived from a zero-mean, unit-variance, complex-valued normal distribution.

`chmat = scatteringchanmtx(txarraypos,rxarraypos,numscat,angrange)` also specifies the angular range for transmitting and receiving angles.

`chmat = scatteringchanmtx(txarraypos,rxarraypos,txang,rxang,G)` specifies transmitting angles, receiving angles, and path gains.

Examples

Compute Channel Matrix for Random Signal Paths

Compute the channel matrix for a 13-element transmitting array and a 15-element receiving array. Assume that there are 17 randomly located scatterers. The arrays

are uniform linear arrays with 0.45-wavelength spacing. The receiving array is 300 wavelengths away from the transmitting array. Use the channel matrix to compute a propagated signal from the transmitting array to the receiving array.

Specify the arrays. Element spacing is in units of wavelength.

```
numtx = 13;
sp = 0.45;
txpos = (0:numtx-1)*sp;
numrx = 15;
rxpos = 300 + (0:numrx-1)*sp;
```

Specify the number of scatterers and create the channel matrix.

```
numscat = 17;
chmat = scatteringchanmtx(txpos,rxpos,numscat);
```

Create a signal consisting of zeros and ones. Then, propagate the signal from the transmitter to receiver.

```
x = randi(2,[100 numtx])-1;
y = x*chmat;
```

Compute Channel Matrix for Constrained Random Signal Paths

Compute the channel matrix for a 4-by-4 transmitting URA array and a 5-by-5 receiving URA array. Assume that 17 scatterers are randomly located within a specified angular range. The element spacing for both arrays is one-half wavelength. The receive array is 500 wavelengths away from the transmitting array along the *x*-axis. Use the channel matrix to compute a propagated signal from the transmitting array to the receiving array. Constrain the angular span for the transmitting and receiving directions.

Specify the 4-by-4 transmitting array. Element spacing is in units of wavelength.

```
Nt = 4;
sp = 0.5;
ygridtx = (0:Nt-1)*sp - (Nt-1)/2*sp;
zgridtx = (0:Nt-1)*sp - (Nt-1)/2*sp;
[ytx,ztx] = meshgrid(ygridtx,zgridtx);
txpos = [zeros(1,Nt*Nt);ytx(:).';ztx(:).'];
```

Specify the 5-by-5 receiving array. Element spacing is in units of wavelength.

```
Nr = 5;
```

```
sp = 0.5;
ygridrx = (0:Nr-1)*sp - (Nr-1)/2*sp;
zgridrx = (0:Nr-1)*sp - (Nr-1)/2*sp;
[yrx,zrx] = meshgrid(ygridrx,zgridrx);
rxpos = [500*ones(1,Nr*Nr);yrx(:).';zrx(:).'];
```

Set the angular limits for transmitting and receiving.

- The azimuth angle limits for the transmitter are −45° to +45°.
- The azimuth angle limits for the receiver are −75° to +50°.
- The elevation angle limits for the transmitter are −12° to +12°.
- The elevation angle limits for the receiver are −30° to +30°.

```
angrange = [-45 45 -75 50; -12 12 -30 30];
```

Specify the number of scatterers and create the channel matrix.

```
numscat = 6;
chmat = scatteringchanmtx(txpos,rxpos,numscat,angrange);
```

Create a 100-sample signal consisting of zeros and ones. Then, propagate the signal from the transmitting array to the receiving array.

```
x = randi(2,[100 Nt*Nt])-1;
y = x*chmat;
```

Compute Channel Matrix for Specified Signal Paths

Compute the channel matrix for a 4-by-4 transmitting URA array and a 5-by-5 receiving URA array. Assume there are 3 scatterers with known directions. The element spacings for both arrays is one-half wavelength. The receive array is 500 wavelengths away from the transmitting array along the *x*-axis. Use the channel matrix to compute a propagated signal from the transmitting array to the receiving array. Specify the transmitting and receiving directions. The number of directions determines the number of scatterers.

Specify the 4-by-4 transmitting array. Element spacing is in units of wavelength.

```
Nt = 4;
sp = 0.5;
ygridtx = (0:Nt-1)*sp - (Nt-1)/2*sp;
zgridtx = (0:Nt-1)*sp - (Nt-1)/2*sp;
[ytx,ztx] = meshgrid(ygridtx,zgridtx);
```

```
txpos = [zeros(1,Nt*Nt);ytx(:).';ztx(:).'];
```

Specify the 5-by-5 receiving array. Element spacing is in units of wavelength.

```
Nr = 5;
sp = 0.5;
ygridrx = (0:Nr-1)*sp - (Nr-1)/2*sp;
zgridrx = (0:Nr-1)*sp - (Nr-1)/2*sp;
[yrx,zrx] = meshgrid(ygridrx,zgridrx);
rxpos = [500*ones(1,Nr*Nr);yrx(:).';zrx(:).'];
```

Specify the transmitting and receiving angles and the gains. Then, create the channel matrix.

```
txang = [20 -10 40; 0 12 -12];
rxang = [70 -5.5 27.2; 4 1 -10];
gains = [1 1+1i 2-3*1i];
chmat = scatteringchanmtx(txpos,rxpos,txang,rxang,gains);
```

Create a 100-sample signal consisting of zeros and ones. Then, propagate the signal from the transmitting array to the receiving array.

```
x = randi(2,[100 Nt*Nt])-1;
y = x*chmat;
```

Input Arguments

`txarraypos` — Positions of elements in transmitting array

real-valued 1-by-N_t row vector | real-valued 2-by-$N_t$matrix | real-valued 3-by-N_t matrix

Transmitting array element positions, specified as a real-valued 1-by-N_t row vector, 2-by-$N_t$matrix, or 3-by-N_t matrix. N_t is the number of elements in the transmitting array.

`txarraypos`	Dimensions of Transmitting Array
1-by-N_t row vector	All transmitting array elements lie along the y-axis. The vector specifies the y-coordinates of the array elements.
2-by-N_t matrix	All transmitting array elements lie in the yz-plane. Each column of the matrix specifies the y and z coordinates of an array element.

txarraypos	Dimensions of Transmitting Array
3-by-N_t matrix	The transmitting array elements have arbitrary 3-D coordinates. Each column of the matrix specifies the x, y, and z coordinates of an array element.

Units are in wavelengths.

Example: `[-2.0,-1.0,0.0,1.0,2.0]`

Data Types: `double`

rxarraypos — Positions of elements in receiving array

real-valued 1-by-N_r row vector | real-valued 2-by-$N_r$matrix | real-valued 3-by-N_r matrix

Receiving array element positions, specified as a real-valued 1-by-N_r row vector, 2-by-vmatrix, or 3-by-N_r matrix. N_t is the number of elements in the transmitting array.

rxarraypos	Dimensions of Receiving Array
1-by-N_r row vector	All receiving array elements lie along the y-axis. The vector specifies the y-coordinates of the array elements.
2-by-N_r matrix	All receiving array elements lie in the yz-plane. Each column of the matrix specifies the y and z coordinates of an array element.
3-by-N_r matrix	The receiving array elements have arbitrary 3-D coordinates. Each column of the matrix specifies the x, y, and z coordinates of an array element.

Units are in wavelengths.

Example: `[-2.0,-1.0,0.0,1.0,2.0]`

Data Types: `double`

numscat — Number of scatterers

positive integer

Number of scatters, specified as a positive integer

Example: 7

Data Types: `double`

`angrange` — Angular range of transmission and reception directions

real-valued 1-by-2 row vector | real-valued row 1-by-4 vector | real-valued 2-by-2 matrix | real-valued 2-by-4 matrix

Angular range of transmitting and receiving directions, specified as one of the values in this table.

Size of angrange	Angular range
real-valued 1-by-2 row vector	Specify the same azimuth angle direction span for the transmitting and receiving arrays by using the minimum and maximum azimuth angles, `[az_min az_max]`. The elevation direction span is –90° to +90°.
real-valued 1-by-4 row vector	Specify the azimuth angle direction range for the transmitting and receiving arrays by using `[tx_az_min tx_az_max rx_az_min rx_az_max]`. The first two values are the minimum and maximum of the transmitting array directions. The last two values are the minimum and maximum of the receiving array directions. The range of the elevation angles is –90° to +90°.
real-valued 2-by-2 matrix	Specify the same azimuth and elevation angle direction spans for the transmitting and receiving arrays by using the minimum and maximum azimuth and elevation angles, `[az_min az_max; el_min el_max]`.
real-valued 2-by-4 matrix	Specify separate azimuth and elevation angle direction spans by using `[tx_az_min tx_az_max rx_az_min rx_az_max; tx_el_min tx_el_max rx_el_min rx_el_max]`. The first and second columns form the transmitting array direction span. The last two columns form the receiving array direction span.

Units are in degrees.

Example: `[-45 45 -30 30; -10 20 -5 30]`

Data Types: `double`

`txang` — Transmission path angles

real-valued 1-by-N_s row vector | real-valued 2-by-N_s matrix

Transmission path angles, specified as a real-valued 1-by-N_s row vector or a 2-by-N_s matrix. N_s is the number of scatterers specified by `numscat`.

- When `txang` is a vector, each element specifies the azimuth angle of a path. The elevation angle of the path is zero degrees.
- When `txang` is a matrix, each column specifies the azimuth and elevation angles of a path in the form `[az;el]`.

Example: `[4 -2; 0 35]`

Data Types: `double`

`rxang` — Receiving path angles

real-valued 1-by-N_s row vector | real-valued 2-by-N_s matrix

Receiving path angles, specified as a real-valued 1-by-N_s row vector or a 2-by-N_s matrix. N_s is the number of scatterers specified by `numscat`.

- When `rxang` is a vector, each element specifies the azimuth angle of a path. The elevation angle of the path is zero degrees.
- When `rxang` is a matrix, each column specifies the azimuth and elevation angles of a path in the form `[az;el]`.

Example: `[4 -2; 0 35]`

Data Types: `double`

`G` — Path gains

1-by-N_s complex-valued row vector

Path gains, specified as a 1-by-N_s complex-valued row vector. N_s is the number of scatterers specified by `numscat`. The gains apply to the corresponding paths. Units are dimensionless.

Example: `exp(1i*pi/3)`

Data Types: `double`
Complex Number Support: Yes

Output Arguments

`chmat` — MIMO channel matrix
N_t-by-N_r complex-valued matrix

MIMO channel matrix, returned as an N_t-by-N_r complex-valued matrix. N_t is the number of elements in the transmitting array. N_r is the number of elements in the receiving array.

Data Types: `double`
Complex Number Support: Yes

speed2dop

Convert speed to Doppler shift

Syntax

```
Doppler_shift = speed2dop(radvel,lambda)
```

Description

`Doppler_shift = speed2dop(radvel,lambda)` returns the one-way Doppler shift in hertz corresponding to the radial velocity, `radvel`, for the wavelength `lambda`.

Examples

Calculate Doppler Shift from Speed

Calculate the Doppler shift in hertz for a given carrier wavelength and source speed. The radar frequency is 24.15 GHz. Assume a radial speed of 35.76 m/s.

```
radvel = 35.76;
f0 = 24.15e9;
lambda = physconst('LightSpeed')/f0;
doppler_shift = speed2dop(radvel,lambda)
```

```
doppler_shift =

   2.8807e+03
```

Definitions

Doppler-Radial Velocity Relation

The Doppler shift of a source relative to a receiver can be computed from the relative radial velocity between the source and receiver:

$$\Delta f = \frac{V_{s,r}}{\lambda}$$

where Δf is the Doppler shift in hertz, $V_{s,r}$ denotes the radial velocity of the source relative to the receiver, and λ is the carrier frequency wavelength in meters.

`dop2speed` | `dopsteeringvec`

Introduced in R2011a

sph2cartvec

Convert vector from spherical basis components to Cartesian components

Syntax

```
vr = sph2cartvec(vs,az,el)
```

Description

`vr = sph2cartvec(vs,az,el)` converts the components of a vector or set of vectors, `vs`, from their *spherical basis representation* to their representation in a local Cartesian coordinate system. A spherical basis representation is the set of components of a vector projected into the right-handed spherical basis given by $(\mathbf{e}_{az}, \mathbf{e}_{el}, \mathbf{e}_R)$. The orientation of a spherical basis depends upon its location on the sphere as determined by azimuth, `az`, and elevation, `el`.

Examples

Cartesian Representation of Azimuthal Vector

Start with a vector in a spherical basis located at 45° azimuth, 45° elevation. The vector points along the azimuth direction. Compute the vector components with respect to Cartesian coordinates.

```
vs = [1;0;0];
vr = sph2cartvec(vs,45,45)
```

```
vr =

   -0.7071
    0.7071
         0
```

Input Arguments

vs — Vector in spherical basis representation

3-by-1 column vector | 3-by-N matrix

Vector in spherical basis representation specified as a 3-by-1 column vector or 3-by-N matrix. Each column of `vs` contains the three components of a vector in the right-handed spherical basis $(\mathbf{e}_{az}, \mathbf{e}_{el}, \mathbf{e}_R)$.

Example: `[4.0; -3.5; 6.3]`

Data Types: `double`
Complex Number Support: Yes

az — Azimuth angle

scalar in range [–180,180]

Azimuth angle specified as a scalar in the closed range [–180,180]. Angle units are in degrees. To define the azimuth angle of a point on a sphere, construct a vector from the origin to the point. The azimuth angle is the angle in the *xy*-plane from the positive *x*-axis to the vector's orthogonal projection into the *xy*-plane. As examples, zero azimuth angle and zero elevation angle specify a point on the *x*-axis while an azimuth angle of 90° and an elevation angle of zero specify a point on the *y*-axis.

Example: `45`

Data Types: `double`

el — Elevation angle

scalar in range [–90,90]

Elevation angle specified as a scalar in the closed range [–90,90]. Angle units are in degrees. To define the elevation of a point on the sphere, construct a vector from the origin to the point. The elevation angle is the angle from its orthogonal projection into the *xy*-plane to the vector itself. As examples, zero elevation angle defines the equator of the sphere and ±90° elevation define the north and south poles, respectively.

Example: `30`

Data Types: `double`

Output Arguments

`vr` — Vector in Cartesian representation
3-by-1 column vector | 3-by-N matrix

Cartesian vector returned as a 3-by-1 column vector or 3-by-N matrix having the same dimensions as `vs`. Each column of `vr` contains the three components of the vector in the right-handed *x,y,z* basis.

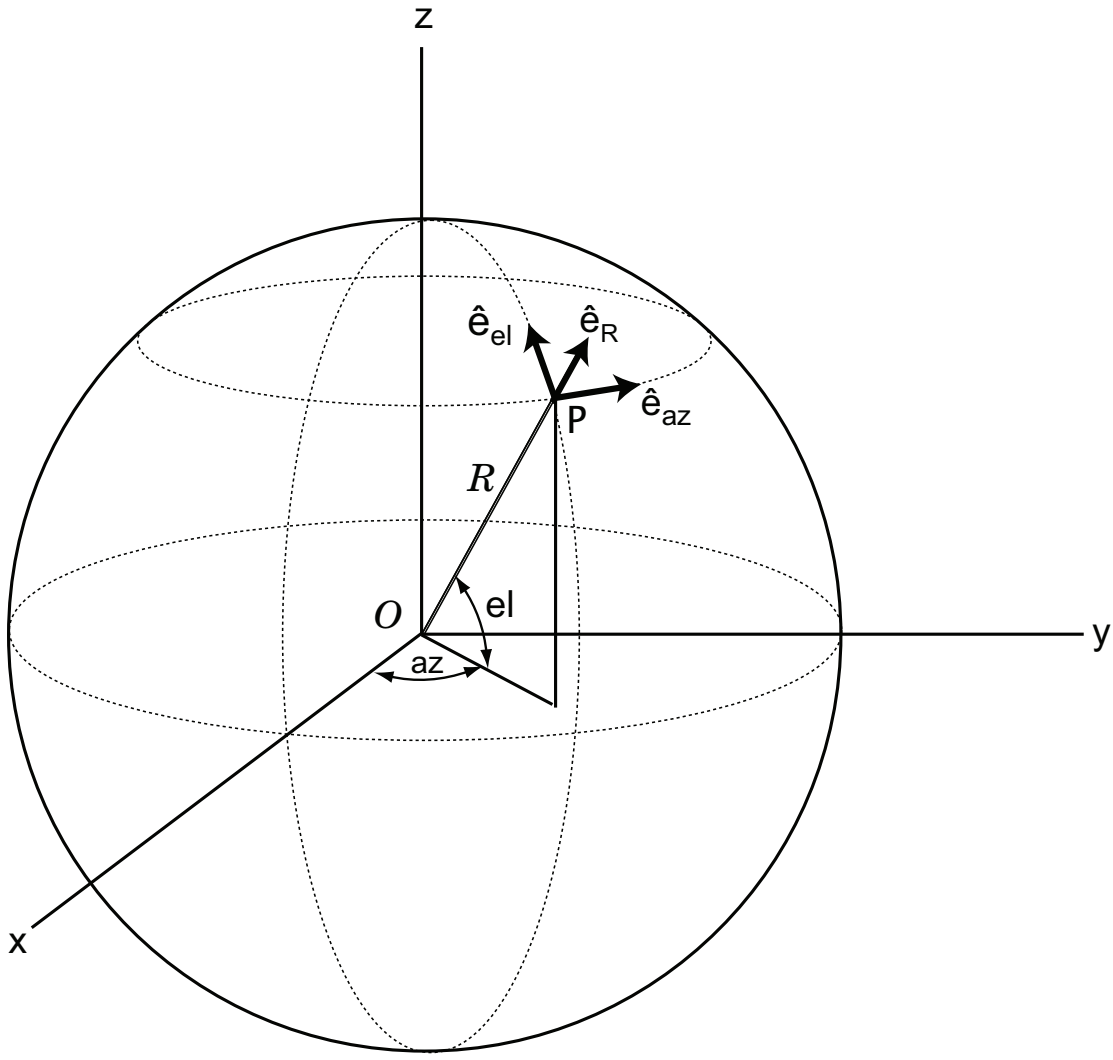
Definitions

Spherical basis representation of vectors

Spherical basis vectors are a local set of basis vectors which point along the radial and angular directions at any point in space.

The spherical basis is a set of three mutually orthogonal unit vectors $(\mathbf{e}_{az}, \mathbf{e}_{el}, \mathbf{e}_R)$ defined at a point on the sphere. The first unit vector points along lines of azimuth at constant radius and elevation. The second points along the lines of elevation at constant azimuth and radius. Both are tangent to the surface of the sphere. The third unit vector points radially outward.

The orientation of the basis changes from point to point on the sphere but is independent of R so as you move out along the radius, the basis orientation stays the same. The following figure illustrates the orientation of the spherical basis vectors as a function of azimuth and elevation:



For any point on the sphere specified by *az* and *el*, the basis vectors are given by:

$$\begin{aligned}\hat{\mathbf{e}}_{\mathbf{az}} &= -\sin(az)\hat{\mathbf{i}} + \cos(az)\hat{\mathbf{j}} \\ \hat{\mathbf{e}}_{\mathbf{el}} &= -\sin(el)\cos(az)\hat{\mathbf{i}} - \sin(el)\sin(az)\hat{\mathbf{j}} + \cos(el)\hat{\mathbf{k}} \\ \hat{\mathbf{e}}_{\mathbf{R}} &= \cos(el)\cos(az)\hat{\mathbf{i}} + \cos(el)\sin(az)\hat{\mathbf{j}} + \sin(el)\hat{\mathbf{k}} \quad .\end{aligned}$$

Any vector can be written in terms of components in this basis as $\mathbf{v} = v_{az}\hat{\mathbf{e}}_{\mathbf{az}} + v_{el}\hat{\mathbf{e}}_{\mathbf{el}} + v_R\hat{\mathbf{e}}_{\mathbf{R}}$. The transformations between spherical basis components and Cartesian components take the form

$$\begin{bmatrix} v_x \\ v_y \\ v_z \end{bmatrix} = \begin{bmatrix} -\sin(az) & -\sin(el)\cos(az) & \cos(el)\cos(az) \\ \cos(az) & -\sin(el)\sin(az) & \cos(el)\sin(az) \\ 0 & \cos(el) & \sin(el) \end{bmatrix} \begin{bmatrix} v_{az} \\ v_{el} \\ v_R \end{bmatrix}$$

.

and

$$\begin{bmatrix} v_{az} \\ v_{el} \\ v_R \end{bmatrix} = \begin{bmatrix} -\sin(az) & \cos(az) & 0 \\ -\sin(el)\cos(az) & -\sin(el)\sin(az) & \cos(el) \\ \cos(el)\cos(az) & \cos(el)\sin(az) & \sin(el) \end{bmatrix} \begin{bmatrix} v_x \\ v_y \\ v_z \end{bmatrix}.$$

spsmooth

Spatial smoothing

Syntax

```
RSM = spsmooth(R,L)
RSM = spsmooth(R,L,'fb')
```

Description

`RSM = spsmooth(R,L)` computes an averaged spatial covariance matrix, `RSM`, from the full spatial covariance matrix, `R`, using *spatial smoothing* (see Van Trees [1], p. 605). Spatial smoothing creates a smaller averaged covariance matrix over L maximum overlapped subarrays. L is a positive integer less than N. The resulting covariance matrix, `RSM`, has dimensions (N–L+1)-by-(N–L+1). Spatial smoothing is useful when two or more signals are correlated.

`RSM = spsmooth(R,L,'fb')` computes an averaged covariance matrix and at the same time performing *forward-backward averaging*. This syntax can use any of the input arguments in the previous syntax.

Examples

Comparison of Smoothed and Nonsmoothed Covariance Matrices

Construct a 10-element half-wavelength-spaced uniform line array receiving two plane waves arriving from 0° and -25° azimuth. Both elevation angles are 0°. Assume the two signals are partially correlated. The SNR for each signal is 5 dB. The noise is spatially and temporally Gaussian white noise. First, create the spatial covariance matrix from the signal and noise. Then, solve for the number of signals, using `rootmusicdoa`. Next, perform spatial smoothing on the covariance matrix, using `spsmooth`, and solve for the signal arrival angles again using `rootmusicdoa`.

Set up the array and signals. Then, generate the spatial covariance matrix for the array from the signals and noise.

```
N = 10;
d = 0.5;
elementPos = (0:N-1)*d;
angles = [0 -25];
ac = [1 1/5];
scov = ac'*ac;
R = sensorcov(elementPos,angles,db2pow(-5),scov);
```

Solve for the arrival angles using the original covariance matrix.

```
Nsig = 2;
doa =  rootmusicdoa(R,Nsig)
```

```
doa =

    0.3482   77.4120
```

The solved-for arrival angles are wrong - they do not agree with the known angles of arrival used to create the covariance matrix.

Next, solve for the arrival angles using a smoothed covariance matrix. Perform spatial smoothing to detect L-1 coherent signals. Choose L = 3.

```
Nsig = 2;
L = 2;
RSM = spsmooth(R,L);
doasm = rootmusicdoa(RSM,Nsig)
```

```
doasm =

    0.0000  -25.0000
```

In this case, computed angles do agree with the known angles of arrival.

Input Arguments

`R` — Spatial covariance matrix

complex-valued positive-definite *N*-by-*N* matrix.

Spatial covariance matrix, specified as a complex-valued, positive-definite *N*-by-*N* matrix. In this matrix, *N* represents the number of sensor elements.

Example: [4.3162, –0.2777 –0.2337i; –0.2777 + 0.2337i , 4.3162]

Data Types: `double`
Complex Number Support: Yes

`L` — Maximum number of overlapped subarrays
positive integer

Maximum number of overlapped subarrays, specified as a positive integer. The value *L* must be less than the number of sensors, *N*.

Example: 2

Data Types: `double`

Output Arguments

`RSM` — Smoothed covariance matrix
complex-valued *M*-by-*M* matrix

Smoothed covariance matrix, returned as a complex-valued, *M*-by-*M* matrix. The dimension *M* is given by $M = N–L+1$.

steervec

Steering vector

Syntax

```
sv = steervec(pos,ang)
sv = steervec(pos,ang,nqbits)
```

Description

`sv = steervec(pos,ang)` returns the steering vector `sv` for each incoming plane wave or set of plane waves impinging on a sensor array. The steering vector represents the set of phase-delays for an incoming wave at each sensor element. The `pos` argument specifies the positions of the sensor array elements. The `ang` argument specifies the incoming wave arrival directions in terms of azimuth and elevation angles. The steering vector, `sv`, is an *N*-by-*M* complex-valued matrix. In this matrix, *N* represents the number of element positions in the sensor array while *M* represents the number of incoming waves. Each column of `sv` contains the steering vector for the corresponding direction specified in `ang`. All elements in the sensor array are assumed to be isotropic.

`sv = steervec(pos,ang,nqbits)` returns quantized narrowband steering vector when the number of phase shifter bits is set to `nqbits`.

Examples

Line Array Steering Vector

Specify a uniform line array of five elements spaced 10 cm apart. Then, specify an incoming plane wave with a frequency of 1 GHz and an arrival direction of 45° azimuth and 0° elevation. Compute the steering vector of this wave.

```
elementPos = (0:.1:.4);
c = physconst('LightSpeed');
fc = 1e9;
lam = c/fc;
ang = [45;0];
sv = steervec(elementPos/lam,ang)
```

```
sv =

   1.0000 + 0.0000i
   0.0887 + 0.9961i
  -0.9843 + 0.1767i
  -0.2633 - 0.9647i
   0.9376 - 0.3478i
```

Quantized Line Array Steering Vector

Specify a uniform line array (ULA) containing five isotropic elements spaced 10 cm apart. Then, specify an incoming plane wave having a frequency of 1 GHz and an arrival direction of 45° azimuth and 0° elevation. Compute the steering vector of this wave. Quantize the steering vector to three bits.

```
elementPos = (0:.1:.4);
c = physconst('LightSpeed');
fc = 1e9;
lam = c/fc;
ang = [45;0];
sv = steervec(elementPos/lam,ang,3)
```

```
sv =

   1.0000 + 0.0000i
   0.0000 + 1.0000i
  -1.0000 + 0.0000i
  -0.0000 - 1.0000i
   1.0000 + 0.0000i
```

Input Arguments

pos — Positions of array sensor elements

1-by-*N* real-valued vector | 2-by-*N* real-valued matrix | 3-by-*N* real-valued matrix

Positions of the elements of a sensor array specified as a 1-by-*N* vector, a 2-by-*N* matrix, or a 3-by-*N* matrix. In this vector or matrix, *N* represents the number of elements of the array. Each column of `pos` represents the coordinates of an element. You define sensor

position units in term of signal wavelength. If `pos` is a 1-by-*N* vector, then it represents the *y*-coordinate of the sensor elements of a line array. The *x* and *z*-coordinates are assumed to be zero. When `pos` is a 2-by-*N* matrix, it represents the *(y,z)*-coordinates of the sensor elements of a planar array. This array is assumed to lie in the *yz*-plane. The *x*-coordinates are assumed to be zero. When `pos` is a 3-by-*N* matrix, then the array has arbitrary shape.

Example: `[0,0,0; 0.1,0.4,0.3;1,1,1]`

Data Types: `double`

`ang` — Arrival directions of incoming signals

1-by-*M* real-valued vector | 2-by-*M* real-valued matrix

Arrival directions of incoming signals specified as a 1-by-*M* vector or a 2-by-*M* matrix, where *M* is the number of incoming signals. If `ang` is a 2-by-*M* matrix, each column specifies the direction in azimuth and elevation of the incoming signal `[az;el]`. Angular units are specified in degrees. The azimuth angle must lie between –180° and 180° and the elevation angle must lie between –90° and 90°. The azimuth angle is the angle between the *x*-axis and the projection of the arrival direction vector onto the *xy* plane. It is positive when measured from the *x*-axis toward the *y*-axis. The elevation angle is the angle between the arrival direction vector and *xy*-plane. It is positive when measured towards the *z* axis. If `ang` is a 1-by-*M* vector, then it represents a set of azimuth angles with the elevation angles assumed to be zero.

Example: [45;0]

Data Types: `double`

`nqbits` — Number of phase shifter quantization bits

0 (default) | non-negative integer

Number of bits used to quantize the phase shift in beamformer or steering vector weights, specified as a non-negative integer. A value of zero indicates that no quantization is performed.

Example: `5`

Output Arguments

`sv` — Steering vector

N-by-*M* complex-valued matrix

Steering vector returned as an *N*-by-*M* complex-valued matrix. In this matrix, *N* represents the number of sensor elements of the array and *M* represents the number of incoming plane waves. Each column of `sv` corresponds to the same column in `ang`.

Introduced in R2013a

stokes

Stokes parameters of polarized field

Syntax

```
G = stokes(fv)
stokes(fv)
```

Description

`G = stokes(fv)` returns the four *Stokes* parameters `G` of a polarized field or set of fields specified in `fv`. The field should be expressed in terms of linear polarization components. The expression of a field in terms of a two-row vector of linear polarization components is called the *Jones vector formalism*.

`stokes(fv)` displays the Stokes parameters corresponding to `fv` as points on the *Poincare* sphere.

Examples

Stokes Vector

Create a left circularly-polarized field. Convert it to a linear representation and compute the Stokes vector.

```
cfv = [2;0];
fv = circpol2pol(cfv);
G = stokes(fv)
```

```
G =

    4.0000
         0
         0
    4.0000
```

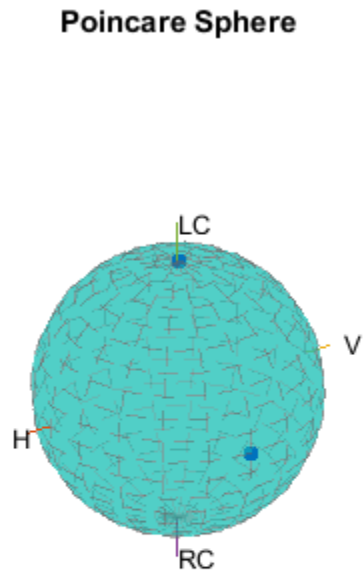
Poincare Sphere

Display points on the Poincare sphere for a left circularly-polarized field and a 45° linear polarized field.

```
fv = [sqrt(2)/2, 1; sqrt(2)/2*1i, 1];
G = stokes(fv)
stokes(fv);
```

```
G =

    1.0000    2.0000
         0         0
         0    2.0000
    1.0000         0
```



The point at the north pole represents the left circularly-polarized field. The point on the equator represents the 45° linear polarized field.

Input Arguments

`fv` — Field vector in linear polarization representation or linear polarization ratio

1-by-*N* complex-value row vector or 2-by-*N* complex-value matrix

Field vector in its linear polarization representation specified as a 2-by-*N* complex-valued matrix or in its linear polarization ratio representation specified as a 1-by-*N* complex-valued row vector. If `fv` is a matrix, each column of `fv` represents a field in

the form `[Eh;Ev]`, where `Eh` and `Ev` are its horizontal and vertical linear polarization components. The expression of a field in terms of a two-row vector of linear polarization components is called the *Jones vector formalism*. If `fv` is a vector, each entry in `fv` is contains the polarization ratio, `Ev/Eh`.

Example: [sqrt(2)/2*1i; 1]

Data Types: `double`
Complex Number Support: Yes

Output Arguments

`G` — Stokes parameters

4-by-*N* matrix of Stokes parameters.

`G` contains the four Stokes parameters for each polarized field specified in `fv`. The Stokes parameters are computed from combinations of intensities of the field:

- G_0 describes the total intensity of the field.
- G_1 describes the preponderance of horizontal linear polarization intensity over vertical linear polarization intensity.
- G_2 describes the preponderance of +45° linear polarization intensity over -45° linear polarization intensity.
- G_3 describes the preponderance of right circular polarization intensity over left circular polarization intensity.

stretchfreq2rng

Convert frequency offset to range

Syntax

```
R = stretchfreq2rng(FREQ,SLOPE,REFRNG)
R = stretchfreq2rng(FREQ,SLOPE,REFRNG,V)
```

Description

`R = stretchfreq2rng(FREQ,SLOPE,REFRNG)` returns the range corresponding to the frequency offset `FREQ`. The computation assumes you obtained `FREQ` through stretch processing with a reference range of `REFRNG`. The sweeping slope of the linear FM waveform is `SLOPE`.

`R = stretchfreq2rng(FREQ,SLOPE,REFRNG,V)` specifies the propagation speed `V`.

Input Arguments

FREQ

Frequency offset in hertz, specified as a scalar or vector.

SLOPE

Sweeping slope of the linear FM waveform, in hertz per second, specified as a nonzero scalar.

REFRNG

Reference range, in meters, specified as a scalar.

V

Propagation speed, in meters per second, specified as a positive scalar.

Default: Speed of light

Output Arguments

R

Range in meters. R has the same dimensions as FREQ .

Examples

Range Corresponding to Frequency Offset

Calculate the range corresponding to a frequency offset of 2 kHz obtained from stretch processing. Assume the reference range is 5000 m and the linear FM waveform has a sweeping slope of 2 GHz/s.

```
r = stretchfreq2rng(2e3,2e9,5000)
```

```
r =

   4.8501e+03
```

surfacegamma

Gamma value for different terrains

Syntax

```
G = surfacegamma(TerrainType)
G = surfacegamma(TerrainType,FREQ)
surfacegamma
```

Description

`G = surfacegamma(TerrainType)` returns the γ value for the specified terrain. The γ value is for an operating frequency of 10 GHz.

`G = surfacegamma(TerrainType,FREQ)` specifies the operating frequency of the system.

`surfacegamma` displays several terrain types and their corresponding γ values. These γ values are for an operating frequency of 10 GHz.

Input Arguments

`TerrainType`

Character vectors that describe the terrain type. Valid values are:

- `'sea state 3'`
- `'sea state 5'`
- `'woods'`
- `'metropolitan'`
- `'rugged mountain'`

- `'farmland'`
- `'wooded hill'`
- `'flatland'`

FREQ

Operating frequency of radar system in hertz. This value can be a scalar or vector.

Default: `10e9`

Output Arguments

G

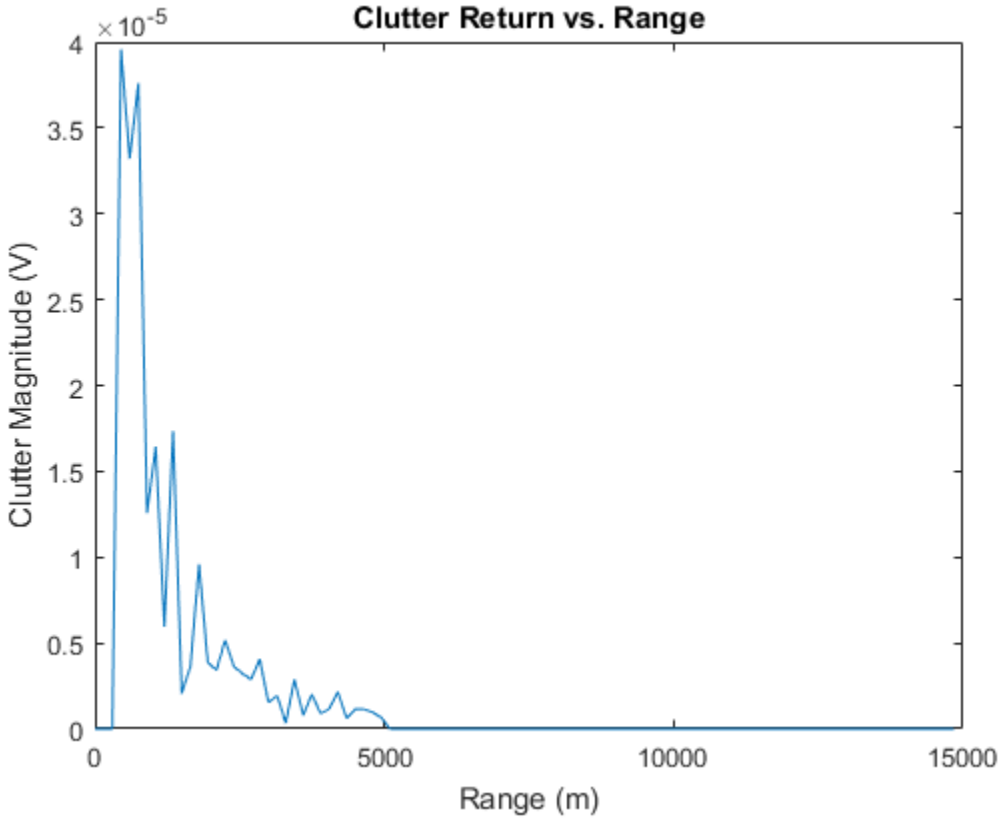
Value of γ in decibels, for constant γ clutter model.

Examples

Simulate Constant Gamma Clutter

Determine the γ value for a wooded area, and then simulate the clutter return from that area. Assume the radar system uses a single cosine pattern antenna element and has an operating frequency of 300 MHz.

```
fc = 300e6;
g = surfacegamma('woods',fc);
clutter = phased.ConstantGammaClutter('Gamma',g,...
    'Sensor',phased.CosineAntennaElement,...
    'OperatingFrequency',fc);
x = clutter();
r = (0:numel(x)-1)/(2*clutter.SampleRate) * ...
    clutter.PropagationSpeed;
plot(r,abs(x))
xlabel('Range (m)')
ylabel('Clutter Magnitude (V)')
title('Clutter Return vs. Range')
```



Definitions

Gamma

A frequently used model for clutter simulation is the constant gamma model. This model uses a parameter, γ, to describe clutter characteristics of different types of terrain. Values of γ are derived from measurements.

Algorithms

The γ values for the terrain types `'sea state 3'`, `'sea state 5'`, `'woods'`, `'metropolitan'`, and `'rugged mountain'` are from [2].

The γ values for the terrain types `'farmland'`, `'wooded hill'`, and `'flatland'` are from [3].

Measurements provide values of γ for a system operating at 10 GHz. The γ value for a system operating at frequency *f* is:

$$\gamma = \gamma_0 + 5\log\left(\frac{f}{f_0}\right)$$

where γ_0 is the value at frequency f_0 = 10 GHz.

surfclutterrcs

Surface clutter radar cross section (RCS)

Syntax

```
RCS = surfclutterrcs(NRCS,R,az,el,graz,tau)
RCS = surfclutterrcs(NRCS,R,az,el,graz,tau,c)
```

Description

`RCS = surfclutterrcs(NRCS,R,az,el,graz,tau)` returns the radar cross section (RCS) of a clutter patch that is of range `R` meters away from the radar system. `az` and `el` are the radar system azimuth and elevation beamwidths, respectively, corresponding to the clutter patch. `graz` is the grazing angle of the clutter patch relative to the radar. `tau` is the pulse width of the transmitted signal. The calculation automatically determines whether the surface clutter area is beam limited or pulse limited, based on the values of the input arguments.

`RCS = surfclutterrcs(NRCS,R,az,el,graz,tau,c)` specifies the propagation speed in meters per second.

Input Arguments

`NRCS`

Normalized radar cross section of clutter patch in units of square meters/square meters.

`R`

Range of clutter patch from radar system, in meters.

`az`

Azimuth beamwidth of radar system corresponding to clutter patch, in degrees.

`el`

Elevation beamwidth of radar system corresponding to clutter patch, in degrees.

`graz`

Grazing angle of clutter patch relative to radar system, in degrees.

`tau`

Pulse width of transmitted signal, in seconds.

`c`

Propagation speed, in meters per second.

Default: Speed of light

Output Arguments

`RCS`

Radar cross section of clutter patch.

Examples

Compute Surface Clutter RCS

Calculate the RCS of a clutter patch and estimate the clutter-to-noise ratio (CNR) at the receiver. Assume that the patch has a normalized radar cross section (NRCS) of 1 m^2/m^2 and is 1.0 km away from the radar system. The azimuth and elevation beamwidths are 1° and 3°, respectively. The grazing angle is 10°. The pulse width is 10μs. The radar operates at a wavelength of 1 cm with a peak power of 5 kW.

```
nrcs = 1;
rng = 1.0e3;
az = 1;
el = 3;
graz = 10;
tau = 10e-6;
lambda = 0.01;
```

```
ppow = 5000;
rcs = surfclutterrcs(nrcs,rng,az,el,graz,tau)
```

```
rcs =

   5.2627e+03
```

```
cnr = radareqsnr(lambda,rng,ppow,tau,'rcs',rcs)
```

```
cnr =

   75.2006
```

Tips

- You can calculate the clutter-to-noise ratio using the output of this function as the `RCS` input argument value in `radareqsnr`.

systemp

Receiver system-noise temperature

Syntax

```
STEMP = systemp(NF)
STEMP = systemp(NF,REFTEMP)
```

Description

`STEMP = systemp(NF)` calculates the effective system-noise temperature, `STEMP`, in kelvin, based on the noise figure, `NF`. The reference temperature is 290 K.

`STEMP = systemp(NF,REFTEMP)` specifies the reference temperature.

Input Arguments

NF

Noise figure in decibels. The noise figure is the ratio of the actual output noise power in a receiver to the noise power output of an ideal receiver.

REFTEMP

Reference temperature in kelvin, specified as a nonnegative scalar. The output of an ideal receiver has a white noise power spectral density that is approximately the Boltzmann constant times the reference temperature in kelvin.

Default: 290

Output Arguments

STEMP

Effective system-noise temperature in kelvin. The effective system-noise temperature is `REFTEMP*10^(NF/10)`.

Examples

Compute System Noise Temperature

Calculate the system noise temperature of a receiver with a 300 K reference temperature and a 5 dB noise figure.

```
T = systemp(5,300)
```

```
T =

  948.6833
```

taylortaperc

Taylor nbar taper for arrays

Syntax

```
W = taylortaperc(pos,diam)
W = taylortaperc(pos,diam,nbar)
W = taylortaperc(pos,diam,nbar,sll)
W = taylortaperc(pos,diam,nbar,sll,cpos)
```

Description

`W = taylortaperc(pos,diam)` returns the value of a Taylor n-bar taper, `W`, at sensor element positions specified by `pos` in a circular aperture having diameter `diam`.

`W = taylortaperc(pos,diam,nbar)` also specifies, `nbar`, the number of approximately constant-level sidelobes next to the mainlobe.

`W = taylortaperc(pos,diam,nbar,sll)` also specifies the maximum sidelobe level, `sll`, relative to the mainlobe peak.

`W = taylortaperc(pos,diam,nbar,sll,cpos)` also specifies the center of the array, `cpos`. Without this argument, the function sets the array center to the computed centroid of the array.

Examples

Default Taylor Taper Circular Array

Apply a Taylor nbar taper to a circular aperture array. Obtain the circular aperture by cropping a square uniform rectangular array into a circle. Let all the parameters remain at their default values: nbar is 4 and the sidelobe level is –30. Let the center of the array be the centroid of the array elements. Plot the array power pattern at 300 MHz.

Create a square URA with a side length of 10 m. Set the element spacing to 1/2 m. The spacing is equal to one-half wavelength at this frequency.

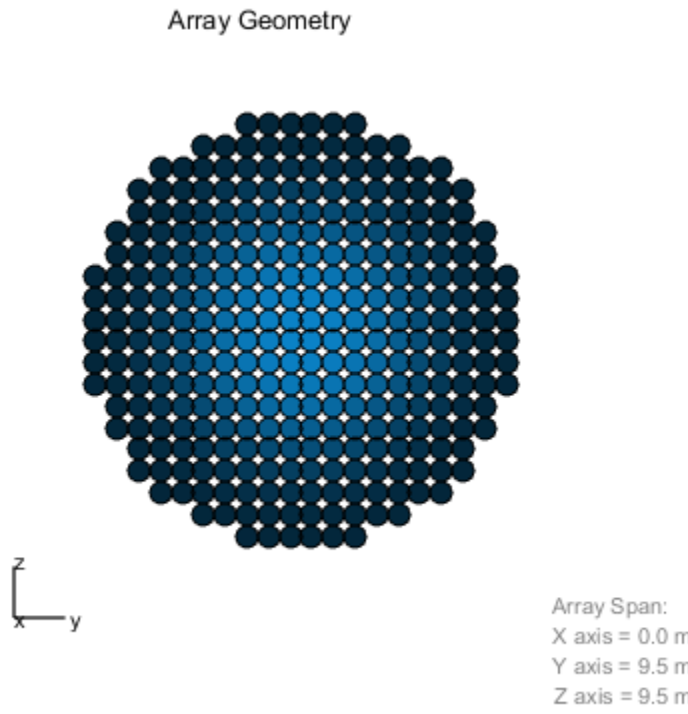
```
fc = 300.0e6;
diam = 10.0;
d = 0.5;
nelem = ceil(diam/d);
pos = getElementPosition(phased.URA(nelem,d));
```

Use the `phased.ConformalArray` System object™ to model a circular array. Create a circular array by removing all elements outside a radius one-half the side-length of the URA. Then apply the Taylor nbar tapering to the array.

```
pos(:,sum(pos.^2) > (diam/2)^2) = [];
antenna = phased.ConformalArray('ElementPosition',pos);
antenna.Taper = taylortaperc(pos,diam);
```

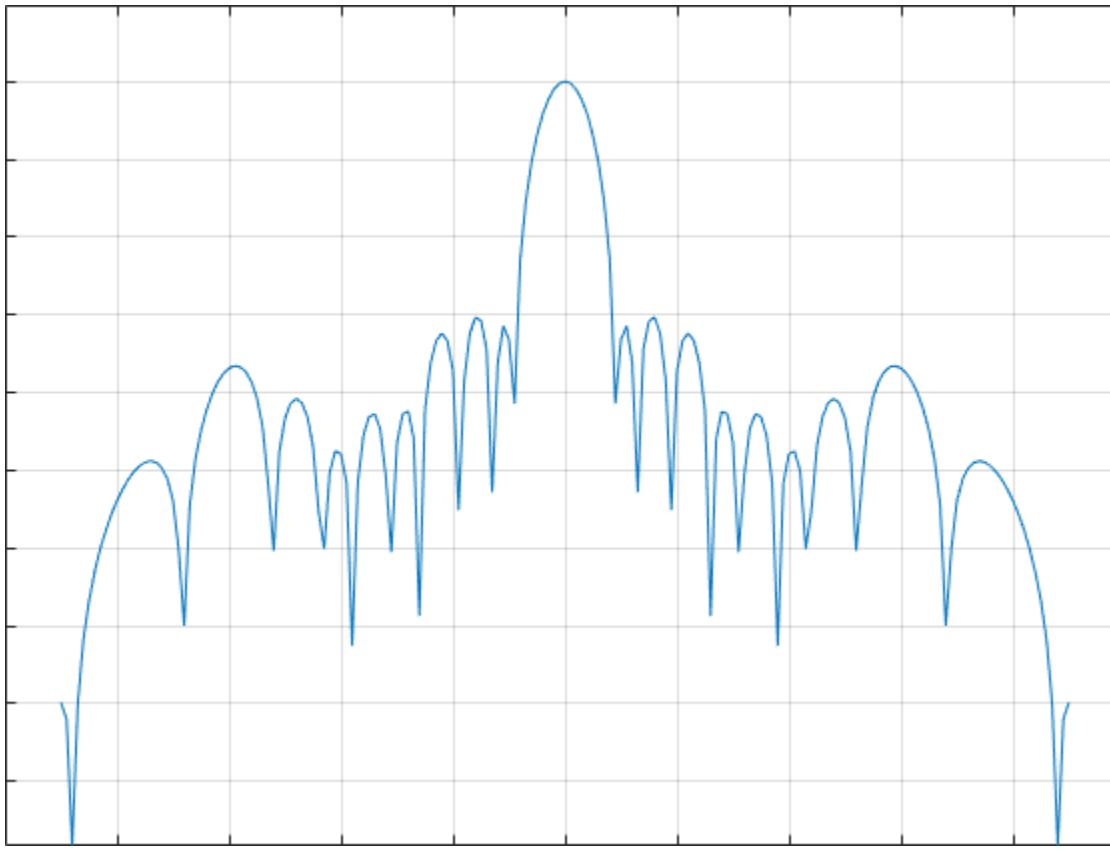
View the array.

```
viewArray(antenna,'ShowTaper',true)
```



Display the array power pattern as a function of azimuth angle.

```
pattern(antenna,fc,-90:1:90,0,'CoordinateSystem','rectangular','Type','powerdb')
```



Taylor Taper Circular Array Specifying Nbar

Apply a Taylor nbar taper to a circular aperture array. Create the circular aperture by cropping a square uniform rectangular array into a circle. Set the value of nbar to 2. Let the sidelobe level assume a default value of –30. Let the center of the array be the centroid of the array elements. Plot the array power pattern at 300 MHz.

Create a square URA with a side length of 10 m. Set the element spacing to 0.5 m. The spacing is equal to one-half wavelength at this frequency.

```
fc = 300.0e6;
diam = 10.0;
d = 0.5;
nbar = 2;
```

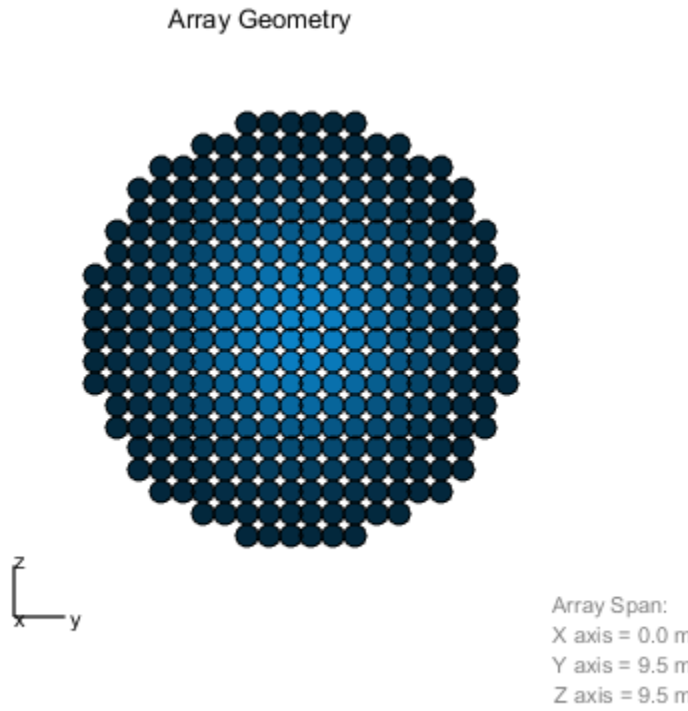
```
nelem = ceil(diam/d);
pos = getElementPosition(phased.URA(nelem,d));
```

Use the `phased.ConformalArray` System object™ to model a circular array. Create a circular array by removing all elements outside a radius one-half the side-length of the URA. Then apply the Taylor nbar tapering to the array.

```
pos(:,sum(pos.^2) > (diam/2)^2) = [];
antenna = phased.ConformalArray('ElementPosition',pos);
antenna.Taper = taylortaperc(pos,diam,nbar);
```

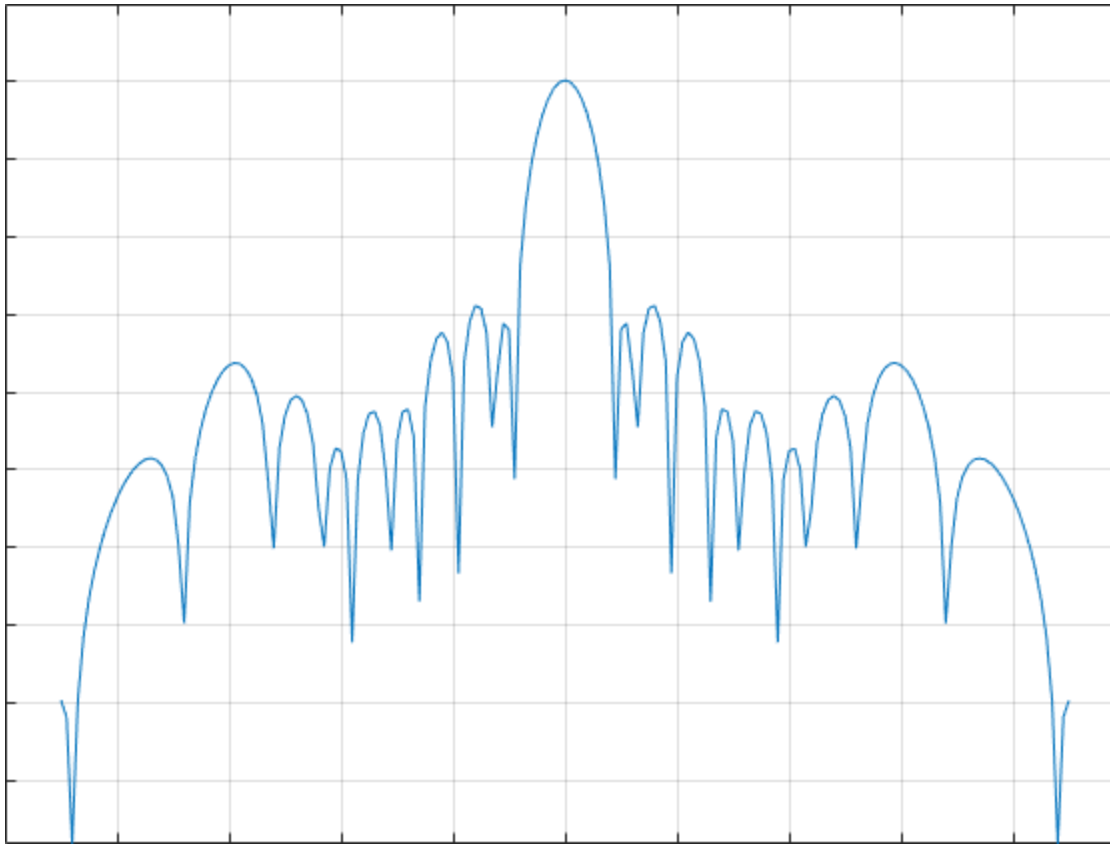
View the array.

```
viewArray(antenna,'ShowTaper',true)
```



Display the array power pattern as a function of azimuth angle.

```
pattern(antenna,fc,-90:1:90,0,'CoordinateSystem','rectangular','Type','powerdb')
```



Taylor Taper Circular Array Specifying Sidelobe Level

Apply a Taylor nbar taper to a circular aperture array. Create the circular aperture by cropping a square uniform rectangular array into a circle. Set the value of nbar to 4. Set the sidelobe level to –25. Let the center of the array be the centroid of the array elements. Plot the array power pattern at 300 MHz.

First, create a square URA with a side length of 10 m. Set the element spacing to 0.5 m. The spacing is equal to one-half wavelength at this frequency.

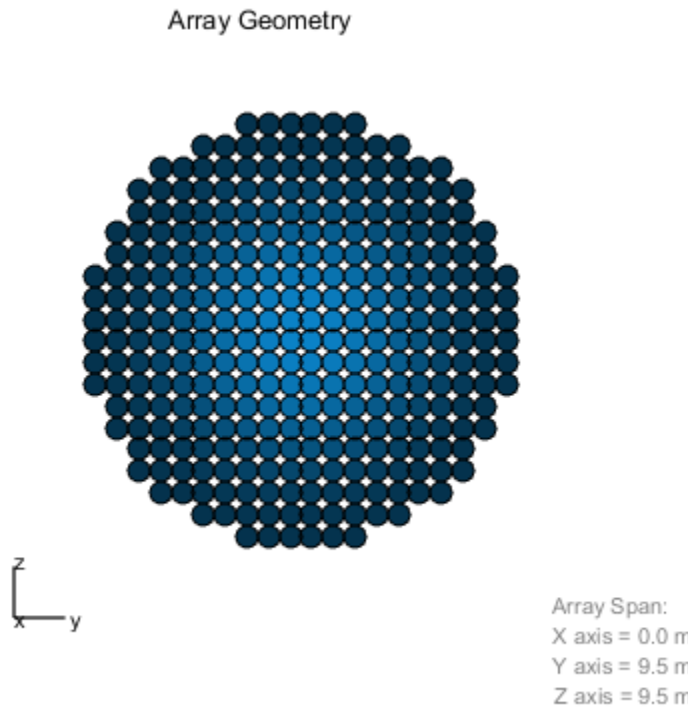
```
fc = 300.0e6;
diam = 10.0;
d = 0.5;
nbar = 2;
sll = -25;
nelem = ceil(diam/d);
pos = getElementPosition(phased.URA(nelem,d));
```

Use the `phased.ConformalArray` System object™ to model a circular array. Create a circular array by removing all elements outside a radius one-half the side-length of the URA. Then apply the Taylor nbar tapering to the array.

```
pos(:,sum(pos.^2) > (diam/2)^2) = [];
antenna = phased.ConformalArray('ElementPosition',pos);
antenna.Taper = taylortaperc(pos,diam,nbar,sll);
```

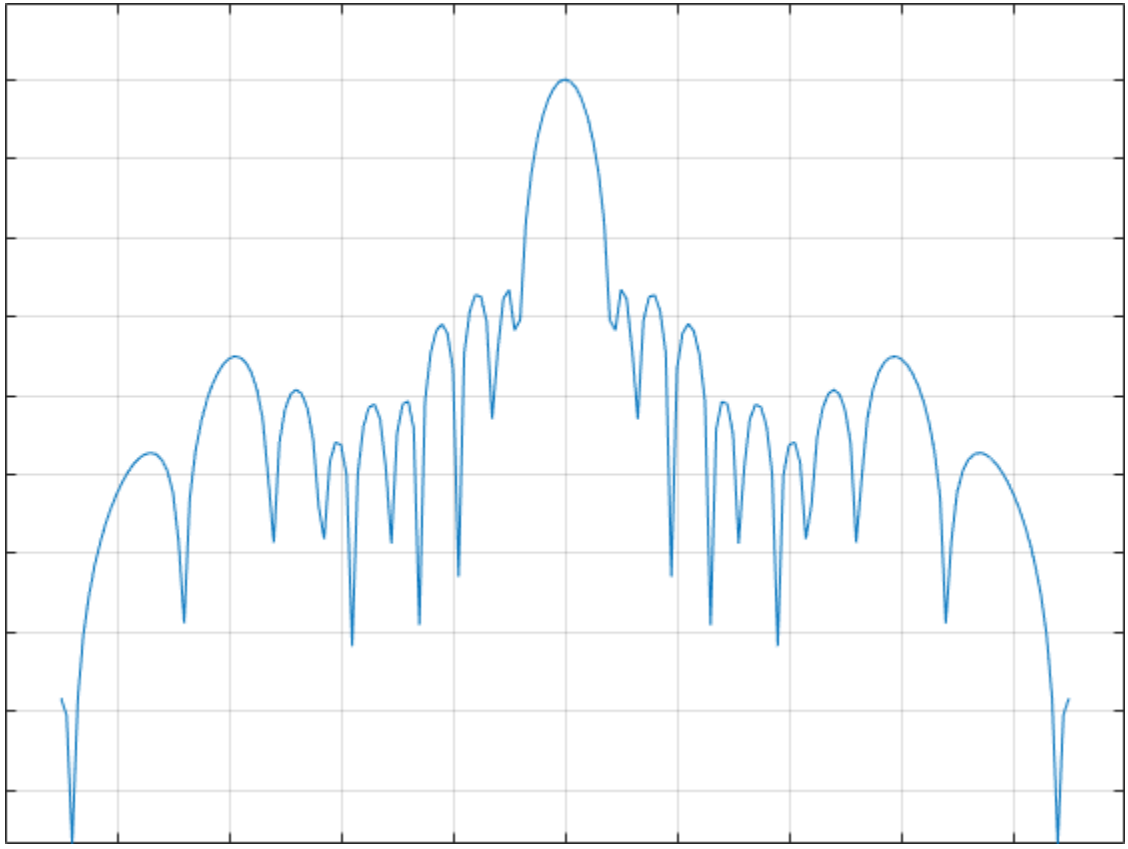
View the array.

```
viewArray(antenna,'ShowTaper',true)
```



Display the array power pattern as a function of azimuth angle.

```
pattern(antenna,fc,-90:1:90,0,'CoordinateSystem','rectangular','Type','powerdb')
```



Taylor Taper Circular Array Specifying Array Center

Apply a Taylor nbar taper to a circular aperture array. Create the circular aperture by cropping a square uniform rectangular array into a circle. Set the sidelobe level to –25. Set the center of the array to the origin. Plot the array power pattern at 300 MHz.

Create a square URA with a side length of 10 m. Set the element spacing to 0.5 m. The spacing is equal to one-half wavelength at this frequency.

```
fc = 300.0e6;
diam = 10.0;
d = 0.5;
sll = -25;
```

Compute nbar from the sidelobe level.

```
A = acosh(10^(-sll/20))/pi;
nbar = ceil(2*A^2 + 0.5)
```

```
nbar =

     4
```

Create the URA element positions.

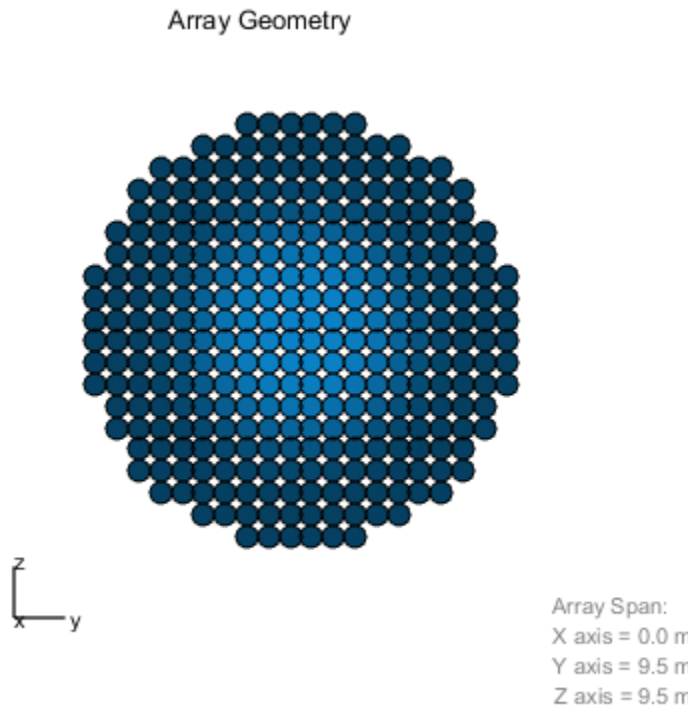
```
cpos = [0;0;0];
nelem = ceil(diam/d);
pos = getElementPosition(phased.URA(nelem,d));
```

Use the `phased.ConformalArray` System object™ to model a circular array. Create a circular array by removing all elements outside a radius one-half the side-length of the URA. Then apply the Taylor nbar tapering to the array.

```
pos(:,sum(pos.^2) > (diam/2)^2) = [];
antenna = phased.ConformalArray('ElementPosition',pos);
antenna.Taper = taylortaperc(pos,diam,nbar,sll,cpos);
```

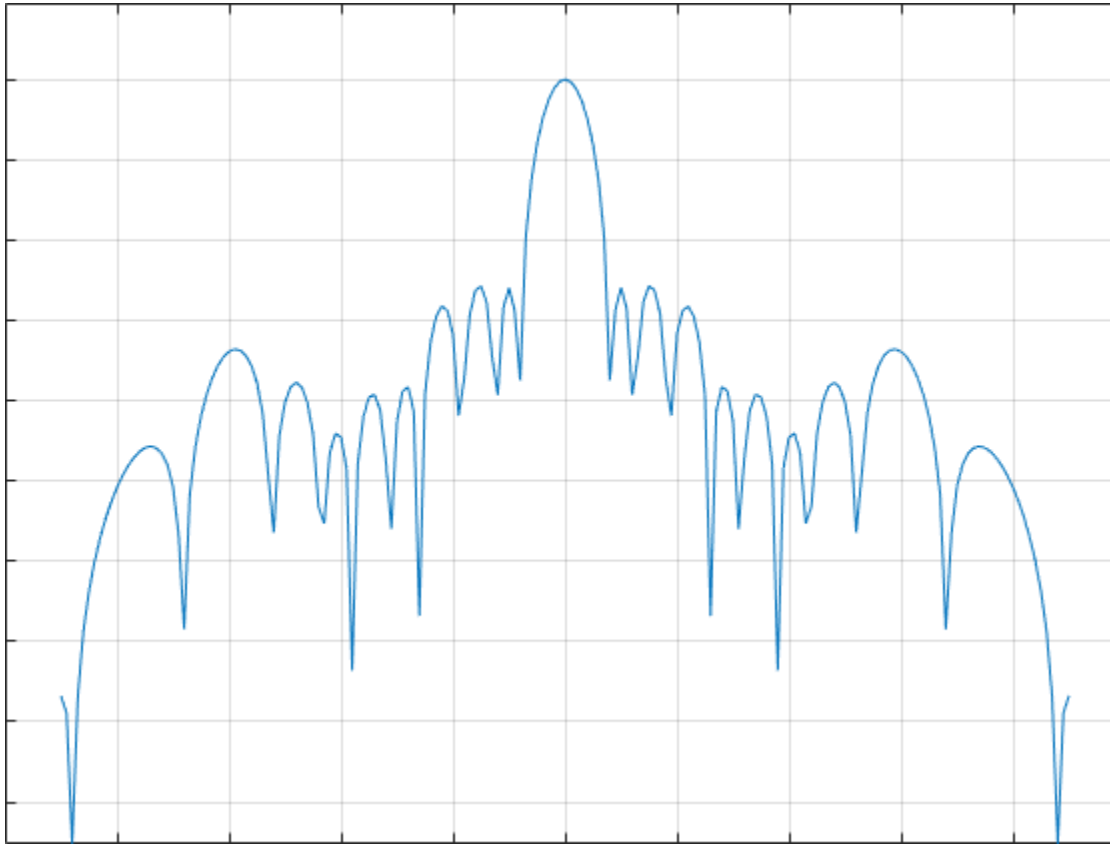
View the array.

```
viewArray(antenna,'ShowTaper',true)
```



Display the array power pattern as a function of azimuth angle.

```
pattern(antenna,fc,-90:1:90,0,'CoordinateSystem','rectangular','Type','powerdb')
```



Input Arguments

pos — Position of array elements

2-by-*N* real-valued matrix | 3-by-*N* real-valued matrix

Position of array elements, specified as a 2-by-*N* or 3-by-*N* real-valued matrix where *N* is the number of elements. If `pos` is a 2-by-*N* matrix, then all elements lie in the $z = 0$ plane. Each column specifies the position, `[x;y]`, of the element. If `pos` is a 3-by-*N* matrix, its columns represent the positions of array elements in `[x;y;z]` format. `W` is an *N*-by-1 column vector containing the Taylor tapers. The 2-by-*N* form is designed

for planar arrays although you can use the 3-by-*N* form and set the third row to zero. Position units are in meters.

Example: `[–5,–5,5,5;-5,5,5,-5]`

Data Types: `double`

`diam` — Array diameter

positive scalar

Array diameter, specified as a positive scalar. Diameter units are in meters.

Example: `15.5`

Data Types: `double`

`nbar` — Number of nearly equal sidelobes

`4` (default) | positive integer

Number of nearly equal sidelobes on each side of the mainlobe, specified as a positive integer. Units are dimensionless.

Example: `3`

Data Types: `double`

`sll` — Maximum sidelobe level

`-30.0` (default) | negative scalar

Maximum sidelobe, specified as a negative scalar. Sidelobe levels are referenced to the mainlobe. Units are in dB.

Example: `-10.0`

Data Types: `double`

`cpos` — Array center

array centroid (default) | real-valued 2-by-1 vector | real-valued 3-by-1 vector

Array center, specified as a real-valued 2-by-1 or 3-by-1 vector. Units are in meters. Use a 2-by-1 vector when the element positions are specified as a 2-by-*N* matrix. The default value is the computed centroid of all the array elements.

Example: `[5;-10;3]`

Data Types: `double`

Output Arguments

W — Taylor weights

real-valued *N*-by-1 column vector

Taylor weights, returned as a real-valued *N*-by-1 column vector. *N* is the number of array elements. Units are dimensionless.

Algorithms

Compute Minimum Value of N-bar

A useful guideline for choosing a value of `nbar` that meets the required sidelobe level (*sll*), as specified in the `sll` argument, is to satisfy the inequality

$$\bar{n} \geq \frac{2}{\pi^2}\left(\cosh^{-1}\left(10^{-\frac{sll}{20}}\right)\right)^2 + 0.5$$

This is a recommendation and you may be able to use a smaller value.

`taylorwin`

Introduced in R2016b

time2range

Convert propagation time to propagation distance

Syntax

```
r = time2range(t)
r = time2range(t,c)
```

Description

`r = time2range(t)` returns the distance a signal propagates during `t` seconds. The propagation is assumed to be two-way, as in a monostatic radar system.

`r = time2range(t,c)` specifies the signal propagation speed.

Examples

Minimum Detectable Range for Specified Pulse Width

Calculate the minimum detectable range for a monostatic radar system where the pulse width is 2 ms.

```
t = 2e-3;
r = time2range(t)
```

```
r =

   2.9979e+05
```

Input Arguments

`t` — Propagation time

array of positive numbers

Propagation time in seconds, specified as an array of positive numbers.

`c` — Signal propagation speed
speed of light (default) | positive scalar

Signal propagation speed, specified as a positive scalar in meters per second.

Data Types: `double`

Output Arguments

`r` — Propagation distance
array of positive numbers

Propagation distance in meters, returned as an array of positive numbers. The dimensions of `r` are the same as those of `t`.

Data Types: `double`

Algorithms

The function computes `c*t/2`.

Introduced in R2012b

unigrid

Uniform grid

Syntax

```
Grid = unigrid(StartValue,Step,EndValue)
Grid = unigrid(StartValue,Step,EndValue,IntervalType)
```

Description

`Grid = unigrid(StartValue,Step,EndValue)` returns a uniformly sampled grid from the closed interval `[StartValue,EndValue]`, starting from `StartValue`. `Step` specifies the step size. This syntax is the same as calling `StartValue:Step:EndValue`.

`Grid = unigrid(StartValue,Step,EndValue,IntervalType)` specifies whether the interval is closed, or semi-open. Valid values of `IntervalType` are `'[]'` (default), and `'[)'`. Specifying a closed interval does not always cause `Grid` to contain the value `EndValue`. The inclusion of `EndValue` in a closed interval also depends on the step size `Step`.

Examples

Create Uniform Grids

Create a uniform closed interval grid with a positive increment.

```
grid = unigrid(0,0.1,1);
grid(1)
```

```
ans =

     0
```

```
grid(end)
```

```
ans =

     1
```

Note that `grid(1) = 0` and `grid(end) = 1`.

Create a uniform grid with a semi-open interval.

```
grid = unigrid(0,0.1,1,'[)');
grid(1)
```

```
ans =

     0
```

```
grid(end)
```

```
ans =

    0.9000
```

In this case, `grid(end) = 0.9`

Create a decreasing grid with a semi-open interval.

```
grid = unigrid(1,-0.2,0,'[)')
```

```
grid =

    1.0000    0.8000    0.6000    0.4000    0.2000

uv2azel

Convert u/v coordinates to azimuth/elevation angles

Syntax

```
AzEl = uv2azel(UV)
```

Description

`AzEl = uv2azel(UV)` converts the *u*/*v* space coordinates to their corresponding azimuth/elevation angle pairs.

Examples

Conversion of U/V Coordinates to AzEl

Find the corresponding azimuth/elevation representation for $u = 0.5$ and $v = 0$.

```
azel = uv2azel([0.5; 0])
```

```
azel =

   30.0000
         0
```

Input Arguments

UV — Angle in u/v space

two-row matrix

Angle in *u*/*v* space, specified as a two-row matrix. Each column of the matrix represents a pair of coordinates in the form [*u*; *v*]. Each coordinate is between –1 and 1, inclusive. Also, each pair must satisfy $u^2 + v^2 \leq 1$.

Data Types: `double`

Output Arguments

`AzEl` — Azimuth/elevation angle pairs

two-row matrix

Azimuth and elevation angles, returned as a two-row matrix. Each column of the matrix represents an angle in degrees, in the form [azimuth; elevation]. The matrix dimensions of `AzEl` are the same as those of `UV`.

Definitions

U/V Space

The *u*/*v* coordinates for the positive hemisphere $x \geq 0$ can be derived from the phi and theta angles.

The relation between the two coordinates is

$$u = \sin\theta\cos\phi$$
$$v = \sin\theta\sin\phi$$

In these expressions, φ and θ are the phi and theta angles, respectively.

In terms of azimuth and elevation, the *u* and *v* coordinates are

$$u = \cos el\sin az$$
$$v = \sin el$$

The values of *u* and *v* satisfy the inequalities

$$-1 \leq u \leq 1$$
$$-1 \leq v \leq 1$$
$$u^2 + v^2 \leq 1$$

Conversely, the phi and theta angles can be written in terms of *u* and *v* using

$$\tan\phi = u / v$$

$$\sin\theta = \sqrt{u^2 + v^2}$$

The azimuth and elevation angles can also be written in terms of u and v

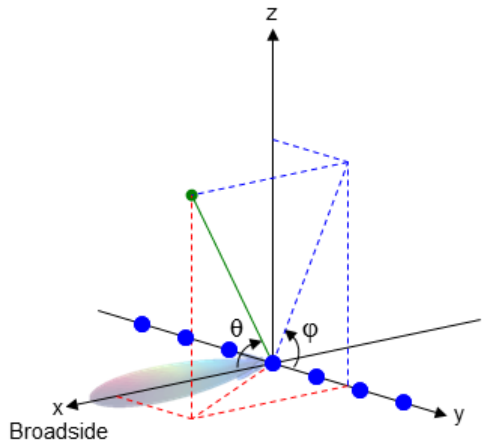
$$\sin el = v$$

$$\tan az = \frac{u}{\sqrt{1 - u^2 - v^2}}$$

Phi Angle, Theta Angle

The φ angle is the angle from the positive *y*-axis toward the positive *z*-axis, to the vector's orthogonal projection onto the *yz* plane. The φ angle is between 0 and 360 degrees. The θ angle is the angle from the *x*-axis toward the *yz* plane, to the vector itself. The θ angle is between 0 and 180 degrees.

The figure illustrates φ and θ for a vector that appears as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue circles.



The coordinate transformations between φ/θ and *az*/*el* are described by the following equations

$$\sin(\text{el}) = \sin\phi\sin\theta$$
$$\tan(\text{az}) = \cos\phi\tan\theta$$

$$\cos\theta = \cos(\text{el})\cos(\text{az})$$
$$\tan\phi = \tan(\text{el}) / \sin(\text{az})$$

Azimuth Angle, Elevation Angle

The *azimuth angle* of a vector is the angle between the *x*-axis and the orthogonal projection of the vector onto the *xy* plane. The angle is positive in going from the *x* axis toward the *y* axis. Azimuth angles lie between –180 and 180 degrees. The *elevation angle* is the angle between the vector and its orthogonal projection onto the *xy*-plane. The angle is positive when going toward the positive *z*-axis from the *xy* plane. These definitions assume the boresight direction is the positive *x*-axis.

Note: The elevation angle is sometimes defined in the literature as the angle a vector makes with the positive *z*-axis. The MATLAB and Phased Array System Toolbox products do not use this definition.

This figure illustrates the azimuth angle and elevation angle for a vector that appears as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue circles.

"Spherical Coordinates"

Introduced in R2012a

uv2azelpat

Convert radiation pattern from u/v form to azimuth/elevation form

Syntax

```
pat_azel = uv2azelpat(pat_uv,u,v)
pat_azel = uv2azelpat(pat_uv,u,v,az,el)
[pat_azel,az,el] = uv2azelpat( ___ )
```

Description

`pat_azel = uv2azelpat(pat_uv,u,v)` expresses the antenna radiation pattern `pat_azel` in azimuth/elevation angle coordinates instead of u/v space coordinates. `pat_uv` samples the pattern at u angles in `u` and v angles in `v`. The `pat_azel` matrix uses a default grid that covers azimuth values from –90 to 90 degrees and elevation values from –90 to 90 degrees. In this grid, `pat_azel` is uniformly sampled with a step size of 1 for azimuth and elevation. The function interpolates to estimate the response of the antenna at a given direction.

`pat_azel = uv2azelpat(pat_uv,u,v,az,el)` uses vectors `az` and `el` to specify the grid at which to sample `pat_azel`. To avoid interpolation errors, `az` should cover the range [–90, 90] and `el` should cover the range [–90, 90].

`[pat_azel,az,el] = uv2azelpat( ___ )` returns vectors containing the azimuth and elevation angles at which `pat_azel` samples the pattern, using any of the input arguments in the previous syntaxes.

Examples

Convert Radiation Pattern

Convert a radiation pattern to azimuth/elevation form with the angles spaced 1° apart.

Define the pattern in terms of u and v. Because u and v values outside the unit circle are not physical, set the pattern values in this region to zero.

```
u = -1:0.01:1;
v = -1:0.01:1;
[u_grid,v_grid] = meshgrid(u,v);
pat_uv = sqrt(1 - u_grid.^2 - v_grid.^2);
pat_uv(hypot(u_grid,v_grid) >= 1) = 0;
```

Convert the pattern to azimuth/elevation space.

```
pat_azel = uv2azelpat(pat_uv,u,v);
```

Plot Converted Radiation Pattern

Convert a radiation pattern to azimuth/elevation form with the angles spaced 1° apart.

Define the pattern in terms of u and v. Because u and v values outside the unit circle are not physical, set the pattern values in this region to zero.

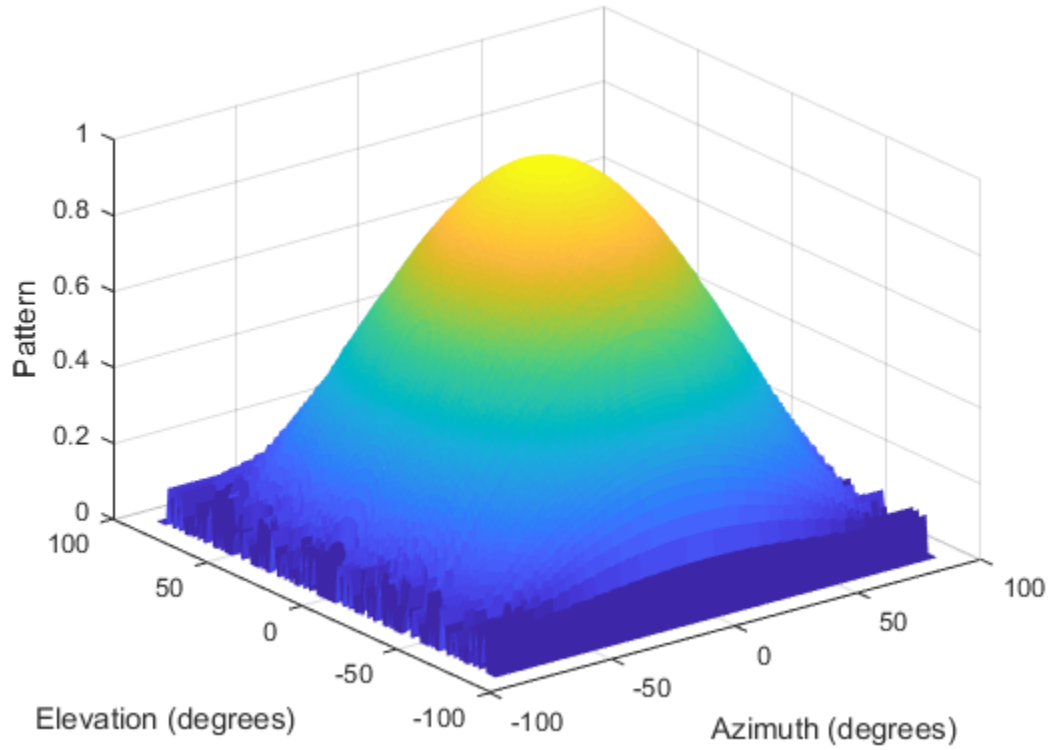
```
u = -1:0.01:1;
v = -1:0.01:1;
[u_grid,v_grid] = meshgrid(u,v);
pat_uv = sqrt(1 - u_grid.^2 - v_grid.^2);
pat_uv(hypot(u_grid,v_grid) >= 1) = 0;
```

Convert the pattern to azimuth/elevation space. Store the azimuth and elevation angles for plotting.

```
[pat_azel,az,el] = uv2azelpat(pat_uv,u,v);
```

Plot the pattern.

```
H = surf(az,el,pat_azel);
H.LineStyle = 'none';
xlabel('Azimuth (degrees)')
ylabel('Elevation (degrees)')
zlabel('Pattern')
```



Convert Radiation Pattern Using Specific Azimuth/Elevation Values

Convert a radiation pattern to azimuth/elevation form, with the angles spaced 5° apart.

Define the pattern in terms of u and v. Because u and v values outside the unit circle are not physical, set the pattern values in this region to zero.

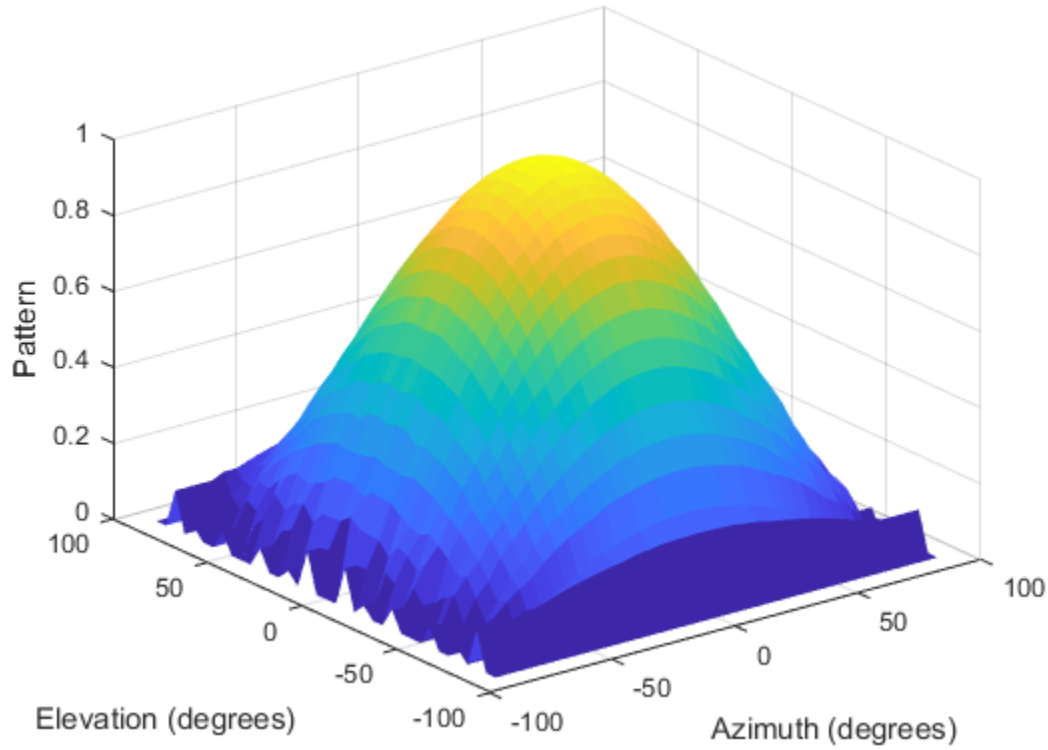
```
u = -1:0.01:1;
v = -1:0.01:1;
[u_grid,v_grid] = meshgrid(u,v);
pat_uv = sqrt(1 - u_grid.^2 - v_grid.^2);
pat_uv(hypot(u_grid,v_grid) >= 1) = 0;
```

Define the set of azimuth and elevation angles at which to sample the pattern. Then convert the pattern.

```
az = -90:5:90;
el = -90:5:90;
pat_azel = uv2azelpat(pat_uv,u,v,az,el);
```

Plot the pattern.

```
H = surf(az,el,pat_azel);
H.LineStyle = 'none';
xlabel('Azimuth (degrees)')
ylabel('Elevation (degrees)')
zlabel('Pattern')
```



Input Arguments

`pat_uv` — Antenna radiation pattern in *u*/*v* form

Q-by-P matrix

Antenna radiation pattern in *u*/*v* form, specified as a Q-by-P matrix. `pat_uv` samples the 3-D magnitude pattern in decibels in terms of *u* and *v* coordinates. P is the length of the `u` vector and Q is the length of the `v` vector.

Data Types: `double`

u — *u* coordinates
vector of length P

u coordinates at which `pat_uv` samples the pattern, specified as a vector of length P. Each coordinate is between –1 and 1.

Data Types: `double`

v — *v* coordinates
vector of length Q

v coordinates at which `pat_uv` samples the pattern, specified as a vector of length Q. Each coordinate is between –1 and 1.

Data Types: `double`

az — Azimuth angles
`[-90:90]` (default) | vector of length L

Azimuth angles at which `pat_azel` samples the pattern, specified as a vector of length L. Each azimuth angle is in degrees, between –90 and 90. Such azimuth angles are in the hemisphere for which *u* and *v* are defined.

Data Types: `double`

el — Elevation angles
`[-90:90]` (default) | vector of length M

Elevation angles at which `pat_azel` samples the pattern, specified as a vector of length M. Each elevation angle is in degrees, between –90 and 90.

Data Types: `double`

Output Arguments

pat_azel — Antenna radiation pattern in azimuth/elevation form
M-by-L matrix

Antenna radiation pattern in azimuth/elevation form, returned as an M-by-L matrix. `pat_azel` samples the 3-D magnitude pattern in decibels, in terms of azimuth and elevation angles. L is the length of the `az` vector, and M is the length of the `el` vector.

`az` — Azimuth angles

vector of length L

Azimuth angles at which `pat_azel` samples the pattern, returned as a vector of length L. Angles are expressed in degrees.

`el` — Elevation angles

vector of length M

Elevation angles at which `pat_azel` samples the pattern, returned as a vector of length M. Angles are expressed in degrees.

Definitions

U/V Space

The u and v coordinates are the direction cosines of a vector with respect to the y-axis and z-axis, respectively.

The u/v coordinates for the hemisphere $x \geq 0$ are derived from the phi and theta angles, as follows:

$$u = \sin\theta\cos\phi$$
$$v = \sin\theta\sin\phi$$

In these expressions, φ and θ are the phi and theta angles, respectively.

In terms of azimuth and elevation, the u and v coordinates are

$$u = \cos el \sin az$$
$$v = \sin el$$

The values of u and v satisfy the inequalities

$$-1 \leq u \leq 1$$
$$-1 \leq v \leq 1$$
$$u^2 + v^2 \leq 1$$

Conversely, the phi and theta angles can be written in terms of u and v using

$$\tan\phi = u / v$$

$$\sin\theta = \sqrt{u^2 + v^2}$$

The azimuth and elevation angles can also be written in terms of u and v

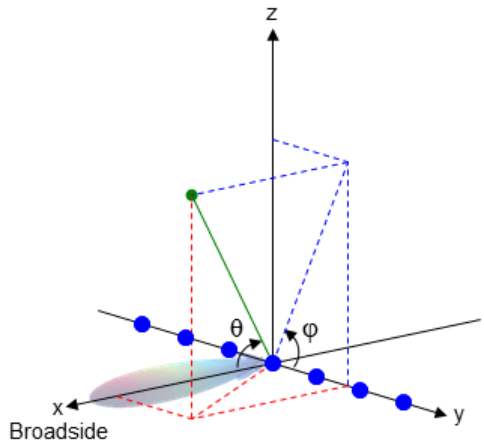
$$\sin el = v$$

$$\tan az = \frac{u}{\sqrt{1 - u^2 - v^2}}$$

Phi Angle, Theta Angle

The φ angle is the angle from the positive *y*-axis toward the positive *z*-axis, to the vector's orthogonal projection onto the *yz* plane. The φ angle is between 0 and 360 degrees. The θ angle is the angle from the *x*-axis toward the *yz* plane, to the vector itself. The θ angle is between 0 and 180 degrees.

The figure illustrates φ and θ for a vector that appears as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue circles.



The coordinate transformations between φ/θ and *az*/*el* are described by the following equations

$$\sin(\text{el}) = \sin\phi\sin\theta$$
$$\tan(\text{az}) = \cos\phi\tan\theta$$

$$\cos\theta = \cos(\text{el})\cos(\text{az})$$
$$\tan\phi = \tan(\text{el}) / \sin(\text{az})$$

Azimuth Angle, Elevation Angle

The *azimuth angle* of a vector is the angle between the *x*-axis and the orthogonal projection of the vector onto the *xy* plane. The angle is positive in going from the *x* axis toward the *y* axis. Azimuth angles lie between –180 and 180 degrees. The *elevation angle* is the angle between the vector and its orthogonal projection onto the *xy*-plane. The angle is positive when going toward the positive *z*-axis from the *xy* plane. These definitions assume the boresight direction is the positive *x*-axis.

Note: The elevation angle is sometimes defined in the literature as the angle a vector makes with the positive *z*-axis. The MATLAB and Phased Array System Toolbox products do not use this definition.

This figure illustrates the azimuth angle and elevation angle for a vector that appears as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue circles.

uv2phitheta

Convert u/v coordinates to phi/theta angles

Syntax

```
PhiTheta = uv2phitheta(UV)
```

Description

`PhiTheta = uv2phitheta(UV)` converts the *u*/*v* space coordinates to their corresponding phi/theta angle pairs.

Examples

Conversion of U/V Coordinates

Find the corresponding φ/θ representation for $u = 0.5$ and $v = 0$.

```
PhiTheta = uv2phitheta([0.5; 0])
```

```
PhiTheta =

         0
   30.0000
```

Input Arguments

UV — Angle in u/v space

two-row matrix

Angle in *u*/*v* space, specified as a two-row matrix. Each column of the matrix represents a pair of coordinates in the form [*u*; *v*]. Each coordinate is between –1 and 1, inclusive. Also, each pair must satisfy $u^2 + v^2 \leq 1$.

Data Types: `double`

Output Arguments

`PhiTheta` — Phi/theta angle pairs

two-row matrix

Phi and theta angles, returned as a two-row matrix. Each column of the matrix represents an angle in degrees, in the form [phi; theta]. The matrix dimensions of `PhiTheta` are the same as those of `UV`.

Definitions

U/V Space

The u/v coordinates for the positive hemisphere $x \geq 0$ can be derived from the phi and theta angles.

The relation between the two coordinates is

"Spherical Coordinates"

Introduced in R2012a

uv2phithetapat

Convert radiation pattern from u/v form to phi/theta form

Syntax

```
pat_phitheta = uv2phithetapat(pat_uv,u,v)
pat_phitheta = uv2phithetapat(pat_uv,u,v,phi,theta)
[pat_phitheta,phi,theta] = uv2phithetapat( ___ )
```

Description

`pat_phitheta = uv2phithetapat(pat_uv,u,v)` expresses the antenna radiation pattern `pat_phitheta` in φ/θ angle coordinates instead of u/v space coordinates. `pat_uv` samples the pattern at u angles in `u` and v angles in `v`. The `pat_phitheta` matrix uses a default grid that covers φ values from 0 to 360 degrees and θ values from 0 to 90 degrees. In this grid, `pat_phitheta` is uniformly sampled with a step size of 1 for φ and θ. The function interpolates to estimate the response of the antenna at a given direction.

`pat_phitheta = uv2phithetapat(pat_uv,u,v,phi,theta)` uses vectors `phi` and `theta` to specify the grid at which to sample `pat_phitheta`. To avoid interpolation errors, `phi` should cover the range [0, 360], and `theta` should cover the range [0, 90].

`[pat_phitheta,phi,theta] = uv2phithetapat( ___ )` returns vectors containing the φ and θ angles at which `pat_phitheta` samples the pattern, using any of the input arguments in the previous syntaxes.

Examples

Convert Radiation Pattern to φ-θ

Convert a radiation pattern to φ-θ space with the angles spaced 1° apart.

Define the pattern in terms of u and v. Because u and v values outside the unit circle are not physical, set the pattern values in this region to zero.

```
u = -1:0.01:1;
v = -1:0.01:1;
[u_grid,v_grid] = meshgrid(u,v);
pat_uv = sqrt(1 - u_grid.^2 - v_grid.^2);
pat_uv(hypot(u_grid,v_grid) >= 1) = 0;
```

Convert the pattern to φ-θ space.

```
[pat_phitheta,phi,theta] = uv2phithetapat(pat_uv,u,v);
```

Plot Converted Radiation Pattern

Convert a radiation pattern to $\phi - \theta$ space with the angles spaced one degree apart.

Define the pattern in terms of u and v. For values outside the unit circle, u and v are undefined, and the pattern value is 0.

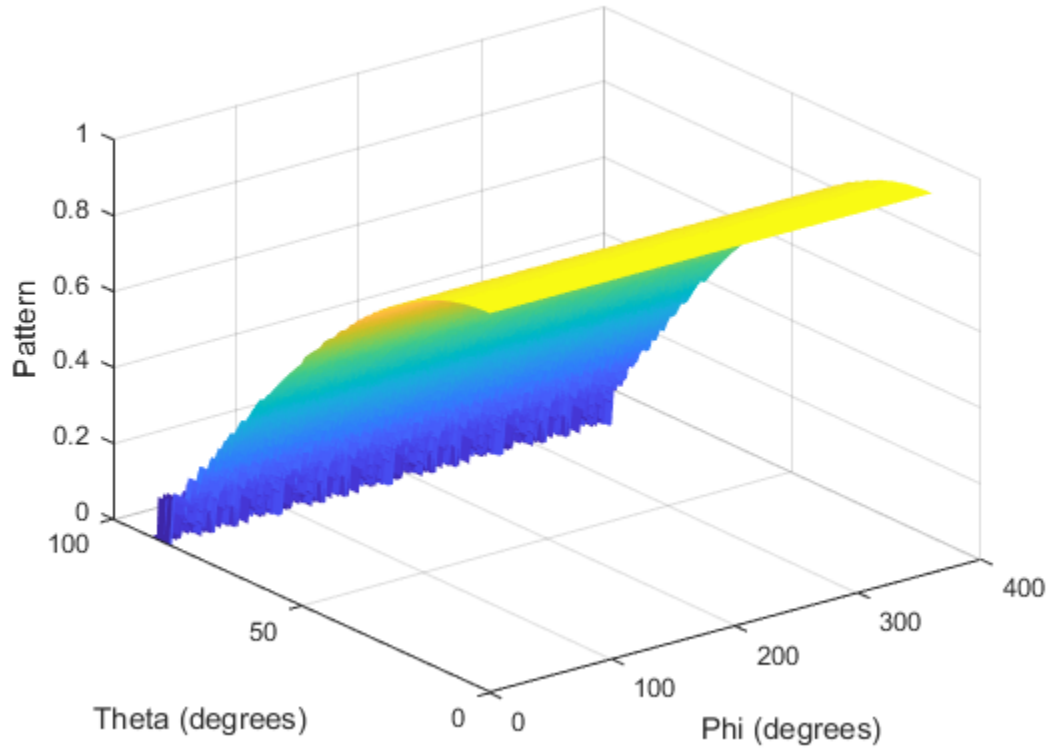
```
u = -1:0.01:1;
v = -1:0.01:1;
[u_grid,v_grid] = meshgrid(u,v);
pat_uv = sqrt(1 - u_grid.^2 - v_grid.^2);
pat_uv(hypot(u_grid,v_grid) >= 1) = 0;
```

Convert the pattern to $\phi - \theta$ space. Store the ϕ and θ angles for use in plotting.

```
[pat_phitheta,phi,theta] = uv2phithetapat(pat_uv,u,v);
```

Plot the result.

```
H = surf(phi,theta,pat_phitheta);
H.LineStyle = 'none';
xlabel('Phi (degrees)');
ylabel('Theta (degrees)');
zlabel('Pattern');
```



Convert Radiation Pattern Using Specific Phi/Theta Values

Convert a radiation pattern to $\phi - \theta$ space with the angles spaced five degrees apart.

Define the pattern in terms of u and v. For values outside the unit circle, u and v are undefined, and the pattern value is 0.

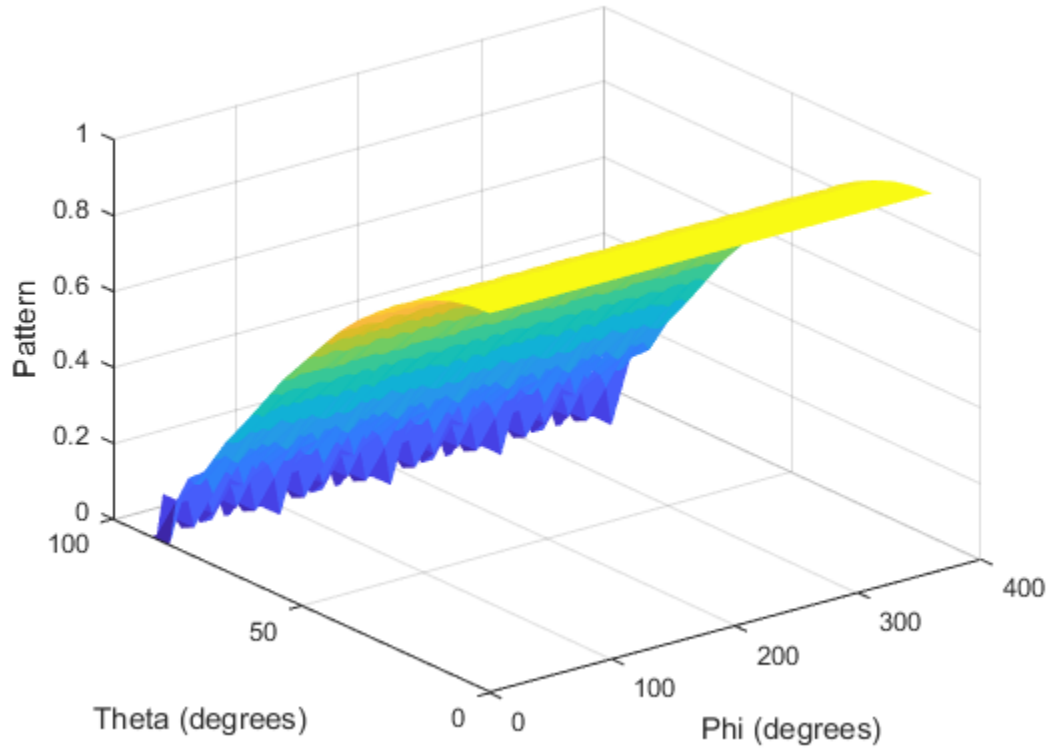
```
u = -1:0.01:1;
v = -1:0.01:1;
[u_grid,v_grid] = meshgrid(u,v);
pat_uv = sqrt(1 - u_grid.^2 - v_grid.^2);
pat_uv(hypot(u_grid,v_grid) >= 1) = 0;
```

Define the set of ϕ and θ angles at which to sample the pattern. Then, convert the pattern.

```
phi = 0:5:360;
theta = 0:5:90;
pat_phitheta = uv2phithetapat(pat_uv,u,v,phi,theta);
```

Plot the result.

```
H = surf(phi,theta,pat_phitheta);
H.LineStyle = 'none';
xlabel('Phi (degrees)');
ylabel('Theta (degrees)');
zlabel('Pattern');
```



Input Arguments

`pat_uv` — Antenna radiation pattern in *u*/*v* form

Q-by-P matrix

Antenna radiation pattern in *u*/*v* form, specified as a Q-by-P matrix. `pat_uv` samples the 3-D magnitude pattern in decibels, in terms of *u* and *v* coordinates. P is the length of the `u` vector, and Q is the length of the `v` vector.

Data Types: `double`

u — *u* coordinates
vector of length P

u coordinates at which `pat_uv` samples the pattern, specified as a vector of length P. Each coordinate is between –1 and 1.

Data Types: `double`

v — *v* coordinates
vector of length Q

v coordinates at which `pat_uv` samples the pattern, specified as a vector of length Q. Each coordinate is between –1 and 1.

Data Types: `double`

`phi` — Phi angles
`[0:360]` (default) | vector of length L

Phi angles at which `pat_phitheta` samples the pattern, specified as a vector of length L. Each φ angle is in degrees, between 0 and 360.

Data Types: `double`

`theta` — Theta angles
`[0:90]` (default) | vector of length M

Theta angles at which `pat_phitheta` samples the pattern, specified as a vector of length M. Each θ angle is in degrees, between 0 and 90. Such θ angles are in the hemisphere for which *u* and *v* are defined.

Data Types: `double`

Output Arguments

`pat_phitheta` — Antenna radiation pattern in phi/theta form
M-by-L matrix

Antenna radiation pattern in phi/theta form, returned as an M-by-L matrix. `pat_phitheta` samples the 3-D magnitude pattern in decibels, in terms of φ and θ angles. L is the length of the `phi` vector, and M is the length of the `theta` vector.

`phi` — Phi angles
vector of length L

Phi angles at which `pat_phitheta` samples the pattern, returned as a vector of length L. Angles are expressed in degrees.

`theta` — Theta angles
vector of length M

Theta angles at which `pat_phitheta` samples the pattern, returned as a vector of length M. Angles are expressed in degrees.

Definitions

U/V Space

The u and v coordinates are the direction cosines of a vector with respect to the y-axis and z-axis, respectively.

The u/v coordinates for the hemisphere $x \geq 0$ are derived from the phi and theta angles, as follows:

$$u = \sin\theta\cos\phi$$
$$v = \sin\theta\sin\phi$$

In these expressions, φ and θ are the phi and theta angles, respectively.

In terms of azimuth and elevation, the u and v coordinates are

$$u = \cos el \sin az$$
$$v = \sin el$$

The values of u and v satisfy the inequalities

$$-1 \leq u \leq 1$$
$$-1 \leq v \leq 1$$
$$u^2 + v^2 \leq 1$$

Conversely, the phi and theta angles can be written in terms of u and v using

$$\tan\phi = u / v$$
$$\sin\theta = \sqrt{u^2 + v^2}$$

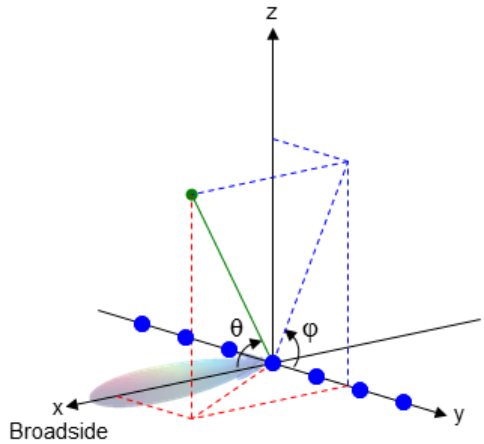
The azimuth and elevation angles can also be written in terms of u and v

$$\sin el = v$$
$$\tan az = \frac{u}{\sqrt{1 - u^2 - v^2}}$$

Phi Angle, Theta Angle

The φ angle is the angle from the positive y-axis toward the positive z-axis, to the vector's orthogonal projection onto the yz plane. The φ angle is between 0 and 360 degrees. The θ angle is the angle from the x-axis toward the yz plane, to the vector itself. The θ angle is between 0 and 180 degrees.

The figure illustrates φ and θ for a vector that appears as a green solid line. The coordinate system is relative to the center of a uniform linear array, whose elements appear as blue circles.



The coordinate transformations between φ/θ and *az*/*el* are described by the following equations

val2ind

Uniform grid index

Syntax

```
Ind = val2ind(Value,Delta)
Ind = val2ind(Value,Delta,GridStartValue)
```

Description

`Ind = val2ind(Value,Delta)` returns the index of the value `Value` in a uniform grid with a spacing between elements of `Delta`. The first element of the uniform grid is zero. If `Value` does not correspond exactly to an element of the grid, the next element is returned. If `Value` is a row vector, `Ind` is a row vector of the same size.

`Ind = val2ind(Value,Delta,GridStartValue)` specifies the starting value of the uniform grid as `GridStartValue`.

Examples

Compute Index of Value in Grid

Find the index corresponding to 0.0001 in a uniform grid with 1 MHz sampling rate.

```
fs = 1e6;
indx = val2ind(0.0001,1/fs)
```

```
indx =

   101
```

Compute Indices of Values in Grid

Find the indices corresponding to a vector of values in a uniform grid with 1 kHz sampling rate. Values are not divisible by 1/fs.

```
fs = 1.0e3;
values =[0.0095 0.0125 0.0225];
indx = val2ind(values,1/fs)

indx =

    11    14    24
```

Introduced in R2011a

waterfill

Waterfill MIMO power distribution

Syntax

```
P = waterfill(Pt,Pn)
waterfill(Pt,Pn)
```

Description

`P = waterfill(Pt,Pn)` optimally distributes the total transmitted power, `Pt`, among multiple channels to maximize channel capacity. The argument `Pn` represents the noise in each channel. The function can optimize independent subcarriers simultaneously.

`waterfill(Pt,Pn)` displays a waterfill diagram.

Examples

Compute Distributed Power Using Waterfill

Using the waterfill algorithm, compute the distributed power per channel for two subcarriers. There are four channels per subcarrier.

Specify the same total power for both subcarriers using a scalar value.

```
Pt = 10;
```

Specify the noise power. The rows correspond to the subcarriers and the columns to the channels.

```
Pn = [1 4 6 3; 5 4 3 6];
P = waterfill(Pt,Pn)
```

```
P =

     5     2     0     3
     2     3     4     1
```

Now, specify a different total power for each subcarrier.

```
Pt = [10,5];
P = waterfill(Pt,Pn)
```

```
P =

    5.0000    2.0000         0    3.0000

```

Plot Distributed Power Using Waterfill

Using the waterfill algorithm, plot the distributed power per channel for two subcarriers. There are four channels per subcarrier.

Specify a different total power for each subcarrier.

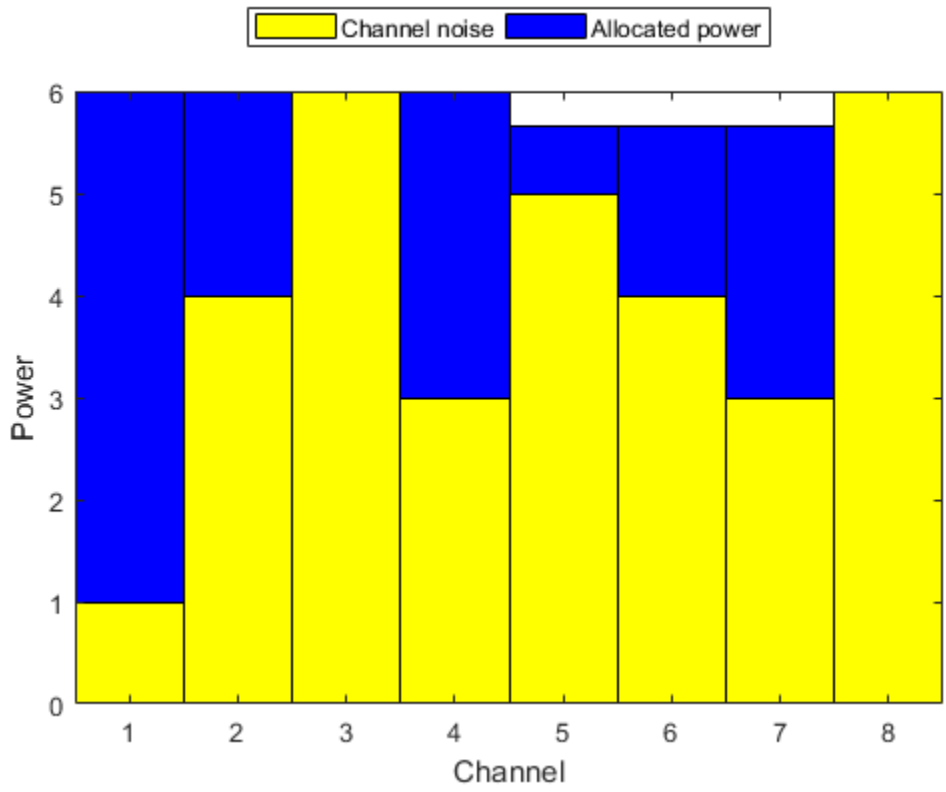
```
Pt = [10,5];
```

Specify the noise power. The rows correspond to the subcarriers and the columns to the channels.

```
Pn = [1 4 6 3; 5 4 3 6];
```

Display the waterfill plot.

```
waterfill(Pt,Pn)
```



Input Arguments

`Pt` — Total transmitted power

positive scalar | positive-valued L-element row or column vector

Total transmitted power per subcarrier, specified as a positive-valued L-element row or column vector where L is the number of subcarriers. When `Pt` is a scalar, all subcarriers have the same power. When `Pt` is a vector, the total power in a subcarriers is given by the corresponding element in `Pt`. Units are arbitrary.

Example: `[20 30]`

Data Types: `double`

`Pn` — Channel noise power

positive-valued N-element row or column vector | positive-valued L-by-N-element matrix

Channel noise powers, specified as a positive-valued N-element row or column vector or a positive-valued L-by-N-element matrix. N is the number of channels and L is the number of subcarriers. If `Pn` is a vector, each element represents the noise power in the corresponding channel. The noise powers for each channel is the same for all subcarriers. If `Pn` is a matrix, an element in the matrix represents the noise power in the corresponding channel at the corresponding subcarrier. Units are arbitrary but must match the units for `Pt`.

Example: `[10 20 15]`

Data Types: `double`

Output Arguments

`P` — Allocated power per channel

positive-valued L-by-N-element matrix

Allocated power per channel, specified as a positive-valued L-by-N-element matrix. N is the number of channels and L is the number of subcarriers. Units are the same as the transmitted power, `Pt`. Each row corresponds to a subcarrier and specifies the distributed power for the channels in the subcarrier. Units are the same as for `Pt` and `Pn`.

Data Types: `double`

Algorithms

The number of subcarriers is determined by either the dimensions of `Pt` or `Pn`.

- When you specify `Pt` as an L-element vector, there are L subcarriers with different total powers. If you specify `Pn` as N-element vector, this noise power vector is the same for all subcarriers. If you specify `Pn` as an L-by-N matrix, each row applies to the corresponding subcarrier.
- When you specify `Pt` as a scalar, `Pn` determines the number of subcarriers. If you specify `Pn` as an N-element vector, each element is the noise power in a channel

and there is only one subcarrier. If you specify `Pn` as an *L*-by-*N* matrix, there are *L* subcarriers all having the same transmitted power.

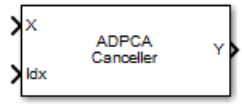
phased.ScatteringMIMOChannel

Introduced in R2017a

Blocks — Alphabetical List

ADPCA Canceller

Adaptive displaced phase center array (ADPCA) pulse canceller for a uniform linear array



Library

Space-Time Adaptive Processing

`phasedstaplib`

Description

The ADPCA Canceller block implements an adaptive displaced phase center array pulse canceller for a uniform linear array.

Parameters

Signal Propagation speed (m/s)

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

Operating frequency (Hz)

Specify the operating frequency of the system, in hertz, as a positive scalar.

Pulse repetition frequency (Hz)

Specify the pulse repetition frequency, PRF, as a scalar or a row vector. Units for PRF are hertz. This parameter should be set to the same value as used in any `Waveforms` library block.

Specify direction as

Specify whether the targeting direction for this STAP processor block comes from a block parameter or via an input port. Values of this parameter are

`Property`	• For the ADPCA Canceller and DPCA Canceller blocks, targeting direction is specified using **Receiving mainlobe direction (deg)**. • For the SMI Beamformer block, targeting direction is specified using **Targeting direction**. These parameters appear only when the **Specify direction as** parameter is set to `Property`.
`Input port`	Enter the targeting directions using the `Ang` port. This port appears only when **Specify direction as** is set to `Input port`.

Receiving mainlobe direction (deg)

Specify the mainlobe direction in degrees of the receiving sensor array as a 2-by-1 vector. The direction is specified in the format of `[AzimuthAngle; ElevationAngle]`. The azimuth angle should be between –180° and 180° and the elevation angle should be between –90° and 90°. This parameter appears only when you set **Specify direction as** to `Property`.

Number of bits in phase shifters

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

Specify targeting Doppler as

Specify whether targeting Doppler values for the STAP processor comes from the **Targeting Doppler (Hz)** parameter of this block or via an input port. For the ADPCA Cancellerand DPCA Canceller blocks, this parameter appears only when the **Output pre-Doppler result** check box is cleared. Values of this parameter are

`Property`	Targeting Doppler values are specified by the **Targeting Doppler** parameter of the block. The **Targeting Doppler** parameter appears only when **Specify targeting Doppler as** is set to `Property`.
`Input port`	Targeting Doppler values are entered using the `Dop` port. This port appears only when **Specify targeting Doppler as** is set to `Input port`.

Targeting Doppler (Hz)

Specify the targeting Doppler of the STAP processor as a scalar. This parameter appears only when you set **Specify targeting Doppler as** to `Property` and when, for the ADPCA Cancellerand DPCA Canceller blocks only, the **Output pre-Doppler result** check box is cleared.

Number of guard cells

Specify the number of guard cells used in the training as an even integer. This parameter specifies the total number of cells on both sides of the cell under test.

Number of training cells

Specify the number of training cells used in training as an even integer. Whenever possible, the training cells are equally divided into regions before and after the test cell.

Enable weights output

Select this check box to obtain the weights used in the STAP processor via the output port `W`. The output port `W` only appears when you select this check box.

Output pre-Doppler result

Select this check box to output the processing results before applying Doppler filtering. Clear this check box to output the processing result after Doppler filtering. Selecting this check box will remove the **Specify targeting Doppler as** and **Targeting Doppler (Hz)** parameters.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see "Choosing a Simulation Mode" (Simulink) from the Simulink documentation.

Array Parameters

Specify sensor array as

Specify a ULA sensor array directly or by using a MATLAB expression.

Types

`Array (no subarrays)`
`MATLAB expression`

Number of elements

Specifies the number of elements in the array as an integer.

Element spacing

Specify the spacing, in meters, between two adjacent elements in the array.

Array axis

This parameter appears when the **Geometry** parameter is set to `ULA` or when the block only supports a ULA array geometry. Specify the array axis as `x`, `y`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

Taper

Tapers, also known as *element weights*, are applied to sensor elements in the array. Tapers are used to modify both the amplitude and phase of the transmitted or received data.

Specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array. If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

Expression

A valid MATLAB expression containing a constructor for a uniform linear array, for example, `phased.ULA`.

Sensor Array Tab: Element Parameters

Element type

Specify antenna or microphone type as

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

Exponent of cosine pattern

This parameter appears when you set **Element type** to `Cosine Antenna`.

Specify the exponent of the cosine pattern as a scalar or a 1-by-2 vector. You must specify all values as non-negative real numbers. When you set **Exponent of cosine pattern** to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the specified value. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern and the second element is the exponent for the elevation direction cosine pattern.

Operating frequency range (Hz)

This parameter appears when **Element type** is set to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

Specify the operating frequency range, in hertz, of the antenna element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The antenna element has no response outside the specified frequency range.

Operating frequency vector (Hz)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify the frequencies, in Hz, at which to set the antenna and microphone frequency responses as a 1-by-*L* row vector of increasing values. Use **Frequency responses** to set the frequency responses. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of **Operating frequency vector (Hz)**.

Frequency responses (dB)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify this parameter as the frequency response of an antenna or microphone, in decibels, for the frequencies defined by **Operating frequency vector (Hz)**. Specify **Frequency responses (dB)** as a 1-by-*L* vector matching the dimensions of the vector specified in **Operating frequency vector (Hz)**.

Azimuth angles (deg)

This parameter appears when **Element type** is set to `Custom Antenna`.

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Angle units are in degrees. Azimuth angles must lie between –180° and 180° and be in strictly increasing order.

Elevation angles (deg)

This parameter appears when the **Element type** is set to `Custom Antenna`.

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90° and be in strictly increasing order.

Radiation pattern (dB)

This parameter appears when the **Element type** is set to `Custom Antenna`.

The magnitude in db of the combined polarized antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The value of *Q* must match the value of *Q* specified by **Elevation angles (deg)**. The value of *P* must match the value of *P* specified by **Azimuth angles (deg_**. The value of *L* must match the value of *L* specified by **Operating frequency vector (Hz)**.

Polar pattern frequencies (Hz)

This parameter appears when the **Element type** is set to `Custom Microphone`.

Specify the measuring frequencies of the polar patterns as a 1-by-*M* vector. The measuring frequencies lie within the frequency range specified by**Operating frequency vector (Hz)**. Frequency units are in Hz.

Polar pattern angles (deg)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the measuring angles of the polar patterns, as a 1-by-*N* vector. The angles are measured from the central pickup axis of the microphone, and must be between –180° and 180°, inclusive.

Polar pattern (dB)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the magnitude of the microphone element polar pattern as an *M*-by-*N* matrix. *M* is the number of measuring frequencies specified in **Polar pattern frequencies (Hz)**. *N* is the number of measuring angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

Baffle the back of the element

This check box appears only when the **Element type** parameter is set to `Isotropic Antenna` or `Omni Microphone`.

Select this check box to baffle the back of the antenna element. In this case, the antenna responses to all azimuth angles beyond ±90° from *broadside* are set to zero. Define the broadside direction as 0° azimuth angle and 0° elevation angle.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Description	Supported Data Types
`X`	Input signal The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.	Double-precision floating point
`Ang`	Targeting direction	Double-precision floating point
`Dop`	Targeting Doppler frequency	Double-precision floating point
`Idx`	Range cell index	Double-precision floating point
`W`	Processing weights	Double-precision floating point
`Y`	Doppler output	Double-precision floating point

Angle Doppler Response

Angle-Doppler response

Library

Space-Time Adaptive Processing

`phasedstaplib`

Description

The Angle Doppler Response block computes the angle-Doppler response of the input signal. The output response is a matrix whose rows represent Doppler bins and whose columns represent angle bins.

Parameters

Signal Propagation speed (m/s)

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

Operating frequency (Hz)

Specify the operating frequency of the system, in hertz, as a positive scalar.

Pulse repetition frequency (Hz)

Specify the pulse repetition frequency, PRF, as a scalar or a row vector. Units for PRF are hertz. This parameter should be set to the same value as used in any `Waveforms` library block.

Source of elevation angle

Specify whether the elevation angle comes from the **Elevation angle** parameter or from an input port. Values of this parameter are

`Property`	The **Elevation angle** parameter of this block specifies the elevation angle.
`Input port`	The elevation angle is set via the `El` input port.

Elevation angle (deg)

Specify the elevation angle used to calculate the angle-Doppler response as a scalar. Units are degrees. The angle must be between –90° and 90°. This parameter appears when you set **Source of elevation angle** to `Property`.

Number of angle bins

Specify the number of samples in the angular domain used to calculate the angle-Doppler response as a positive integer. This value must be greater than 2.

Number of Doppler bins

Specify the number of samples in the Doppler domain used to calculate the angle-Doppler response as a positive integer. This value must be greater than 2.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see "Choosing a Simulation Mode" (Simulink) from the Simulink documentation.

Array Parameters

Specify sensor array as

Sensor element or sensor array specified. A sensor array can also contain subarrays or as a partitioned array. This parameter can also be expressed as a MATLAB expression.

Types

`Array (no subarrays)`
`Partitioned array`
`Replicated subarray`
`MATLAB expression`

Geometry

Specify the array geometry as one of the following:

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array
- `Conformal Array` — arbitrary element positions

Number of elements

Number of array elements.

Number of array elements, specified as a positive integer. This parameter appears when the **Geometry** is set to ULA or UCA. If **Sensor Array** has a `Replicated subarray` option, this parameter applies to the sub-array.

Array size

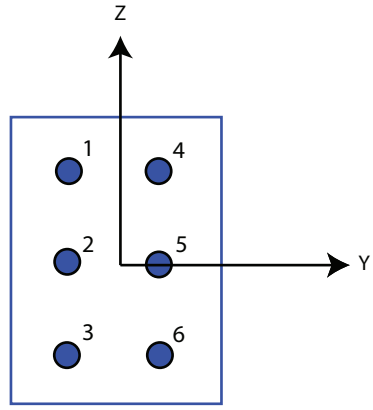
This parameter appears when **Geometry** is set to URA. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to the subarrays.

Specify the size of the array as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of rows and columns.

For a URA, elements are indexed from top to bottom along a column and continuing to the next columns from left to right. In this figure, an **Array size** of `[3,2]` produces an array of three rows and two columns.

Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]



Element spacing (m)

This parameter appears when **Geometry** is set to ULA or URA. When **Sensor Array** has the `Replicated subarray` option, this parameter applies to the subarrays.

- For a ULA, specify the spacing, in meters, between two adjacent elements in the array as a scalar.
- For a URA, specify the element spacing of the array, in meters, as a 1-by-2 vector or a scalar. If **Element spacing** is a 1-by-2 vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumns]`. For a discussion of these quantities, see phased.URA. If **Element spacing** is a scalar, the spacings between rows and columns are equal.

Array axis

This parameter appears when the **Geometry** parameter is set to ULA or when the block only supports a ULA array geometry. Specify the array axis as `x`, `y`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

Array normal

This parameter appears when you set **Geometry**to ULA or UCA. Specify the **Array normal** as `x`, `y`, or `z`. All URA and UCA array elements are placed in the *yz*, *zx*, or *xy*planes, respectively, of the array coordinate system.

Radius of UCA (m)

Radius of a uniform circular array specified as a positive scalar. Units are meters.

This parameter appears when the **Geometry** is set to UCA.

Taper

Tapers, also known as *element weights*, are applied to sensor elements in the array. Tapers are used to modify both the amplitude and phase of the transmitted or received data.

This parameter applies to all array types, but when you set **Sensor Array** to `Replicated subarray`, this parameter applies to subarrays.

- For a ULA or UCA, specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array. If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.
- For a URA, specify element tapering as a complex-valued scalar or complex-valued *M*-by-*N* matrix. In this matrix, *M* is the number of elements along the *z*-axis, and *N* is the number of elements along the *y*-axis. *M* and *N* correspond to the values

of `[NumberofArrayRows,NumberOfArrayColumns]` in the **Array size** matrix. If `Taper` is a scalar, the same weight is applied to each element. If **Taper** is a matrix, a weight from the matrix is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

- For a `Conformal Array`, specify element tapering as a complex-valued scalar or complex-valued 1-by-*N* vector. In this vector, *N* is the number of elements in the array as determined by the size of the **Element positions** vector. If **Taper** is a scalar, the same weight is applied to each element. If the value of **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

Element lattice

This parameter appears when **Geometry** is set to `URA`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to the subarray.

Specify the element lattice as `Rectangular` or `Triangular`

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular`— Shifts the even-row elements of a rectangular lattice toward the positive-row axis direction. The displacement is one-half the element spacing along the row dimension.

Element positions (m)

This parameter appears when **Geometry** is set to `Conformal Array`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to subarrays.

Specify the positions of conformal array elements as a 3-by-*N* matrix, where *N* is the number of elements in the conformal array. Each column of **Element positions (m)** represents the position of a single element, in the form `[x;y;z]`, in the array's local coordinate system. The local coordinate system has its origin at an arbitrary point. Units are in meters.

Element normals (deg)

This parameter appears when **Geometry** is set to `Conformal Array`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to subarrays.

Specify the normal directions of the elements in a conformal array as a 2-by-*N* matrix or a 2-by-1 column vector in degrees. The variable *N* indicates the number of elements in the array. If **Element normals (deg)** is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]`, with respect to the local coordinate system. The local

coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If **Element normals (deg)** is a 2-by-1 column vector, the vector specifies the same pointing direction for all elements in the array.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. You can combine translation, azimuth rotation, and elevation rotation transformations. However, you cannot use transformations that require rotation about the normal.

Subarray definition matrix

This parameter appears when **Sensor array** is set to `Partitioned array`.

Specify the subarray selection as an *M*-by-*N* matrix. *M* is the number of subarrays and *N* is the total number of elements in the array. Each row of the matrix indicates which elements belong to the corresponding subarray. Each entry in the matrix is 1 or 0, where 1 indicates that the element appears in the subarray and 0 indicates the opposite. Each row must contain at least one 1.

The phase center of each subarray is its geometric center. **Subarray definition matrix** and **Geometry** determine the geometric center.

Subarray steering method

This parameter appears when **Sensor array** is set to `Partitioned array` or `Replicated subarray`.

Specify the subarray steering method as

- `None`
- `Phase`
- `Time`

When using the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, or Wideband Transmit Arrayblocks, selecting `Phase` or `Time` opens the block input port, `Steer`.

Phase shifter frequency (Hz)

This parameter appears when you set **Sensor array** to `Partitioned array` or `Replicated subarray` and you set **Subarray steering method** to `Phase`.

Specify the operating frequency, in hertz, of phase shifters to perform subarray steering as a positive scalar.

Number of bits in phase shifters

This parameter appears when you set **Sensor array** to `Partitioned array` or `Replicated subarray` and you set **Subarray steering method** to `Phase`.

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

Subarrays layout

This parameter appears when you set **Sensor array** to `Replicated subarray`.

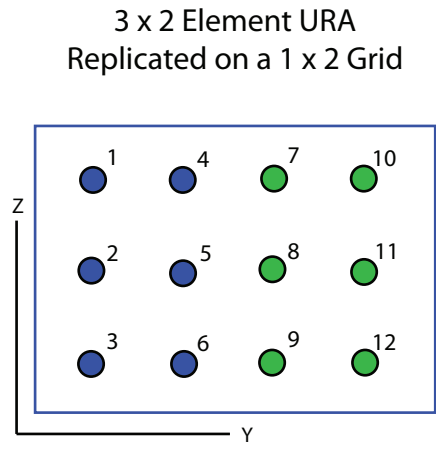
Specify the layout of the replicated subarrays as `Rectangular` or `Custom`.

Grid size

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

Rectangular subarray grid size, specified as a single positive integer or a positive integer-valued 1-by-2 row vector.

If **Grid size** is an integer scalar, the array has an equal number of subarrays in each row and column. If **Grid size** is a 1-by-2 vector of the form `[NumberOfRows, NumberOfColumns]`, the first entry is the number of subarrays along each column. The second entry is the number of subarrays in each row. A row is along the local *y*-axis, and a column is along the local *z*-axis. The figure here shows how you can replicate a 3-by-2 URA subarray using a **Grid size** of `[1,2]`.



Grid spacing

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

Specify the rectangular grid spacing of subarrays as a real-valued positive scalar, a 1-by-2 row vector, or `Auto`. Grid spacing units are expressed in meters.

- If **Grid spacing** is a scalar, the spacing along the row and the spacing along the column is the same.
- If **Grid spacing** is a 1-by-2 row vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumn]`. The first entry specifies the spacing between rows along a column. The second entry specifies the spacing between columns along a row.
- If **Grid spacing** is set to `Auto`, replication preserves the element spacing of the subarray for both rows and columns while building the full array. This option is available only when you specify **Geometry** as `ULA` or `URA`.

Subarray positions (m)

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Custom`.

Specify the positions of the subarrays in the custom grid as a 3-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix represents the position of a single subarray, in meters, in the array's local coordinate system. The coordinates are expressed in the form `[x; y; z]`.

Subarray normals

This parameter appears when you set the **Sensor array** parameter to `Replicated subarray` and the **Subarrays layout** to `Custom`.

Specify the normal directions of the subarrays in the array. This parameter value is a 2-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix specifies the normal direction of the corresponding subarray, in the form `[azimuth; elevation]`. Each angle is in degrees and is defined in the local coordinate system.

You can use the **Subarray positions** and **Subarray normals** parameters to represent any arrangement in which pairs of subarrays differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal.

Expression

A valid MATLAB expression containing an array constructor, for example, `phased.URA`.

Sensor Array Tab: Element Parameters

Element type

Specify antenna or microphone type as

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

Exponent of cosine pattern

This parameter appears when you set **Element type** to `Cosine Antenna`.

Specify the exponent of the cosine pattern as a scalar or a 1-by-2 vector. You must specify all values as non-negative real numbers. When you set **Exponent of cosine pattern** to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the specified value. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern and the second element is the exponent for the elevation direction cosine pattern.

Operating frequency range (Hz)

This parameter appears when **Element type** is set to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

Specify the operating frequency range, in hertz, of the antenna element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The antenna element has no response outside the specified frequency range.

Operating frequency vector (Hz)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify the frequencies, in Hz, at which to set the antenna and microphone frequency responses as a 1-by-*L* row vector of increasing values. Use **Frequency responses**

to set the frequency responses. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of **Operating frequency vector (Hz)**.

Frequency responses (dB)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify this parameter as the frequency response of an antenna or microphone, in decibels, for the frequencies defined by **Operating frequency vector (Hz)**. Specify **Frequency responses (dB)** as a 1-by-*L* vector matching the dimensions of the vector specified in **Operating frequency vector (Hz)**.

Azimuth angles (deg)

This parameter appears when **Element type** is set to `Custom Antenna`.

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Angle units are in degrees. Azimuth angles must lie between –180° and 180° and be in strictly increasing order.

Elevation angles (deg)

This parameter appears when the **Element type** is set to `Custom Antenna`.

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90° and be in strictly increasing order.

Radiation pattern (dB)

This parameter appears when the **Element type** is set to `Custom Antenna`.

The magnitude in db of the combined polarized antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The value of *Q* must match the value of *Q* specified by **Elevation angles (deg)**. The value of *P* must match the value of *P* specified by **Azimuth angles (deg_**. The value of *L* must match the value of *L* specified by **Operating frequency vector (Hz)**.

Polar pattern frequencies (Hz)

This parameter appears when the **Element type** is set to `Custom Microphone`.

Specify the measuring frequencies of the polar patterns as a 1-by-*M* vector. The measuring frequencies lie within the frequency range specified by**Operating frequency vector (Hz)**. Frequency units are in Hz.

Polar pattern angles (deg)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the measuring angles of the polar patterns, as a 1-by-*N* vector. The angles are measured from the central pickup axis of the microphone, and must be between –180° and 180°, inclusive.

Polar pattern (dB)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the magnitude of the microphone element polar pattern as an *M*-by-*N* matrix. *M* is the number of measuring frequencies specified in **Polar pattern frequencies (Hz)**. *N* is the number of measuring angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

Baffle the back of the element

This check box appears only when the **Element type** parameter is set to `Isotropic Antenna` or `Omni Microphone`.

Select this check box to baffle the back of the antenna element. In this case, the antenna responses to all azimuth angles beyond ±90° from *broadside* are set to zero. Define the broadside direction as 0° azimuth angle and 0° elevation angle.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Supported Data Types
`X`	Double-precision floating point

Port	Supported Data Types
`El`	Double-precision floating point
`Resp`	Double-precision floating point
`Ang`	Double-precision floating point
`Dop`	Double-precision floating point

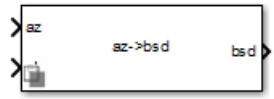
Azimuth Broadside Converter

Convert azimuth angle to broadside angle and vice versa



Library

Environment and Targets

`phasedenvlib`

Description

The Azimuth Broadside Converter block converts a direction expressed in terms of broadside angle for a given elevation angle to the corresponding azimuth angle or from azimuth angle to broadside angle.

Parameters

Conversion mode

Specify the direction of the conversion from broadside angle to azimuth angle or azimuth angle to broadside angle..

`broadside-> azimuth`	Convert a broadside angle and elevation angle to azimuth angle.
`azimuth-> broadside`	Convert a azimuth angle and elevation angle to broadside angle.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Supported Data Types
`bsd`	Double-precision floating point
`el`	Double-precision floating point
`az`	Double-precision floating point

Backscatter Radar Target

Backscatter radar target

Library

Environment and Targets

`phasedenvlib`

Description

The Backscatter Radar Target block models the monostatic case of reflection of nonpolarized electromagnetic signals from a radar target. Target model includes all four Swerling target fluctuation models and non-fluctuating model. You can model several targets simultaneously by specifying multiple radar cross-section matrices.

Parameters

Azimuth angles (deg)

Azimuth angles used to define the angular coordinates of the **RCS pattern (m^2)** parameter. Specify azimuth angles as a length P vector. Units are degrees. P must be greater than two. This parameter determines the incident azimuthal arrival angle of any element of the cross-section patterns.

Elevation angles (deg)

Elevation angles used to define the angular coordinates of the **RCS pattern (m^2)** parameter. Specify elevation angles as a length Q vector. Units are degrees. Q must be greater than two. This parameter determines the incident elevation arrival angle of any element of the cross-section patterns.

RCS pattern (m^2)

Radar cross-section pattern, specified as a *Q*-by-*P* complex-valued matrix or a *Q*-by-*P*-by-*M* complex-valued array.

- *Q* is the length of the vector in the **Elevation angles (deg)** parameter.
- *P* is the length of the vector in the **Azimuth angles (deg)** parameter.
- *M* is the number of target patterns. The number of patterns corresponds to the number of signals passed into the input port `X`. You can, however, use a single pattern to model multiple signals reflecting from a single target.

You can, however, use a single pattern to model multiple signals reflecting from a single target. Pattern units are square-meters.

Pattern units are square-meters.

Fluctuation model

Specify the statistical model of the target as either `Nonfluctuating`, `Swerling1`, `Swerling2`, `Swerling3`, or `Swerling4`. When you set this parameter to a value other than `Nonfluctuating`, you then set radar cross-sections parameters using the `Update` input port.

Signal Propagation speed (m/s)

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

Operating frequency (Hz)

Specify the carrier frequency of the signal that reflects from the target, as a positive scalar in hertz.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see "Choosing a Simulation Mode" (Simulink) from the Simulink documentation.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Description	Supported Data Types
`X`	Input signals. The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.	Double-precision floating point

Port	Description	Supported Data Types
`Ang`	Incident angle	Double-precision floating point
`Update`	Update RCS at block execution.	Double-precision floating point
`Out`	Scattered signal	Double-precision floating point

phased.BackscatterRadarTarget

Introduced in R2016a

Barrage Jammer

Barrage jammer interference source

Library

Environment and Target

`phasedenvlib`

Description

The Barrage Jammer block generates a wideband noise-like jamming signal.

Parameters

Effective radiated power (W)

Specify the effective radiated power (ERP) in watts of the jamming signal as a positive scalar.

Source of number of samples per frame

Specify the source for number of samples per frame as `Property` or `Derive from reference input port`. When you choose `Property`, the block obtains the number of samples from the **Number of samples per frame** parameter. When you choose `Derive from reference input port` the block uses the number of samples from a reference signal passed into the `Ref` input port.

Number of samples per frame

Specify the number of samples in the jamming signal output as a positive integer. The number of samples must match the number of samples produced by a signal source. This parameter appears only when **Source of number of samples per frame** is set to `Property`. As an example, if you use the Rectangular Waveform block as a signal source and set its **Output signal format** to `Samples`, the value

of **Number of samples per frame** should match the Rectangular Waveform block's **Number of samples in output** parameter. If you set the **Output signal format** to `Pulses`, the **Number of samples per frame** should match the product of **Sample rate** and **Number of pulses in output** divided by the **Pulse repetition frequency**.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see “Choosing a Simulation Mode” (Simulink) from the Simulink documentation.

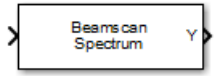
phased.BarrageJammer

Introduced in R2014b

Beamscan Spectrum

Beamscan spatial spectrum estimator



Library

Direction of Arrival (DOA)

`phaseddoalib`

Description

The Beamscan Spectrum block estimates the spatial spectrum of incoming narrowband signals by scanning a range of azimuth and elevation angles using a narrowband conventional beamformer. The block optionally calculates the direction of arrival of a specified number of signals by locating peaks of the spectrum.

Parameters

Signal Propagation speed (m/s)

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

Operating frequency (Hz)

Specify the operating frequency of the system, in hertz, as a positive scalar.

Number of bits in phase shifters

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

Forward-backward averaging

Select this parameter to use forward-backward averaging to estimate the covariance matrix for sensor arrays with a conjugate symmetric array manifold.

Azimuth scan angles (deg)

Specify the azimuth scan angles, in degrees, as a real vector. The angles must be between –180° and 180°, inclusive. You must specify the angles in ascending order.

Elevation scan angles (deg)

Specify the elevation scan angles, in degrees, as a real vector or scalar. The angles must be between –90° and 90°, inclusive. You must specify the angles in an ascending order.

Enable DOA output

Select this parameter to output the signals directions of arrival (DOA) through the **Ang** output port. Selecting this parameter enables the **Number of signals** parameter.

Number of signals

Specify the number of signals for DOA estimation as a positive scalar integer. This parameter appears when you select the **Enable DOA output** check box.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see "Choosing a Simulation Mode" (Simulink) from the Simulink documentation.

Array Parameters

Specify sensor array as

Specify a sensor array directly or by using a MATLAB expression.

Types

`Array (no subarrays)`
`MATLAB expression`

Geometry

Specify the array geometry as one of the following:

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array
- `Conformal Array` — arbitrary element positions

Number of elements

Number of array elements.

Number of array elements, specified as a positive integer. This parameter appears when the **Geometry** is set to `ULA` or `UCA`. If **Sensor Array** has a `Replicated subarray` option, this parameter applies to the sub-array.

Array size

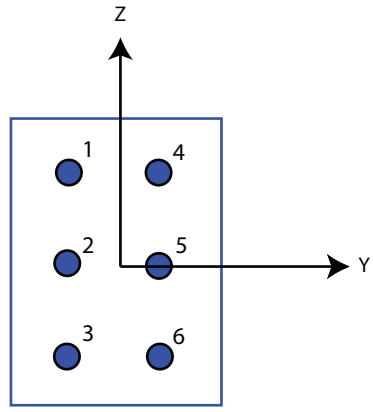
This parameter appears when **Geometry** is set to URA. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to the subarrays.

Specify the size of the array as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of rows and columns.

For a URA, elements are indexed from top to bottom along a column and continuing to the next columns from left to right. In this figure, an **Array size** of `[3,2]` produces an array of three rows and two columns.

Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]



Element spacing (m)

This parameter appears when **Geometry** is set to ULA or URA. When **Sensor Array** has the `Replicated subarray` option, this parameter applies to the subarrays.

- For a ULA, specify the spacing, in meters, between two adjacent elements in the array as a scalar.
- For a URA, specify the element spacing of the array, in meters, as a 1-by-2 vector or a scalar. If **Element spacing** is a 1-by-2 vector, the vector has the form

`[SpacingBetweenRows,SpacingBetweenColumns]`. For a discussion of these quantities, see phased.URA. If **Element spacing** is a scalar, the spacings between rows and columns are equal.

Array axis

This parameter appears when the **Geometry** parameter is set to `ULA` or when the block only supports a ULA array geometry. Specify the array axis as `x`, `y`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

Array normal

This parameter appears when you set **Geometry**to `URA` or `UCA`. Specify the **Array normal** as `x`, `y`, or `z`. All URA and UCA array elements are placed in the *yz*, *zx*, or *xy*planes, respectively, of the array coordinate system.

Radius of UCA (m)

Radius of a uniform circular array specified as a positive scalar. Units are meters.

This parameter appears when the **Geometry** is set to `UCA`.

Taper

Tapers, also known as *element weights*, are applied to sensor elements in the array. Tapers are used to modify both the amplitude and phase of the transmitted or received data.

This parameter applies to all array types, but when you set **Sensor Array** to `Replicated subarray`, this parameter applies to subarrays.

- For a `ULA` or `UCA`, specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array. If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.
- For a `URA`, specify element tapering as a complex-valued scalar or complex-valued *M*-by-*N* matrix. In this matrix, *M* is the number of elements along the *z*-axis, and *N* is the number of elements along the *y*-axis. *M* and *N* correspond to the values of `[NumberofArrayRows,NumberOfArrayColumns]` in the **Array size** matrix. If `Taper` is a scalar, the same weight is applied to each element. If **Taper** is a matrix, a weight from the matrix is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

- For a `Conformal Array`, specify element tapering as a complex-valued scalar or complex-valued 1-by-*N* vector. In this vector, *N* is the number of elements in the array as determined by the size of the **Element positions** vector. If **Taper** is a scalar, the same weight is applied to each element. If the value of **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

Element lattice

This parameter appears when **Geometry** is set to `URA`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to the subarray.

Specify the element lattice as `Rectangular` or `Triangular`

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular`— Shifts the even-row elements of a rectangular lattice toward the positive-row axis direction. The displacement is one-half the element spacing along the row dimension.

Element positions (m)

This parameter appears when **Geometry** is set to `Conformal Array`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to subarrays.

Specify the positions of conformal array elements as a 3-by-*N* matrix, where *N* is the number of elements in the conformal array. Each column of **Element positions (m)** represents the position of a single element, in the form `[x;y;z]`, in the array's local coordinate system. The local coordinate system has its origin at an arbitrary point. Units are in meters.

Element normals (deg)

This parameter appears when **Geometry** is set to `Conformal Array`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to subarrays.

Specify the normal directions of the elements in a conformal array as a 2-by-*N* matrix or a 2-by-1 column vector in degrees. The variable *N* indicates the number of elements in the array. If **Element normals (deg)** is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]`, with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If **Element normals (deg)** is a 2-by-1 column vector, the vector specifies the same pointing direction for all elements in the array.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. You can combine translation, azimuth rotation, and elevation rotation transformations. However, you cannot use transformations that require rotation about the normal.

Expression

A valid MATLAB expression containing an array constructor, for example, `phased.URA`.

Sensor Array Tab: Element Parameters

Element type

Specify antenna or microphone type as

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

Exponent of cosine pattern

This parameter appears when you set **Element type** to `Cosine Antenna`.

Specify the exponent of the cosine pattern as a scalar or a 1-by-2 vector. You must specify all values as non-negative real numbers. When you set **Exponent of cosine pattern** to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the specified value. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern and the second element is the exponent for the elevation direction cosine pattern.

Operating frequency range (Hz)

This parameter appears when **Element type** is set to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

Specify the operating frequency range, in hertz, of the antenna element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The antenna element has no response outside the specified frequency range.

Operating frequency vector (Hz)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify the frequencies, in Hz, at which to set the antenna and microphone frequency responses as a 1-by-L row vector of increasing values. Use **Frequency responses** to set the frequency responses. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of **Operating frequency vector (Hz)**.

Frequency responses (dB)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify this parameter as the frequency response of an antenna or microphone, in decibels, for the frequencies defined by **Operating frequency vector (Hz)**. Specify **Frequency responses (dB)** as a 1-by-L vector matching the dimensions of the vector specified in **Operating frequency vector (Hz)**.

Azimuth angles (deg)

This parameter appears when **Element type** is set to `Custom Antenna`.

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-P row vector. P must be greater than 2. Angle units are in degrees. Azimuth angles must lie between –180° and 180° and be in strictly increasing order.

Elevation angles (deg)

This parameter appears when the **Element type** is set to `Custom Antenna`.

Specify the elevation angles at which to compute the radiation pattern as a 1-by-Q vector. Q must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90° and be in strictly increasing order.

Radiation pattern (dB)

This parameter appears when the **Element type** is set to `Custom Antenna`.

The magnitude in db of the combined polarized antenna radiation pattern specified as a Q-by-P matrix or a Q-by-P-by-L array. The value of Q must match the value of Q specified by **Elevation angles (deg)**. The value of P must match the value of P specified by **Azimuth angles (deg_**. The value of L must match the value of L specified by **Operating frequency vector (Hz)**.

Polar pattern frequencies (Hz)

This parameter appears when the **Element type** is set to `Custom Microphone`.

Specify the measuring frequencies of the polar patterns as a 1-by-*M* vector. The measuring frequencies lie within the frequency range specified by**Operating frequency vector (Hz)**. Frequency units are in Hz.

Polar pattern angles (deg)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the measuring angles of the polar patterns, as a 1-by-*N* vector. The angles are measured from the central pickup axis of the microphone, and must be between –180° and 180°, inclusive.

Polar pattern (dB)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the magnitude of the microphone element polar pattern as an *M*-by-*N* matrix. *M* is the number of measuring frequencies specified in **Polar pattern frequencies (Hz)**. *N* is the number of measuring angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

Baffle the back of the element

This check box appears only when the **Element type** parameter is set to `Isotropic Antenna` or `Omni Microphone`.

Select this check box to baffle the back of the antenna element. In this case, the antenna responses to all azimuth angles beyond ±90° from *broadside* are set to zero. Define the broadside direction as 0° azimuth angle and 0° elevation angle.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Description	Supported Data Types
`In`	Input signal. The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.	Double-precision floating point
`Ang`	Signal direction of arrival.	Double-precision floating point
`Y`	Estimated spectrum.	Double-precision floating point

phased.BeamscanEstimator2D

Introduced in R2014b

Beamspace ESPRIT DOA

Beamspace ESPRIT direction of arrival (DOA) estimator for ULA

Library

Direction of Arrival (DOA)

`phaseddoalib`

Description

The Beamspace ESPRIT DOA block estimates the direction of arrival of a specified number of narrowband signals incident on a uniform linear array using the estimation of signal parameters via rotational invariance technique (ESPRIT) algorithm in beamspace.

Parameters

Signal Propagation speed (m/s)

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

Operating frequency (Hz)

Specify the operating frequency of the system, in hertz, as a positive scalar.

Number of signals

Specify the number of signals as a positive integer scalar.

Spatial smoothing

Specify the amount of averaging, *L*, used by spatial smoothing to estimate the covariance matrix as a nonnegative integer. Each increase in smoothing handles

one extra coherent source, but reduces the effective number of elements by one. The maximum value of this parameter is $N - 2$, where N is the number of sensors.

Type of least squares method

Specify the least squares method used for ESPRIT as one of `TLS` or `LS` where `TLS` refers to total least squares and `LS`refers to least squares.

Beam fan center direction (deg)

Specify the direction of the center of the beam fan, in degrees, as a real scalar value between –90° and 90°.

Source of number of beams

Specify the source of the number of beams as one of `Auto` or `Property`. If you set this parameter to `Auto`, the number of beams equals $N - L$, where N is the number of array elements and L is the value of **Spatial smoothing**.

Number of beams

Specify the number of beams as a positive scalar integer. The lower the number of beams, the greater the reduction in computational cost. This parameter appears when you set **Source of number of beams** to `Property`.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see "Choosing a Simulation Mode" (Simulink) from the Simulink documentation.

Array Parameters

Specify sensor array as

Specify a ULA sensor array directly or by using a MATLAB expression.

Types

`Array (no subarrays)`
`MATLAB expression`

Number of elements

Specifies the number of elements in the array as an integer.

Element spacing

Specify the spacing, in meters, between two adjacent elements in the array.

Array axis

This parameter appears when the **Geometry** parameter is set to `ULA` or when the block only supports a ULA array geometry. Specify the array axis as `x`, `y`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

Taper

Tapers, also known as *element weights*, are applied to sensor elements in the array. Tapers are used to modify both the amplitude and phase of the transmitted or received data.

Specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array. If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

Expression

A valid MATLAB expression containing a constructor for a uniform linear array, for example, `phased.ULA`.

Sensor Array Tab: Element Parameters

Element type

Specify antenna or microphone type as

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`

- `Custom Microphone`

Exponent of cosine pattern

This parameter appears when you set **Element type** to `Cosine Antenna`.

Specify the exponent of the cosine pattern as a scalar or a 1-by-2 vector. You must specify all values as non-negative real numbers. When you set **Exponent of cosine pattern** to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the specified value. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern and the second element is the exponent for the elevation direction cosine pattern.

Operating frequency range (Hz)

This parameter appears when **Element type** is set to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

Specify the operating frequency range, in hertz, of the antenna element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The antenna element has no response outside the specified frequency range.

Operating frequency vector (Hz)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify the frequencies, in Hz, at which to set the antenna and microphone frequency responses as a 1-by-L row vector of increasing values. Use **Frequency responses** to set the frequency responses. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of **Operating frequency vector (Hz)**.

Frequency responses (dB)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify this parameter as the frequency response of an antenna or microphone, in decibels, for the frequencies defined by **Operating frequency vector (Hz)**. Specify **Frequency responses (dB)** as a 1-by-L vector matching the dimensions of the vector specified in **Operating frequency vector (Hz)**.

Azimuth angles (deg)

This parameter appears when **Element type** is set to `Custom Antenna`.

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-P row vector. P must be greater than 2. Angle units are in degrees. Azimuth angles must lie between –180° and 180° and be in strictly increasing order.

Elevation angles (deg)

This parameter appears when the **Element type** is set to `Custom Antenna`.

Specify the elevation angles at which to compute the radiation pattern as a 1-by-Q vector. Q must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90° and be in strictly increasing order.

Radiation pattern (dB)

This parameter appears when the **Element type** is set to `Custom Antenna`.

The magnitude in db of the combined polarized antenna radiation pattern specified as a Q-by-P matrix or a Q-by-P-by-L array. The value of Q must match the value of Q specified by **Elevation angles (deg)**. The value of P must match the value of P specified by **Azimuth angles (deg_**. The value of L must match the value of L specified by **Operating frequency vector (Hz)**.

Polar pattern frequencies (Hz)

This parameter appears when the **Element type** is set to `Custom Microphone`.

Specify the measuring frequencies of the polar patterns as a 1-by-*M* vector. The measuring frequencies lie within the frequency range specified by**Operating frequency vector (Hz)**. Frequency units are in Hz.

Polar pattern angles (deg)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the measuring angles of the polar patterns, as a 1-by-*N* vector. The angles are measured from the central pickup axis of the microphone, and must be between –180° and 180°, inclusive.

Polar pattern (dB)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the magnitude of the microphone element polar pattern as an *M*-by-*N* matrix. *M* is the number of measuring frequencies specified in **Polar pattern frequencies (Hz)**. *N* is the number of measuring angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

Baffle the back of the element

This check box appears only when the **Element type** parameter is set to `Isotropic Antenna` or `Omni Microphone`.

Select this check box to baffle the back of the antenna element. In this case, the antenna responses to all azimuth angles beyond ±90° from *broadside* are set to zero. Define the broadside direction as 0° azimuth angle and 0° elevation angle.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Description	Supported Data Types
`In`	Input signal. The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.	Double-precision floating point
`Ang`	Estimated DOA angles.	Double-precision floating point

CFAR Detector

Constant false alarm rate (CFAR) detector

Library

Detection

`phaseddetectlib`

Description

The CA CFAR block implements a constant false-alarm rate detector using an estimate of the noise power. The CFAR detector estimates noise power from neighboring cells surrounding the cell under test. There are four methods for estimating noise: cell-averaging (CA), greatest-of cell averaging (GOCA), smallest-of cell averaging (SOCA), and order statistics (OS).

Parameters

CFAR algorithm

Specify the CFAR detection algorithm using one of the values

`CA`	Cell-averaging
`GOCA`	Greatest-of cell averaging
`OS`	Order statistic
`SOCA`	Smallest-of cell averaging

Number of guard cells

Specify the number of guard cells used in training as an even integer. This parameter specifies the total number of cells on both sides of the cell under test.

Number of training cells

Specify the number of training cells used in training as an even integer. Whenever possible, the training cells are equally divided before and after the cell under test.

Rank of order statistic

This parameter appears when **CFAR algorithm** is set to `OS`. Specify the rank of the order statistic as a positive integer scalar. The value must be less than or equal to the value of **Number of training cells**.

Threshold factor method

Specify whether the threshold factor comes from an automatic calculation, the **Custom threshold factor** parameter, or an input argument. Values of this parameter are:

`Auto`	The application calculates the threshold factor automatically based on the desired probability of false alarm specified in the **Probability of false alarm** parameter. The calculation assumes each independent signal in the input is a single pulse coming out of a square law detector with no pulse integration. The calculation also assumes the noise is white Gaussian.
`Custom`	The **Custom threshold factor** parameter specifies the threshold factor.
`Input port`	Threshold factor is set using the input port `K`. This port appears only when **Threshold factor method** is set to `Input port`.

Probability of false alarm

This parameter appears only when you set **Threshold factor method** to `Auto`. Specify the desired probability of false alarm as a scalar between 0 and 1 (not inclusive).

Custom threshold factor

This parameter appears only when you set **Threshold factor method** to `Custom`. Specify the custom threshold factor as a positive scalar.

Output format

Format of detection results returned in output port `Y`, by the specified as `'CUT result'` or `'Detection index'`.

- When set to `'CUT result'`, the results are logical detection values (`1` or `0`) for each tested cell. `1` indicates that the value of the tested cell exceeds a detection threshold.
- When set to `'Detection index'`, the results form a vector or matrix containing the indices of tested cells which exceed a detection threshold.

Output detection threshold

Select this check box to create an output port `Th` containing the detection threshold.

Output estimated noise power

Select this check box to create an output port `N` containing the estimated noise.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`

`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see "Choosing a Simulation Mode" (Simulink) from the Simulink documentation.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Description	Supported Data Types
`X`	Input cell matrix. The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.	Double-precision floating point
`Idx`	Cells under test.	Double-precision floating point
`K`	Threshold factor.	Double-precision floating point
`N`	Noise power.	Double-precision floating point
`Y`	Detection results.	Double-precision floating point

Blocks
`2-D CFAR Detector`

Introduced in R2014b

2-D CFAR Detector

Two-dimensional constant false alarm rate (CFAR) detector
Library: Phased Array System Toolbox / Detection

Description

The 2-D CFAR Detector block implements a constant false-alarm rate detector for two dimensional image data. A detection is declared when an image cell value exceeds a threshold. To maintain a constant false alarm-rate, the threshold is set to a multiple of the image noise power. The detector estimates noise power from neighboring cells surrounding the cell-under-test *(CUT)* using one of three cell averaging methods, or an order statistics method. The cell-averaging methods are cell-averaging (CA), greatest-of cell averaging (GOCA), or smallest-of cell averaging (SOCA).

For each test cell, the detector:

1. estimates the noise statistic from the cell values in the training band surrounding the CUT cell.
2. computes the threshold by multiplying the noise estimate by the threshold factor.
3. compares the CUT cell value to the threshold to determine whether a target is present or absent. If the value is greater than the threshold, a target is present.

Ports

Input

X — Input image

real *M*-by-*N* matrix | real *M*-by-*N*-by-*P* array

Input image, specified as a real *M*-by-*N* matrix or real *M*-by-*N*-by-*P* array. *M* and *N* represent the rows and columns of the matrix. Each page is a different 2-D signal.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Data Types: `double`
Complex Number Support: Yes

`idx` — Location of test cells

2-by-*L* matrix of positive integers

Location of test cells, specified as a *2*-by-*L* matrix of positive integers, where *L* is the number of test cells. Each column of `idx` specifies the row and column index of a CUT cell. The locations of CUT cells are restricted so that their training regions lie completely within the input images.

Data Types: `double`

`K` — Detection threshold factor

positive scalar

Threshold factor used to calculate the detection threshold, specified as a positive scalar.

Dependencies

To enable this port, set the **Threshold factor method** parameter to `'Input port'`

Data Types: `double`

Output

`Y` — Detection results

logical matrix (default) | real-valued matrix

Detection results, whose format depends on the `Output Format` property

- When `OutputFormat` is `'Cut result'`, `Y` is a *D*-by-*P* matrix containing logical detection results for cells under test. *D* is the length of `cutidx` and *P* is the number of pages of `X`. The rows of `Y` correspond to the rows of `cutidx`. For each row, `Y` contains `1`

in a column if there is a detection in the corresponding cell in `X`. Otherwise, `Y` contains a `0`.

- When `OutputFormat` is `Detection index`, `Y` is a K-by-L matrix containing detections indices. K is the number of dimensions of `X`. L is the number of detections found in the input data. When `X` is a matrix, `Y` contains the row and column indices of each detection in `X` in the form `[detrow;detcol]`. When `X` is an array, `Y` contains the row, column, and page indices of each detection in `X` in the form `[detrow;detcol;detpage]`. When the `NumDetectionsSource` property is set to `'Property'`, L equals the value of the `NumDetections` property. If the number of actual detections is less than this value, columns without detections are set to `NaN`.

Data Types: `double`

`Th` — Computed detection threshold

real-valued matrix

Computed detection threshold for each detected cell, returned as a real-valued matrix. `Th` has the same dimensions as `Y`.

- When `OutputFormat` is `'CUT result'`, `Th` returns the detection threshold whenever an element of `Y` is `1` and `NaN` whenever an element of `Y` is `0`.
- When `OutputFormat` is `Detection index`, `th` returns a detection threshold for each corresponding detection in `Y`. When the `NumDetectionsSource` property is set to `'Property'`, L equals the value of the `NumDetections` property. If the number of actual detections is less than this value, columns without detections are set to `NaN`.

Dependencies

To enable this port, select the **Output detection threshold** checkbox.

Data Types: `double`

`N` — Estimated noise power

real-valued matrix

Estimated noise power for each detected cell, returned as a real-valued matrix. `noise` has the same dimensions as `Y`.

- When `OutputFormat` is `'CUT result'`, `noise` returns the noise power whenever an element of `Y` is `1` and `NaN` whenever an element of `Y` is `0`.

- When `OutputFormat` is `'Detection index'`, `noise` returns a noise power for each corresponding detection in `Y`. When the `NumDetectionsSource` property is set to `'Property'`, L equals the value of the `NumDetections` property. If the number of actual detections is less than this value, columns without detections are set to `NaN`.

Dependencies

To enable this port, select the **Output estimated noise power** checkbox.

Data Types: `double`

Parameters

`CFAR algorithm` — Noise power estimation algorithm

`CA` (default) | `GOCA` | `SOCA` | `OS`

Noise power estimation algorithm, specified as `CA`, `GOCA`, `SOCA`, or `OS`. For `CA`, `GOCA`, `SOCA`, the noise power is the sample mean derived from the training band. For `OS`, the noise power is the kth cell value obtained from a numerical ordering of all training cell values. Set k by the **Rank of order statistic** parameter. See "Training cells" on page 3-60.

Averaging Method	Description
`CA` — Cell-averaging algorithm	Computes the sample mean of all training cells surrounding the CUT cell.
`GOCA` — Greatest-of cell-averaging algorithm	Splits the 2-D training window surrounding the CUT cell into left and right halves. Then, the algorithm computes the sample mean for each half and selects the largest mean.
`SOCA` — Smallest-of cell-averaging algorithm	Splits the 2-D training window surrounding the CUT cell into left and right halves. Then, the algorithm computes the sample mean for each half and selects the smallest mean.
`OS` — Order statistic algorithm	Sorts training cells in ascending order of numeric values. Then the algorithm selects

Averaging Method	Description
	the kth value from the list. k is the rank specified by the `Rank` parameter.

`Rank of order statistic` — Rank of order statistic
`1` (default) | positive integer

Specify the rank of the order statistic used in the 2-D CFAR algorithm as a positive integer. The value of this parameter must lie between 1 and N_{train}, where N_{train} is the number of training cells. A value of 1 selects the smallest value in the training region.

Dependencies

To enable this parameter, set the **CFAR Algorithm** parameter to `OS`.

`Size in cells of the guard region band` — Widths of guard band
`[1,1]` (default) | nonnegative integer scalar | 2-element vector of positive integers

The number of row and column guard cells on each side of the cell under test as nonnegative integers. The first element specifies the guard band size along the row dimension. The second element specifies the guard band size along the row dimension. Specifying **Size in cells of the guard region band** as a scalar is equivalent to specifying a vector with the same value for both dimensions. For example, a value of `[1 1]`, indicates that there is a one-guard-cell-wide region surrounding each CUT cell.

`Size in cells of the training region band` — Widths of training band
`[1,1]` (default) | nonnegative integer scalar | 2-element vector of positive integers

Size in cells of the training region band, specified as a nonnegative integer or 1-by-2 matrix of nonnegative integers. The first element specifies the training band size along the row dimension, and the second along the column dimension. Specifying **Size in cells of the training region band** as a scalar is equivalent to specifying a vector with the same value for both dimensions. For example, a value of `[1 1]` indicates that there is a one-training-cell-wide region surrounding the guard region for each cell under test.

`Threshold factor method` — Method to determine threshold factor
`Auto` (default) | `Input port` | `Custom`

Method to determine threshold factor, specified as `Auto`, `Input port`, or `Custom`.

- When you choose `Auto`, the threshold factor is determined from the estimated noise statistic and the probability of false alarm.
- When you choose `Input Port`, set the threshold factor using the `K` input port.
- When you choose `Custom`, set the threshold factor using the **Custom threshold factor** parameter.

`Custom threshold factor` — Custom threshold factor

`1` (default) | positive scalar

Custom threshold factor, specified as a positive scalar.

Dependencies

To enable this parameter, set the **Threshold factor method** parameter to `Custom`.

`Probability of false alarm` — Probability of false alarm

`0.1` (default) | real scalar between 0 and 1

Probability of false alarm, specified as a real scalar between 0 and 1. You can calculate the threshold factor from the required probability of false alarm.

Dependencies

To enable this parameter, set the **Threshold factor method** property to `Auto`.

`OutputFormat` — Format of detection results

`CUT result` (default) | `Detection index`

Format of detection results, specified as `CUT result` or `Detection index`.

- When set to `'CUT result'`, the detection results are logical detection values (`1` or `0`) for each tested cell.
- When set to `'Detection index'`, the results form a vector or matrix containing the indices of tested cells that exceed a detection threshold.

`Output threshold detection` — Enable detection threshold output

off (default)

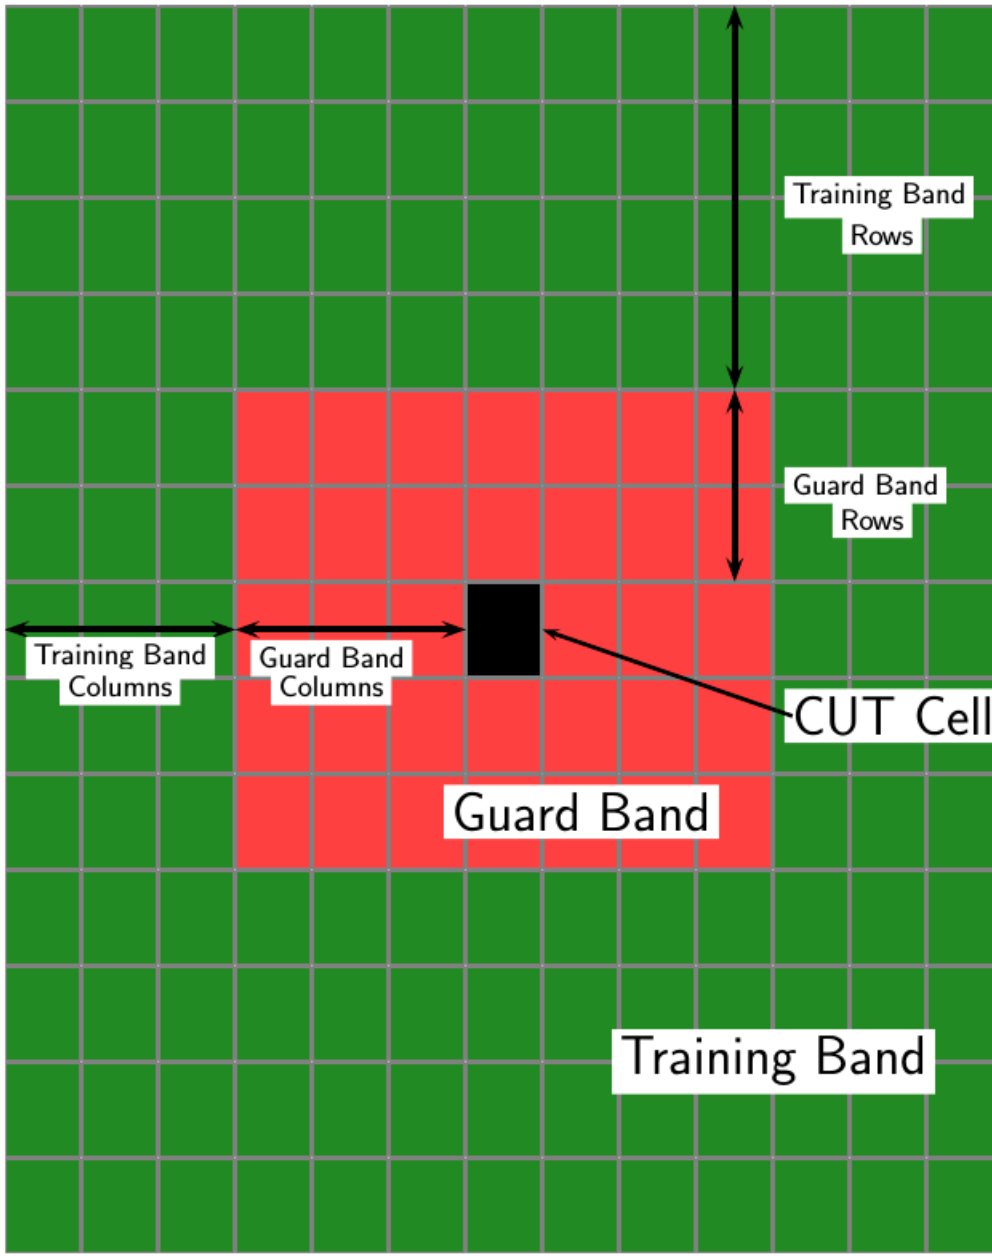
Select this checkbox to enable the output of detection thresholds via the `Th` output port.

`Output estimated noise power` — Enable detection threshold output
off (default)

Select this checkbox to enable the output of estimated noise power via the `N` output port.

Training cells

CFAR 2-D requires an estimate of the noise power. Noise power is computed from cells that are assumed not to contain any target signal. These cells are the *training cells*. Training cells form a band around the cell-under-test (CUT) cell but may be separated from the CUT cell by a guard band. The detection threshold is computed by multiplying the noise power by the threshold factor.



Training Band
Rows
Guard Band
Rows
Training Band
Columns
Guard Band
Columns
CUT Cell
Guard Band
Training Band

For GOCA and SOCA averaging, the noise power is derived from the mean value of one of the left or right halves of the training cell region.

Because the number of columns in the training region is odd, the cells in the middle column are assigned equally to either the left or right half.

When using the order-statistic method, the rank cannot be larger than the number of cells in the training cell region, N_{train}. You can compute N_{train}.

- N_{TC} is the number of training band columns.
- N_{TR} is the number of training band rows.
- N_{GC} is the number of guard band columns.
- N_{GR} is the number of guard band rows.

The total number of cells in the combined training region, guard region, and CUT cell is $N_{total} = (2N_{TC} + 2N_{GC} + 1)(2N_{TR} + 2N_{GR} + 1)$.

The total number of cells in the combined guard region and CUT cell is $N_{guard} = (2N_{GC} + 1)(2N_{GR} + 1)$.

The number of training cells is $N_{train} = N_{total} - N_{guard}$.

By construction, the number of training cells is always even. Therefore, to implement a median filter, you can choose a rank of $N_{train}/2$ or $N_{train}/2 + 1$.

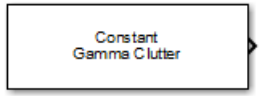
Blocks

`CFAR Detector`

Introduced in R2016b

Constant Gamma Clutter

Constant gamma clutter simulation



Library

Environment and Targets

`phasedenvlib`

Description

The Constant Gamma Clutter block generates constant gamma clutter reflected from homogeneous terrain for a monostatic radar transmitting a narrowband signal into free space. The radar is assumed to be at constant altitude moving at constant speed.

Parameters

Terrain gamma value (dB)

Specify the γ value used in the constant γ clutter model, as a scalar in dB. The γ value depends on both terrain type and the operating frequency.

Earth model

Specify the earth model used in clutter simulation as `Flat` or `Curved`. When you set this parameter to `Flat`, the earth is assumed to be a flat plane. When you set this parameter to `Curved`, the earth is assumed to be a sphere.

Maximum range (m)

Specify the maximum range in meters for the clutter simulation as a positive scalar. The maximum range must be greater than the value specified in the **Radar height** parameter on the **Radar** panel.

Azimuth coverage (deg)

Specify the azimuth coverage in degrees as a positive scalar. The clutter simulation covers a region having the specified azimuth span, symmetric to zero degrees azimuth. Typically, all clutter patches have their azimuth centers within the region, but by setting the **Clutter patch azimuth span** value, you can cause some patches to extend beyond the region.

Clutter patch azimuth span (deg)

Specify the azimuth span of each clutter patch in degrees as a positive scalar.

Clutter coherence time (s)

Specify the coherence time in seconds for the clutter simulation as a positive scalar. After the coherence time elapses, block updates the random numbers it uses for the clutter simulation at the next pulse. A value of `inf` means the random numbers are never updated.

Signal Propagation speed (m/s)

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

Sample rate (Hz)

Specify the signal sample rate in hertz as a positive scalar. This parameter should be set to the same value as used in any of the **Waveforms** library blocks.

Pulse repetition frequency (Hz)

Specify the pulse repetition frequency, PRF, as a scalar or a row vector. Units for PRF are hertz. This parameter should be set to the same value as used in any `Waveforms` library block.

Output signal format

Specify the format of the output signal as one of `Pulses` or `Samples`.

This parameter should be set to the same value as used in any **Waveforms** library blocks.

Number of pulses in output

Specify the number of pulses in the block output as a positive integer. This parameter appears only when you set the **Output signal format** parameter to `Pulses` and should be set to the same value as used in any **Waveforms** library blocks.

Number of samples in output

Specify the number of samples in the block output as a positive integer. This parameter appears only when you set the **Output signal format** parameter to `Samples` and should be set to the same value as used in any **Waveforms** library blocks.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see “Choosing a Simulation Mode” (Simulink) from the Simulink documentation.

Operating frequency (Hz)

Specify the operating frequency of the system, in hertz, as a positive scalar.

Effective transmitted power (W)

Specify the transmitted effective radiated power (ERP) of the radar system in watts as a positive scalar.

Radar height (m)

Specify the radar platform height (in meters) measured upward from the surface as a nonnegative scalar.

Radar speed (m/s)

Specify the radar platform's speed as a nonnegative scalar in meters per second.

Radar motion direction (deg)

Specify the direction of radar platform motion as a 2-by-1 vector in the form `[AzimuthAngle; ElevationAngle]` in degrees. Both azimuth and elevation angle are measured in the local coordinate system of the radar antenna or antenna array. Azimuth angle must be between –180° and 180°. Elevation angle must be between –90° and 90°.

Broadside depression angle (deg)

Specify the depression angle of the radar antenna array in degrees with respect to broadside as a scalar. Broadside is defined as zero degrees azimuth and zero degrees elevation. The depression angle is measured downward from the horizontal.

Array Parameters

Specify sensor array as

Sensor element or sensor array specified. A sensor array can also contain subarrays or as a partitioned array. This parameter can also be expressed as a MATLAB expression.

Types

`Single element`
`Array (no subarrays)`
`Partitioned array`
`Replicated subarray`

```
MATLAB expression
```

Geometry

Specify the array geometry as one of the following:

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array
- `Conformal Array` — arbitrary element positions

Number of elements

Number of array elements.

Number of array elements, specified as a positive integer. This parameter appears when the **Geometry** is set to `ULA` or `UCA`. If **Sensor Array** has a `Replicated subarray` option, this parameter applies to the sub-array.

Array size

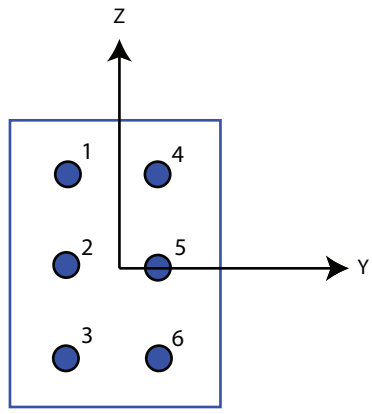
This parameter appears when **Geometry** is set to `URA`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to the subarrays.

Specify the size of the array as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of rows and columns.

For a URA, elements are indexed from top to bottom along a column and continuing to the next columns from left to right. In this figure, an **Array size** of `[3,2]` produces an array of three rows and two columns.

Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]



Element spacing (m)

This parameter appears when **Geometry** is set to ULA or URA. When **Sensor Array** has the `Replicated subarray` option, this parameter applies to the subarrays.

- For a ULA, specify the spacing, in meters, between two adjacent elements in the array as a scalar.
- For a URA, specify the element spacing of the array, in meters, as a 1-by-2 vector or a scalar. If **Element spacing** is a 1-by-2 vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumns]`. For a discussion of these quantities, see phased.URA. If **Element spacing** is a scalar, the spacings between rows and columns are equal.

Array axis

This parameter appears when the **Geometry** parameter is set to ULA or when the block only supports a ULA array geometry. Specify the array axis as `x`, `y`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

Array normal

This parameter appears when you set **Geometry**to URA or UCA. Specify the **Array normal** as `x`, `y`, or `z`. All URA and UCA array elements are placed in the *yz*, *zx*, or *xy*planes, respectively, of the array coordinate system.

Radius of UCA (m)

Radius of a uniform circular array specified as a positive scalar. Units are meters.

This parameter appears when the **Geometry** is set to UCA.

Taper

Tapers, also known as *element weights*, are applied to sensor elements in the array. Tapers are used to modify both the amplitude and phase of the transmitted or received data.

This parameter applies to all array types, but when you set **Sensor Array** to `Replicated subarray`, this parameter applies to subarrays.

- For a ULA or UCA, specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array. If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.
- For a URA, specify element tapering as a complex-valued scalar or complex-valued *M*-by-*N* matrix. In this matrix, *M* is the number of elements along the *z*-axis, and *N* is the number of elements along the *y*-axis. *M* and *N* correspond to the values of `[NumberofArrayRows,NumberOfArrayColumns]` in the **Array size** matrix. If `Taper` is a scalar, the same weight is applied to each element. If **Taper** is a matrix, a weight from the matrix is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.
- For a `Conformal Array`, specify element tapering as a complex-valued scalar or complex-valued 1-by-*N* vector. In this vector, *N* is the number of elements in the array as determined by the size of the **Element positions** vector. If **Taper** is a scalar, the same weight is applied to each element. If the value of **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

Element lattice

This parameter appears when **Geometry** is set to URA. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to the subarray.

Specify the element lattice as `Rectangular` or `Triangular`

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular`— Shifts the even-row elements of a rectangular lattice toward the positive-row axis direction. The displacement is one-half the element spacing along the row dimension.

Element positions (m)

This parameter appears when **Geometry** is set to `Conformal Array`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to subarrays.

Specify the positions of conformal array elements as a 3-by-*N* matrix, where *N* is the number of elements in the conformal array. Each column of **Element positions (m)** represents the position of a single element, in the form `[x;y;z]`, in the array's local coordinate system. The local coordinate system has its origin at an arbitrary point. Units are in meters.

Element normals (deg)

This parameter appears when **Geometry** is set to `Conformal Array`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to subarrays.

Specify the normal directions of the elements in a conformal array as a 2-by-*N* matrix or a 2-by-1 column vector in degrees. The variable *N* indicates the number of elements in the array. If **Element normals (deg)** is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]`, with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If **Element normals (deg)** is a 2-by-1 column vector, the vector specifies the same pointing direction for all elements in the array.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. You can combine translation, azimuth rotation, and elevation rotation transformations. However, you cannot use transformations that require rotation about the normal.

Subarray definition matrix

This parameter appears when **Sensor array** is set to `Partitioned array`.

Specify the subarray selection as an *M*-by-*N* matrix. *M* is the number of subarrays and *N* is the total number of elements in the array. Each row of the matrix indicates

which elements belong to the corresponding subarray. Each entry in the matrix is 1 or 0, where 1 indicates that the element appears in the subarray and 0 indicates the opposite. Each row must contain at least one 1.

The phase center of each subarray is its geometric center. **Subarray definition matrix** and **Geometry** determine the geometric center.

Subarray steering method

This parameter appears when **Sensor array** is set to `Partitioned array` or `Replicated subarray`.

Specify the subarray steering method as

- `None`
- `Phase`
- `Time`

When using the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, or Wideband Transmit Arrayblocks, selecting `Phase` or `Time` opens the block input port, `Steer`.

Phase shifter frequency (Hz)

This parameter appears when you set **Sensor array** to `Partitioned array` or `Replicated subarray` and you set **Subarray steering method** to `Phase`.

Specify the operating frequency, in hertz, of phase shifters to perform subarray steering as a positive scalar.

Number of bits in phase shifters

This parameter appears when you set **Sensor array** to `Partitioned array` or `Replicated subarray` and you set **Subarray steering method** to `Phase`.

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

Subarrays layout

This parameter appears when you set **Sensor array** to `Replicated subarray`.

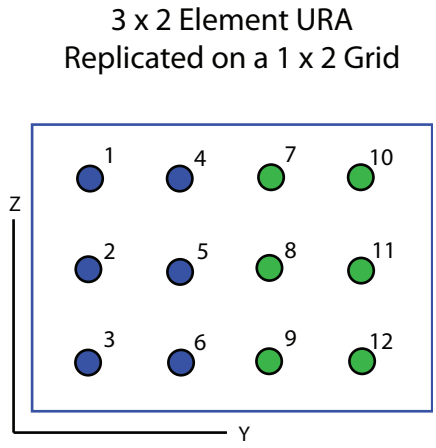
Specify the layout of the replicated subarrays as `Rectangular` or `Custom`.

Grid size

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

Rectangular subarray grid size, specified as a single positive integer or a positive integer-valued 1-by-2 row vector.

If **Grid size** is an integer scalar, the array has an equal number of subarrays in each row and column. If **Grid size** is a 1-by-2 vector of the form `[NumberOfRows, NumberOfColumns]`, the first entry is the number of subarrays along each column. The second entry is the number of subarrays in each row. A row is along the local *y*-axis, and a column is along the local *z*-axis. The figure here shows how you can replicate a 3-by-2 URA subarray using a **Grid size** of `[1,2]`.



Grid spacing

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

Specify the rectangular grid spacing of subarrays as a real-valued positive scalar, a 1-by-2 row vector, or `Auto`. Grid spacing units are expressed in meters.

- If **Grid spacing** is a scalar, the spacing along the row and the spacing along the column is the same.
- If **Grid spacing** is a 1-by-2 row vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumn]`. The first entry specifies

the spacing between rows along a column. The second entry specifies the spacing between columns along a row.

- If **Grid spacing** is set to `Auto`, replication preserves the element spacing of the subarray for both rows and columns while building the full array. This option is available only when you specify **Geometry** as `ULA` or `URA`.

Subarray positions (m)

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Custom`.

Specify the positions of the subarrays in the custom grid as a 3-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix represents the position of a single subarray, in meters, in the array's local coordinate system. The coordinates are expressed in the form `[x; y; z]`.

Subarray normals

This parameter appears when you set the **Sensor array** parameter to `Replicated subarray` and the **Subarrays layout** to `Custom`.

Specify the normal directions of the subarrays in the array. This parameter value is a 2-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix specifies the normal direction of the corresponding subarray, in the form `[azimuth; elevation]`. Each angle is in degrees and is defined in the local coordinate system.

You can use the **Subarray positions** and **Subarray normals** parameters to represent any arrangement in which pairs of subarrays differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal.

Expression

A valid MATLAB expression containing an array constructor, for example, `phased.URA`.

Sensor Array Tab: Element Parameters

Element type

Specify the antenna or microphone type as

- `Isotropic Antenna`

- `Cosine Antenna`
- `Custom Antenna`

Exponent of cosine pattern

This parameter appears when you set **Element type** to `Cosine Antenna`.

Specify the exponent of the cosine pattern as a scalar or a 1-by-2 vector. You must specify all values as non-negative real numbers. When you set **Exponent of cosine pattern** to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the specified value. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern and the second element is the exponent for the elevation direction cosine pattern.

Operating frequency range

This parameter appears when **Element type** is set to `Isotropic Antenna` or `Cosine Antenna`.

Specify the operating frequency range, in hertz, of the antenna element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The antenna element has no response outside the specified frequency range.

Operating frequency vector (Hz)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify the frequencies, in Hz, at which to set the antenna and microphone frequency responses as a 1-by-*L* row vector of increasing values. Use **Frequency responses** to set the frequency responses. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of **Operating frequency vector (Hz)**.

Frequency responses (dB)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify this parameter as the frequency response of an antenna or microphone, in decibels, for the frequencies defined by **Operating frequency vector (Hz)**. Specify **Frequency responses (dB)** as a 1-by-*L* vector matching the dimensions of the vector specified in **Operating frequency vector (Hz)**.

Azimuth angles (deg)

This parameter appears when **Element type** is set to `Custom Antenna`.

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Angle units are in degrees. Azimuth angles must lie between –180° and 180° and be in strictly increasing order.

Elevation angles (deg)

This parameter appears when the **Element type** is set to `Custom Antenna`.

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90° and be in strictly increasing order.

Radiation pattern (dB)

This parameter appears when the **Element type** is set to `Custom Antenna`.

The magnitude in db of the combined polarized antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The value of *Q* must match the value of *Q* specified by **Elevation angles (deg)**. The value of *P* must match the value of *P* specified by **Azimuth angles (deg_**. The value of *L* must match the value of *L* specified by **Operating frequency vector (Hz)**.

Baffle the back of the element

This check box appears only when the **Element type** parameter is set to `Isotropic Antenna` or `Omni Microphone`.

Select this check box to baffle the back of the antenna element. In this case, the antenna responses to all azimuth angles beyond ±90° from *broadside* are set to zero. Define the broadside direction as 0° azimuth angle and 0° elevation angle.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Supported Data Types
`Out`	Double-precision floating point

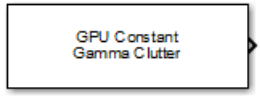
phased.ConstantGammaClutter

Introduced in R2014b

GPU Constant Gamma Clutter

Constant gamma clutter simulation using gpu



Library

Environment and Targets

`phasedenvlib`

Description

The GPU Constant Gamma Clutter block generates, using a GPU, constant gamma clutter reflected from homogeneous terrain for a monostatic radar transmitting a narrowband signal into free space. The radar is assumed to be at constant altitude moving at constant speed.

Parameters

Terrain gamma value (dB)

Specify the γ value used in the constant γ clutter model, as a scalar in dB. The γ value depends on both terrain type and the operating frequency.

Earth model

Specify the earth model used in clutter simulation as `Flat` or `Curved`. When you set this parameter to `Flat`, the earth is assumed to be a flat plane. When you set this parameter to `Curved`, the earth is assumed to be a sphere.

Maximum range (m)

Specify the maximum range in meters for the clutter simulation as a positive scalar. The maximum range must be greater than the value specified in the **Radar height** parameter on the **Radar** panel.

Azimuth coverage (deg)

Specify the azimuth coverage in degrees as a positive scalar. The clutter simulation covers a region having the specified azimuth span, symmetric to zero degrees azimuth. Typically, all clutter patches have their azimuth centers within the region, but by setting the **Clutter patch azimuth span** value, you can cause some patches to extend beyond the region.

Clutter patch azimuth span (deg)

Specify the azimuth span of each clutter patch in degrees as a positive scalar.

Clutter coherence time (s)

Specify the coherence time in seconds for the clutter simulation as a positive scalar. After the coherence time elapses, block updates the random numbers it uses for the clutter simulation at the next pulse. A value of `inf` means the random numbers are never updated.

Signal Propagation speed (m/s)

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

Sample rate (Hz)

Specify the signal sample rate in hertz as a positive scalar. This parameter should be set to the same value as used in any of the **Waveforms** library blocks.

Pulse repetition frequency (Hz)

Specify the pulse repetition frequency, PRF, as a scalar or a row vector. Units for PRF are hertz. This parameter should be set to the same value as used in any `Waveforms` library block.

Output signal format

Specify the format of the output signal as one of `Pulses` or `Samples`.

This parameter should be set to the same value as used in any **Waveforms** library blocks.

Number of pulses in output

Specify the number of pulses in the block output as a positive integer. This parameter appears only when you set the **Output signal format** parameter to `Pulses` and should be set to the same value as used in any **Waveforms** library blocks.

Number of samples in output

Specify the number of samples in the block output as a positive integer. This parameter appears only when you set the **Output signal format** parameter to `Samples` and should be set to the same value as used in any **Waveforms** library blocks.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see “Choosing a Simulation Mode” (Simulink) from the Simulink documentation.

Operating frequency (Hz)

Specify the operating frequency of the system, in hertz, as a positive scalar.

Effective transmitted power (W)

Specify the transmitted effective radiated power (ERP) of the radar system in watts as a positive scalar.

Radar height (m)

Specify the radar platform height in meters, measured upward from the surface as a nonnegative scalar.

Radar speed (m/s)

Specify the radar platform's speed as a nonnegative scalar in meters per second.

Radar motion direction (deg)

Specify the direction of radar platform motion as a 2-by-1 vector in the form `[AzimuthAngle; ElevationAngle]` in degrees. Both azimuth and elevation angle are measured in the local coordinate system of the radar antenna or antenna array. Azimuth angle must be between –180° and 180°. Elevation angle must be between –90° and 90°.

Broadside depression angle (deg)

Specify the depression angle of the radar antenna array in degrees with respect to broadside. This value is a scalar. Broadside is defined as zero degrees azimuth and zero degrees elevation. The depression angle is measured downward from horizontal.

Array Parameters

Specify sensor array as

Sensor element or sensor array specified. A sensor array can also contain subarrays or as a partitioned array. This parameter can also be expressed as a MATLAB expression.

Types

`Single element`
`Array (no subarrays)`
`Partitioned array`

`Replicated subarray`
`MATLAB expression`

Geometry

Specify the array geometry as one of the following:

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array
- `Conformal Array` — arbitrary element positions

Number of elements

Number of array elements.

Number of array elements, specified as a positive integer. This parameter appears when the **Geometry** is set to `ULA` or `UCA`. If **Sensor Array** has a `Replicated subarray` option, this parameter applies to the sub-array.

Array size

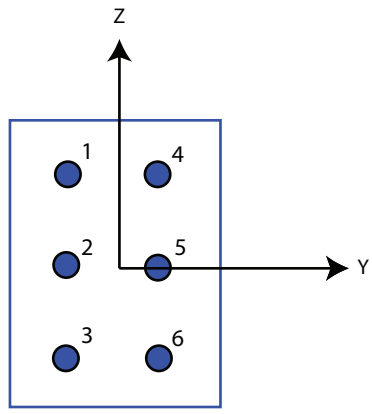
This parameter appears when **Geometry** is set to `URA`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to the subarrays.

Specify the size of the array as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of rows and columns.

For a URA, elements are indexed from top to bottom along a column and continuing to the next columns from left to right. In this figure, an **Array size** of `[3,2]` produces an array of three rows and two columns.

Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]



Element spacing (m)

This parameter appears when **Geometry** is set to ULA or URA. When **Sensor Array** has the `Replicated subarray` option, this parameter applies to the subarrays.

- For a ULA, specify the spacing, in meters, between two adjacent elements in the array as a scalar.
- For a URA, specify the element spacing of the array, in meters, as a 1-by-2 vector or a scalar. If **Element spacing** is a 1-by-2 vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumns]`. For a discussion of these quantities, see phased.URA. If **Element spacing** is a scalar, the spacings between rows and columns are equal.

Array axis

This parameter appears when the **Geometry** parameter is set to ULA or when the block only supports a ULA array geometry. Specify the array axis as `x`, `y`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

Array normal

This parameter appears when you set **Geometry**to `URA` or `UCA`. Specify the **Array normal** as `x`, `y`, or `z`. All URA and UCA array elements are placed in the *yz*, *zx*, or *xy*planes, respectively, of the array coordinate system.

Radius of UCA (m)

Radius of a uniform circular array specified as a positive scalar. Units are meters.

This parameter appears when the **Geometry** is set to `UCA`.

Taper

Tapers, also known as *element weights*, are applied to sensor elements in the array. Tapers are used to modify both the amplitude and phase of the transmitted or received data.

This parameter applies to all array types, but when you set **Sensor Array** to `Replicated subarray`, this parameter applies to subarrays.

- For a `ULA` or `UCA`, specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array. If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.
- For a `URA`, specify element tapering as a complex-valued scalar or complex-valued *M*-by-*N* matrix. In this matrix, *M* is the number of elements along the *z*-axis, and *N* is the number of elements along the *y*-axis. *M* and *N* correspond to the values of `[NumberofArrayRows,NumberOfArrayColumns]` in the **Array size** matrix. If `Taper` is a scalar, the same weight is applied to each element. If **Taper** is a matrix, a weight from the matrix is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.
- For a `Conformal Array`, specify element tapering as a complex-valued scalar or complex-valued 1-by-*N* vector. In this vector, *N* is the number of elements in the array as determined by the size of the **Element positions** vector. If **Taper** is a scalar, the same weight is applied to each element. If the value of **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

Element lattice

This parameter appears when **Geometry** is set to `URA`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to the subarray.

Specify the element lattice as `Rectangular` or `Triangular`

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular`— Shifts the even-row elements of a rectangular lattice toward the positive-row axis direction. The displacement is one-half the element spacing along the row dimension.

Element positions (m)

This parameter appears when **Geometry** is set to `Conformal Array`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to subarrays.

Specify the positions of conformal array elements as a 3-by-*N* matrix, where *N* is the number of elements in the conformal array. Each column of **Element positions (m)** represents the position of a single element, in the form `[x;y;z]`, in the array's local coordinate system. The local coordinate system has its origin at an arbitrary point. Units are in meters.

Element normals (deg)

This parameter appears when **Geometry** is set to `Conformal Array`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to subarrays.

Specify the normal directions of the elements in a conformal array as a 2-by-*N* matrix or a 2-by-1 column vector in degrees. The variable *N* indicates the number of elements in the array. If **Element normals (deg)** is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]`, with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If **Element normals (deg)** is a 2-by-1 column vector, the vector specifies the same pointing direction for all elements in the array.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. You can combine translation, azimuth rotation, and elevation rotation transformations. However, you cannot use transformations that require rotation about the normal.

Subarray definition matrix

This parameter appears when **Sensor array** is set to `Partitioned array`.

Specify the subarray selection as an *M*-by-*N* matrix. *M* is the number of subarrays and *N* is the total number of elements in the array. Each row of the matrix indicates

which elements belong to the corresponding subarray. Each entry in the matrix is 1 or 0, where 1 indicates that the element appears in the subarray and 0 indicates the opposite. Each row must contain at least one 1.

The phase center of each subarray is its geometric center. **Subarray definition matrix** and **Geometry** determine the geometric center.

Subarray steering method

This parameter appears when **Sensor array** is set to `Partitioned array` or `Replicated subarray`.

Specify the subarray steering method as

- `None`
- `Phase`
- `Time`

When using the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, or Wideband Transmit Arrayblocks, selecting `Phase` or `Time` opens the block input port, `Steer`.

Phase shifter frequency (Hz)

This parameter appears when you set **Sensor array** to `Partitioned array` or `Replicated subarray` and you set **Subarray steering method** to `Phase`.

Specify the operating frequency, in hertz, of phase shifters to perform subarray steering as a positive scalar.

Number of bits in phase shifters

This parameter appears when you set **Sensor array** to `Partitioned array` or `Replicated subarray` and you set **Subarray steering method** to `Phase`.

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

Subarrays layout

This parameter appears when you set **Sensor array** to `Replicated subarray`.

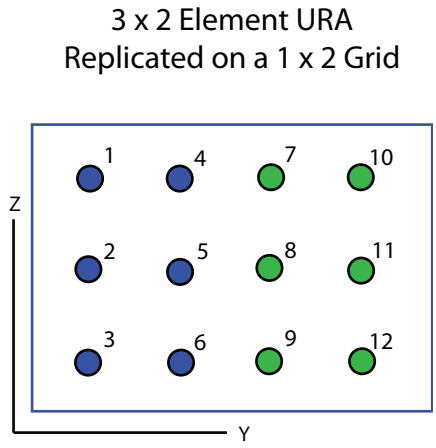
Specify the layout of the replicated subarrays as `Rectangular` or `Custom`.

Grid size

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

Rectangular subarray grid size, specified as a single positive integer or a positive integer-valued 1-by-2 row vector.

If **Grid size** is an integer scalar, the array has an equal number of subarrays in each row and column. If **Grid size** is a 1-by-2 vector of the form `[NumberOfRows, NumberOfColumns]`, the first entry is the number of subarrays along each column. The second entry is the number of subarrays in each row. A row is along the local *y*-axis, and a column is along the local *z*-axis. The figure here shows how you can replicate a 3-by-2 URA subarray using a **Grid size** of `[1,2]`.



Grid spacing

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

Specify the rectangular grid spacing of subarrays as a real-valued positive scalar, a 1-by-2 row vector, or `Auto`. Grid spacing units are expressed in meters.

- If **Grid spacing** is a scalar, the spacing along the row and the spacing along the column is the same.
- If **Grid spacing** is a 1-by-2 row vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumn]`. The first entry specifies

the spacing between rows along a column. The second entry specifies the spacing between columns along a row.

- If **Grid spacing** is set to `Auto`, replication preserves the element spacing of the subarray for both rows and columns while building the full array. This option is available only when you specify **Geometry** as `ULA` or `URA`.

Subarray positions (m)

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Custom`.

Specify the positions of the subarrays in the custom grid as a 3-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix represents the position of a single subarray, in meters, in the array's local coordinate system. The coordinates are expressed in the form `[x; y; z]`.

Subarray normals

This parameter appears when you set the **Sensor array** parameter to `Replicated subarray` and the **Subarrays layout** to `Custom`.

Specify the normal directions of the subarrays in the array. This parameter value is a 2-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix specifies the normal direction of the corresponding subarray, in the form `[azimuth; elevation]`. Each angle is in degrees and is defined in the local coordinate system.

You can use the **Subarray positions** and **Subarray normals** parameters to represent any arrangement in which pairs of subarrays differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal.

Expression

A valid MATLAB expression containing an array constructor, for example, `phased.URA`.

Sensor Array Tab: Element Parameters

Element type

Specify the antenna or microphone type as

- `Isotropic Antenna`

- `Cosine Antenna`
- `Custom Antenna`

Exponent of cosine pattern

This parameter appears when you set **Element type** to `Cosine Antenna`.

Specify the exponent of the cosine pattern as a scalar or a 1-by-2 vector. You must specify all values as non-negative real numbers. When you set **Exponent of cosine pattern** to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the specified value. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern and the second element is the exponent for the elevation direction cosine pattern.

Operating frequency range

This parameter appears when **Element type** is set to `Isotropic Antenna` or `Cosine Antenna`.

Specify the operating frequency range, in hertz, of the antenna element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The antenna element has no response outside the specified frequency range.

Operating frequency vector (Hz)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify the frequencies, in Hz, at which to set the antenna and microphone frequency responses as a 1-by-*L* row vector of increasing values. Use **Frequency responses** to set the frequency responses. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of **Operating frequency vector (Hz)**.

Frequency responses (dB)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify this parameter as the frequency response of an antenna or microphone, in decibels, for the frequencies defined by **Operating frequency vector (Hz)**. Specify **Frequency responses (dB)** as a 1-by-*L* vector matching the dimensions of the vector specified in **Operating frequency vector (Hz)**.

Azimuth angles (deg)

This parameter appears when **Element type** is set to `Custom Antenna`.

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Angle units are in degrees. Azimuth angles must lie between –180° and 180° and be in strictly increasing order.

Elevation angles (deg)

This parameter appears when the **Element type** is set to `Custom Antenna`.

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90° and be in strictly increasing order.

Radiation pattern (dB)

This parameter appears when the **Element type** is set to `Custom Antenna`.

The magnitude in db of the combined polarized antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The value of *Q* must match the value of *Q* specified by **Elevation angles (deg)**. The value of *P* must match the value of *P* specified by **Azimuth angles (deg_**. The value of *L* must match the value of *L* specified by **Operating frequency vector (Hz)**.

Baffle the back of the element

This check box appears only when the **Element type** parameter is set to `Isotropic Antenna` or `Omni Microphone`.

Select this check box to baffle the back of the antenna element. In this case, the antenna responses to all azimuth angles beyond ±90° from *broadside* are set to zero. Define the broadside direction as 0° azimuth angle and 0° elevation angle.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

phased.gpu.ConstantGammaClutter

Introduced in R2014b

Data Cube Slicer

Slice a data cube along specified dimensions

Library

Space-Time Adaptive Processing

`phasedstaplib`

Description

The Data Cube Slicer block slices a data cube along the specified dimensions. The input is a data cube of dimensions *M*-by-*Q*-by-*N*. The first dimension is range, or fast time. The second dimension is angle, or channels. The third dimension is Doppler, or slow time. If you set **Output Slice** to `Angle-Doppler`, the output has dimension *Q*-by-*N*. If you set **Output Slice** to `Range-Doppler`, the output has dimension *M*-by-*N*. If you set **Output Slice** to `Range-angle`, the output has dimension *M*-by-*Q*.

Parameters

Output slice

Select desired output for a *M*-by-*Q*-by-*N* data cube. Parameter values are

Value	Dimension
`Angle-Doppler`	*Q*-by-*N*
`Range-Doppler`	*M*-by-*N*
`Range-angle`	*M*-by-*Q*

Ports

Port	Supported Data Types
`X`	Double-precision floating point
`Idx`	Double-precision floating point
`Out`	Double-precision floating point

Introduced in R2014b

Dechirp Mixer

Dechirping operation on input signal

Library

Detection

`phaseddetectlib`

Description

The Dechirp Mixer block mixes the incoming signal with a reference signal incoming through the `Ref` port. The signals can be complex baseband signals. The input signal can be a matrix where each column is an independent channel. The reference signal is a vector. The reference signal is complex conjugated and then multiplied with each signal column to compute the output.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Supported Data Types
`X`	Double-precision floating point
`RefX`	Double-precision floating point
`Out`	Double-precision floating point

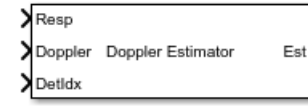
Doppler Estimator

Doppler estimation
Library: Phased Array System Toolbox / Detection



Description

The Doppler Estimator block estimates the Doppler (radial speed) of target detections obtained from the radar response data.

Ports

Input

`Resp` — Doppler-processed response data cube

complex-valued *P*-by-1 column vector | complex-valued *M*-by-*P* matrix | complex-valued *M*-by-*N*-by-*P* array

Doppler-processed response data cube, specified as a complex-valued *P*-by-1 column vector, a complex-valued *M*-by-*P* matrix, or a complex-valued *M*-by-*N*-by-*P* array.*M* represents the number of range samples, *N* is the number of sensor elements or beams, and *P* is the number of Doppler bins.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Data Types: `double`
Complex Number Support: Yes

`Doppler` — Doppler grid values along Doppler dimension

real-valued *P*-by-1 column vector

Doppler grid values along the Doppler dimension, specified as a real-valued *P*-by-1 column vector. `Doppler` defines the Doppler values corresponding to the Doppler

dimension of data input to the **Resp** port. Doppler values must be monotonically increasing and equally spaced. Units are in hertz or meters/sec.

Example: `[-0.3,-0.2,-0.1,0,0.1,0.2,0.3]`

Data Types: `double`

`DetIdx` — Detection indices

real-valued N_d-by-Q matrix

Detection indices, specified as a real-valued N_d-by-Q matrix. Q is the number of detections and N_d is the number of dimensions in the response data cube, **Resp**. Each column of **DetIdx** contains the indices of a detection in the response data cube.

`NoisePower` — Noise power at detection locations

positive scalar | real-valued 1-by-Q row vector of positive values

Noise power at detection locations, specified as a positive scalar or real-valued 1-by-Q row vector positive values. Q is the number of detections specified in the **DetIdx** input port.

Dependencies

To enable this port, select the **Output variance for parameter estimates** parameter, and then set **Source of noise power parameter** to `Input port`.

`Clusters` — Cluster IDs

real-valued 1-by-Q row vector of positive values

Cluster IDs, specified as a real-valued 1-by-Q row vector, where Q is the number of detections specified in the **DetIdx** input port. Each element of **Clusters** corresponds to an element of **DetIdx**.

Dependencies

To enable this input port, select the **Enable cluster ID input** checkbox.

Output

`Est` — Doppler estimate

real-valued K-by-1 column vector

Doppler estimates, returned as a real-valued K-by-1 column vector.

- When **Enable cluster ID input** is not selected, each Doppler estimate corresponds to one of the columns in the **DetIdx** input port. Then K equals the number of elements, Q, of **DetIdx**.
- When **Enable cluster ID input** is selected, each Doppler estimate corresponds to one of the cluster IDs in the **Clusters**input port. Then K equals the number of unique cluster IDs.

`Var` — Doppler estimation variance

positive, real-valued K-by-1 column vector

Doppler estimation variance, returned as a positive, real-valued K-by-1 column vector, where K is the dimension of **Est**. Each element of **Var** corresponds to an element of **Est**. The estimator variance is computed using the Ziv-Zakai bound.

Dependencies

To enable this port, select the **Output variance for parameter estimates** parameter.

Parameters

`Maximum number of estimates` — Maximum number of estimates to report

`1` (default) | positive integer

The maximum number of estimates to report, specified as a positive integer. When the number of requested estimates is greater than the number elements in **DetIdx**, the remainder is filled with `NaN`.

Data Types: `double`

`Enable cluster ID input` — Enable cluster ID input

`off` (default) | `on`

Enable the **Cluster** input port to pass in cluster association information.

Data Types: `Boolean`

`Output variance for parameter estimates` — Enable output variance port

`off` (default) | `on`

Enables the output of the parameter estimate variances via the **Var** port.

Data Types: `Boolean`

`Number of pulses in Doppler processed waveform` — Number of pulses
`2` (default) | positive integer

Number of pulses in Doppler processed waveform, specified as a positive integer.

Dependencies

To enable this parameter, select the **Output variance for parameter estimates** `Output variance for parameter estimates` parameter.

Data Types: `double`

`Source of noise power` — Source of noise power values
`Property` (default) | `Input port`

Source of the noise power, specified as `Property` or `Input port`. If you set this parameter to `Property`, use the **Noise power** parameter to set the noise power at the detection locations. When set the parameter to `Input port`, specify noise power via the `NoisePower` input port.

`Noise power` — Noise power values
`1.0` (default) | positive scalar

Noise power for detections, specified as a positive scalar. The same noise power value is applied to all detections. Noise power is in linear units.

Dependencies

To enable this parameter, select the **Output variance for parameter estimates** checkbox and set the **Source of noise power** parameter to `Property`.

Data Types: `double`

`Simulate using` — Block simulation method
`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If

you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see “Choosing a Simulation Mode” (Simulink) from the Simulink documentation.

Data Types: `char`

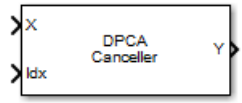
DPCA Canceller

Displaced phase center array (DPCA) pulse canceller for a uniform linear array



Library

Space-Time Adaptive Processing

`phasedstaplib`

Description

The DPCA Canceller block filters clutter for a uniform linear array using a displaced phase center array (DPCA) pulse canceller.

Parameters

Signal Propagation speed (m/s)

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

Operating frequency (Hz)

Specify the operating frequency of the system, in hertz, as a positive scalar.

Pulse repetition frequency (Hz)

Specify the pulse repetition frequency, PRF, as a scalar or a row vector. Units for PRF are hertz. This parameter should be set to the same value as used in any `Waveforms` library block.

Specify direction as

Specify whether the targeting direction for this STAP processor block comes from a block parameter or via an input port. Values of this parameter are

`Property`	• For the ADPCA Canceller and DPCA Canceller blocks, targeting direction is specified using **Receiving mainlobe direction (deg)**. • For the SMI Beamformer block, targeting direction is specified using **Targeting direction**. These parameters appear only when the **Specify direction as** parameter is set to `Property`.
`Input port`	Enter the targeting directions using the `Ang` port. This port appears only when **Specify direction as** is set to `Input port`.

Receiving mainlobe direction (deg)

Specify the mainlobe direction in degrees of the receiving sensor array as a 2-by-1 vector. The direction is specified in the format of `[AzimuthAngle; ElevationAngle]`. The azimuth angle should be between –180° and 180° and the elevation angle should be between –90° and 90°. This parameter appears only when you set **Specify direction as** to `Property`.

Number of bits in phase shifters

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

Specify targeting Doppler as

Specify whether targeting Doppler values for the STAP processor comes from the **Targeting Doppler (Hz)** parameter of this block or via an input port. For the ADPCA Cancellerand DPCA Canceller blocks, this parameter appears only when the **Output pre-Doppler result** check box is cleared. Values of this parameter are

`Property`	Targeting Doppler values are specified by the **Targeting Doppler** parameter of the block. The **Targeting Doppler** parameter appears only when **Specify targeting Doppler as** is set to `Property`.
`Input port`	Targeting Doppler values are entered using the `Dop` port. This port appears only when **Specify targeting Doppler as** is set to `Input port`.

Targeting Doppler (Hz)

Specify the targeting Doppler of the STAP processor as a scalar. This parameter appears only when you set **Specify targeting Doppler as** to `Property` and when, for the ADPCA Cancellerand DPCA Canceller blocks only, the **Output pre-Doppler result** check box is cleared.

Enable weights output

Select this check box to obtain the weights used in the STAP processor via the output port `W`. The output port `W` only appears when you select this check box.

Output pre-Doppler result

Select this check box to output the processing results before applying Doppler filtering. Clear this check box to output the processing result after Doppler filtering. Selecting this check box will remove the **Specify targeting Doppler as** and **Targeting Doppler (Hz)** parameters.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`

`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see "Choosing a Simulation Mode" (Simulink) from the Simulink documentation.

Array Parameters

Specify sensor array as

Specify a ULA sensor array directly or by using a MATLAB expression.

Types

`Array (no subarrays)`
`MATLAB expression`

Number of elements

Specifies the number of elements in the array as an integer.

Element spacing

Specify the spacing, in meters, between two adjacent elements in the array.

Array axis

This parameter appears when the **Geometry** parameter is set to `ULA` or when the block only supports a ULA array geometry. Specify the array axis as `x`, `y`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

Taper

Tapers, also known as *element weights*, are applied to sensor elements in the array. Tapers are used to modify both the amplitude and phase of the transmitted or received data.

Specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array. If **Taper** is

a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

Expression

A valid MATLAB expression containing a constructor for a uniform linear array, for example, `phased.ULA`.

Sensor Array Tab: Element Parameters

Element type

Specify antenna or microphone type as

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

Exponent of cosine pattern

This parameter appears when you set **Element type** to `Cosine Antenna`.

Specify the exponent of the cosine pattern as a scalar or a 1-by-2 vector. You must specify all values as non-negative real numbers. When you set **Exponent of cosine pattern** to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the specified value. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern and the second element is the exponent for the elevation direction cosine pattern.

Operating frequency range (Hz)

This parameter appears when **Element type** is set to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

Specify the operating frequency range, in hertz, of the antenna element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The antenna element has no response outside the specified frequency range.

Operating frequency vector (Hz)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify the frequencies, in Hz, at which to set the antenna and microphone frequency responses as a 1-by-L row vector of increasing values. Use **Frequency responses** to set the frequency responses. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of **Operating frequency vector (Hz)**.

Frequency responses (dB)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify this parameter as the frequency response of an antenna or microphone, in decibels, for the frequencies defined by **Operating frequency vector (Hz)**. Specify **Frequency responses (dB)** as a 1-by-L vector matching the dimensions of the vector specified in **Operating frequency vector (Hz)**.

Azimuth angles (deg)

This parameter appears when **Element type** is set to `Custom Antenna`.

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-P row vector. P must be greater than 2. Angle units are in degrees. Azimuth angles must lie between –180° and 180° and be in strictly increasing order.

Elevation angles (deg)

This parameter appears when the **Element type** is set to `Custom Antenna`.

Specify the elevation angles at which to compute the radiation pattern as a 1-by-Q vector. Q must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90° and be in strictly increasing order.

Radiation pattern (dB)

This parameter appears when the **Element type** is set to `Custom Antenna`.

The magnitude in db of the combined polarized antenna radiation pattern specified as a Q-by-P matrix or a Q-by-P-by-L array. The value of Q must match the value of Q specified by **Elevation angles (deg)**. The value of P must match the value of P specified by **Azimuth angles (deg_**. The value of L must match the value of L specified by **Operating frequency vector (Hz)**.

Polar pattern frequencies (Hz)

This parameter appears when the **Element type** is set to `Custom Microphone`.

Specify the measuring frequencies of the polar patterns as a 1-by-*M* vector. The measuring frequencies lie within the frequency range specified by**Operating frequency vector (Hz)**. Frequency units are in Hz.

Polar pattern angles (deg)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the measuring angles of the polar patterns, as a 1-by-*N* vector. The angles are measured from the central pickup axis of the microphone, and must be between –180° and 180°, inclusive.

Polar pattern (dB)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the magnitude of the microphone element polar pattern as an *M*-by-*N* matrix. *M* is the number of measuring frequencies specified in **Polar pattern frequencies (Hz)**. *N* is the number of measuring angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

Baffle the back of the element

This check box appears only when the **Element type** parameter is set to `Isotropic Antenna` or `Omni Microphone`.

Select this check box to baffle the back of the antenna element. In this case, the antenna responses to all azimuth angles beyond ±90° from *broadside* are set to zero. Define the broadside direction as 0° azimuth angle and 0° elevation angle.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Description	Supported Data Types
`X`	Input signal The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.	Double-precision floating point
`Ang`	Targeting direction	Double-precision floating point
`Dop`	Targeting Doppler frequency	Double-precision floating point
`Idx`	Range cell index	Double-precision floating point
`W`	Processing weights	Double-precision floating point
`Y`	Doppler output	Double-precision floating point

ESPRIT DOA

ESPRIT direction of arrival (DOA) estimator for ULA

Library

Direction of Arrival (DOA)

`phaseddoalib`

Description

The ESPRIT DOA block estimates the direction of arrival of a specified number of narrowband signals incident on a uniform linear array using the ESPRIT algorithm.

Parameters

Signal Propagation speed (m/s)

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

Operating frequency (Hz)

Specify the operating frequency of the system, in hertz, as a positive scalar.

Number of signals

Specify the number of signals as a positive integer scalar.

Spatial smoothing

Specify the amount of averaging, L, used by spatial smoothing to estimate the covariance matrix as a nonnegative integer. Each increase in smoothing handles one extra coherent source, but reduces the effective number of elements by one. The maximum value of this parameter is $N - 2$, where N is the number of sensors.

Type of least squares method

Specify the least squares method used for ESPRIT as one of `TLS` or `LS` where `TLS` refers to total least squares and `LS`refers to least squares.

Forward-backward averaging

Select this parameter to use forward-backward averaging to estimate the covariance matrix for sensor arrays with a conjugate symmetric array manifold.

Row weighting factor

Specify the row weighting factor for signal subspace eigenvectors as a positive integer scalar. This parameter controls the weights applied to the selection matrices. In most cases higher value are better. However, the value can never be greater than *(N-1)/2* where *N* is the number of elements of the array.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`

`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see "Choosing a Simulation Mode" (Simulink) from the Simulink documentation.

Array Parameters

Specify sensor array as

Specify a ULA sensor array directly or by using a MATLAB expression.

Types

`Array (no subarrays)`
`MATLAB expression`

Number of elements

Specifies the number of elements in the array as an integer.

Element spacing

Specify the spacing, in meters, between two adjacent elements in the array.

Array axis

This parameter appears when the **Geometry** parameter is set to `ULA` or when the block only supports a ULA array geometry. Specify the array axis as `x`, `y`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

Taper

Tapers, also known as *element weights*, are applied to sensor elements in the array. Tapers are used to modify both the amplitude and phase of the transmitted or received data.

Specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array. If **Taper** is

a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

Expression

A valid MATLAB expression containing a constructor for a uniform linear array, for example, `phased.ULA`.

Sensor Array Tab: Element Parameters

Element type

Specify antenna or microphone type as

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

Exponent of cosine pattern

This parameter appears when you set **Element type** to `Cosine Antenna`.

Specify the exponent of the cosine pattern as a scalar or a 1-by-2 vector. You must specify all values as non-negative real numbers. When you set **Exponent of cosine pattern** to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the specified value. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern and the second element is the exponent for the elevation direction cosine pattern.

Operating frequency range (Hz)

This parameter appears when **Element type** is set to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

Specify the operating frequency range, in hertz, of the antenna element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The antenna element has no response outside the specified frequency range.

Operating frequency vector (Hz)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify the frequencies, in Hz, at which to set the antenna and microphone frequency responses as a 1-by-L row vector of increasing values. Use **Frequency responses** to set the frequency responses. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of **Operating frequency vector (Hz)**.

Frequency responses (dB)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify this parameter as the frequency response of an antenna or microphone, in decibels, for the frequencies defined by **Operating frequency vector (Hz)**. Specify **Frequency responses (dB)** as a 1-by-L vector matching the dimensions of the vector specified in **Operating frequency vector (Hz)**.

Azimuth angles (deg)

This parameter appears when **Element type** is set to `Custom Antenna`.

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-P row vector. P must be greater than 2. Angle units are in degrees. Azimuth angles must lie between –180° and 180° and be in strictly increasing order.

Elevation angles (deg)

This parameter appears when the **Element type** is set to `Custom Antenna`.

Specify the elevation angles at which to compute the radiation pattern as a 1-by-Q vector. Q must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90° and be in strictly increasing order.

Radiation pattern (dB)

This parameter appears when the **Element type** is set to `Custom Antenna`.

The magnitude in db of the combined polarized antenna radiation pattern specified as a Q-by-P matrix or a Q-by-P-by-L array. The value of Q must match the value of Q specified by **Elevation angles (deg)**. The value of P must match the value of P specified by **Azimuth angles (deg_**. The value of L must match the value of L specified by **Operating frequency vector (Hz)**.

Polar pattern frequencies (Hz)

This parameter appears when the **Element type** is set to `Custom Microphone`.

Specify the measuring frequencies of the polar patterns as a 1-by-*M* vector. The measuring frequencies lie within the frequency range specified by**Operating frequency vector (Hz)**. Frequency units are in Hz.

Polar pattern angles (deg)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the measuring angles of the polar patterns, as a 1-by-*N* vector. The angles are measured from the central pickup axis of the microphone, and must be between –180° and 180°, inclusive.

Polar pattern (dB)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the magnitude of the microphone element polar pattern as an *M*-by-*N* matrix. *M* is the number of measuring frequencies specified in **Polar pattern frequencies (Hz)**. *N* is the number of measuring angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

Baffle the back of the element

This check box appears only when the **Element type** parameter is set to `Isotropic Antenna` or `Omni Microphone`.

Select this check box to baffle the back of the antenna element. In this case, the antenna responses to all azimuth angles beyond ±90° from *broadside* are set to zero. Define the broadside direction as 0° azimuth angle and 0° elevation angle.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Description	Supported Data Types
`In`	Input signals. The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.	Double-precision floating point
`Ang`	Estimated broadside DOA angles.	Double-precision floating point

FMCW Waveform

Frequency-modulated continuous (FMCW) waveform source

Library

Waveforms

`phasedwavlib`

Description

The FMCW Waveform block generates a frequency modulated continuous wave (FMCW) waveform with a specified sweep time and sweep bandwidth. The block output can be either an integer number of pulses or samples.

Parameters

Sample rate

Specify the sample rate of the signal as a positive scalar. Units are hertz. The product of **Sample rate** and **Sweep time** must be integers.

Sweep time

Specify the duration, in seconds, of the upsweep or the downsweep of the signal as a scalar or row vector of positive, real numbers. The product of the **Sample rate** value and each **Sweep time** entry must be an integer.

To implement a varying sweep time, specify **Sweep time** as a row vector. The waveform uses successive entries of the vector as the sweep time for successive periods of the waveform. If the last element of the vector is reached, the process continues cyclically with the first entry of the vector.

If **Sweep time** and **Sweep bandwidth** are both row vectors, the vectors must have the same length.

If **Sweep direction** is `Up` or `Down`, the sweep period equals the sweep time. If **Sweep direction** is `Triangle`, the sweep period is twice the sweep time because each period consists of an upsweep segment and a downsweep segment.

Sweep bandwidth

Specify the bandwidth of the linear FM sweeping, in hertz, as a scalar or row vector of positive, real numbers.

To implement a varying bandwidth, specify **Sweep bandwidth** as a row vector. The waveform uses successive entries of the vector as the sweep bandwidth for successive periods of the waveform. If the waveform reaches the last element of the **Sweep bandwidth** vector, the process continues cyclically with the first entry of the vector.

If **Sweep time** and **Sweep bandwidth** are both row vectors, the vectors must have the same length.

Sweep direction

Specify the direction of the linear FM sweep as one of `Up`, `Down`, or `Triangle`.

Sweep interval

If you set this parameter value to `Positive`, the waveform sweeps in the interval between 0 and B, where B is the value of the **Sweep bandwidth** parameter. If you set this parameter to `Symmetric`, the waveform sweeps in the interval between $–B/2$ and $B/2$.

Output signal format

Specify the format of the output signal as `Sweeps` or `Samples`.

If you set this parameter to `Sweeps`, the output of the block is in the form of multiple sweeps. The number of sweeps is the value of the **Number of sweeps in output** parameter.

If you set this parameter to `Samples`, the output of the block is in the form of multiple samples. The number of samples is the value of the **Number of samples in output** parameter.

If the **Sweep direction** parameter is set to `Triangle`, each sweep is one-half of a period.

Number of sweeps in output

Specify the number of sweeps in the block output as a positive integer. This parameter appears only when you set **Output signal format** to `Sweeps`.

Number of samples in output

Number of samples in the block output, specified as a positive integer. This parameter appears only when you set **Output signal format** to `Samples`.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see “Choosing a Simulation Mode” (Simulink) from the Simulink documentation.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Supported Data Types
`Out`	Double-precision floating point

Free Space

Free space environment

Library

Environment and Targets

`phasedenvlib`

Description

The Free Space Channel block propagates the signal from one point to another in space. The block models propagation time, free space propagation loss and Doppler shift. The block assumes that the propagation speed is much greater than the target or array speed in which case the stop-and-hop model is valid.

When propagating a signal in free-space to an object and back, you have the choice of either using a single block to compute a two-way free space propagation delay or two blocks to perform one-way propagation delays in each direction. Because the free-space propagation delay is not necessarily an integer multiple of the sampling interval, it may turn out that the total round trip delay in samples when you use a two-way propagation block differs from the delay in samples when you use two one-way propagation blocks. For this reason, it is recommended that, when possible, you use a single two-way propagation block.

Parameters

Signal Propagation speed (m/s)

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

Signal carrier frequency (Hz)

Specify the carrier frequency of the signal in hertz of the narrowband signal as a positive scalar.

Perform two-way propagation

Select this check box to perform round-trip propagation between the origin and destination. Otherwise the block performs one-way propagation from the origin to the destination.

Inherit sample rate

Select this check box to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate** parameter.

Sample rate

Specify the signal sampling rate (in hertz) as a positive scalar. This parameter appears only when the **Inherit sample rate** parameter is not selected.

Maximum one-way propagation distance (m)

The maximum distance , in meters, between the origin and the destination as a positive scalar. Amplitudes of any signals that propagate beyond this distance will be set to zero.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see "Choosing a Simulation Mode" (Simulink) from the Simulink documentation.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Description	Supported Data Types
`X`	Input signal. The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.	Double-precision floating point
`Pos1`	Signal origin position.	Double-precision floating point
`Pos2`	Signal destination position.	Double-precision floating point

Port	Description	Supported Data Types
`Vel1`	Signal origin velocity.	Double-precision floating point
`Vel2`	Signal destination velocity.	Double-precision floating point
`Out`	Output signal.	Double-precision floating point

Algorithms

When the origin and destination are stationary relative to each other, the block output can be written as $y(t) = x(t - \tau)/L$. The quantity τ is the delay and L is the propagation loss. The delay is computed from $\tau = R/c$ where R is the propagation distance and c is the propagation speed. The free space path loss is given by

$$L_{fsp} = \frac{(4\pi R)^2}{\lambda^2},$$

where λ is the signal wavelength.

This formula assumes that the target is in the far-field of the transmitting element or array. In the near-field, the free-space path loss formula is not valid and can result in losses smaller than one, equivalent to a signal gain. For this reason, the loss is set to unity for range values, $R \le \lambda/4\pi$.

When there is relative motion between the origin and destination, the processing also introduces a frequency shift. This shift corresponds to the Doppler shift between the origin and destination. The frequency shift is v/λ for one-way propagation and $2v/\lambda$ for two-way propagation. The parameter v is the relative speed of the destination with respect to the origin.

Frost Beamformer

Frost beamformer
Library: Phased Array System Toolbox / Beamforming

Description

The Frost Beamformer block implements a Frost beamformer. The Frost beamformer consists of a time-domain MVDR beamformer followed by a bank of FIR filters. The MVDR beamformer steers the beam towards a given direction while the FIR filters preserve the input signal power.

Ports

Input

X — Input signal
M-by-*N* complex-valued matrix

Input signal, specified as an *M*-by-*N* matrix, where *M* is the number of samples in the data, and *N* is the number of array elements.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Data Types: `double`
Complex Number Support: Yes

XT — Training signal
M-by-*N* complex-valued matrix

Input signal, specified as an *M*-by-*N* matrix, where *M* is the number of samples in the data, and *N* is the number of array elements.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Dependencies

To enable this port, select the **Enable training data input** check box.

Data Types: `double`
Complex Number Support: Yes

`Ang` — Beamforming direction

2-by-1 real-valued vector | 2-by-*L* real-valued matrix

Beamforming direction, specified as a 2-by-*L* real-valued matrix, where *L* is the number of beamforming directions. Each column takes the form of `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°, inclusive, and the elevation angle must lie between –90° and 90°, inclusive. Angles are defined with respect to the local coordinate system of the array.

Dependencies

To enable this port, set the **Source of beamforming direction** parameter to `Input port`.

Data Types: `double`

Output

`Y` — Beamformed output

M-by-*L* complex-valued matrix

Beamformed output, returned as an *M*-by-*L* complex-valued matrix. The quantity *M* is the number of signal samples and *L* is the number of desired beamforming directions specified by the `Beamforming direction` parameter or from the `Ang` port.

Data Types: `double`
Complex Number Support: Yes

`W` — Beamforming weights

N-by-*L* complex-valued matrix

Beamformed weights, returned as an *N*-by-*L* complex-valued matrix. The quantity *N* is the number of array elements. When the **Specify sensor array as** parameter is

set to `Partitioned array` or `Replicated subarray`, *N* represents the number of subarrays. *L* is the number of desired beamforming directions specified in the `Ang` port or by the `Beamforming direction (deg)` property. There is one set of weights for each beamforming direction.

Dependencies

To enable this port, select the **Enable weights output** checkbox.

Data Types: `double`
Complex Number Support: Yes

Parameters

Main Tab

`Signal propagation speed (m/s)` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value return by `physconst('LightSpeed')`.

`Inherit sample rate` — Inherit sample rate from upstream blocks

on (default) | off

Select this parameter to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate (Hz)** parameter.

Data Types: `Boolean`

`Sample rate (Hz)` — Sampling rate of signal

`1e6` (default) | positive real-valued scalar

Specify the signal sampling rate as a positive scalar. Units are in Hz.

Dependencies

To enable this parameter, clear the **Inherit sample rate** parameter.

Data Types: `double`

`FIR filter length` — FIR filter length
1 (default) | positive integer

The length of the FIR filter used to process each sensor element data, specified as a positive integer.

Data Types: `double`

`Diagonal loading factor` — Diagonal loading factor for stability
nonnegative scalar

Specify the diagonal loading factor as a nonnegative scalar. Diagonal loading is a technique used to achieve robust beamforming performance, especially when the sample support is small.

`Enable training data input` — Enable the use of training data
off (default) | on

Select this check box to specify additional training data via the input port `XT`. To use the input signal as the training data, clear the check box which removes the port.

`Source of beamforming direction` — Source of beamforming direction
`Property` (default) | `Input port`

Source of beamforming direction, specified as `Property` or `Input port`. When you set **Source of beamforming direction** to `Property`, you then set the direction using the **Beamforming direction (deg)** parameter. When you select `Input port`, the direction is determined by the input to the `Ang` port.

`Beamforming direction (deg)` — Beamforming directions
2-by-*L* real-valued matrix

Beamforming directions, specified as a *2*-by-*L* real-valued matrix, where *L* is the number of beamforming directions. Each column takes the form `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°. Angles are defined with respect to the local coordinate system of the array.

Dependencies

To enable this parameter, set the **Source of beamforming direction** parameter to `Property`.

`Enable weights output` — Option to output beamformer weights

off (default) | on

Select this checkbox to obtain the beamformer weights from the output port, `W`.

`Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see “Choosing a Simulation Mode” (Simulink) from the Simulink documentation.

Data Types: `char`

Sensor Arrays Tab

`Specify sensor array as` — Method to specify array
`Array (no subarrays)` (default) | `MATLAB expression`

Method to specify array, specified as `Array (no subarrays)` or `MATLAB expression`.

- `Array (no subarrays)` — use the block parameters to specify the array.
- `MATLAB expression` — create the array using a MATLAB expression.

`Expression` — MATLAB expression used to create an array
Phased Array System Toolbox array System object

MATLAB expression used to create an array, specified as a valid Phased Array System Toolbox array System object.

Example: `phased.URA('Size',[5,3])`

Dependencies

To enable this parameter, set **Specify sensor array as** to `MATLAB expression`.

`Element type` — Array element types
`Isotropic Antenna` (default) | `Cosine Antenna` | `Custom Antenna` | `Omni Microphone` | `Custom Microphone`

Antenna or microphone type, specified as one of the following:

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

`Operating frequency range (Hz)` — Operating frequency range of the antenna or microphone element
`[0,1.0e20]` (default) | real-valued 1-by-2 row vector

Specify the operating frequency range of the antenna or microphone element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The element has no response outside this frequency range. Frequency units are in Hz.

Dependencies

To enable this parameter, set **Element type** to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

`Operating frequency vector (Hz)` — Operating frequency range of custom antenna or microphone elements
`[0,1.0e20]` (default) | real-valued row vector

Specify the frequencies at which to set antenna and microphone frequency responses as a 1-by-*L* row vector of increasing real values. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of this vector. Frequency units are in Hz.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`. Use **Frequency responses (dB)** to set the responses at these frequencies.

`Baffle the back of the element` — Set back response of an `Isotropic Antenna` element or an `Omni Microphone` element to zero
off (default) | on

Select this checkbox to baffle the back response of the element. When backbaffled, the responses at all azimuth angles beyond ±90° from broadside are set to zero. The broadside direction is 0° azimuth angle and 0° elevation angle.

Dependencies

To enable this checkbox, set **Element type** to `Isotropic Antenna` or `Omni Microphone`.

`Exponent of cosine pattern` — Exponents of azimuth and elevation cosine patterns
`[1.5 1.5]` (default) | nonnegative scalar | real-valued 1-by-2 matrix of nonnegative values

Specify the exponents of the cosine pattern as a nonnegative scalar or a real-valued 1-by-2 matrix of nonnegative values. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern, and the second element is the exponent for the elevation direction cosine pattern. When you set this parameter to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the same power.

Dependencies

To enable this parameter, set **Element type** to `Cosine Antenna`.

`Frequency responses (dB)` — Antenna and microphone frequency response
`[0,0]` (default) | real-valued row vector

Frequency response of a custom antenna or custom microphone for the frequencies defined by the **Operating frequency vector (Hz)** parameter. The dimensions of **Frequency responses (dB)** must match the dimensions of the vector specified by the **Operating frequency vector (Hz)** parameter.

Dependencies

To enable this parameter , set **Element type** to `Custom Antenna` or `Custom Microphone`.

`Azimuth angles (deg)` — Azimuth angles of antenna radiation pattern
`[-180:180]` (default) | real-valued row vector

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Azimuth angles must lie between –180° and 180°, inclusive, and be in strictly increasing order.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Elevation angles (deg)` — Elevation angles of antenna radiation pattern
`[-90:90]` (default) | real-valued row vector

Specify the elevation angles at which to compute the radiation pattern as a 1-by-Q vector. Q must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive, and be in strictly increasing order.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Magnitude pattern (dB)` — Magnitude of combined antenna radiation pattern
`zeros(181,361)` (default) | real-valued Q-by-P matrix | real-valued Q-by-P-by-L array

Magnitude of the combined antenna radiation pattern, specified as a Q-by-P matrix or a Q-by-P-by-L array. The quantity Q equals the length of the vector specified by **Elevation angles (deg)**. The quantity P equals length of the vector specified by **Azimuth angles (deg)**. The quantity L equal the length of the **Operating frequency vector (Hz)**.

- If this parameter is a Q-by-P matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a Q-by-P-by-L array, each Q-by-P page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Phase pattern (deg)` — Custom antenna radiation phase pattern
`zeros(181,361)` (default) | real-valued Q-by-P matrix | real-valued Q-by-P-by-L array

Phase of the combined antenna radiation pattern, specified as a Q-by-P matrix or a Q-by-P-by-L array. The quantity Q equals the length of the vector specified by **Elevation angles (deg)**. The quantity P equals length of the vector specified by **Azimuth angles (deg)**. The quantity L equal the length of the **Operating frequency vector (Hz)**.

- If this parameter is a Q-by-P matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.

- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Polar pattern frequencies (Hz)` — Custom microphone response frequencies

`1e3` (default) | real scalar | real-valued 1-by-*L* row vector

Response frequencies of the custom microphone of the polar pattern, specified as a real scalar or real-valued 1-by-*L* vector. The response frequencies lie within the frequency range specified by the **Operating frequency vector (Hz)** vector.

Dependencies

To enable this parameter, set **Element type** is set to `Custom Microphone`.

`Polar pattern angles (deg)` — Polar pattern response angles

`[-180:180]` (default) | real-valued -by-*P* row vector

Specify the polar pattern response angles, as a 1-by-*P* vector. The angles are measured from the central pickup axis of the microphone and must be between –180° and 180°, inclusive.

Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

`Polar pattern (dB)` — Custom microphone polar response

`zeros(1,361)` (default) | real-valued *L*-by-*P* matrix

Specify the magnitude of the custom microphone element polar patterns as an *L*-by-*P* matrix. *L* is the number of frequencies specified in **Polar pattern frequencies (Hz)**. *P* is the number of angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding

frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume also that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

Array Parameters

`Geometry` — Array geometry

`ULA` (default) | `URA` | `UCA` | `Conformal Array`

Array geometry, specified as one of

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array
- `Conformal Array` — arbitrary element positions

`Number of elements` — Number of array elements

`2` for ULA arrays and `5` for UCA arrays (default) | integer greater than or equal to 2

The number of array elements for ULA or UCA arrays, specified as an integer greater than or equal to 2.

Dependencies

To enable this parameter, set **Geometry** to `ULA` or `UCA`.

`Element spacing (m)` — Spacing between array elements

`0.5` for ULA arrays and `[0.5,0.5]` for URA arrays (default) | positive scalar for ULA or URA arrays | 2-element vector of positive values for URA arrays

Spacing between adjacent array elements:

- ULA — specify the spacing between two adjacent elements in the array as a positive scalar.
- URA — specify the spacing as a positive scalar or a 1-by-2 vector of positive values. If **Element spacing (m)** is a scalar, the row and column spacings are equal. If **Element spacing (m)** is a vector, the vector has the form `[SpacingBetweenArrayRows,SpacingBetweenArrayColumns]`.

Dependencies

To enable this parameter, set **Geometry** to ULA or URA.

`Array axis` — Linear axis direction of ULA

`y` (default) | `x` | `z`

Linear axis direction of ULA, specified as `y`, `x`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

Dependencies

To enable this parameter, set **Geometry** to ULA. This parameter is also enabled when the block supports only ULA arrays.

`Array size` — Dimensions of URA array

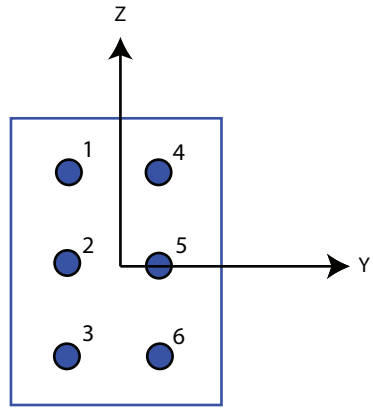
`[2,2]` (default) | positive integer | 1-by-2 vector of positive integers

Dimensions of a URA array, specified as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of elements in each row and column.

For a URA, array elements are indexed from top to bottom along a column, and continuing to the next columns from left to right. In this figure, the **Array size** value of `[3,2]` creates an array having three rows and two columns.

Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]



Dependencies

To enable this parameter, set **Geometry** to URA.

`Element lattice` — Lattice of URA element positions
`Rectangular` (default) | `Triangular`

Lattice of URA element positions, specified as `Rectangular` or `Triangular`.

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular` — Shifts the even-row elements of a rectangular lattice toward the positive row-axis direction. The displacement is one-half the element spacing along the row dimension.

Dependencies

To enable this parameter, set **Geometry** to URA.

`Array normal` — Array normal direction

`x` for URA arrays or `z` for UCA arrays (default) | `y`

Array normal direction, specified as `x`, `y`, or `z`.

Elements of planar arrays lie in a plane orthogonal to the selected array normal direction. Element boresight directions point along the array normal direction.

Array Normal Parameter Value	Element Positions and Boresight Directions
`x`	Array elements lie in the *yz*-plane. All element boresight vectors point along the *x*-axis.
`y`	Array elements lie in the *zx*-plane. All element boresight vectors point along the *y*-axis.
`z`	Array elements lie in the *xy*-plane. All element boresight vectors point along the *z*-axis.

Dependencies

To enable this parameter, set **Geometry**to `URA` or `UCA`.

`Radius of UCA (m)` — UCA array radius

0.5 (default) | positive scalar

Radius of UCA array, specified as a positive scalar.

Dependencies

To enable this parameter, set **Geometry** to `UCA`.

`Element positions (m)` — Positions of conformal array elements

`[0;0;0]` (default) | 3-by-*N*matrix of real values

Positions of the elements in a conformal array, specified as a 3-by-*N* matrix of real values, where *N* is the number of elements in the conformal array. Each column of this matrix represents the position `[x;y;z]`of an array element in the array local coordinate system. The origin of the local coordinate system is *(0,0,0)*. Units are in meters.

Dependencies

To enable this parameter set **Geometry** to `Conformal Array`.

Data Types: `double`

`Element normals (deg)` — Direction of conformal array element normal vectors

`[0;0]` | 2-by-1 column vector | 2-by-*N* matrix

Direction of element normal vectors in a conformal array, specified as a 2-by-1 column vector or a 2-by-*N* matrix. *N* indicates the number of elements in the array. If the parameter value is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]` with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If the parameter value is a 2-by-1 column vector, the same pointing direction is used for all array elements.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal direction.

To enable this parameter, set **Geometry** to `Conformal Array`.

Data Types: `double`

`Taper` — Array element tapers

1 (default) | complex scalar | complex-valued row vector

Specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array.

Also known as *element weights*, tapers multiply the array element responses. Tapers modify both amplitude and phase of the response to reduce sidelobes or steer the main response axis.

If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. The number of weights must match the number of elements of the array.

Data Types: `double`

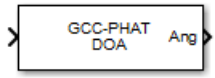
phased.FrostBeamformer

Introduced in R2014b

GCC DOA and TOA

Generalized crosscorrelator with phase transform



Library

Direction of arrival

`phaseddoalib`

Description

The GCC DOA and TOA block estimates direction of arrival and time of arrival of a signal at an array. The block uses a generalized crosscorrelation with phased transform *(GCC-PHAT)* algorithm.

Parameters

Signal propagation speed (m/s)

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

Inherit sample rate

Select this check box to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate** parameter.

Sample rate

Specify the signal sampling rate (in hertz) as a positive scalar. This parameter appears only when the **Inherit sample rate** parameter is not selected.

Source of sensor pairs

Source

`Property`	When you set this parameter to `Property`, specify the sensor pairs for computing correlation using the **Sensor pairs** parameter.
`Auto`	When you set this parameter to `Auto`, correlations are computed between the first element and all other elements. The first element serves as the reference channel.

Sensor pairs

Sensor pairs, specified as a 2-by-*M* matrix of strictly positive integers. This parameter appears only when you set the **Source of sensor pairs** parameter to `Property`.

Enable correlation output

Check this box to output the correlations computed using the GCC-PHAT algorithm as well as the corresponding lags between each sensor pairs. Correlation values are output via the `Rxy` port. Lag values are output via the `Lags` port. These ports appear only when you check the **Enable correlation output** box. Clear this checkbox to disable output of correlations.

Enable delay output

Check this box to output the delay corresponding to the arrival angle of a signal between each sensor pair. The delay is output in the `Tau` port. This port appears only when you check the **Enable delay output** box. Clear this checkboixbox to disable output of delays.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see “Choosing a Simulation Mode” (Simulink) from the Simulink documentation.

Array Parameters

Specify sensor array as

Sensor element or sensor array specified. A sensor array can also contain subarrays or as a partitioned array. This parameter can also be expressed as a MATLAB expression.

Types

`Array (no subarrays)`
`Partitioned array`
`Replicated subarray`
`MATLAB expression`

Geometry

Specify the array geometry as one of the following:

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array
- `Conformal Array` — arbitrary element positions

Number of elements

Number of array elements.

Number of array elements, specified as a positive integer. This parameter appears when the **Geometry** is set to `ULA` or `UCA`. If **Sensor Array** has a `Replicated subarray` option, this parameter applies to the sub-array.

Array size

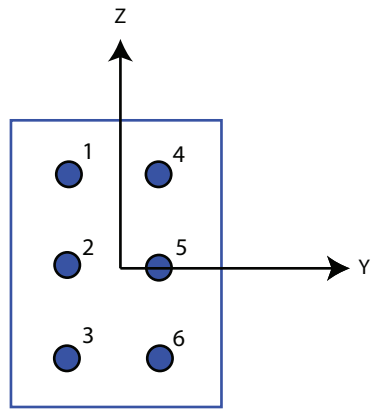
This parameter appears when **Geometry** is set to `URA`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to the subarrays.

Specify the size of the array as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of rows and columns.

For a URA, elements are indexed from top to bottom along a column and continuing to the next columns from left to right. In this figure, an **Array size** of `[3,2]` produces an array of three rows and two columns.

Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]



Element spacing (m)

This parameter appears when **Geometry** is set to ULA or URA. When **Sensor Array** has the `Replicated subarray` option, this parameter applies to the subarrays.

- For a ULA, specify the spacing, in meters, between two adjacent elements in the array as a scalar.
- For a URA, specify the element spacing of the array, in meters, as a 1-by-2 vector or a scalar. If **Element spacing** is a 1-by-2 vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumns]`. For a discussion of these quantities, see phased.URA. If **Element spacing** is a scalar, the spacings between rows and columns are equal.

Array axis

This parameter appears when the **Geometry** parameter is set to ULA or when the block only supports a ULA array geometry. Specify the array axis as `x`, `y`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

Array normal

This parameter appears when you set **Geometry**to URA or UCA. Specify the **Array normal** as x, y, or z. All URA and UCA array elements are placed in the *yz*, *zx*, or *xy*planes, respectively, of the array coordinate system.

Radius of UCA (m)

Radius of a uniform circular array specified as a positive scalar. Units are meters.

This parameter appears when the **Geometry** is set to UCA.

Taper

Tapers, also known as *element weights*, are applied to sensor elements in the array. Tapers are used to modify both the amplitude and phase of the transmitted or received data.

This parameter applies to all array types, but when you set **Sensor Array** to `Replicated subarray`, this parameter applies to subarrays.

- For a ULA or UCA, specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array. If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.
- For a URA, specify element tapering as a complex-valued scalar or complex-valued *M*-by-*N* matrix. In this matrix, *M* is the number of elements along the *z*-axis, and *N* is the number of elements along the *y*-axis. *M* and *N* correspond to the values of `[NumberofArrayRows,NumberOfArrayColumns]` in the **Array size** matrix. If `Taper` is a scalar, the same weight is applied to each element. If **Taper** is a matrix, a weight from the matrix is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.
- For a `Conformal Array`, specify element tapering as a complex-valued scalar or complex-valued 1-by-*N* vector. In this vector, *N* is the number of elements in the array as determined by the size of the **Element positions** vector. If **Taper** is a scalar, the same weight is applied to each element. If the value of **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

Element lattice

This parameter appears when **Geometry** is set to URA. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to the subarray.

Specify the element lattice as `Rectangular` or `Triangular`

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular`— Shifts the even-row elements of a rectangular lattice toward the positive-row axis direction. The displacement is one-half the element spacing along the row dimension.

Element positions (m)

This parameter appears when **Geometry** is set to `Conformal Array`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to subarrays.

Specify the positions of conformal array elements as a 3-by-*N* matrix, where *N* is the number of elements in the conformal array. Each column of **Element positions (m)** represents the position of a single element, in the form `[x;y;z]`, in the array's local coordinate system. The local coordinate system has its origin at an arbitrary point. Units are in meters.

Element normals (deg)

This parameter appears when **Geometry** is set to `Conformal Array`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to subarrays.

Specify the normal directions of the elements in a conformal array as a 2-by-*N* matrix or a 2-by-1 column vector in degrees. The variable *N* indicates the number of elements in the array. If **Element normals (deg)** is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]`, with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If **Element normals (deg)** is a 2-by-1 column vector, the vector specifies the same pointing direction for all elements in the array.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. You can combine translation, azimuth rotation, and elevation rotation transformations. However, you cannot use transformations that require rotation about the normal.

Subarray definition matrix

This parameter appears when **Sensor array** is set to `Partitioned array`.

Specify the subarray selection as an *M*-by-*N* matrix. *M* is the number of subarrays and *N* is the total number of elements in the array. Each row of the matrix indicates

which elements belong to the corresponding subarray. Each entry in the matrix is 1 or 0, where 1 indicates that the element appears in the subarray and 0 indicates the opposite. Each row must contain at least one 1.

The phase center of each subarray is its geometric center. **Subarray definition matrix** and **Geometry** determine the geometric center.

Subarray steering method

This parameter appears when **Sensor array** is set to `Partitioned array` or `Replicated subarray`.

Specify the subarray steering method as

- `None`
- `Phase`
- `Time`

When using the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, or Wideband Transmit Arrayblocks, selecting `Phase` or `Time` opens the block input port, `Steer`.

Phase shifter frequency (Hz)

This parameter appears when you set **Sensor array** to `Partitioned array` or `Replicated subarray` and you set **Subarray steering method** to `Phase`.

Specify the operating frequency, in hertz, of phase shifters to perform subarray steering as a positive scalar.

Number of bits in phase shifters

This parameter appears when you set **Sensor array** to `Partitioned array` or `Replicated subarray` and you set **Subarray steering method** to `Phase`.

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

Subarrays layout

This parameter appears when you set **Sensor array** to `Replicated subarray`.

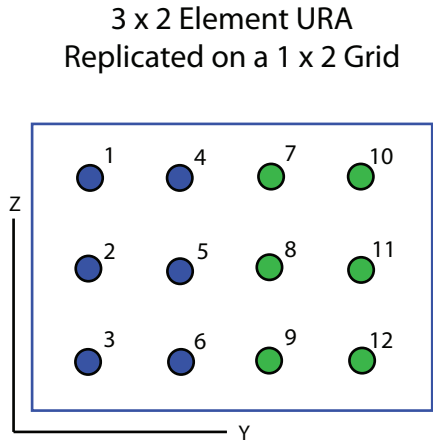
Specify the layout of the replicated subarrays as `Rectangular` or `Custom`.

Grid size

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

Rectangular subarray grid size, specified as a single positive integer or a positive integer-valued 1-by-2 row vector.

If **Grid size** is an integer scalar, the array has an equal number of subarrays in each row and column. If **Grid size** is a 1-by-2 vector of the form `[NumberOfRows, NumberOfColumns]`, the first entry is the number of subarrays along each column. The second entry is the number of subarrays in each row. A row is along the local *y*-axis, and a column is along the local *z*-axis. The figure here shows how you can replicate a 3-by-2 URA subarray using a **Grid size** of `[1,2]`.



Grid spacing

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

Specify the rectangular grid spacing of subarrays as a real-valued positive scalar, a 1-by-2 row vector, or `Auto`. Grid spacing units are expressed in meters.

- If **Grid spacing** is a scalar, the spacing along the row and the spacing along the column is the same.
- If **Grid spacing** is a 1-by-2 row vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumn]`. The first entry specifies the spacing between rows along a column. The second entry specifies the spacing between columns along a row.

- If **Grid spacing** is set to `Auto`, replication preserves the element spacing of the subarray for both rows and columns while building the full array. This option is available only when you specify **Geometry** as `ULA` or `URA`.

Subarray positions (m)

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Custom`.

Specify the positions of the subarrays in the custom grid as a 3-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix represents the position of a single subarray, in meters, in the array's local coordinate system. The coordinates are expressed in the form `[x; y; z]`.

Subarray normals

This parameter appears when you set the **Sensor array** parameter to `Replicated subarray` and the **Subarrays layout** to `Custom`.

Specify the normal directions of the subarrays in the array. This parameter value is a 2-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix specifies the normal direction of the corresponding subarray, in the form `[azimuth; elevation]`. Each angle is in degrees and is defined in the local coordinate system.

You can use the **Subarray positions** and **Subarray normals** parameters to represent any arrangement in which pairs of subarrays differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal.

Expression

A valid MATLAB expression containing an array constructor, for example, `phased.URA`.

Sensor Array Tab: Element Parameters

Element type

Specify antenna or microphone type as

- `Isotropic Antenna`
- `Cosine Antenna`

- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

Exponent of cosine pattern

This parameter appears when you set **Element type** to `Cosine Antenna`.

Specify the exponent of the cosine pattern as a scalar or a 1-by-2 vector. You must specify all values as non-negative real numbers. When you set **Exponent of cosine pattern** to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the specified value. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern and the second element is the exponent for the elevation direction cosine pattern.

Operating frequency range (Hz)

This parameter appears when **Element type** is set to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

Specify the operating frequency range, in hertz, of the antenna element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The antenna element has no response outside the specified frequency range.

Operating frequency vector (Hz)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify the frequencies, in Hz, at which to set the antenna and microphone frequency responses as a 1-by-*L* row vector of increasing values. Use **Frequency responses** to set the frequency responses. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of **Operating frequency vector (Hz)**.

Frequency responses (dB)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify this parameter as the frequency response of an antenna or microphone, in decibels, for the frequencies defined by **Operating frequency vector (Hz)**. Specify **Frequency responses (dB)** as a 1-by-*L* vector matching the dimensions of the vector specified in **Operating frequency vector (Hz)**.

Azimuth angles (deg)

This parameter appears when **Element type** is set to `Custom Antenna`.

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Angle units are in degrees. Azimuth angles must lie between –180° and 180° and be in strictly increasing order.

Elevation angles (deg)

This parameter appears when the **Element type** is set to `Custom Antenna`.

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90° and be in strictly increasing order.

Radiation pattern (dB)

This parameter appears when the **Element type** is set to `Custom Antenna`.

The magnitude in db of the combined polarized antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The value of *Q* must match the value of *Q* specified by **Elevation angles (deg)**. The value of *P* must match the value of *P* specified by **Azimuth angles (deg_**. The value of *L* must match the value of *L* specified by **Operating frequency vector (Hz)**.

Polar pattern frequencies (Hz)

This parameter appears when the **Element type** is set to `Custom Microphone`.

Specify the measuring frequencies of the polar patterns as a 1-by-*M* vector. The measuring frequencies lie within the frequency range specified by**Operating frequency vector (Hz)**. Frequency units are in Hz.

Polar pattern angles (deg)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the measuring angles of the polar patterns, as a 1-by-*N* vector. The angles are measured from the central pickup axis of the microphone, and must be between –180° and 180°, inclusive.

Polar pattern (dB)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the magnitude of the microphone element polar pattern as an *M*-by-*N* matrix. *M* is the number of measuring frequencies specified in **Polar pattern frequencies (Hz)**. *N* is the number of measuring angles specified in **Polar pattern angles (deg)**.

Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

Baffle the back of the element

This check box appears only when the **Element type** parameter is set to `Isotropic Antenna` or `Omni Microphone`.

Select this check box to baffle the back of the antenna element. In this case, the antenna responses to all azimuth angles beyond ±90° from *broadside* are set to zero. Define the broadside direction as 0° azimuth angle and 0° elevation angle.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Description	Supported Data Types
`In`	Input signal. The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.	Double-precision floating point
`Ang`	Estimated DOA angles.	Double-precision floating point
`Rxy`	Estimated crosscorrelation.	Double-precision floating point

Port	Description	Supported Data Types
`Lag`	Time lags.	Double-precision floating point
`Tau`	Time delays of arrival.	Double-precision floating point

Introduced in R2015b

GSC Beamformer

Generalized sidelobe canceller
Library: Phased Array System Toolbox / Beamforming

Description

The GSC Beamformerblock implements a generalized sidelobe cancellation (GSC) beamformer. A GSC beamformer splits an arrays incoming signals and sends them through a conventional beamformer path and a sidelobe canceling path. The algorithm first presteers the array to the beamforming direction and then adaptively chooses filter weights to minimize power at the output of the sidelobe canceling path. The algorithm uses least mean squares (LMS) to compute the adaptive weights. The final beamformed signal is the difference between the outputs of the two paths.

Ports

Input

X — Input signal

M-by-*N* complex-valued matrix

Input signal, specified as an *M*-by-*N* matrix, where *M* is the number of samples in the data, and *N* is the number of array elements.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Data Types: `double`
Complex Number Support: Yes

Ang — Beamforming direction

2-by-*L* real-valued matrix

Beamforming direction, specified as a *2*-by-*L* real-valued matrix, where *L* is the number of beamforming directions. Each column takes the form of

`[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°, inclusive, and the elevation angle must lie between –90° and 90°, inclusive. Angles are defined with respect to the local coordinate system of the array.

Dependencies

To enable this port, set the **Source of beamforming direction** parameter to `Input port`.

Data Types: `double`

Output

Y — Beamformed output

M-by-*L* complex-valued matrix

Beamformed output, returned as an *M*-by-*L* complex-valued matrix. The quantity *M* is the number of signal samples and *L* is the number of desired beamforming directions specified in the Ang port.

Parameters

Main Tab

`Signal propagation speed (m/s)` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value return by `physconst('LightSpeed')`.

`Inherit sample rate` — Inherit sample rate from upstream blocks

on (default) | off

Select this parameter to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate (Hz)** parameter.

Data Types: `Boolean`

`Sample rate (Hz)` — Sampling rate of signal
`1e6` (default) | positive real-valued scalar

Specify the signal sampling rate as a positive scalar. Units are in Hz.

Dependencies

To enable this parameter, clear the **Inherit sample rate** parameter.

Data Types: `double`

`Signal path FIR filter length` — Length of the FIR filter along the signal path
`1` (default) | positive integer

Length of the signal path FIR filter, specified as a positive integer. The FIR filter is a delta function.

`Adaptive filter step size` — LMS adaptive filter step size factor
`0.1` (default) | positive scalar

The adaptive filter step size factor, specified as a positive scalar. This quantity, when divided by the total power in the sidelobe canceling path, determines the actual adaptive filter step size used by the LMS algorithm.

`Beamforming direction (deg)` — Beamforming directions
2-by-*L* real-valued matrix

Beamforming directions, specified as a *2*-by-*L* real-valued matrix, where *L* is the number of beamforming directions. Each column takes the form `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°. Angles are defined with respect to the local coordinate system of the array.

Dependencies

To enable this parameter, set the **Source of beamforming direction** parameter to `Property`.

`Source of beamforming direction` — Source of beamforming direction
`Property` (default) | `Input port`

Source of beamforming direction, specified as `Property` or `Input port`. When you set **Source of beamforming direction** to `Property`, you then set the direction using the **Beamforming direction (deg)** parameter. When you select `Input port`, the direction is determined by the input to the `Ang` port.

`Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see “Choosing a Simulation Mode” (Simulink) from the Simulink documentation.

Data Types: `char`

Sensor Arrays Tab

`Specify sensor array as` — Method to specify array

`Array (no subarrays)` (default) | `MATLAB expression`

Method to specify array, specified as `Array (no subarrays)` or `MATLAB expression`.

- `Array (no subarrays)` — use the block parameters to specify the array.
- `MATLAB expression` — create the array using a MATLAB expression.

`Expression` — MATLAB expression used to create an array

Phased Array System Toolbox array System object

MATLAB expression used to create an array, specified as a valid Phased Array System Toolbox array System object.

Example: `phased.URA('Size',[5,3])`

Dependencies

To enable this parameter, set **Specify sensor array as** to `MATLAB expression`.

Element Parameters

`Element type` — Array element types

`Isotropic Antenna` (default) | `Cosine Antenna` | `Custom Antenna` | `Omni Microphone` | `Custom Microphone`

Antenna or microphone type, specified as one of the following:

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

`Operating frequency range (Hz)` — Operating frequency range of the antenna or microphone element
`[0,1.0e20]` (default) | real-valued 1-by-2 row vector

Specify the operating frequency range of the antenna or microphone element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The element has no response outside this frequency range. Frequency units are in Hz.

Dependencies

To enable this parameter, set **Element type** to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

`Operating frequency vector (Hz)` — Operating frequency range of custom antenna or microphone elements
`[0,1.0e20]` (default) | real-valued row vector

Specify the frequencies at which to set antenna and microphone frequency responses as a 1-by-L row vector of increasing real values. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of this vector. Frequency units are in Hz.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`. Use **Frequency responses (dB)** to set the responses at these frequencies.

`Baffle the back of the element` — Set back response of an `Isotropic Antenna` element or an `Omni Microphone` element to zero
off (default) | on

Select this checkbox to baffle the back response of the element. When backbaffled, the responses at all azimuth angles beyond ±90° from broadside are set to zero. The broadside direction is 0° azimuth angle and 0° elevation angle.

Dependencies

To enable this checkbox, set **Element type** to `Isotropic Antenna` or `Omni Microphone`.

`Exponent of cosine pattern` — Exponents of azimuth and elevation cosine patterns
`[1.5 1.5]` (default) | nonnegative scalar | real-valued 1-by-2 matrix of nonnegative values

Specify the exponents of the cosine pattern as a nonnegative scalar or a real-valued 1-by-2 matrix of nonnegative values. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern, and the second element is the exponent for the elevation direction cosine pattern. When you set this parameter to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the same power.

Dependencies

To enable this parameter, set **Element type** to `Cosine Antenna`.

`Frequency responses (dB)` — Antenna and microphone frequency response
`[0,0]` (default) | real-valued row vector

Frequency response of a custom antenna or custom microphone for the frequencies defined by the **Operating frequency vector (Hz)** parameter. The dimensions of **Frequency responses (dB)** must match the dimensions of the vector specified by the **Operating frequency vector (Hz)** parameter.

Dependencies

To enable this parameter , set **Element type** to `Custom Antenna` or `Custom Microphone`.

`Azimuth angles (deg)` — Azimuth angles of antenna radiation pattern
`[-180:180]` (default) | real-valued row vector

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Azimuth angles must lie between –180° and 180°, inclusive, and be in strictly increasing order.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Elevation angles (deg)` — Elevation angles of antenna radiation pattern
`[-90:90]` (default) | real-valued row vector

Specify the elevation angles at which to compute the radiation pattern as a 1-by-Q vector. Q must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive, and be in strictly increasing order.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Magnitude pattern (dB)` — Magnitude of combined antenna radiation pattern
`zeros(181,361)` (default) | real-valued Q-by-P matrix | real-valued Q-by-P-by-L array

Magnitude of the combined antenna radiation pattern, specified as a Q-by-P matrix or a Q-by-P-by-L array. The quantity Q equals the length of the vector specified by **Elevation angles (deg)**. The quantity P equals length of the vector specified by **Azimuth angles (deg)**. The quantity L equal the length of the **Operating frequency vector (Hz)**.

- If this parameter is a Q-by-P matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a Q-by-P-by-L array, each Q-by-P page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Phase pattern (deg)` — Custom antenna radiation phase pattern
`zeros(181,361)` (default) | real-valued Q-by-P matrix | real-valued Q-by-P-by-L array

Phase of the combined antenna radiation pattern, specified as a Q-by-P matrix or a Q-by-P-by-L array. The quantity Q equals the length of the vector specified by **Elevation angles (deg)**. The quantity P equals length of the vector specified by **Azimuth angles (deg)**. The quantity L equal the length of the **Operating frequency vector (Hz)**.

- If this parameter is a Q-by-P matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.

- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Polar pattern frequencies (Hz)` — Custom microphone response frequencies

1e3 (default) | real scalar | real-valued 1-by-*L* row vector

Response frequencies of the custom microphone of the polar pattern, specified as a real scalar or real-valued 1-by-*L* vector. The response frequencies lie within the frequency range specified by the **Operating frequency vector (Hz)** vector.

Dependencies

To enable this parameter, set **Element type** is set to `Custom Microphone`.

`Polar pattern angles (deg)` — Polar pattern response angles

`[-180:180]` (default) | real-valued -by-*P* row vector

Specify the polar pattern response angles, as a 1-by-*P* vector. The angles are measured from the central pickup axis of the microphone and must be between –180° and 180°, inclusive.

Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

`Polar pattern (dB)` — Custom microphone polar response

`zeros(1,361)` (default) | real-valued *L*-by-*P* matrix

Specify the magnitude of the custom microphone element polar patterns as an *L*-by-*P* matrix. *L* is the number of frequencies specified in **Polar pattern frequencies (Hz)**. *P* is the number of angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding

frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume also that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

Array Parameters

`Geometry` — Array geometry

`ULA` (default) | `URA` | `UCA` | `Conformal Array`

Array geometry, specified as one of

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array
- `Conformal Array` — arbitrary element positions

`Number of elements` — Number of array elements

`2` for ULA arrays and `5` for UCA arrays (default) | integer greater than or equal to 2

The number of array elements for ULA or UCA arrays, specified as an integer greater than or equal to 2.

Dependencies

To enable this parameter, set **Geometry** to `ULA` or `UCA`.

`Element spacing (m)` — Spacing between array elements

`0.5` for ULA arrays and `[0.5,0.5]` for URA arrays (default) | positive scalar for ULA or URA arrays | 2-element vector of positive values for URA arrays

Spacing between adjacent array elements:

- ULA — specify the spacing between two adjacent elements in the array as a positive scalar.
- URA — specify the spacing as a positive scalar or a 1-by-2 vector of positive values. If **Element spacing (m)** is a scalar, the row and column spacings are equal. If **Element spacing (m)** is a vector, the vector has the form `[SpacingBetweenArrayRows,SpacingBetweenArrayColumns]`.

Dependencies

To enable this parameter, set **Geometry** to ULA or URA.

`Array axis` — Linear axis direction of ULA

`y` (default) | `x` | `z`

Linear axis direction of ULA, specified as `y`, `x`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

Dependencies

To enable this parameter, set **Geometry** to ULA. This parameter is also enabled when the block supports only ULA arrays.

`Array size` — Dimensions of URA array

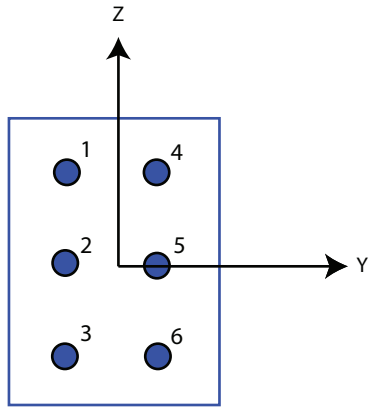
`[2,2]` (default) | positive integer | 1-by-2 vector of positive integers

Dimensions of a URA array, specified as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of elements in each row and column.

For a URA, array elements are indexed from top to bottom along a column, and continuing to the next columns from left to right. In this figure, the **Array size** value of `[3,2]` creates an array having three rows and two columns.

Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]



Dependencies

To enable this parameter, set **Geometry** to URA.

`Element lattice` — Lattice of URA element positions
`Rectangular` (default) | `Triangular`

Lattice of URA element positions, specified as `Rectangular` or `Triangular`.

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular` — Shifts the even-row elements of a rectangular lattice toward the positive row-axis direction. The displacement is one-half the element spacing along the row dimension.

Dependencies

To enable this parameter, set **Geometry** to URA.

`Array normal` — Array normal direction

`x` for URA arrays or `z` for UCA arrays (default) | `y`

Array normal direction, specified as `x`, `y`, or `z`.

Elements of planar arrays lie in a plane orthogonal to the selected array normal direction. Element boresight directions point along the array normal direction.

Array Normal Parameter Value	Element Positions and Boresight Directions
`x`	Array elements lie in the *yz*-plane. All element boresight vectors point along the *x*-axis.
`y`	Array elements lie in the *zx*-plane. All element boresight vectors point along the *y*-axis.
`z`	Array elements lie in the *xy*-plane. All element boresight vectors point along the *z*-axis.

Dependencies

To enable this parameter, set **Geometry**to URA or UCA.

`Radius of UCA (m)` — UCA array radius

0.5 (default) | positive scalar

Radius of UCA array, specified as a positive scalar.

Dependencies

To enable this parameter, set **Geometry** to UCA.

`Element positions (m)` — Positions of conformal array elements

`[0;0;0]` (default) | 3-by-*N*matrix of real values

Positions of the elements in a conformal array, specified as a 3-by-*N* matrix of real values, where *N* is the number of elements in the conformal array. Each column of this matrix represents the position `[x;y;z]`of an array element in the array local coordinate system. The origin of the local coordinate system is *(0,0,0)*. Units are in meters.

Dependencies

To enable this parameter set **Geometry** to `Conformal Array`.

Data Types: `double`

`Element normals (deg)` — Direction of conformal array element normal vectors

`[0;0]` | 2-by-1 column vector | 2-by-*N* matrix

Direction of element normal vectors in a conformal array, specified as a 2-by-1 column vector or a 2-by-*N* matrix. *N* indicates the number of elements in the array. If the parameter value is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]` with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If the parameter value is a 2-by-1 column vector, the same pointing direction is used for all array elements.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal direction.

To enable this parameter, set **Geometry** to `Conformal Array`.

Data Types: `double`

`Taper` — Array element tapers

1 (default) | complex scalar | complex-valued row vector

Specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array.

Also known as *element weights*, tapers multiply the array element responses. Tapers modify both amplitude and phase of the response to reduce sidelobes or steer the main response axis.

If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. The number of weights must match the number of elements of the array.

Data Types: `double`

Definitions

Generalized Sidelobe Cancellation

The *generalized sidelobe canceller* (GSC) is an efficient implementation of a *linear constraint minimum variance* (LCMV) beamformer. LCMV beamforming minimizes the output power of an array while preserving the power in one or more specified directions. This type of beamformer is called a *constrained beamformer*. You can compute exact weights for the constrained beamformer but the computation is costly when the number of elements is large. The computation requires the inversion of a large spatial covariance matrix. The GSC formulation converts the adaptive constrained optimization LCMV problem into an adaptive unconstrained problem, which simplifies the implementation.

In the GSC algorithm, incoming sensor data is split into two signal paths as shown in the block diagram. The upper path is a conventional beamformer. The lower path is an adaptive unconstrained beamformer whose purpose is to minimize the GSC output power. The GSC algorithm consists of these steps:

1. Presteer the element sensor data by time-shifting the incoming signals. Presteering time-aligns all sensor element signals. The time shifts depend on the arrival angle of the signal.
2. Pass the presteered signals through the upper path into a conventional beamformer with fixed weights, $\mathbf{w}_{conv}$.
3. Also pass the presteered signals through the lower path into the blocking matrix, **B**. The blocking matrix is orthogonal to the signal and removes the signal from the lower path.
4. Filter the lower path signals through a bank of FIR filters. The `FilterLength` property sets the length of the filters. The filter coefficients are the adaptive filter weights, $\mathbf{w}_{ad}$.
5. Compute the difference between the upper and lower signal paths. This difference is the beamformed GSC output.
6. Feed the beamformed output back into the filter. Adapt the filter weights using a least mean-square (LMS) algorithm. The adaptive LMS step size is the quantity set by the `LMSStepSizeFactor` property, divided by the total signal power.

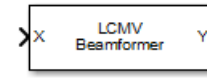
LCMV Beamformer

Narrowband linear constraint minimum variance (LCMV) beamformer
Library: Phased Array System Toolbox / Beamforming



Description

The LCMV Beamformer block performs narrowband linear-constraint minimum-variance (LCMV) beamforming. The number of constraints must be less than the number of elements or subarrays in the array.

Ports

Input

X — Input signal

M-by-*N* complex-valued matrix

Input signals to beamformer, specified as an *M*-by-*N* complex-valued matrix. *M* is the number of signal samples. *N* is the number of sensor array elements.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Data Types: `double`
Complex Number Support: Yes

XT — Training signal

P-by-*N* complex-valued matrix

Training input signal, specified as a *P*-by-*N* complex-valued matrix. *P* is the number of samples in the training input signal. *N* is the number of elements of the sensor array. *P* must be greater than *N*.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Dependencies

To enable this port, select the **Enable training data input** checkbox.

Data Types: `double`
Complex Number Support: Yes

Output

`Y` — Beamformed output

M-by-1 complex-valued column vector

Beamformed output, specified as an *M*-by-1 complex-valued column vector. *M* is the number of signal samples.

Data Types: `double`
Complex Number Support: Yes

`W` — Beamformer weights output

N-by-1 complex-valued column vector

Beamformer weights output, specified as an *N*-by-1 complex-valued column vector. *N* is the number of array elements.

Dependencies

To enable this port, select the **Enable weights output** checkbox.

Data Types: `double`
Complex Number Support: Yes

Parameters

`Constraint matrix` — LCMV beamformer constraint matrix

`complex([1;1])` (default) | *N*-by-*K* complex-valued matrix

LCMV beamformer constraint matrix specified as an N-by-K complex-valued matrix. Each column of the matrix is a constraint. N is the number of elements in the sensor array and K is the number of constraints. K must be less than or equal to the number of sensors, $N,K \le N$

`Desired response vector` — Desired response for LCMV beamforming
`1` (default) | real-valued K-by-1 column vector

Desired response of the LCMV beamformer, specified as a real-valued K-by-1 column vector. K is the number of constraints in the **Constraint matrix**. Each element in the vector defines the desired response of the constraint specified in the corresponding column of the **Constraint matrix** parameter.

`Diagonal loading factor` — Diagonal loading factor
positive scalar

Diagonal loading factor, specified as a positive scalar. Diagonal loading is a technique used to achieve robust beamforming performance, especially when the sample support is small.

`Enable training data input` — Enable training data input port
`off` (default) | `on`

Enable training data input port, specified as `off` or `on`. To enable the training data input port, `XT`, select this checkbox.

`Enable weights output` — Enable output of beamformer weights
`off` (default) | `on`

Enable beamforming weights output port, specified as `off` or `on`. To enable the beamforming weights output port, `W`, select this checkbox.

`Simulate using` — Block simulation method
`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model

quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see “Choosing a Simulation Mode” (Simulink) from the Simulink documentation.

Data Types: `char`

Linear FM Waveform

Linear FM (LFM) pulse waveform

Library

Waveforms

`phasedwavlib`

Description

The Linear FM Waveform block generates a linear FM pulse waveform with specified pulse width, pulse repetition frequency (PRF), and sweep bandwidth. The block outputs an integer number of pulses or samples.

Parameters

Sample rate

Specify the sample rate, in hertz, as a positive scalar. The ratio of the **Sample rate** parameter to the **Pulse repetition frequency** parameter must be an integer. This is equivalent to requiring that the pulse repetition interval be an integer multiple of the sample interval.

Method to specify pulse duration

Specify the method to set the pulse duration as `Pulse width` or `Duty cycle`. When you set this parameter to `Pulse width`, the pulse duration is set using the **PulseWidth** parameter. When you set this parameter to `Duty cycle`, the pulse duration is computed from the values of the **Pulse repetition frequency (Hz)** and **Duty Cycle** parameters.

Pulse width (s)

Specify the duration of each pulse as a positive scalar. The product of **Pulse width** and **Pulse repetition frequency** must be less than or equal to one. Units are in seconds.

Duty Cycle

Specify the waveform duty cycle as a scalar between 0 and 1, inclusive. This parameter appears when you set the **Method to specify pulse duration** parameter to `Duty cycle`

Pulse repetition frequency (Hz)

Pulse repetition frequency, *PRF*, specified as a scalar or a row vector. Units are in Hz. The pulse repetition interval *PRI* is the inverse of the *PRF*. The value of **Pulse repetition frequency (Hz)** must satisfy these constraints:

- The product of **Pulse width** and **Pulse repetition frequency (Hz)** must be less than or equal to one. This is equivalent to the requirement that the pulse width is less than a pulse repetition interval. For the phase-coded waveform, the pulse width is the product of the chip width and number of chips.
- The ratio of sample rate to any element of **Pulse repetition frequency** must be an integer. This is equivalent to requiring that the number of samples in one pulse repetition interval be an integer.

You can select the value of *PRF* by using block parameter settings or an input port.

- When the **Enable PRF selection input** check box is not selected, you set the *PRF* using block parameters.
  - To implement a constant *PRF*, specify **Pulse repetition frequency (Hz)** as a positive scalar.
  - To implement a staggered *PRF*, specify **Pulse repetition frequency (Hz)** as a row vector with all strictly positive values. After the waveform reaches the last element of the vector, the process continues cyclically with the first element of the vector. When *PRF* is staggered, the time between successive output pulses is determined sequentially by the successive values of the *PRF* vector.
- When the **Enable PRF selection input** check box is selected, you can implement a selectable *PRF* by specifying **Pulse repetition frequency (Hz)** as a row vector with positive real-valued entries. But this time, when you execute block, select a *PRF* by passing an index into the *PRF* vector into the `PRFIdx` port.

In all cases, when you use a varying *PRF* and choose **Output signal format** as `Pulses`, the number of samples per pulse can vary as well. When you choose `Samples`, the number of samples per pulse is fixed.

Enable PRF selection input

Check this box to select which predefined PRF to use during the simulation via input. Uncheck this box to use the **Pulse repetition frequency** parameter to define the PRF sequence used in the simulation.

Sweep bandwidth

Specify the bandwidth of the linear FM sweep, in hertz, as a positive scalar.

Sweep direction

Specify the direction of the linear FM sweep as `Up` or `Down`.

Sweep interval

If you set this parameter to `Positive`, the waveform sweeps in the interval between *0* and *B*, where *B* is the value of the **Sweep bandwidth** parameter. If you set this parameter value to `Symmetric`, the waveform sweeps in the interval between *–B/2* and *B/2*.

Envelope function

Specify the envelope function as `Rectangular` or `Gaussian`.

Output signal format

Specify the format of the output signal as `Pulses` or `Samples`.

If you set this parameter to `Samples`, the output of the block is in the form of multiple samples. The number of samples is the value of the **Number of samples in output** parameter.

If you set this parameter to `Pulses`, the output of the block is in the form of multiple pulses. The number of pulses is the value of the **Number of pulses in output** parameter.

The value of **Output signal format** must be set to `Samples` when the **Pulse repetition frequency (Hz)** parameter is a row vector.

Number of samples in output

Number of samples in the block output, specified as a positive integer. This parameter appears only when you set **Output signal format** to `Samples`.

Number of pulses in output

Specify the number of pulses in the block output as a positive integer. This parameter appears only when you set **Output signal format** to `Pulses`.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see “Choosing a Simulation Mode” (Simulink) from the Simulink documentation.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Description	Supported Data Types
`PRFIdx`	PRF selection index.	Double-precision floating point
`Out`	Output waveform.	Double-precision floating point

LOS Channel

Narrowband line-of-sight propagation channel

Library

Environment and Targets

`phasedenvlib`

Description

The LOS Channel block propagates signals from one point in space to multiple points or from multiple points back to one point via line-of-sight (LOS) channels. The block models propagation time, free-space propagation loss, Doppler shift, and atmospheric as well as weather loss. The block assumes that the propagation speed is much greater than the object's speed in which case the stop-and-hop model is valid.

When propagating a signal in an LOS channel to an object and back, you have the choice of either using a single block to compute two-way LOS channel propagation delay or two blocks to perform one-way propagation delays in each direction. Because the LOS channel propagation delay is not necessarily an integer multiple of the sampling interval, it may turn out that the total round trip delay in samples when you use a two-way propagation block differs from the delay in samples when you use two one-way propagation blocks. For this reason, it is recommended that, when possible, you use a single two-way propagation block.

Parameters

Signal Propagation speed (m/s)

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

Signal carrier frequency (Hz)

Specify the carrier frequency of the signal in hertz of the narrowband signal as a positive scalar.

Specify atmospheric parameters

Select this check box to enable atmospheric attenuation modeling.

Temperature (degrees Celsius)

Ambient atmospheric temperature, specified as a real-valued scalar. Units are degrees Celsius. This parameter appears when you select the **Specify atmospheric parameters** check box. Units are degrees Celsius.

Dry air pressure (Pa)

Atmospheric dry air pressure, specified as a positive real-valued scalar. Units are Pascals (Pa). The value 101325 for this property corresponds to one standard atmosphere. This parameter appears when you select the **Specify atmospheric parameters** check box.

Water vapour density (g/m^3)

Atmospheric water vapor density, specified as a positive real-valued scalar. Units are gm/m^3. This parameter appears when you select the **Specify atmospheric parameters** check box.

Liquid water density (g/m^3)

Liquid water density of fog or clouds, specified as a non-negative real-valued scalar. Units are gm/m^3. Typical values for liquid water density are 0.05 for medium fog and 0.5 for thick fog. This parameter appears when you select the **Specify atmospheric parameters** check box.

Rain rate (mm/hr)

Rainfall rate, specified as a non-negative real-valued scalar. Units are in mm/hour. This parameter appears when you select the **Specify atmospheric parameters** check box.

Perform two-way propagation

Select this check box to perform round-trip propagation between the origin and destination. Otherwise the block performs one-way propagation from the origin to the destination.

Inherit sample rate

Select this check box to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate** parameter.

Sample rate

Specify the signal sampling rate (in hertz) as a positive scalar. This parameter appears only when the **Inherit sample rate** parameter is not selected.

Maximum one-way propagation distance (m)

The maximum distance between the signal origin and the destination, specified as a positive scalar. Units are in meters. Amplitudes of any signals that propagate beyond this distance will be set to zero.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see “Choosing a Simulation Mode” (Simulink) from the Simulink documentation.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Description	Supported Data Types
`X`	Input signal.	Double-precision floating point
`Pos1`	Signal source position.	Double-precision floating point
`Pos2`	Signal destination position.	Double-precision floating point
`Vel1`	Signal source velocity.	Double-precision floating point
`Vel2`	Signal destination velocity.	Double-precision floating point
`Out`	Propagated signal.	Double-precision floating point

Definitions

Attenuation and Loss Factors

Attenuation or path loss in the Wideband LOS channel consists of four components. $L = L_{fsp}L_gL_cL_r$, where

- L_{fsp} is the free-space path attenuation
- L_g is the atmospheric path attenuation

- L_c is the fog and cloud path attenuation
- L_r is the rain path attenuation

Each component is in magnitude units, not in dB.

Propagation Delay, Doppler, and Free-Space Path Loss

When the origin and destination are stationary relative to each other, you can write the output signal of a free-space channel as $Y(t) = x(t-\tau)/L_{fsp}$. The quantity τ is the signal delay and L_{fsp} is the free-space path loss. The delay τ is given by R/c, where R is the propagation distance and c is the propagation speed. The free-space path loss is given by

$$L_{fsp} = \frac{(4\pi R)^2}{\lambda^2},$$

where λ is the signal wavelength.

This formula assumes that the target is in the far field of the transmitting element or array. In the near field, the free-space path loss formula is not valid and can result in a loss smaller than one, equivalent to a signal gain. Therefore, the loss is set to unity for range values, $R \le \lambda/4\pi$.

When the origin and destination have relative motion, the processing also introduces a Doppler frequency shift. The frequency shift is v/λ for one-way propagation and $2v/\lambda$ for two-way propagation. The quantity v is the relative speed of the destination with respect to the origin.

Atmospheric Gas Attenuation Model

This model calculates the attenuation of signals that propagate through atmospheric gases.

Electromagnetic signals attenuate when they propagate through the atmosphere. This effect is due primarily to the absorption resonance lines of oxygen and water vapor, with smaller contributions coming from nitrogen gas. The model also includes a continuous absorption spectrum below 10 GHz. Phased Array System Toolbox uses the ITU model *Recommendation ITU-R P.676-10: Attenuation by atmospheric gases*. The model computes the specific attenuation (attenuation per kilometer) as a function of temperature, pressure, water vapor density, and signal frequency. The atmospheric

gas model is valid for frequencies from 1–1000 GHz and applies to polarized and nonpolarized fields.

The formula for specific attenuation at each frequency is

$$\gamma = \gamma_o(f) + \gamma_w(f) = 0.1820 f N''(f).$$

The quantity *N''()* is the imaginary part of the complex atmospheric refractivity. It consists of a spectral line component and a continuous component:

$$N''(f) = \sum_i S_i F_i + N_D''(f)$$

The spectral component consists of a sum of discrete spectrum terms composed of a localized frequency bandwidth function, $F(f)_i$, multiplied by a spectral line strength, S_i. For atmospheric oxygen, each spectral line strength is

$$S_i = a_1 \times 10^{-7} \left(\frac{300}{T}\right)^3 \exp\left[a_2 \left(1 - \left(\frac{300}{T}\right)\right)\right] P.$$

For atmospheric water vapor, each spectral line strength is

$$S_i = b_1 \times 10^{-1} \left(\frac{300}{T}\right)^{3.5} \exp\left[b_2 \left(1 - \left(\frac{300}{T}\right)\right)\right] W.$$

P is the atmospheric pressure, W is the water vapor density, and T is the ambient temperature.

For each oxygen line, S_i depends on constants a_1 and a_2. Similarly, each water vapor line has constants b_1 and b_2. The ITU documentation cited at the end of this section contains tabulations of these constants.

The localized frequency bandwidth functions $F_i(f)$ are complicated functions of frequency described in the ITU references cited below. The functions depend on empirical model parameters that are also tabulated in the reference.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length, R. Then, the total attenuation is $L_g = R(\gamma_o + \gamma_w)$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

Fog and Cloud Attenuation Model

This model calculates the attenuation of signals that propagate through fog or clouds.

Fog and cloud attenuation are the same atmospheric phenomenon. Phased Array System Toolbox uses the ITU model, *Recommendation ITU-R P.840-6: Attenuation due to clouds and fog*. The model computes the specific attenuation (attenuation per kilometer), of a signal as a function of liquid water density, signal frequency, and temperature. The model applies to polarized and nonpolarized fields. The formula for specific attenuation at each frequency is

$$\gamma_c = K_l(f)M,$$

where M is the liquid water density in gm/m^3. The quantity $K_l(f)$ is the specific attenuation coefficient and depends on frequency. The cloud and fog attenuation model is valid for frequencies 10–1000 GHz. Units for the specific attenuation coefficient are (dB/km)/(g/m^3).

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length R. Total attenuation is $L_c = R\gamma_c$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply narrowband attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

Rainfall Attenuation Model

This model calculates the attenuation of signals that propagate through regions of rainfall.

Electromagnetic signals are attenuate when propagating through a region of rainfall. Rainfall attenuation is computed according to the ITU rainfall model *Recommendation ITU-R P.838-3: Specific attenuation model for rain for use in prediction methods*. The model computes the specific attenuation (attenuation per kilometer) of a signal as a

function of rainfall rate, signal frequency, polarization, and path elevation angle. To compute the attenuation, this model uses

$$\gamma_r = kr^{\alpha},$$

where r is the rain rate in mm/hr. The parameter k and exponent α depend on the frequency, the polarization state, and the elevation angle of the signal path. The specific attenuation model is valid for frequencies from 1–1000 GHz.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by a propagation distance, R. Then, total attenuation is $L_r = R\gamma_r$. Instead of using geometric range as the propagation distance, the toolbox uses a modified range. The modified range is the geometric range multiplied by a range factor

$$\frac{1}{1+\frac{R}{R_0}}$$

where

$$R_0 = 35e^{-0.015r}$$

is the effective path length in kilometers (see Seybold, J. *Introduction to RF Propagation*.) When there is no rain, the effective path length is 35 km. When the rain rate is, for example, 10 mm/hr, the effective path length is 30.1 km. At short range, the propagation distance is approximately the geometric range. For longer ranges, the propagation distance asymptotically approaches the effective path length.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

Matched Filter

Matched filter

Library

Detection

`phaseddetectlib`

Description

The Matched Filter block implements matched filtering of an input signal. Matched filtering is an FIR filtering operation with the coefficients equal to the time reversed samples of the transmitted signal. The filter can improve SNR before detection.

Parameters

Source of coefficients

Specify whether the matched filter coefficients come from **Coefficients** or from an input port.

`Property`	Matched filter coefficients are specified by **Coefficients**.
`Input port`	Matched filter coefficients are specified via the input port `Coeff`.

Coefficients

Specify the matched filter coefficients as a column vector. This parameter appears when you set **Source of coefficients** to `Property`.

Spectrum window

Specify the window used for spectrum weighting using one of

`None`
`Hamming`
`Chebyshev`
`Hann`
`Kaiser`
`Taylor`

Spectrum weighting is often used with linear FM waveforms to reduce sidelobe levels in the time domain. The block computes the window length internally to match the FFT length.

Spectrum window range

This parameter appears when you set the **Spectrum window** parameter to any value other than `None`. Specify the spectrum region, in hertz, on which the spectrum window is applied as a 1-by-2 vector in the form of `[StartFrequency,EndFrequency]`.

Note that both `StartFrequency` and `EndFrequency` are measured in baseband. That is, they are within `[-Fs/2,Fs/2]`, where `Fs` is the sample rate specified in any of the waveform library blocks. The parameter `StartFrequency` must be less than `EndFrequency`.

Sidelobe attenuation level

This parameter appears when you set **Spectrum window** to `Chebyshev` or `Taylor`. Specify the sidelobe attenuation level, in dB, of a Chebyshev or Taylor window as a positive scalar.

Kaiser shape parameter

This parameter appears when you set the **Spectrum window** parameter to `Kaiser`. Specify the parameter that affects the Kaiser window sidelobe attenuation as a nonnegative scalar. Please refer to the function `kaiser` for more details.

Number of constant level sidelobes

This parameter appears when you set the **Spectrum window** parameter to `Taylor`. Specify the number of nearly-constant-level sidelobes adjacent to the mainlobe in a Taylor window as a positive integer.

Enable SNR gain output

Select this check this box to obtain the matched filter SNR gain via the output port `G`. The output port appears only when this box is selected.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see “Choosing a Simulation Mode” (Simulink) from the Simulink documentation.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port		Supported Data Types
`X`	Input signal matrix. The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.	Double-precision floating point
`Coeff`	Matched filter coefficients.	Double-precision floating point
`Y`	Filter output.	Double-precision floating point
`G`	Matched-filter gain.	Double-precision floating point

MFSK waveform

Multiple frequency shift keying (MFSK) continuous waveform

Library

Waveforms

`phasedwavlib`

Description

The MFSK Waveform block generates a multiple frequency- shift keying (MFSK) continuous waveform with a specified step time, sweep bandwidth, frequency offset, and number of steps. The block outputs an integer number of samples, steps, or sweeps. For details on the structure of an MFSK waveform, see phased.MFSKWaveform.

Parameters

Sample rate (Hz)

Sample rate of the signal, specified as a positive scalar. Units are in hertz.

Sweep bandwidth (Hz)

Bandwidth of the MFSK sweep, specified as a positive scalar. Units are in hertz.

Frequency step burst time (s)

Time duration of each frequency step, specified as a positive scalar. Units are in seconds.

Number of steps per sweep

Total number of steps in each sweep, specified as an even positive integer.

Chirp offset frequency (Hz)

Chirp offset frequency, specified as a real scalar. Units are in hertz. The offset determines the frequency translation between the two sequences.

Output signal format

Format of the output signal, specified as one of the following:

- `'Steps'` — The block outputs the number of samples contained in an integer number of frequency steps, **Number of steps in output**.
- `'Samples'` — The block outputs the number of samples specified in **Number of samples in output**.
- `'Sweeps'` — The block outputs the number of samples contained in an integer number of sweeps, **Number of sweeps in output**.

Number of sweeps in output

Number of sweeps in the block output, specified as a positive integer. This parameter appears only when you set **Output signal format** to `Sweeps`.

Number of samples in output

Number of samples in the block output, specified as a positive integer. This parameter appears only when you set **Output signal format** to `Samples`.

Number of steps in output

Number of steps in the block output, specified as a positive integer. This parameter appears only when you set **Output signal format** to `Steps`.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see "Choosing a Simulation Mode" (Simulink) from the Simulink documentation.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Supported Data Types

MVDR Beamformer

Narrowband MVDR (Capon) beamformer
Library: Phased Array System Toolbox / Beamforming

Description

The MVDR Beamformer block performs minimum variance distortionless response (MVDR) beamforming. The block preserves the signal power in the given direction while suppressing interference and noise from other directions. The MVDR beamformer is also called the Capon beamformer.

Ports

Input

X — Input signal

M-by-*N* complex-valued matrix

Input signal, specified as an *M*-by-*N* matrix, where *M* is the number of samples in the data, and *N* is the number of array elements.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Data Types: `double`
Complex Number Support: Yes

XT — Training signal

M-by-*N* complex-valued matrix

Input signal, specified as an *M*-by-*N* matrix, where *M* is the number of samples in the data, and *N* is the number of array elements.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Dependencies

To enable this port, select the **Enable training data input** check box.

Data Types: `double`
Complex Number Support: Yes

`Ang` — Beamforming direction

2-by-1 real-valued vector | 2-by-*L* real-valued matrix

Beamforming direction, specified as a 2-by-*L* real-valued matrix, where *L* is the number of beamforming directions. Each column takes the form of `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°, inclusive, and the elevation angle must lie between –90° and 90°, inclusive. Angles are defined with respect to the local coordinate system of the array.

Dependencies

To enable this port, set the **Source of beamforming direction** parameter to `Input port`.

Data Types: `double`

Output

`Y` — Beamformed output

M-by-*L* complex-valued matrix

Beamformed output, returned as an *M*-by-*L* complex-valued matrix. The quantity *M* is the number of signal samples and *L* is the number of desired beamforming directions specified by the `Beamforming direction` parameter or from the `Ang` port.

Data Types: `double`
Complex Number Support: Yes

`W` — Beamforming weights

N-by-*L* complex-valued matrix

Beamformed weights, returned as an *N*-by-*L* complex-valued matrix. The quantity *N* is the number of array elements. When the **Specify sensor array as** parameter is

set to `Partitioned array` or `Replicated subarray`, N represents the number of subarrays. L is the number of desired beamforming directions specified in the `Ang` port or by the `Beamforming direction (deg)` property. There is one set of weights for each beamforming direction.

Dependencies

To enable this port, select the **Enable weights output** checkbox.

Data Types: `double`
Complex Number Support: Yes

Parameters

Main tab

`Signal propagation speed (m/s)` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value return by `physconst('LightSpeed')`.

`Operating frequency (Hz)` — System operating frequency

`300.0e6` (default) | positive real scalar

Specify the operating frequency of the system as a positive scalar. Units are in Hz.

`Diagonal loading factor` — Diagonal loading factor for stability

nonnegative scalar

Specify the diagonal loading factor as a nonnegative scalar. Diagonal loading is a technique used to achieve robust beamforming performance, especially when the sample support is small.

`Enable training data input` — Enable the use of training data

off (default) | on

Select this check box to specify additional training data via the input port `XT`. To use the input signal as the training data, clear the check box which removes the port.

`Source of beamforming direction` — Source of beamforming direction
`Property` (default) | `Input port`

Source of beamforming direction, specified as `Property` or `Input port`. When you set **Source of beamforming direction** to `Property`, you then set the direction using the **Beamforming direction (deg)** parameter. When you select `Input port`, the direction is determined by the input to the `Ang` port.

`Beamforming direction (deg)` — Beamforming directions
2-by-*L* real-valued matrix

Beamforming directions, specified as a *2*-by-*L* real-valued matrix, where *L* is the number of beamforming directions. Each column takes the form `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°. Angles are defined with respect to the local coordinate system of the array.

Dependencies

To enable this parameter, set the **Source of beamforming direction** parameter to `Property`.

`Number of bits in phase shifters` — Number of phase shift quantization bits
`0` (default) | nonnegative integer

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

`Enable weights output` — Option to output beamformer weights
off (default) | on

Select this checkbox to obtain the beamformer weights from the output port, `W`.

`Simulate using` — Block simulation method
`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see “Choosing a Simulation Mode” (Simulink) from the Simulink documentation.

Data Types: `char`

Sensor Arrays Tab

`Specify sensor array as` — Method to specify array

`Array (no subarrays)` (default) | `Partitioned array` | `Replicated subarray` | `MATLAB expression`

Method to specify array, specified as `Array (no subarrays)` or `MATLAB expression`.

- `Array (no subarrays)` — use the block parameters to specify the array.

- `Partitioned array` — use the block parameters to specify the array.
- `Replicated subarray` — use the block parameters to specify the array.
- `MATLAB expression` — create the array using a MATLAB expression.

`Expression` — MATLAB expression used to create an array
Phased Array System Toolbox array System object

MATLAB expression used to create an array, specified as a valid Phased Array System Toolbox array System object.

Example: `phased.URA('Size',[5,3])`

Dependencies

To enable this parameter, set **Specify sensor array as** to `MATLAB expression`.

Element Parameters

`Element type` — Array element types
`Isotropic Antenna` (default) | `Cosine Antenna` | `Custom Antenna` | `Omni Microphone` | `Custom Microphone`

Antenna or microphone type, specified as one of the following:

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

`Operating frequency range (Hz)` — Operating frequency range of the antenna or microphone element
`[0,1.0e20]` (default) | real-valued 1-by-2 row vector

Specify the operating frequency range of the antenna or microphone element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The element has no response outside this frequency range. Frequency units are in Hz.

Dependencies

To enable this parameter, set **Element type** to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

`Operating frequency vector (Hz)` — Operating frequency range of custom antenna or microphone elements
`[0,1.0e20]` (default) | real-valued row vector

Specify the frequencies at which to set antenna and microphone frequency responses as a 1-by-*L* row vector of increasing real values. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of this vector. Frequency units are in Hz.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`. Use **Frequency responses (dB)** to set the responses at these frequencies.

`Baffle the back of the element` — Set back response of an `Isotropic Antenna` element or an `Omni Microphone` element to zero
off (default) | on

Select this checkbox to baffle the back response of the element. When backbaffled, the responses at all azimuth angles beyond ±90° from broadside are set to zero. The broadside direction is 0° azimuth angle and 0° elevation angle.

Dependencies

To enable this checkbox, set **Element type** to `Isotropic Antenna` or `Omni Microphone`.

`Exponent of cosine pattern` — Exponents of azimuth and elevation cosine patterns
`[1.5 1.5]` (default) | nonnegative scalar | real-valued 1-by-2 matrix of nonnegative values

Specify the exponents of the cosine pattern as a nonnegative scalar or a real-valued 1-by-2 matrix of nonnegative values. When you set **Exponent of cosine pattern** to a 1-

by-2 vector, the first element is the exponent for the azimuth direction cosine pattern, and the second element is the exponent for the elevation direction cosine pattern. When you set this parameter to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the same power.

Dependencies

To enable this parameter, set **Element type** to `Cosine Antenna`.

`Frequency responses (dB)` — Antenna and microphone frequency response

`[0,0]` (default) | real-valued row vector

Frequency response of a custom antenna or custom microphone for the frequencies defined by the **Operating frequency vector (Hz)** parameter. The dimensions of **Frequency responses (dB)** must match the dimensions of the vector specified by the **Operating frequency vector (Hz)** parameter.

Dependencies

To enable this parameter , set **Element type** to `Custom Antenna` or `Custom Microphone`.

`Azimuth angles (deg)` — Azimuth angles of antenna radiation pattern

`[-180:180]` (default) | real-valued row vector

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Azimuth angles must lie between –180° and 180°, inclusive, and be in strictly increasing order.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Elevation angles (deg)` — Elevation angles of antenna radiation pattern

`[-90:90]` (default) | real-valued row vector

Specify the elevation angles at which to compute the radiation pattern as a 1-by-Q vector. Q must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive, and be in strictly increasing order.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Magnitude pattern (dB)` — Magnitude of combined antenna radiation pattern
`zeros(181,361)` (default) | real-valued Q-by-P matrix | real-valued Q-by-P-by-L array

Magnitude of the combined antenna radiation pattern, specified as a Q-by-P matrix or a Q-by-P-by-L array. The quantity Q equals the length of the vector specified by **Elevation angles (deg)**. The quantity P equals length of the vector specified by **Azimuth angles (deg)**. The quantity L equal the length of the **Operating frequency vector (Hz)**.

- If this parameter is a Q-by-P matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a Q-by-P-by-L array, each Q-by-P page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Phase pattern (deg)` — Custom antenna radiation phase pattern
`zeros(181,361)` (default) | real-valued Q-by-P matrix | real-valued Q-by-P-by-L array

Phase of the combined antenna radiation pattern, specified as a Q-by-P matrix or a Q-by-P-by-L array. The quantity Q equals the length of the vector specified by **Elevation angles (deg)**. The quantity P equals length of the vector specified by **Azimuth angles (deg)**. The quantity L equal the length of the **Operating frequency vector (Hz)**.

- If this parameter is a Q-by-P matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a Q-by-P-by-L array, each Q-by-P page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Polar pattern frequencies (Hz)` — Custom microphone response frequencies
1e3 (default) | real scalar | real-valued 1-by-*L* row vector

Response frequencies of the custom microphone of the polar pattern, specified as a real scalar or real-valued 1-by-*L* vector. The response frequencies lie within the frequency range specified by the **Operating frequency vector (Hz)** vector.

Dependencies

To enable this parameter, set **Element type** is set to `Custom Microphone`.

`Polar pattern angles (deg)` — Polar pattern response angles
`[-180:180]` (default) | real-valued -by-*P* row vector

Specify the polar pattern response angles, as a 1-by-*P* vector. The angles are measured from the central pickup axis of the microphone and must be between –180° and 180°, inclusive.

Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

`Polar pattern (dB)` — Custom microphone polar response
`zeros(1,361)` (default) | real-valued *L*-by-*P* matrix

Specify the magnitude of the custom microphone element polar patterns as an *L*-by-*P* matrix. *L* is the number of frequencies specified in **Polar pattern frequencies (Hz)**. *P* is the number of angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume also that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

Array Parameters

`Geometry` — Array geometry

`ULA` (default) | `URA` | `UCA` | `Conformal Array`

Array geometry, specified as one of

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array
- `Conformal Array` — arbitrary element positions

`Number of elements` — Number of array elements

`2` for ULA arrays and `5` for UCA arrays (default) | integer greater than or equal to 2

The number of array elements for ULA or UCA arrays, specified as an integer greater than or equal to 2.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

Dependencies

To enable this parameter, set **Geometry** to `ULA` or `UCA`.

`Element spacing (m)` — Spacing between array elements

`0.5` for ULA arrays and `[0.5,0.5]` for URA arrays (default) | positive scalar for ULA or URA arrays | 2-element vector of positive values for URA arrays

Spacing between adjacent array elements:

- ULA — specify the spacing between two adjacent elements in the array as a positive scalar.

- URA — specify the spacing as a positive scalar or a 1-by-2 vector of positive values. If **Element spacing (m)** is a scalar, the row and column spacings are equal. If **Element spacing (m)** is a vector, the vector has the form `[SpacingBetweenArrayRows,SpacingBetweenArrayColumns]`.
- When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

Dependencies

To enable this parameter, set **Geometry** to ULA or URA.

`Array axis` — Linear axis direction of ULA

`y` (default) | `x` | `z`

Linear axis direction of ULA, specified as `y`, `x`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

Dependencies

To enable this parameter, set **Geometry** to ULA. This parameter is also enabled when the block supports only ULA arrays.

`Array size` — Dimensions of URA array

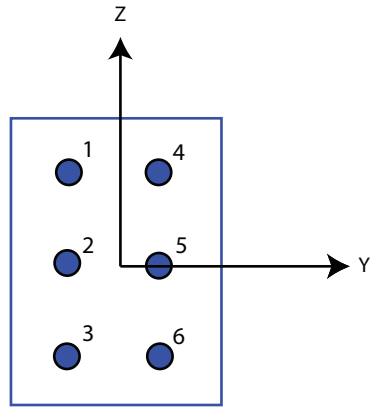
`[2,2]` (default) | positive integer | 1-by-2 vector of positive integers

Dimensions of a URA array, specified as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of rows and columns.
- When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

For a URA, array elements are indexed from top to bottom along a column, and continues to the next columns from left to right. In this figure, the **Array size** value of `[3,2]` creates an array having three rows and two columns.

Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]



Dependencies

To enable this parameter, set **Geometry** to URA.

`Element lattice` — Lattice of URA element positions
`Rectangular` (default) | `Triangular`

Lattice of URA element positions, specified as `Rectangular` or `Triangular`.

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular` — Shifts the even-row elements of a rectangular lattice toward the positive row-axis direction. The displacement is one-half the element spacing along the row dimension.

Dependencies

To enable this parameter, set **Geometry** to URA.

`Array normal` — Array normal direction

`x` for URA arrays or `z` for UCA arrays (default) | `y`

Array normal direction, specified as `x`, `y`, or `z`.

Elements of planar arrays lie in a plane orthogonal to the selected array normal direction. Element boresight directions point along the array normal direction.

Array Normal Parameter Value	Element Positions and Boresight Directions
`x`	Array elements lie in the *yz*-plane. All element boresight vectors point along the *x*-axis.
`y`	Array elements lie in the *zx*-plane. All element boresight vectors point along the *y*-axis.
`z`	Array elements lie in the *xy*-plane. All element boresight vectors point along the *z*-axis.

Dependencies

To enable this parameter, set **Geometry**to URA or UCA.

`Radius of UCA (m)` — UCA array radius

0.5 (default) | positive scalar

Radius of UCA array, specified as a positive scalar.

Dependencies

To enable this parameter, set **Geometry** to UCA.

`Element positions (m)` — Positions of conformal array elements

`[0;0;0]` (default) | 3-by-*N*matrix of real values

Positions of the elements in a conformal array, specified as a 3-by-*N* matrix of real values, where *N* is the number of elements in the conformal array. Each column of this

matrix represents the position `[x;y;z]`of an array element in the array local coordinate system. The origin of the local coordinate system is *(0,0,0)*. Units are in meters.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

Dependencies

To enable this parameter set **Geometry** to `Conformal Array`.

`Element normals (deg)` — Direction of conformal array element normal vectors

`[0;0]` | 2-by-1 column vector | 2-by-*N* matrix

Direction of element normal vectors in a conformal array, specified as a 2-by-1 column vector or a 2-by-*N* matrix. *N* indicates the number of elements in the array. If the parameter value is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]` with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If the parameter value is a 2-by-1 column vector, the same pointing direction is used for all array elements.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal direction.

Dependencies

To enable this parameter, set **Geometry** to `Conformal Array`.

`Taper` — Array element tapers

1 (default) | complex-valued scalar | complex-valued row vector

Element tapering, specified as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array.

Also known as *element weights*, tapers multiply the array element responses. Tapers modify both amplitude and phase of the response to reduce sidelobes or steer the main response axis.

If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. The number of weights must match the number of elements of the array.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

`Subarray definition matrix` — Define elements belonging to subarrays
logical matrix

Subarray selection matrix, specified as an *M*-by-*N* matrix of ones and zeros. *M* is the required number of subarrays and *N* is the total number of elements in the array. Each row of the matrix indicates which elements belong to the corresponding subarray. Entries in the matrix are `1` or `0`. A value of `1` indicates that the element belongs to the subarray and `0` indicates it is not in the subarray. Each row must contain at least one `1`. An element can belong to more than one subarray.

The phase center of each subarray is located at the subarray geometric center. The subarray geometric center depends on the **Subarray definition matrix** and **Geometry** parameters.

Dependencies

To enable this parameter, set **Sensor array** to `Partitioned array`.

`Subarray steering method` — Specify subarray steering method
`None` (default) | `Phase` | `Time`

Subarray steering method, specified as one of

- `None`
- `Phase`
- `Time`

When using the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, or Wideband Transmit Arrayblocks, selecting `Phase` or `Time` opens the block input port, `Steer`.

Dependencies

To enable this parameter, set **Sensor array** to `Partitioned array` or `Replicated subarray`.

`Phase shifter frequency (Hz)` — Subarray phase shifting frequency
`3.0e8` (default) | positive real-valued scalar

Operating frequency of subarray steering phase shifters, specified as a positive real-valued scalar. Units are Hz.

Dependencies

To enable this parameter, set **Sensor array** to `Partitioned array` or `Replicated subarray` and set **Subarray steering method** to `Phase`.

`Number of bits in phase shifters` — Subarray steering phase shift quantization bits
`0` (default) | non-negative integer

Subarray steering phase shift quantization bits, specified as a non-negative integer. A value of zero indicates that no quantization is performed.

Dependencies

To enable this parameter, set **Sensor array** to `Partitioned array` or `Replicated subarray` and set **Subarray steering method** to `Phase`.

`Subarrays layout` — Subarray position specification
`Rectangular` (default) | `Custom`

Specify the layout of replicated subarrays as `Rectangular` or `Custom`.

- When you set this parameter to `Rectangular`, use the **Grid size** and **Grid spacing** parameters to place the subarrays.
- When you set this parameter to `Custom`, use the **Subarray positions (m)** and **Subarray normals** parameters to place the subarrays.

Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray`

`Grid size` — Dimensions of rectangular subarray grid
`[1,2]` (default)

Rectangular subarray grid size, specified as a single positive integer or a positive integer-valued 1-by-2 row vector.

If **Grid size** is an integer scalar, the array has an equal number of subarrays in each row and column. If **Grid size** is a 1-by-2 vector of the form `[NumberOfRows, NumberOfColumns]`, the first entry is the number of subarrays along each column. The second entry is the number of subarrays in each row. A row is along the local *y*-axis, and a column is along the local *z*-axis. The figure here shows how you can replicate a 3-by-2 URA subarray using a **Grid size** of `[1,2]`.

Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

`Grid spacing (m)` — Spacing between subarrays on rectangular grid
`Auto` (default) | positive real-valued scalar | 1-by-2 vector of positive real-values

The rectangular grid spacing of subarrays, specified as a positive, real-valued scalar, a 1-by-2 row vector of positive, real-values, or `Auto`. Units are in meters.

- If **Grid spacing** is a scalar, the spacing along the row and the spacing along the column is the same.
- If **Grid spacing** is a 1-by-2 row vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumn]`. The first entry specifies the spacing between rows along a column. The second entry specifies the spacing between columns along a row.
- If **Grid spacing** is set to `Auto`, replication preserves the element spacing of the subarray for both rows and columns while building the full array. This option is available only when you specify **Geometry** as `ULA` or `URA`.

Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

`Subarray positions (m)` — Positions of subarrays

`[0,0;0.5,0.5;0,0]` (default) | 3-by-*N* real-valued matrix

Positions of the subarrays in the custom grid, specified as a real 3-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix represents the position of a single subarray in the array local coordinate system. The coordinates are expressed in the form `[x; y; z]`. Units are in meters.

Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Custom`.

`Subarray normals` — Direction of subarray normal vectors

`[0,0;0,0]` (default) | 2-by-*N* real matrix

Specify the normal directions of the subarrays in the array. This parameter value is a 2-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix specifies the normal direction of the corresponding subarray, in the form

`[azimuth;elevation]`. Angle units are in degrees. Angles are defined with respect to the local coordinate system.

You can use the **Subarray positions** and **Subarray normals** parameters to represent any arrangement in which pairs of subarrays differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal.

Dependencies

To enable this parameter, set the **Sensor array** parameter to `Replicated subarray` and the **Subarrays layout** to `Custom`.

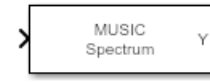
phased.MVDRBeamformer

Introduced in R2014b

MUSIC Spectrum

MUSIC 2D spatial spectrum estimator
Library: Phased Array System Toolbox / Direction of Arrival



Description

The MUSIC Spectrum block uses the MUltiple SIgnal Classification (MUSIC) algorithm to estimate the spatial spectrum of incoming narrowband signals. The block optionally calculates the direction of arrival of a specified number of signals by finding the peaks of the spectrum.

Ports

Input

`Port 1` — Received signal
M-by-*N* complex-valued matrix

Received signal, specified as an *M*-by-*N* complex-valued matrix. The quantity *M* is the length of the signal, the number of sample values contained in the signal. The quantity *N* is the number of sensor elements in the array.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Data Types: `double`
Complex Number Support: Yes

Output

`Y` — MUSIC 2-D spatial spectrum
non-negative, real-valued column vector

2-D MUSIC spatial spectrum, returned as a non-negative, real-valued K-length column vector representing the magnitude of the estimated MUSIC spatial spectrum. Each entry corresponds to an angle specified by the **Azimuth scan angles (deg)** and **Elevation scan angles (deg)** parameters.

Data Types: `double`

`Ang` — Directions of arrival

non-negative, real-valued column vector

Directions of arrival of the signals, returned as a real-valued 2-by-L matrix. L is the number of signals specified by the **Number of signals** parameter. The direction of arrival angle is defined by the azimuth and elevation angles of the source with respect to the array local coordinate system. The first row of the matrix contains the azimuth angles and the second row contains the elevation angles. Angle units are in degrees.

Dependencies

Select the **Enable DOA output** parameter to enable this output port.

Data Types: `double`

Parameters

Main Tab

`Signal propagation speed (m/s)` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value return by `physconst('LightSpeed')`.

`Operating frequency (Hz)` — System operating frequency

`300.0e6` (default) | positive real scalar

Specify the operating frequency of the system as a positive scalar. Units are in Hz.

`Forward-backward averaging` — Enable forward-backward averaging

off (default) | on

Select this parameter to use forward-backward averaging to estimate the covariance matrix for sensor arrays with a conjugate symmetric array manifold structure.

`Azimuth scan angles (deg)` — Azimuth scan angles
`[-90:90]` (default) | real-valued scalar | real-valued row vector

Azimuth scan angles, specified as a real-valued row vector. Angle units are in degrees. The angle values must lie between –180° and 180°, inclusive, and specified in ascending order.

`Elevation scan angles (deg)` — Elevation scan angles
`0` (default) | real-valued scalar | real-valued row vector

Elevation scan angles, specified as a scalar or real-valued row vector. Angle units are in degrees. The angle values must lie between –90° and 90°, inclusive, and specified in ascending order.

`Enable DOA output` — Output directions of arrival through output port
off (default) | on

Select this parameter to output the signals directions of arrival (DOA) through the **Ang** output port.

`Number of signals` — Expected number of arriving signals
`1` (default) | positive integer

Specify the expected number of signals for DOA estimation as a positive scalar integer.

`Simulate using` — Block simulation method
`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see "Choosing a Simulation Mode" (Simulink) from the Simulink documentation.

Data Types: `char`

Sensor Array Tab

`Specify sensor array as` — Method to specify array

`Array (no subarrays)` (default) | `MATLAB expression`

Method to specify array, specified as `Array (no subarrays)` or `MATLAB expression`.

- `Array (no subarrays)` — use the block parameters to specify the array.
- `MATLAB expression` — create the array using a MATLAB expression.

`Expression` — MATLAB expression used to create an array

Phased Array System Toolbox array System object

MATLAB expression used to create an array, specified as a valid Phased Array System Toolbox array System object.

Example: `phased.URA('Size',[5,3])`

Dependencies

To enable this parameter, set **Specify sensor array as** to `MATLAB expression`.

Element Parameters

`Element type` — Array element types

`Isotropic Antenna` (default) | `Cosine Antenna` | `Custom Antenna` | `Omni Microphone` | `Custom Microphone`

Antenna or microphone type, specified as one of the following:

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

`Operating frequency range (Hz)` — Operating frequency range of the antenna or microphone element

`[0,1.0e20]` (default) | real-valued 1-by-2 row vector

Specify the operating frequency range of the antenna or microphone element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The element has no response outside this frequency range. Frequency units are in Hz.

Dependencies

To enable this parameter, set **Element type** to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

`Operating frequency vector (Hz)` — Operating frequency range of custom antenna or microphone elements

`[0,1.0e20]` (default) | real-valued row vector

Specify the frequencies at which to set antenna and microphone frequency responses as a 1-by-L row vector of increasing real values. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of this vector. Frequency units are in Hz.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`. Use **Frequency responses (dB)** to set the responses at these frequencies.

`Baffle the back of the element` — Set back response of an `Isotropic Antenna` element or an `Omni Microphone` element to zero
off (default) | on

Select this checkbox to baffle the back response of the element. When backbaffled, the responses at all azimuth angles beyond ±90° from broadside are set to zero. The broadside direction is 0° azimuth angle and 0° elevation angle.

Dependencies

To enable this checkbox, set **Element type** to `Isotropic Antenna` or `Omni Microphone`.

`Exponent of cosine pattern` — Exponents of azimuth and elevation cosine patterns
`[1.5 1.5]` (default) | nonnegative scalar | real-valued 1-by-2 matrix of nonnegative values

Specify the exponents of the cosine pattern as a nonnegative scalar or a real-valued 1-by-2 matrix of nonnegative values. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern, and the second element is the exponent for the elevation direction cosine pattern. When you set this parameter to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the same power.

Dependencies

To enable this parameter, set **Element type** to `Cosine Antenna`.

`Frequency responses (dB)` — Antenna and microphone frequency response
`[0,0]` (default) | real-valued row vector

Frequency response of a custom antenna or custom microphone for the frequencies defined by the **Operating frequency vector (Hz)** parameter. The dimensions of

Frequency responses (dB) must match the dimensions of the vector specified by the **Operating frequency vector (Hz)** parameter.

Dependencies

To enable this parameter , set **Element type** to `Custom Antenna` or `Custom Microphone`.

`Azimuth angles (deg)` — Azimuth angles of antenna radiation pattern

`[-180:180]` (default) | real-valued row vector

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-P row vector. P must be greater than 2. Azimuth angles must lie between –180° and 180°, inclusive, and be in strictly increasing order.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Elevation angles (deg)` — Elevation angles of antenna radiation pattern

`[-90:90]` (default) | real-valued row vector

Specify the elevation angles at which to compute the radiation pattern as a 1-by-Q vector. Q must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive, and be in strictly increasing order.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Magnitude pattern (dB)` — Magnitude of combined antenna radiation pattern

`zeros(181,361)` (default) | real-valued Q-by-P matrix | real-valued Q-by-P-by-L array

Magnitude of the combined antenna radiation pattern, specified as a Q-by-P matrix or a Q-by-P-by-L array. The quantity Q equals the length of the vector specified by **Elevation angles (deg)**. The quantity P equals length of the vector specified by **Azimuth angles (deg)**. The quantity L equal the length of the **Operating frequency vector (Hz)**.

- If this parameter is a Q-by-P matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a Q-by-P-by-L array, each Q-by-P page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Phase pattern (deg)` — Custom antenna radiation phase pattern
`zeros(181,361)` (default) | real-valued Q-by-P matrix | real-valued Q-by-P-by-L array

Phase of the combined antenna radiation pattern, specified as a Q-by-P matrix or a Q-by-P-by-L array. The quantity Q equals the length of the vector specified by **Elevation angles (deg)**. The quantity P equals length of the vector specified by **Azimuth angles (deg)**. The quantity L equal the length of the **Operating frequency vector (Hz)**.

- If this parameter is a Q-by-P matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a Q-by-P-by-L array, each Q-by-P page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Polar pattern frequencies (Hz)` — Custom microphone response frequencies
1e3 (default) | real scalar | real-valued 1-by-L row vector

Response frequencies of the custom microphone of the polar pattern, specified as a real scalar or real-valued 1-by-L vector. The response frequencies lie within the frequency range specified by the **Operating frequency vector (Hz)** vector.

Dependencies

To enable this parameter, set **Element type** is set to `Custom Microphone`.

`Polar pattern angles (deg)` — Polar pattern response angles
`[-180:180]` (default) | real-valued -by-P row vector

Specify the polar pattern response angles, as a 1-by-P vector. The angles are measured from the central pickup axis of the microphone and must be between –180° and 180°, inclusive.

Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

`Polar pattern (dB)` — Custom microphone polar response
`zeros(1,361)` (default) | real-valued L-by-P matrix

Specify the magnitude of the custom microphone element polar patterns as an L-by-P matrix. L is the number of frequencies specified in **Polar pattern frequencies (Hz)**. P is the number of angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume also that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

Array Parameters

`Geometry` — Array geometry
`ULA` (default) | `URA` | `UCA` | `Conformal Array`

Array geometry, specified as one of

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array

- `Conformal Array` — arbitrary element positions

`Number of elements` — Number of array elements
2 for ULA arrays and 5 for UCA arrays (default) | integer greater than or equal to 2

The number of array elements for ULA or UCA arrays, specified as an integer greater than or equal to 2.

Dependencies

To enable this parameter, set **Geometry** to ULA or UCA.

`Element spacing (m)` — Spacing between array elements
`0.5` for ULA arrays and `[0.5,0.5]` for URA arrays (default) | positive scalar for ULA or URA arrays | 2-element vector of positive values for URA arrays

Spacing between adjacent array elements:

- ULA — specify the spacing between two adjacent elements in the array as a positive scalar.
- URA — specify the spacing as a positive scalar or a 1-by-2 vector of positive values. If **Element spacing (m)** is a scalar, the row and column spacings are equal. If **Element spacing (m)** is a vector, the vector has the form `[SpacingBetweenArrayRows,SpacingBetweenArrayColumns]`.

Dependencies

To enable this parameter, set **Geometry** to ULA or URA.

`Array axis` — Linear axis direction of ULA
`y` (default) | `x` | `z`

Linear axis direction of ULA, specified as `y`, `x`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

Dependencies

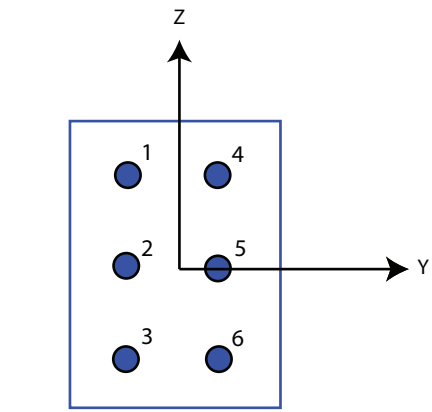
To enable this parameter, set **Geometry** to ULA. This parameter is also enabled when the block supports only ULA arrays.

`Array size` — Dimensions of URA array
`[2,2]` (default) | positive integer | 1-by-2 vector of positive integers

Dimensions of a URA array, specified as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of elements in each row and column.

For a URA, array elements are indexed from top to bottom along a column, and continuing to the next columns from left to right. In this figure, the **Array size** value of `[3,2]` creates an array having three rows and two columns.



Dependencies

To enable this parameter, set **Geometry** to URA.

`Element lattice` — Lattice of URA element positions
`Rectangular` (default) | `Triangular`

Lattice of URA element positions, specified as `Rectangular` or `Triangular`.

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular` — Shifts the even-row elements of a rectangular lattice toward the positive row-axis direction. The displacement is one-half the element spacing along the row dimension.

Dependencies

To enable this parameter, set **Geometry** to URA.

`Array normal` — Array normal direction

`x` for URA arrays or `z` for UCA arrays (default) | `y`

Array normal direction, specified as `x`, `y`, or `z`.

Elements of planar arrays lie in a plane orthogonal to the selected array normal direction. Element boresight directions point along the array normal direction.

Array Normal Parameter Value	Element Positions and Boresight Directions
`x`	Array elements lie in the *yz*-plane. All element boresight vectors point along the *x*-axis.
`y`	Array elements lie in the *zx*-plane. All element boresight vectors point along the *y*-axis.
`z`	Array elements lie in the *xy*-plane. All element boresight vectors point along the *z*-axis.

Dependencies

To enable this parameter, set **Geometry**to URA or UCA.

`Radius of UCA (m)` — UCA array radius

0.5 (default) | positive scalar

Radius of UCA array, specified as a positive scalar.

Dependencies

To enable this parameter, set **Geometry** to UCA.

`Element positions (m)` — Positions of conformal array elements

`[0;0;0]` (default) | 3-by-*N* matrix of real values

Positions of the elements in a conformal array, specified as a 3-by-*N* matrix of real values, where *N* is the number of elements in the conformal array. Each column of this matrix represents the position `[x;y;z]` of an array element in the array local coordinate system. The origin of the local coordinate system is *(0,0,0)*. Units are in meters.

Dependencies

To enable this parameter set **Geometry** to `Conformal Array`.

Data Types: `double`

`Element normals (deg)` — Direction of conformal array element normal vectors

`[0;0]` | 2-by-1 column vector | 2-by-*N* matrix

Direction of element normal vectors in a conformal array, specified as a 2-by-1 column vector or a 2-by-*N* matrix. *N* indicates the number of elements in the array. If the parameter value is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]` with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If the parameter value is a 2-by-1 column vector, the same pointing direction is used for all array elements.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal direction.

To enable this parameter, set **Geometry** to `Conformal Array`.

Data Types: `double`

`Taper` — Array element tapers

1 (default) | complex scalar | complex-valued row vector

Specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array.

Also known as *element weights*, tapers multiply the array element responses. Tapers modify both amplitude and phase of the response to reduce sidelobes or steer the main response axis.

If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. The number of weights must match the number of elements of the array.

Data Types: `double`

Functions

`musicdoa`

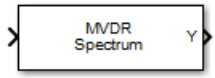
Topics

"MUSIC Super-Resolution DOA Estimation"

Introduced in R2016b

MVDR Spectrum

Minimum variation distortionless response (MVDR) spatial spectrum estimator



Library

Direction of Arrival (DOA)

`phaseddoalib`

Description

The narrowband MVDR Spectrum block estimates the spatial spectrum of incoming narrowband signals by scanning a range of azimuth and elevation angles using an MVDR conventional beamformer. The block optionally calculate the direction of arrival of a specified number of signals by estimating the peaks of the spectrum. This estimator is also referred to as a Capon estimator.

Parameters

Signal Propagation speed (m/s)

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

Operating frequency (Hz)

Specify the operating frequency of the system, in hertz, as a positive scalar.

Number of bits in phase shifters

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

Forward-backward averaging

Select this parameter to use forward-backward averaging to estimate the covariance matrix for sensor arrays with a conjugate symmetric array manifold.

Azimuth scan angles (deg)

Specify the azimuth scan angles, in degrees, as a real vector. The angles must be between –180° and 180°, inclusive. You must specify the angles in ascending order.

Elevation scan angles (deg)

Specify the elevation scan angles, in degrees, as a real vector or scalar. The angles must be between –90° and 90°, inclusive. You must specify the angles in an ascending order.

Enable DOA output

Select this parameter to output the signals directions of arrival (DOA) through the **Ang** output port. Selecting this parameter enables the **Number of signals** parameter.

Number of signals

Specify the number of signals for DOA estimation as a positive scalar integer. This parameter appears when you select the **Enable DOA output** check box.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see "Choosing a Simulation Mode" (Simulink) from the Simulink documentation.

Array Parameters

Specify sensor array as

Specify a sensor array directly or by using a MATLAB expression.

Types

`Array (no subarrays)`
`MATLAB expression`

Geometry

Specify the array geometry as one of the following:

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array
- `Conformal Array` — arbitrary element positions

Number of elements

Number of array elements.

Number of array elements, specified as a positive integer. This parameter appears when the **Geometry** is set to `ULA` or `UCA`. If **Sensor Array** has a `Replicated subarray` option, this parameter applies to the sub-array.

Array size

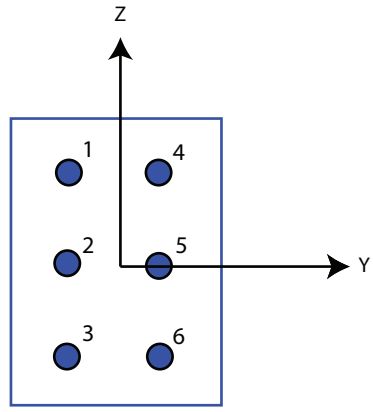
This parameter appears when **Geometry** is set to URA. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to the subarrays.

Specify the size of the array as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of rows and columns.

For a URA, elements are indexed from top to bottom along a column and continuing to the next columns from left to right. In this figure, an **Array size** of `[3,2]` produces an array of three rows and two columns.

Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]



Element spacing (m)

This parameter appears when **Geometry** is set to ULA or URA. When **Sensor Array** has the `Replicated subarray` option, this parameter applies to the subarrays.

- For a ULA, specify the spacing, in meters, between two adjacent elements in the array as a scalar.
- For a URA, specify the element spacing of the array, in meters, as a 1-by-2 vector or a scalar. If **Element spacing** is a 1-by-2 vector, the vector has the form

`[SpacingBetweenRows,SpacingBetweenColumns]`. For a discussion of these quantities, see phased.URA. If **Element spacing** is a scalar, the spacings between rows and columns are equal.

Array axis

This parameter appears when the **Geometry** parameter is set to `ULA` or when the block only supports a ULA array geometry. Specify the array axis as `x`, `y`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

Array normal

This parameter appears when you set **Geometry**to `URA` or `UCA`. Specify the **Array normal** as `x`, `y`, or `z`. All URA and UCA array elements are placed in the *yz*, *zx*, or *xy*planes, respectively, of the array coordinate system.

Radius of UCA (m)

Radius of a uniform circular array specified as a positive scalar. Units are meters.

This parameter appears when the **Geometry** is set to `UCA`.

Taper

Tapers, also known as *element weights*, are applied to sensor elements in the array. Tapers are used to modify both the amplitude and phase of the transmitted or received data.

This parameter applies to all array types, but when you set **Sensor Array** to `Replicated subarray`, this parameter applies to subarrays.

- For a `ULA` or `UCA`, specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array. If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.
- For a `URA`, specify element tapering as a complex-valued scalar or complex-valued *M*-by-*N* matrix. In this matrix, *M* is the number of elements along the *z*-axis, and *N* is the number of elements along the *y*-axis. *M* and *N* correspond to the values of `[NumberofArrayRows,NumberOfArrayColumns]` in the **Array size** matrix. If `Taper` is a scalar, the same weight is applied to each element. If **Taper** is a matrix, a weight from the matrix is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

- For a `Conformal Array`, specify element tapering as a complex-valued scalar or complex-valued 1-by-*N* vector. In this vector, *N* is the number of elements in the array as determined by the size of the **Element positions** vector. If **Taper** is a scalar, the same weight is applied to each element. If the value of **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

Element lattice

This parameter appears when **Geometry** is set to `URA`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to the subarray.

Specify the element lattice as `Rectangular` or `Triangular`

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular`— Shifts the even-row elements of a rectangular lattice toward the positive-row axis direction. The displacement is one-half the element spacing along the row dimension.

Element positions (m)

This parameter appears when **Geometry** is set to `Conformal Array`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to subarrays.

Specify the positions of conformal array elements as a 3-by-*N* matrix, where *N* is the number of elements in the conformal array. Each column of **Element positions (m)** represents the position of a single element, in the form `[x;y;z]`, in the array's local coordinate system. The local coordinate system has its origin at an arbitrary point. Units are in meters.

Element normals (deg)

This parameter appears when **Geometry** is set to `Conformal Array`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to subarrays.

Specify the normal directions of the elements in a conformal array as a 2-by-*N* matrix or a 2-by-1 column vector in degrees. The variable *N* indicates the number of elements in the array. If **Element normals (deg)** is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]`, with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If **Element normals (deg)** is a 2-by-1 column vector, the vector specifies the same pointing direction for all elements in the array.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. You can combine translation, azimuth rotation, and elevation rotation transformations. However, you cannot use transformations that require rotation about the normal.

Expression

A valid MATLAB expression containing an array constructor, for example, `phased.URA`.

Sensor Array Tab: Element Parameters

Element type

Specify antenna or microphone type as

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

Exponent of cosine pattern

This parameter appears when you set **Element type** to `Cosine Antenna`.

Specify the exponent of the cosine pattern as a scalar or a 1-by-2 vector. You must specify all values as non-negative real numbers. When you set **Exponent of cosine pattern** to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the specified value. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern and the second element is the exponent for the elevation direction cosine pattern.

Operating frequency range (Hz)

This parameter appears when **Element type** is set to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

Specify the operating frequency range, in hertz, of the antenna element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The antenna element has no response outside the specified frequency range.

Operating frequency vector (Hz)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify the frequencies, in Hz, at which to set the antenna and microphone frequency responses as a 1-by-L row vector of increasing values. Use **Frequency responses** to set the frequency responses. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of **Operating frequency vector (Hz)**.

Frequency responses (dB)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify this parameter as the frequency response of an antenna or microphone, in decibels, for the frequencies defined by **Operating frequency vector (Hz)**. Specify **Frequency responses (dB)** as a 1-by-L vector matching the dimensions of the vector specified in **Operating frequency vector (Hz)**.

Azimuth angles (deg)

This parameter appears when **Element type** is set to `Custom Antenna`.

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-P row vector. P must be greater than 2. Angle units are in degrees. Azimuth angles must lie between –180° and 180° and be in strictly increasing order.

Elevation angles (deg)

This parameter appears when the **Element type** is set to `Custom Antenna`.

Specify the elevation angles at which to compute the radiation pattern as a 1-by-Q vector. Q must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90° and be in strictly increasing order.

Radiation pattern (dB)

This parameter appears when the **Element type** is set to `Custom Antenna`.

The magnitude in db of the combined polarized antenna radiation pattern specified as a Q-by-P matrix or a Q-by-P-by-L array. The value of Q must match the value of Q specified by **Elevation angles (deg)**. The value of P must match the value of P specified by **Azimuth angles (deg_**. The value of L must match the value of L specified by **Operating frequency vector (Hz)**.

Polar pattern frequencies (Hz)

This parameter appears when the **Element type** is set to `Custom Microphone`.

Specify the measuring frequencies of the polar patterns as a 1-by-*M* vector. The measuring frequencies lie within the frequency range specified by**Operating frequency vector (Hz)**. Frequency units are in Hz.

Polar pattern angles (deg)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the measuring angles of the polar patterns, as a 1-by-*N* vector. The angles are measured from the central pickup axis of the microphone, and must be between –180° and 180°, inclusive.

Polar pattern (dB)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the magnitude of the microphone element polar pattern as an *M*-by-*N* matrix. *M* is the number of measuring frequencies specified in **Polar pattern frequencies (Hz)**. *N* is the number of measuring angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

Baffle the back of the element

This check box appears only when the **Element type** parameter is set to `Isotropic Antenna` or `Omni Microphone`.

Select this check box to baffle the back of the antenna element. In this case, the antenna responses to all azimuth angles beyond ±90° from *broadside* are set to zero. Define the broadside direction as 0° azimuth angle and 0° elevation angle.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Description	Supported Data Types
`In`	Input signal. The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.	Double-precision floating point
`Y`	Spatial spectrum.	Double-precision floating point
`Ang`	Estimated DOA angle.	Double-precision floating point

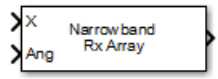
Introduced in R2014b

Narrowband Receive Array

Narrowband receive array



Library

Transmitters and Receivers

`phasedtxrxlib`

Description

The Narrowband Receive Array block implements a narrowband receive array. The array processes narrowband plane waves incident on the sensor elements of the array. The delay at each element is approximated using a corresponding phase shift in the time domain.

Parameters

Signal Propagation speed (m/s)

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

Operating frequency (Hz)

Specify the operating frequency of the system, in hertz, as a positive scalar.

Enable weights input

Select this check box to specify array weights via the input port `W`. The input port appears only when this box is selected.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose

`Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see “Choosing a Simulation Mode” (Simulink) from the Simulink documentation.

Clicking the **Analyze** button launches the `sensorArrayAnalyzer` app. The app lets you examine important array properties such as array response and array geometry.

Array Parameters

Specify sensor array as

Sensor element or sensor array specified. A sensor array can also contain subarrays or as a partitioned array. This parameter can also be expressed as a MATLAB expression.

Types

`Single element`
`Array (no subarrays)`
`Partitioned array`
`Replicated subarray`
`MATLAB expression`

Geometry

Specify the array geometry as one of the following:

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array
- `Conformal Array` — arbitrary element positions

Number of elements

Number of array elements.

Number of array elements, specified as a positive integer. This parameter appears when the **Geometry** is set to `ULA` or `UCA`. If **Sensor Array** has a `Replicated subarray` option, this parameter applies to the sub-array.

Array size

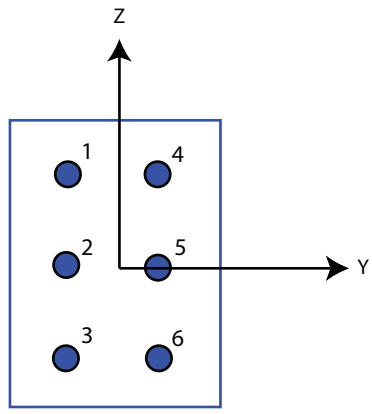
This parameter appears when **Geometry** is set to `URA`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to the subarrays.

Specify the size of the array as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of rows and columns.

For a URA, elements are indexed from top to bottom along a column and continuing to the next columns from left to right. In this figure, an **Array size** of `[3,2]` produces an array of three rows and two columns.

Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]



Element spacing (m)

This parameter appears when **Geometry** is set to ULA or URA. When **Sensor Array** has the `Replicated subarray` option, this parameter applies to the subarrays.

- For a ULA, specify the spacing, in meters, between two adjacent elements in the array as a scalar.
- For a URA, specify the element spacing of the array, in meters, as a 1-by-2 vector or a scalar. If **Element spacing** is a 1-by-2 vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumns]`. For a discussion of these quantities, see phased.URA. If **Element spacing** is a scalar, the spacings between rows and columns are equal.

Array axis

This parameter appears when the **Geometry** parameter is set to ULA or when the block only supports a ULA array geometry. Specify the array axis as `x`, `y`, or

`z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

Array normal

This parameter appears when you set **Geometry**to `URA` or `UCA`. Specify the **Array normal** as `x`, `y`, or `z`. All URA and UCA array elements are placed in the *yz*, *zx*, or *xy*planes, respectively, of the array coordinate system.

Radius of UCA (m)

Radius of a uniform circular array specified as a positive scalar. Units are meters.

This parameter appears when the **Geometry** is set to `UCA`.

Taper

Tapers, also known as *element weights*, are applied to sensor elements in the array. Tapers are used to modify both the amplitude and phase of the transmitted or received data.

This parameter applies to all array types, but when you set **Sensor Array** to `Replicated subarray`, this parameter applies to subarrays.

- For a `ULA` or `UCA`, specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array. If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.
- For a `URA`, specify element tapering as a complex-valued scalar or complex-valued *M*-by-*N* matrix. In this matrix, *M* is the number of elements along the *z*-axis, and *N* is the number of elements along the *y*-axis. *M* and *N* correspond to the values of `[NumberofArrayRows,NumberOfArrayColumns]` in the **Array size** matrix. If `Taper` is a scalar, the same weight is applied to each element. If **Taper** is a matrix, a weight from the matrix is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.
- For a `Conformal Array`, specify element tapering as a complex-valued scalar or complex-valued 1-by-*N* vector. In this vector, *N* is the number of elements in the array as determined by the size of the **Element positions** vector. If **Taper** is a scalar, the same weight is applied to each element. If the value of **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

Element lattice

This parameter appears when **Geometry** is set to `URA`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to the subarray.

Specify the element lattice as `Rectangular` or `Triangular`

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular`— Shifts the even-row elements of a rectangular lattice toward the positive-row axis direction. The displacement is one-half the element spacing along the row dimension.

Element positions (m)

This parameter appears when **Geometry** is set to `Conformal Array`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to subarrays.

Specify the positions of conformal array elements as a 3-by-*N* matrix, where *N* is the number of elements in the conformal array. Each column of **Element positions (m)** represents the position of a single element, in the form `[x;y;z]`, in the array's local coordinate system. The local coordinate system has its origin at an arbitrary point. Units are in meters.

Element normals (deg)

This parameter appears when **Geometry** is set to `Conformal Array`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to subarrays.

Specify the normal directions of the elements in a conformal array as a 2-by-*N* matrix or a 2-by-1 column vector in degrees. The variable *N* indicates the number of elements in the array. If **Element normals (deg)** is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]`, with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If **Element normals (deg)** is a 2-by-1 column vector, the vector specifies the same pointing direction for all elements in the array.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. You can combine translation, azimuth rotation, and elevation rotation transformations. However, you cannot use transformations that require rotation about the normal.

Subarray definition matrix

This parameter appears when **Sensor array** is set to `Partitioned array`.

Specify the subarray selection as an *M*-by-*N* matrix. *M* is the number of subarrays and *N* is the total number of elements in the array. Each row of the matrix indicates which elements belong to the corresponding subarray. Each entry in the matrix is 1 or 0, where 1 indicates that the element appears in the subarray and 0 indicates the opposite. Each row must contain at least one 1.

The phase center of each subarray is its geometric center. **Subarray definition matrix** and **Geometry** determine the geometric center.

Subarray steering method

This parameter appears when **Sensor array** is set to `Partitioned array` or `Replicated subarray`.

Specify the subarray steering method as

- `None`
- `Phase`
- `Time`

When using the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, or Wideband Transmit Arrayblocks, selecting `Phase` or `Time` opens the block input port, `Steer`.

Phase shifter frequency (Hz)

This parameter appears when you set **Sensor array** to `Partitioned array` or `Replicated subarray` and you set **Subarray steering method** to `Phase`.

Specify the operating frequency, in hertz, of phase shifters to perform subarray steering as a positive scalar.

Number of bits in phase shifters

This parameter appears when you set **Sensor array** to `Partitioned array` or `Replicated subarray` and you set **Subarray steering method** to `Phase`.

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

Subarrays layout

This parameter appears when you set **Sensor array** to `Replicated subarray`.

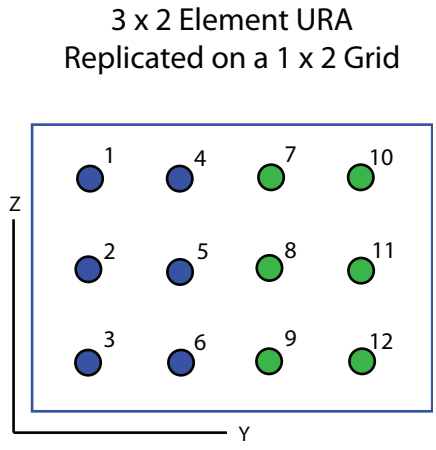
Specify the layout of the replicated subarrays as `Rectangular` or `Custom`.

Grid size

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

Rectangular subarray grid size, specified as a single positive integer or a positive integer-valued 1-by-2 row vector.

If **Grid size** is an integer scalar, the array has an equal number of subarrays in each row and column. If **Grid size** is a 1-by-2 vector of the form `[NumberOfRows, NumberOfColumns]`, the first entry is the number of subarrays along each column. The second entry is the number of subarrays in each row. A row is along the local *y*-axis, and a column is along the local *z*-axis. The figure here shows how you can replicate a 3-by-2 URA subarray using a **Grid size** of `[1,2]`.



Grid spacing

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

Specify the rectangular grid spacing of subarrays as a real-valued positive scalar, a 1-by-2 row vector, or `Auto`. Grid spacing units are expressed in meters.

- If **Grid spacing** is a scalar, the spacing along the row and the spacing along the column is the same.
- If **Grid spacing** is a 1-by-2 row vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumn]`. The first entry specifies

the spacing between rows along a column. The second entry specifies the spacing between columns along a row.

- If **Grid spacing** is set to `Auto`, replication preserves the element spacing of the subarray for both rows and columns while building the full array. This option is available only when you specify **Geometry** as `ULA` or `URA`.

Subarray positions (m)

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Custom`.

Specify the positions of the subarrays in the custom grid as a 3-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix represents the position of a single subarray, in meters, in the array's local coordinate system. The coordinates are expressed in the form `[x; y; z]`.

Subarray normals

This parameter appears when you set the **Sensor array** parameter to `Replicated subarray` and the **Subarrays layout** to `Custom`.

Specify the normal directions of the subarrays in the array. This parameter value is a 2-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix specifies the normal direction of the corresponding subarray, in the form `[azimuth; elevation]`. Each angle is in degrees and is defined in the local coordinate system.

You can use the **Subarray positions** and **Subarray normals** parameters to represent any arrangement in which pairs of subarrays differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal.

Expression

A valid MATLAB expression containing an array constructor, for example, `phased.URA`.

Sensor Array Tab: Element Parameters

Element type

Specify antenna or microphone type as

- `Isotropic Antenna`

- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

Exponent of cosine pattern

This parameter appears when you set **Element type** to `Cosine Antenna`.

Specify the exponent of the cosine pattern as a scalar or a 1-by-2 vector. You must specify all values as non-negative real numbers. When you set **Exponent of cosine pattern** to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the specified value. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern and the second element is the exponent for the elevation direction cosine pattern.

Operating frequency range (Hz)

This parameter appears when **Element type** is set to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

Specify the operating frequency range, in hertz, of the antenna element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The antenna element has no response outside the specified frequency range.

Operating frequency vector (Hz)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify the frequencies, in Hz, at which to set the antenna and microphone frequency responses as a 1-by-L row vector of increasing values. Use **Frequency responses** to set the frequency responses. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of **Operating frequency vector (Hz)**.

Frequency responses (dB)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify this parameter as the frequency response of an antenna or microphone, in decibels, for the frequencies defined by **Operating frequency vector (Hz)**. Specify

Frequency responses (dB) as a 1-by-*L* vector matching the dimensions of the vector specified in **Operating frequency vector (Hz)**.

Azimuth angles (deg)

This parameter appears when **Element type** is set to `Custom Antenna`.

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Angle units are in degrees. Azimuth angles must lie between –180° and 180° and be in strictly increasing order.

Elevation angles (deg)

This parameter appears when the **Element type** is set to `Custom Antenna`.

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90° and be in strictly increasing order.

Radiation pattern (dB)

This parameter appears when the **Element type** is set to `Custom Antenna`.

The magnitude in db of the combined polarized antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The value of *Q* must match the value of *Q* specified by **Elevation angles (deg)**. The value of *P* must match the value of *P* specified by **Azimuth angles (deg_**. The value of *L* must match the value of *L* specified by **Operating frequency vector (Hz)**.

Polar pattern frequencies (Hz)

This parameter appears when the **Element type** is set to `Custom Microphone`.

Specify the measuring frequencies of the polar patterns as a 1-by-*M* vector. The measuring frequencies lie within the frequency range specified by**Operating frequency vector (Hz)**. Frequency units are in Hz.

Polar pattern angles (deg)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the measuring angles of the polar patterns, as a 1-by-*N* vector. The angles are measured from the central pickup axis of the microphone, and must be between –180° and 180°, inclusive.

Polar pattern (dB)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the magnitude of the microphone element polar pattern as an *M*-by-*N* matrix. *M* is the number of measuring frequencies specified in **Polar pattern frequencies (Hz)**. *N* is the number of measuring angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

Baffle the back of the element

This check box appears only when the **Element type** parameter is set to `Isotropic Antenna` or `Omni Microphone`.

Select this check box to baffle the back of the antenna element. In this case, the antenna responses to all azimuth angles beyond ±90° from *broadside* are set to zero. Define the broadside direction as 0° azimuth angle and 0° elevation angle.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Description	Supported Data Types
`X`	Arriving signals The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.	Double-precision floating point
`Ang`	Incident directions of signals	Double-precision floating point

Port	Description	Supported Data Types
`W`	Array weights	Double-precision floating point
`Steer`	Steering angle	Double-precision floating point
`Out`	Output signals	Double-precision floating point

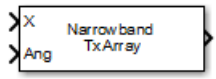
Narrowband Transmit Array

Narrowband transmit array



Library

Transmitters and Receivers

`phasedtxrxlib`

Description

The Narrowband Transmit Array block generates narrowband plane waves in the far field of the array by adding the far-field radiated signals of each element. Think of the block output as the field at a reference distance from the element or from the center of the array.

Parameters

Signal Propagation speed (m/s)

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

Operating frequency (Hz)

Specify the operating frequency of the system, in hertz, as a positive scalar.

Enable weights input

Select this check box to specify array weights using the input port `W`. The input port appears only when this box is checked.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose

`Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see “Choosing a Simulation Mode” (Simulink) from the Simulink documentation.

Clicking the **Analyze** button launches the `sensorArrayAnalyzer` app. The app lets you examine important array properties such as array response and array geometry.

Array Parameters

Specify sensor array as

Sensor element or sensor array specified. A sensor array can also contain subarrays or as a partitioned array. This parameter can also be expressed as a MATLAB expression.

Types

`Single element`
`Array (no subarrays)`
`Partitioned array`
`Replicated subarray`
`MATLAB expression`

Geometry

Specify the array geometry as one of the following:

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array
- `Conformal Array` — arbitrary element positions

Number of elements

Number of array elements.

Number of array elements, specified as a positive integer. This parameter appears when the **Geometry** is set to `ULA` or `UCA`. If **Sensor Array** has a `Replicated subarray` option, this parameter applies to the sub-array.

Array size

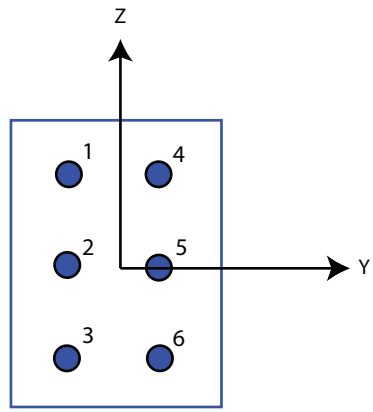
This parameter appears when **Geometry** is set to `URA`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to the subarrays.

Specify the size of the array as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of rows and columns.

For a URA, elements are indexed from top to bottom along a column and continuing to the next columns from left to right. In this figure, an **Array size** of `[3,2]` produces an array of three rows and two columns.

Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]



Element spacing (m)

This parameter appears when **Geometry** is set to ULA or URA. When **Sensor Array** has the `Replicated subarray` option, this parameter applies to the subarrays.

- For a ULA, specify the spacing, in meters, between two adjacent elements in the array as a scalar.
- For a URA, specify the element spacing of the array, in meters, as a 1-by-2 vector or a scalar. If **Element spacing** is a 1-by-2 vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumns]`. For a discussion of these quantities, see phased.URA. If **Element spacing** is a scalar, the spacings between rows and columns are equal.

Array axis

This parameter appears when the **Geometry** parameter is set to ULA or when the block only supports a ULA array geometry. Specify the array axis as `x`, `y`, or

z. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

Array normal

This parameter appears when you set **Geometry**to URA or UCA. Specify the **Array normal** as x, y, or z. All URA and UCA array elements are placed in the *yz*, *zx*, or *xy*planes, respectively, of the array coordinate system.

Radius of UCA (m)

Radius of a uniform circular array specified as a positive scalar. Units are meters.

This parameter appears when the **Geometry** is set to UCA.

Taper

Tapers, also known as *element weights*, are applied to sensor elements in the array. Tapers are used to modify both the amplitude and phase of the transmitted or received data.

This parameter applies to all array types, but when you set **Sensor Array** to `Replicated subarray`, this parameter applies to subarrays.

- For a ULA or UCA, specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array. If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.
- For a URA, specify element tapering as a complex-valued scalar or complex-valued *M*-by-*N* matrix. In this matrix, *M* is the number of elements along the *z*-axis, and *N* is the number of elements along the *y*-axis. *M* and *N* correspond to the values of `[NumberofArrayRows,NumberOfArrayColumns]` in the **Array size** matrix. If `Taper` is a scalar, the same weight is applied to each element. If **Taper** is a matrix, a weight from the matrix is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.
- For a `Conformal Array`, specify element tapering as a complex-valued scalar or complex-valued 1-by-*N* vector. In this vector, *N* is the number of elements in the array as determined by the size of the **Element positions** vector. If **Taper** is a scalar, the same weight is applied to each element. If the value of **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

Element lattice

This parameter appears when **Geometry** is set to `URA`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to the subarray.

Specify the element lattice as `Rectangular` or `Triangular`

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular`— Shifts the even-row elements of a rectangular lattice toward the positive-row axis direction. The displacement is one-half the element spacing along the row dimension.

Element positions (m)

This parameter appears when **Geometry** is set to `Conformal Array`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to subarrays.

Specify the positions of conformal array elements as a 3-by-*N* matrix, where *N* is the number of elements in the conformal array. Each column of **Element positions (m)** represents the position of a single element, in the form `[x;y;z]`, in the array's local coordinate system. The local coordinate system has its origin at an arbitrary point. Units are in meters.

Element normals (deg)

This parameter appears when **Geometry** is set to `Conformal Array`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to subarrays.

Specify the normal directions of the elements in a conformal array as a 2-by-*N* matrix or a 2-by-1 column vector in degrees. The variable *N* indicates the number of elements in the array. If **Element normals (deg)** is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]`, with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If **Element normals (deg)** is a 2-by-1 column vector, the vector specifies the same pointing direction for all elements in the array.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. You can combine translation, azimuth rotation, and elevation rotation transformations. However, you cannot use transformations that require rotation about the normal.

Subarray definition matrix

This parameter appears when **Sensor array** is set to `Partitioned array`.

Specify the subarray selection as an *M*-by-*N* matrix. *M* is the number of subarrays and *N* is the total number of elements in the array. Each row of the matrix indicates which elements belong to the corresponding subarray. Each entry in the matrix is 1 or 0, where 1 indicates that the element appears in the subarray and 0 indicates the opposite. Each row must contain at least one 1.

The phase center of each subarray is its geometric center. **Subarray definition matrix** and **Geometry** determine the geometric center.

Subarray steering method

This parameter appears when **Sensor array** is set to `Partitioned array` or `Replicated subarray`.

Specify the subarray steering method as

- `None`
- `Phase`
- `Time`

When using the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, or Wideband Transmit Arrayblocks, selecting `Phase` or `Time` opens the block input port, `Steer`.

Phase shifter frequency (Hz)

This parameter appears when you set **Sensor array** to `Partitioned array` or `Replicated subarray` and you set **Subarray steering method** to `Phase`.

Specify the operating frequency, in hertz, of phase shifters to perform subarray steering as a positive scalar.

Number of bits in phase shifters

This parameter appears when you set **Sensor array** to `Partitioned array` or `Replicated subarray` and you set **Subarray steering method** to `Phase`.

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

Subarrays layout

This parameter appears when you set **Sensor array** to `Replicated subarray`.

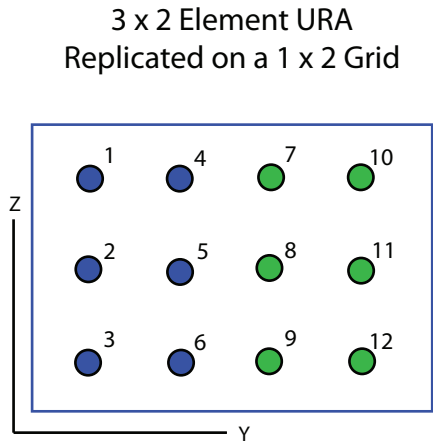
Specify the layout of the replicated subarrays as `Rectangular` or `Custom`.

Grid size

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

Rectangular subarray grid size, specified as a single positive integer or a positive integer-valued 1-by-2 row vector.

If **Grid size** is an integer scalar, the array has an equal number of subarrays in each row and column. If **Grid size** is a 1-by-2 vector of the form `[NumberOfRows, NumberOfColumns]`, the first entry is the number of subarrays along each column. The second entry is the number of subarrays in each row. A row is along the local *y*-axis, and a column is along the local *z*-axis. The figure here shows how you can replicate a 3-by-2 URA subarray using a **Grid size** of `[1,2]`.



Grid spacing

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

Specify the rectangular grid spacing of subarrays as a real-valued positive scalar, a 1-by-2 row vector, or `Auto`. Grid spacing units are expressed in meters.

- If **Grid spacing** is a scalar, the spacing along the row and the spacing along the column is the same.
- If **Grid spacing** is a 1-by-2 row vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumn]`. The first entry specifies

the spacing between rows along a column. The second entry specifies the spacing between columns along a row.

- If **Grid spacing** is set to `Auto`, replication preserves the element spacing of the subarray for both rows and columns while building the full array. This option is available only when you specify **Geometry** as `ULA` or `URA`.

Subarray positions (m)

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Custom`.

Specify the positions of the subarrays in the custom grid as a 3-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix represents the position of a single subarray, in meters, in the array's local coordinate system. The coordinates are expressed in the form `[x; y; z]`.

Subarray normals

This parameter appears when you set the **Sensor array** parameter to `Replicated subarray` and the **Subarrays layout** to `Custom`.

Specify the normal directions of the subarrays in the array. This parameter value is a 2-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix specifies the normal direction of the corresponding subarray, in the form `[azimuth; elevation]`. Each angle is in degrees and is defined in the local coordinate system.

You can use the **Subarray positions** and **Subarray normals** parameters to represent any arrangement in which pairs of subarrays differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal.

Expression

A valid MATLAB expression containing an array constructor, for example, `phased.URA`.

Sensor Array Tab: Element Parameters

Element type

Specify antenna or microphone type as

- `Isotropic Antenna`

- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

Exponent of cosine pattern

This parameter appears when you set **Element type** to `Cosine Antenna`.

Specify the exponent of the cosine pattern as a scalar or a 1-by-2 vector. You must specify all values as non-negative real numbers. When you set **Exponent of cosine pattern** to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the specified value. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern and the second element is the exponent for the elevation direction cosine pattern.

Operating frequency range (Hz)

This parameter appears when **Element type** is set to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

Specify the operating frequency range, in hertz, of the antenna element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The antenna element has no response outside the specified frequency range.

Operating frequency vector (Hz)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify the frequencies, in Hz, at which to set the antenna and microphone frequency responses as a 1-by-*L* row vector of increasing values. Use **Frequency responses** to set the frequency responses. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of **Operating frequency vector (Hz)**.

Frequency responses (dB)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify this parameter as the frequency response of an antenna or microphone, in decibels, for the frequencies defined by **Operating frequency vector (Hz)**. Specify

Frequency responses (dB) as a 1-by-*L* vector matching the dimensions of the vector specified in **Operating frequency vector (Hz)**.

Azimuth angles (deg)

This parameter appears when **Element type** is set to `Custom Antenna`.

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Angle units are in degrees. Azimuth angles must lie between –180° and 180° and be in strictly increasing order.

Elevation angles (deg)

This parameter appears when the **Element type** is set to `Custom Antenna`.

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90° and be in strictly increasing order.

Radiation pattern (dB)

This parameter appears when the **Element type** is set to `Custom Antenna`.

The magnitude in db of the combined polarized antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The value of *Q* must match the value of *Q* specified by **Elevation angles (deg)**. The value of *P* must match the value of *P* specified by **Azimuth angles (deg_**. The value of *L* must match the value of *L* specified by **Operating frequency vector (Hz)**.

Polar pattern frequencies (Hz)

This parameter appears when the **Element type** is set to `Custom Microphone`.

Specify the measuring frequencies of the polar patterns as a 1-by-*M* vector. The measuring frequencies lie within the frequency range specified by**Operating frequency vector (Hz)**. Frequency units are in Hz.

Polar pattern angles (deg)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the measuring angles of the polar patterns, as a 1-by-*N* vector. The angles are measured from the central pickup axis of the microphone, and must be between –180° and 180°, inclusive.

Polar pattern (dB)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the magnitude of the microphone element polar pattern as an *M*-by-*N* matrix. *M* is the number of measuring frequencies specified in **Polar pattern frequencies (Hz)**. *N* is the number of measuring angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

Baffle the back of the element

This check box appears only when the **Element type** parameter is set to `Isotropic Antenna` or `Omni Microphone`.

Select this check box to baffle the back of the antenna element. In this case, the antenna responses to all azimuth angles beyond ±90° from *broadside* are set to zero. Define the broadside direction as 0° azimuth angle and 0° elevation angle.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Description	Supported Data Types
`X`	Signals to radiate. The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.	Double-precision floating point
`Ang`	Radiating directions of signals.	Double-precision floating point

Port	Description	Supported Data Types
`W`	Array weight vector.	Double-precision floating point
`Steer`	Steering angle.	Double-precision floating point
`Out`	Radiated signals.	Double-precision floating point

phased.Radiator

Introduced in R2014b

Phase Coded Waveform

Phase-coded pulse waveform

Library

Waveforms

`phasedwavlib`

Description

The Phase-Coded Waveform block generates samples of a phase-coded pulse waveform with specified chip width, pulse repetition frequency (PRF), and phase code. The block outputs an integer number of pulses or samples.

Parameters

Sample rate

Specify the sample rate, in hertz, as a positive scalar. The value of this parameter must satisfy these constraints:

- The ratio of **Sample rate** to **Pulse repetition frequency** must be an integer scalar or row vector of integers.
- The product of **Sample rate** and **Chip width** must be an integer.

Phase code

Specify the phase code type to use in phase modulation. Valid values are:

- `Barker`
- `Frank`

- `P1`
- `P2`
- `P3`
- `P4`
- `Px`
- `Zadoff-Chu`

Chip width (s)

Specify the duration, in seconds, of each chip in a phase-coded waveform as a positive scalar.

The value of this parameter must satisfy these constraints:

- The product of **Chip width**, **Number of chips**, and **Pulse repetition frequency** must be less than or equal to one.
- The product of **Sample rate** and **Chip width** must be an integer.

Number of chips

Specify the number of chips in a phase-coded waveform as a positive integer. The product of the **Chip width**, **Number of chips**, and **Pulse repetition frequency** parameters must be less than or equal to one.

The table shows additional constraints on the number of chips for different code types.

If the Phase code parameter is...	Then the Number of chips parameter must be...
`Frank`, `P1`, or `Px`	A perfect square
`P2`	An even number that is a perfect square
`Barker`	2, 3, 4, 5, 7, 11, or 13

Zadoff-Chu sequence index

Specify the sequence index used in Zadoff-Chu code as a positive integer. This parameter appears only when you set **Phase code** to `Zadoff-Chu`. The value of the **Zadoff-Chu sequence index** parameter must be prime, relative to the value of the **Number of chips** parameter.

Pulse repetition frequency (Hz)

Pulse repetition frequency, *PRF*, specified as a scalar or a row vector. Units are in Hz. The pulse repetition interval *PRI* is the inverse of the *PRF*. The value of **Pulse repetition frequency (Hz)** must satisfy these constraints:

- The product of **Pulse width** and **Pulse repetition frequency (Hz)** must be less than or equal to one. This is equivalent to the requirement that the pulse width is less than a pulse repetition interval. For the phase-coded waveform, the pulse width is the product of the chip width and number of chips.
- The ratio of sample rate to any element of **Pulse repetition frequency** must be an integer. This is equivalent to requiring that the number of samples in one pulse repetition interval be an integer.

You can select the value of *PRF* by using block parameter settings or an input port.

- When the **Enable PRF selection input** check box is not selected, you set the *PRF* using block parameters.
  - To implement a constant *PRF*, specify **Pulse repetition frequency (Hz)** as a positive scalar.
  - To implement a staggered *PRF*, specify **Pulse repetition frequency (Hz)** as a row vector with all strictly positive values. After the waveform reaches the last element of the vector, the process continues cyclically with the first element of the vector. When *PRF* is staggered, the time between successive output pulses is determined sequentially by the successive values of the *PRF* vector.
- When the **Enable PRF selection input** check box is selected, you can implement a selectable *PRF* by specifying **Pulse repetition frequency (Hz)** as a row vector with positive real-valued entries. But this time, when you execute block, select a *PRF* by passing an index into the *PRF* vector into the `PRFIdx` port.

In all cases, when you use a varying *PRF* and choose **Output signal format** as `Pulses`, the number of samples per pulse can vary as well. When you choose `Samples`, the number of samples per pulse is fixed.

Enable PRF selection input

Check this box to select which predefined PRF to use during the simulation via input. Uncheck this box to use the **Pulse repetition frequency** parameter to define the PRF sequence used in the simulation.

Output signal format

Specify the format of the output signal as `Pulses` or `Samples`.

If you set this parameter to `Samples`, the output of the block is in the form of multiple samples. The number of samples is the value of the **Number of samples in output** parameter.

If you set this parameter to `Pulses`, the output of the block is in the form of multiple pulses. The number of pulses is the value of the **Number of pulses in output** parameter.

The value of **Output signal format** must be set to `Samples` when the **Pulse repetition frequency (Hz)** parameter is a row vector.

Number of samples in output

Number of samples in the block output, specified as a positive integer. This parameter appears only when you set **Output signal format** to `Samples`.

Number of pulses in output

Specify the number of pulses in the block output as a positive integer. This parameter appears only when you set **Output signal format** to `Pulses`.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see "Choosing a Simulation Mode" (Simulink) from the Simulink documentation.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Description	Supported Data Types
`PRFIdx`	PRF selection index.	Double-precision floating point
`Out`	Output waveform.	Double-precision floating point

phased.PhaseCodedWaveform

Introduced in R2014b

Phase Shift Beamformer

Narrowband phase-shift beamformer
Library: Phased Array System Toolbox / Beamforming

Description

The Phase Shift Beamformer block performs delay-and-sum beamforming. The delay is approximated using the phase-shift approximation in the time domain.

Ports

Input

X — Input signal

M-by-*N* complex-valued matrix

Input signal, specified as an *M*-by-*N* matrix, where *M* is the number of samples in the data, and *N* is the number of array elements.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Data Types: `double`
Complex Number Support: Yes

Ang — Beamforming direction

2-by-1 real-valued vector | 2-by-*L* real-valued matrix

Beamforming direction, specified as a 2-by-*L* real-valued matrix, where *L* is the number of beamforming directions. Each column takes the form of `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°, inclusive, and the elevation angle must lie between –90° and 90°, inclusive. Angles are defined with respect to the local coordinate system of the array.

Dependencies

To enable this port, set the **Source of beamforming direction** parameter to `Input port`.

Data Types: `double`

Output

`Y` — Beamformed output

M-by-*L* complex-valued matrix

Beamformed output, returned as an *M*-by-*L* complex-valued matrix. The quantity *M* is the number of signal samples and *L* is the number of desired beamforming directions specified by the `Beamforming direction` parameter or from the `Ang` port.

Data Types: `double`
Complex Number Support: Yes

`W` — Beamforming weights

N-by-*L* complex-valued matrix

Beamformed weights, returned as an *N*-by-*L* complex-valued matrix. The quantity *N* is the number of array elements. When the **Specify sensor array as** parameter is set to `Partitioned array` or `Replicated subarray`, *N* represents the number of subarrays. *L* is the number of desired beamforming directions specified in the `Ang` port or by the `Beamforming direction (deg)` property. There is one set of weights for each beamforming direction.

Dependencies

To enable this port, select the **Enable weights output** checkbox.

Data Types: `double`
Complex Number Support: Yes

Parameters

Main tab

`Signal propagation speed (m/s)` — Signal propagation speed
`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value return by `physconst('LightSpeed')`.

`Operating frequency (Hz)` — System operating frequency
`300.0e6` (default) | positive real scalar

Specify the operating frequency of the system as a positive scalar. Units are in Hz.

`Source of beamforming direction` — Source of beamforming direction
`Property` (default) | `Input port`

Source of beamforming direction, specified as `Property` or `Input port`. When you set **Source of beamforming direction** to `Property`, you then set the direction using the **Beamforming direction (deg)** parameter. When you select `Input port`, the direction is determined by the input to the `Ang` port.

`Beamforming direction (deg)` — Beamforming directions
2-by-*L* real-valued matrix

Beamforming directions, specified as a *2*-by-*L* real-valued matrix, where *L* is the number of beamforming directions. Each column takes the form `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°. Angles are defined with respect to the local coordinate system of the array.

Dependencies

To enable this parameter, set the **Source of beamforming direction** parameter to `Property`.

`Number of bits in phase shifters` — Number of phase shift quantization bits
`0` (default) | nonnegative integer

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

`Weights normalizing method` — Specify weights normalization method
`Distortionless` (default) | `Preserve power`

Specify this parameter to set the weights normalizing method. Choose `Distortionless` to set the gain in the beamforming direction to zero dB. Choose `Preserve power` to set the norm of the weights to one.

`Enable weights output` — Option to output beamformer weights
off (default) | on

Select this checkbox to obtain the beamformer weights from the output port, `W`.

`Simulate using` — Block simulation method
`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior

	Normal	Accelerator	Rapid Accelerator
Interpreted Execution	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
Code Generation	The block is compiled.	All blocks in the model are compiled.	

For more information, see "Choosing a Simulation Mode" (Simulink) from the Simulink documentation.

Data Types: `char`

Sensor Arrays Tab

`Specify sensor array as` — Method to specify array

`Array (no subarrays)` (default) | `Partitioned array` | `Replicated subarray` | `MATLAB expression`

Method to specify array, specified as `Array (no subarrays)` or `MATLAB expression`.

- `Array (no subarrays)` — use the block parameters to specify the array.
- `Partitioned array` — use the block parameters to specify the array.
- `Replicated subarray` — use the block parameters to specify the array.
- `MATLAB expression` — create the array using a MATLAB expression.

`Expression` — MATLAB expression used to create an array

Phased Array System Toolbox array System object

MATLAB expression used to create an array, specified as a valid Phased Array System Toolbox array System object.

Example: `phased.URA('Size',[5,3])`

Dependencies

To enable this parameter, set **Specify sensor array as** to `MATLAB expression`.

Element Parameters

`Element type` — Array element types
`Isotropic Antenna` (default) | `Cosine Antenna` | `Custom Antenna` | `Omni Microphone` | `Custom Microphone`

Antenna or microphone type, specified as one of the following:

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

`Operating frequency range (Hz)` — Operating frequency range of the antenna or microphone element
`[0,1.0e20]` (default) | real-valued 1-by-2 row vector

Specify the operating frequency range of the antenna or microphone element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The element has no response outside this frequency range. Frequency units are in Hz.

Dependencies

To enable this parameter, set **Element type** to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

`Operating frequency vector (Hz)` — Operating frequency range of custom antenna or microphone elements
`[0,1.0e20]` (default) | real-valued row vector

Specify the frequencies at which to set antenna and microphone frequency responses as a 1-by-L row vector of increasing real values. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of this vector. Frequency units are in Hz.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`. Use **Frequency responses (dB)** to set the responses at these frequencies.

`Baffle the back of the element` — Set back response of an `Isotropic Antenna` element or an `Omni Microphone` element to zero
off (default) | on

Select this checkbox to baffle the back response of the element. When backbaffled, the responses at all azimuth angles beyond ±90° from broadside are set to zero. The broadside direction is 0° azimuth angle and 0° elevation angle.

Dependencies

To enable this checkbox, set **Element type** to `Isotropic Antenna` or `Omni Microphone`.

`Exponent of cosine pattern` — Exponents of azimuth and elevation cosine patterns
`[1.5 1.5]` (default) | nonnegative scalar | real-valued 1-by-2 matrix of nonnegative values

Specify the exponents of the cosine pattern as a nonnegative scalar or a real-valued 1-by-2 matrix of nonnegative values. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern, and the second element is the exponent for the elevation direction cosine pattern. When you set this parameter to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the same power.

Dependencies

To enable this parameter, set **Element type** to `Cosine Antenna`.

`Frequency responses (dB)` — Antenna and microphone frequency response
`[0,0]` (default) | real-valued row vector

Frequency response of a custom antenna or custom microphone for the frequencies defined by the **Operating frequency vector (Hz)** parameter. The dimensions of **Frequency responses (dB)** must match the dimensions of the vector specified by the **Operating frequency vector (Hz)** parameter.

Dependencies

To enable this parameter , set **Element type** to `Custom Antenna` or `Custom Microphone`.

`Azimuth angles (deg)` — Azimuth angles of antenna radiation pattern
`[-180:180]` (default) | real-valued row vector

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-P row vector. P must be greater than 2. Azimuth angles must lie between –180° and 180°, inclusive, and be in strictly increasing order.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Elevation angles (deg)` — Elevation angles of antenna radiation pattern
`[-90:90]` (default) | real-valued row vector

Specify the elevation angles at which to compute the radiation pattern as a 1-by-Q vector. Q must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive, and be in strictly increasing order.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Magnitude pattern (dB)` — Magnitude of combined antenna radiation pattern
`zeros(181,361)` (default) | real-valued Q-by-P matrix | real-valued Q-by-P-by-L array

Magnitude of the combined antenna radiation pattern, specified as a Q-by-P matrix or a Q-by-P-by-L array. The quantity Q equals the length of the vector specified by **Elevation angles (deg)**. The quantity P equals length of the vector specified by **Azimuth angles (deg)**. The quantity L equal the length of the **Operating frequency vector (Hz)**.

- If this parameter is a Q-by-P matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a Q-by-P-by-L array, each Q-by-P page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Phase pattern (deg)` — Custom antenna radiation phase pattern
`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Phase of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equal the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Polar pattern frequencies (Hz)` — Custom microphone response frequencies
1e3 (default) | real scalar | real-valued 1-by-*L* row vector

Response frequencies of the custom microphone of the polar pattern, specified as a real scalar or real-valued 1-by-*L* vector. The response frequencies lie within the frequency range specified by the **Operating frequency vector (Hz)** vector.

Dependencies

To enable this parameter, set **Element type** is set to `Custom Microphone`.

`Polar pattern angles (deg)` — Polar pattern response angles
`[-180:180]` (default) | real-valued -by-*P* row vector

Specify the polar pattern response angles, as a 1-by-*P* vector. The angles are measured from the central pickup axis of the microphone and must be between –180° and 180°, inclusive.

Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

`Polar pattern (dB)` — Custom microphone polar response
`zeros(1,361)` (default) | real-valued L-by-P matrix

Specify the magnitude of the custom microphone element polar patterns as an L-by-P matrix. L is the number of frequencies specified in **Polar pattern frequencies (Hz)**. P is the number of angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume also that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

Array Parameters

`Geometry` — Array geometry
`ULA` (default) | `URA` | `UCA` | `Conformal Array`

Array geometry, specified as one of

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array
- `Conformal Array` — arbitrary element positions

`Number of elements` — Number of array elements
2 for ULA arrays and 5 for UCA arrays (default) | integer greater than or equal to 2

The number of array elements for ULA or UCA arrays, specified as an integer greater than or equal to 2.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

Dependencies

To enable this parameter, set **Geometry** to ULA or UCA.

`Element spacing (m)` — Spacing between array elements

`0.5` for ULA arrays and `[0.5,0.5]` for URA arrays (default) | positive scalar for ULA or URA arrays | 2-element vector of positive values for URA arrays

Spacing between adjacent array elements:

- ULA — specify the spacing between two adjacent elements in the array as a positive scalar.
- URA — specify the spacing as a positive scalar or a 1-by-2 vector of positive values. If **Element spacing (m)** is a scalar, the row and column spacings are equal. If **Element spacing (m)** is a vector, the vector has the form `[SpacingBetweenArrayRows,SpacingBetweenArrayColumns]`.
- When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

Dependencies

To enable this parameter, set **Geometry** to ULA or URA.

`Array axis` — Linear axis direction of ULA

`y` (default) | `x` | `z`

Linear axis direction of ULA, specified as `y`, `x`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

Dependencies

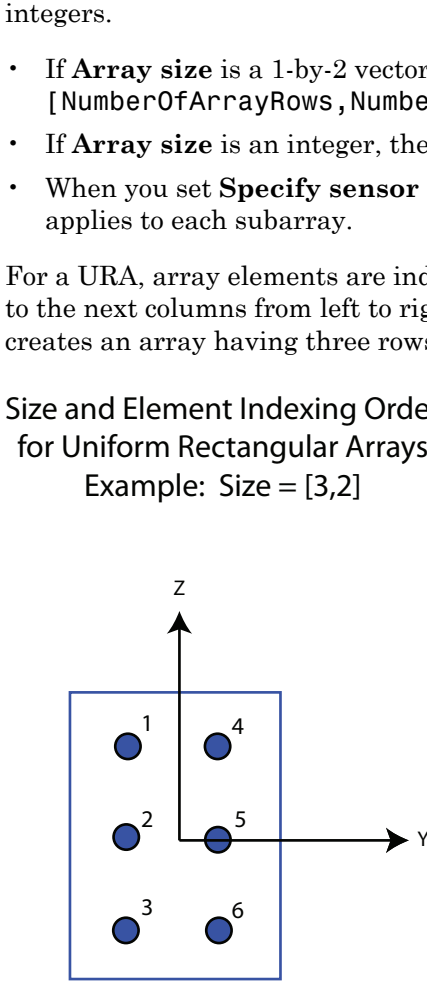
To enable this parameter, set **Geometry** to ULA. This parameter is also enabled when the block supports only ULA arrays.

`Array size` — Dimensions of URA array
`[2,2]` (default) | positive integer | 1-by-2 vector of positive integers

Dimensions of a URA array, specified as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of rows and columns.
- When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

For a URA, array elements are indexed from top to bottom along a column, and continues to the next columns from left to right. In this figure, the **Array size** value of `[3,2]` creates an array having three rows and two columns.



Dependencies

To enable this parameter, set **Geometry** to URA.

`Element lattice` — Lattice of URA element positions
`Rectangular` (default) | `Triangular`

Lattice of URA element positions, specified as `Rectangular` or `Triangular`.

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular` — Shifts the even-row elements of a rectangular lattice toward the positive row-axis direction. The displacement is one-half the element spacing along the row dimension.

Dependencies

To enable this parameter, set **Geometry** to URA.

`Array normal` — Array normal direction
`x` for URA arrays or `z` for UCA arrays (default) | `y`

Array normal direction, specified as `x`, `y`, or `z`.

Elements of planar arrays lie in a plane orthogonal to the selected array normal direction. Element boresight directions point along the array normal direction.

Array Normal Parameter Value	Element Positions and Boresight Directions
`x`	Array elements lie in the *yz*-plane. All element boresight vectors point along the *x*-axis.
`y`	Array elements lie in the *zx*-plane. All element boresight vectors point along the *y*-axis.
`z`	Array elements lie in the *xy*-plane. All element boresight vectors point along the *z*-axis.

Dependencies

To enable this parameter, set **Geometry**to URA or UCA.

`Radius of UCA (m)` — UCA array radius
0.5 (default) | positive scalar

Radius of UCA array, specified as a positive scalar.

Dependencies

To enable this parameter, set **Geometry** to UCA.

`Element positions (m)` — Positions of conformal array elements
`[0;0;0]` (default) | 3-by-*N* matrix of real values

Positions of the elements in a conformal array, specified as a 3-by-*N* matrix of real values, where *N* is the number of elements in the conformal array. Each column of this matrix represents the position `[x;y;z]` of an array element in the array local coordinate system. The origin of the local coordinate system is *(0,0,0)*. Units are in meters.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

Dependencies

To enable this parameter set **Geometry** to `Conformal Array`.

`Element normals (deg)` — Direction of conformal array element normal vectors
`[0;0]` | 2-by-1 column vector | 2-by-*N* matrix

Direction of element normal vectors in a conformal array, specified as a 2-by-1 column vector or a 2-by-*N* matrix. *N* indicates the number of elements in the array. If the parameter value is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]` with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If the parameter value is a 2-by-1 column vector, the same pointing direction is used for all array elements.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal direction.

Dependencies

To enable this parameter, set **Geometry** to `Conformal Array`.

`Taper` — Array element tapers

1 (default) | complex-valued scalar | complex-valued row vector

Element tapering, specified as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array.

Also known as *element weights*, tapers multiply the array element responses. Tapers modify both amplitude and phase of the response to reduce sidelobes or steer the main response axis.

If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. The number of weights must match the number of elements of the array.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

`Subarray definition matrix` — Define elements belonging to subarrays

logical matrix

Subarray selection matrix, specified as an *M*-by-*N* matrix of ones and zeros. *M* is the required number of subarrays and *N* is the total number of elements in the array. Each row of the matrix indicates which elements belong to the corresponding subarray. Entries in the matrix are `1` or `0`. A value of `1` indicates that the element belongs to the subarray and `0` indicates it is not in the subarray. Each row must contain at least one `1`. An element can belong to more than one subarray.

The phase center of each subarray is located at the subarray geometric center. The subarray geometric center depends on the **Subarray definition matrix** and **Geometry** parameters.

Dependencies

To enable this parameter, set **Sensor array** to `Partitioned array`.

`Subarray steering method` — Specify subarray steering method

`None` (default) | `Phase` | `Time`

Subarray steering method, specified as one of

- `None`
- `Phase`
- `Time`

When using the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, or Wideband Transmit Arrayblocks, selecting `Phase` or `Time` opens the block input port, `Steer`.

Dependencies

To enable this parameter, set **Sensor array** to `Partitioned array` or `Replicated subarray`.

`Phase shifter frequency (Hz)` — Subarray phase shifting frequency
`3.0e8` (default) | positive real-valued scalar

Operating frequency of subarray steering phase shifters, specified as a positive real-valued scalar. Units are Hz.

Dependencies

To enable this parameter, set **Sensor array** to `Partitioned array` or `Replicated subarray` and set **Subarray steering method** to `Phase`.

`Number of bits in phase shifters` — Subarray steering phase shift quantization bits
`0` (default) | non-negative integer

Subarray steering phase shift quantization bits, specified as a non-negative integer. A value of zero indicates that no quantization is performed.

Dependencies

To enable this parameter, set **Sensor array** to `Partitioned array` or `Replicated subarray` and set **Subarray steering method** to `Phase`.

`Subarrays layout` — Subarray position specification
`Rectangular` (default) | `Custom`

Specify the layout of replicated subarrays as `Rectangular` or `Custom`.

- When you set this parameter to `Rectangular`, use the **Grid size** and **Grid spacing** parameters to place the subarrays.
- When you set this parameter to `Custom`, use the **Subarray positions (m)** and **Subarray normals** parameters to place the subarrays.

Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray`

`Grid size` — Dimensions of rectangular subarray grid

`[1,2]` (default)

Rectangular subarray grid size, specified as a single positive integer or a positive integer-valued 1-by-2 row vector.

If **Grid size** is an integer scalar, the array has an equal number of subarrays in each row and column. If **Grid size** is a 1-by-2 vector of the form `[NumberOfRows, NumberOfColumns]`, the first entry is the number of subarrays along each column. The second entry is the number of subarrays in each row. A row is along the local *y*-axis, and a column is along the local *z*-axis. The figure here shows how you can replicate a 3-by-2 URA subarray using a **Grid size** of `[1,2]`.

Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

`Grid spacing (m)` — Spacing between subarrays on rectangular grid
`Auto` (default) | positive real-valued scalar | 1-by-2 vector of positive real-values

The rectangular grid spacing of subarrays, specified as a positive, real-valued scalar, a 1-by-2 row vector of positive, real-values, or `Auto`. Units are in meters.

- If **Grid spacing** is a scalar, the spacing along the row and the spacing along the column is the same.
- If **Grid spacing** is a 1-by-2 row vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumn]`. The first entry specifies the spacing between rows along a column. The second entry specifies the spacing between columns along a row.
- If **Grid spacing** is set to `Auto`, replication preserves the element spacing of the subarray for both rows and columns while building the full array. This option is available only when you specify **Geometry** as `ULA` or `URA`.

Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

`Subarray positions (m)` — Positions of subarrays
`[0,0;0.5,0.5;0,0]` (default) | 3-by-*N* real-valued matrix

Positions of the subarrays in the custom grid, specified as a real 3-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix represents the position of a single subarray in the array local coordinate system. The coordinates are expressed in the form `[x; y; z]`. Units are in meters.

Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Custom`.

`Subarray normals` — Direction of subarray normal vectors

`[0,0;0,0]` (default) | 2-by-*N* real matrix

Specify the normal directions of the subarrays in the array. This parameter value is a 2-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix specifies the normal direction of the corresponding subarray, in the form `[azimuth;elevation]`. Angle units are in degrees. Angles are defined with respect to the local coordinate system.

You can use the **Subarray positions** and **Subarray normals** parameters to represent any arrangement in which pairs of subarrays differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal.

Dependencies

To enable this parameter, set the **Sensor array** parameter to `Replicated subarray` and the **Subarrays layout** to `Custom`.

Motion Platform

Motion platform

Library

Environment and Targets

`phasedenvlib`

Description

The Motion Platform block models the motion of multiple platforms such as airplanes, ground vehicles, and/or receiving and transmitting sensors arrays, determining their positions and velocities. The platforms move along trajectories determined by initial positions and velocities, according to which motion model you choose — the velocity or acceleration model. The platform positions and velocities are updated at each simulation step. In addition, you can specify initial orientations for the platforms and obtain orientation updates.

Parameters

Model of object motion

Specify the motion model as either `Velocity` or `Acceleration`. The same motion model applies to all platforms.

Initial position (m)

Specify the initial position of the platform in meters as a 3-by-*N* matrix where each column represents the initial position of a platform in the form `[x;y;z]`. The quantity *N* is the number of platforms.

Initial velocity (m/s)

Specify the initial velocity of the platform in m/s as a 3-by-*N* matrix where each column represents the initial velocity of a platform in the form `[vx;vy;vz]`. The quantity *N* is the number of platforms. This parameter appears only when you set the **Source of velocity** or the **Source of acceleration** parameters to `Input port`.

Source of velocity

This parameter appears only when you set the **Model of object motion** parameter to `Velocity`. Then, you must supply velocity data for the model. Specify the **Source of velocity** data as either coming from a `Property` or an `Input port`.

Source of velocity	Use these model parameters or ports
`Property`	**Initial position (m)** parameter **Velocity (m/s)** parameter
`Input port`	**Initial position (m)** parameter **Initial velocity (m/s)** parameter `Vel` input port

Velocity (m/s)

Specify the current velocity of the platforms in m/s as a 3-by-*N* matrix where each column represents the current velocity of a platform in the form `[vx;vy;vz]`. This parameter appears only when you set the **Model of object motion** parameter to `Velocity` and set the **Source of velocity** parameter to `Property`.

Source of acceleration

This parameter appears only when you set the **Model of object motion** parameter to `Acceleration`. Then, you must supply acceleration values for the model. Specify the **Source of acceleration** data as either coming from a `Property` or an `Input port`.

Source of acceleration	Use these model parameters or ports
`Property`	**Initial Position (m)** parameter **Initial Velocity (m/s)** parameter **Acceleration (m/s^2)** parameter

Source of acceleration	Use these model parameters or ports
`Input port`	**Initial Position (m)** parameter **Initial Velocity (m/s)** parameter `Acl` input port

Acceleration (m/s^2)

Specify the current acceleration of the platforms in m/s^2 as a 3-by-*N* matrix where each column represents the current acceleration of a platform in the form `[ax;ay;az]`. This parameter appears only when you set the **Model of object motion** parameter to `Acceleration` and set the **Source of acceleration** parameter to `Property`.

Initial orientation axes

Specify the three axes that define the initial local *(x, y, z)* coordinate system at the platform as a 3-by-3-by-*N* matrix. Each column of the matrix represents an axis of the local coordinate system. The three axes must be orthonormal.

Enable orientation axes output

Select this check box to obtain the instantaneous orientation axes of the platform via the output port `LAxes`. The port appears only when the checkbox is selected.

Source of elapsed simulation time

Specify the source for elapsed simulation time as `Auto` or `Derive from reference input port`. When you choose `Auto`, the block computes the elapsed time. When you choose `Derive from reference input port` the block uses the time duration of a reference signal passed into the `Ref` input port.

Inherit sample rate

Select this check box to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate** parameter.

Sample rate

Specify the signal sampling rate (in hertz) as a positive scalar. This parameter appears only when the **Inherit sample rate** parameter is not selected.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose

`Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see “Choosing a Simulation Mode” (Simulink) from the Simulink documentation.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Description	Supported Data Types
`Vel`	Platform velocity input	Double-precision floating point
`Acl`	Platform acceleration input	Double-precision floating point
`Ref`	Reference signal input	Double-precision floating point
`Pos`	Platform position output	Double-precision floating point
`Vel`	Platform velocity output	Double-precision floating point
`LAxes`	Platform orientation output	Double-precision floating point

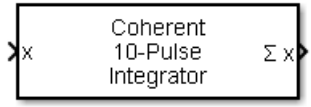
Pulse Integrator

Coherent or noncoherent pulse integration



Library

Detection

`phaseddetectlib`

Description

The Pulse Integrator block performs coherent or noncoherent integration of successive pulses of a signal and puts out an integrated output. You can specify how many pulses to integrate and the number of overlapped pulses in successive integrations.

Parameters

Integration method

Specify the integration method as `Coherent` or `Noncoherent`.

Number of pulses to integrate

Specify the number of pulses to integrate as an integer.

Integration overlap (in pulses)

Specify the number of overlapped pulses in successive integrations as an integer. This number must be less than the value specified in **Number of pulses to integrate**.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Supported Data Types
X	Double-precision floating point
∑ X	Double-precision floating point

Radar Target

Radar target

Library

Environment and Targets

`phasedenvlib`

Description

The Radar Target block models a radar target that reflects the signal according to the specified radar cross section (RCS). The block supports all four Swerling models.

Parameters

Source of mean radar cross section

Specify whether the target's mean radar cross-section (RCS) value comes from the **Mean radar cross section** parameter of this block or from an input port. Values of this parameter are

`Property`	The **Mean radar cross section** parameter for this block specifies the mean RCS value.
`Input port`	Choosing this value creates the `RCS` input port to specify the mean radar cross-section.

Mean radar cross section (m^2)

Specify the mean value of the target's radar cross section, in square meters, as a nonnegative scalar. This parameter appears only when the **Source of mean radar cross section** parameter is set to `Property`.

Fluctuation model

Specify the statistical model of the target as one of `Nonfluctuating`, `Swerling1`, `Swerling2`, `Swerling3`, or `Swerling4`. Setting this parameter to a value other than `Nonfluctuating`, allows setting cross-sections parameters via an input port, `Update`.

Signal Propagation speed (m/s)

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

Operating frequency (Hz)

Specify the carrier frequency of the signal that reflects from the target, as a positive scalar in hertz.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone

`Code Generation`	The block is compiled.	All blocks in the model are compiled.	executable from the model.

For more information, see “Choosing a Simulation Mode” (Simulink) from the Simulink documentation.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Description	Supported Data Types
`X`	Incident signal. The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.	Double-precision floating point
`RCS`	Mean radar cross-section.	Double-precision floating point
`Update`	Update RCS at block execution.	Double-precision floating point
`Out`	Scattered signal.	Double-precision floating point

Range Angle Calculator

Range and angle calculations

Library

Environment and Targets

`phasedenvlib`

Description

The Range Angle Calculator block calculates the ranges and/or the azimuth and elevation angles of several positions with respect to a reference position and with respect to a reference axes orientation. The reference position and reference axes can be specified in the block dialog or using input ports.

Parameters

Propagation model

Specify the propagation model by setting this parameter to `Free space` or `Two-ray`.

Reference position source

Specify the reference position source by setting this parameter to `Property` or `Input port`. If **Reference position source** is set to `Property`, set the position using the **Reference position** parameter. If **Reference position source** is set to `Input port`, use the input port labeled `RefPos`.

Reference position

Specify the reference position as a 3-by-1 vector of rectangular coordinates in meters in the form `[x;y;z]`. The reference position serves as the origin of the local

coordinate system. Ranges and angles of the input positions are measured with respect to the reference position. This parameter appears only when **Reference position source** is set to `Property`.

Reference axes source

Specify the reference axes source by setting this parameter to `Property` or `Input port`. If **Reference axes source** is set to `Property`, set the axes using the **Reference axes** parameter. If **Reference axes source** is set to `Input port`, use the input port labeled `RefAxes`.

Reference axes

Specify the reference axes of the local coordinate system with which to calculate range and angles in the form of a 3-by-3 orthonormal matrix. Each column of the matrix specifies the direction of an axis for the local coordinate system in the form of `[x; y; z]` with origin at the reference position. This parameter appears only when **Reference axes source** is set to `Property`.

Output(s)

Specify the desired output(s) of the block. Each type of output is sent to a different port depending on the parameter value.

Value	Port
`Angle`	`Ang`
`Range`	`Range`
`Range and Angle`	`Ang` and `Range`

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see "Choosing a Simulation Mode" (Simulink) from the Simulink documentation.

`rangeangle`

Introduced in R2014b

Range Doppler Response

Range-Doppler response

Library

Detection

`phaseddetectlib`

Description

The Range-Doppler Response block computes the range-doppler map of an input signal. The output response is a matrix whose rows represent range gates and whose columns represent Doppler bins.

Parameters

Range processing method

Specify the method of range processing as `Matched filter` or `FFT`

`Matched filter`	Applies a matched filter to the incoming signal. This technique is commonly used for pulsed signals, where the matched filter is the time reverse of the transmitted signal. Choosing this option creates the `Coeff` input port.
`FFT`	Performs range processing by applying an FFT to the input signal. This approach is commonly used with FMCW and linear FM pulsed signals.

Signal propagation speed (m/s)

Specify the propagation speed of the signal, in meters per second, as a positive scalar.

Source of pulse repetition frequency

Source of pulse repetition frequency, specified as

- `Auto` — automatically compute the pulse repetition frequency (PRF). The PRF is the sample rate of the signal divided by the number of rows in the input port signal, `X`.
- `Property`— specify the pulse repetition frequency using the `PRF` parameter.
- `Input port`— specify the PRF using the `PRF` input port.

Use the `Property` or `Input port` option when the pulse repetition frequency cannot be determined by the signal duration, as is the case with range-gated data.

Pulse repetition frequency of the input signal (Hz)

Pulse repetition frequency of the input signal, specified as a positive scalar. `PRF` must be less than or equal to the sample rate divided by the number of rows of the input signal. When the signal length is variable, use the maximum possible number of rows of the input signal instead.

To enable this parameter, set the **Source of pulse repetition frequency** parameter to `Property`.

Inherit sample rate

Select this check box to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate** parameter.

Sample rate

Specify the signal sampling rate (in hertz) as a positive scalar. This parameter appears only when the **Inherit sample rate** parameter is not selected.

Source of FFT length in Doppler processing

Specify how the block determines the length of the FFT used in Doppler processing. Values of this parameter are

`Auto`	The FFT length equals the number of rows of the input signal.
`Property`	The **FFT length in Doppler processing** parameter of this block specifies the FFT length.

FFT length in Doppler processing

This parameter appears only when you set **Source of FFT length in Doppler processing** to `Property`. Specify the length of the FFT used in Doppler processing as a positive integer.

Doppler processing window

Specify the window used for Doppler processing using one of

```
None
Hamming
Chebyshev
Hann
Kaiser
Taylor
```

If you set this parameter to `Taylor`, the generated Taylor window has four nearly-constant sidelobes adjacent to the mainlobe.

Doppler sidelobe attenuation level

This parameter appears only when **Doppler processing window** is set to `Kaiser`, `Chebyshev`, or `Taylor`. Specify the sidelobe attenuation level as a positive scalar, in decibels.

Doppler output

Specify the Doppler domain output as `Frequency` or `Speed`

`Frequency`	Doppler shift, in hertz.
`Speed`	Radial speed corresponding to Doppler shift, in meters per second.

Signal carrier frequency (Hz)

This parameter appears only when you set **Doppler output** to `Speed`. Specify the carrier frequency, in hertz, as a scalar.

FM sweep slope (Hz/s)

This parameter appears only when you set **Range processing method** to `FFT`. Specify the slope of the linear FM sweeping, in hertz per second, as a scalar.

Dechirp input signal

This check box appears only when you set **Range processing method** to `FFT`. Select this check box to make the block perform the dechirp operation on the input signal.

Clear this check box to indicate that the input signal is already dechirped and no dechirp operation is necessary.

Source of FFT length in range processing

Specify how the block determines the FFT length in range processing. Values of this parameter are

`Auto`	The FFT length equals the number of rows of the input signal.
`Property`	The FFT length is specified by **FFT length in range processing**.

This parameter appears only when you set **Range processing method** to `FFT`.

FFT length in range processing

This parameter appears only when you set **Range processing method** to `FFT` and **Source of FFT length in range processing** to `Property`. Specify the FFT length in the range domain as a positive integer.

Range processing window

This parameter appears only when you set **Range processing method** to `FFT`. Specify the window used for range processing using one of

```
None
Hamming
Chebyshev
Hann
Kaiser
Taylor
```

If you set this parameter to `Taylor`, the generated Taylor window has four nearly-constant sidelobes adjacent to the mainlobe.

Range sidelobe attenuation level

This parameter appears only when you set **Range processing method** to `FFT` and **Range processing window** to `Kaiser`, `Chebyshev`, or `Taylor`. Specify the sidelobe attenuation level as a positive scalar, in decibels.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose

`Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see “Choosing a Simulation Mode” (Simulink) from the Simulink documentation.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Description	Supported Data Types
`X`	Input signal. The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency. Signal lengths can vary when you use pulse waveforms. Then you can only apply the `Matched filter` option of the **Range processing method** parameter.	Double-precision floating point
`Coeff`	Matched-filter coefficients.	Double-precision floating point
`XRef`	Reference signal	Double-precision floating point
`PRF`	Pulse repetition frequency	Double-precision floating point
`Resp`	Range-Doppler response.	Double-precision floating point
`Range`	Range grid.	Double-precision floating point
`Dop`	Doppler grid.	Double-precision floating point

Range Estimator

Range estimation
Library: Phased Array System Toolbox / Detection

Description

The Range Estimator block estimates the range of target detections obtained from the radar response data.

Ports

Input

`Resp` — Range-processed response data cube

complex-valued *P*-by-1 column vector | complex-valued *M*-by-*P* matrix | complex-valued *M*-by-*N*-by-*P* matrix

Range-processed response data cube, specified as a complex-valued *P*-by-1 column vector, a complex-valued *M*-by-*P* matrix, or a complex-valued *M*-by-*N*-by-*P* array. *M* represents the number of range samples, *N* is the number of sensor elements or beams, and *P* is the number of Doppler bins.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Data Types: `double`
Complex Number Support: Yes

`Range` — Range grid values along range dimension

real-valued *M*-by-1 column vector

Range grid values along the range dimension of the data cube input, **Resp**, specified as a real-valued *M*-by-1 column vector. Range values must be monotonically increasing and equally spaced. Units are in meters.

Example: `[-0.3,-0.2,-0.1,0,0.1,0.2,0.3]`

Data Types: `double`

`DetIdx` — Detection indices

real-valued N_d-by-Q matrix

Detection indices, specified as a real-valued N_d-by-Q matrix. Q is the number of detections and N_d is the number of dimensions in the response data cube, **Resp**. Each column of **DetIdx** contains the indices of a detection in the response data cube.

`NoisePower` — Noise power at detection locations

positive scalar | real-valued 1-by-Q row vector of positive values

Noise power at detection locations, specified as a positive scalar or real-valued 1-by-Q row vector positive values. Q is the number of detections specified in the **DetIdx** input port.

Dependencies

To enable this port, select the **Output variance for parameter estimates** parameter, and then set **Source of noise power parameter** to `Input port`.

`Clusters` — Cluster IDs

real-valued 1-by-Q row vector of positive values

Cluster IDs, specified as a real-valued 1-by-Q row vector, where Q is the number of detections specified in the **DetIdx** input port. Each element of **Clusters** corresponds to an element of **DetIdx**.

Dependencies

To enable this input port, select the **Enable cluster ID input** checkbox.

Output

`Est` — Range estimate

real-valued K-by-1 column vector

Range estimates, specified as a real-valued K-by-1 column vector.

- When **Enable cluster ID input** is not selected, each range estimate corresponds to one of the columns of the **DetIdx** input port. Then K equals the column dimension, Q, of **DetIdx**.
- When **Enable cluster ID input** is selected, each range estimate corresponds to one of the cluster IDs in the **Clusters** input port. Then K equals the number of unique cluster IDs.

`Var` — Range estimation variance

positive, real-valued K-by-1 column vector

Range estimation variance, returned as a positive, real-valued K-by-1 column vector, where K is the dimension of **Est**. Each element of **Var** corresponds to an element of **Est**. The estimator variance is computed using the Ziv-Zakai bound.

Dependencies

To enable this output port, select the **Output variance for parameter estimates** parameter.

Parameters

`Maximum number of estimates` — Maximum number of estimates to report

`1` (default) | positive integer

The maximum number of estimates to report, specified as a positive integer. When the number of requested estimates is greater than the number elements in **DetIdx**, the remainder is filled with `NaN`.

Data Types: `double`

`Enable cluster ID input` — Enable cluster ID input

`off` (default) | `on`

Enable the **Cluster** input port to pass in cluster association information.

Data Types: `Boolean`

`Output variance for parameter estimates` — Enable output variance port

`off` (default) | `on`

Enables the output of the parameter estimate variances via the **Var** port.

Data Types: `Boolean`

`Root-mean-square range resolution` — Range resolution
`2` (default) | positive scalar

Root-mean-square range resolution of the detection, specified as a positive scalar. This parameter must have the same units as the **Range** input port.

Dependencies

To enable this parameter, select the `Output variance for parameter estimates` parameter.

Data Types: `double`

`Source of noise power` — Source of noise power values
`Property` (default) | `Input port`

Source of the noise power, specified as `Property` or `Input port`. If you set this parameter to `Property`, use the **Noise power** parameter to set the noise power at the detection locations. When set the parameter to `Input port`, specify noise power via the `NoisePower` input port.

`Noise power` — Noise power values
`1.0` (default) | positive scalar

Noise power for detections, specified as a positive scalar. The same noise power value is applied to all detections. Noise power is in linear units.

Dependencies

To enable this parameter, select the **Output variance for parameter estimates** checkbox and set the **Source of noise power** parameter to `Property`.

Data Types: `double`

`Simulate using` — Block simulation method
`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If

you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see “Choosing a Simulation Mode” (Simulink) from the Simulink documentation.

Range Response

Range response
Library: Phased Array System Toolbox / Detection

Description

The Range Response block performs range filtering on fast-time (range) data, using either a matched filter or an FFT-based algorithm. The output is typically used as input to a detector. Matched filtering improves the SNR of pulsed waveforms. For continuous FM signals, FFT processing extracts the beat frequency of FMCW waveforms. Beat frequency is directly related to range.

The input to the block is a radar data cube. The organization of the data cube follows the Phased Array System Toolbox convention. The first dimension of the cube represents the fast time samples or ranges of the received signals. The second dimension represents multiple spatial channels such as different sensors or beams. The third dimension, slow time, represent pulses. Range filtering operates along the fast-time dimension of the cube. Processing along the other dimensions is not performed. If the data contains only one channel or pulse, the data cube can contain fewer than three dimensions. Because this object performs no Doppler processing, you can use it to process noncoherent radar pulses.

The output of the block is also a data cube with the same number of dimensions as the input. Its first dimension contains range-processed data but its length can differ from the first dimension of the input data cube.

Ports

Input

X — Input data cube

complex-valued *K*-by-1 column vector | complex-valued *K*-by-*L* matrix | complex-valued *K*-by-*N*-by-*L* array

Input data cube, specified as a complex-valued *K*-by-1 column vector, a complex-valued *K*-by-*L* matrix, or a complex-valued *K*-by-*N*-by-*L* array.

- *K* is the number of range or time samples.
- *N* is the number of independent channels such as sensors or directions.
- *L* is the number of pulses or sweeps in the input signal.

See “Radar Data Cube Concept”.

Each *K*-element column vector is processed independently.

For an FMCW waveform, with a triangle sweep, the sweeps alternate between positive and negative slopes. However, Range Response is designed to process consecutive sweeps of the same slope. To apply the Range Response block for a triangle-sweep system, use one of the following approaches:

- Specify a positive **Sweep slope** parameter value, with `X` corresponding to upsweeps only. After obtaining the Doppler or speed values, divide them by 2.
- Specify a negative **Sweep slope** parameter value, with `X` corresponding to downsweeps only. After obtaining the Doppler or speed values, divide them by 2.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Data Types: `double`
Complex Number Support: Yes

`Coeff` — Matched filter coefficients

complex-valued column vector

Matched filter coefficients, specified as a complex-valued column vector. The length of the vector must be less than or equal to the number of rows in the input data, *K*.

Dependencies

To enable this port, set **Range processing method** to `Matched filter`.

Data Types: `double`
Complex Number Support: Yes

`XRef` — Reference signal

complex-valued *K*-by-1 column vector

Reference signal used for dechirping the input signal, specified as a complex-valued *K*-by-1 column vector. The number of rows must equal the length of the first dimension of `X`.

Dependencies

To enable this port, set **Range processing method** to `FFT` and select the **Dechirp input signal** parameter.

Data Types: `double`
Complex Number Support: Yes

Output

`Resp` — Range response data cube

complex-valued *M*-element column vector | complex-valued *M*-by-*L* matrix | complex-valued *M*-by-*N* by-*L* array

Range response data cube, returned as a

- Complex-valued *M*-element column vector
- Complex-valued *M*-by-*L* matrix
- Complex-valued *M*-by-*N* by-*L* array

See “Radar Data Cube Concept”. The value of *M* depends on the type of processing

Range processing method	Dechirp input signal	Value of *M*
`FFT`	`off`	If you set the **Source of FFT length in range processing** to `Auto`,*M* = *K*, the length of the first dimension of `x`. Otherwise, *M* equals the value of the **FFT length in range processing** parameter.
	`on`	*M* equals the number of rows, *K*, of the input signal.

Range processing method	Dechirp input signal	Value of *M*
`Matched filter`	N/A	*M* equals the number of rows, *K*, of the input signal.

Data Types: `double`
Complex Number Support: Yes

`Range` — Range values along range dimension

real-valued *M*-by-1 column vector

Range values along the first dimension of the **Resp** output data port, specified as a real-valued *M*-by-1 column vector. This quantity defines the range values along the first dimension of the `Resp` output port data. Units are in meters.

Data Types: `double`

Parameters

`Range processing method` — Range processing method

`Matched filter` (default) | `FFT`

Range processing method, specified as `Matched filter` or `FFT`.

`Matched filter`	The block applies a matched filter to the incoming signal. This approach is commonly used for pulsed signals, where the matched filter is the time reverse of the transmitted signal.
`FFT`	The block applies an FFT to the input signal. This approach is commonly used for FMCW and linear FM pulsed signals.

Data Types: `char`

`Propagation speed (m/s)` — Signal propagation speed

`physconst('LightSpeed')` (default) | positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value returned by `physconst('LightSpeed')`.

Data Types: `double`

`Inherit sample rate` — Inherit sample rate from upstream blocks
on (default) | off

Select this parameter to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate (Hz)** parameter.

Data Types: `Boolean`

`Sample rate (Hz)` — Sampling rate of signal
`1e6` (default) | positive real-valued scalar

Specify the signal sampling rate as a positive scalar. Units are in Hz.

Dependencies

To enable this parameter, clear the **Inherit sample rate** parameter.

Data Types: `double`

`FM sweep slope (Hz/s)` — FM sweep slope
`1e9` (default) | scalar

Specify the slope of the linear FM sweep as a scalar. This parameter must match the actual sweep of the input data in port `X`.

Dependencies

To enable this parameter, set **Range processing method** to `FFT`.

Data Types: `double`

`Dechirp input signal` — Enable dechirping of input signal
`on` (default) | `off`

Select this parameter to enable dechirping of input signal.

Dependencies

To enable this parameter, set **Range processing method** to `FFT`.

Data Types: `Boolean`

`Source of FFT length in range processing` — Source of FFT length for range processing

`Auto` (default) | `Property`

Source of FFT length for range processing, specified as `Auto` or `Property`

`Auto`	The FFT length equals the number of rows of the input data cube.
`Property`	Specify FFT length in the **FFT length in range processing** parameter.

Dependencies

To enable this parameter, set **Range processing method** to `FFT`.

Data Types: `char`

`FFT length in range processing` — Range processing FFT length

`1024` (default) | positive integer

FFT length for range processing, specified as a positive integer.

Dependencies

To enable this parameter, set **Range processing method** to `FFT` and **Source of FFT length in range processing** to `Property`.

Data Types: `double`

`Range processing window` — Range FFT weighting window

`None` (default) | `Hamming` | `Chebyshev` | `Hann` | `Kaiser` | `Taylor`

Range FFT weighting window, specified as `None`, `Hamming`, `Chebyshev`, `Hann`, `Kaiser`, or `Taylor`.

If you set this property to `Taylor`, the generated Taylor window has four nearly constant sidelobes next to the mainlobe.

Dependencies

To enable this parameter, set **Range processing method** to `FFT`.

Data Types: `char`

`Range sidelobe attenuation level` — Sidelobe attenuation for range processing

`30` (default) | positive scalar

Sidelobe attenuation for range processing, specified as a positive scalar. Units are in dB.

Dependencies

To enable this parameter, set **Range processing method** to `FFT` and **Range processing window** to `Kaiser`, `Chebyshev`, or `Taylor`.

Data Types: `double`

`Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see "Choosing a Simulation Mode" (Simulink) from the Simulink documentation.

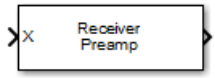
Receiver Preamp

Receiver preamplifier



Library

Transmitters and Receivers

`phasedtxrxlib`

Description

The Receiver Preamp block implements a receiver preamplifier that amplifies an input signal and adds thermal noise. In addition, you can add phase noise using an input port.

Parameters

Gain (dB)

Specify a scalar containing the gain in dB of the receiver preamplifier.

Loss factor (dB)

Specify a scalar containing the loss factor in dB of the receiver preamplifier.

Noise specification method

Specify the receiver noise as `Noise power` or `Noise temperature`.

Noise power

Specify a scalar containing the noise power in watts at the receiver preamplifier. If the receiver has multiple channels or sensors, the noise bandwidth applies to each channel or sensor. This parameter appears only when you set **Noise specification method** to `Noise power`.

Noise figure (dB)

Specify a scalar containing the noise figure of the receiver preamplifier. Units are in dB. If the receiver has multiple channels or sensors, the noise figure applies to each

channel or sensor. This parameter appears only when you set **Noise specification method** to `Noise temperature`.

Reference temperature (K)

A scalar containing the reference temperature in degrees kelvin of the receiver preamplifier. If the receiver has multiple channels or sensors, the reference temperature applies to each channel or sensor. This parameter appears only when you set **Noise specification method** to `Noise temperature`.

Inherit sample rate

Select this check box to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate** parameter. This parameter appears only when **Noise specification method** is set to `Noise temperature`.

Sample rate

Specify the signal sampling rate (in hertz) as a positive scalar. This parameter appears only when the **Inherit sample rate** parameter is not selected.

Enable enabling signal input

Select this check box to allow input of the receiver-enabling signal via the input port `TR`. This parameter appears only when **Noise specification method** is set to `Noise temperature`.

Enable phase noise input

Select this check box to allow input of phase noise for each incoming sample using the input port `Ph`. You can use this information to emulate coherent-on-receive systems. This parameter appears only when you set **Noise specification method** to `Noise temperature`.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see "Choosing a Simulation Mode" (Simulink) from the Simulink documentation.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Rectangular Waveform

Rectangular pulse waveform

Library

Waveforms

`phasedwavlib`

Description

The Rectangular Waveform block generates a rectangular pulse waveform with a specified pulse width and pulse repetition frequency (PRF). The block outputs an integer number of pulses or samples.

Parameters

Sample rate

Specify the sample rate, in hertz, as a positive scalar. The ratio of the **Sample rate** parameter to the **Pulse repetition frequency** parameter must be an integer. This is equivalent to requiring that the pulse repetition interval be an integer multiple of the sample interval.

Method to specify pulse duration

Specify the method to set the pulse duration as `Pulse width` or `Duty cycle`. When you set this parameter to `Pulse width`, the pulse duration is set using the **PulseWidth** parameter. When you set this parameter to `Duty cycle`, the pulse duration is computed from the values of the **Pulse repetition frequency (Hz)** and **Duty Cycle** parameters.

Pulse width (s)

Specify the duration of each pulse as a positive scalar. The product of **Pulse width** and **Pulse repetition frequency** must be less than or equal to one. Units are in seconds.

Duty Cycle

Specify the waveform duty cycle as a scalar between 0 and 1, inclusive. This parameter appears when you set the **Method to specify pulse duration** parameter to `Duty cycle`

Pulse repetition frequency (Hz)

Pulse repetition frequency, *PRF*, specified as a scalar or a row vector. Units are in Hz. The pulse repetition interval *PRI* is the inverse of the *PRF*. The value of **Pulse repetition frequency (Hz)** must satisfy these constraints:

- The product of **Pulse width** and **Pulse repetition frequency (Hz)** must be less than or equal to one. This is equivalent to the requirement that the pulse width is less than a pulse repetition interval. For the phase-coded waveform, the pulse width is the product of the chip width and number of chips.
- The ratio of sample rate to any element of **Pulse repetition frequency** must be an integer. This is equivalent to requiring that the number of samples in one pulse repetition interval be an integer.

You can select the value of *PRF* by using block parameter settings or an input port.

- When the **Enable PRF selection input** check box is not selected, you set the *PRF* using block parameters.
  - To implement a constant *PRF*, specify **Pulse repetition frequency (Hz)** as a positive scalar.
  - To implement a staggered *PRF*, specify **Pulse repetition frequency (Hz)** as a row vector with all strictly positive values. After the waveform reaches the last element of the vector, the process continues cyclically with the first element of the vector. When *PRF* is staggered, the time between successive output pulses is determined sequentially by the successive values of the *PRF* vector.
- When the **Enable PRF selection input** check box is selected, you can implement a selectable *PRF* by specifying **Pulse repetition frequency (Hz)** as a row vector with positive real-valued entries. But this time, when you execute block, select a *PRF* by passing an index into the *PRF* vector into the `PRFIdx` port.

In all cases, when you use a varying *PRF* and choose **Output signal format** as `Pulses`, the number of samples per pulse can vary as well. When you choose `Samples`, the number of samples per pulse is fixed.

Enable PRF selection input

Check this box to select which predefined PRF to use during the simulation via input. Uncheck this box to use the **Pulse repetition frequency** parameter to define the PRF sequence used in the simulation.

Output signal format

Specify the format of the output signal as `Pulses` or `Samples`.

If you set this parameter to `Samples`, the output of the block is in the form of multiple samples. The number of samples is the value of the **Number of samples in output** parameter.

If you set this parameter to `Pulses`, the output of the block is in the form of multiple pulses. The number of pulses is the value of the **Number of pulses in output** parameter.

The value of **Output signal format** must be set to `Samples` when the **Pulse repetition frequency (Hz)** parameter is a row vector.

Number of samples in output

Number of samples in the block output, specified as a positive integer. This parameter appears only when you set **Output signal format** to `Samples`.

Number of pulses in output

Specify the number of pulses in the block output as a positive integer. This parameter appears only when you set **Output signal format** to `Pulses`.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling.

However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see "Choosing a Simulation Mode" (Simulink) from the Simulink documentation.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Description	Supported Data Types
`PRFIdx`	PRF selection index.	Double-precision floating point
`Out`	Output waveform.	Double-precision floating point

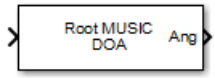
Root MUSIC DOA

Root multiple signal classification (MUSIC) direction of arrival (DOA) estimator for ULA



Library

Direction of Arrival (DOA)

`phaseddoalib`

Description

The Root MUSIC DOA block estimates the direction of arrival of a specified number of narrowband signals incident on a uniform linear array using the root multiple signal classification (Root MUSIC) algorithm.

Parameters

Signal Propagation speed (m/s)

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

Operating frequency (Hz)

Specify the operating frequency of the system, in hertz, as a positive scalar.

Number of signals

Specify the number of signals as a positive integer scalar.

Forward-backward averaging

Select this parameter to use forward-backward averaging to estimate the covariance matrix for sensor arrays with a conjugate symmetric array manifold.

Spatial smoothing

Specify the amount of averaging, *L*, used by spatial smoothing to estimate the covariance matrix as a nonnegative integer. Each increase in smoothing handles

one extra coherent source, but reduces the effective number of elements by one. The maximum value of this parameter is $N - 2$, where N is the number of sensors.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see “Choosing a Simulation Mode” (Simulink) from the Simulink documentation.

Array Parameters

Specify sensor array as

Specify a ULA sensor array directly or by using a MATLAB expression.

Types

`Array (no subarrays)`
`MATLAB expression`

Geometry

Specify the array geometry as one of the following

- `ULA` — Uniform Line Array
- `UCA` — Uniform Circular Array

Number of elements

Number of array elements.

Number of array elements, specified as a positive integer. This parameter appears when the **Geometry** is set to `ULA` or `UCA`. If **Sensor Array** has a `Replicated subarray` option, this parameter applies to the sub-array.

Element spacing

Specify the spacing, in meters, between two adjacent elements in the array.

Array axis

This parameter appears when the **Geometry** parameter is set to `ULA` or when the block only supports a ULA array geometry. Specify the array axis as `x`, `y`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

Array normal

This parameter appears when you set **Geometry**to `URA` or `UCA`. Specify the **Array normal** as `x`, `y`, or `z`. All URA and UCA array elements are placed in the *yz*, *zx*, or *xy*planes, respectively, of the array coordinate system.

Radius of UCA (m)

Radius of a uniform circular array specified as a positive scalar. Units are meters.

This parameter appears when the **Geometry** is set to `UCA`.

Taper

Tapers, also known as *element weights*, are applied to sensor elements in the array. Tapers are used to modify both the amplitude and phase of the transmitted or received data.

Specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array. If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

Expression

A valid MATLAB expression containing a constructor for a uniform linear array, for example, `phased.ULA`.

Sensor Array Tab: Element Parameters

Element type

Specify antenna or microphone type as

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

Exponent of cosine pattern

This parameter appears when you set **Element type** to `Cosine Antenna`.

Specify the exponent of the cosine pattern as a scalar or a 1-by-2 vector. You must specify all values as non-negative real numbers. When you set **Exponent of cosine pattern** to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the specified value. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern and the second element is the exponent for the elevation direction cosine pattern.

Operating frequency range (Hz)

This parameter appears when **Element type** is set to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

Specify the operating frequency range, in hertz, of the antenna element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The antenna element has no response outside the specified frequency range.

Operating frequency vector (Hz)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify the frequencies, in Hz, at which to set the antenna and microphone frequency responses as a 1-by-L row vector of increasing values. Use **Frequency responses** to set the frequency responses. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of **Operating frequency vector (Hz)**.

Frequency responses (dB)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify this parameter as the frequency response of an antenna or microphone, in decibels, for the frequencies defined by **Operating frequency vector (Hz)**. Specify **Frequency responses (dB)** as a 1-by-L vector matching the dimensions of the vector specified in **Operating frequency vector (Hz)**.

Azimuth angles (deg)

This parameter appears when **Element type** is set to `Custom Antenna`.

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-P row vector. P must be greater than 2. Angle units are in degrees. Azimuth angles must lie between –180° and 180° and be in strictly increasing order.

Elevation angles (deg)

This parameter appears when the **Element type** is set to `Custom Antenna`.

Specify the elevation angles at which to compute the radiation pattern as a 1-by-Q vector. Q must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90° and be in strictly increasing order.

Radiation pattern (dB)

This parameter appears when the **Element type** is set to `Custom Antenna`.

The magnitude in db of the combined polarized antenna radiation pattern specified as a Q-by-P matrix or a Q-by-P-by-L array. The value of Q must match the value of Q specified by **Elevation angles (deg)**. The value of P must match the value of P specified by **Azimuth angles (deg_**. The value of L must match the value of L specified by **Operating frequency vector (Hz)**.

Polar pattern frequencies (Hz)

This parameter appears when the **Element type** is set to `Custom Microphone`.

Specify the measuring frequencies of the polar patterns as a 1-by-*M* vector. The measuring frequencies lie within the frequency range specified by**Operating frequency vector (Hz)**. Frequency units are in Hz.

Polar pattern angles (deg)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the measuring angles of the polar patterns, as a 1-by-*N* vector. The angles are measured from the central pickup axis of the microphone, and must be between –180° and 180°, inclusive.

Polar pattern (dB)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the magnitude of the microphone element polar pattern as an *M*-by-*N* matrix. *M* is the number of measuring frequencies specified in **Polar pattern frequencies (Hz)**. *N* is the number of measuring angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

Baffle the back of the element

This check box appears only when the **Element type** parameter is set to `Isotropic Antenna` or `Omni Microphone`.

Select this check box to baffle the back of the antenna element. In this case, the antenna responses to all azimuth angles beyond ±90° from *broadside* are set to zero. Define the broadside direction as 0° azimuth angle and 0° elevation angle.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Description	Supported Data Types
`In`	Input signal. The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.	Double-precision floating point
`Ang`	Estimated broadside DOA angles.	Double-precision floating point

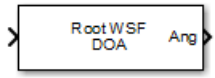
phased.RootMUSICEstimator

Introduced in R2014b

Root WSF DOA

Root weighted subspace fitting (WSF) direction of arrival (DOA) estimator for ULA



Library

Direction of Arrival (DOA)

`phaseddoalib`

Description

The Root WSF DOA block estimates the direction of arrival of a specified number of narrowband signals incident on a uniform linear array using the Root weighted subspace fitting (RootWSF) algorithm.

Parameters

Signal Propagation speed (m/s)

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

Operating frequency (Hz)

Specify the operating frequency of the system, in hertz, as a positive scalar.

Number of signals

Specify the number of signals as a positive integer.

Iterative method

Specify the iterative method as one of `IMODE` or `IQML`.

Maximum number of iterations

Specify the maximum number of iterations as a positive integer or `Inf`.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see “Choosing a Simulation Mode” (Simulink) from the Simulink documentation.

Array Parameters

Specify sensor array as

Specify a ULA sensor array directly or by using a MATLAB expression.

Types

`Array (no subarrays)`
`MATLAB expression`

Number of elements

Specifies the number of elements in the array as an integer.

Element spacing

Specify the spacing, in meters, between two adjacent elements in the array.

Array axis

This parameter appears when the **Geometry** parameter is set to `ULA` or when the block only supports a ULA array geometry. Specify the array axis as `x`, `y`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

Taper

Tapers, also known as *element weights*, are applied to sensor elements in the array. Tapers are used to modify both the amplitude and phase of the transmitted or received data.

Specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array. If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

Expression

A valid MATLAB expression containing a constructor for a uniform linear array, for example, `phased.ULA`.

Sensor Array Tab: Element Parameters

Element type

Specify antenna or microphone type as

- `Isotropic Antenna`

- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

Exponent of cosine pattern

This parameter appears when you set **Element type** to `Cosine Antenna`.

Specify the exponent of the cosine pattern as a scalar or a 1-by-2 vector. You must specify all values as non-negative real numbers. When you set **Exponent of cosine pattern** to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the specified value. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern and the second element is the exponent for the elevation direction cosine pattern.

Operating frequency range (Hz)

This parameter appears when **Element type** is set to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

Specify the operating frequency range, in hertz, of the antenna element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The antenna element has no response outside the specified frequency range.

Operating frequency vector (Hz)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify the frequencies, in Hz, at which to set the antenna and microphone frequency responses as a 1-by-*L* row vector of increasing values. Use **Frequency responses** to set the frequency responses. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of **Operating frequency vector (Hz)**.

Frequency responses (dB)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify this parameter as the frequency response of an antenna or microphone, in decibels, for the frequencies defined by **Operating frequency vector (Hz)**. Specify

Frequency responses (dB) as a 1-by-*L* vector matching the dimensions of the vector specified in **Operating frequency vector (Hz)**.

Azimuth angles (deg)

This parameter appears when **Element type** is set to `Custom Antenna`.

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Angle units are in degrees. Azimuth angles must lie between –180° and 180° and be in strictly increasing order.

Elevation angles (deg)

This parameter appears when the **Element type** is set to `Custom Antenna`.

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90° and be in strictly increasing order.

Radiation pattern (dB)

This parameter appears when the **Element type** is set to `Custom Antenna`.

The magnitude in db of the combined polarized antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The value of *Q* must match the value of *Q* specified by **Elevation angles (deg)**. The value of *P* must match the value of *P* specified by **Azimuth angles (deg_**. The value of *L* must match the value of *L* specified by **Operating frequency vector (Hz)**.

Polar pattern frequencies (Hz)

This parameter appears when the **Element type** is set to `Custom Microphone`.

Specify the measuring frequencies of the polar patterns as a 1-by-*M* vector. The measuring frequencies lie within the frequency range specified by**Operating frequency vector (Hz)**. Frequency units are in Hz.

Polar pattern angles (deg)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the measuring angles of the polar patterns, as a 1-by-*N* vector. The angles are measured from the central pickup axis of the microphone, and must be between –180° and 180°, inclusive.

Polar pattern (dB)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the magnitude of the microphone element polar pattern as an *M*-by-*N* matrix. *M* is the number of measuring frequencies specified in **Polar pattern frequencies (Hz)**. *N* is the number of measuring angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

Baffle the back of the element

This check box appears only when the **Element type** parameter is set to `Isotropic Antenna` or `Omni Microphone`.

Select this check box to baffle the back of the antenna element. In this case, the antenna responses to all azimuth angles beyond ±90° from *broadside* are set to zero. Define the broadside direction as 0° azimuth angle and 0° elevation angle.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Description	Supported Data Types
`In`	Input signal. The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.	Double-precision floating point
`Ang`	Estimated broadside DOA angles.	Double-precision floating point

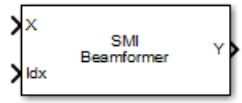
phased.RootWSFEstimator

Introduced in R2014b

SMI Beamformer

Sample matrix inversion (SMI) beamformer



Library

Space-Time Adaptive Processing

`phasedstaplib`

Description

The SMI Beamformer block implements a sample matrix inversion (SMI) space-time adaptive beamformer employing the sample space-time covariance matrix.

Parameters

Signal Propagation speed (m/s)

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

Operating frequency (Hz)

Specify the operating frequency of the system, in hertz, as a positive scalar.

Pulse repetition frequency (Hz)

Specify the pulse repetition frequency, PRF, as a scalar or a row vector. Units for PRF are hertz. This parameter should be set to the same value as used in any `Waveforms` library block.

Specify direction as

Specify whether the targeting direction for this STAP processor block comes from a block parameter or via an input port. Values of this parameter are

`Property`	• For the ADPCA Canceller and DPCA Canceller blocks, targeting direction is specified using **Receiving mainlobe direction (deg)**. • For the SMI Beamformer block, targeting direction is specified using **Targeting direction**. These parameters appear only when the **Specify direction as** parameter is set to `Property`.
`Input port`	Enter the targeting directions using the `Ang` port. This port appears only when **Specify direction as** is set to `Input port`.

Targeting direction (deg)

Specify the targeting direction of the SMI processor as a column vector of length 2. The direction is specified in the format of `[AzimuthAngle; ElevationAngle]` (in degrees). Azimuth angle should be between –180° and 180°. Elevation angle should be between –90° and 90°. This parameter appear only when you set **Specify direction as** to `Property`.

Number of bits in phase shifters

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

Specify targeting Doppler as

Specify whether targeting Doppler values for the STAP processor comes from the **Targeting Doppler (Hz)** parameter of this block or via an input port. For the ADPCA Cancellerand DPCA Canceller blocks, this parameter appears only when the **Output pre-Doppler result** check box is cleared. Values of this parameter are

`Property`	Targeting Doppler values are specified by the **Targeting Doppler** parameter of the block. The **Targeting Doppler** parameter appears only when **Specify targeting Doppler as** is set to `Property`.
`Input port`	Targeting Doppler values are entered using the `Dop` port. This port appears only when **Specify targeting Doppler as** is set to `Input port`.

Targeting Doppler (Hz)

Specify the targeting Doppler of the STAP processor as a scalar. This parameter appears only when you set **Specify targeting Doppler as** to `Property` and when, for the ADPCA Cancellerand DPCA Canceller blocks only, the **Output pre-Doppler result** check box is cleared.

Number of guard cells

Specify the number of guard cells used in the training as an even integer. This parameter specifies the total number of cells on both sides of the cell under test.

Number of training cells

Specify the number of training cells used in training as an even integer. Whenever possible, the training cells are equally divided into regions before and after the test cell.

Enable weights output

Select this check box to obtain the beamformer weights from the output port `W`.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`

`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see "Choosing a Simulation Mode" (Simulink) from the Simulink documentation.

Array Parameters

Specify sensor array as

Sensor element or sensor array specified. A sensor array can also contain subarrays or as a partitioned array. This parameter can also be expressed as a MATLAB expression.

Types

`Array (no subarrays)`
`Partitioned array`
`Replicated subarray`
`MATLAB expression`

Geometry

Specify the array geometry as one of the following:

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array
- `Conformal Array` — arbitrary element positions

Number of elements

Number of array elements.

Number of array elements, specified as a positive integer. This parameter appears when the **Geometry** is set to `ULA` or `UCA`. If **Sensor Array** has a `Replicated subarray` option, this parameter applies to the sub-array.

Array size

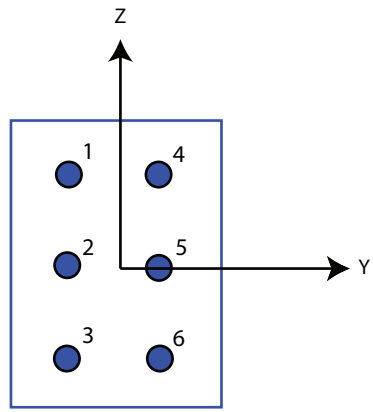
This parameter appears when **Geometry** is set to URA. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to the subarrays.

Specify the size of the array as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of rows and columns.

For a URA, elements are indexed from top to bottom along a column and continuing to the next columns from left to right. In this figure, an **Array size** of `[3,2]` produces an array of three rows and two columns.

Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]



Element spacing (m)

This parameter appears when **Geometry** is set to ULA or URA. When **Sensor Array** has the `Replicated subarray` option, this parameter applies to the subarrays.

- For a ULA, specify the spacing, in meters, between two adjacent elements in the array as a scalar.

- For a URA, specify the element spacing of the array, in meters, as a 1-by-2 vector or a scalar. If **Element spacing** is a 1-by-2 vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumns]`. For a discussion of these quantities, see phased.URA. If **Element spacing** is a scalar, the spacings between rows and columns are equal.

Array axis

This parameter appears when the **Geometry** parameter is set to ULA or when the block only supports a ULA array geometry. Specify the array axis as `x`, `y`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

Array normal

This parameter appears when you set **Geometry**to URA or UCA. Specify the **Array normal** as `x`, `y`, or `z`. All URA and UCA array elements are placed in the *yz*, *zx*, or *xy*planes, respectively, of the array coordinate system.

Radius of UCA (m)

Radius of a uniform circular array specified as a positive scalar. Units are meters.

This parameter appears when the **Geometry** is set to UCA.

Taper

Tapers, also known as *element weights*, are applied to sensor elements in the array. Tapers are used to modify both the amplitude and phase of the transmitted or received data.

This parameter applies to all array types, but when you set **Sensor Array** to `Replicated subarray`, this parameter applies to subarrays.

- For a ULA or UCA, specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array. If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.
- For a URA, specify element tapering as a complex-valued scalar or complex-valued *M*-by-*N* matrix. In this matrix, *M* is the number of elements along the *z*-axis, and *N* is the number of elements along the *y*-axis. *M* and *N* correspond to the values of `[NumberofArrayRows,NumberOfArrayColumns]` in the **Array size** matrix. If `Taper` is a scalar, the same weight is applied to each element. If **Taper** is a

matrix, a weight from the matrix is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

- For a `Conformal Array`, specify element tapering as a complex-valued scalar or complex-valued 1-by-*N* vector. In this vector, *N* is the number of elements in the array as determined by the size of the **Element positions** vector. If **Taper** is a scalar, the same weight is applied to each element. If the value of **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

Element lattice

This parameter appears when **Geometry** is set to `URA`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to the subarray.

Specify the element lattice as `Rectangular` or `Triangular`

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular`— Shifts the even-row elements of a rectangular lattice toward the positive-row axis direction. The displacement is one-half the element spacing along the row dimension.

Element positions (m)

This parameter appears when **Geometry** is set to `Conformal Array`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to subarrays.

Specify the positions of conformal array elements as a 3-by-*N* matrix, where *N* is the number of elements in the conformal array. Each column of **Element positions (m)** represents the position of a single element, in the form `[x;y;z]`, in the array's local coordinate system. The local coordinate system has its origin at an arbitrary point. Units are in meters.

Element normals (deg)

This parameter appears when **Geometry** is set to `Conformal Array`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to subarrays.

Specify the normal directions of the elements in a conformal array as a 2-by-*N* matrix or a 2-by-1 column vector in degrees. The variable *N* indicates the number of elements in the array. If **Element normals (deg)** is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]`, with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the

conformal array. If **Element normals (deg)** is a 2-by-1 column vector, the vector specifies the same pointing direction for all elements in the array.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. You can combine translation, azimuth rotation, and elevation rotation transformations. However, you cannot use transformations that require rotation about the normal.

Subarray definition matrix

This parameter appears when **Sensor array** is set to `Partitioned array`.

Specify the subarray selection as an *M*-by-*N* matrix. *M* is the number of subarrays and *N* is the total number of elements in the array. Each row of the matrix indicates which elements belong to the corresponding subarray. Each entry in the matrix is 1 or 0, where 1 indicates that the element appears in the subarray and 0 indicates the opposite. Each row must contain at least one 1.

The phase center of each subarray is its geometric center. **Subarray definition matrix** and **Geometry** determine the geometric center.

Subarray steering method

This parameter appears when **Sensor array** is set to `Partitioned array` or `Replicated subarray`.

Specify the subarray steering method as

- `None`
- `Phase`
- `Time`

When using the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, or Wideband Transmit Arrayblocks, selecting `Phase` or `Time` opens the block input port, `Steer`.

Phase shifter frequency (Hz)

This parameter appears when you set **Sensor array** to `Partitioned array` or `Replicated subarray` and you set **Subarray steering method** to `Phase`.

Specify the operating frequency, in hertz, of phase shifters to perform subarray steering as a positive scalar.

Number of bits in phase shifters

This parameter appears when you set **Sensor array** to `Partitioned array` or `Replicated subarray` and you set **Subarray steering method** to `Phase`.

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

Subarrays layout

This parameter appears when you set **Sensor array** to `Replicated subarray`.

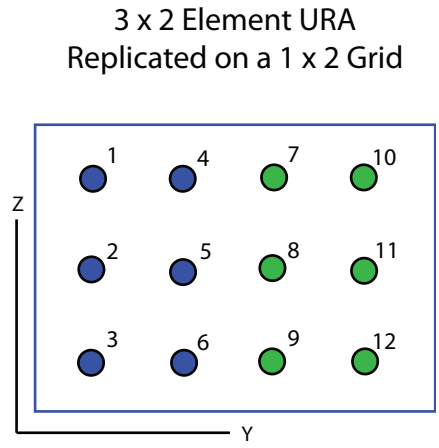
Specify the layout of the replicated subarrays as `Rectangular` or `Custom`.

Grid size

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

Rectangular subarray grid size, specified as a single positive integer or a positive integer-valued 1-by-2 row vector.

If **Grid size** is an integer scalar, the array has an equal number of subarrays in each row and column. If **Grid size** is a 1-by-2 vector of the form `[NumberOfRows, NumberOfColumns]`, the first entry is the number of subarrays along each column. The second entry is the number of subarrays in each row. A row is along the local *y*-axis, and a column is along the local *z*-axis. The figure here shows how you can replicate a 3-by-2 URA subarray using a **Grid size** of `[1,2]`.



Grid spacing

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

Specify the rectangular grid spacing of subarrays as a real-valued positive scalar, a 1-by-2 row vector, or `Auto`. Grid spacing units are expressed in meters.

- If **Grid spacing** is a scalar, the spacing along the row and the spacing along the column is the same.
- If **Grid spacing** is a 1-by-2 row vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumn]`. The first entry specifies the spacing between rows along a column. The second entry specifies the spacing between columns along a row.
- If **Grid spacing** is set to `Auto`, replication preserves the element spacing of the subarray for both rows and columns while building the full array. This option is available only when you specify **Geometry** as `ULA` or `URA`.

Subarray positions (m)

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Custom`.

Specify the positions of the subarrays in the custom grid as a 3-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix represents the position of a single subarray, in meters, in the array's local coordinate system. The coordinates are expressed in the form `[x; y; z]`.

Subarray normals

This parameter appears when you set the **Sensor array** parameter to `Replicated subarray` and the **Subarrays layout** to `Custom`.

Specify the normal directions of the subarrays in the array. This parameter value is a 2-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix specifies the normal direction of the corresponding subarray, in the form `[azimuth; elevation]`. Each angle is in degrees and is defined in the local coordinate system.

You can use the **Subarray positions** and **Subarray normals** parameters to represent any arrangement in which pairs of subarrays differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal.

Expression

A valid MATLAB expression containing an array constructor, for example, `phased.URA`.

Sensor Array Tab: Element Parameters

Element type

Specify antenna or microphone type as

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

Exponent of cosine pattern

This parameter appears when you set **Element type** to `Cosine Antenna`.

Specify the exponent of the cosine pattern as a scalar or a 1-by-2 vector. You must specify all values as non-negative real numbers. When you set **Exponent of cosine pattern** to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the specified value. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern and the second element is the exponent for the elevation direction cosine pattern.

Operating frequency range (Hz)

This parameter appears when **Element type** is set to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

Specify the operating frequency range, in hertz, of the antenna element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The antenna element has no response outside the specified frequency range.

Operating frequency vector (Hz)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify the frequencies, in Hz, at which to set the antenna and microphone frequency responses as a 1-by-*L* row vector of increasing values. Use **Frequency responses** to set the frequency responses. The antenna or microphone element has no response

outside the frequency range specified by the minimum and maximum elements of **Operating frequency vector (Hz)**.

Frequency responses (dB)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify this parameter as the frequency response of an antenna or microphone, in decibels, for the frequencies defined by **Operating frequency vector (Hz)**. Specify **Frequency responses (dB)** as a 1-by-*L* vector matching the dimensions of the vector specified in **Operating frequency vector (Hz)**.

Azimuth angles (deg)

This parameter appears when **Element type** is set to `Custom Antenna`.

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Angle units are in degrees. Azimuth angles must lie between –180° and 180° and be in strictly increasing order.

Elevation angles (deg)

This parameter appears when the **Element type** is set to `Custom Antenna`.

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90° and be in strictly increasing order.

Radiation pattern (dB)

This parameter appears when the **Element type** is set to `Custom Antenna`.

The magnitude in db of the combined polarized antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The value of *Q* must match the value of *Q* specified by **Elevation angles (deg)**. The value of *P* must match the value of *P* specified by **Azimuth angles (deg_**. The value of *L* must match the value of *L* specified by **Operating frequency vector (Hz)**.

Polar pattern frequencies (Hz)

This parameter appears when the **Element type** is set to `Custom Microphone`.

Specify the measuring frequencies of the polar patterns as a 1-by-*M* vector. The measuring frequencies lie within the frequency range specified by**Operating frequency vector (Hz)**. Frequency units are in Hz.

Polar pattern angles (deg)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the measuring angles of the polar patterns, as a 1-by-*N* vector. The angles are measured from the central pickup axis of the microphone, and must be between –180° and 180°, inclusive.

Polar pattern (dB)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the magnitude of the microphone element polar pattern as an *M*-by-*N* matrix. *M* is the number of measuring frequencies specified in **Polar pattern frequencies (Hz)**. *N* is the number of measuring angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

Baffle the back of the element

This check box appears only when the **Element type** parameter is set to `Isotropic Antenna` or `Omni Microphone`.

Select this check box to baffle the back of the antenna element. In this case, the antenna responses to all azimuth angles beyond ±90° from *broadside* are set to zero. Define the broadside direction as 0° azimuth angle and 0° elevation angle.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Description	Supported Data Types
`X`	Input signal The size of the first dimension of this input matrix can vary to simulate	Double-precision floating point

Port	Description	Supported Data Types
	a changing signal length, such as a pulse waveform with variable pulse repetition frequency.	
`Ang`	Targeting direction	Double-precision floating point
`Dop`	Targeting Doppler frequency	Double-precision floating point
`Idx`	Range cell index	Double-precision floating point
`W`	Processing weights	Double-precision floating point
`Y`	Doppler output	Double-precision floating point

Scattering MIMO Channel

Scattering MIMO propagation channel
Library: Phased Array System Toolbox / Environment and Target

Description

The Scattering MIMO Channel models a 3-D multipath propagation channel in which radiated signals from a transmitting array are reflected from multiple scatters back towards a receiving array. In this channel, propagation paths are direct paths (line-of-sight) from point to point. The block models range-dependent time delay, gain, Doppler shift, phase change, and atmospheric loss due to gases, rain, fog, and clouds. You can optionally propagate a signal via a direct path from transmitter to receiver.

The attenuation models for atmospheric gases and rain are valid for electromagnetic signals in the frequency range 1–1000 GHz but the attenuation model for fog and clouds is valid for only 10–1000 GHz. Outside these frequency ranges, the object uses the nearest valid value.

Ports

Input

X — Transmitted narrowband signal

M-by-N_t complex-valued matrix

The transmitted narrowband signal, specified as an *M*-by-N_t complex-valued matrix. The quantity *M* is the number of samples in the signal, and N_t is the number of transmitting array elements. Each column represents the signal transmitted by the corresponding array element.

Example: `[1,1;j,1;0.5,0]`

Data Types: `double`
Complex Number Support: Yes

`TxPos` — Position of transmitting antenna array

3-by-1 real-valued column vector

Position of transmitting antenna array, specified as a 3-by-1 real-valued column vector taking the form `[x;y;z]`. The vector elements correspond to the *x*, *y*, and *z* positions of the array. Units are in meters.

Dependencies

To enable this port, set the **Source of transmit array motion** parameter to `Input port`.

Data Types: `double`

`TxVel` — Velocity of transmitting antenna array

3-by-1 real-valued column vector

Velocity of transmitting antenna array, specified as a 3-by-1 real-valued column vector taking the form `[vx;vy;vz]`. The vector elements correspond to the *x*, *y*, and *z* velocities of the array. Units are in meters per second.

Dependencies

To enable this port, set the **Source of transmit array motion** parameter to `Input port`.

Data Types: `double`

`TxAxes` — Axes orientation of transmitting antenna array

3-by-3 real orthonormal matrix

Axes orientation of transmitting antenna array, specified as a 3-by-3 real orthonormal matrix. The matrix defines the orientation of the array local coordinate system with respect to the global coordinates. Matrix columns correspond to the directions of the *x*, *y*, and *z* axes of the local coordinate system. Units are dimensionless.

Dependencies

To enable this port, set the **Source of transmit array motion** parameter to `Input port`.

Data Types: `double`

`RxPos` — Position of receiving antenna array

3-by-1 real-valued column vector

Position of receiving antenna array, specified as a 3-by-1 real-valued column vector taking the form `[x;y;z]`. The vector elements correspond to the *x*, *y*, and *z* positions of the array. Units are in meters.

Dependencies

To enable this port, set the **Source of receive array motion** parameter to `Input port`.

Data Types: `double`

`RxVel` — Velocity of receiving antenna array

3-by-1 real-valued column vector

Velocity of receiving antenna array, specified as a 3-by-1 real-valued column vector taking the form `[vx;vy;vz]`. The vector elements correspond to the *x*, *y*, and *z* velocities of the array. Units are in meters per second.

Dependencies

To enable this port, set the **Source of receive array motion** parameter to `Input port`.

Data Types: `double`

`RxAxes` — Axes orientation of receiving antenna array

3-by-3 real orthonormal matrix

Axes orientation of receiving antenna array, specified as a 3-by-3 real orthonormal matrix. The matrix defines the orientation of the array local coordinate system with respect to the global coordinates. Matrix columns correspond to the directions of the *x*, *y*, and *z* axes of the local coordinate system. Units are dimensionless.

Dependencies

To enable this port, set the **Source of receive array motion** parameter to `Input port`.

Data Types: `double`

`ScatPos` — Positions of scatterers

3-by-N_s real-valued matrix

Position of scatterers, specified as a 3-by-N_s real-valued matrix. Each column of the matrix takes the form `[x;y;z]`, containing the x, y, and z positions of a scatterer. Units are in meters.

Dependencies

To enable this port, set the **Scatterer specification** parameter to `Input port`.

Data Types: `double`

`ScatVel` — Velocities of scatterers

3-by-N_s real-valued matrix

Velocities of scatterers, specified as a 3-by-N_s real-valued matrix. Each matrix column has the form `[vx;vy;vz]`, containing the x, y, and z velocities of a scatterer. Units are in meters per second.

Dependencies

To enable this port, set the **Scatterer specification** parameter to `Input port`.

Data Types: `double`

`ScatCoef` — Scattering coefficients

1-by-N_s complex-valued row vector

Scattering coefficients, specified as a 1-by-N_s complex-valued row vector. Each vector element specifies the scattering coefficient of the corresponding scatterer. Units are dimensionless.

Dependencies

To enable this port, set the **Scatterer specification** parameter to `Input port`.

Data Types: `double`
Complex Number Support: Yes

Output

Y — Received narrowband signal

M-by-N_r complex-valued matrix

Received narrowband signal, returned as an M-by-N_r complex-valued matrix. The quantity M is the number of samples in the signal, and N_r is the number of receiving array elements. Each column represents the signal received by the corresponding array element.

Data Types: `double`
Complex Number Support: Yes

CS — Channel response

N_t-by-N_r-by-N_s complex-valued MATLAB array

Channel response, returned as an N_t-by-N_r-by-N_s complex-valued MATLAB array. N_t is the number of transmitting array elements. N_r is the number of receiving array elements. N_s is the number of scatterers. Each page of the array corresponds to the channel response matrix for a specific scatterer.

Dependencies

To enable this port, select the **Output channel response** checkbox.

Data Types: `double`
Complex Number Support: Yes

Tau — Path delays

1-by-N_s real-valued vector

Path delays, returned as a 1-by-N_s real-valued vector. N_s is the number of scatterers. Each element corresponds to the path time delay from the transmitting array phase center to the scatterer and then to the receiving array phase center.

Dependencies

To enable this port, select the **Output channel response** checkbox.

Data Types: `double`

Parameters

Main Tab

`Propagation speed (m/s)` — Signal propagation speed

`physconst('LightSpeed')` (default) | positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value returned by `physconst('LightSpeed')`.

Data Types: `double`

`Signal carrier frequency (Hz)` — Signal carrier frequency

`300e6` (default) | positive real-valued scalar

Signal carrier frequency, specified as a positive real-valued scalar. Units are in hertz.

Data Types: `double`

`Specify atmospheric parameters` — Enable atmospheric attenuation model

off (default) | on

Select this parameter to enable to add signal attenuation caused by atmospheric gases, rain, fog, or clouds. When you select this parameter, the **Temperature (degrees Celsius)**, **Dry air pressure (Pa)**, **Water vapour density (g/m^3)**, **Liquid water density (g/m^3)**, and **Rain rate (mm/hr)** parameters appear in the dialog box.

Data Types: `Boolean`

`Temperature (degrees Celsius)` — Ambient temperature

`15` (default) | real-valued scalar

Ambient temperature, specified as a real-valued scalar. Units are in degrees Celsius.

Dependencies

To enable this parameter, select the **Specify atmospheric parameters** checkbox.

Data Types: `double`

`Dry air pressure (Pa)` — Atmospheric dry air pressure

`101.325e3` (default) | positive real-valued scalar

Atmospheric dry air pressure, specified as a positive real-valued scalar. Units are in pascals (Pa). The default value of this parameter corresponds to one standard atmosphere.

Dependencies

To enable this parameter, select the **Specify atmospheric parameters** checkbox.

Data Types: `double`

`Water vapour density (g/m^3)` — Atmospheric water vapor density

`7.5` (default) | positive real-valued scalar

Atmospheric water vapor density, specified as a positive real-valued scalar. Units are in g/m^3.

Dependencies

To enable this parameter, select the **Specify atmospheric parameters** checkbox.

Data Types: `datetime`

`Liquid water density (g/m^3)` — Liquid water density

`0.0` (default) | nonnegative real-valued scalar

Liquid water density of fog or clouds, specified as a nonnegative real-valued scalar. Units are in g/m^3. Typical values for liquid water density are 0.05 for medium fog and 0.5 for thick fog.

Dependencies

To enable this parameter, select the **Specify atmospheric parameters** checkbox.

Data Types: `double`

`Rain rate (mm/hr)` — Rainfall rate
`0.0` (default) | non-negative real-valued scalar

Rainfall rate, specified as a nonnegative real-valued scalar. Units are in mm/hr.

Dependencies

To enable this parameter, select the **Specify atmospheric parameters** checkbox.

Data Types: `double`

`Inherit sample rate` — Inherit sample rate from upstream blocks
on (default) | off

Select this parameter to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate (Hz)** parameter.

Data Types: `Boolean`

`Sample rate (Hz)` — Sampling rate of signal
`1e6` (default) | positive real-valued scalar

Specify the signal sampling rate as a positive scalar. Units are in Hz.

Dependencies

To enable this parameter, clear the **Inherit sample rate** parameter.

Data Types: `double`

`Simulate direct path propagation` — Enable propagation along direct path
off (default) | on

Select this check box to enable signal propagation along the line-of-sight direct path from the transmitting array to the receiving array with no scattering.

Data Types: `Boolean`

`Maximum delay (s)` — Maximum signal delay

`10e-6` (default) | positive scalar

The maximum signal delay, specified as a positive scalar. Delays greater than this value are ignored.

Data Types: `double`

`Output channel response` — Enable output of channel response

off (default) | on

Select this checkbox to output the channel response and time delay via the output ports `CS` and `Tau`.

Data Types: `Boolean`

`Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior

	Normal	Accelerator	Rapid Accelerator
Interpreted Execution	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
Code Generation	The block is compiled.	All blocks in the model are compiled.	

For more information, see "Choosing a Simulation Mode" (Simulink) from the Simulink documentation.

Data Types: `char`

Transmit and Receive Array Tabs

`Specify sensor array as` — Method to specify array

`Array (no subarrays)` (default) | `MATLAB expression`

Method to specify array, specified as `Array (no subarrays)` or `MATLAB expression`.

- `Array (no subarrays)` — use the block parameters to specify the array.
- `MATLAB expression` — create the array using a MATLAB expression.

`Expression` — MATLAB expression used to create an array

Phased Array System Toolbox array System object

MATLAB expression used to create an array, specified as a valid Phased Array System Toolbox array System object.

Example: `phased.URA('Size',[5,3])`

Dependencies

To enable this parameter, set **Specify sensor array as** to `MATLAB expression`.

Element Parameters

`Element type` — Array element types

`Isotropic Antenna` (default) | `Cosine Antenna` | `Custom Antenna` | `Omni Microphone` | `Custom Microphone`

Antenna or microphone type, specified as one of the following:

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

`Operating frequency range (Hz)` — Operating frequency range of the antenna or microphone element
`[0,1.0e20]` (default) | real-valued 1-by-2 row vector

Specify the operating frequency range of the antenna or microphone element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The element has no response outside this frequency range. Frequency units are in Hz.

Dependencies

To enable this parameter, set **Element type** to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

`Operating frequency vector (Hz)` — Operating frequency range of custom antenna or microphone elements
`[0,1.0e20]` (default) | real-valued row vector

Specify the frequencies at which to set antenna and microphone frequency responses as a 1-by-*L* row vector of increasing real values. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of this vector. Frequency units are in Hz.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`. Use **Frequency responses (dB)** to set the responses at these frequencies.

`Baffle the back of the element` — Set back response of an `Isotropic Antenna` element or an `Omni Microphone` element to zero
off (default) | on

Select this checkbox to baffle the back response of the element. When backbaffled, the responses at all azimuth angles beyond ±90° from broadside are set to zero. The broadside direction is 0° azimuth angle and 0° elevation angle.

Dependencies

To enable this checkbox, set **Element type** to `Isotropic Antenna` or `Omni Microphone`.

`Exponent of cosine pattern` — Exponents of azimuth and elevation cosine patterns
`[1.5 1.5]` (default) | nonnegative scalar | real-valued 1-by-2 matrix of nonnegative values

Specify the exponents of the cosine pattern as a nonnegative scalar or a real-valued 1-by-2 matrix of nonnegative values. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern, and the second element is the exponent for the elevation direction cosine pattern. When you set this parameter to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the same power.

Dependencies

To enable this parameter, set **Element type** to `Cosine Antenna`.

`Frequency responses (dB)` — Antenna and microphone frequency response
`[0,0]` (default) | real-valued row vector

Frequency response of a custom antenna or custom microphone for the frequencies defined by the **Operating frequency vector (Hz)** parameter. The dimensions of **Frequency responses (dB)** must match the dimensions of the vector specified by the **Operating frequency vector (Hz)** parameter.

Dependencies

To enable this parameter , set **Element type** to `Custom Antenna` or `Custom Microphone`.

`Azimuth angles (deg)` — Azimuth angles of antenna radiation pattern
`[-180:180]` (default) | real-valued row vector

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Azimuth angles must lie between –180° and 180°, inclusive, and be in strictly increasing order.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Elevation angles (deg)` — Elevation angles of antenna radiation pattern
`[-90:90]` (default) | real-valued row vector

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive, and be in strictly increasing order.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Magnitude pattern (dB)` — Magnitude of combined antenna radiation pattern
`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Magnitude of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equal the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Phase pattern (deg)` — Custom antenna radiation phase pattern
`zeros(181,361)` (default) | real-valued Q-by-P matrix | real-valued Q-by-P-by-L array

Phase of the combined antenna radiation pattern, specified as a Q-by-P matrix or a Q-by-P-by-L array. The quantity Q equals the length of the vector specified by **Elevation angles (deg)**. The quantity P equals length of the vector specified by **Azimuth angles (deg)**. The quantity L equal the length of the **Operating frequency vector (Hz)**.

- If this parameter is a Q-by-P matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a Q-by-P-by-L array, each Q-by-P page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Polar pattern frequencies (Hz)` — Custom microphone response frequencies
1e3 (default) | real scalar | real-valued 1-by-L row vector

Response frequencies of the custom microphone of the polar pattern, specified as a real scalar or real-valued 1-by-L vector. The response frequencies lie within the frequency range specified by the **Operating frequency vector (Hz)** vector.

Dependencies

To enable this parameter, set **Element type** is set to `Custom Microphone`.

`Polar pattern angles (deg)` — Polar pattern response angles
`[-180:180]` (default) | real-valued -by-P row vector

Specify the polar pattern response angles, as a 1-by-P vector. The angles are measured from the central pickup axis of the microphone and must be between –180° and 180°, inclusive.

Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

`Polar pattern (dB)` — Custom microphone polar response

`zeros(1,361)` (default) | real-valued L-by-P matrix

Specify the magnitude of the custom microphone element polar patterns as an L-by-P matrix. L is the number of frequencies specified in **Polar pattern frequencies (Hz)**. P is the number of angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume also that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

Array Parameters

`Geometry` — Array geometry

`ULA` (default) | `URA` | `UCA` | `Conformal Array`

Array geometry, specified as one of

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array
- `Conformal Array` — arbitrary element positions

`Number of elements` — Number of array elements

`2` for ULA arrays and `5` for UCA arrays (default) | integer greater than or equal to 2

The number of array elements for ULA or UCA arrays, specified as an integer greater than or equal to 2.

Dependencies

To enable this parameter, set **Geometry** to `ULA` or `UCA`.

`Element spacing (m)` — Spacing between array elements

`0.5` for ULA arrays and `[0.5,0.5]` for URA arrays (default) | positive scalar for ULA or URA arrays | 2-element vector of positive values for URA arrays

Spacing between adjacent array elements:

- ULA — specify the spacing between two adjacent elements in the array as a positive scalar.
- URA — specify the spacing as a positive scalar or a 1-by-2 vector of positive values. If **Element spacing (m)** is a scalar, the row and column spacings are equal. If **Element spacing (m)** is a vector, the vector has the form `[SpacingBetweenArrayRows,SpacingBetweenArrayColumns]`.

Dependencies

To enable this parameter, set **Geometry** to ULA or URA.

`Array axis` — Linear axis direction of ULA

`y` (default) | `x` | `z`

Linear axis direction of ULA, specified as `y`, `x`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

Dependencies

To enable this parameter, set **Geometry** to ULA. This parameter is also enabled when the block supports only ULA arrays.

`Array size` — Dimensions of URA array

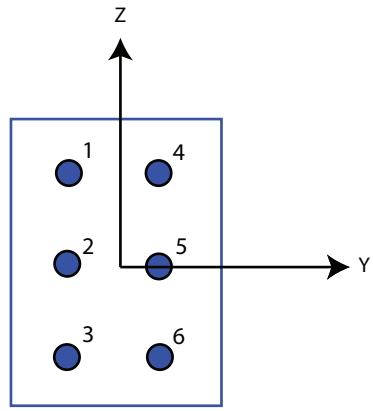
`[2,2]` (default) | positive integer | 1-by-2 vector of positive integers

Dimensions of a URA array, specified as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of elements in each row and column.

For a URA, array elements are indexed from top to bottom along a column, and continuing to the next columns from left to right. In this figure, the **Array size** value of `[3,2]` creates an array having three rows and two columns.

Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]



Dependencies

To enable this parameter, set **Geometry** to URA.

`Element lattice` — Lattice of URA element positions
`Rectangular` (default) | `Triangular`

Lattice of URA element positions, specified as `Rectangular` or `Triangular`.

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular` — Shifts the even-row elements of a rectangular lattice toward the positive row-axis direction. The displacement is one-half the element spacing along the row dimension.

Dependencies

To enable this parameter, set **Geometry** to URA.

`Array normal` — Array normal direction
`x` for URA arrays or `z` for UCA arrays (default) | `y`

Array normal direction, specified as `x`, `y`, or `z`.

Elements of planar arrays lie in a plane orthogonal to the selected array normal direction. Element boresight directions point along the array normal direction.

Array Normal Parameter Value	Element Positions and Boresight Directions
`x`	Array elements lie in the *yz*-plane. All element boresight vectors point along the *x*-axis.
`y`	Array elements lie in the *zx*-plane. All element boresight vectors point along the *y*-axis.
`z`	Array elements lie in the *xy*-plane. All element boresight vectors point along the *z*-axis.

Dependencies

To enable this parameter, set **Geometry**to URA or UCA.

`Radius of UCA (m)` — UCA array radius
0.5 (default) | positive scalar

Radius of UCA array, specified as a positive scalar.

Dependencies

To enable this parameter, set **Geometry** to UCA.

`Element positions (m)` — Positions of conformal array elements
`[0;0;0]` (default) | 3-by-*N*matrix of real values

Positions of the elements in a conformal array, specified as a 3-by-*N* matrix of real values, where *N* is the number of elements in the conformal array. Each column of this matrix represents the position `[x;y;z]`of an array element in the array local coordinate system. The origin of the local coordinate system is *(0,0,0)*. Units are in meters.

Dependencies

To enable this parameter set **Geometry** to `Conformal Array`.

Data Types: `double`

`Element normals (deg)` — Direction of conformal array element normal vectors

`[0;0]` | 2-by-1 column vector | 2-by-*N* matrix

Direction of element normal vectors in a conformal array, specified as a 2-by-1 column vector or a 2-by-*N* matrix. *N* indicates the number of elements in the array. If the parameter value is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]` with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If the parameter value is a 2-by-1 column vector, the same pointing direction is used for all array elements.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal direction.

To enable this parameter, set **Geometry** to `Conformal Array`.

Data Types: `double`

`Taper` — Array element tapers

1 (default) | complex scalar | complex-valued row vector

Specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array.

Also known as *element weights*, tapers multiply the array element responses. Tapers modify both amplitude and phase of the response to reduce sidelobes or steer the main response axis.

If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. The number of weights must match the number of elements of the array.

Data Types: `double`

Motion Tab

`Source of transmit array motion` — Specify the source of the transmitting array motion parameters

`Property` (default) | `Input port`

Source of transmitting array motion parameters, specified as `Property` or `Input port`.

- When you select `Property`, specify the array location and orientation using the **Position of the transmit array (m)** and **Orientation of the transmit array** parameters. The array is stationary.
- When you select `Input port`, specify the array location, velocity, and orientation using the `TxPos`, `TxVel`, and `TxAxes` input ports of the block.

Data Types: `char`

`Position of the transmit array (m)` — Position of transmitting array

`[0;0;0]` (default) | real-valued 3-by-1 vector

The position of the transmitting array phase center, specified as a real-valued, 3-by-1 vector in Cartesian form `[x;y;z]` with respect to the global coordinate system. Units are in meters.

Dependencies

To enable this parameter, set the **Source of transmit array motion** parameter to `Property`.

Data Types: `double`

`Orientation of the transmit array` — Set the orientation of transmitting array axes

`eye(3,3)` (default) | real-valued 3-by-3 orthonormal matrix

The orientation of transmitting array, specified as a real-valued, 3-by-3 orthonormal matrix. The matrix specifies the directions of the three axes that define the local

coordinate system of the array with respect to the global coordinate system. The columns of the array correspond to the *x*, *y*, and *z* axes, respectively.

Dependencies

To enable this parameter, set the **Source of transmit array motion** parameter to `Property`.

Data Types: `double`

`Source of receive array motion` — Specify the source of the receiving array motion parameters

`Property` (default) | `Input port`

Source of receiving array motion parameters, specified as `Property` or `Input port`.

- When you select `Property`, specify the array location and orientation using the **Position of the receive array (m)** and **Orientation of the receive array** parameters. The array is stationary.
- When you select `Input port`, specify the array location, velocity, and orientation using the `RxPos`, `RxVel`, and `RxAxes` input ports of the block.

Data Types: `char`

`Position of the receive array (m)` — Position of receiving array

`[physconst('LightSpeed' )/1e5; 0;0]` (default) | real-valued 3-by-1 vector

The position of the receiving array phase center, specified as a real-valued, 3-by-1 vector in Cartesian form `[x;y;z]` with respect to the global coordinate system. Units are in meters.

Dependencies

To enable this parameter, set the **Source of receive array motion** parameter to `Property`.

Data Types: `double`

`Orientation of the receive array` — Set the orientation of receiving array axes

`eye(3,3)` (default) | real-valued 3-by-3 orthonormal matrix

The orientation of receiving array, specified as a real-valued, 3-by-3 orthonormal matrix. The matrix specifies the directions of the three axes that define the local coordinate system of the array with respect to the global coordinate system. The columns of the array correspond to the *x*, *y*, and *z* axes, respectively.

Dependencies

To enable this parameter, set the **Source of receive array motion** parameter to `Property`.

Data Types: `double`

`Scatterer specification` — Specify source of scatterer parameters

`Auto` (default) | `Property` | `Input port`

The source of scatterer parameters, specified as `Auto`, `Property`, or `Input port`.

- When you set this parameter to `Auto`, all scatterer positions and coefficients are randomly generated. Scatterer velocities are zero. The generated positions are contained within the region set by the **Boundary of scatterer positions** parameter. Set the number of scatterers using the **Number of scatterers** parameter.
- When you set this property to `Property`, set the scatterer positions using the **Positions of scatterers (m)** parameter. Set the scattering coefficients using the **Scattering coefficients** parameter. Scatterer velocities are zero.
- When you set this parameter to `Input port`, you specify the scatterer positions, velocities, and scattering coefficients using the `ScatPos`, `ScatVel`, and `ScatCoef` block input ports.

Data Types: `char`

`Number of scatterers` — Number of scatterers

1 (default) | nonnegative integer

The number of scatterers, specified as a nonnegative integer.

Dependencies

To enable this property, set the **Scatterer specification** parameter to `Auto`.

Data Types: `double`

`Boundary of scatterer positions` — Constrain scatterer positions within a boundary
`[0,1000]` (default) | 1-by-2 real-valued vector | 3-by-2 real-valued matrix

The boundary scatterer positions, specified as a 1-by-2 real-valued row vector or a 3-by-2 real-valued matrix. If the boundary is a 1-by-2 row vector, the vector contains the minimum and maximum, `[minbdry maxbdry]`, for all three dimensions. If the boundary is a 3-by-2 matrix, the matrix specifies boundaries in all three dimensions in the form `[x_minbdry x_maxbdry;y_minbdry y_maxbdry; z_minbdry z_maxbdry]`.

Dependencies

To enable this property, set the **Scatterer specification** parameter to `Auto`.

Data Types: `double`

`Positions of scatterers (m)` — Positions of scatterers
`[physconst('LightSpeed' )*5e-6;0;0]` (default) | real-valued 3-by-N_s matrix

The positions of the scatterers, specified as real-valued 3-by-N_s matrix. N_s is the number of scatterers. Each column represents a different scatterer and has the Cartesian form `[x;y;z]` with respect to the global coordinate system. Units are in meters.

Dependencies

To enable this property, set the **Scatterer specification** parameter to `Property`.

Data Types: `double`

`ScattererCoefficient` — Scattering coefficients
1 (default) | complex-valued 1-by-N_s matrix

Scattering coefficients, specified as a complex-valued 1-by-N_s vector. N_s is the number of scatterers. Units are dimensionless.

Dependencies

To enable this property, set the **Scatterer specification** parameter to `Property`.

Data Types: `double`
Complex Number Support: Yes

Stepped FM Waveform

Stepped FM pulse waveform

Library

Waveforms

`phasedwavlib`

Description

The Stepped FM Waveform block generates a stepped FM pulse waveform with a specified pulse width, pulse repetition frequency (PRF), and number of frequency steps. The transmitted frequency is incremented in constant steps over the duration of the pulse. The block outputs an integer number of pulses or samples.

Parameters

Sample rate

Specify the sample rate, in hertz, as a positive scalar. The ratio of the **Sample rate** parameter to the **Pulse repetition frequency** parameter must be an integer. This is equivalent to requiring that the pulse repetition interval be an integer multiple of the sample interval.

Method to specify pulse duration

Specify the method to set the pulse duration as `Pulse width` or `Duty cycle`. When you set this parameter to `Pulse width`, the pulse duration is set using the **PulseWidth** parameter. When you set this parameter to `Duty cycle`, the pulse duration is computed from the values of the **Pulse repetition frequency (Hz)** and **Duty Cycle** parameters.

Pulse width (s)

Specify the duration of each pulse as a positive scalar. The product of **Pulse width** and **Pulse repetition frequency** must be less than or equal to one. Units are in seconds.

Duty Cycle

Specify the waveform duty cycle as a scalar between 0 and 1, inclusive. This parameter appears when you set the **Method to specify pulse duration** parameter to `Duty cycle`

Pulse repetition frequency (Hz)

Pulse repetition frequency, *PRF*, specified as a scalar or a row vector. Units are in Hz. The pulse repetition interval *PRI* is the inverse of the *PRF*. The value of **Pulse repetition frequency (Hz)** must satisfy these constraints:

- The product of **Pulse width** and **Pulse repetition frequency (Hz)** must be less than or equal to one. This is equivalent to the requirement that the pulse width is less than a pulse repetition interval. For the phase-coded waveform, the pulse width is the product of the chip width and number of chips.
- The ratio of sample rate to any element of **Pulse repetition frequency** must be an integer. This is equivalent to requiring that the number of samples in one pulse repetition interval be an integer.

You can select the value of *PRF* by using block parameter settings or an input port.

- When the **Enable PRF selection input** check box is not selected, you set the *PRF* using block parameters.
  - To implement a constant *PRF*, specify **Pulse repetition frequency (Hz)** as a positive scalar.
  - To implement a staggered *PRF*, specify **Pulse repetition frequency (Hz)** as a row vector with all strictly positive values. After the waveform reaches the last element of the vector, the process continues cyclically with the first element of the vector. When *PRF* is staggered, the time between successive output pulses is determined sequentially by the successive values of the *PRF* vector.
- When the **Enable PRF selection input** check box is selected, you can implement a selectable *PRF* by specifying **Pulse repetition frequency (Hz)** as a row vector with positive real-valued entries. But this time, when you execute block, select a *PRF* by passing an index into the *PRF* vector into the `PRFIdx` port.

In all cases, when you use a varying *PRF* and choose **Output signal format** as `Pulses`, the number of samples per pulse can vary as well. When you choose `Samples`, the number of samples per pulse is fixed.

Enable PRF selection input

Check this box to select which predefined PRF to use during the simulation via input. Uncheck this box to use the **Pulse repetition frequency** parameter to define the PRF sequence used in the simulation.

Frequency step

Specify the linear frequency step size, in hertz, as a positive scalar.

Number of frequency steps

Specify the number of frequency steps as a positive integer. When the **Number of frequency steps** is 1, the stepped FM waveform reduces to a rectangular waveform.

Output signal format

Specify the format of the output signal as `Pulses` or `Samples`.

If you set this parameter to `Samples`, the output of the block is in the form of multiple samples. The number of samples is the value of the **Number of samples in output** parameter.

If you set this parameter to `Pulses`, the output of the block is in the form of multiple pulses. The number of pulses is the value of the **Number of pulses in output** parameter.

The value of **Output signal format** must be set to `Samples` when the **Pulse repetition frequency (Hz)** parameter is a row vector.

Number of samples in output

Number of samples in the block output, specified as a positive integer. This parameter appears only when you set **Output signal format** to `Samples`.

Number of pulses in output

Specify the number of pulses in the block output as a positive integer. This parameter appears only when you set **Output signal format** to `Pulses`.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see “Choosing a Simulation Mode” (Simulink) from the Simulink documentation.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Description	Supported Data Types
`PRFIdx`	PRF selection index.	Double-precision floating point
`Out`	Output waveform.	Double-precision floating point

Stretch Processor

Stretch processor for linear FM waveforms

Library

Detection

`phaseddetectlib`

Description

The Stretch Processor block applies stretch processing on a linear FM waveform. Also known as dechirping, stretch processing is an alternative to matched filtering for linear FM waveforms.

Parameters

Pulse width (s)

Specify the duration of each pulse as a positive scalar. The product of **Pulse width** and **Pulse repetition frequency** must be less than or equal to one. Units are in seconds.

Pulse repetition frequency (Hz)

Pulse repetition frequency, *PRF*, specified as a scalar or a row vector. Units are in Hz. The pulse repetition interval *PRI* is the inverse of the *PRF*. The value of **Pulse repetition frequency (Hz)** must satisfy these constraints:

- The product of **Pulse width** and **Pulse repetition frequency (Hz)** must be less than or equal to one. This is equivalent to the requirement that the pulse width

is less than a pulse repetition interval. For the phase-coded waveform, the pulse width is the product of the chip width and number of chips.

- The ratio of sample rate to any element of **Pulse repetition frequency** must be an integer. This is equivalent to requiring that the number of samples in one pulse repetition interval be an integer.

You can select the value of *PRF* by using block parameter settings or an input port.

- When the **Enable PRF selection input** check box is not selected, you set the *PRF* using block parameters.
  - To implement a constant *PRF*, specify **Pulse repetition frequency (Hz)** as a positive scalar.
  - To implement a staggered *PRF*, specify **Pulse repetition frequency (Hz)** as a row vector with all strictly positive values. After the waveform reaches the last element of the vector, the process continues cyclically with the first element of the vector. When *PRF* is staggered, the time between successive output pulses is determined sequentially by the successive values of the *PRF* vector.
- When the **Enable PRF selection input** check box is selected, you can implement a selectable *PRF* by specifying **Pulse repetition frequency (Hz)** as a row vector with positive real-valued entries. But this time, when you execute block, select a *PRF* by passing an index into the *PRF* vector into the `PRFIdx` port.

In all cases, when you use a varying *PRF* and choose **Output signal format** as `Pulses`, the number of samples per pulse can vary as well. When you choose `Samples`, the number of samples per pulse is fixed.

FM sweep slope (Hz/s)

Specify the slope of the linear FM sweeping, in hertz per second, as a scalar.

FM sweep interval

Specify the FM sweep interval as `Positive` or `Symmetric`. If you set this parameter value to `Positive`, the waveform sweeps in the interval between *0* and *B*, where *B* is the value set in **Sweep bandwidth**. If you set this parameter value to `Symmetric`, the waveform sweeps in the interval between *–B/2* and *B/2*.

Signal Propagation speed (m/s)

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

Reference range (m)

Specify the center of ranges of interest, in meters, as a positive scalar. The reference range must be within the unambiguous range of one pulse.

Range span (m)

Specify the length of the interval of ranges of interest, in meters, as a positive scalar. The range span is centered at the range value specified in **Reference range**.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see “Choosing a Simulation Mode” (Simulink) from the Simulink documentation.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Description	Supported Data Types
`In`	Input signal. The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.	Double-precision floating point
`Out`	Processed signal.	Double-precision floating point

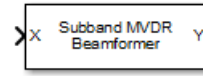
Subband MVDR Beamformer

Subband MVDR (Capon) beamformer
Library: Phased Array System Toolbox / Beamforming



Description

The Subband MVDR Beamformer block performs minimum variance distortionless response (MVDR) beamforming on wideband signals. Signals are decomposed into frequency subbands and narrowband MVDR beamforming is performed in each band. The resulting subband signals are summed to form the output signal. MVDR beamforming preserves signal power in a given direction while suppressing interference and noise from other directions. The MVDR beamformer is also called the Capon beamformer.

Ports

Input

X — Input signal

M-by-*N* complex-valued matrix

Input signal, specified as an *M*-by-*N* matrix, where *M* is the number of samples in the data, and *N* is the number of array elements.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Data Types: `double`
Complex Number Support: Yes

XT — Training signal

M-by-*N* complex-valued matrix

Input signal, specified as an *M*-by-*N* matrix, where *M* is the number of samples in the data, and *N* is the number of array elements.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Dependencies

To enable this port, select the **Enable training data input** check box.

Data Types: `double`
Complex Number Support: Yes

`Ang` — Beamforming direction

2-by-1 real-valued vector | 2-by-*L* real-valued matrix

Beamforming direction, specified as a 2-by-*L* real-valued matrix, where *L* is the number of beamforming directions. Each column takes the form of `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°, inclusive, and the elevation angle must lie between –90° and 90°, inclusive. Angles are defined with respect to the local coordinate system of the array.

Dependencies

To enable this port, set the **Source of beamforming direction** parameter to `Input port`.

Data Types: `double`

Output

`Y` — Beamformed output

M-by-*L* complex-valued matrix

Beamformed output, returned as an *M*-by-*L* complex-valued matrix. The quantity *M* is the number of signal samples and *L* is the number of desired beamforming directions specified by the `Beamforming direction` parameter or from the `Ang` port.

Data Types: `double`
Complex Number Support: Yes

`Freq` — Subband center frequencies

K-by-1 real-valued column vector

Subband center frequencies, returned as *K*-by-1 real-valued column vector. The quantity *K* is the number of subbands specified by the `Number of subbands` property.

Dependencies

To enable this port, select the **Enable subband center frequencies output** checkbox.

Data Types: `double`

`W` — Beamforming weights

N-by-*L* complex-valued matrix

Beamformed weights, returned as an *N*-by-*L* complex-valued matrix. The quantity *N* is the number of array elements. When the **Specify sensor array as** parameter is set to `Partitioned array` or `Replicated subarray`, *N* represents the number of subarrays. *L* is the number of desired beamforming directions specified in the `Ang` port or by the `Beamforming direction (deg)` property. There is one set of weights for each beamforming direction.

Dependencies

To enable this port, select the **Enable weights output** checkbox.

Data Types: `double`
Complex Number Support: Yes

Parameters

Main tab

`Signal propagation speed (m/s)` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value return by `physconst('LightSpeed')`.

`Operating frequency (Hz)` — System operating frequency
`300.0e6` (default) | positive real scalar

Specify the operating frequency of the system as a positive scalar. Units are in Hz.

`Inherit sample rate` — Inherit sample rate from upstream blocks
on (default) | off

Select this parameter to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate (Hz)** parameter.

Data Types: `Boolean`

`Sample rate (Hz)` — Sampling rate of signal
`1e6` (default) | positive real-valued scalar

Specify the signal sampling rate as a positive scalar. Units are in Hz.

Dependencies

To enable this parameter, clear the **Inherit sample rate** parameter.

Data Types: `double`

`Number of subbands` — Number of processing subbands
`64` (default) | positive integer

Number of processing subbands, specified as a positive integer.

Example: `128`

`Diagonal loading factor` — Diagonal loading factor for stability
nonnegative scalar

Specify the diagonal loading factor as a nonnegative scalar. Diagonal loading is a technique used to achieve robust beamforming performance, especially when the sample support is small.

`Enable training data input` — Enable the use of training data
off (default) | on

Select this check box to specify additional training data via the input port `XT`. To use the input signal as the training data, clear the check box which removes the port.

`Source of beamforming direction` — Source of beamforming direction
`Property` (default) | `Input port`

Source of beamforming direction, specified as `Property` or `Input port`. When you set **Source of beamforming direction** to `Property`, you then set the direction using the **Beamforming direction (deg)** parameter. When you select `Input port`, the direction is determined by the input to the `Ang` port.

`Beamforming direction (deg)` — Beamforming directions
2-by-*L* real-valued matrix

Beamforming directions, specified as a *2*-by-*L* real-valued matrix, where *L* is the number of beamforming directions. Each column takes the form `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°. Angles are defined with respect to the local coordinate system of the array.

Dependencies

To enable this parameter, set the **Source of beamforming direction** parameter to `Property`.

`Enable weights output` — Option to output beamformer weights
off (default) | on

Select this checkbox to obtain the beamformer weights from the output port, `W`.

`Enable subband center frequencies output` — Enable the output of subband center frequencies
off (default) | on

Select this check box to obtain the center frequencies of each subband via the output port, `Freq`.

`Simulate using` — Block simulation method
`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see “Choosing a Simulation Mode” (Simulink) from the Simulink documentation.

Data Types: `char`

Sensor Arrays Tab

`Specify sensor array as` — Method to specify array

`Array (no subarrays)` (default) | `Partitioned array` | `Replicated subarray` | `MATLAB expression`

Method to specify array, specified as `Array (no subarrays)` or `MATLAB expression`.

- `Array (no subarrays)` — use the block parameters to specify the array.

- `Partitioned array` — use the block parameters to specify the array.
- `Replicated subarray` — use the block parameters to specify the array.
- `MATLAB expression` — create the array using a MATLAB expression.

`Expression` — MATLAB expression used to create an array
Phased Array System Toolbox array System object

MATLAB expression used to create an array, specified as a valid Phased Array System Toolbox array System object.

Example: `phased.URA('Size',[5,3])`

Dependencies

To enable this parameter, set **Specify sensor array as** to `MATLAB expression`.

Element Parameters

`Element type` — Array element types
`Isotropic Antenna` (default) | `Cosine Antenna` | `Custom Antenna` | `Omni Microphone` | `Custom Microphone`

Antenna or microphone type, specified as one of the following:

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

`Operating frequency range (Hz)` — Operating frequency range of the antenna or microphone element
`[0,1.0e20]` (default) | real-valued 1-by-2 row vector

Specify the operating frequency range of the antenna or microphone element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The element has no response outside this frequency range. Frequency units are in Hz.

Dependencies

To enable this parameter, set **Element type** to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

`Operating frequency vector (Hz)` — Operating frequency range of custom antenna or microphone elements
`[0,1.0e20]` (default) | real-valued row vector

Specify the frequencies at which to set antenna and microphone frequency responses as a 1-by-*L* row vector of increasing real values. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of this vector. Frequency units are in Hz.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`. Use **Frequency responses (dB)** to set the responses at these frequencies.

`Baffle the back of the element` — Set back response of an `Isotropic Antenna` element or an `Omni Microphone` element to zero
off (default) | on

Select this checkbox to baffle the back response of the element. When backbaffled, the responses at all azimuth angles beyond ±90° from broadside are set to zero. The broadside direction is 0° azimuth angle and 0° elevation angle.

Dependencies

To enable this checkbox, set **Element type** to `Isotropic Antenna` or `Omni Microphone`.

`Exponent of cosine pattern` — Exponents of azimuth and elevation cosine patterns
`[1.5 1.5]` (default) | nonnegative scalar | real-valued 1-by-2 matrix of nonnegative values

Specify the exponents of the cosine pattern as a nonnegative scalar or a real-valued 1-by-2 matrix of nonnegative values. When you set **Exponent of cosine pattern** to a 1-

by-2 vector, the first element is the exponent for the azimuth direction cosine pattern, and the second element is the exponent for the elevation direction cosine pattern. When you set this parameter to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the same power.

Dependencies

To enable this parameter, set **Element type** to `Cosine Antenna`.

`Frequency responses (dB)` — Antenna and microphone frequency response

`[0,0]` (default) | real-valued row vector

Frequency response of a custom antenna or custom microphone for the frequencies defined by the **Operating frequency vector (Hz)** parameter. The dimensions of **Frequency responses (dB)** must match the dimensions of the vector specified by the **Operating frequency vector (Hz)** parameter.

Dependencies

To enable this parameter , set **Element type** to `Custom Antenna` or `Custom Microphone`.

`Azimuth angles (deg)` — Azimuth angles of antenna radiation pattern

`[-180:180]` (default) | real-valued row vector

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-P row vector. P must be greater than 2. Azimuth angles must lie between –180° and 180°, inclusive, and be in strictly increasing order.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Elevation angles (deg)` — Elevation angles of antenna radiation pattern

`[-90:90]` (default) | real-valued row vector

Specify the elevation angles at which to compute the radiation pattern as a 1-by-Q vector. Q must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive, and be in strictly increasing order.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Magnitude pattern (dB)` — Magnitude of combined antenna radiation pattern

`zeros(181,361)` (default) | real-valued Q-by-P matrix | real-valued Q-by-P-by-L array

Magnitude of the combined antenna radiation pattern, specified as a Q-by-P matrix or a Q-by-P-by-L array. The quantity Q equals the length of the vector specified by **Elevation angles (deg)**. The quantity P equals length of the vector specified by **Azimuth angles (deg)**. The quantity L equal the length of the **Operating frequency vector (Hz)**.

- If this parameter is a Q-by-P matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a Q-by-P-by-L array, each Q-by-P page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Phase pattern (deg)` — Custom antenna radiation phase pattern

`zeros(181,361)` (default) | real-valued Q-by-P matrix | real-valued Q-by-P-by-L array

Phase of the combined antenna radiation pattern, specified as a Q-by-P matrix or a Q-by-P-by-L array. The quantity Q equals the length of the vector specified by **Elevation angles (deg)**. The quantity P equals length of the vector specified by **Azimuth angles (deg)**. The quantity L equal the length of the **Operating frequency vector (Hz)**.

- If this parameter is a Q-by-P matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a Q-by-P-by-L array, each Q-by-P page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Polar pattern frequencies (Hz)` — Custom microphone response frequencies
1e3 (default) | real scalar | real-valued 1-by-*L* row vector

Response frequencies of the custom microphone of the polar pattern, specified as a real scalar or real-valued 1-by-*L* vector. The response frequencies lie within the frequency range specified by the **Operating frequency vector (Hz)** vector.

Dependencies

To enable this parameter, set **Element type** is set to `Custom Microphone`.

`Polar pattern angles (deg)` — Polar pattern response angles
`[-180:180]` (default) | real-valued -by-*P* row vector

Specify the polar pattern response angles, as a 1-by-*P* vector. The angles are measured from the central pickup axis of the microphone and must be between –180° and 180°, inclusive.

Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

`Polar pattern (dB)` — Custom microphone polar response
`zeros(1,361)` (default) | real-valued *L*-by-*P* matrix

Specify the magnitude of the custom microphone element polar patterns as an *L*-by-*P* matrix. *L* is the number of frequencies specified in **Polar pattern frequencies (Hz)**. *P* is the number of angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume also that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

Array Parameters

`Geometry` — Array geometry
`ULA` (default) | `URA` | `UCA` | `Conformal Array`

Array geometry, specified as one of

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array
- `Conformal Array` — arbitrary element positions

`Number of elements` — Number of array elements
`2` for ULA arrays and `5` for UCA arrays (default) | integer greater than or equal to 2

The number of array elements for ULA or UCA arrays, specified as an integer greater than or equal to 2.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

Dependencies

To enable this parameter, set **Geometry** to `ULA` or `UCA`.

`Element spacing (m)` — Spacing between array elements
`0.5` for ULA arrays and `[0.5,0.5]` for URA arrays (default) | positive scalar for ULA or URA arrays | 2-element vector of positive values for URA arrays

Spacing between adjacent array elements:

- ULA — specify the spacing between two adjacent elements in the array as a positive scalar.

- URA — specify the spacing as a positive scalar or a 1-by-2 vector of positive values. If **Element spacing (m)** is a scalar, the row and column spacings are equal. If **Element spacing (m)** is a vector, the vector has the form `[SpacingBetweenArrayRows,SpacingBetweenArrayColumns]`.
- When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

Dependencies

To enable this parameter, set **Geometry** to ULA or URA.

`Array axis` — Linear axis direction of ULA

`y` (default) | `x` | `z`

Linear axis direction of ULA, specified as `y`, `x`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

Dependencies

To enable this parameter, set **Geometry** to ULA. This parameter is also enabled when the block supports only ULA arrays.

`Array size` — Dimensions of URA array

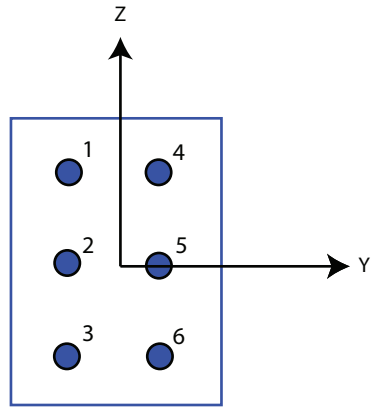
`[2,2]` (default) | positive integer | 1-by-2 vector of positive integers

Dimensions of a URA array, specified as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of rows and columns.
- When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

For a URA, array elements are indexed from top to bottom along a column, and continues to the next columns from left to right. In this figure, the **Array size** value of `[3,2]` creates an array having three rows and two columns.

Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]



Dependencies

To enable this parameter, set **Geometry** to URA.

`Element lattice` — Lattice of URA element positions
`Rectangular` (default) | `Triangular`

Lattice of URA element positions, specified as `Rectangular` or `Triangular`.

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular` — Shifts the even-row elements of a rectangular lattice toward the positive row-axis direction. The displacement is one-half the element spacing along the row dimension.

Dependencies

To enable this parameter, set **Geometry** to URA.

`Array normal` — Array normal direction

`x` for URA arrays or `z` for UCA arrays (default) | `y`

Array normal direction, specified as `x`, `y`, or `z`.

Elements of planar arrays lie in a plane orthogonal to the selected array normal direction. Element boresight directions point along the array normal direction.

Array Normal Parameter Value	Element Positions and Boresight Directions
`x`	Array elements lie in the *yz*-plane. All element boresight vectors point along the *x*-axis.
`y`	Array elements lie in the *zx*-plane. All element boresight vectors point along the *y*-axis.
`z`	Array elements lie in the *xy*-plane. All element boresight vectors point along the *z*-axis.

Dependencies

To enable this parameter, set **Geometry**to URA or UCA.

`Radius of UCA (m)` — UCA array radius

0.5 (default) | positive scalar

Radius of UCA array, specified as a positive scalar.

Dependencies

To enable this parameter, set **Geometry** to UCA.

`Element positions (m)` — Positions of conformal array elements

`[0;0;0]` (default) | 3-by-*N*matrix of real values

Positions of the elements in a conformal array, specified as a 3-by-*N* matrix of real values, where *N* is the number of elements in the conformal array. Each column of this

matrix represents the position `[x;y;z]`of an array element in the array local coordinate system. The origin of the local coordinate system is *(0,0,0)*. Units are in meters.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

Dependencies

To enable this parameter set **Geometry** to `Conformal Array`.

`Element normals (deg)` — Direction of conformal array element normal vectors

`[0;0]` | 2-by-1 column vector | 2-by-*N* matrix

Direction of element normal vectors in a conformal array, specified as a 2-by-1 column vector or a 2-by-*N* matrix. *N* indicates the number of elements in the array. If the parameter value is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]` with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If the parameter value is a 2-by-1 column vector, the same pointing direction is used for all array elements.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal direction.

Dependencies

To enable this parameter, set **Geometry** to `Conformal Array`.

`Taper` — Array element tapers

1 (default) | complex-valued scalar | complex-valued row vector

Element tapering, specified as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array.

Also known as *element weights*, tapers multiply the array element responses. Tapers modify both amplitude and phase of the response to reduce sidelobes or steer the main response axis.

If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. The number of weights must match the number of elements of the array.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

`Subarray definition matrix` — Define elements belonging to subarrays
logical matrix

Subarray selection matrix, specified as an *M*-by-*N* matrix of ones and zeros. *M* is the required number of subarrays and *N* is the total number of elements in the array. Each row of the matrix indicates which elements belong to the corresponding subarray. Entries in the matrix are `1` or `0`. A value of `1` indicates that the element belongs to the subarray and `0` indicates it is not in the subarray. Each row must contain at least one `1`. An element can belong to more than one subarray.

The phase center of each subarray is located at the subarray geometric center. The subarray geometric center depends on the **Subarray definition matrix** and **Geometry** parameters.

Dependencies

To enable this parameter, set **Sensor array** to `Partitioned array`.

`Subarray steering method` — Specify subarray steering method
`None` (default) | `Phase` | `Time`

Subarray steering method, specified as one of

- `None`
- `Phase`
- `Time`

When using the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, or Wideband Transmit Arrayblocks, selecting `Phase` or `Time` opens the block input port, `Steer`.

Dependencies

To enable this parameter, set **Sensor array** to `Partitioned array` or `Replicated subarray`.

`Phase shifter frequency (Hz)` — Subarray phase shifting frequency
`3.0e8` (default) | positive real-valued scalar

Operating frequency of subarray steering phase shifters, specified as a positive real-valued scalar. Units are Hz.

Dependencies

To enable this parameter, set **Sensor array** to `Partitioned array` or `Replicated subarray` and set **Subarray steering method** to `Phase`.

`Number of bits in phase shifters` — Subarray steering phase shift quantization bits
`0` (default) | non-negative integer

Subarray steering phase shift quantization bits, specified as a non-negative integer. A value of zero indicates that no quantization is performed.

Dependencies

To enable this parameter, set **Sensor array** to `Partitioned array` or `Replicated subarray` and set **Subarray steering method** to `Phase`.

`Subarrays layout` — Subarray position specification
`Rectangular` (default) | `Custom`

Specify the layout of replicated subarrays as `Rectangular` or `Custom`.

- When you set this parameter to `Rectangular`, use the **Grid size** and **Grid spacing** parameters to place the subarrays.
- When you set this parameter to `Custom`, use the **Subarray positions (m)** and **Subarray normals** parameters to place the subarrays.

Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray`

`Grid size` — Dimensions of rectangular subarray grid
`[1,2]` (default)

Rectangular subarray grid size, specified as a single positive integer or a positive integer-valued 1-by-2 row vector.

If **Grid size** is an integer scalar, the array has an equal number of subarrays in each row and column. If **Grid size** is a 1-by-2 vector of the form `[NumberOfRows, NumberOfColumns]`, the first entry is the number of subarrays along each column. The second entry is the number of subarrays in each row. A row is along the local *y*-axis, and a column is along the local *z*-axis. The figure here shows how you can replicate a 3-by-2 URA subarray using a **Grid size** of `[1,2]`.

Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

`Grid spacing (m)` — Spacing between subarrays on rectangular grid
`Auto` (default) | positive real-valued scalar | 1-by-2 vector of positive real-values

The rectangular grid spacing of subarrays, specified as a positive, real-valued scalar, a 1-by-2 row vector of positive, real-values, or `Auto`. Units are in meters.

- If **Grid spacing** is a scalar, the spacing along the row and the spacing along the column is the same.
- If **Grid spacing** is a 1-by-2 row vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumn]`. The first entry specifies the spacing between rows along a column. The second entry specifies the spacing between columns along a row.
- If **Grid spacing** is set to `Auto`, replication preserves the element spacing of the subarray for both rows and columns while building the full array. This option is available only when you specify **Geometry** as `ULA` or `URA`.

Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

`Subarray positions (m)` — Positions of subarrays

`[0,0;0.5,0.5;0,0]` (default) | 3-by-*N* real-valued matrix

Positions of the subarrays in the custom grid, specified as a real 3-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix represents the position of a single subarray in the array local coordinate system. The coordinates are expressed in the form `[x; y; z]`. Units are in meters.

Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Custom`.

`Subarray normals` — Direction of subarray normal vectors

`[0,0;0,0]` (default) | 2-by-*N* real matrix

Specify the normal directions of the subarrays in the array. This parameter value is a 2-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix specifies the normal direction of the corresponding subarray, in the form

`[azimuth;elevation]`. Angle units are in degrees. Angles are defined with respect to the local coordinate system.

You can use the **Subarray positions** and **Subarray normals** parameters to represent any arrangement in which pairs of subarrays differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal.

Dependencies

To enable this parameter, set the **Sensor array** parameter to `Replicated subarray` and the **Subarrays layout** to `Custom`.

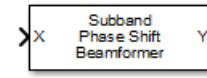
phased.SubbandMVDRBeamformer

Introduced in R2015b

Subband Phase Shift Beamformer

Subband phase shift beamformer
Library: Phased Array System Toolbox / Beamforming



Description

The Subband Phase Shift Beamformer block performs delay-and-sum beamforming in the frequency domain. The signal is divided into frequency subbands. In each subband, a phase shift at the subband center frequency approximates the time delay. The resulting subband signals are summed to form the frequency-domain output signal and then converted to the time domain.

Ports

Input

X — Input signal

M-by-*N* complex-valued matrix

Input signal, specified as an *M*-by-*N* matrix, where *M* is the number of samples in the data, and *N* is the number of array elements.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Data Types: `double`
Complex Number Support: Yes

Ang — Beamforming direction

2-by-1 real-valued vector | 2-by-*L* real-valued matrix

Beamforming direction, specified as a 2-by-*L* real-valued matrix, where *L* is the number of beamforming directions. Each column takes the form of

`[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°, inclusive, and the elevation angle must lie between –90° and 90°, inclusive. Angles are defined with respect to the local coordinate system of the array.

Dependencies

To enable this port, set the **Source of beamforming direction** parameter to `Input port`.

Data Types: `double`

Output

`Y` — Beamformed output

M-by-*L* complex-valued matrix

Beamformed output, returned as an *M*-by-*L* complex-valued matrix. The quantity *M* is the number of signal samples and *L* is the number of desired beamforming directions specified by the `Beamforming direction` parameter or from the `Ang` port.

Data Types: `double`
Complex Number Support: Yes

`Freq` — Subband center frequencies

K-by-1 real-valued column vector

Subband center frequencies, returned as *K*-by-1 real-valued column vector. The quantity *K* is the number of subbands specified by the `Number of subbands` property.

Dependencies

To enable this port, select the **Enable subband center frequencies output** checkbox.

Data Types: `double`

`W` — Beamforming weights

N-by-*L* complex-valued matrix

Beamformed weights, returned as an *N*-by-*L* complex-valued matrix. The quantity *N* is the number of array elements. When the **Specify sensor array as** parameter is set to `Partitioned array` or `Replicated subarray`, *N* represents the number of subarrays. *L* is the number of desired beamforming directions specified in the `Ang` port or by the `Beamforming direction (deg)` property. There is one set of weights for each beamforming direction.

Dependencies

To enable this port, select the **Enable weights output** checkbox.

Data Types: `double`
Complex Number Support: Yes

Parameters

Main tab

`Signal propagation speed (m/s)` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value return by `physconst('LightSpeed')`.

`Operating frequency (Hz)` — System operating frequency

`300.0e6` (default) | positive real scalar

Specify the operating frequency of the system as a positive scalar. Units are in Hz.

`Inherit sample rate` — Inherit sample rate from upstream blocks

on (default) | off

Select this parameter to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate (Hz)** parameter.

Data Types: `Boolean`

`Sample rate (Hz)` — Sampling rate of signal

`1e6` (default) | positive real-valued scalar

Specify the signal sampling rate as a positive scalar. Units are in Hz.

Dependencies

To enable this parameter, clear the **Inherit sample rate** parameter.

Data Types: `double`

`Number of subbands` — Number of processing subbands

`64` (default) | positive integer

Number of processing subbands, specified as a positive integer.

Example: `128`

`Source of beamforming direction` — Source of beamforming direction

`Property` (default) | `Input port`

Source of beamforming direction, specified as `Property` or `Input port`. When you set **Source of beamforming direction** to `Property`, you then set the direction using the **Beamforming direction (deg)** parameter. When you select `Input port`, the direction is determined by the input to the `Ang` port.

`Beamforming direction (deg)` — Beamforming directions

2-by-*L* real-valued matrix

Beamforming directions, specified as a *2*-by-*L* real-valued matrix, where *L* is the number of beamforming directions. Each column takes the form `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°. Angles are defined with respect to the local coordinate system of the array.

Dependencies

To enable this parameter, set the **Source of beamforming direction** parameter to `Property`.

`Enable weights output` — Option to output beamformer weights

off (default) | on

Select this checkbox to obtain the beamformer weights from the output port, `W`.

`Enable subband center frequencies output` — Enable the output of subband center frequencies

off (default) | on

Select this check box to obtain the center frequencies of each subband via the output port, `Freq`.

`Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see “Choosing a Simulation Mode” (Simulink) from the Simulink documentation.

Data Types: `char`

Sensor Arrays Tab

`Specify sensor array as` — Method to specify array

`Array (no subarrays)` (default) | `Partitioned array` | `Replicated subarray` | `MATLAB expression`

Method to specify array, specified as `Array (no subarrays)` or `MATLAB expression`.

- `Array (no subarrays)` — use the block parameters to specify the array.
- `Partitioned array` — use the block parameters to specify the array.
- `Replicated subarray` — use the block parameters to specify the array.
- `MATLAB expression` — create the array using a MATLAB expression.

`Expression` — MATLAB expression used to create an array

Phased Array System Toolbox array System object

MATLAB expression used to create an array, specified as a valid Phased Array System Toolbox array System object.

Example: `phased.URA('Size',[5,3])`

Dependencies

To enable this parameter, set **Specify sensor array as** to `MATLAB expression`.

Element Parameters

`Element type` — Array element types

`Isotropic Antenna` (default) | `Cosine Antenna` | `Custom Antenna` | `Omni Microphone` | `Custom Microphone`

Antenna or microphone type, specified as one of the following:

- `Isotropic Antenna`
- `Cosine Antenna`

- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

`Operating frequency range (Hz)` — Operating frequency range of the antenna or microphone element
`[0,1.0e20]` (default) | real-valued 1-by-2 row vector

Specify the operating frequency range of the antenna or microphone element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The element has no response outside this frequency range. Frequency units are in Hz.

Dependencies

To enable this parameter, set **Element type** to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

`Operating frequency vector (Hz)` — Operating frequency range of custom antenna or microphone elements
`[0,1.0e20]` (default) | real-valued row vector

Specify the frequencies at which to set antenna and microphone frequency responses as a 1-by-*L* row vector of increasing real values. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of this vector. Frequency units are in Hz.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`. Use **Frequency responses (dB)** to set the responses at these frequencies.

`Baffle the back of the element` — Set back response of an `Isotropic Antenna` element or an `Omni Microphone` element to zero
off (default) | on

Select this checkbox to baffle the back response of the element. When backbaffled, the responses at all azimuth angles beyond ±90° from broadside are set to zero. The broadside direction is 0° azimuth angle and 0° elevation angle.

Dependencies

To enable this checkbox, set **Element type** to `Isotropic Antenna` or `Omni Microphone`.

`Exponent of cosine pattern` — Exponents of azimuth and elevation cosine patterns
`[1.5 1.5]` (default) | nonnegative scalar | real-valued 1-by-2 matrix of nonnegative values

Specify the exponents of the cosine pattern as a nonnegative scalar or a real-valued 1-by-2 matrix of nonnegative values. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern, and the second element is the exponent for the elevation direction cosine pattern. When you set this parameter to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the same power.

Dependencies

To enable this parameter, set **Element type** to `Cosine Antenna`.

`Frequency responses (dB)` — Antenna and microphone frequency response
`[0,0]` (default) | real-valued row vector

Frequency response of a custom antenna or custom microphone for the frequencies defined by the **Operating frequency vector (Hz)** parameter. The dimensions of **Frequency responses (dB)** must match the dimensions of the vector specified by the **Operating frequency vector (Hz)** parameter.

Dependencies

To enable this parameter , set **Element type** to `Custom Antenna` or `Custom Microphone`.

`Azimuth angles (deg)` — Azimuth angles of antenna radiation pattern
`[-180:180]` (default) | real-valued row vector

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-P row vector. P must be greater than 2. Azimuth angles must lie between –180° and 180°, inclusive, and be in strictly increasing order.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Elevation angles (deg)` — Elevation angles of antenna radiation pattern
`[-90:90]` (default) | real-valued row vector

Specify the elevation angles at which to compute the radiation pattern as a 1-by-Q vector. Q must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive, and be in strictly increasing order.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Magnitude pattern (dB)` — Magnitude of combined antenna radiation pattern
`zeros(181,361)` (default) | real-valued Q-by-P matrix | real-valued Q-by-P-by-L array

Magnitude of the combined antenna radiation pattern, specified as a Q-by-P matrix or a Q-by-P-by-L array. The quantity Q equals the length of the vector specified by **Elevation angles (deg)**. The quantity P equals length of the vector specified by **Azimuth angles (deg)**. The quantity L equal the length of the **Operating frequency vector (Hz)**.

- If this parameter is a Q-by-P matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a Q-by-P-by-L array, each Q-by-P page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Phase pattern (deg)` — Custom antenna radiation phase pattern
`zeros(181,361)` (default) | real-valued Q-by-P matrix | real-valued Q-by-P-by-L array

Phase of the combined antenna radiation pattern, specified as a Q-by-P matrix or a Q-by-P-by-L array. The quantity Q equals the length of the vector specified by **Elevation**

angles (deg). The quantity P equals length of the vector specified by **Azimuth angles (deg)**. The quantity L equal the length of the **Operating frequency vector (Hz)**.

- If this parameter is a Q-by-P matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a Q-by-P-by-L array, each Q-by-P page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Polar pattern frequencies (Hz)` — Custom microphone response frequencies

`1e3` (default) | real scalar | real-valued 1-by-L row vector

Response frequencies of the custom microphone of the polar pattern, specified as a real scalar or real-valued 1-by-L vector. The response frequencies lie within the frequency range specified by the **Operating frequency vector (Hz)** vector.

Dependencies

To enable this parameter, set **Element type** is set to `Custom Microphone`.

`Polar pattern angles (deg)` — Polar pattern response angles

`[-180:180]` (default) | real-valued -by-P row vector

Specify the polar pattern response angles, as a 1-by-P vector. The angles are measured from the central pickup axis of the microphone and must be between –180° and 180°, inclusive.

Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

`Polar pattern (dB)` — Custom microphone polar response

`zeros(1,361)` (default) | real-valued L-by-P matrix

Specify the magnitude of the custom microphone element polar patterns as an L-by-P matrix. L is the number of frequencies specified in **Polar pattern frequencies (Hz)**. P is the number of angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume also that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

Array Parameters

`Geometry` — Array geometry

`ULA` (default) | `URA` | `UCA` | `Conformal Array`

Array geometry, specified as one of

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array
- `Conformal Array` — arbitrary element positions

`Number of elements` — Number of array elements

`2` for ULA arrays and `5` for UCA arrays (default) | integer greater than or equal to 2

The number of array elements for ULA or UCA arrays, specified as an integer greater than or equal to 2.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

Dependencies

To enable this parameter, set **Geometry** to `ULA` or `UCA`.

`Element spacing (m)` — Spacing between array elements

`0.5` for ULA arrays and `[0.5,0.5]` for URA arrays (default) | positive scalar for ULA or URA arrays | 2-element vector of positive values for URA arrays

Spacing between adjacent array elements:

- ULA — specify the spacing between two adjacent elements in the array as a positive scalar.
- URA — specify the spacing as a positive scalar or a 1-by-2 vector of positive values. If **Element spacing (m)** is a scalar, the row and column spacings are equal. If **Element spacing (m)** is a vector, the vector has the form `[SpacingBetweenArrayRows,SpacingBetweenArrayColumns]`.
- When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

Dependencies

To enable this parameter, set **Geometry** to `ULA` or `URA`.

`Array axis` — Linear axis direction of ULA

`y` (default) | `x` | `z`

Linear axis direction of ULA, specified as `y`, `x`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

Dependencies

To enable this parameter, set **Geometry** to `ULA`. This parameter is also enabled when the block supports only ULA arrays.

`Array size` — Dimensions of URA array

`[2,2]` (default) | positive integer | 1-by-2 vector of positive integers

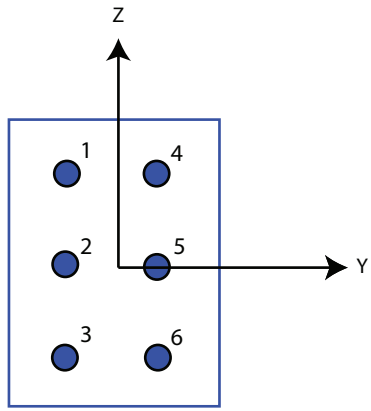
Dimensions of a URA array, specified as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of rows and columns.

- When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

For a URA, array elements are indexed from top to bottom along a column, and continues to the next columns from left to right. In this figure, the **Array size** value of `[3,2]` creates an array having three rows and two columns.

Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]



Dependencies

To enable this parameter, set **Geometry** to URA.

`Element lattice` — Lattice of URA element positions
`Rectangular` (default) | `Triangular`

Lattice of URA element positions, specified as `Rectangular` or `Triangular`.

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular` — Shifts the even-row elements of a rectangular lattice toward the positive row-axis direction. The displacement is one-half the element spacing along the row dimension.

Dependencies

To enable this parameter, set **Geometry** to URA.

`Array normal` — Array normal direction
x for URA arrays or z for UCA arrays (default) | y

Array normal direction, specified as `x`, `y`, or `z`.

Elements of planar arrays lie in a plane orthogonal to the selected array normal direction. Element boresight directions point along the array normal direction.

Array Normal Parameter Value	Element Positions and Boresight Directions
x	Array elements lie in the *yz*-plane. All element boresight vectors point along the *x*-axis.
y	Array elements lie in the *zx*-plane. All element boresight vectors point along the *y*-axis.
z	Array elements lie in the *xy*-plane. All element boresight vectors point along the *z*-axis.

Dependencies

To enable this parameter, set **Geometry**to URA or UCA.

`Radius of UCA (m)` — UCA array radius
0.5 (default) | positive scalar

Radius of UCA array, specified as a positive scalar.

Dependencies

To enable this parameter, set **Geometry** to UCA.

`Element positions (m)` — Positions of conformal array elements

`[0;0;0]` (default) | 3-by-*N* matrix of real values

Positions of the elements in a conformal array, specified as a 3-by-*N* matrix of real values, where *N* is the number of elements in the conformal array. Each column of this matrix represents the position `[x;y;z]` of an array element in the array local coordinate system. The origin of the local coordinate system is *(0,0,0)*. Units are in meters.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

Dependencies

To enable this parameter set **Geometry** to `Conformal Array`.

`Element normals (deg)` — Direction of conformal array element normal vectors

`[0;0]` | 2-by-1 column vector | 2-by-*N* matrix

Direction of element normal vectors in a conformal array, specified as a 2-by-1 column vector or a 2-by-*N* matrix. *N* indicates the number of elements in the array. If the parameter value is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]` with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If the parameter value is a 2-by-1 column vector, the same pointing direction is used for all array elements.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal direction.

Dependencies

To enable this parameter, set **Geometry** to `Conformal Array`.

`Taper` — Array element tapers

1 (default) | complex-valued scalar | complex-valued row vector

Element tapering, specified as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array.

Also known as *element weights*, tapers multiply the array element responses. Tapers modify both amplitude and phase of the response to reduce sidelobes or steer the main response axis.

If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. The number of weights must match the number of elements of the array.

When you set **Specify sensor array as** to `Replicated subarray`, this parameter applies to each subarray.

`Subarray definition matrix` — Define elements belonging to subarrays

logical matrix

Subarray selection matrix, specified as an *M*-by-*N* matrix of ones and zeros. *M* is the required number of subarrays and *N* is the total number of elements in the array. Each row of the matrix indicates which elements belong to the corresponding subarray. Entries in the matrix are `1` or `0`. A value of `1` indicates that the element belongs to the subarray and `0` indicates it is not in the subarray. Each row must contain at least one `1`. An element can belong to more than one subarray.

The phase center of each subarray is located at the subarray geometric center. The subarray geometric center depends on the **Subarray definition matrix** and **Geometry** parameters.

Dependencies

To enable this parameter, set **Sensor array** to `Partitioned array`.

`Subarray steering method` — Specify subarray steering method

`None` (default) | `Phase` | `Time`

Subarray steering method, specified as one of

- `None`

- `Phase`
- `Time`

When using the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, or Wideband Transmit Arrayblocks, selecting `Phase` or `Time` opens the block input port, `Steer`.

Dependencies

To enable this parameter, set **Sensor array** to `Partitioned array` or `Replicated subarray`.

`Phase shifter frequency (Hz)` — Subarray phase shifting frequency
`3.0e8` (default) | positive real-valued scalar

Operating frequency of subarray steering phase shifters, specified as a positive real-valued scalar. Units are Hz.

Dependencies

To enable this parameter, set **Sensor array** to `Partitioned array` or `Replicated subarray` and set **Subarray steering method** to `Phase`.

`Number of bits in phase shifters` — Subarray steering phase shift quantization bits
`0` (default) | non-negative integer

Subarray steering phase shift quantization bits, specified as a non-negative integer. A value of zero indicates that no quantization is performed.

Dependencies

To enable this parameter, set **Sensor array** to `Partitioned array` or `Replicated subarray` and set **Subarray steering method** to `Phase`.

`Subarrays layout` — Subarray position specification
`Rectangular` (default) | `Custom`

Specify the layout of replicated subarrays as `Rectangular` or `Custom`.

- When you set this parameter to `Rectangular`, use the **Grid size** and **Grid spacing** parameters to place the subarrays.
- When you set this parameter to `Custom`, use the **Subarray positions (m)** and **Subarray normals** parameters to place the subarrays.

Dependencies

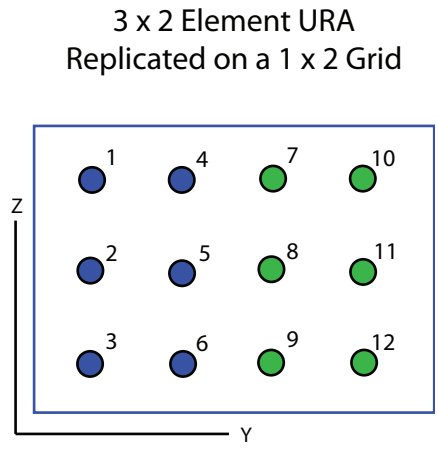
To enable this parameter, set **Sensor array** to `Replicated subarray`

`Grid size` — Dimensions of rectangular subarray grid

`[1,2]` (default)

Rectangular subarray grid size, specified as a single positive integer or a positive integer-valued 1-by-2 row vector.

If **Grid size** is an integer scalar, the array has an equal number of subarrays in each row and column. If **Grid size** is a 1-by-2 vector of the form `[NumberOfRows, NumberOfColumns]`, the first entry is the number of subarrays along each column. The second entry is the number of subarrays in each row. A row is along the local *y*-axis, and a column is along the local *z*-axis. The figure here shows how you can replicate a 3-by-2 URA subarray using a **Grid size** of `[1,2]`.



Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

`Grid spacing (m)` — Spacing between subarrays on rectangular grid
`Auto` (default) | positive real-valued scalar | 1-by-2 vector of positive real-values

The rectangular grid spacing of subarrays, specified as a positive, real-valued scalar, a 1-by-2 row vector of positive, real-values, or `Auto`. Units are in meters.

- If **Grid spacing** is a scalar, the spacing along the row and the spacing along the column is the same.
- If **Grid spacing** is a 1-by-2 row vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumn]`. The first entry specifies the spacing between rows along a column. The second entry specifies the spacing between columns along a row.
- If **Grid spacing** is set to `Auto`, replication preserves the element spacing of the subarray for both rows and columns while building the full array. This option is available only when you specify **Geometry** as `ULA` or `URA`.

Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

`Subarray positions (m)` — Positions of subarrays
`[0,0;0.5,0.5;0,0]` (default) | 3-by-*N* real-valued matrix

Positions of the subarrays in the custom grid, specified as a real 3-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix represents the position of a single subarray in the array local coordinate system. The coordinates are expressed in the form `[x; y; z]`. Units are in meters.

Dependencies

To enable this parameter, set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Custom`.

`Subarray normals` — Direction of subarray normal vectors

`[0,0;0,0]` (default) | 2-by-*N* real matrix

Specify the normal directions of the subarrays in the array. This parameter value is a 2-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix specifies the normal direction of the corresponding subarray, in the form `[azimuth;elevation]`. Angle units are in degrees. Angles are defined with respect to the local coordinate system.

You can use the **Subarray positions** and **Subarray normals** parameters to represent any arrangement in which pairs of subarrays differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal.

Dependencies

To enable this parameter, set the **Sensor array** parameter to `Replicated subarray` and the **Subarrays layout** to `Custom`.

phased.SubbandPhaseShiftBeamformer

Introduced in R2014b

Time Delay Beamformer

Time-delay beamformer
Library: Phased Array System Toolbox / Beamforming

Description

The Time Delay Beamformer block performs delay-and-sum beamforming. Plane-wave signals arriving at the array elements are time-aligned and then summed. Time alignment is achieved by transforming the signals into the frequency domain and applying linear phase shifts corresponding to a time delay. The individual signals are then added and converted back to the time domain.

Ports

Input

X — Input signal

M-by-*N* complex-valued matrix

Input signal, specified as an *M*-by-*N* matrix, where *M* is the number of samples in the data, and *N* is the number of array elements.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Data Types: `double`
Complex Number Support: Yes

Ang — Beamforming direction

2-by-1 real-valued vector | 2-by-*L* real-valued matrix

Beamforming direction, specified as a 2-by-*L* real-valued matrix, where *L* is the number of beamforming directions. Each column takes the form of `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle

must lie between –180° and 180°, inclusive, and the elevation angle must lie between –90° and 90°, inclusive. Angles are defined with respect to the local coordinate system of the array.

Dependencies

To enable this port, set the **Source of beamforming direction** parameter to `Input port`.

Data Types: `double`

Output

`Y` — Beamformed output

M-by-*L* complex-valued matrix

Beamformed output, returned as an *M*-by-*L* complex-valued matrix. The quantity *M* is the number of signal samples and *L* is the number of desired beamforming directions specified by the `Beamforming direction` parameter or from the `Ang` port.

Data Types: `double`
Complex Number Support: Yes

`W` — Beamforming weights

N-by-*L* complex-valued matrix

Beamformed weights, returned as an *N*-by-*L* complex-valued matrix. The quantity *N* is the number of array elements. When the **Specify sensor array as** parameter is set to `Partitioned array` or `Replicated subarray`, *N* represents the number of subarrays. *L* is the number of desired beamforming directions specified in the `Ang` port or by the `Beamforming direction (deg)` property. There is one set of weights for each beamforming direction.

Dependencies

To enable this port, select the **Enable weights output** checkbox.

Data Types: `double`
Complex Number Support: Yes

Parameters

Main tab

`Signal propagation speed (m/s)` — Signal propagation speed
`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value return by `physconst('LightSpeed')`.

`Inherit sample rate` — Inherit sample rate from upstream blocks
on (default) | off

Select this parameter to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate (Hz)** parameter.

Data Types: `Boolean`

`Sample rate (Hz)` — Sampling rate of signal
`1e6` (default) | positive real-valued scalar

Specify the signal sampling rate as a positive scalar. Units are in Hz.

Dependencies

To enable this parameter, clear the **Inherit sample rate** parameter.

Data Types: `double`

`Source of beamforming direction` — Source of beamforming direction
`Property` (default) | `Input port`

Source of beamforming direction, specified as `Property` or `Input port`. When you set **Source of beamforming direction** to `Property`, you then set the direction using the **Beamforming direction (deg)** parameter. When you select `Input port`, the direction is determined by the input to the `Ang` port.

`Beamforming direction (deg)` — Beamforming directions
2-by-*L* real-valued matrix

Beamforming directions, specified as a *2*-by-*L* real-valued matrix, where *L* is the number of beamforming directions. Each column takes the form `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°. Angles are defined with respect to the local coordinate system of the array.

Dependencies

To enable this parameter, set the **Source of beamforming direction** parameter to `Property`.

`Enable weights output` — Option to output beamformer weights

off (default) | on

Select this checkbox to obtain the beamformer weights from the output port, `W`.

`Simulate using` — Block simulation method

`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior

	Normal	Accelerator	Rapid Accelerator
Interpreted Execution	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
Code Generation	The block is compiled.	All blocks in the model are compiled.	

For more information, see "Choosing a Simulation Mode" (Simulink) from the Simulink documentation.

Data Types: `char`

Sensor Arrays Tab

`Specify sensor array as` — Method to specify array

`Array (no subarrays)` (default) | `MATLAB expression`

Method to specify array, specified as `Array (no subarrays)` or `MATLAB expression`.

- `Array (no subarrays)` — use the block parameters to specify the array.
- `MATLAB expression` — create the array using a MATLAB expression.

`Expression` — MATLAB expression used to create an array

Phased Array System Toolbox array System object

MATLAB expression used to create an array, specified as a valid Phased Array System Toolbox array System object.

Example: `phased.URA('Size',[5,3])`

Dependencies

To enable this parameter, set **Specify sensor array as** to `MATLAB expression`.

Element Parameters

`Element type` — Array element types

`Isotropic Antenna` (default) | `Cosine Antenna` | `Custom Antenna` | `Omni Microphone` | `Custom Microphone`

Antenna or microphone type, specified as one of the following:

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

`Operating frequency range (Hz)` — Operating frequency range of the antenna or microphone element
`[0,1.0e20]` (default) | real-valued 1-by-2 row vector

Specify the operating frequency range of the antenna or microphone element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The element has no response outside this frequency range. Frequency units are in Hz.

Dependencies

To enable this parameter, set **Element type** to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

`Operating frequency vector (Hz)` — Operating frequency range of custom antenna or microphone elements
`[0,1.0e20]` (default) | real-valued row vector

Specify the frequencies at which to set antenna and microphone frequency responses as a 1-by-*L* row vector of increasing real values. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of this vector. Frequency units are in Hz.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`. Use **Frequency responses (dB)** to set the responses at these frequencies.

`Baffle the back of the element` — Set back response of an `Isotropic Antenna` element or an `Omni Microphone` element to zero
off (default) | on

Select this checkbox to baffle the back response of the element. When backbaffled, the responses at all azimuth angles beyond ±90° from broadside are set to zero. The broadside direction is 0° azimuth angle and 0° elevation angle.

Dependencies

To enable this checkbox, set **Element type** to `Isotropic Antenna` or `Omni Microphone`.

`Exponent of cosine pattern` — Exponents of azimuth and elevation cosine patterns

`[1.5 1.5]` (default) | nonnegative scalar | real-valued 1-by-2 matrix of nonnegative values

Specify the exponents of the cosine pattern as a nonnegative scalar or a real-valued 1-by-2 matrix of nonnegative values. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern, and the second element is the exponent for the elevation direction cosine pattern. When you set this parameter to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the same power.

Dependencies

To enable this parameter, set **Element type** to `Cosine Antenna`.

`Frequency responses (dB)` — Antenna and microphone frequency response

`[0,0]` (default) | real-valued row vector

Frequency response of a custom antenna or custom microphone for the frequencies defined by the **Operating frequency vector (Hz)** parameter. The dimensions of **Frequency responses (dB)** must match the dimensions of the vector specified by the **Operating frequency vector (Hz)** parameter.

Dependencies

To enable this parameter , set **Element type** to `Custom Antenna` or `Custom Microphone`.

`Azimuth angles (deg)` — Azimuth angles of antenna radiation pattern
`[-180:180]` (default) | real-valued row vector

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-P row vector. P must be greater than 2. Azimuth angles must lie between –180° and 180°, inclusive, and be in strictly increasing order.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Elevation angles (deg)` — Elevation angles of antenna radiation pattern
`[-90:90]` (default) | real-valued row vector

Specify the elevation angles at which to compute the radiation pattern as a 1-by-Q vector. Q must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive, and be in strictly increasing order.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Magnitude pattern (dB)` — Magnitude of combined antenna radiation pattern
`zeros(181,361)` (default) | real-valued Q-by-P matrix | real-valued Q-by-P-by-L array

Magnitude of the combined antenna radiation pattern, specified as a Q-by-P matrix or a Q-by-P-by-L array. The quantity Q equals the length of the vector specified by **Elevation angles (deg)**. The quantity P equals length of the vector specified by **Azimuth angles (deg)**. The quantity L equal the length of the **Operating frequency vector (Hz)**.

- If this parameter is a Q-by-P matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a Q-by-P-by-L array, each Q-by-P page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Phase pattern (deg)` — Custom antenna radiation phase pattern
`zeros(181,361)` (default) | real-valued Q-by-P matrix | real-valued Q-by-P-by-L array

Phase of the combined antenna radiation pattern, specified as a Q-by-P matrix or a Q-by-P-by-L array. The quantity Q equals the length of the vector specified by **Elevation angles (deg)**. The quantity P equals length of the vector specified by **Azimuth angles (deg)**. The quantity L equal the length of the **Operating frequency vector (Hz)**.

- If this parameter is a Q-by-P matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a Q-by-P-by-L array, each Q-by-P page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Polar pattern frequencies (Hz)` — Custom microphone response frequencies
1e3 (default) | real scalar | real-valued 1-by-L row vector

Response frequencies of the custom microphone of the polar pattern, specified as a real scalar or real-valued 1-by-L vector. The response frequencies lie within the frequency range specified by the **Operating frequency vector (Hz)** vector.

Dependencies

To enable this parameter, set **Element type** is set to `Custom Microphone`.

`Polar pattern angles (deg)` — Polar pattern response angles
`[-180:180]` (default) | real-valued -by-P row vector

Specify the polar pattern response angles, as a 1-by-P vector. The angles are measured from the central pickup axis of the microphone and must be between –180° and 180°, inclusive.

Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

`Polar pattern (dB)` — Custom microphone polar response
`zeros(1,361)` (default) | real-valued L-by-P matrix

Specify the magnitude of the custom microphone element polar patterns as an L-by-P matrix. L is the number of frequencies specified in **Polar pattern frequencies (Hz)**. P is the number of angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume also that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

Array Parameters

`Geometry` — Array geometry
`ULA` (default) | `URA` | `UCA` | `Conformal Array`

Array geometry, specified as one of

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array
- `Conformal Array` — arbitrary element positions

`Number of elements` — Number of array elements
`2` for ULA arrays and `5` for UCA arrays (default) | integer greater than or equal to 2

The number of array elements for ULA or UCA arrays, specified as an integer greater than or equal to 2.

Dependencies

To enable this parameter, set **Geometry** to `ULA` or `UCA`.

`Element spacing (m)` — Spacing between array elements

`0.5` for ULA arrays and `[0.5,0.5]` for URA arrays (default) | positive scalar for ULA or URA arrays | 2-element vector of positive values for URA arrays

Spacing between adjacent array elements:

- ULA — specify the spacing between two adjacent elements in the array as a positive scalar.
- URA — specify the spacing as a positive scalar or a 1-by-2 vector of positive values. If **Element spacing (m)** is a scalar, the row and column spacings are equal. If **Element spacing (m)** is a vector, the vector has the form `[SpacingBetweenArrayRows,SpacingBetweenArrayColumns]`.

Dependencies

To enable this parameter, set **Geometry** to ULA or URA.

`Array axis` — Linear axis direction of ULA

`y` (default) | `x` | `z`

Linear axis direction of ULA, specified as `y`, `x`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

Dependencies

To enable this parameter, set **Geometry** to ULA. This parameter is also enabled when the block supports only ULA arrays.

`Array size` — Dimensions of URA array

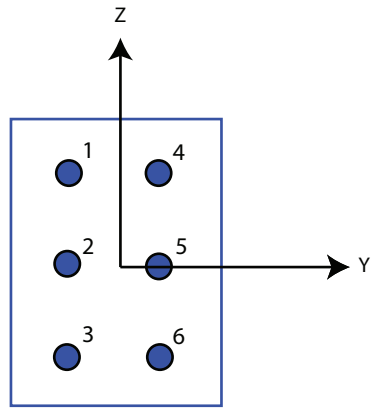
`[2,2]` (default) | positive integer | 1-by-2 vector of positive integers

Dimensions of a URA array, specified as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of elements in each row and column.

For a URA, array elements are indexed from top to bottom along a column, and continuing to the next columns from left to right. In this figure, the **Array size** value of `[3,2]` creates an array having three rows and two columns.

Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]



Dependencies

To enable this parameter, set **Geometry** to URA.

`Element lattice` — Lattice of URA element positions
`Rectangular` (default) | `Triangular`

Lattice of URA element positions, specified as `Rectangular` or `Triangular`.

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular` — Shifts the even-row elements of a rectangular lattice toward the positive row-axis direction. The displacement is one-half the element spacing along the row dimension.

Dependencies

To enable this parameter, set **Geometry** to URA.

`Array normal` — Array normal direction
x for URA arrays or z for UCA arrays (default) | y

Array normal direction, specified as `x`, `y`, or `z`.

Elements of planar arrays lie in a plane orthogonal to the selected array normal direction. Element boresight directions point along the array normal direction.

Array Normal Parameter Value	Element Positions and Boresight Directions
x	Array elements lie in the *yz*-plane. All element boresight vectors point along the *x*-axis.
y	Array elements lie in the *zx*-plane. All element boresight vectors point along the *y*-axis.
z	Array elements lie in the *xy*-plane. All element boresight vectors point along the *z*-axis.

Dependencies

To enable this parameter, set **Geometry**to URA or UCA.

`Radius of UCA (m)` — UCA array radius
0.5 (default) | positive scalar

Radius of UCA array, specified as a positive scalar.

Dependencies

To enable this parameter, set **Geometry** to UCA.

`Element positions (m)` — Positions of conformal array elements
`[0;0;0]` (default) | 3-by-*N*matrix of real values

Positions of the elements in a conformal array, specified as a 3-by-*N* matrix of real values, where *N* is the number of elements in the conformal array. Each column of this matrix represents the position `[x;y;z]`of an array element in the array local coordinate system. The origin of the local coordinate system is *(0,0,0)*. Units are in meters.

Dependencies

To enable this parameter set **Geometry** to `Conformal Array`.

Data Types: `double`

`Element normals (deg)` — Direction of conformal array element normal vectors

`[0;0]` | 2-by-1 column vector | 2-by-*N* matrix

Direction of element normal vectors in a conformal array, specified as a 2-by-1 column vector or a 2-by-*N* matrix. *N* indicates the number of elements in the array. If the parameter value is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]` with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If the parameter value is a 2-by-1 column vector, the same pointing direction is used for all array elements.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal direction.

To enable this parameter, set **Geometry** to `Conformal Array`.

Data Types: `double`

`Taper` — Array element tapers

1 (default) | complex scalar | complex-valued row vector

Specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array.

Also known as *element weights*, tapers multiply the array element responses. Tapers modify both amplitude and phase of the response to reduce sidelobes or steer the main response axis.

If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. The number of weights must match the number of elements of the array.

Data Types: `double`

phased.TimeDelayBeamformer

Introduced in R2014b

Time Delay LCMV Beamformer

Time delay LCMV beamformer
Library: Phased Array System Toolbox / Beamforming

Description

The Time Delay LCMV Beamformer block performs time-delay linear constraint minimum variance (LCMV) beamforming.

Ports

Input

X — Input signal

M-by-*N* complex-valued matrix

Input signal, specified as an *M*-by-*N* matrix, where *M* is the number of samples in the data, and *N* is the number of array elements.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Data Types: `double`
Complex Number Support: Yes

XT — Training signal

M-by-*N* complex-valued matrix

Input signal, specified as an *M*-by-*N* matrix, where *M* is the number of samples in the data, and *N* is the number of array elements.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Dependencies

To enable this port, select the **Enable training data input** check box.

Data Types: `double`
Complex Number Support: Yes

`Ang` — Beamforming direction

2-by-1 real-valued vector | 2-by-*L* real-valued matrix

Beamforming direction, specified as a 2-by-*L* real-valued matrix, where *L* is the number of beamforming directions. Each column takes the form of `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°, inclusive, and the elevation angle must lie between –90° and 90°, inclusive. Angles are defined with respect to the local coordinate system of the array.

Dependencies

To enable this port, set the **Source of beamforming direction** parameter to `Input port`.

Data Types: `double`

Output

`Y` — Beamformed output

M-by-*L* complex-valued matrix

Beamformed output, returned as an *M*-by-*L* complex-valued matrix. The quantity *M* is the number of signal samples and *L* is the number of desired beamforming directions specified by the `Beamforming direction` parameter or from the `Ang` port.

Data Types: `double`
Complex Number Support: Yes

`W` — Beamforming weights

N-by-*L* complex-valued matrix

Beamformed weights, returned as an *N*-by-*L* complex-valued matrix. The quantity *N* is the number of array elements. When the **Specify sensor array as** parameter is

set to `Partitioned array` or `Replicated subarray`, *N* represents the number of subarrays. *L* is the number of desired beamforming directions specified in the `Ang` port or by the `Beamforming direction (deg)` property. There is one set of weights for each beamforming direction.

Dependencies

To enable this port, select the **Enable weights output** checkbox.

Data Types: `double`
Complex Number Support: Yes

Parameters

Main tab

`Signal propagation speed (m/s)` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value return by `physconst('LightSpeed')`.

`Inherit sample rate` — Inherit sample rate from upstream blocks

on (default) | off

Select this parameter to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate (Hz)** parameter.

Data Types: `Boolean`

`Sample rate (Hz)` — Sampling rate of signal

`1e6` (default) | positive real-valued scalar

Specify the signal sampling rate as a positive scalar. Units are in Hz.

Dependencies

To enable this parameter, clear the **Inherit sample rate** parameter.

Data Types: `double`

`FIR filter length` — FIR filter length

1 (default) | positive integer

The length of the FIR filter used to process each sensor element data, specified as a positive integer.

Data Types: `double`

`Constraint matrix` — Constraint matrix used for time-delay LCMV beamformer

`[1;1]` | complex-valued *M*-by-*K* matrix

The constraint matrix used for time-delay LCMV beamformer, specified as a complex-valued*M*-by-*K* matrix. Each column of the matrix is a constraint and *M* is the degrees of freedom of the beamformer. For a time delay LCMV beamformer, *M* is given by the product of the number of elements of the array and the value of the **FIR filter length** parameter.

Data Types: `double`
Complex Number Support: Yes

`Desired response vector` — Desired response of time-delay LCMV beamformer

1 (default) | *K* column vector

Desired response used for time-delay LCMV beamformer, specified as a length-*K* column vector. *K* is the number of constraints in the **Constraint matrix** parameter. Each element in the vector defines the desired response of the constraint specified in the corresponding column of the **Constraint matrix** parameter matrix.

`Diagonal loading factor` — Diagonal loading factor for stability

nonnegative scalar

Specify the diagonal loading factor as a nonnegative scalar. Diagonal loading is a technique used to achieve robust beamforming performance, especially when the sample support is small.

`Enable training data input` — Enable the use of training data

off (default) | on

Select this check box to specify additional training data via the input port `XT`. To use the input signal as the training data, clear the check box which removes the port.

`Source of beamforming direction` — Source of beamforming direction
`Property` (default) | `Input port`

Source of beamforming direction, specified as `Property` or `Input port`. When you set **Source of beamforming direction** to `Property`, you then set the direction using the **Beamforming direction (deg)** parameter. When you select `Input port`, the direction is determined by the input to the `Ang` port.

`Beamforming direction (deg)` — Beamforming directions
2-by-*L* real-valued matrix

Beamforming directions, specified as a *2*-by-*L* real-valued matrix, where *L* is the number of beamforming directions. Each column takes the form `[AzimuthAngle;ElevationAngle]`. Angle units are in degrees. The azimuth angle must lie between –180° and 180°. The elevation angle must lie between –90° and 90°. Angles are defined with respect to the local coordinate system of the array.

Dependencies

To enable this parameter, set the **Source of beamforming direction** parameter to `Property`.

`Enable weights output` — Option to output beamformer weights
off (default) | on

Select this checkbox to obtain the beamformer weights from the output port, `W`.

`Simulate using` — Block simulation method
`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see "Choosing a Simulation Mode" (Simulink) from the Simulink documentation.

Data Types: `char`

Sensor Arrays Tab

`Specify sensor array as` — Method to specify array

`Array (no subarrays)` (default) | `MATLAB expression`

Method to specify array, specified as `Array (no subarrays)` or `MATLAB expression`.

- `Array (no subarrays)` — use the block parameters to specify the array.
- `MATLAB expression` — create the array using a MATLAB expression.

`Expression` — MATLAB expression used to create an array

Phased Array System Toolbox array System object

MATLAB expression used to create an array, specified as a valid Phased Array System Toolbox array System object.

Example: `phased.URA('Size',[5,3])`

Dependencies

To enable this parameter, set **Specify sensor array as** to `MATLAB expression`.

Element Parameters

`Element type` — Array element types

`Isotropic Antenna` (default) | `Cosine Antenna` | `Custom Antenna` | `Omni Microphone` | `Custom Microphone`

Antenna or microphone type, specified as one of the following:

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

`Operating frequency range (Hz)` — Operating frequency range of the antenna or microphone element

`[0,1.0e20]` (default) | real-valued 1-by-2 row vector

Specify the operating frequency range of the antenna or microphone element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The element has no response outside this frequency range. Frequency units are in Hz.

Dependencies

To enable this parameter, set **Element type** to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

`Operating frequency vector (Hz)` — Operating frequency range of custom antenna or microphone elements

`[0,1.0e20]` (default) | real-valued row vector

Specify the frequencies at which to set antenna and microphone frequency responses as a 1-by-L row vector of increasing real values. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of this vector. Frequency units are in Hz.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`. Use **Frequency responses (dB)** to set the responses at these frequencies.

`Baffle the back of the element` — Set back response of an `Isotropic Antenna` element or an `Omni Microphone` element to zero
off (default) | on

Select this checkbox to baffle the back response of the element. When backbaffled, the responses at all azimuth angles beyond ±90° from broadside are set to zero. The broadside direction is 0° azimuth angle and 0° elevation angle.

Dependencies

To enable this checkbox, set **Element type** to `Isotropic Antenna` or `Omni Microphone`.

`Exponent of cosine pattern` — Exponents of azimuth and elevation cosine patterns
`[1.5 1.5]` (default) | nonnegative scalar | real-valued 1-by-2 matrix of nonnegative values

Specify the exponents of the cosine pattern as a nonnegative scalar or a real-valued 1-by-2 matrix of nonnegative values. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern, and the second element is the exponent for the elevation direction cosine pattern. When you set this parameter to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the same power.

Dependencies

To enable this parameter, set **Element type** to `Cosine Antenna`.

`Frequency responses (dB)` — Antenna and microphone frequency response
`[0,0]` (default) | real-valued row vector

Frequency response of a custom antenna or custom microphone for the frequencies defined by the **Operating frequency vector (Hz)** parameter. The dimensions of

Frequency responses (dB) must match the dimensions of the vector specified by the **Operating frequency vector (Hz)** parameter.

Dependencies

To enable this parameter , set **Element type** to `Custom Antenna` or `Custom Microphone`.

`Azimuth angles (deg)` — Azimuth angles of antenna radiation pattern

`[-180:180]` (default) | real-valued row vector

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-P row vector. P must be greater than 2. Azimuth angles must lie between –180° and 180°, inclusive, and be in strictly increasing order.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Elevation angles (deg)` — Elevation angles of antenna radiation pattern

`[-90:90]` (default) | real-valued row vector

Specify the elevation angles at which to compute the radiation pattern as a 1-by-Q vector. Q must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive, and be in strictly increasing order.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Magnitude pattern (dB)` — Magnitude of combined antenna radiation pattern

`zeros(181,361)` (default) | real-valued Q-by-P matrix | real-valued Q-by-P-by-L array

Magnitude of the combined antenna radiation pattern, specified as a Q-by-P matrix or a Q-by-P-by-L array. The quantity Q equals the length of the vector specified by **Elevation angles (deg)**. The quantity P equals length of the vector specified by **Azimuth angles (deg)**. The quantity L equal the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Phase pattern (deg)` — Custom antenna radiation phase pattern
`zeros(181,361)` (default) | real-valued *Q*-by-*P* matrix | real-valued *Q*-by-*P*-by-*L* array

Phase of the combined antenna radiation pattern, specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The quantity *Q* equals the length of the vector specified by **Elevation angles (deg)**. The quantity *P* equals length of the vector specified by **Azimuth angles (deg)**. The quantity *L* equal the length of the **Operating frequency vector (Hz)**.

- If this parameter is a *Q*-by-*P* matrix, the same pattern is applied to *all* frequencies specified in the **Operating frequency vector (Hz)** parameter.
- If the value is a *Q*-by-*P*-by-*L* array, each *Q*-by-*P* page of the array specifies a pattern for the *corresponding* frequency specified in the **Operating frequency vector (Hz)** parameter.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Polar pattern frequencies (Hz)` — Custom microphone response frequencies
1e3 (default) | real scalar | real-valued 1-by-*L* row vector

Response frequencies of the custom microphone of the polar pattern, specified as a real scalar or real-valued 1-by-*L* vector. The response frequencies lie within the frequency range specified by the **Operating frequency vector (Hz)** vector.

Dependencies

To enable this parameter, set **Element type** is set to `Custom Microphone`.

`Polar pattern angles (deg)` — Polar pattern response angles
`[-180:180]` (default) | real-valued -by-P row vector

Specify the polar pattern response angles, as a 1-by-P vector. The angles are measured from the central pickup axis of the microphone and must be between –180° and 180°, inclusive.

Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

`Polar pattern (dB)` — Custom microphone polar response
`zeros(1,361)` (default) | real-valued L-by-P matrix

Specify the magnitude of the custom microphone element polar patterns as an L-by-P matrix. L is the number of frequencies specified in **Polar pattern frequencies (Hz)**. P is the number of angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume also that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

Array Parameters

`Geometry` — Array geometry
`ULA` (default) | `URA` | `UCA` | `Conformal Array`

Array geometry, specified as one of

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array

- `Conformal Array` — arbitrary element positions

`Number of elements` — Number of array elements
2 for ULA arrays and 5 for UCA arrays (default) | integer greater than or equal to 2

The number of array elements for ULA or UCA arrays, specified as an integer greater than or equal to 2.

Dependencies

To enable this parameter, set **Geometry** to ULA or UCA.

`Element spacing (m)` — Spacing between array elements
`0.5` for ULA arrays and `[0.5,0.5]` for URA arrays (default) | positive scalar for ULA or URA arrays | 2-element vector of positive values for URA arrays

Spacing between adjacent array elements:

- ULA — specify the spacing between two adjacent elements in the array as a positive scalar.
- URA — specify the spacing as a positive scalar or a 1-by-2 vector of positive values. If **Element spacing (m)** is a scalar, the row and column spacings are equal. If **Element spacing (m)** is a vector, the vector has the form `[SpacingBetweenArrayRows,SpacingBetweenArrayColumns]`.

Dependencies

To enable this parameter, set **Geometry** to ULA or URA.

`Array axis` — Linear axis direction of ULA
`y` (default) | `x` | `z`

Linear axis direction of ULA, specified as `y`, `x`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

Dependencies

To enable this parameter, set **Geometry** to ULA. This parameter is also enabled when the block supports only ULA arrays.

`Array size` — Dimensions of URA array

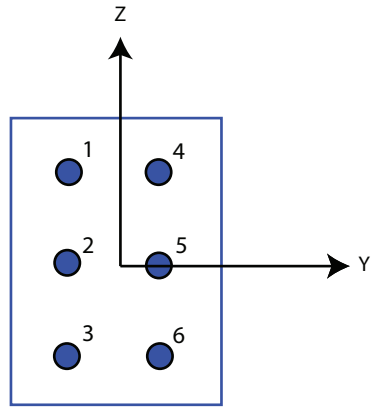
`[2,2]` (default) | positive integer | 1-by-2 vector of positive integers

Dimensions of a URA array, specified as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of elements in each row and column.

For a URA, array elements are indexed from top to bottom along a column, and continuing to the next columns from left to right. In this figure, the **Array size** value of `[3,2]` creates an array having three rows and two columns.

Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]



Dependencies

To enable this parameter, set **Geometry** to URA.

`Element lattice` — Lattice of URA element positions

`Rectangular` (default) | `Triangular`

Lattice of URA element positions, specified as `Rectangular` or `Triangular`.

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular` — Shifts the even-row elements of a rectangular lattice toward the positive row-axis direction. The displacement is one-half the element spacing along the row dimension.

Dependencies

To enable this parameter, set **Geometry** to URA.

`Array normal` — Array normal direction

`x` for URA arrays or `z` for UCA arrays (default) | `y`

Array normal direction, specified as `x`, `y`, or `z`.

Elements of planar arrays lie in a plane orthogonal to the selected array normal direction. Element boresight directions point along the array normal direction.

Array Normal Parameter Value	Element Positions and Boresight Directions
`x`	Array elements lie in the *yz*-plane. All element boresight vectors point along the *x*-axis.
`y`	Array elements lie in the *zx*-plane. All element boresight vectors point along the *y*-axis.
`z`	Array elements lie in the *xy*-plane. All element boresight vectors point along the *z*-axis.

Dependencies

To enable this parameter, set **Geometry**to URA or UCA.

`Radius of UCA (m)` — UCA array radius

0.5 (default) | positive scalar

Radius of UCA array, specified as a positive scalar.

Dependencies

To enable this parameter, set **Geometry** to UCA.

`Element positions (m)` — Positions of conformal array elements

`[0;0;0]` (default) | 3-by-*N* matrix of real values

Positions of the elements in a conformal array, specified as a 3-by-*N* matrix of real values, where *N* is the number of elements in the conformal array. Each column of this matrix represents the position `[x;y;z]` of an array element in the array local coordinate system. The origin of the local coordinate system is *(0,0,0)*. Units are in meters.

Dependencies

To enable this parameter set **Geometry** to `Conformal Array`.

Data Types: `double`

`Element normals (deg)` — Direction of conformal array element normal vectors

`[0;0]` | 2-by-1 column vector | 2-by-*N* matrix

Direction of element normal vectors in a conformal array, specified as a 2-by-1 column vector or a 2-by-*N* matrix. *N* indicates the number of elements in the array. If the parameter value is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]` with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If the parameter value is a 2-by-1 column vector, the same pointing direction is used for all array elements.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal direction.

To enable this parameter, set **Geometry** to `Conformal Array`.

Data Types: `double`

`Taper` — Array element tapers

1 (default) | complex scalar | complex-valued row vector

Specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array.

Also known as *element weights*, tapers multiply the array element responses. Tapers modify both amplitude and phase of the response to reduce sidelobes or steer the main response axis.

If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. The number of weights must match the number of elements of the array.

Data Types: `double`

phased.TimeDelayLCMVBeamformer

Introduced in R2014b

Time Varying Gain

Time varying gain (TVG) control

Library

Detection

`phaseddetectlib`

Description

The Time Varying Gain block applies a time varying gain to input signals to compensate for range loss at each range gate. Time varying gain (TVG) is sometimes called automatic gain control (AGC).

Parameters

Source of range losses

Specify the range loss source as either `Property` or `Input Port`

`Property`	Range losses are specified by the **Range loss (dB)** parameter.
`Input port`	Range losses are specified using the input port `L`.

Range loss (dB)

Specify the loss due to range as a vector — elements correspond to the samples in the input signal. Units are in dB

Reference range loss (dB)

Specify the loss, in dB, at a given reference range as a scalar.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see “Choosing a Simulation Mode” (Simulink) from the Simulink documentation.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Description	Supported Data Types
`In`	Input signal. The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.	Double-precision floating point
`L`	Range loss. The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.	
`Out`	Compensated signal.	Double-precision floating point

Transmitter

Amplify and transmit a signal

Library

Transmitters and Receivers

`phasedtxrxlib`

Description

The Transmitter block amplifies and transmits waveform pulses. The transmitter can either maintain coherence between pulses or insert phase noise.

Parameters

Peak power (W)

Specify the transmit peak power in watts as a positive scalar.

Gain (dB)

Specify the transmit gain in dB as a real scalar.

Loss factor (dB)

Specify the transmit loss factor in dB as a nonnegative scalar.

Enable transmitter status output

Select this check box to send the transmitter-in-use status for each output sample from the output port `TR`. From the output port, a 1 indicates that the transmitter is on, and a 0 indicates that the transmitter is off.

Preserve coherence among pulses

Select this check box to preserve coherence among transmitted pulses. When you select this box, the transmitter does not introduce any random phases to the output pulses. When you clear this box, the transmitter adds a random phase noise to each

transmitted pulse. The random phase noise is introduced by multiplying the pulse value by $e^{j\phi}$ where ϕ is a uniform random variable on the interval $[0,2\pi]$.

Enable pulse phase noise output

This check box appears only when **Preserve coherence among pulses** is cleared.

Select this check box to create an output port, `Ph`, with the output sample's random phase noise introduced if **Preserve coherence among pulses** is cleared. The output port can be directed to a receiver to simulate coherent-on-receive systems.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see “Choosing a Simulation Mode” (Simulink) from the Simulink documentation.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Description	Supported Data Types
`X`	Input signal. The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.	Double-precision floating point
`Ph`	Added phase noise.	Double-precision floating point
`TR`	Transmitter status.	Double-precision floating point
`Y`	Transmitted signal.	Double-precision floating point

Two-Ray Channel

Two-ray channel environment

Library

Environment and Targets

`phasedenvlib`

Description

The Two-Ray Channel block propagates narrowband signals from one point in space to multiple points or from multiple points back to one point via both the direct path and the ground reflection path. The block models propagation time, free-space propagation loss, and Doppler shift. The block assumes that the propagation speed is much greater than the object's speed in which case the stop-and-hop model is valid.

Parameters

Signal Propagation speed (m/s)

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

Signal carrier frequency (Hz)

Specify the carrier frequency of the signal in hertz of the narrowband signal as a positive scalar.

Specify atmospheric parameters

Select this check box to enable atmospheric attenuation modeling.

Temperature (degrees Celsius)

Ambient atmospheric temperature, specified as a real-valued scalar. Units are degrees Celsius. This parameter appears when you select the **Specify atmospheric parameters** check box. Units are degrees Celsius.

Dry air pressure (Pa)

Atmospheric dry air pressure, specified as a positive real-valued scalar. Units are Pascals (Pa). The value 101325 for this property corresponds to one standard atmosphere. This parameter appears when you select the **Specify atmospheric parameters** check box.

Water vapour density (g/m^3)

Atmospheric water vapor density, specified as a positive real-valued scalar. Units are gm/m^3. This parameter appears when you select the **Specify atmospheric parameters** check box.

Liquid water density (g/m^3)

Liquid water density of fog or clouds, specified as a non-negative real-valued scalar. Units are gm/m^3. Typical values for liquid water density are 0.05 for medium fog and 0.5 for thick fog. This parameter appears when you select the **Specify atmospheric parameters** check box.

Rain rate (mm/hr)

Rainfall rate, specified as a non-negative real-valued scalar. Units are in mm/hour. This parameter appears when you select the **Specify atmospheric parameters** check box.

Inherit sample rate

Select this check box to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate** parameter.

Sample rate

Specify the signal sampling rate (in hertz) as a positive scalar. This parameter appears only when the **Inherit sample rate** parameter is not selected.

Ground reflection coefficient

Fraction of incident signal amplitude reflected towards receiver.

Combine two rays at output

Select this checkbox to coherently sum the direct-path and reflected-path signals at output. Clear the checkbox to keep the two rays separate.

Maximum one-way propagation distance (m)

The maximum distance between the signal origin and the destination, specified as a positive scalar. Units are in meters. Amplitudes of any signals that propagate beyond this distance will be set to zero.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see “Choosing a Simulation Mode” (Simulink) from the Simulink documentation.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Description	Supported Data Types
`X`	Input signal.	Double-precision floating point
`Pos1`	Signal source position.	Double-precision floating point
`Pos2`	Signal destination position.	Double-precision floating point
`Vel1`	Signal source velocity.	Double-precision floating point
`Vel2`	Signal destination velocity.	Double-precision floating point
`Out`	Propagated signal.	Double-precision floating point

Algorithms

When the origin and destination are stationary relative to each other, the block output can be written as $y(t) = x(t - \tau)/L$. The quantity τ is the delay and L is the propagation loss. The delay is computed from $\tau = R/c$ where R is the propagation distance and c is the propagation speed. The free space path loss is given by

$$L_{fsp} = \frac{(4\pi R)^2}{\lambda^2},$$

where λ is the signal wavelength.

This formula assumes that the target is in the far-field of the transmitting element or array. In the near-field, the free-space path loss formula is not valid and can result in

losses smaller than one, equivalent to a signal gain. For this reason, the loss is set to unity for range values, $R \le \lambda/4\pi$.

When there is relative motion between the origin and destination, the processing also introduces a frequency shift. This shift corresponds to the Doppler shift between the origin and destination. The frequency shift is v/λ for one-way propagation and $2v/\lambda$ for two-way propagation. The parameter v is the relative speed of the destination with respect to the origin.

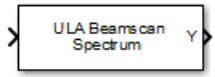
Introduced in R2015b

ULA Beamscan Spectrum

Beamscan spatial spectrum estimator for ULA



Library

Direction of Arrival (DOA)

`phaseddoalib`

Description

The ULA Beamscan Spectrum block estimates the spatial spectrum of incoming narrowband signals by scanning a region of broadside angles using a narrowband conventional beamformer applied to a uniform linear array. The block optionally calculates the direction of arrival of a specified number of signals by estimating peaks of the spectrum.

Parameters

Signal Propagation speed (m/s)

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

Operating frequency (Hz)

Specify the operating frequency of the system, in hertz, as a positive scalar.

Number of bits in phase shifters

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

Forward-backward averaging

Select this parameter to use forward-backward averaging to estimate the covariance matrix for sensor arrays with a conjugate symmetric array manifold.

Spatial smoothing

Specify the amount of averaging, L, used by spatial smoothing to estimate the covariance matrix as a nonnegative integer. Each increase in smoothing handles one extra coherent source, but reduces the effective number of elements by one. The maximum value of this parameter is $N - 2$, where N is the number of sensors.

Scan angles (deg)

Specify the scan angles in degrees as a real vector. The angles are broadside angles and must be between –90° and 90°, inclusive. You must specify the angles in increasing order.

Enable DOA output

Select this parameter to output the signals directions of arrival (DOA) through the **Ang** output port. Selecting this parameter enables the **Number of signals** parameter.

Number of signals

Specify the number of signals for DOA estimation as a positive scalar integer. This parameter appears when you select the **Enable DOA output** check box.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see "Choosing a Simulation Mode" (Simulink) from the Simulink documentation.

Array Parameters

Specify sensor array as

Specify a ULA sensor array directly or by using a MATLAB expression.

Types

`Array (no subarrays)`
`MATLAB expression`

Number of elements

Specifies the number of elements in the array as an integer.

Element spacing

Specify the spacing, in meters, between two adjacent elements in the array.

Array axis

This parameter appears when the **Geometry** parameter is set to `ULA` or when the block only supports a ULA array geometry. Specify the array axis as `x`, `y`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

Taper

Tapers, also known as *element weights*, are applied to sensor elements in the array. Tapers are used to modify both the amplitude and phase of the transmitted or received data.

Specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array. If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

Expression

A valid MATLAB expression containing a constructor for a uniform linear array, for example, `phased.ULA`.

Sensor Array Tab: Element Parameters

Element type

Specify antenna or microphone type as

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

Exponent of cosine pattern

This parameter appears when you set **Element type** to `Cosine Antenna`.

Specify the exponent of the cosine pattern as a scalar or a 1-by-2 vector. You must specify all values as non-negative real numbers. When you set **Exponent of cosine pattern** to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the specified value. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern and the second element is the exponent for the elevation direction cosine pattern.

Operating frequency range (Hz)

This parameter appears when **Element type** is set to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

Specify the operating frequency range, in hertz, of the antenna element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The antenna element has no response outside the specified frequency range.

Operating frequency vector (Hz)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify the frequencies, in Hz, at which to set the antenna and microphone frequency responses as a 1-by-L row vector of increasing values. Use **Frequency responses** to set the frequency responses. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of **Operating frequency vector (Hz)**.

Frequency responses (dB)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify this parameter as the frequency response of an antenna or microphone, in decibels, for the frequencies defined by **Operating frequency vector (Hz)**. Specify **Frequency responses (dB)** as a 1-by-L vector matching the dimensions of the vector specified in **Operating frequency vector (Hz)**.

Azimuth angles (deg)

This parameter appears when **Element type** is set to `Custom Antenna`.

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-P row vector. P must be greater than 2. Angle units are in degrees. Azimuth angles must lie between –180° and 180° and be in strictly increasing order.

Elevation angles (deg)

This parameter appears when the **Element type** is set to `Custom Antenna`.

Specify the elevation angles at which to compute the radiation pattern as a 1-by-Q vector. Q must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90° and be in strictly increasing order.

Radiation pattern (dB)

This parameter appears when the **Element type** is set to `Custom Antenna`.

The magnitude in db of the combined polarized antenna radiation pattern specified as a Q-by-P matrix or a Q-by-P-by-L array. The value of Q must match the value of Q specified by **Elevation angles (deg)**. The value of P must match the value of P specified by **Azimuth angles (deg_**. The value of L must match the value of L specified by **Operating frequency vector (Hz)**.

Polar pattern frequencies (Hz)

This parameter appears when the **Element type** is set to `Custom Microphone`.

Specify the measuring frequencies of the polar patterns as a 1-by-*M* vector. The measuring frequencies lie within the frequency range specified by**Operating frequency vector (Hz)**. Frequency units are in Hz.

Polar pattern angles (deg)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the measuring angles of the polar patterns, as a 1-by-*N* vector. The angles are measured from the central pickup axis of the microphone, and must be between –180° and 180°, inclusive.

Polar pattern (dB)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the magnitude of the microphone element polar pattern as an *M*-by-*N* matrix. *M* is the number of measuring frequencies specified in **Polar pattern frequencies (Hz)**. *N* is the number of measuring angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

Baffle the back of the element

This check box appears only when the **Element type** parameter is set to `Isotropic Antenna` or `Omni Microphone`.

Select this check box to baffle the back of the antenna element. In this case, the antenna responses to all azimuth angles beyond ±90° from *broadside* are set to zero. Define the broadside direction as 0° azimuth angle and 0° elevation angle.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Description	Supported Data Types
`In`	Input signal. The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.	Double-precision floating point
`Ang`	Signal direction of arrival.	Double-precision floating point
`Y`	Estimated spectrum.	Double-precision floating point

phased.BeamscanEstimator

Introduced in R2014b

ULA MVDR Spectrum

MVDR spatial spectrum estimator for ULA

Library

Direction of Arrival (DOA)

`phaseddoalib`

Description

The ULA MVDR Spectrum block estimates the spatial spectrum of incoming narrowband signals by scanning a region of broadside angles using a narrowband minimum variance distortionless response (MVDR) beamformer for a uniform linear array. The block optionally calculates the direction of arrival (DOA) of a specified number of signals by estimating peaks of the spectrum. The MVDR DOA estimator is also called the Capon DOA estimator.

Parameters

Signal Propagation speed (m/s)

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

Operating frequency (Hz)

Specify the operating frequency of the system, in hertz, as a positive scalar.

Number of bits in phase shifters

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

Forward-backward averaging

Select this parameter to use forward-backward averaging to estimate the covariance matrix for sensor arrays with a conjugate symmetric array manifold.

Spatial smoothing

Specify the amount of averaging, L, used by spatial smoothing to estimate the covariance matrix as a nonnegative integer. Each increase in smoothing handles one extra coherent source, but reduces the effective number of elements by one. The maximum value of this parameter is $N - 2$, where N is the number of sensors.

Scan angles (deg)

Specify the scan angles in degrees as a real vector. The angles are broadside angles and must be between –90° and 90°, inclusive. You must specify the angles in increasing order.

Enable DOA output

Select this parameter to output the signals directions of arrival (DOA) through the **Ang** output port. Selecting this parameter enables the **Number of signals** parameter.

Number of signals

Specify the number of signals for DOA estimation as a positive scalar integer. This parameter appears when you select the **Enable DOA output** check box.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see "Choosing a Simulation Mode" (Simulink) from the Simulink documentation.

Array Parameters

Specify sensor array as

Specify a ULA sensor array directly or by using a MATLAB expression.

Types

`Array (no subarrays)`
`MATLAB expression`

Number of elements

Specifies the number of elements in the array as an integer.

Element spacing

Specify the spacing, in meters, between two adjacent elements in the array.

Array axis

This parameter appears when the **Geometry** parameter is set to `ULA` or when the block only supports a ULA array geometry. Specify the array axis as `x`, `y`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

Taper

Tapers, also known as *element weights*, are applied to sensor elements in the array. Tapers are used to modify both the amplitude and phase of the transmitted or received data.

Specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array. If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

Expression

A valid MATLAB expression containing a constructor for a uniform linear array, for example, `phased.ULA`.

Sensor Array Tab: Element Parameters

Element type

Specify antenna or microphone type as

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

Exponent of cosine pattern

This parameter appears when you set **Element type** to `Cosine Antenna`.

Specify the exponent of the cosine pattern as a scalar or a 1-by-2 vector. You must specify all values as non-negative real numbers. When you set **Exponent of cosine pattern** to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the specified value. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern and the second element is the exponent for the elevation direction cosine pattern.

Operating frequency range (Hz)

This parameter appears when **Element type** is set to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

Specify the operating frequency range, in hertz, of the antenna element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The antenna element has no response outside the specified frequency range.

Operating frequency vector (Hz)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify the frequencies, in Hz, at which to set the antenna and microphone frequency responses as a 1-by-L row vector of increasing values. Use **Frequency responses** to set the frequency responses. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of **Operating frequency vector (Hz)**.

Frequency responses (dB)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify this parameter as the frequency response of an antenna or microphone, in decibels, for the frequencies defined by **Operating frequency vector (Hz)**. Specify **Frequency responses (dB)** as a 1-by-L vector matching the dimensions of the vector specified in **Operating frequency vector (Hz)**.

Azimuth angles (deg)

This parameter appears when **Element type** is set to `Custom Antenna`.

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-P row vector. P must be greater than 2. Angle units are in degrees. Azimuth angles must lie between –180° and 180° and be in strictly increasing order.

Elevation angles (deg)

This parameter appears when the **Element type** is set to `Custom Antenna`.

Specify the elevation angles at which to compute the radiation pattern as a 1-by-Q vector. Q must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90° and be in strictly increasing order.

Radiation pattern (dB)

This parameter appears when the **Element type** is set to `Custom Antenna`.

The magnitude in db of the combined polarized antenna radiation pattern specified as a Q-by-P matrix or a Q-by-P-by-L array. The value of Q must match the value of Q specified by **Elevation angles (deg)**. The value of P must match the value of P specified by **Azimuth angles (deg_**. The value of L must match the value of L specified by **Operating frequency vector (Hz)**.

Polar pattern frequencies (Hz)

This parameter appears when the **Element type** is set to `Custom Microphone`.

Specify the measuring frequencies of the polar patterns as a 1-by-*M* vector. The measuring frequencies lie within the frequency range specified by**Operating frequency vector (Hz)**. Frequency units are in Hz.

Polar pattern angles (deg)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the measuring angles of the polar patterns, as a 1-by-*N* vector. The angles are measured from the central pickup axis of the microphone, and must be between –180° and 180°, inclusive.

Polar pattern (dB)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the magnitude of the microphone element polar pattern as an *M*-by-*N* matrix. *M* is the number of measuring frequencies specified in **Polar pattern frequencies (Hz)**. *N* is the number of measuring angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

Baffle the back of the element

This check box appears only when the **Element type** parameter is set to `Isotropic Antenna` or `Omni Microphone`.

Select this check box to baffle the back of the antenna element. In this case, the antenna responses to all azimuth angles beyond ±90° from *broadside* are set to zero. Define the broadside direction as 0° azimuth angle and 0° elevation angle.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Description	Supported Data Types
`In`	Input signal. The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.	Double-precision floating point
`Ang`	Estimated broadside DOA angles.	Double-precision floating point
`Y`	Estimated spatial spectrum.	Double-precision floating point

ULA MUSIC Spectrum

MUSIC spatial spectrum estimator for ULA
Library: Phased Array System Toolbox / Direction of Arrival

Description

The ULA MUSIC Spectrum block estimates the spatial spectrum of incoming narrowband signals using the MUSIC algorithm. The algorithm computes the MUSIC pseudo-spectrum of a ULA by scanning a region of broadside angles. The block optionally calculates the direction of arrival (DOA) of a specified number of signals by estimating peaks of the spectrum.

Ports

Input

`Port 1` — Received signal

M-by-*N* complex-valued matrix

Received signal, specified as an *M*-by-*N* complex-valued matrix. The quantity *M* is the number of sample values (snapshots) contained in the signal and *N* is the number of sensor elements in the array.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Data Types: `double`
Complex Number Support: Yes

Output

`Y` — MUSIC spatial spectrum

non-negative, real-valued column vector

MUSIC spatial spectrum, returned as a non-negative, real-valued column vector representing the magnitude of the estimated MUSIC spatial spectrum. Each entry corresponds to an angle specified by the **Scan angles (deg)** parameter.

Data Types: `double`

Ang — Directions of arrival

non-negative, real-valued column vector

Directions of arrival of the signals, returned as a real-valued row vector. The direction of arrival angle is the broadside angle between the source direction and the array axis. Angle units are in degrees. The length of the vector is the number of signals specified by the `Number of signals` parameter.

Dependencies

Select the **Enable DOA output** parameter to enable this output port.

Data Types: `double`

Parameters

Main Tab

`Signal propagation speed (m/s)` — Signal propagation speed

`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value return by `physconst('LightSpeed')`.

`Operating frequency (Hz)` — System operating frequency

`300.0e6` (default) | positive real scalar

Specify the operating frequency of the system as a positive scalar. Units are in Hz.

`Forward-backward averaging` — Enable forward-backward averaging

off (default) | on

Select this parameter to use forward-backward averaging to estimate the covariance matrix for sensor arrays with a conjugate symmetric array manifold structure.

`Spatial smoothing` — Enable spatial smoothing
`0` (default) | non-negative integer

Specify the amount of averaging used by spatial smoothing to estimate the covariance matrix as a nonnegative integer. Each increase in smoothing handles one extra coherent source, but reduces the effective number of elements by one. The maximum value of this parameter is $N - 2$, where N is the number of sensors in the ULA.

`Scan angles (deg)` — Search angles for spectrum peaks
`-90:90` (default) | real-valued row vector

Specify the scan angles in degrees as a real-valued row vector. The angles are array broadside angles and must lie between –90° and 90°, inclusive. You must specify the angles in increasing order.

`Enable DOA output` — Output directions of arrival through output port
off (default) | on

Select this parameter to output the signals directions of arrival (DOA) through the **Ang** output port.

`Number of signals` — Expected number of arriving signals
`1` (default) | positive integer

Specify the expected number of signals for DOA estimation as a positive scalar integer.

`Simulate using` — Block simulation method
`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see "Choosing a Simulation Mode" (Simulink) from the Simulink documentation.

Data Types: `char`

Sensor Array Tab

`Specify sensor array as` — Method to specify array

`Array (no subarrays)` (default) | `MATLAB expression`

Method to specify array, specified as `Array (no subarrays)` or `MATLAB expression`.

- `Array (no subarrays)` — use the block parameters to specify the array.
- `MATLAB expression` — create the array using a MATLAB expression.

`Expression` — MATLAB expression used to create an array

Phased Array System Toolbox array System object

MATLAB expression used to create an array, specified as a valid Phased Array System Toolbox array System object.

Example: `phased.URA('Size',[5,3])`

Dependencies

To enable this parameter, set **Specify sensor array as** to `MATLAB expression`.

Element Parameters

`Element type` — Array element types

`Isotropic Antenna` (default) | `Cosine Antenna` | `Custom Antenna` | `Omni Microphone` | `Custom Microphone`

Antenna or microphone type, specified as one of the following:

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

`Operating frequency range (Hz)` — Operating frequency range of the antenna or microphone element

`[0,1.0e20]` (default) | real-valued 1-by-2 row vector

Specify the operating frequency range of the antenna or microphone element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The element has no response outside this frequency range. Frequency units are in Hz.

Dependencies

To enable this parameter, set **Element type** to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

`Operating frequency vector (Hz)` — Operating frequency range of custom antenna or microphone elements

`[0,1.0e20]` (default) | real-valued row vector

Specify the frequencies at which to set antenna and microphone frequency responses as a 1-by-L row vector of increasing real values. The antenna or microphone element has no

response outside the frequency range specified by the minimum and maximum elements of this vector. Frequency units are in Hz.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna` or `Custom Microphone`. Use **Frequency responses (dB)** to set the responses at these frequencies.

`Baffle the back of the element` — Set back response of an `Isotropic Antenna` element or an `Omni Microphone` element to zero
off (default) | on

Select this checkbox to baffle the back response of the element. When backbaffled, the responses at all azimuth angles beyond ±90° from broadside are set to zero. The broadside direction is 0° azimuth angle and 0° elevation angle.

Dependencies

To enable this checkbox, set **Element type** to `Isotropic Antenna` or `Omni Microphone`.

`Exponent of cosine pattern` — Exponents of azimuth and elevation cosine patterns
`[1.5 1.5]` (default) | nonnegative scalar | real-valued 1-by-2 matrix of nonnegative values

Specify the exponents of the cosine pattern as a nonnegative scalar or a real-valued 1-by-2 matrix of nonnegative values. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern, and the second element is the exponent for the elevation direction cosine pattern. When you set this parameter to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the same power.

Dependencies

To enable this parameter, set **Element type** to `Cosine Antenna`.

`Frequency responses (dB)` — Antenna and microphone frequency response
`[0,0]` (default) | real-valued row vector

Frequency response of a custom antenna or custom microphone for the frequencies defined by the **Operating frequency vector (Hz)** parameter. The dimensions of **Frequency responses (dB)** must match the dimensions of the vector specified by the **Operating frequency vector (Hz)** parameter.

Dependencies

To enable this parameter , set **Element type** to `Custom Antenna` or `Custom Microphone`.

`Azimuth angles (deg)` — Azimuth angles of antenna radiation pattern
`[-180:180]` (default) | real-valued row vector

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-P row vector. P must be greater than 2. Azimuth angles must lie between –180° and 180°, inclusive, and be in strictly increasing order.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Elevation angles (deg)` — Elevation angles of antenna radiation pattern
`[-90:90]` (default) | real-valued row vector

Specify the elevation angles at which to compute the radiation pattern as a 1-by-Q vector. Q must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90°, inclusive, and be in strictly increasing order.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Radiation pattern (dB)` — Custom antenna radiation pattern
`zeros(181,361)` | complex-valued matrix | complex-valued MATLAB array

Magnitude of the combined polarized antenna radiation pattern, specified as a Q-by-P matrix or a Q-by-P-by-L array. The value of Q must equal the value of Q specified by

Elevation angles (deg). The value of *P* must equal the value of *P* specified by **Azimuth angles (deg)**. The value of *L* must equal the value of *L* specified by **Operating frequency vector (Hz)**.

Dependencies

To enable this parameter, set **Element type** to `Custom Antenna`.

`Polar pattern frequencies (Hz)` — Custom microphone response frequencies

1e3 (default) | real scalar | real-valued 1-by-*L* row vector

Response frequencies of the custom microphone of the polar pattern, specified as a real scalar or real-valued 1-by-*L* vector. The response frequencies lie within the frequency range specified by the **Operating frequency vector (Hz)** vector.

Dependencies

To enable this parameter, set **Element type** is set to `Custom Microphone`.

`Polar pattern angles (deg)` — Polar pattern response angles

`[-180:180]` (default) | real-valued -by-*P* row vector

Specify the polar pattern response angles, as a 1-by-*P* vector. The angles are measured from the central pickup axis of the microphone and must be between –180° and 180°, inclusive.

Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

`Polar pattern (dB)` — Custom microphone polar response

`zeros(1,361)` (default) | real-valued *L*-by-*P* matrix

Specify the magnitude of the custom microphone element polar patterns as an *L*-by-*P* matrix. *L* is the number of frequencies specified in **Polar pattern frequencies (Hz)**. *P* is the number of angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding

frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume also that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

Dependencies

To enable this parameter, set **Element type** to `Custom Microphone`.

Array Parameters

`Number of elements` — Number of array elements

`2` (default) | positive integer

The number of array elements for ULA arrays, specified as an integer greater than or equal to two.

`Element spacing` — Distance between ULA elements

`0.5` (default) | positive scalar

Distance between adjacent ULA elements, specified as a positive scalar. Units are in meters.

`Array axis` — Linear axis direction of ULA

`y` (default) | `x` | `z`

Linear axis direction of ULA, specified as `y`, `x`, or `z`. Then, all ULA array elements are uniformly spaced along this axis in the local array coordinate system.

`Taper` — Array element tapers

1 (default) | complex scalar | complex-valued row vector

Specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array.

Also known as *element weights*, tapers multiply the array element responses. Tapers modify both amplitude and phase of the response to reduce sidelobes or steer the main response axis.

If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. The number of weights must match the number of elements of the array.

Data Types: `double`

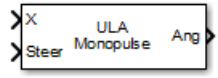
ULA Sum and Difference Monopulse

Sum-and-difference monopulse tracker for ULA



Library

Direction of Arrival (DOA)

`phaseddoalib`

Description

The ULA Sum-and-Difference Monopulse block estimates the direction of arrival of a narrowband signal on a uniform linear array based on an initial guess using a sum-and-difference monopulse algorithm. The block obtains the difference steering vector by phase-reversing the latter half of the sum steering vector.

Parameters

Signal Propagation speed (m/s)

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

Operating frequency (Hz)

Specify the operating frequency of the system, in hertz, as a positive scalar.

Number of bits in phase shifters

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see “Choosing a Simulation Mode” (Simulink) from the Simulink documentation.

Array Parameters

Specify sensor array as

Specify a ULA sensor array directly or by using a MATLAB expression.

Types

`Array (no subarrays)`
`MATLAB expression`

Number of elements

Specifies the number of elements in the array as an integer.

Element spacing

Specify the spacing, in meters, between two adjacent elements in the array.

Array axis

This parameter appears when the **Geometry** parameter is set to `ULA` or when the block only supports a ULA array geometry. Specify the array axis as `x`, `y`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

Taper

Tapers, also known as *element weights*, are applied to sensor elements in the array. Tapers are used to modify both the amplitude and phase of the transmitted or received data.

Specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array. If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

Expression

A valid MATLAB expression containing a constructor for a uniform linear array, for example, `phased.ULA`.

Sensor Array Tab: Element Parameters

Element type

Specify antenna or microphone type as

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`

- `Omni Microphone`
- `Custom Microphone`

Exponent of cosine pattern

This parameter appears when you set **Element type** to `Cosine Antenna`.

Specify the exponent of the cosine pattern as a scalar or a 1-by-2 vector. You must specify all values as non-negative real numbers. When you set **Exponent of cosine pattern** to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the specified value. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern and the second element is the exponent for the elevation direction cosine pattern.

Operating frequency range (Hz)

This parameter appears when **Element type** is set to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

Specify the operating frequency range, in hertz, of the antenna element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The antenna element has no response outside the specified frequency range.

Operating frequency vector (Hz)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify the frequencies, in Hz, at which to set the antenna and microphone frequency responses as a 1-by-*L* row vector of increasing values. Use **Frequency responses** to set the frequency responses. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of **Operating frequency vector (Hz)**.

Frequency responses (dB)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify this parameter as the frequency response of an antenna or microphone, in decibels, for the frequencies defined by **Operating frequency vector (Hz)**. Specify **Frequency responses (dB)** as a 1-by-*L* vector matching the dimensions of the vector specified in **Operating frequency vector (Hz)**.

Azimuth angles (deg)

This parameter appears when **Element type** is set to `Custom Antenna`.

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Angle units are in degrees. Azimuth angles must lie between –180° and 180° and be in strictly increasing order.

Elevation angles (deg)

This parameter appears when the **Element type** is set to `Custom Antenna`.

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90° and be in strictly increasing order.

Radiation pattern (dB)

This parameter appears when the **Element type** is set to `Custom Antenna`.

The magnitude in db of the combined polarized antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The value of *Q* must match the value of *Q* specified by **Elevation angles (deg)**. The value of *P* must match the value of *P* specified by **Azimuth angles (deg_**. The value of *L* must match the value of *L* specified by **Operating frequency vector (Hz)**.

Polar pattern frequencies (Hz)

This parameter appears when the **Element type** is set to `Custom Microphone`.

Specify the measuring frequencies of the polar patterns as a 1-by-*M* vector. The measuring frequencies lie within the frequency range specified by**Operating frequency vector (Hz)**. Frequency units are in Hz.

Polar pattern angles (deg)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the measuring angles of the polar patterns, as a 1-by-*N* vector. The angles are measured from the central pickup axis of the microphone, and must be between –180° and 180°, inclusive.

Polar pattern (dB)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the magnitude of the microphone element polar pattern as an *M*-by-*N* matrix. *M* is the number of measuring frequencies specified in **Polar pattern frequencies (Hz)**. *N* is the number of measuring angles specified in **Polar pattern angles (deg)**.

Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

Baffle the back of the element

This check box appears only when the **Element type** parameter is set to `Isotropic Antenna` or `Omni Microphone`.

Select this check box to baffle the back of the antenna element. In this case, the antenna responses to all azimuth angles beyond ±90° from *broadside* are set to zero. Define the broadside direction as 0° azimuth angle and 0° elevation angle.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Description	Supported Data Types
`X`	Input signal. The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.	Double-precision floating point
`Steer`	Initial estimate of broadside DOA angles.	Double-precision floating point
`Ang`	Estimated broadside DOA angles.	Double-precision floating point

URA Sum and Difference Monopulse

Sum-and-difference monopulse for URA

Library

Direction of Arrival (DOA)

`phaseddoalib`

Description

The URA Sum-and-Difference Monopulse block estimates the direction of arrival of a narrowband signal on a uniform rectangular array (URA) based on an initial guess using a sum-and-difference monopulse algorithm. The block obtains the difference steering vector by phase-reversing the latter half of the sum steering vector.

Parameters

Signal Propagation speed (m/s)

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

Operating frequency (Hz)

Specify the operating frequency of the system, in hertz, as a positive scalar.

Number of bits in phase shifters

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see “Choosing a Simulation Mode” (Simulink) from the Simulink documentation.

Array Parameters

Specify sensor array as

Specify a ULA sensor array directly or by using a MATLAB expression.

Types

Array (no subarrays)
MATLAB expression

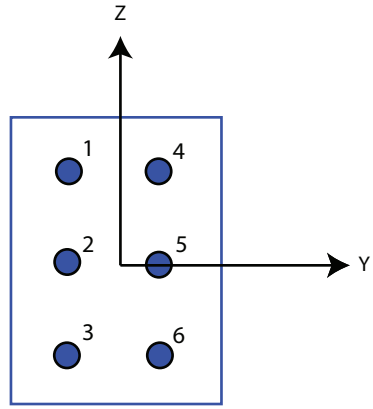
Array size

Specify the size of the array as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of rows and columns.

Elements are indexed from top to bottom along a column and continuing to the next columns from left to right. In this figure, an **Array size** of `[3,2]` produces an array has three rows and two columns.

Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]



Element spacing

Specify the element spacing of the array, in meters, as a 1-by-2 vector or a scalar. If **Element spacing** is a 1-by-2 vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumns]`. For a discussion of these

quantities, see phased.URA. If **Element spacing** is a scalar, the spacings between rows and columns are equal.

Element lattice

Specify the element lattice as one of `Rectangular` or `Triangular`.

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular` — Shifts the even-row elements of a rectangular lattice toward the positive-row axis direction. The elements are shifted a distance of half the element spacing along the row.

Array normal

This parameter appears when you set **Geometry**to `URA` or `UCA`. Specify the **Array normal** as `x`, `y`, or `z`. All URA and UCA array elements are placed in the *yz*, *zx*, or *xy*planes, respectively, of the array coordinate system.

Taper

Tapers, also known as *element weights*, are applied to sensor elements in the array. Tapers are used to modify both the amplitude and phase of the transmitted or received data.

Specify element tapering as a complex-valued scalar or complex-valued *M*-by-*N* matrix. In this matrix, *M* is the number of elements along the *z*-axis, and *N* is the number of elements along the *y*-axis. *M* and *N* correspond to the values of `[NumberofRows, NumberOfColumns]` in the **Array size** matrix. If `Taper` is a scalar, the same weight is applied to each element. If the value of **Taper** is a matrix, a weight from the matrix is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

Expression

A valid MATLAB expression containing a constructor for a uniform rectangular array, for example, `phased.URA`.

Sensor Array Tab: Element Parameters

Element type

Specify antenna or microphone type as

- `Isotropic Antenna`
- `Cosine Antenna`

- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

Exponent of cosine pattern

This parameter appears when you set **Element type** to `Cosine Antenna`.

Specify the exponent of the cosine pattern as a scalar or a 1-by-2 vector. You must specify all values as non-negative real numbers. When you set **Exponent of cosine pattern** to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the specified value. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern and the second element is the exponent for the elevation direction cosine pattern.

Operating frequency range (Hz)

This parameter appears when **Element type** is set to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

Specify the operating frequency range, in hertz, of the antenna element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The antenna element has no response outside the specified frequency range.

Operating frequency vector (Hz)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify the frequencies, in Hz, at which to set the antenna and microphone frequency responses as a 1-by-*L* row vector of increasing values. Use **Frequency responses** to set the frequency responses. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of **Operating frequency vector (Hz)**.

Frequency responses (dB)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify this parameter as the frequency response of an antenna or microphone, in decibels, for the frequencies defined by **Operating frequency vector (Hz)**. Specify **Frequency responses (dB)** as a 1-by-*L* vector matching the dimensions of the vector specified in **Operating frequency vector (Hz)**.

Azimuth angles (deg)

This parameter appears when **Element type** is set to `Custom Antenna`.

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Angle units are in degrees. Azimuth angles must lie between –180° and 180° and be in strictly increasing order.

Elevation angles (deg)

This parameter appears when the **Element type** is set to `Custom Antenna`.

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90° and be in strictly increasing order.

Radiation pattern (dB)

This parameter appears when the **Element type** is set to `Custom Antenna`.

The magnitude in db of the combined polarized antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The value of *Q* must match the value of *Q* specified by **Elevation angles (deg)**. The value of *P* must match the value of *P* specified by **Azimuth angles (deg_**. The value of *L* must match the value of *L* specified by **Operating frequency vector (Hz)**.

Polar pattern frequencies (Hz)

This parameter appears when the **Element type** is set to `Custom Microphone`.

Specify the measuring frequencies of the polar patterns as a 1-by-*M* vector. The measuring frequencies lie within the frequency range specified by**Operating frequency vector (Hz)**. Frequency units are in Hz.

Polar pattern angles (deg)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the measuring angles of the polar patterns, as a 1-by-*N* vector. The angles are measured from the central pickup axis of the microphone, and must be between –180° and 180°, inclusive.

Polar pattern (dB)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the magnitude of the microphone element polar pattern as an *M*-by-*N* matrix. *M* is the number of measuring frequencies specified in **Polar pattern frequencies (Hz)**. *N* is the number of measuring angles specified in **Polar pattern angles (deg)**.

Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

Baffle the back of the element

This check box appears only when the **Element type** parameter is set to `Isotropic Antenna` or `Omni Microphone`.

Select this check box to baffle the back of the antenna element. In this case, the antenna responses to all azimuth angles beyond ±90° from *broadside* are set to zero. Define the broadside direction as 0° azimuth angle and 0° elevation angle.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Description	Supported Data Types
`X`	Input signal. The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.	Double-precision floating point
`Steer`	Initial estimate of arrival directions.	Double-precision floating point
`Ang`	Estimate of arrival directions.	Double-precision floating point

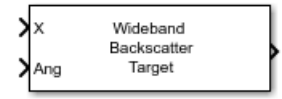
Introduced in R2014b

Wideband Backscatter Radar Target

Backscatter wideband signals from radar target

Library: Phased Array System Toolbox / Environment and Target



Description

The Wideband Backscatter Radar Target block models the monostatic reflection of nonpolarized wideband electromagnetic signals from a radar target. The target radar cross-section (RCS) model includes all four Swerling target fluctuation models and a nonfluctuating model. You can model several targets simultaneously by specifying multiple RCS matrices.

Ports

Input

X — Wideband incident nonpolarized signal

N-by-*M* complex-valued matrix

Wideband incident nonpolarized signal, specified as an *N*-by-*M* complex-valued matrix. The quantity *N* is the number of signal samples, and *M* is the number of independent signals reflecting off the target. Each column contains an independent signal to be reflected from the target.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Data Types: `double`
Complex Number Support: Yes

Ang — Incident signal direction

2-by-1 real-valued column vector of positive values | 2-by-*M* real-valued column vector of positive values

Incident signal direction, specified as a 2-by-1 or 2-by-*M* real-valued column matrix of positive values. Each column of `Ang` specifies the incident direction of the corresponding signal. The number of columns in `Ang` must match the number of independent signals in `X`. The columns take the form `[AzimuthAngle;ElevationAngle]`. Units are in degrees.

Data Types: `double`

`Update` — Enable update of RCS

`false` (default) | `true`

Option to enable updating of RCS values for fluctuation models, specified as `false` or `true`. When `Update` is `true`, a new RCS value is generated each time you run the block. If `Update` is `false`, the RCS remains unchanged.

Dependencies

To enable this port, set the **Fluctuation model** parameter to one of the Swerling models.

Data Types: `Boolean`

Output

`Out` — Wideband reflected nonpolarized signal

N-by-*M* complex-valued matrix

Wideband reflected nonpolarized signal, returned as an *N*-by-*M* complex-valued matrix. The quantity *N* is the number of signal samples, and *M* is the number of independent signals reflected from the target. Each column contains an independent signal reflected from the target.

Data Types: `double`

Parameters

`Backscatter pattern frequency vector (Hz)` — Wideband backscatter pattern frequencies

`[0,1e20]` (default) | real-valued row vector of positive values in strictly increasing order

Specify the frequencies used in the RCS matrix. The elements of this vector must be in strictly increasing order. The target has no response outside this frequency range. Frequency units are in hertz.

`Azimuth angles (deg)` — Azimuth angles

`[-180:180]` (default) | 1-by-*P* real-valued row vector | *P*-by-1 real-valued column vector

Azimuth angles used to define the angular coordinates of each column of the matrices specified by the **RCS pattern (m^2)** parameter. Specify the azimuth angles as a length *P* vector. *P* must be greater than two. Angle units are in degrees.

Example: `[-45:0.1:45]`

Data Types: `double`

`Elevation angles (deg)` — Elevation angles

`[-90:90]` (default) | 1-by-*Q* real-valued row vector | *Q*-by-1 real-valued column vector

Elevation angles used to define the angular coordinates of each row of the matrices specified by the **RCS pattern (m^2)** parameter. Specify the elevation angles as a length *Q* vector. *Q* must be greater than two. Angle units are in degrees.

Example: `[-30:0.1:30]`

Data Types: `double`

`RCS pattern (m^2)` — Radar cross-section pattern

`ones(181,361)` (default) | *Q*-by-*P* complex-valued matrix | *Q*-by-*P*-by-*K* complex-valued array | 1-by-*P*-by-*K* complex-valued array | *K*-by-*P* complex-valued matrix

Radar cross-section pattern, specified as a complex-valued matrix or array.

Dimensions	Application
Q-by-*P* matrix	Specifies a matrix of RCS values as a function of *Q* elevation angles and *P* azimuth angles. The same RCS matrix is used for all frequencies.
Q-by-*P*-by-*K* array	Specifies an array of RCS patterns as a function of *Q* elevation angles, *P* azimuth angles, and *K* frequencies. If K = 1, the RCS pattern is equivalent to a *Q*-by-*P* matrix.

Dimensions	Application
1-by-*P*-by-*K* array	Specifies a matrix of RCS values as a function of *P* azimuth angles and *K* frequencies. These dimension formats apply when there is only one elevation angle.
K-by-*P* matrix	

- *Q* is the length of the vector specified by the **Elevation angles (deg)** parameter.
- *P* is the length of the vector specified by the **Azimuth angles (deg)** parameter.
- *K* is the number of frequencies specified by the **Backscatter pattern frequency vector (Hz)** parameter.

You can specify patterns for *L* targets by putting *L* patterns into a cell array. All patterns must have the same dimensions. The value of *L* must match the column dimensions of the signals passed as input into the block. You can, however, use one pattern to model *L* multiple targets.

RCS units are in square meters.

Example: `[1,1;1i,1i]`

Data Types: `double`
Complex Number Support: Yes

`Fluctuation model` — Target fluctuation model

`Nonfluctuating` (default) | `Swerling1` | `Swerling2` | `Swerling3` | `Swerling4`

Target fluctuation model, specified as `Nonfluctuating`, `Swerling1`, `Swerling2`, `Swerling3`, or `Swerling4`. If you set this parameter to a value other than `Nonfluctuating`, you must pass either `true` or `false` into the **Update** `Update` port.

`Propagation speed (m/s)` — Signal propagation speed

speed of light (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value return by `physconst('LightSpeed')`.

`Operating frequency (Hz)` — Signal carrier frequency

`300.0e6` (default) | positive real-valued scalar

Signal carrier frequency, specified as a positive real-valued scalar. Units are in hertz.

`Inherit sample rate` — Inherit sample rate from upstream blocks
on (default) | off

Select this parameter to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate (Hz)** parameter.

Data Types: `Boolean`

`Sample rate (Hz)` — Sampling rate of signal
`1e6` (default) | positive real-valued scalar

Specify the signal sampling rate as a positive scalar. Units are in Hz.

Dependencies

To enable this parameter, clear the **Inherit sample rate** parameter.

Data Types: `double`

`Number of subbands` — Number of processing subbands
`64` (default) | positive integer

Number of processing subbands, specified as a positive integer.

`Simulate using` — Block simulation method
`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see "Choosing a Simulation Mode" (Simulink) from the Simulink documentation.

Blocks

`Backscatter Radar Target` | `Radar Target`

Introduced in R2016b

Wideband Free Space

Wideband free space environment

Library

Environment and Targets

`phasedenvlib`

Description

The Wideband Free Space Channel block propagates the signal from one point to another in space. The block models propagation time, free space propagation loss and Doppler shift. The block assumes that the propagation speed is much greater than the target or array speed in which case the stop-and-hop model is valid.

When propagating a signal in free-space to an object and back, you have the choice of either using a single block to compute a two-way free space propagation delay or two blocks to perform one-way propagation delays in each direction. Because the free-space propagation delay is not necessarily an integer multiple of the sampling interval, it may turn out that the total round trip delay in samples when you use a two-way propagation block differs from the delay in samples when you use two one-way propagation blocks. For this reason, it is recommended that, when possible, you use a single two-way propagation block.

Parameters

Signal Propagation speed (m/s)

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

Signal carrier frequency (Hz)

Specify the carrier frequency of the signal in hertz of the narrowband signal as a positive scalar.

Number of subbands

The number of subbands used for subband processing, specified as a positive integer.

Perform two-way propagation

Select this check box to perform round-trip propagation between the origin and destination. Otherwise the block performs one-way propagation from the origin to the destination.

Inherit sample rate

Select this check box to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate** parameter.

Sample rate

Specify the signal sampling rate (in hertz) as a positive scalar. This parameter appears only when the **Inherit sample rate** parameter is not selected.

Maximum one-way propagation distance (m)

The maximum distance , in meters, between the origin and the destination as a positive scalar. Amplitudes of any signals that propagate beyond this distance will be set to zero.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see "Choosing a Simulation Mode" (Simulink) from the Simulink documentation.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Description	Supported Data Types
`X`	Input signal.	Double-precision floating point
`Pos1`	Signal source position.	Double-precision floating point
`Pos2`	Signal destination position.	Double-precision floating point
`Vel1`	Signal source velocity.	Double-precision floating point
`Vel2`	Signal destination velocity.	Double-precision floating point

Port	Description	Supported Data Types
`Out`	Propagated signal.	Double-precision floating point

Algorithms

When the origin and destination are stationary relative to each other, the block output can be written as $y(t) = x(t - \tau)/L$. The quantity τ is the delay and L is the propagation loss. The delay is computed from $\tau = R/c$ where R is the propagation distance and c is the propagation speed. The free space path loss is given by

$$L_{fsp} = \frac{(4\pi R)^2}{\lambda^2},$$

where λ is the signal wavelength.

This formula assumes that the target is in the far-field of the transmitting element or array. In the near-field, the free-space path loss formula is not valid and can result in losses smaller than one, equivalent to a signal gain. For this reason, the loss is set to unity for range values, $R \le \lambda/4\pi$.

When there is relative motion between the origin and destination, the processing also introduces a frequency shift. This shift corresponds to the Doppler shift between the origin and destination. The frequency shift is v/λ for one-way propagation and $2v/\lambda$ for two-way propagation. The parameter v is the relative speed of the destination with respect to the origin.

Wideband LOS Channel

Wideband line-of-sight propagation channel

Library

Environment and Targets

`phasedenvlib`

Description

The Wideband LOS Channel block propagates signals from one point in space to multiple points or from multiple points back to one point via line-of-sight (LOS) channels. The block models propagation time, free-space propagation loss, Doppler shift, and atmospheric as well as weather loss. The block assumes that the propagation speed is much greater than the object's speed in which case the stop-and-hop model is valid.

When propagating a signal in an LOS channel to an object and back, you have the choice of either using a single block to compute two-way LOS channel propagation delay or two blocks to perform one-way propagation delays in each direction. Because the LOS channel propagation delay is not necessarily an integer multiple of the sampling interval, it may turn out that the total round trip delay in samples when you use a two-way propagation block differs from the delay in samples when you use two one-way propagation blocks. For this reason, it is recommended that, when possible, you use a single two-way propagation block.

Parameters

Signal Propagation speed (m/s)

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

Signal carrier frequency (Hz)

Specify the carrier frequency of the signal in hertz of the narrowband signal as a positive scalar.

Number of subbands

The number of subbands used for subband processing, specified as a positive integer.

Specify atmospheric parameters

Select this check box to enable atmospheric attenuation modeling.

Temperature (degrees Celsius)

Ambient atmospheric temperature, specified as a real-valued scalar. Units are degrees Celsius. This parameter appears when you select the **Specify atmospheric parameters** check box. Units are degrees Celsius.

Dry air pressure (Pa)

Atmospheric dry air pressure, specified as a positive real-valued scalar. Units are Pascals (Pa). The value 101325 for this property corresponds to one standard atmosphere. This parameter appears when you select the **Specify atmospheric parameters** check box.

Water vapour density (g/m^3)

Atmospheric water vapor density, specified as a positive real-valued scalar. Units are gm/m^3. This parameter appears when you select the **Specify atmospheric parameters** check box.

Liquid water density (g/m^3)

Liquid water density of fog or clouds, specified as a non-negative real-valued scalar. Units are gm/m^3. Typical values for liquid water density are 0.05 for medium fog and 0.5 for thick fog. This parameter appears when you select the **Specify atmospheric parameters** check box.

Rain rate (mm/hr)

Rainfall rate, specified as a non-negative real-valued scalar. Units are in mm/hour. This parameter appears when you select the **Specify atmospheric parameters** check box.

Perform two-way propagation

Select this check box to perform round-trip propagation between the origin and destination. Otherwise the block performs one-way propagation from the origin to the destination.

Inherit sample rate

Select this check box to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate** parameter.

Sample rate

Specify the signal sampling rate (in hertz) as a positive scalar. This parameter appears only when the **Inherit sample rate** parameter is not selected.

Maximum one-way propagation distance (m)

The maximum distance between the signal origin and the destination, specified as a positive scalar. Units are in meters. Amplitudes of any signals that propagate beyond this distance will be set to zero.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see “Choosing a Simulation Mode” (Simulink) from the Simulink documentation.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Description	Supported Data Types
`X`	Input signal.	Double-precision floating point
`Pos1`	Signal source position.	Double-precision floating point
`Pos2`	Signal destination position.	Double-precision floating point
`Vel1`	Signal source velocity.	Double-precision floating point
`Vel2`	Signal destination velocity.	Double-precision floating point
`Out`	Propagated signal.	Double-precision floating point

Definitions

Attenuation and Loss Factors

Attenuation or path loss in the Wideband LOS channel consists of four components. $L = L_{fsp}L_gL_cL_r$, where

- L_{fsp} is the free-space path attenuation
- L_g is the atmospheric path attenuation

- L_c is the fog and cloud path attenuation
- L_r is the rain path attenuation

Each component is in magnitude units, not in dB.

Propagation Delay, Doppler, and Free-Space Path Loss

When the origin and destination are stationary relative to each other, you can write the output signal of a free-space channel as $Y(t) = x(t-\tau)/L_{fsp}$. The quantity τ is the signal delay and L_{fsp} is the free-space path loss. The delay τ is given by R/c, where R is the propagation distance and c is the propagation speed. The free-space path loss is given by

$$L_{fsp} = \frac{(4\pi R)^2}{\lambda^2},$$

where λ is the signal wavelength.

This formula assumes that the target is in the far field of the transmitting element or array. In the near field, the free-space path loss formula is not valid and can result in a loss smaller than one, equivalent to a signal gain. Therefore, the loss is set to unity for range values, $R \le \lambda/4\pi$.

When the origin and destination have relative motion, the processing also introduces a Doppler frequency shift. The frequency shift is v/λ for one-way propagation and $2v/\lambda$ for two-way propagation. The quantity v is the relative speed of the destination with respect to the origin.

Atmospheric Gas Attenuation Model

This model calculates the attenuation of signals that propagate through atmospheric gases.

Electromagnetic signals attenuate when they propagate through the atmosphere. This effect is due primarily to the absorption resonance lines of oxygen and water vapor, with smaller contributions coming from nitrogen gas. The model also includes a continuous absorption spectrum below 10 GHz. Phased Array System Toolbox uses the ITU model *Recommendation ITU-R P.676-10: Attenuation by atmospheric gases*. The model computes the specific attenuation (attenuation per kilometer) as a function of temperature, pressure, water vapor density, and signal frequency. The atmospheric

gas model is valid for frequencies from 1–1000 GHz and applies to polarized and nonpolarized fields.

The formula for specific attenuation at each frequency is

$$\gamma = \gamma_o(f) + \gamma_w(f) = 0.1820 f N''(f).$$

The quantity $N''()$ is the imaginary part of the complex atmospheric refractivity. It consists of a spectral line component and a continuous component:

$$N''(f) = \sum_i S_i F_i + N_D''(f)$$

The spectral component consists of a sum of discrete spectrum terms composed of a localized frequency bandwidth function, $F(f)_i$, multiplied by a spectral line strength, S_i. For atmospheric oxygen, each spectral line strength is

$$S_i = a_1 \times 10^{-7} \left(\frac{300}{T}\right)^3 \exp\left[a_2 \left(1 - \left(\frac{300}{T}\right)\right)\right] P.$$

For atmospheric water vapor, each spectral line strength is

$$S_i = b_1 \times 10^{-1} \left(\frac{300}{T}\right)^{3.5} \exp\left[b_2 \left(1 - \left(\frac{300}{T}\right)\right)\right] W.$$

P is the atmospheric pressure, W is the water vapor density, and T is the ambient temperature.

For each oxygen line, S_i depends on constants a_1 and a_2. Similarly, each water vapor line has constants b_1 and b_2. The ITU documentation cited at the end of this section contains tabulations of these constants.

The localized frequency bandwidth functions $F_i(f)$ are complicated functions of frequency described in the ITU references cited below. The functions depend on empirical model parameters that are also tabulated in the reference.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length, R. Then, the total attenuation is $L_g = R(\gamma_o + \gamma_w)$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

Fog and Cloud Attenuation Model

This model calculates the attenuation of signals that propagate through fog or clouds.

Fog and cloud attenuation are the same atmospheric phenomenon. Phased Array System Toolbox uses the ITU model, *Recommendation ITU-R P.840-6: Attenuation due to clouds and fog*. The model computes the specific attenuation (attenuation per kilometer), of a signal as a function of liquid water density, signal frequency, and temperature. The model applies to polarized and nonpolarized fields. The formula for specific attenuation at each frequency is

$$\gamma_c = K_l(f)M,$$

where M is the liquid water density in gm/m^3. The quantity $K_l(f)$ is the specific attenuation coefficient and depends on frequency. The cloud and fog attenuation model is valid for frequencies 10–1000 GHz. Units for the specific attenuation coefficient are (dB/km)/(g/m^3).

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by the path length R. Total attenuation is $L_c = R\gamma_c$.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands, and apply narrowband attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

Rainfall Attenuation Model

This model calculates the attenuation of signals that propagate through regions of rainfall.

Electromagnetic signals are attenuate when propagating through a region of rainfall. Rainfall attenuation is computed according to the ITU rainfall model *Recommendation ITU-R P.838-3: Specific attenuation model for rain for use in prediction methods*. The model computes the specific attenuation (attenuation per kilometer) of a signal as a

function of rainfall rate, signal frequency, polarization, and path elevation angle. To compute the attenuation, this model uses

$$\gamma_r = kr^{\alpha},$$

where r is the rain rate in mm/hr. The parameter k and exponent a depend on the frequency, the polarization state, and the elevation angle of the signal path. The specific attenuation model is valid for frequencies from 1–1000 GHz.

To compute the total attenuation for narrowband signals along a path, the function multiplies the specific attenuation by a propagation distance, R. Then, total attenuation is $L_r = R\gamma_r$. Instead of using geometric range as the propagation distance, the toolbox uses a modified range. The modified range is the geometric range multiplied by a range factor

$$\frac{1}{1+\frac{R}{R_0}}$$

where

$$R_0 = 35e^{-0.015r}$$

is the effective path length in kilometers (see Seybold, J. *Introduction to RF Propagation*.) When there is no rain, the effective path length is 35 km. When the rain rate is, for example, 10 mm/hr, the effective path length is 30.1 km. At short range, the propagation distance is approximately the geometric range. For longer ranges, the propagation distance asymptotically approaches the effective path length.

You can apply the attenuation model to wideband signals. First, divide the wideband signal into frequency subbands and apply attenuation to each subband. Then, sum all attenuated subband signals into the total attenuated signal.

Subband Frequency Processing

Subband processing decomposes a wideband signal into multiple subbands and applies narrowband processing to the signal in each subband. The signals for all subbands are summed to form the output signal.

When using wideband frequency System objects or blocks, you specify the number of subbands, N_b, in which to decompose the wideband signal. Subband center frequencies and widths are automatically computed from the total bandwidth and number of subbands. The total frequency band is centered on the carrier or operating frequency, f_c. The overall bandwidth is given by the sample rate, f_s. Frequency subband widths are $\Delta f = f_s/N_B$. The center frequencies of the subbands are

$$f_m = \begin{cases} f_c - \frac{f_s}{2} + (m-1)\Delta f, & N_B \text{ even} \\ f_c - \frac{(N-1)f_s}{2N} + (m-1)\Delta f, & N_B \text{ odd} \end{cases}, m = 1, \ldots, N_B$$

Some System objects let you obtain the subband center frequencies as output from the `step` method. The returned subband frequencies are ordered consistent with the ordering of the discrete Fourier transform. Frequencies above the carrier appear first, followed by frequencies below the carrier.

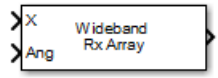
Introduced in R2016a

Wideband Receive Array

Wideband receive array



Library

Transmitters and Receivers

`phasedtxrxlib`

Description

The Wideband Receive Array block receives wideband plane waves incident on the elements of a sensor array. The block divides the input signal into subbands and then applies a phase shift in each subband according to the incident direction. The resulting subband signals are then combined to form the output.

Parameters

Signal Propagation speed (m/s)

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

Inherit sample rate

Select this check box to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate** parameter.

Sample rate

Specify the signal sampling rate (in hertz) as a positive scalar. This parameter appears only when the **Inherit sample rate** parameter is not selected.

Assume modulated input

Select this check this box to indicate that the input signal is demodulated at a carrier frequency.

Carrier frequency

This parameter appears when the **Assume modulated input** check box is selected. The parameter specifies the carrier frequency, in hertz, as a positive scalar.

Number of subbands

Number of processing subbands, specified as a positive integer.

Enable weights input

Select this check box to specify array weights using the input port `W`. The input port appears only when this box is checked.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.

`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see “Choosing a Simulation Mode” (Simulink) from the Simulink documentation.

Array Parameters

Specify sensor array as

Sensor element or sensor array specified. A sensor array can also contain subarrays or as a partitioned array. This parameter can also be expressed as a MATLAB expression.

Types

`Single element`
`Array (no subarrays)`
`Partitioned array`
`Replicated subarray`
`MATLAB expression`

Geometry

Specify the array geometry as one of the following:

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array
- `Conformal Array` — arbitrary element positions

Number of elements

Number of array elements.

Number of array elements, specified as a positive integer. This parameter appears when the **Geometry** is set to `ULA` or `UCA`. If **Sensor Array** has a `Replicated subarray` option, this parameter applies to the sub-array.

Array size

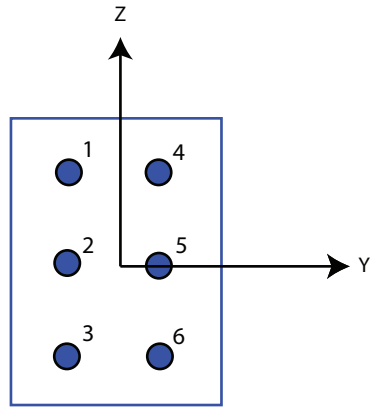
This parameter appears when **Geometry** is set to `URA`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to the subarrays.

Specify the size of the array as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of rows and columns.

For a URA, elements are indexed from top to bottom along a column and continuing to the next columns from left to right. In this figure, an **Array size** of `[3,2]` produces an array of three rows and two columns.

Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]



Element spacing (m)

This parameter appears when **Geometry** is set to ULA or URA. When **Sensor Array** has the `Replicated subarray` option, this parameter applies to the subarrays.

- For a ULA, specify the spacing, in meters, between two adjacent elements in the array as a scalar.
- For a URA, specify the element spacing of the array, in meters, as a 1-by-2 vector or a scalar. If **Element spacing** is a 1-by-2 vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumns]`. For a discussion of these quantities, see phased.URA. If **Element spacing** is a scalar, the spacings between rows and columns are equal.

Array axis

This parameter appears when the **Geometry** parameter is set to ULA or when the block only supports a ULA array geometry. Specify the array axis as x, y, or z. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

Array normal

This parameter appears when you set **Geometry**to URA or UCA. Specify the **Array normal** as x, y, or z. All URA and UCA array elements are placed in the *yz*, *zx*, or *xy*planes, respectively, of the array coordinate system.

Radius of UCA (m)

Radius of a uniform circular array specified as a positive scalar. Units are meters.

This parameter appears when the **Geometry** is set to UCA.

Taper

Tapers, also known as *element weights*, are applied to sensor elements in the array. Tapers are used to modify both the amplitude and phase of the transmitted or received data.

This parameter applies to all array types, but when you set **Sensor Array** to `Replicated subarray`, this parameter applies to subarrays.

- For a ULA or UCA, specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array. If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.
- For a URA, specify element tapering as a complex-valued scalar or complex-valued *M*-by-*N* matrix. In this matrix, *M* is the number of elements along the *z*-axis, and *N* is the number of elements along the *y*-axis. *M* and *N* correspond to the values of `[NumberofArrayRows,NumberOfArrayColumns]` in the **Array size** matrix. If `Taper` is a scalar, the same weight is applied to each element. If **Taper** is a matrix, a weight from the matrix is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.
- For a `Conformal Array`, specify element tapering as a complex-valued scalar or complex-valued 1-by-*N* vector. In this vector, *N* is the number of elements in the array as determined by the size of the **Element positions** vector. If **Taper** is a scalar, the same weight is applied to each element. If the value of **Taper** is a

vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

Element lattice

This parameter appears when **Geometry** is set to `URA`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to the subarray.

Specify the element lattice as `Rectangular` or `Triangular`

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular`— Shifts the even-row elements of a rectangular lattice toward the positive-row axis direction. The displacement is one-half the element spacing along the row dimension.

Element positions (m)

This parameter appears when **Geometry** is set to `Conformal Array`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to subarrays.

Specify the positions of conformal array elements as a 3-by-*N* matrix, where *N* is the number of elements in the conformal array. Each column of **Element positions (m)** represents the position of a single element, in the form `[x;y;z]`, in the array's local coordinate system. The local coordinate system has its origin at an arbitrary point. Units are in meters.

Element normals (deg)

This parameter appears when **Geometry** is set to `Conformal Array`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to subarrays.

Specify the normal directions of the elements in a conformal array as a 2-by-*N* matrix or a 2-by-1 column vector in degrees. The variable *N* indicates the number of elements in the array. If **Element normals (deg)** is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]`, with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If **Element normals (deg)** is a 2-by-1 column vector, the vector specifies the same pointing direction for all elements in the array.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. You can combine translation, azimuth rotation, and elevation rotation transformations. However, you cannot use transformations that require rotation about the normal.

Subarray definition matrix

This parameter appears when **Sensor array** is set to `Partitioned array`.

Specify the subarray selection as an *M*-by-*N* matrix. *M* is the number of subarrays and *N* is the total number of elements in the array. Each row of the matrix indicates which elements belong to the corresponding subarray. Each entry in the matrix is 1 or 0, where 1 indicates that the element appears in the subarray and 0 indicates the opposite. Each row must contain at least one 1.

The phase center of each subarray is its geometric center. **Subarray definition matrix** and **Geometry** determine the geometric center.

Subarray steering method

This parameter appears when **Sensor array** is set to `Partitioned array` or `Replicated subarray`.

Specify the subarray steering method as

- `None`
- `Phase`
- `Time`

When using the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, or Wideband Transmit Arrayblocks, selecting `Phase` or `Time` opens the block input port, `Steer`.

Phase shifter frequency (Hz)

This parameter appears when you set **Sensor array** to `Partitioned array` or `Replicated subarray` and you set **Subarray steering method** to `Phase`.

Specify the operating frequency, in hertz, of phase shifters to perform subarray steering as a positive scalar.

Number of bits in phase shifters

This parameter appears when you set **Sensor array** to `Partitioned array` or `Replicated subarray` and you set **Subarray steering method** to `Phase`.

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

Subarrays layout

This parameter appears when you set **Sensor array** to `Replicated subarray`.

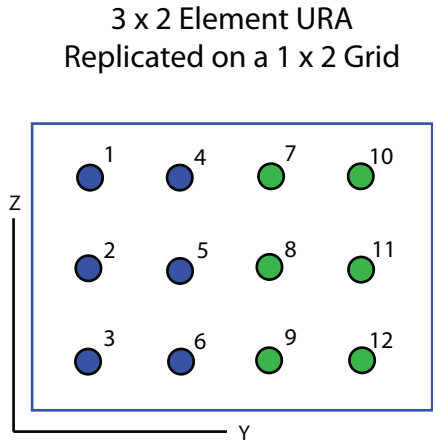
Specify the layout of the replicated subarrays as `Rectangular` or `Custom`.

Grid size

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

Rectangular subarray grid size, specified as a single positive integer or a positive integer-valued 1-by-2 row vector.

If **Grid size** is an integer scalar, the array has an equal number of subarrays in each row and column. If **Grid size** is a 1-by-2 vector of the form `[NumberOfRows, NumberOfColumns]`, the first entry is the number of subarrays along each column. The second entry is the number of subarrays in each row. A row is along the local *y*-axis, and a column is along the local *z*-axis. The figure here shows how you can replicate a 3-by-2 URA subarray using a **Grid size** of `[1,2]`.



Grid spacing

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

Specify the rectangular grid spacing of subarrays as a real-valued positive scalar, a 1-by-2 row vector, or `Auto`. Grid spacing units are expressed in meters.

- If **Grid spacing** is a scalar, the spacing along the row and the spacing along the column is the same.

- If **Grid spacing** is a 1-by-2 row vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumn]`. The first entry specifies the spacing between rows along a column. The second entry specifies the spacing between columns along a row.
- If **Grid spacing** is set to `Auto`, replication preserves the element spacing of the subarray for both rows and columns while building the full array. This option is available only when you specify **Geometry** as `ULA` or `URA`.

Subarray positions (m)

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Custom`.

Specify the positions of the subarrays in the custom grid as a 3-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix represents the position of a single subarray, in meters, in the array's local coordinate system. The coordinates are expressed in the form `[x; y; z]`.

Subarray normals

This parameter appears when you set the **Sensor array** parameter to `Replicated subarray` and the **Subarrays layout** to `Custom`.

Specify the normal directions of the subarrays in the array. This parameter value is a 2-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix specifies the normal direction of the corresponding subarray, in the form `[azimuth; elevation]`. Each angle is in degrees and is defined in the local coordinate system.

You can use the **Subarray positions** and **Subarray normals** parameters to represent any arrangement in which pairs of subarrays differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal.

Expression

A valid MATLAB expression containing an array constructor, for example, `phased.URA`.

Sensor Array Tab: Element Parameters

Element type

Specify antenna or microphone type as

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

Exponent of cosine pattern

This parameter appears when you set **Element type** to `Cosine Antenna`.

Specify the exponent of the cosine pattern as a scalar or a 1-by-2 vector. You must specify all values as non-negative real numbers. When you set **Exponent of cosine pattern** to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the specified value. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern and the second element is the exponent for the elevation direction cosine pattern.

Operating frequency range (Hz)

This parameter appears when **Element type** is set to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

Specify the operating frequency range, in hertz, of the antenna element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The antenna element has no response outside the specified frequency range.

Operating frequency vector (Hz)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify the frequencies, in Hz, at which to set the antenna and microphone frequency responses as a 1-by-*L* row vector of increasing values. Use **Frequency responses** to set the frequency responses. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of **Operating frequency vector (Hz)**.

Frequency responses (dB)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify this parameter as the frequency response of an antenna or microphone, in decibels, for the frequencies defined by **Operating frequency vector (Hz)**. Specify **Frequency responses (dB)** as a 1-by-*L* vector matching the dimensions of the vector specified in **Operating frequency vector (Hz)**.

Azimuth angles (deg)

This parameter appears when **Element type** is set to `Custom Antenna`.

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Angle units are in degrees. Azimuth angles must lie between –180° and 180° and be in strictly increasing order.

Elevation angles (deg)

This parameter appears when the **Element type** is set to `Custom Antenna`.

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90° and be in strictly increasing order.

Radiation pattern (dB)

This parameter appears when the **Element type** is set to `Custom Antenna`.

The magnitude in db of the combined polarized antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The value of *Q* must match the value of *Q* specified by **Elevation angles (deg)**. The value of *P* must match the value of *P* specified by **Azimuth angles (deg_**. The value of *L* must match the value of *L* specified by **Operating frequency vector (Hz)**.

Polar pattern frequencies (Hz)

This parameter appears when the **Element type** is set to `Custom Microphone`.

Specify the measuring frequencies of the polar patterns as a 1-by-*M* vector. The measuring frequencies lie within the frequency range specified by**Operating frequency vector (Hz)**. Frequency units are in Hz.

Polar pattern angles (deg)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the measuring angles of the polar patterns, as a 1-by-*N* vector. The angles are measured from the central pickup axis of the microphone, and must be between –180° and 180°, inclusive.

Polar pattern (dB)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the magnitude of the microphone element polar pattern as an *M*-by-*N* matrix. *M* is the number of measuring frequencies specified in **Polar pattern frequencies (Hz)**. *N* is the number of measuring angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

Baffle the back of the element

This check box appears only when the **Element type** parameter is set to `Isotropic Antenna` or `Omni Microphone`.

Select this check box to baffle the back of the antenna element. In this case, the antenna responses to all azimuth angles beyond ±90° from *broadside* are set to zero. Define the broadside direction as 0° azimuth angle and 0° elevation angle.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Description	Supported Data Types
`X`	Arriving signals The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.	Double-precision floating point

Port	Description	Supported Data Types
`Ang`	Incident directions of signals	Double-precision floating point
`W`	Weights	Double-precision floating point
`Steer`	Subarray steering angle	Double-precision floating point
`Out`	Collected signals	Double-precision floating point

phased.WidebandCollector

Introduced in R2014b

Wideband Two-Ray Channel

Wideband two-ray channel environment

Library: Phased Array System Toolbox / Environment and Target

Description

The Wideband Two-Ray Channel block propagates wideband signals from one point in space to multiple points or from multiple points back to one point via both the direct path and the ground reflection path. The block propagates wideband signals by (1) decomposing them into subbands, (2) propagating subbands independently, and (3) recombining the propagated subbands. The block models propagation time, propagation loss, and Doppler shift. The block assumes that the propagation speed is much greater than the object's speed in which case the stop-and-hop model is valid.

Ports

Input

X — Wideband input signal

M-by-*N* complex-valued matrix | *M*-by-*2N* complex-valued matrix

- Wideband nonpolarized scalar signal, specified as an
  - *M*-by-*N* complex-valued matrix. The quantity *M* is the number of samples in the signal and *N* is the number of two-ray channels. Each channel corresponds to a source-destination pair. Each column contains an identical signal that is propagated along the line-of-sight and reflected paths.
  - *M*-by-*2N* complex-valued matrix. The quantity *M* is the number of samples of the signal and *N* is the number of two-ray channels. Each channel corresponds to a source-destination pair. Each adjacent pair of columns represents a different channel. Within each pair, the first column represents the signal propagated along

the line-of-sight path and the second column represents the signal propagated along the reflected path.

The quantity *M* is the number of samples of the signal and *N* is the number of two-ray channels. Each channel corresponds to a source-destination pair.

The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.

Example: `[1,1;j,1;0.5,0]`

Data Types: `double`
Complex Number Support: Yes

`Pos1` — Position of signal origin

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Origin of the signal or signals, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. The quantity *N* is the number of two-ray channels. If **Pos1** is a column vector, it takes the form `[x;y;z]`. If **Pos1** is a matrix, each column specifies a different signal origin and has the form `[x;y;z]`. Position units are in meters.

Pos1 and **Pos2** cannot both be specified as matrices — at least one must be a 3-by-1 column vector.

Example: `[1000;100;500]`

Data Types: `double`

`Pos2` — Position of signal destination

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Origin of the signal or signals, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. The quantity *N* is the number of two-ray channels. If **Pos2** is a column vector, it takes the form `[x;y;z]`. If **Pos2** is a matrix, each column specifies a different signal origin and has the form `[x;y;z]`. Position units are in meters.

Pos1 and **Pos2** cannot both be specified as matrices — at least one must be a 3-by-1 column vector.

Example: `[-100;300;50]`

Data Types: `double`

`Vel1` — Velocity of signal origin

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Velocity of signal origin, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. The dimensions of **Vel1** must match the dimensions of **Pos1**. If **Vel1** is a column vector, it takes the form `[Vx;Vy;Vz]`. If **Vel1** is a 3-by-*N* matrix, each column specifies a different origin velocity and has the form `[Vx;Vy;Vz]`. Velocity units are in meters per second.

Example: `[-10;3;5]`

Data Types: `double`

`Vel2` — Velocity of signal destination

3-by-1 real-valued column vector | 3-by-*N* real-valued matrix

Velocity of signal origin, specified as a 3-by-1 real-valued column vector or 3-by-*N* real-valued matrix. The dimensions of **Vel2** must match the dimensions of **Pos2**. If **Vel2** is a column vector, it takes the form `[Vx;Vy;Vz]`. If **Vel2** is a 3-by-*N* matrix, each column specifies a different origin velocity and has the form `[Vx;Vy;Vz]`. Velocity units are in meters per second.

Example: `[-1000;300;550]`

Data Types: `double`

Output

`Out` — Propagated signal

M-by-*N* complex-valued matrix | *M*-by-*2N* complex-valued matrix

- *M*-by-*N* complex-valued matrix. To return this format, set the `CombinedRaysOutput` property to `true`. Each matrix column contains the coherently combined signals from the line-of-sight path and the reflected path.
- *M*-by-*2N* complex-valued matrix. To return this format set the `CombinedRaysOutput` property to `false`. Alternate columns of the matrix contain the signals from the line-of-sight path and the reflected path.

The output **Out** contains signal samples arriving at the signal destination within the current input time frame. Whenever it takes longer than the current time frame for the signal to propagate from the origin to the destination, the output may not contain all contributions from the input of the current time frame. The remaining output will appear in the next execution of the block.

Parameters

`Signal propagation speed (m/s)` — Signal propagation speed
`physconst('LightSpeed')` (default) | real-valued positive scalar

Signal propagation speed, specified as a real-valued positive scalar. The default value of the speed of light is the value return by `physconst('LightSpeed')`.

`Signal carrier frequency (Hz)` — Signal carrier frequency
`300e6` (default) | positive real-valued scalar

Signal carrier frequency, specified as a positive real-valued scalar. Units are in hertz.

Data Types: `double`

`Number of subbands` — Number of processing subbands
`64` (default) | positive integer

Number of processing subbands, specified as a positive integer.

Example: `128`

`Specify atmospheric parameters` — Enable atmospheric attenuation model
off (default) | on

Select this parameter to enable to add signal attenuation caused by atmospheric gases, rain, fog, or clouds. When you select this parameter, the **Temperature (degrees Celsius)**, **Dry air pressure (Pa)**, **Water vapour density (g/m^3)**, **Liquid water density (g/m^3)**, and **Rain rate (mm/hr)** parameters appear in the dialog box.

Data Types: `Boolean`

`Temperature (degrees Celsius)` — Ambient temperature
`15` (default) | real-valued scalar

Ambient temperature, specified as a real-valued scalar. Units are in degrees Celsius.

Dependencies

To enable this parameter, select the **Specify atmospheric parameters** checkbox.

Data Types: `double`

`Dry air pressure (Pa)` — Atmospheric dry air pressure
`101.325e3` (default) | positive real-valued scalar

Atmospheric dry air pressure, specified as a positive real-valued scalar. Units are in pascals (Pa). The default value of this parameter corresponds to one standard atmosphere.

Dependencies

To enable this parameter, select the **Specify atmospheric parameters** checkbox.

Data Types: `double`

`Water vapour density (g/m^3)` — Atmospheric water vapor density
`7.5` (default) | positive real-valued scalar

Atmospheric water vapor density, specified as a positive real-valued scalar. Units are in g/m^3.

Dependencies

To enable this parameter, select the **Specify atmospheric parameters** checkbox.

Data Types: `datetime`

`Liquid water density (g/m^3)` — Liquid water density
`0.0` (default) | nonnegative real-valued scalar

Liquid water density of fog or clouds, specified as a nonnegative real-valued scalar. Units are in g/m^3. Typical values for liquid water density are 0.05 for medium fog and 0.5 for thick fog.

Dependencies

To enable this parameter, select the **Specify atmospheric parameters** checkbox.

Data Types: `double`

`Rain rate (mm/hr)` — Rainfall rate
`0.0` (default) | non-negative real-valued scalar

Rainfall rate, specified as a nonnegative real-valued scalar. Units are in mm/hr.

Dependencies

To enable this parameter, select the **Specify atmospheric parameters** checkbox.

Data Types: `double`

`Inherit sample rate` — Inherit sample rate from upstream blocks
on (default) | off

Select this parameter to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate (Hz)** parameter.

Data Types: `Boolean`

`Sample rate (Hz)` — Sampling rate of signal
`1e6` (default) | positive real-valued scalar

Specify the signal sampling rate as a positive scalar. Units are in Hz.

Dependencies

To enable this parameter, clear the **Inherit sample rate** parameter.

Data Types: `double`

`Ground reflection coefficient` — Ground reflection coefficient
-1 (default) | complex-valued scalar | complex-valued 1-by-*N* row vector

Ground reflection coefficient for the field at the reflection point, specified as a complex-valued scalar or a complex-valued 1-by-*N* row vector. Coefficients have an absolute value less than or equal to one. The quantity *N* is the number of two-ray channels. Units are dimensionless.

Example: `-0.5`

`Combine two rays at output` — Option to combine two rays at output
on (default) | off

Select this parameter to combine the two rays at channel output. Combining the two rays coherently adds the line-of-sight propagated signal and the reflected path signal to form the output signal. You can use this mode when you do not need to include the directional gain of an antenna or array in your simulation.

Example: on

`Maximum one-way propagation distance (m)` — Maximum one-way propagation distance
`10.0e3` (default) | positive real-valued scalar

Maximum one-way propagation distance, specified as a real-valued positive scalar. Units are in meters. Any signal that propagates more than the maximum one-way distance is ignored. The maximum distance must be greater than or equal to the largest position-to-position distance.

Example: `5000.0`

`Simulate using` — Block simulation method
`Interpreted Execution` (default) | `Code Generation`

Block simulation, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.
`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see "Choosing a Simulation Mode" (Simulink) from the Simulink documentation.

Data Types: `char`

Algorithms

When the origin and destination are stationary relative to each other, the block output can be written as $y(t) = x(t - \tau)/L$. The quantity τ is the delay and L is the propagation loss. The delay is computed from $\tau = R/c$ where R is the propagation distance and c is the propagation speed. The free space path loss is given by

$$L_{fsp} = \frac{(4\pi R)^2}{\lambda^2},$$

where λ is the signal wavelength.

This formula assumes that the target is in the far-field of the transmitting element or array. In the near-field, the free-space path loss formula is not valid and can result in losses smaller than one, equivalent to a signal gain. For this reason, the loss is set to unity for range values, $R \le \lambda/4\pi$.

When there is relative motion between the origin and destination, the processing also introduces a frequency shift. This shift corresponds to the Doppler shift between the origin and destination. The frequency shift is v/λ for one-way propagation and $2v/\lambda$ for two-way propagation. The parameter v is the relative speed of the destination with respect to the origin.

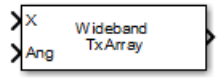
Wideband Transmit Array

Wideband transmit array



Library

Transmitters and Receivers

`phasedtxrxlib`

Description

The Wideband Transmit Array block transmits wideband plane waves from the elements of a sensor array. The block divides the transmitted signals into subbands and then applies a phase shift for each subband according to the radiating direction. The resulting subband signals are then combined to form the output.

Parameters

Signal Propagation speed (m/s)

Specify the propagation speed of the signal, in meters per second, as a positive scalar. You can use the function `physconst` to specify the speed of light.

Inherit sample rate

Select this check box to inherit the sample rate from upstream blocks. Otherwise, specify the sample rate using the **Sample rate** parameter.

Sample rate

Specify the signal sampling rate (in hertz) as a positive scalar. This parameter appears only when the **Inherit sample rate** parameter is not selected.

Assume modulated input

Select this check this box to indicate that the input signal is demodulated at a carrier frequency.

Carrier frequency

This parameter appears when the **Assume modulated input** check box is selected. The parameter specifies the carrier frequency, in hertz, as a positive scalar.

Number of subbands

The number of subbands used for subband processing, specified as a positive integer.

Enable weights input

Select this check box to specify array weights using the input port `W`. The input port appears only when this box is checked.

Simulate using

Block simulation method, specified as `Interpreted Execution` or `Code Generation`. If you want your block to use the MATLAB interpreter, choose `Interpreted Execution`. If you want your block to run as compiled code, choose `Code Generation`. Compiled code requires time to compile but usually runs faster.

Interpreted execution is useful when you are developing and tuning a model. The block runs the underlying System object in MATLAB. You can change and execute your model quickly. When you are satisfied with your results, you can then run the block using `Code Generation`. Long simulations run faster than they would in interpreted execution. You can run repeated executions without recompiling. However, if you change any block parameters, then the block automatically recompiles before execution.

When setting this parameter, you must take into account the overall model simulation mode. The table shows how the **Simulate using** parameter interacts with the overall simulation mode.

When the Simulink model is in `Accelerator` mode, the block mode specified using **Simulate using** overrides the simulation mode.

Acceleration Modes

Block Simulation	Simulation Behavior		
	`Normal`	`Accelerator`	`Rapid Accelerator`
`Interpreted Execution`	The block executes using the MATLAB interpreter.	The block executes using the MATLAB interpreter.	Creates a standalone executable from the model.

`Code Generation`	The block is compiled.	All blocks in the model are compiled.	

For more information, see “Choosing a Simulation Mode” (Simulink) from the Simulink documentation.

Array Parameters

Specify sensor array as

Sensor element or sensor array specified. A sensor array can also contain subarrays or as a partitioned array. This parameter can also be expressed as a MATLAB expression.

Types

`Single element`
`Array (no subarrays)`
`Partitioned array`
`Replicated subarray`
`MATLAB expression`

Geometry

Specify the array geometry as one of the following:

- `ULA` — Uniform linear array
- `URA` — Uniform rectangular array
- `UCA` — Uniform circular array
- `Conformal Array` — arbitrary element positions

Number of elements

Number of array elements.

Number of array elements, specified as a positive integer. This parameter appears when the **Geometry** is set to `ULA` or `UCA`. If **Sensor Array** has a `Replicated subarray` option, this parameter applies to the sub-array.

Array size

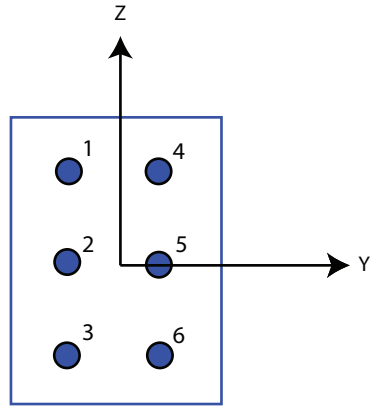
This parameter appears when **Geometry** is set to `URA`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to the subarrays.

Specify the size of the array as a positive integer or 1-by-2 vector of positive integers.

- If **Array size** is a 1-by-2 vector, the vector has the form `[NumberOfArrayRows,NumberOfArrayColumns]`.
- If **Array size** is an integer, the array has the same number of rows and columns.

For a URA, elements are indexed from top to bottom along a column and continuing to the next columns from left to right. In this figure, an **Array size** of `[3,2]` produces an array of three rows and two columns.

Size and Element Indexing Order
for Uniform Rectangular Arrays
Example: Size = [3,2]



Element spacing (m)

This parameter appears when **Geometry** is set to ULA or URA. When **Sensor Array** has the `Replicated subarray` option, this parameter applies to the subarrays.

- For a ULA, specify the spacing, in meters, between two adjacent elements in the array as a scalar.
- For a URA, specify the element spacing of the array, in meters, as a 1-by-2 vector or a scalar. If **Element spacing** is a 1-by-2 vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumns]`. For a discussion of these quantities, see phased.URA. If **Element spacing** is a scalar, the spacings between rows and columns are equal.

Array axis

This parameter appears when the **Geometry** parameter is set to `ULA` or when the block only supports a ULA array geometry. Specify the array axis as `x`, `y`, or `z`. All ULA array elements are uniformly spaced along this axis in the local array coordinate system.

Array normal

This parameter appears when you set **Geometry**to `URA` or `UCA`. Specify the **Array normal** as `x`, `y`, or `z`. All URA and UCA array elements are placed in the *yz*, *zx*, or *xy*planes, respectively, of the array coordinate system.

Radius of UCA (m)

Radius of a uniform circular array specified as a positive scalar. Units are meters.

This parameter appears when the **Geometry** is set to `UCA`.

Taper

Tapers, also known as *element weights*, are applied to sensor elements in the array. Tapers are used to modify both the amplitude and phase of the transmitted or received data.

This parameter applies to all array types, but when you set **Sensor Array** to `Replicated subarray`, this parameter applies to subarrays.

- For a `ULA` or `UCA`, specify element tapering as a complex-valued scalar or a complex-valued 1-by-*N* row vector. In this vector, *N* represents the number of elements in the array. If **Taper** is a scalar, the same weight is applied to each element. If **Taper** is a vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.
- For a `URA`, specify element tapering as a complex-valued scalar or complex-valued *M*-by-*N* matrix. In this matrix, *M* is the number of elements along the *z*-axis, and *N* is the number of elements along the *y*-axis. *M* and *N* correspond to the values of `[NumberofArrayRows,NumberOfArrayColumns]` in the **Array size** matrix. If `Taper` is a scalar, the same weight is applied to each element. If **Taper** is a matrix, a weight from the matrix is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.
- For a `Conformal Array`, specify element tapering as a complex-valued scalar or complex-valued 1-by-*N* vector. In this vector, *N* is the number of elements in the array as determined by the size of the **Element positions** vector. If **Taper** is a scalar, the same weight is applied to each element. If the value of **Taper** is a

vector, a weight from the vector is applied to the corresponding sensor element. A weight must be applied to each element in the sensor array.

Element lattice

This parameter appears when **Geometry** is set to `URA`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to the subarray.

Specify the element lattice as `Rectangular` or `Triangular`

- `Rectangular` — Aligns all the elements in row and column directions.
- `Triangular`— Shifts the even-row elements of a rectangular lattice toward the positive-row axis direction. The displacement is one-half the element spacing along the row dimension.

Element positions (m)

This parameter appears when **Geometry** is set to `Conformal Array`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to subarrays.

Specify the positions of conformal array elements as a 3-by-*N* matrix, where *N* is the number of elements in the conformal array. Each column of **Element positions (m)** represents the position of a single element, in the form `[x;y;z]`, in the array's local coordinate system. The local coordinate system has its origin at an arbitrary point. Units are in meters.

Element normals (deg)

This parameter appears when **Geometry** is set to `Conformal Array`. When **Sensor Array** is set to `Replicated subarray`, this parameter applies to subarrays.

Specify the normal directions of the elements in a conformal array as a 2-by-*N* matrix or a 2-by-1 column vector in degrees. The variable *N* indicates the number of elements in the array. If **Element normals (deg)** is a matrix, each column specifies the normal direction of the corresponding element in the form `[azimuth;elevation]`, with respect to the local coordinate system. The local coordinate system aligns the positive *x*-axis with the direction normal to the conformal array. If **Element normals (deg)** is a 2-by-1 column vector, the vector specifies the same pointing direction for all elements in the array.

You can use the **Element positions (m)** and **Element normals (deg)** parameters to represent any arrangement in which pairs of elements differ by certain transformations. You can combine translation, azimuth rotation, and elevation rotation transformations. However, you cannot use transformations that require rotation about the normal.

Subarray definition matrix

This parameter appears when **Sensor array** is set to `Partitioned array`.

Specify the subarray selection as an *M*-by-*N* matrix. *M* is the number of subarrays and *N* is the total number of elements in the array. Each row of the matrix indicates which elements belong to the corresponding subarray. Each entry in the matrix is 1 or 0, where 1 indicates that the element appears in the subarray and 0 indicates the opposite. Each row must contain at least one 1.

The phase center of each subarray is its geometric center. **Subarray definition matrix** and **Geometry** determine the geometric center.

Subarray steering method

This parameter appears when **Sensor array** is set to `Partitioned array` or `Replicated subarray`.

Specify the subarray steering method as

- `None`
- `Phase`
- `Time`

When using the Narrowband Receive Array, Narrowband Transmit Array, Wideband Receive Array, or Wideband Transmit Arrayblocks, selecting `Phase` or `Time` opens the block input port, `Steer`.

Phase shifter frequency (Hz)

This parameter appears when you set **Sensor array** to `Partitioned array` or `Replicated subarray` and you set **Subarray steering method** to `Phase`.

Specify the operating frequency, in hertz, of phase shifters to perform subarray steering as a positive scalar.

Number of bits in phase shifters

This parameter appears when you set **Sensor array** to `Partitioned array` or `Replicated subarray` and you set **Subarray steering method** to `Phase`.

The number of bits used to quantize the phase shift component of beamformer or steering vector weights. Specify the number of bits as a non-negative integer. A value of zero indicates that no quantization is performed.

Subarrays layout

This parameter appears when you set **Sensor array** to `Replicated subarray`.

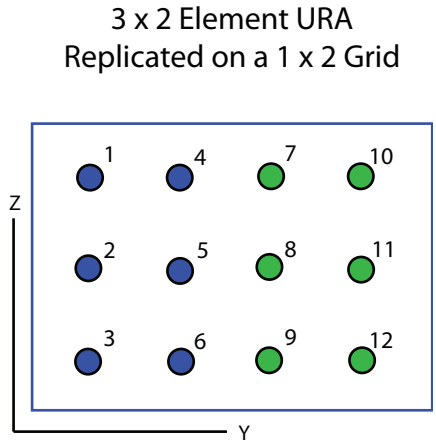
Specify the layout of the replicated subarrays as `Rectangular` or `Custom`.

Grid size

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

Rectangular subarray grid size, specified as a single positive integer or a positive integer-valued 1-by-2 row vector.

If **Grid size** is an integer scalar, the array has an equal number of subarrays in each row and column. If **Grid size** is a 1-by-2 vector of the form `[NumberOfRows, NumberOfColumns]`, the first entry is the number of subarrays along each column. The second entry is the number of subarrays in each row. A row is along the local *y*-axis, and a column is along the local *z*-axis. The figure here shows how you can replicate a 3-by-2 URA subarray using a **Grid size** of `[1,2]`.



Grid spacing

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Rectangular`.

Specify the rectangular grid spacing of subarrays as a real-valued positive scalar, a 1-by-2 row vector, or `Auto`. Grid spacing units are expressed in meters.

- If **Grid spacing** is a scalar, the spacing along the row and the spacing along the column is the same.

- If **Grid spacing** is a 1-by-2 row vector, the vector has the form `[SpacingBetweenRows,SpacingBetweenColumn]`. The first entry specifies the spacing between rows along a column. The second entry specifies the spacing between columns along a row.
- If **Grid spacing** is set to `Auto`, replication preserves the element spacing of the subarray for both rows and columns while building the full array. This option is available only when you specify **Geometry** as `ULA` or `URA`.

Subarray positions (m)

This parameter appears when you set **Sensor array** to `Replicated subarray` and **Subarrays layout** to `Custom`.

Specify the positions of the subarrays in the custom grid as a 3-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix represents the position of a single subarray, in meters, in the array's local coordinate system. The coordinates are expressed in the form `[x; y; z]`.

Subarray normals

This parameter appears when you set the **Sensor array** parameter to `Replicated subarray` and the **Subarrays layout** to `Custom`.

Specify the normal directions of the subarrays in the array. This parameter value is a 2-by-*N* matrix, where *N* is the number of subarrays in the array. Each column of the matrix specifies the normal direction of the corresponding subarray, in the form `[azimuth; elevation]`. Each angle is in degrees and is defined in the local coordinate system.

You can use the **Subarray positions** and **Subarray normals** parameters to represent any arrangement in which pairs of subarrays differ by certain transformations. The transformations can combine translation, azimuth rotation, and elevation rotation. However, you cannot use transformations that require rotation about the normal.

Expression

A valid MATLAB expression containing an array constructor, for example, `phased.URA`.

Sensor Array Tab: Element Parameters

Element type

Specify antenna or microphone type as

- `Isotropic Antenna`
- `Cosine Antenna`
- `Custom Antenna`
- `Omni Microphone`
- `Custom Microphone`

Exponent of cosine pattern

This parameter appears when you set **Element type** to `Cosine Antenna`.

Specify the exponent of the cosine pattern as a scalar or a 1-by-2 vector. You must specify all values as non-negative real numbers. When you set **Exponent of cosine pattern** to a scalar, both the azimuth direction cosine pattern and the elevation direction cosine pattern are raised to the specified value. When you set **Exponent of cosine pattern** to a 1-by-2 vector, the first element is the exponent for the azimuth direction cosine pattern and the second element is the exponent for the elevation direction cosine pattern.

Operating frequency range (Hz)

This parameter appears when **Element type** is set to `Isotropic Antenna`, `Cosine Antenna`, or `Omni Microphone`.

Specify the operating frequency range, in hertz, of the antenna element as a 1-by-2 row vector in the form `[LowerBound,UpperBound]`. The antenna element has no response outside the specified frequency range.

Operating frequency vector (Hz)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify the frequencies, in Hz, at which to set the antenna and microphone frequency responses as a 1-by-*L* row vector of increasing values. Use **Frequency responses** to set the frequency responses. The antenna or microphone element has no response outside the frequency range specified by the minimum and maximum elements of **Operating frequency vector (Hz)**.

Frequency responses (dB)

This parameter appears when **Element type** is set to `Custom Antenna` or `Custom Microphone`.

Specify this parameter as the frequency response of an antenna or microphone, in decibels, for the frequencies defined by **Operating frequency vector (Hz)**. Specify **Frequency responses (dB)** as a 1-by-*L* vector matching the dimensions of the vector specified in **Operating frequency vector (Hz)**.

Azimuth angles (deg)

This parameter appears when **Element type** is set to `Custom Antenna`.

Specify the azimuth angles at which to calculate the antenna radiation pattern as a 1-by-*P* row vector. *P* must be greater than 2. Angle units are in degrees. Azimuth angles must lie between –180° and 180° and be in strictly increasing order.

Elevation angles (deg)

This parameter appears when the **Element type** is set to `Custom Antenna`.

Specify the elevation angles at which to compute the radiation pattern as a 1-by-*Q* vector. *Q* must be greater than 2. Angle units are in degrees. Elevation angles must lie between –90° and 90° and be in strictly increasing order.

Radiation pattern (dB)

This parameter appears when the **Element type** is set to `Custom Antenna`.

The magnitude in db of the combined polarized antenna radiation pattern specified as a *Q*-by-*P* matrix or a *Q*-by-*P*-by-*L* array. The value of *Q* must match the value of *Q* specified by **Elevation angles (deg)**. The value of *P* must match the value of *P* specified by **Azimuth angles (deg_**. The value of *L* must match the value of *L* specified by **Operating frequency vector (Hz)**.

Polar pattern frequencies (Hz)

This parameter appears when the **Element type** is set to `Custom Microphone`.

Specify the measuring frequencies of the polar patterns as a 1-by-*M* vector. The measuring frequencies lie within the frequency range specified by**Operating frequency vector (Hz)**. Frequency units are in Hz.

Polar pattern angles (deg)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the measuring angles of the polar patterns, as a 1-by-*N* vector. The angles are measured from the central pickup axis of the microphone, and must be between –180° and 180°, inclusive.

Polar pattern (dB)

This parameter appears when **Element type** is set to `Custom Microphone`.

Specify the magnitude of the microphone element polar pattern as an *M*-by-*N* matrix. *M* is the number of measuring frequencies specified in **Polar pattern frequencies (Hz)**. *N* is the number of measuring angles specified in **Polar pattern angles (deg)**. Each row of the matrix represents the magnitude of the polar pattern measured at the corresponding frequency specified in **Polar pattern frequencies (Hz)** and all angles specified in **Polar pattern angles (deg)**. Assume that the pattern is measured in the azimuth plane. In the azimuth plane, the elevation angle is 0° and the central pickup axis is 0° degrees azimuth and 0° degrees elevation. Assume that the polar pattern is symmetric around the central axis. You can construct the microphone's response pattern in 3-D space from the polar pattern.

Baffle the back of the element

This check box appears only when the **Element type** parameter is set to `Isotropic Antenna` or `Omni Microphone`.

Select this check box to baffle the back of the antenna element. In this case, the antenna responses to all azimuth angles beyond ±90° from *broadside* are set to zero. Define the broadside direction as 0° azimuth angle and 0° elevation angle.

Ports

Note: The block input and output ports correspond to the input and output parameters described in the `step` method of the underlying System object. See link at the bottom of this page.

Port	Description	Supported Data Types
`X`	Input signals The size of the first dimension of this input matrix can vary to simulate a changing signal length, such as a pulse waveform with variable pulse repetition frequency.	Double-precision floating point

Port	Description	Supported Data Types
`Ang`	Radiating directions	Double-precision floating point
`W`	Weights vector	Double-precision floating point
`Out`	Output signals	Double-precision floating point

App Reference

Radar Equation Calculator

Estimate maximum range, peak power, and SNR of a radar system

Description

The **Radar Equation Calculator** app solves the basic radar equation for monostatic or bistatic radar systems. The radar equation relates target range, transmitted power, and received signal SNR. Using this app, you can:

- Solve for maximum target range based on the transmit power of the radar and specified received SNR
- Calculate required transmit power based on known target range and specified received SNR
- Calculate the received SNR value based on known range and transmit power

Open the Radar Equation Calculator App

- MATLAB Toolstrip: On the **Apps** tab, under **Signal Processing and Communications**, click the app icon.
- MATLAB command prompt: Enter `radarEquationCalculator`.

Examples

Maximum Detection Range of a Monostatic Radar

This example shows how to compute the maximum detection range of a 10 GHz, 1 kW, monostatic radar with a 40 dB antenna gain and a detection threshold of 10 dB.

From the **Calculation Type** drop-down list, choose **Target Range** as the solution.

Choose **Configuration** as `monostatic`.

Enter 40 dB for the antenna **Gain**.

Set the **Wavelength** to 3 cm.

Set the **SNR** detection threshold parameter to 10 dB.

Assuming the target is a large airplane, set the **Target Radar Cross Section** value to 100 m^2.

Specify the **Peak Transmit Power** as 1 kW

Specify the **Pulse Width** as 2 μs.

Assume a total of 5 dB **System Losses**.

Maximum Detection Range of a Monostatic Radar Using Multiple Pulses

This example shows how to use multiple pulses to reduce the transmitted power while maintaining the same maximum target range.

Continue with the results from the previous example.

Click the arrows to the right of the **SNR** label.

The **Detection Specifications for SNR** menu opens.

Set **Probability of Detection** to 0.95.

Set **Probability of False Alarm** to 10^{-6}.

Set **Number of Pulses** to 4.

Reduce **Peak Transmit Power** to 0.75 kW.

Assume a nonfluctuating target model, and set the **Swerling Case Number** is 0.

The maximum detection range is approximately the same as in the previous example, but the transmitted power is reduced by 25%.

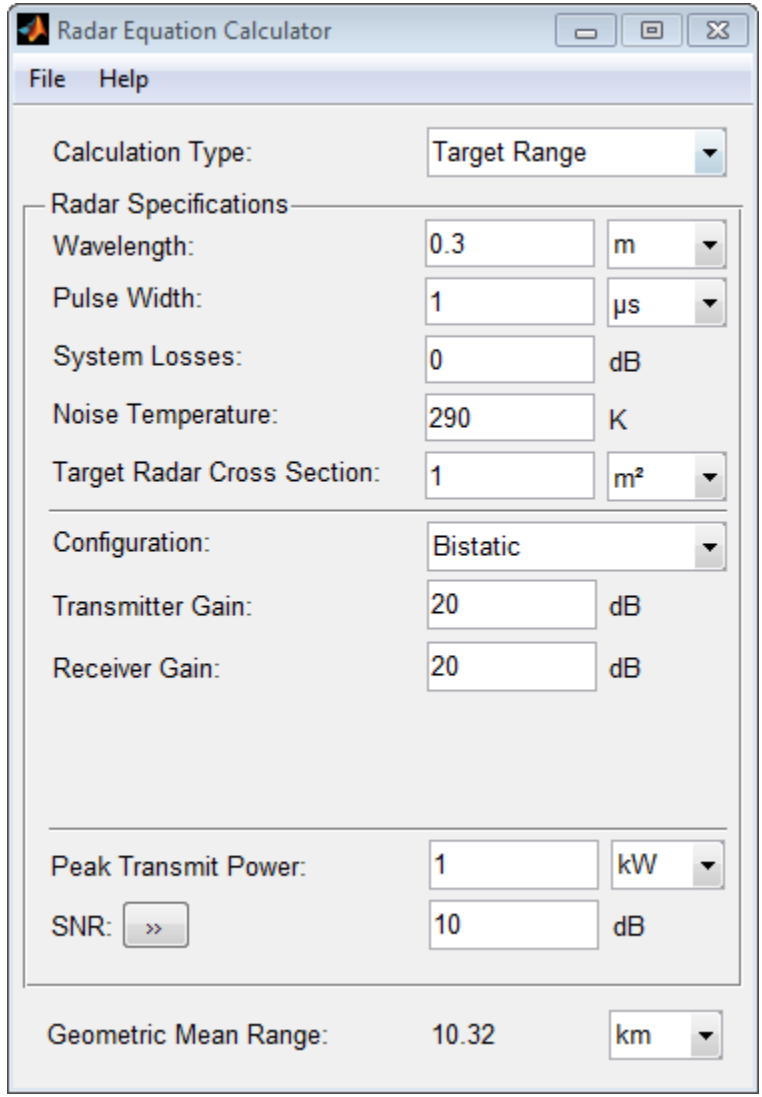
Maximum Detection Range of Bistatic Radar System

This example shows how to solve for the geometric mean range of a target for a bistatic radar system.

Specify the **Calculation Type** as `Target Range`.

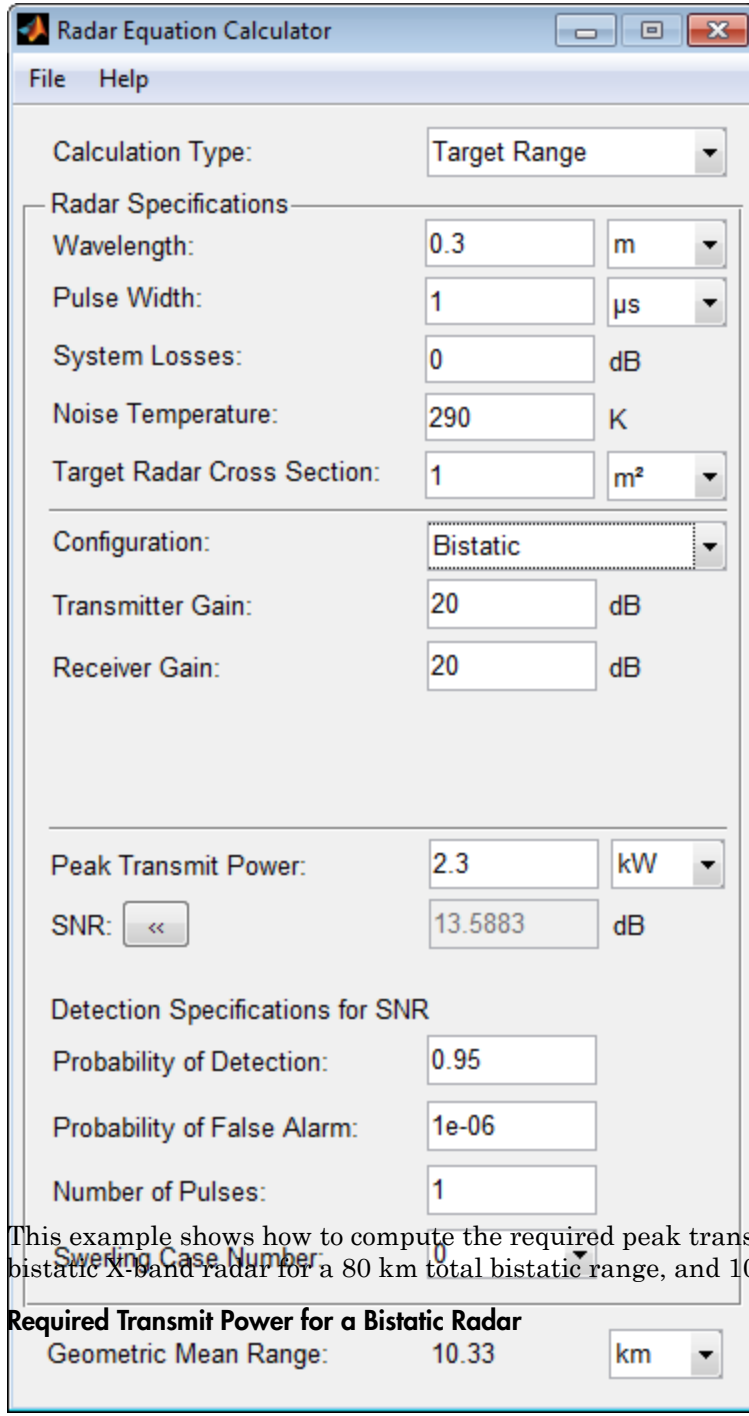
Specify the **Configuration** as `bistatic`.

Provide a **Transmitter Gain** and a **Receiver Gain** parameter, instead of the single gain needed in the monostatic case.



Alternatively, to achieve a particular probability of detection and probability of false alarm, open the **Detection Specifications for SNR** menu.

Enter values for **Probability of Detection** and **Probability of False Alarm**, **Number of Pulses**, and **Swerling Case Number**.



This example shows how to compute the required peak transmit power of a 10 GHz, bistatic X-band radar for a 80 km total bistatic range, and 10 dB received SNR.

The system has a 40 dB transmitter gain and a 20 dB receiver gain. The required receiver SNR is 10 dB.

From the **Calculation Type** drop-down list, choose **Peak Transmit Power** as the solution type.

Choose **Configuration** as `bistatic`.

From the system specifications, set **Transmitter Gain** to 40 dB and **Receiver Gain** to 20 dB.

Set the **SNR** detection threshold to 10 dB and the **Wavelength** to 0.3 m.

Assume the target is a fighter aircraft having a **Target Radar Cross Section** value of 2 m^2.

Choose **Range from Transmitter** as 50 km, and **Range from Receiver** as 30 km.

Set the **Pulse Width** to 2 μs and the **System Losses** to 0 dB.

Receiver SNR for a Monostatic Radar

This example shows how to compute the received SNR for a monostatic radar with 1 kW peak transmit power with a target at a range of 2 km.

Assume a 2 GHz radar frequency and 20 dB antenna gain.

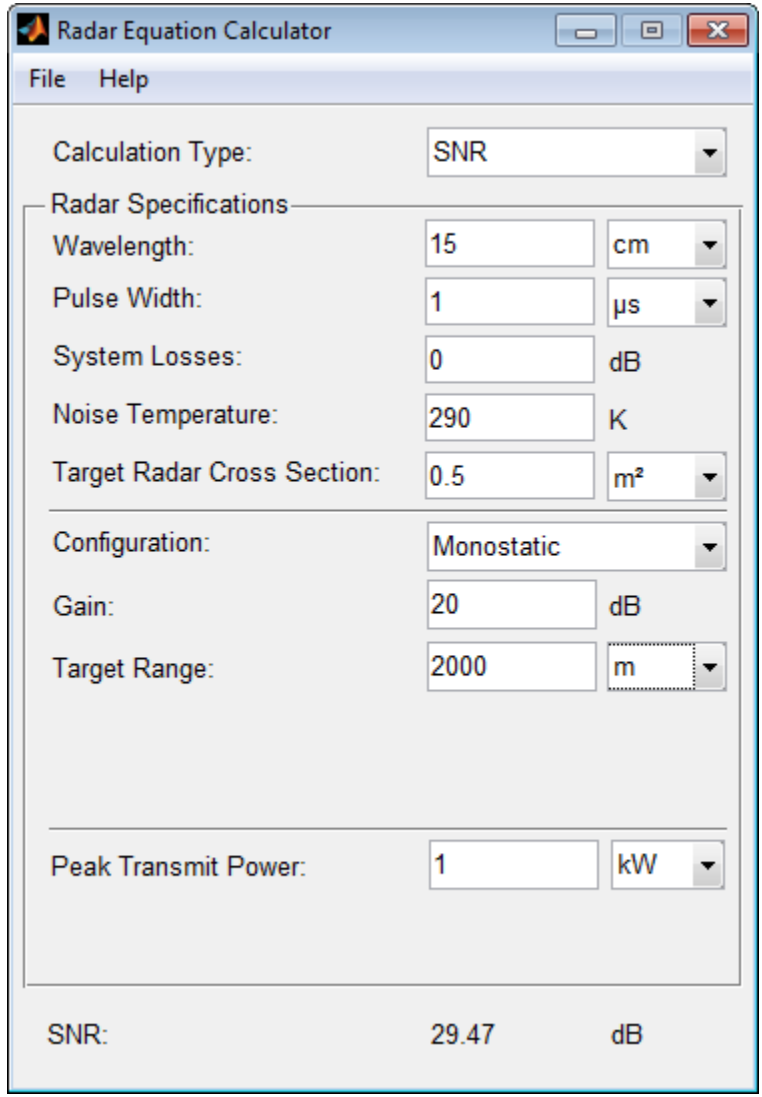
From the **Calculation Type** drop-down list, choose **SNR** as the solution type and set the **Configuration** as `monostatic`.

Set the **Gain** to 20, the **Peak Transmit Power** to 1 kW, and the **Target Range** to 2000 m.

Set the **Wavelength** to 15 cm.

Find the received SNR of a small boat having a **Target Radar Cross Section** value of 0.5 m^2.

The **Pulse Width** is 1 μs and **System Losses** are 0 dB.



- "Detection, Range and Doppler Estimation"

Parameters

`Calculation Type` — Type of calculation to perform

`Target Range` (default) | `Peak Transmit Power` | `SNR`

`Target Range` – solves for maximum target range based on transmit power of the radar and desired received SNR.

`Peak Transmit – Power` computes power needed to transmit based on known target range and desired received SNR.

`SNR` – calculates the received SNR value based on known range and transmit power.

`Wavelength` — Wavelength of radar operating frequency

0.3 m (default) | `m` | `cm` | `mm`

Specify the wavelength of radar operating frequency in `m`, `cm`, or `mm`.

The wavelength is the ratio of the wave propagation speed to frequency. For electromagnetic waves, the speed of propagation is the speed of light.

Denoting the speed of light by c and the frequency (in hertz) of the wave by f, the equation for wavelength is:

$$\lambda = \frac{c}{f}$$

`Pulse Width` — Single pulse duration

1 μs (default) | `μs` | `ms` | `s`

Specify the single pulse duration in `μs`, `ms`, or `s`.

`System Losses` — System loss in decibels (dB)

0 dB (default)

System Losses represents a general loss factor that comprises losses incurred in the system components and in the propagation to and from the target.

`Noise Temperature` — System noise temperature in kelvins

290 K (default)

The system noise temperature is the product of the system temperature and the noise figure.

`Target Radar Cross Section` — Radar cross section (RCS)
`1 m²` (default) | `m²` | `dBsm`

Specify the target radar cross section in `m²`, or `dBsm`.

The target radar cross section is nonfluctuating.

`Configuration` — Type of radar system
`Monostatic` (default) | `Bistatic`

`Monostatic` – Transmitter and receiver are colocated (monostatic radar).

`Bistatic` – Transmitter and receiver are not colocated (bistatic radar).

`Gain` — Transmitter and receiver gain in decibels (dB)
20 dB (default)

When the transmitter and receiver are colocated (monostatic radar), the transmit and receive gains are equal.

This parameter is enabled only if the **Configuration** is set to `Monostatic`.

`Peak Transmit Power` — Transmitter peak power
1 kw (default) | `kW` | `mW` | `W` | `dBW`

Specify the transmitter peak power in `kW`, `mW`, `W`, or `dBW`.

This parameter is enabled only if the **Calculation Type** is set to `Target Range` or `SNR`.

`SNR` — Minimum output signal-to-noise ratio at the receiver in decibels
10 dB (default)

Specify an SNR value, or calculate an SNR value using Detection Specifications for SNR.

You can calculate the SNR required to achieve a particular probability of detection and probability of false alarm using Shnidman's equation. To calculate the SNR value:

1. Click the arrows to the right of the **SNR** label to open the Detection Specifications for SNR menu.

2 Enter values for Probability of Detection, Probability of False Alarm, Number of Pulses, and Swerling Case Number.

This parameter is enabled only if the **Calculation Type** is set to `Target Range` or `Peak Transmit Power`.

`Probability of Detection` — Detection probability used to estimate SNR
0.81029 (default)

Specify the detection probability used to estimate SNR using Shnidman's equation.

This parameter is enabled only when the **Calculation Type** is set to `Peak Transmit Power` or `Target Range`, and you select the Detection Specifications for SNR button for the **SNR** parameter.

`Probability of False Alarm` — False alarm probability used to estimate SNR
0.001 (default)

Specify the false-alarm probability used to estimate SNR using Shnidman's equation.

This parameter is enabled only when the **Calculation Type** is set to `Peak Transmit Power` or `Target Range`, and you select the Detection Specifications for SNR button for the **SNR** parameter.

`Number of Pulses` — Number of pulses used to estimate SNR
1 (default)

Specify a single pulse, or the number of pulses used for noncoherent integration in Shnidman's equation.

Use multiple pulses to reduce the transmitted power while maintaining the same maximum target range.

This parameter is enabled only when the **Calculation Type** is set to `Peak Transmit Power` or `Target Range`, and you select the Detection Specifications for SNR button for the **SNR** parameter.

`Swerling Case Number` — Swerling case number used to estimate SNR
0 (default) | 1 | 2 | 3 | 4

Specify the Swerling case number used to estimate SNR using Shnidman's equation:

- **0** – Nonfluctuating pulses.
- **1** – Scan-to-scan decorrelation. Rayleigh/exponential PDF–A number of randomly distributed scatterers with no dominant scatterer.
- **2** – Pulse-to-pulse decorrelation. Rayleigh/exponential PDF– A number of randomly distributed scatterers with no dominant scatterer.
- **3** – Scan-to-scan decorrelation. Chi-square PDF with 4 degrees of freedom. A number of scatterers with one dominant.
- **4** – Pulse-to-pulse decorrelation. Chi-square PDF with 4 degrees of freedom. A number of scatterers with one dominant.

Swerling case numbers characterize the detection problem for fluctuating pulses in terms of:

- A decorrelation model for the received pulses.
- The distribution of scatterers affecting the probability density function (PDF) of the target radar cross section (RCS).

The Swerling case numbers consider all combinations of two decorrelation models (scan-to-scan; pulse-to-pulse) and two RCS PDFs (based on the presence or absence of a dominant scatterer).

This parameter is enabled only when the **Calculation Type** is set to `Peak Transmit Power` or `Target Range`, and you select the Detection Specifications for SNR button for the **SNR** parameter.

`Target Range` — Range to target

10 km (default) | `km` | `m` | `mi` | `nmi`

Specify target range in `m`, `km`, `mi`, or `nmi`.

This parameter is enabled only when the **Calculation Type** is set to `Peak Transmit Power` or `SNR`, and the **Configuration** is set to `Monostatic`.

`Transmitter Gain` — Transmitter gain in decibels (dB)

20 dB (default)

When the transmitter and receiver are not colocated (bistatic radar), specify the transmitter gain separately from the receiver gain.

This parameter is enabled only if the **Configuration** is set to `Bistatic`.

`Range from Transmitter` — Range from the transmitter to the target
10 km (default) | `km` | `m` | `mi` | `nmi`

When the transmitter and receiver are not colocated (bistatic radar), specify the transmitter range separately from the receiver range.

You can specify range in `m`, `km`, `mi`, or `nmi`.

This parameter is enabled only when the **Calculation Type** is set to `Peak Transmit Power` or `SNR`, and the **Configuration** is set to `Bistatic`.

`Receiver Gain` — Receiver gain in decibels (dB)
20 dB (default)

When the transmitter and receiver are not colocated (bistatic radar), specify the receiver gain separately from the transmitter gain.

This parameter is enabled only if the **Configuration** is set to `Bistatic`.

`Range from Receiver` — Range from the target to the receiver
10 km (default) | `km` | `m` | `mi` | `nmi`

When the transmitter and receiver are not colocated (bistatic radar), specify the receiver range separately from the transmitter range.

You can specify range in `m`, `km`, `mi`, or `nmi`.

This parameter is enabled only when the **Calculation Type** is set to `Peak Transmit Power` or `SNR`, and the **Configuration** is set to `Bistatic`.

Radar Waveform Analyzer

Analyze performance characteristics of pulsed, frequency modulated, and phase-coded waveforms

Description

The **Radar Waveform Analyzer** app lets you explore the properties of signals that are commonly used in radar and sonar systems, and to produce plots and images to visualize waveforms.

The app lets you determine the basic characteristics of these waveforms

- Rectangular
- Linear frequency modulation (LFM)
- Stepped FM
- Phase-coded waveforms
- Frequency modulation constant waveform (FMCW)

You can quickly modify parameters for each waveform, such as pulse repetition frequency (PRF), sample rate, pulse duration, and bandwidth. You can also set the propagation speed to represent electromagnetic waves, or sound waves in air or water.

After you configure parameters, the app displays basic waveform characteristics such as range resolution, Doppler resolution, and maximum range. It also can generate a variety of plots and images to visualize the waveform, including:

- Real and imaginary components
- Magnitude and phase
- Spectrum
- Ambiguity function (AF) representations, including contour, surface, delay cut, and Doppler cut
- Autocorrelation function

Open the Radar Waveform Analyzer App

- MATLAB Toolstrip: On the **Apps** tab, under **Signal Processing and Communications**, click the app icon.

- MATLAB command prompt: Enter `radarWaveformAnalyzer`.

Examples

Rectangular Waveform

This example shows how to analyze a rectangular waveform.

In the Waveform Settings panel, set the **Waveform** to `Rectangular`.

An ideal rectangular waveform jumps instantaneously to a finite value and stays there for some duration.

Assume the radar is designed for a maximum range of 50 km.

For this range, the time for a signal to propagate to that range and return is 333 µs. Therefore, you must allow 333 µs between pulses, equivalent to a maximum pulse repetition frequency (**PRF)**) of 3000 Hz.

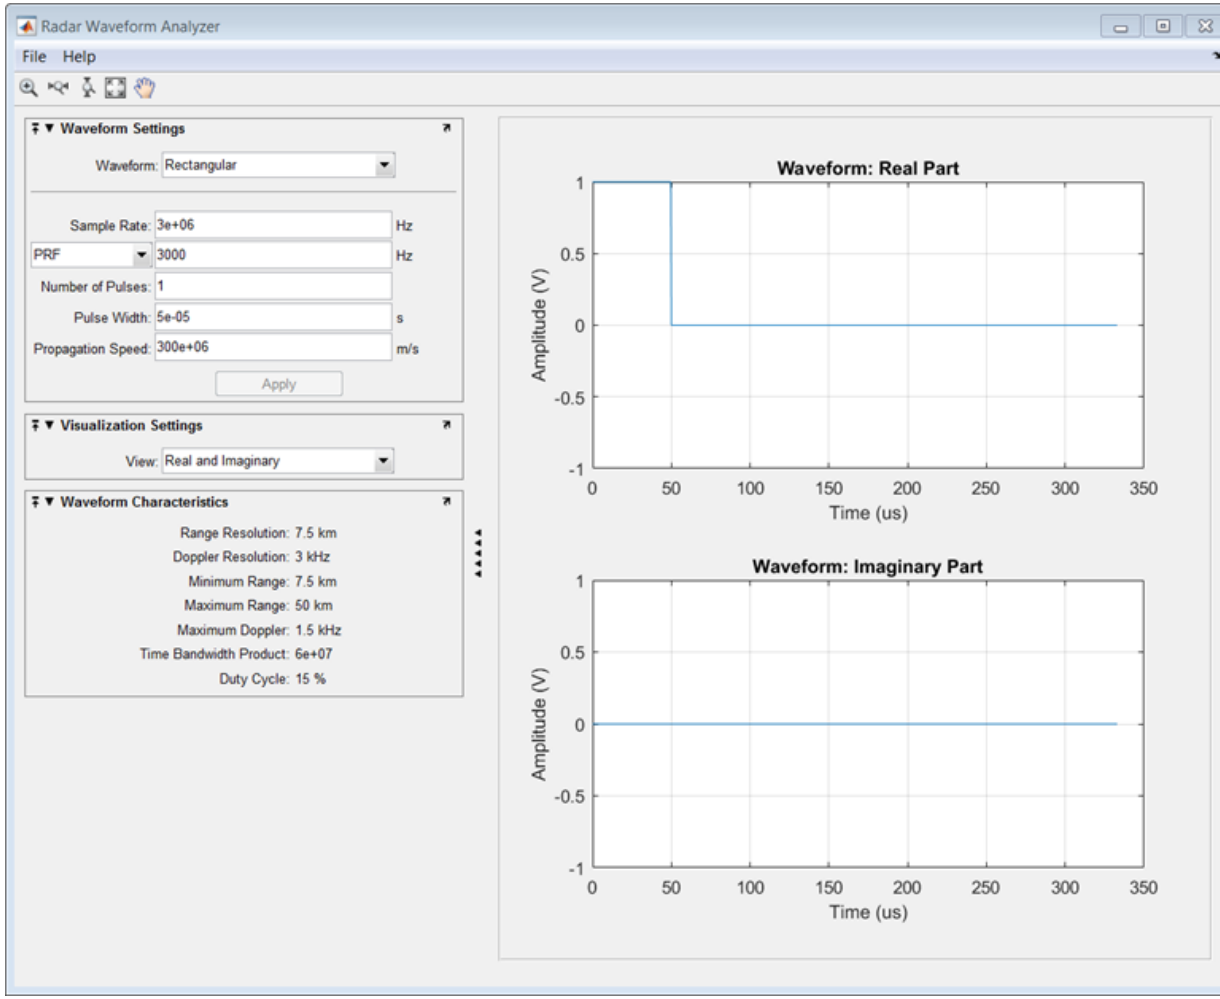
Set the **Pulse Width** to 50 µs.

With these values, the app displays a 7.5 km range resolution.

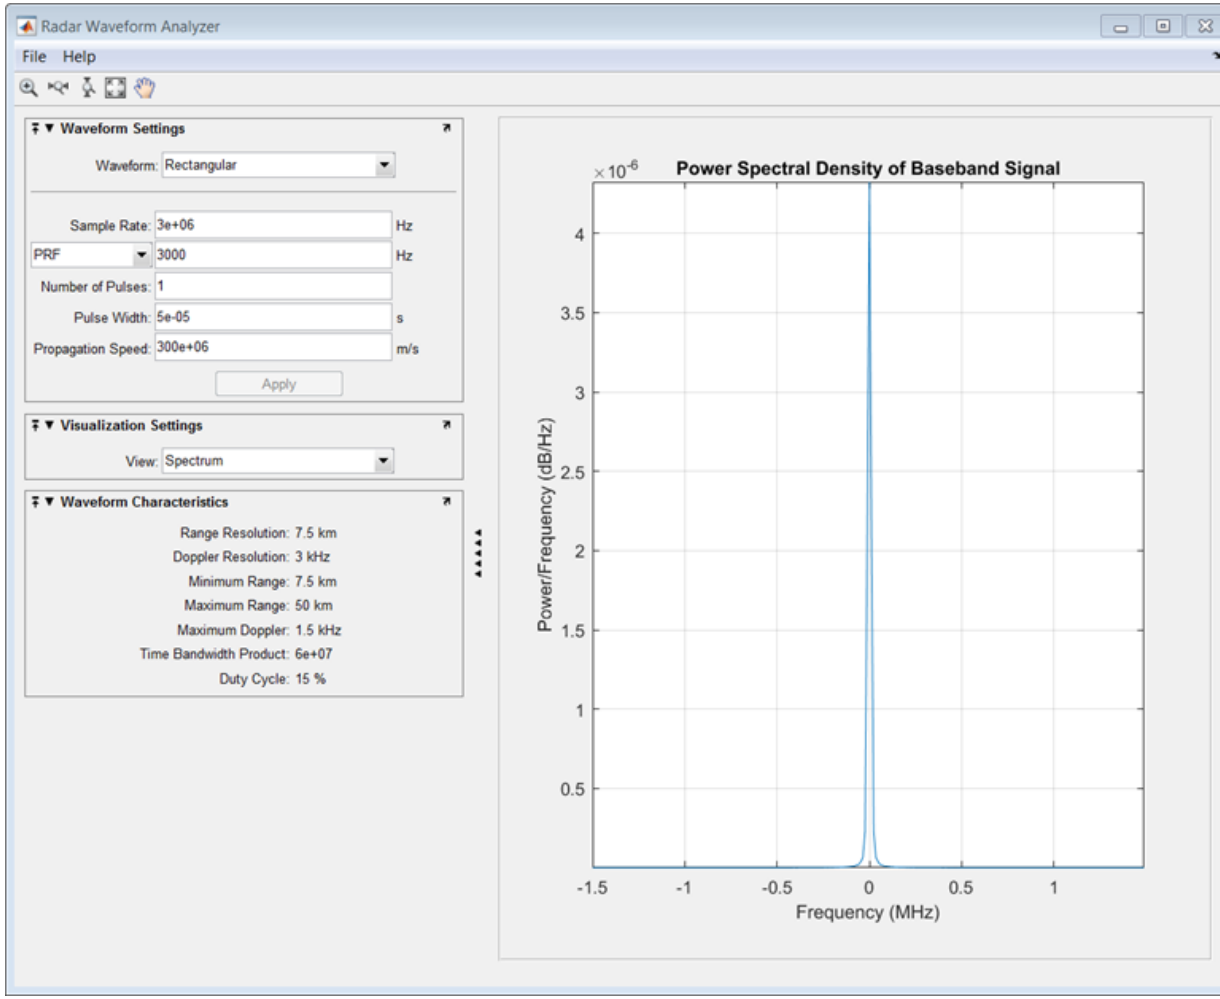
The resolution of a rectangular pulse is roughly 1/2 the pulse-width multiplied by the speed of light, which is entered here in the **Propagation Speed** field as 300e6 m/s. The Doppler resolution is approximately the width of the Fourier transform of the pulse.

The same analysis can be used for sonar if you assume a much smaller speed of propagation, 1500 m/s.

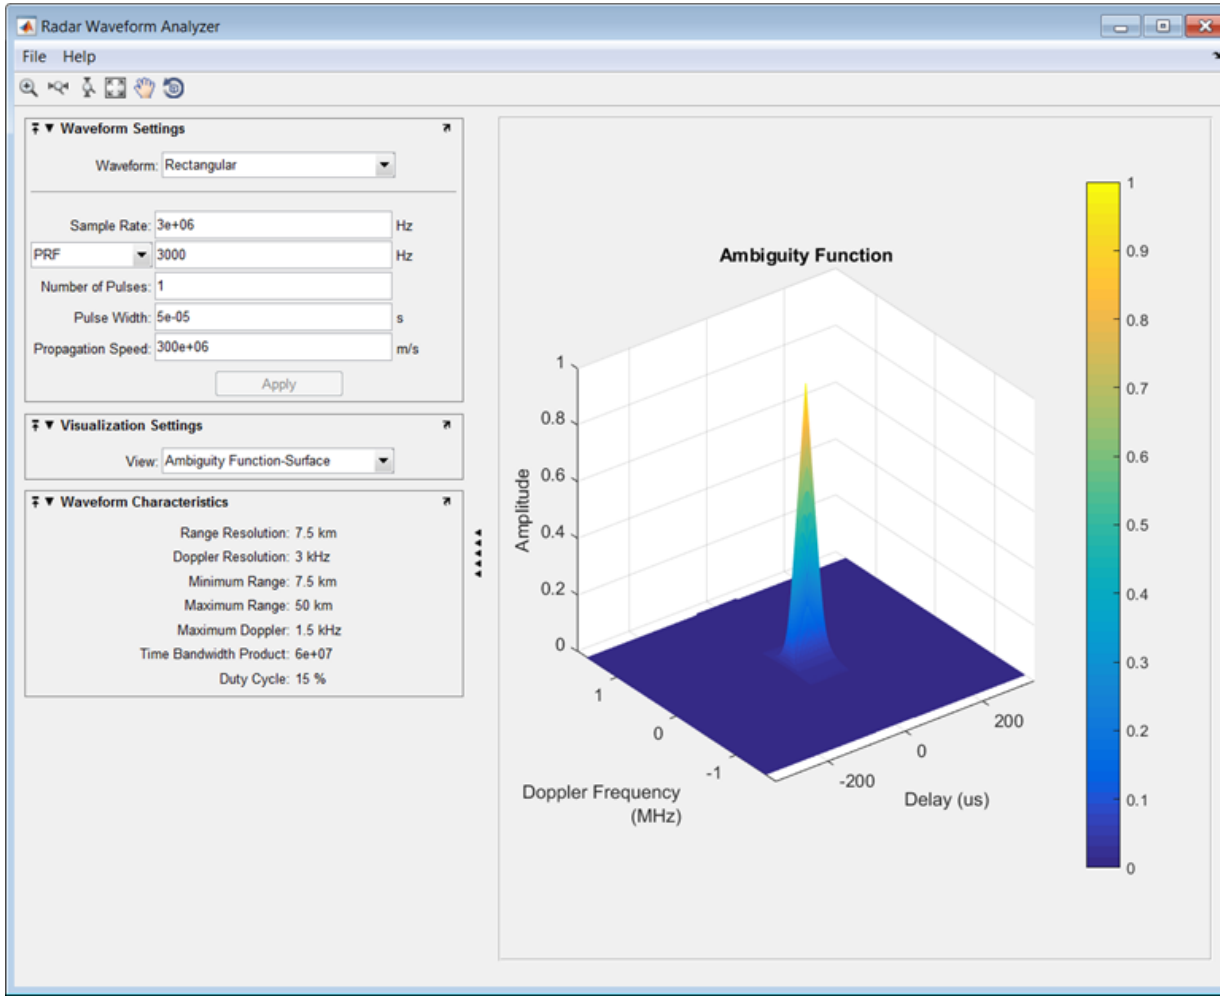
The following figure shows the real and imaginary parts of the waveform. This is the default view on the **View** drop-down list.



Next, you can view the signal spectrum. To do so, select `Spectrum` from the **View** drop-down menu.



Finally, you can display the joint range-Doppler resolution by selecting `Ambigity-Function Surface` from the **View** pull-down menu in the Visualization Settings panel.



Linear FM Waveform

This example shows how to improve range resolution using a linear FM waveform.

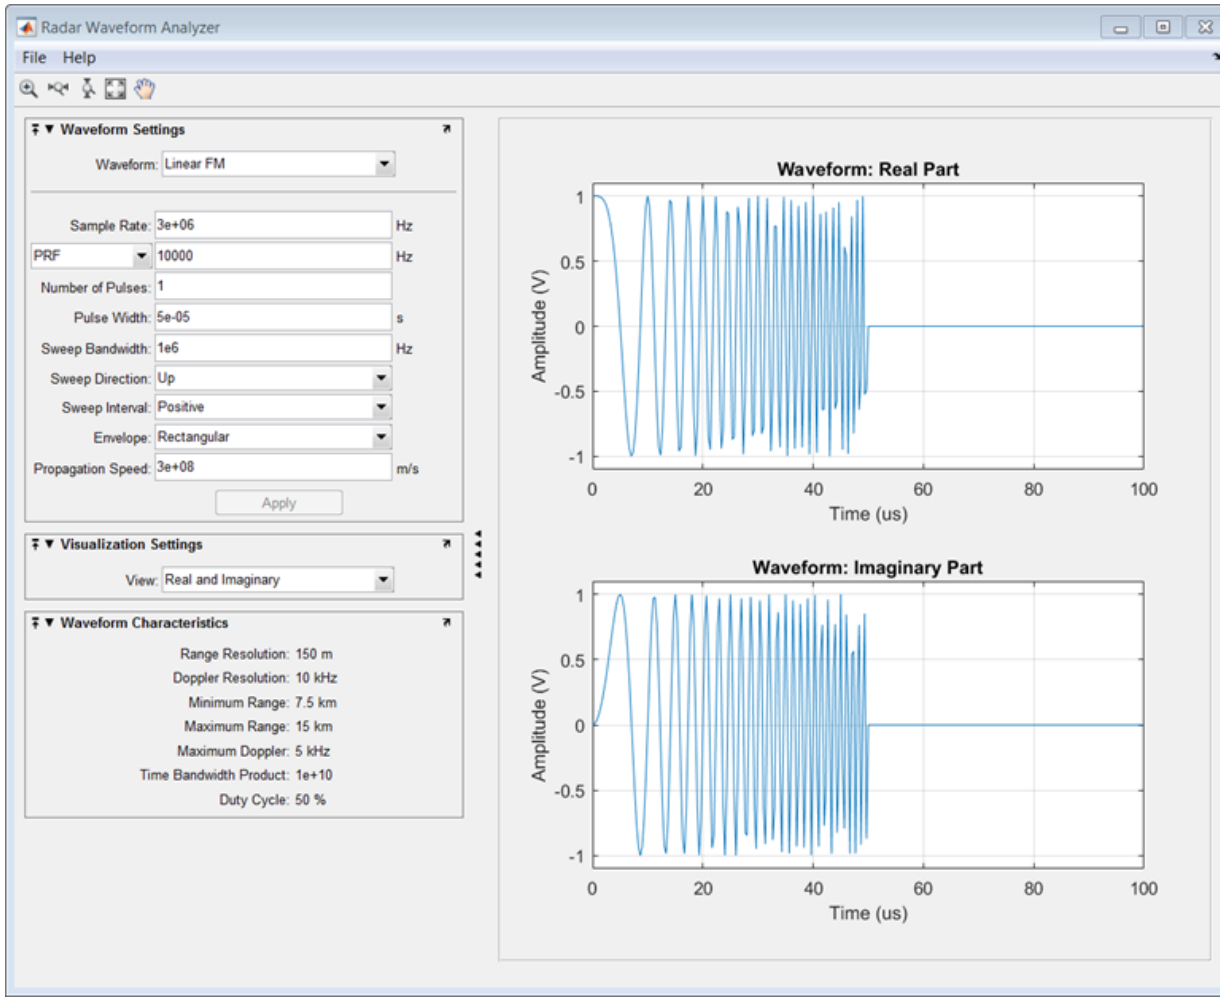
In the previous example, the range resolution of the rectangular pulse was poor, at 7.5 km. You can improve the range resolution by choosing a signal with a larger bandwidth. A good choice is a linear FM pulse.

Set the **Waveform** to `Linear FM`.

This pulse has a variable frequency which can either increase or decrease as a linear function of time.

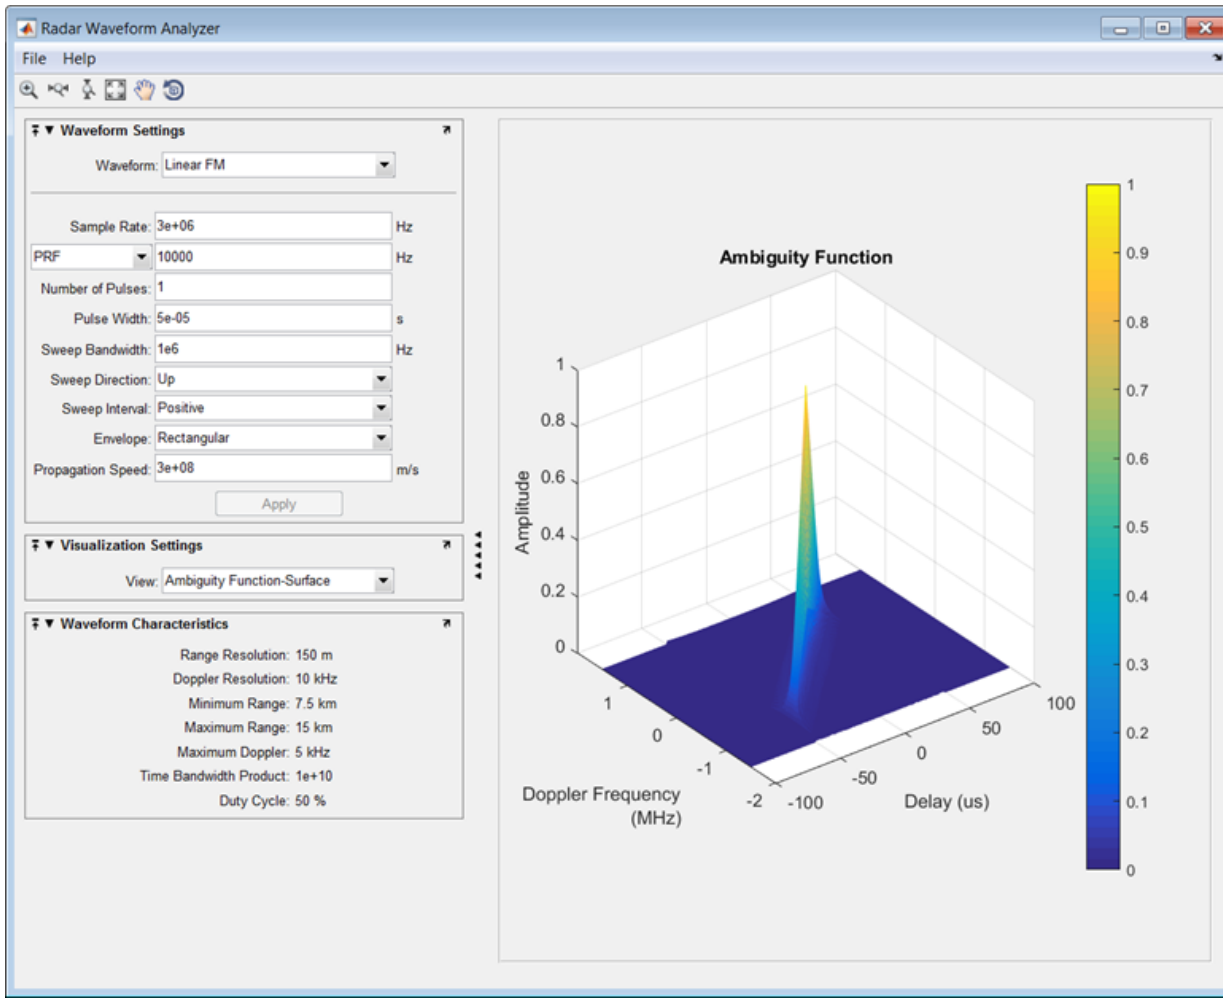
Choose the **Sweep Direction** as `Up`, and the **Sweep Bandwidth** as 1 MHz.

You can see that keeping the same pulse width as before improves the range resolution to 150 m, as shown in the following figure.



Examine the ambiguity function which shows a trade-off.

While the range resolution is better, the Doppler resolution is worse than that of a rectangular waveform.

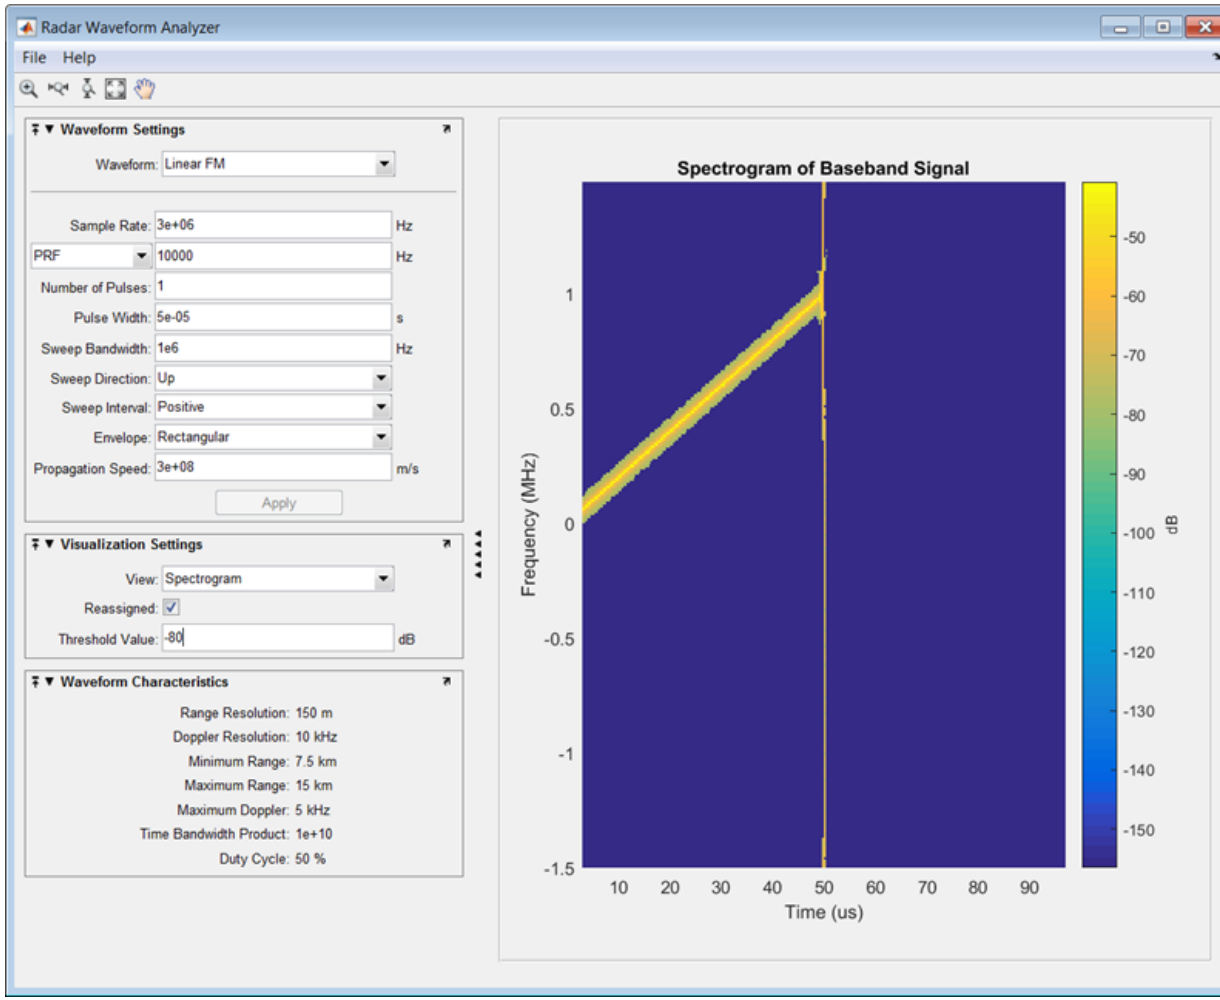


Linear FM Waveform Spectrogram

This example shows how to display the spectrogram of a linear FM waveform with and without frequency reassignment.

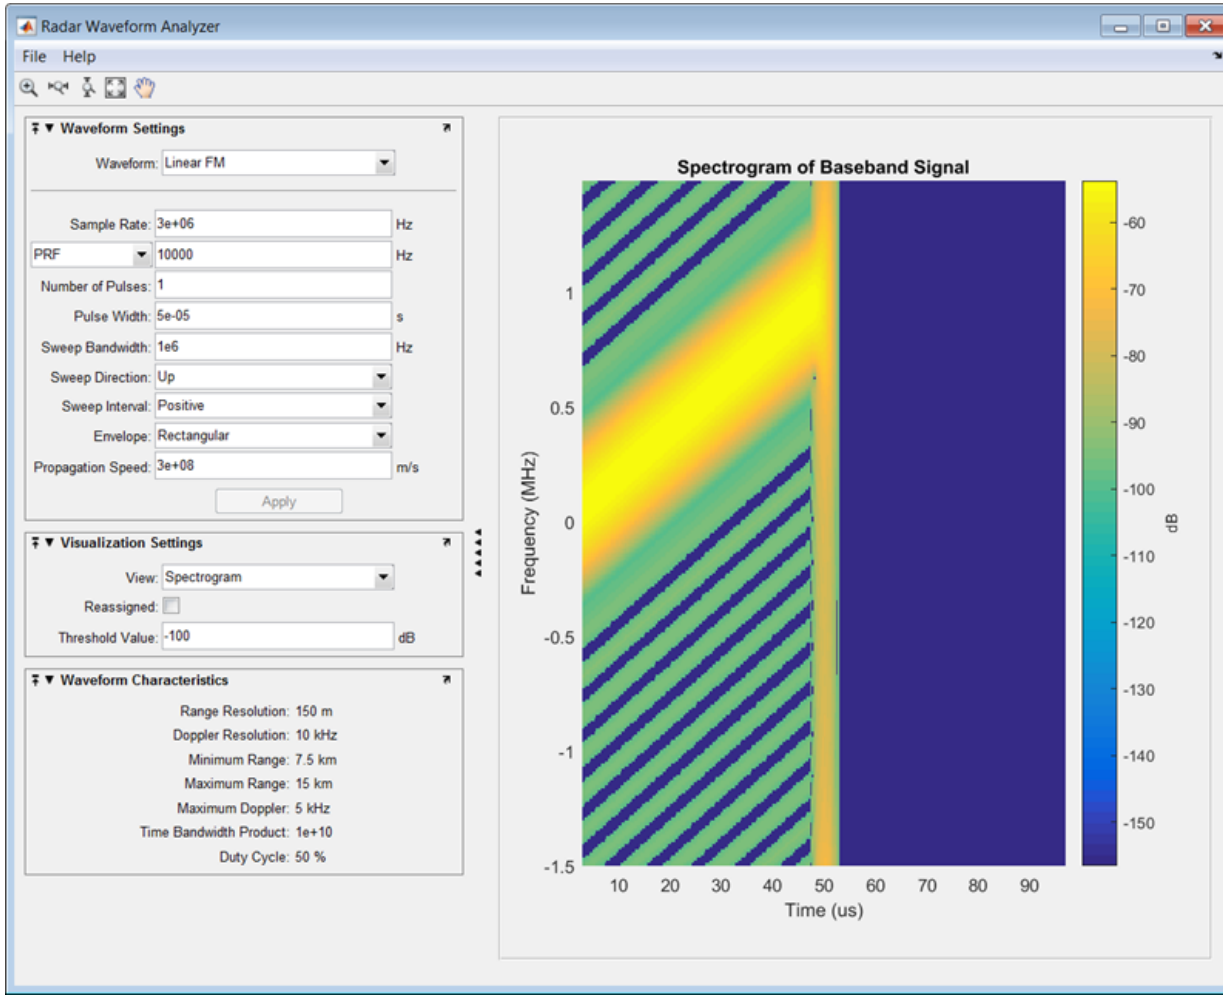
Use the same signal parameters as in the previous example.

Select `Spectrogram` from the **View** drop-down menu in the Visualization Settings panel. Then, click the **Reassigned** checkbox to show the frequency reassigned spectrogram (reassignment is turned on by default). Frequency reassignment is a technique for sharpening the magnitude spectrogram of a signal using information from its phase spectrum. For more information on frequency reassignment, see Fulop and Kelly (2006).



You can vary the **Threshold Value** setting to show or hide weaker spectrum components.

To view the conventional spectrogram, click the **Reassigned** checkbox again.



Again, you can vary the **Threshold Value** setting to show or hide weaker spectrum components.

Sensor Array Analyzer

Analyze beam pattern of linear, planar, and conformal sensor arrays

Description

The **Sensor Array Analyzer** app enables you to construct and analyze common sensor array configurations. These configurations range from 1-D to 3-D arrays of antennas and microphones.

After you specify array parameters, the app displays basic performance characteristics such as array directivity and array dimensions. You can then create a variety of plots and images.

You can use this app to generate the directivity of the following arrays:

- Uniform Linear Array (ULA)
- Uniform Rectangular Array (URA)
- Uniform Circular Array
- Uniform Hexagonal Array
- Circular Plane Array
- Concentric Array
- Spherical Array
- Cylindrical Array
- Arbitrary Geometry

Available Elements

The following elements are available to populate an array:

- Isotropic Antenna
- Cosine Antenna
- Omnidirectional Microphone
- Cardioid Microphone

- Custom Antenna

Available Plots

The **Sensor Array Analyzer** app can create the following plots:

- Array Geometry
- 2D Array Directivity
- 3D Array Directivity
- Grating Lobes

Open the Sensor Array Analyzer App

- MATLAB Toolstrip: On the **Apps** tab, under **Signal Processing and Communications**, click the app icon.
- MATLAB command prompt: Enter `sensorArrayAnalyzer`.

Examples

Uniform Linear Array

This example shows how to analyze a 10-element uniform linear array (ULA) in a sonar application with omnidirectional microphones.

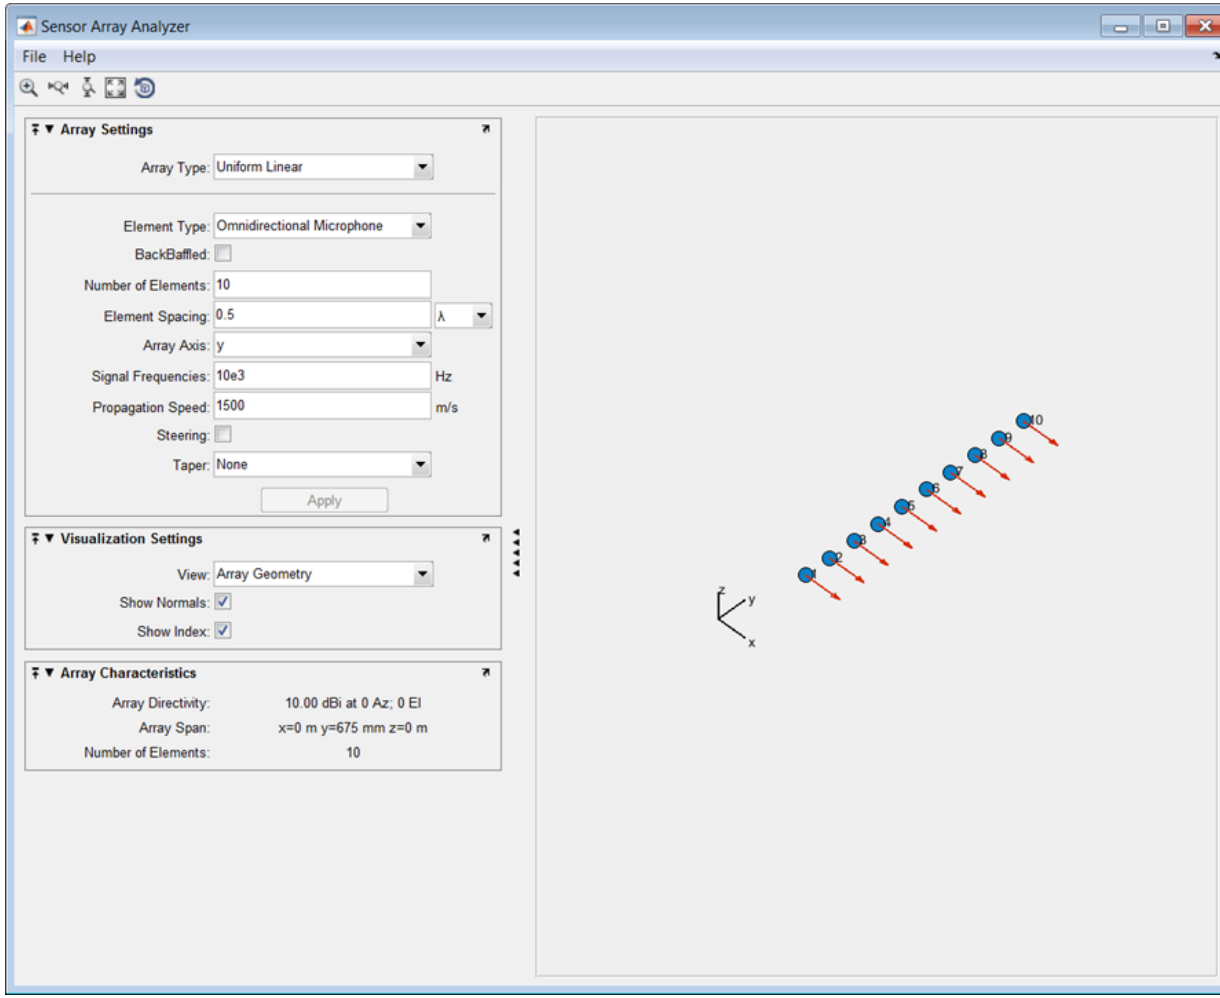
A uniform linear array has sensor elements that are equally-spaced along a line.

Set the **Array Type** to `Uniform Linear` and the **Element Type** to `Omnidirectional Microphone`.

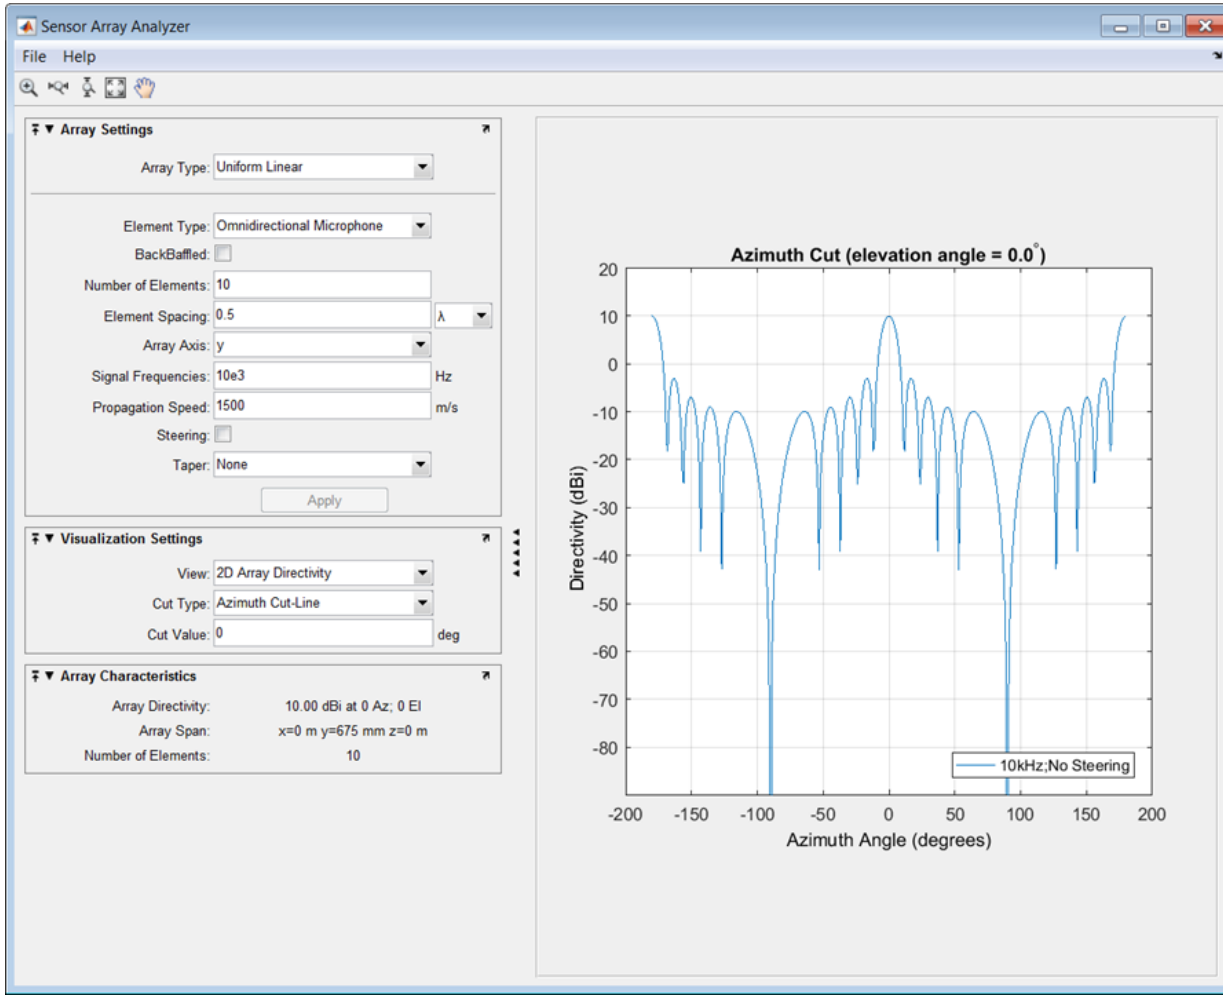
Design the array to find the arrival direction of a 10 kHz signal by setting **Signal Frequencies** to `10000` and the **Element Spacing** to 0.5 wavelengths.

Set the signal **Propagation Speed** to equal the speed of sound in water, `1500` m/s.

In the **View** dropdown menu, choose the `Array Geometry` option to draw the shape of the array.



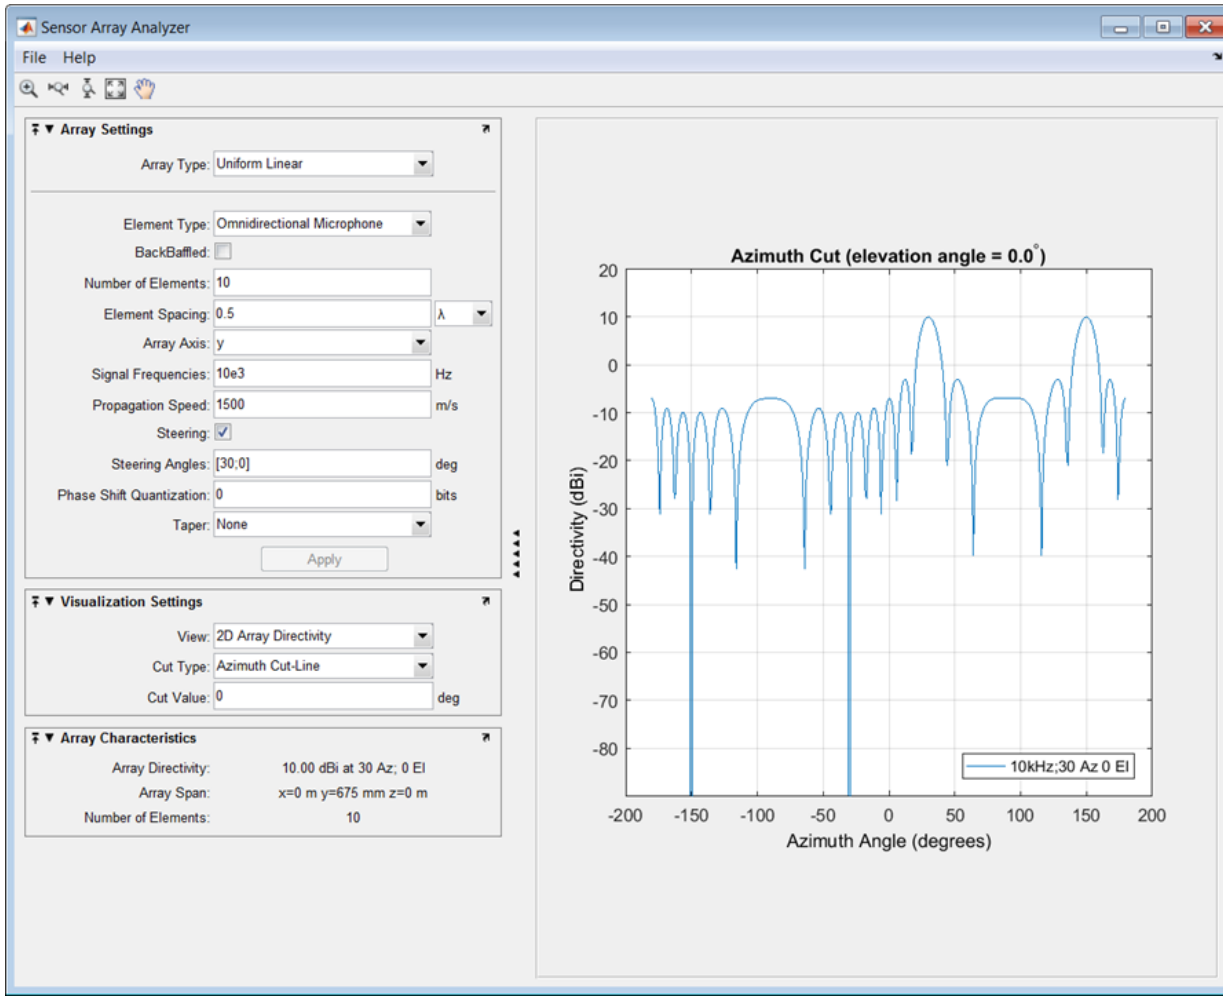
Next, examine the directivity of the array. To do so, select `2D Array Directivity` in the **View** drop-down list. The 2-D array directivity is shown below.



You can see the mainlobe of the array directivity function (also called the main beam) at 0° and another mainlobe at ±180°. Two mainlobes appear because of the cylindrical symmetry of the ULA array.

A beamscanner works by successively pointing the array mainlobe in different directions. Setting the **Steering** option to `On` lets you steer the mainlobe in the direction specified by the **Steering Angles** option.

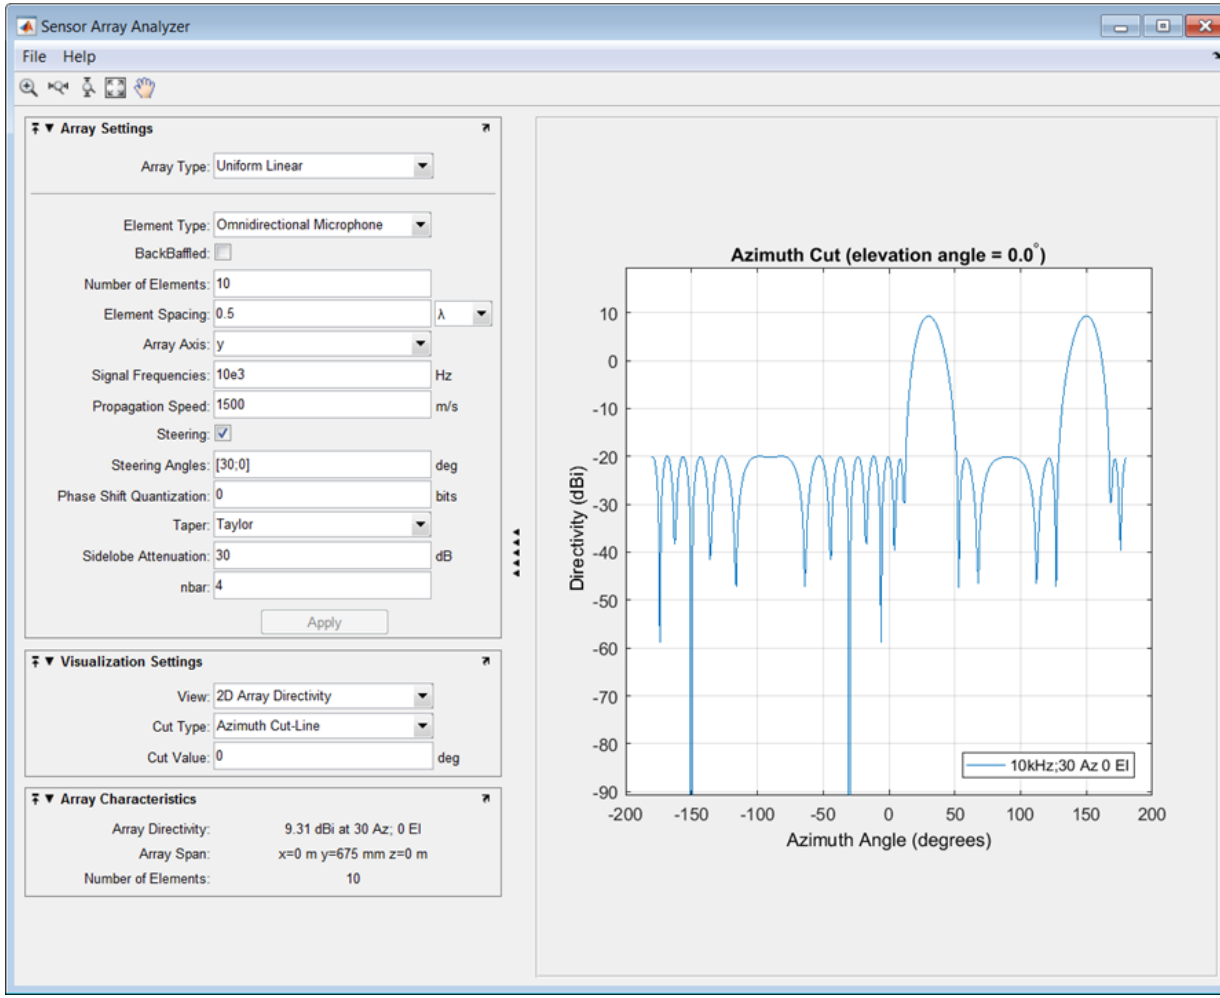
In this case, set the steering angle to `[30;0]` to point the mainlobe to 30° in azimuth and 0° elevation. In the next figure, you can see two mainlobes, one at 30° as expected, and another at 150°. Again, two mainlobes appear because of the cylindrical symmetry of the array.



A disadvantage of the ULA is its large side lobes. An examination of the array directivity shows two side lobes close to each mainlobe, each down by about only 13 dB. A strong

sidelobe inhibits the ability of the array to detect a weaker signal in the presence of a larger nearby signal. By using array tapering, you can reduce the side lobes.

Use the **Taper** option to specify the array taper as a `Taylor` window with **Sidelobe Attenuation** set to `30` dB. The next figure shows how the Taylor window reduces all side lobes to –30 dB—but at the expense of broadening the mainlobe.



Uniform Rectangular Array

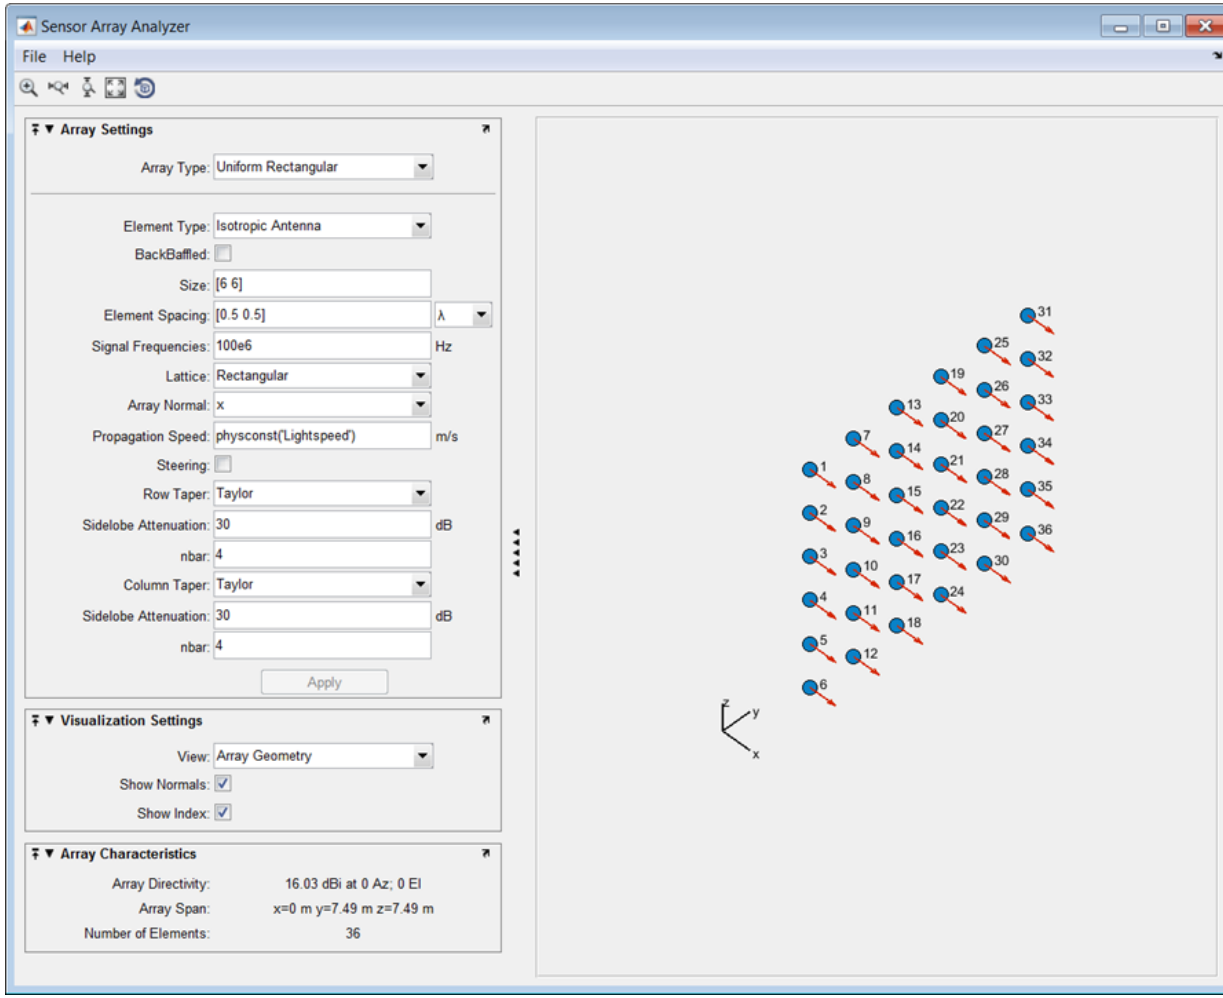
This example shows how to construct a 6-by-6 uniform rectangular array (URA) designed to detect and localize a 100 MHz signal.

Set the **Array Type** to `Uniform Rectangular`, the **Element Type** to `Isotropic Antenna`, and the **Size** to `[6 6]`.

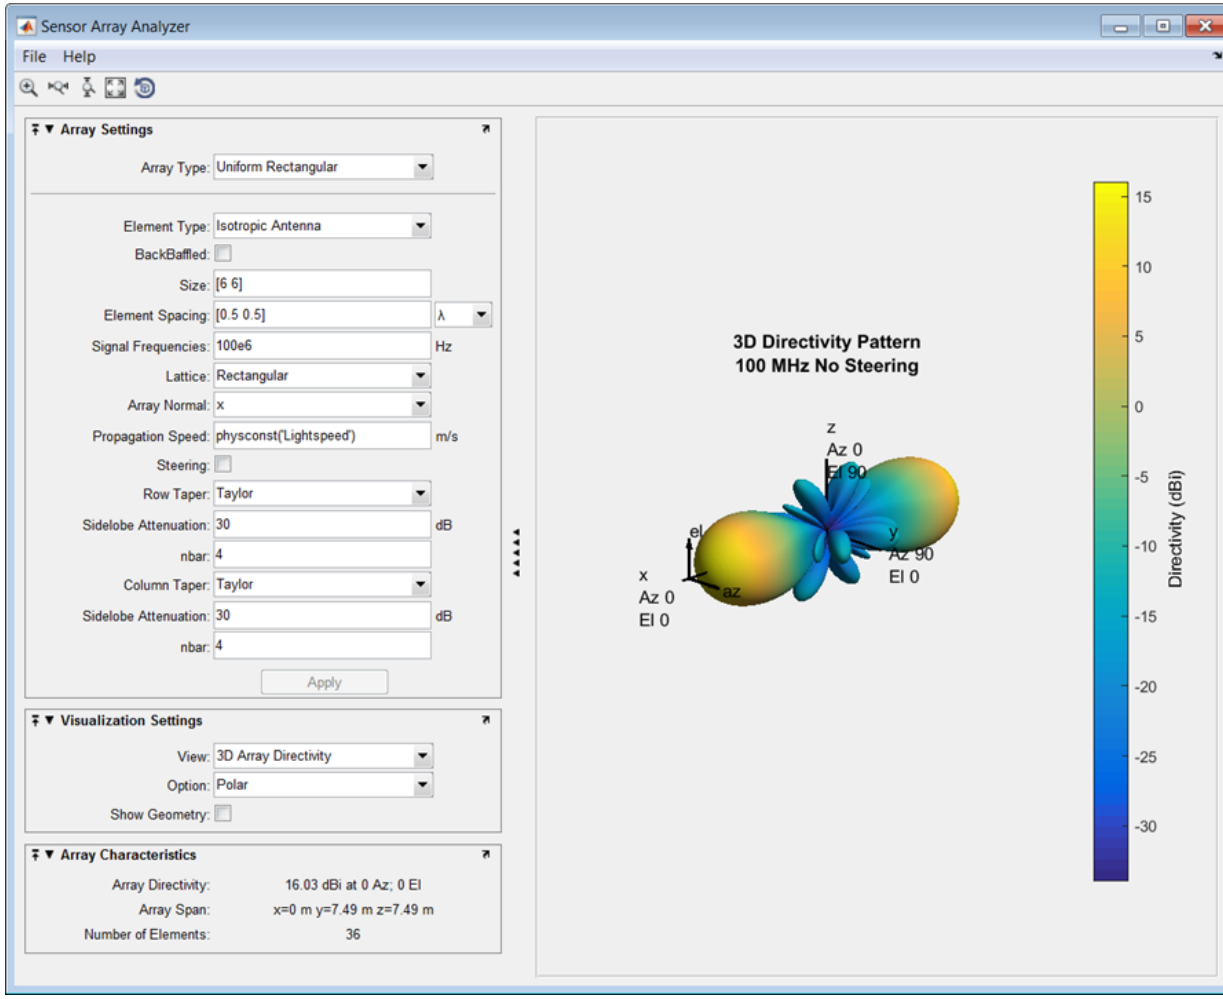
Design the array to find the arrival direction of a 100 MHz signal by setting **Signal Frequencies** to `100e+6` and the row and column **Element Spacing** to 0.5 wavelength.

Set both the **Row Taper** and **Column Taper** to a `Taylor` window.

The shape of the array is shown in the figure below.



Finally, display the 3-D array directivity by setting the **View** option to `3D Array Directivity`, as shown in the following figure:



A significant performance criterion for any array is its array directivity. You can use the app to examine the effects of tapering on array directivity. Without tapering, the array

directivity for this URA is 17.2 dB. With tapering, the array directivity loses 1 dB to yield 16.0 dB.

Grating Lobes for a Rectangular Array

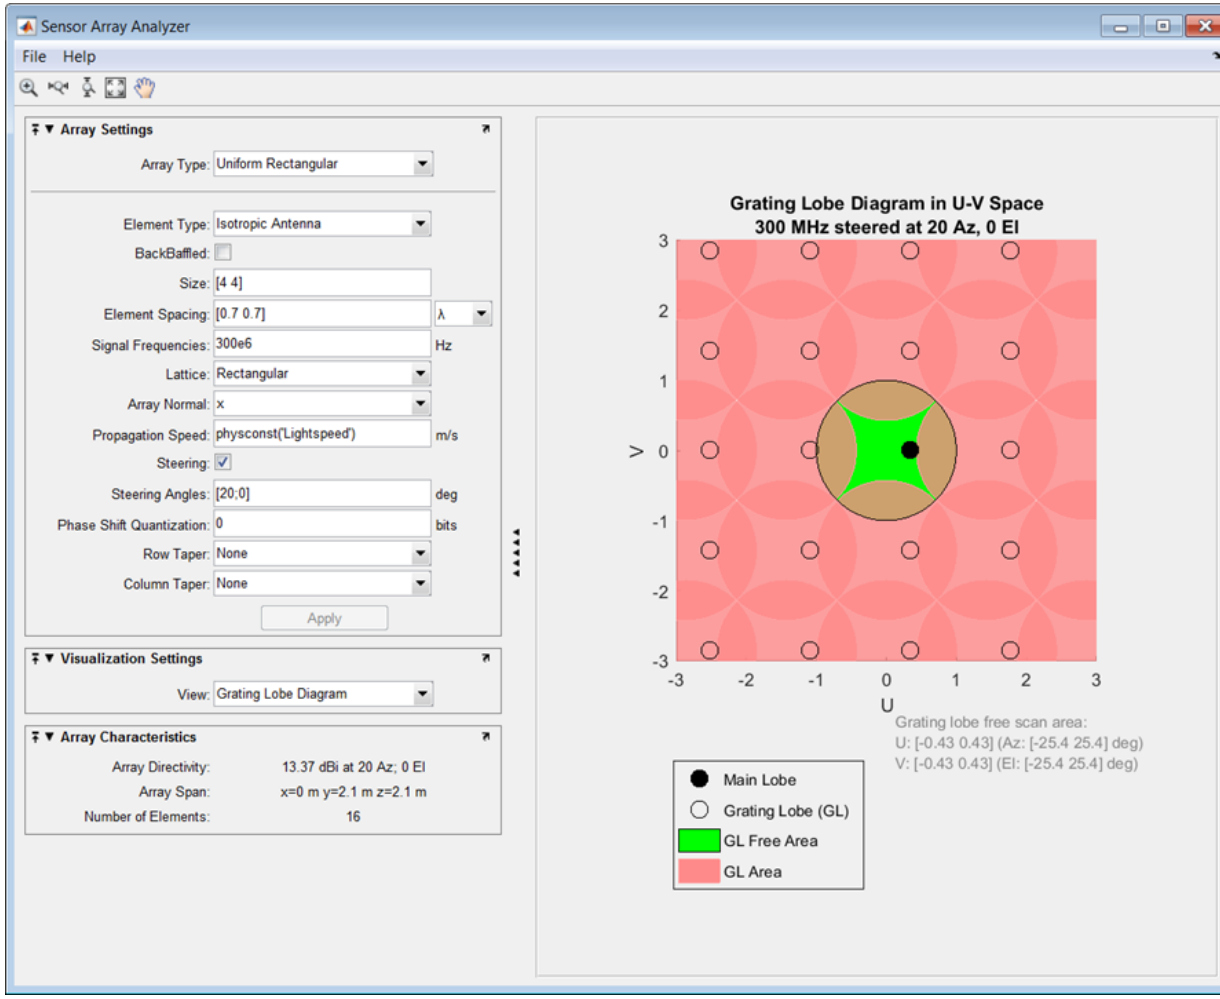
This example shows the grating lobe diagram of a 4-by-4 uniform rectangular array (URA) designed to detect and localize a 300 MHz signal.

Set the **Array Type** to `Uniform Rectangular`, the **Element Type** to `Isotropic Antenna`, and the array **Size** to `[4 4]`.

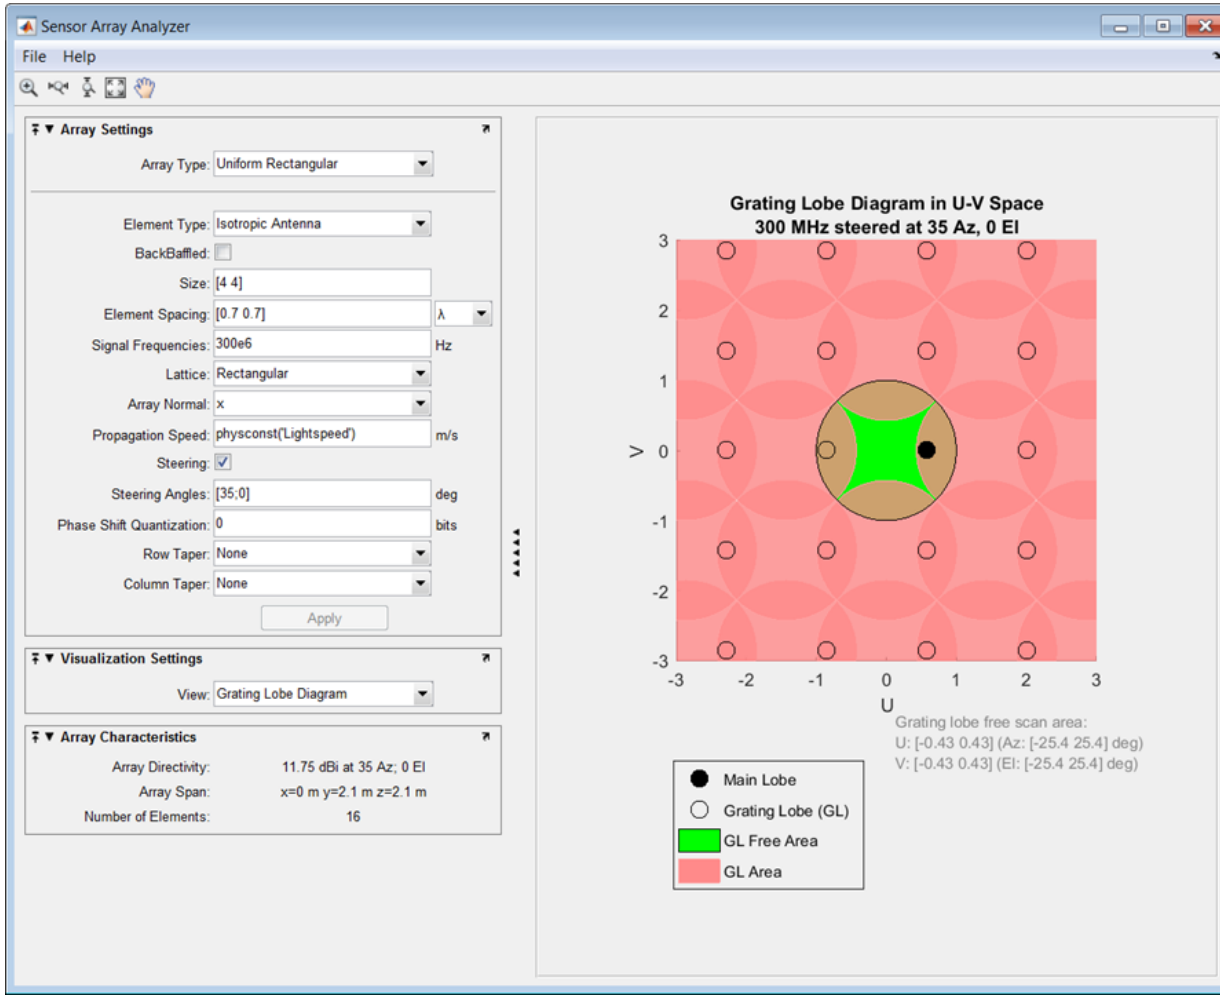
Set the **Signal Frequencies** to `300e+6`.

By setting the row and column **Element Spacing** to 0.7 wavelengths, you create a spatially undersampled array.

This figure shows the grating lobe diagram produced when you beamform the array towards the angle [20,0]. The mainlobe is designated by the small black-filled circle. The multiple grating lobes are designated by the small unfilled black circles. The larger black circle is called the physical region, for which $u^2 + v^2 \leq 1$. The mainlobe always lies in the physical region. The grating lobes may or may not lie in the physical region. Any grating lobe in the physical region leads to an ambiguity in the direction of the incoming wave. The green region shows where the mainlobe can be pointed without any grating lobes appearing in the physical region. If the mainlobe is set to point outside the green region, a grating lobe moves into the physical region.



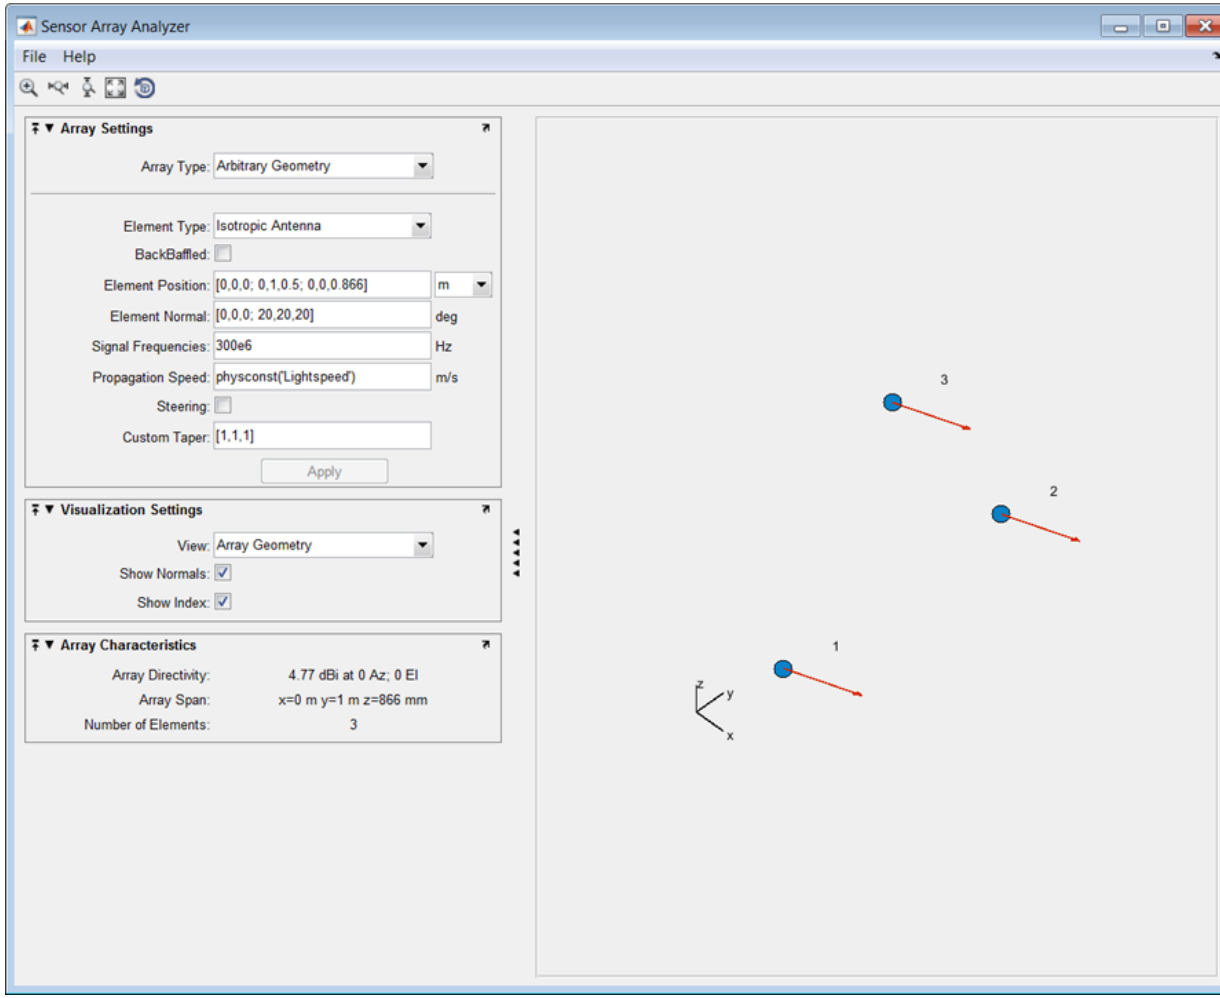
The next figure shows what happens when the pointing direction lies outside the green region. In this case, one grating lobe moves into the physical region.



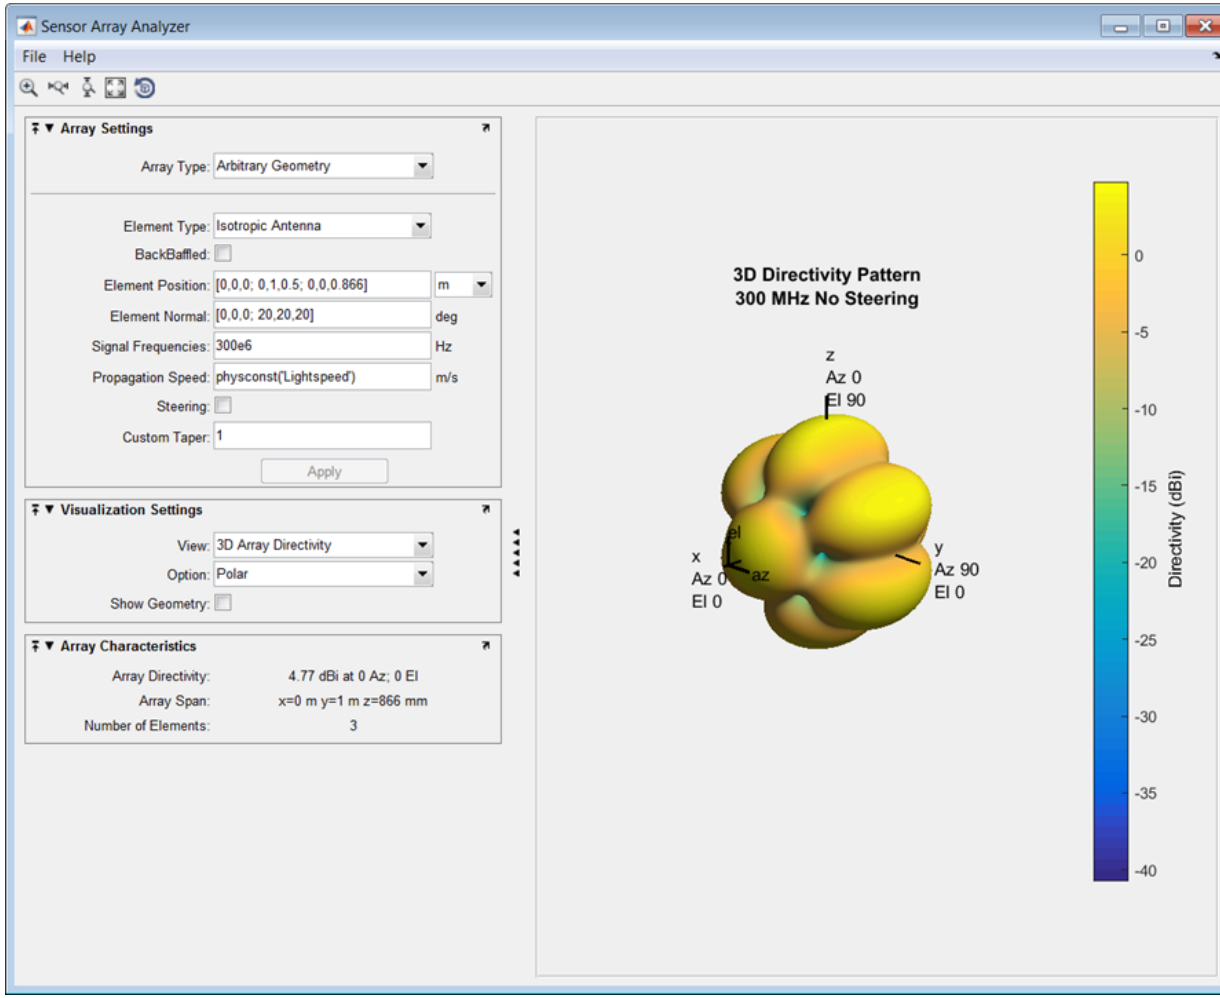
Specify Arbitrary Array Geometry

This example shows how to construct a triangular array of three isotropic antenna elements.

You can specify an array which has an arbitrary placement of sensors. In this example, the elements are placed at `[0,0,0]'`, `[0,1,0.5]'`, and `[0,0,0.866]'`. All elements have the same normal direction `[0,20]`, pointing to 0° in azimuth and 20° in elevation.



Plot the 3-D array directivity in polar coordinates.



Specify Arbitrary Array Geometry Using Variables

This example shows how to specify an array which has an arbitrary placement of sensors, but in this case, create MATLAB variables or arrays at the command line and use them in the appropriate `sensorArrayAnalyzer` fields

At the MATLAB command line, create an element position array, `pos`, an element normal array, `nrm`, and a taper value array, `tpr`.

```
pos = [0,0,0;0,1,0.5;0,0,0.866];
nrm = [0,0,0;20,20,20];
tpr = [1,1,1];
```

Enter these variables in the appropriate `sensorArrayAnalyzer` fields.
