To minimize the chance of dropouts, the block checks to make sure that the queue duration is at least as big as twice the internal buffer size. If it is not, the queue duration is automatically set to twice the internal buffer size.

The **Initial output delay** parameter enables you to preload the buffer before the block starts to output data to the audio device, which can be helpful for models that do not run in real time. However, for real-time applications, it is best to set the initial output delay to zero (one frame of delay), or as close to zero as possible.

Troubleshooting

If you are getting undesirable audio output using the To Wave Device block, first determine whether your model can run in real time. Replace the To Wave Device block with a To Wave File block, run the model, and compare the model's simulation stop time to the elapsed time on your watch. If the model simulation stop time is less than the elapsed time on your watch, your model can probably run in real time. Then,

- If your model can run in real time,
 - 1 Select **Automatically determine internal buffer size**. This alone might solve the problem. If not,
 - 2 Try increasing the **Queue duration** parameter to a relatively large value, such as 0.5 s.

If one or both of these options restores desirable audio output, you can try reducing the internal buffer size and/or queue duration until the quality of the audio output again degrades.

- If your model is not running in real time, try to make it run in real time by
 - 1 Optimizing the model (using a more efficient implementation), or

- 2 Using a Simulink “Acceleration” (Simulink) mode, or
- 3 Generating stand-alone code

If none of these are possible, but the model only runs for a short period of time, set the **Queue duration** parameter to a size equal to a significant fraction of the model stop time and use a similarly large initial delay. This is not an optimal solution, but might work in some cases.

Parameters

Queue duration (seconds)

Specify the overall buffer size. To minimize the chance of dropouts, the block checks to make sure that the queue duration is as least as large as twice the internal buffer size. If it is not, the queue duration is automatically set to twice the internal buffer size.

Automatically determine internal buffer size

Select to have the block automatically select the internal buffer size for you. For details, see “Buffering” on page 2-1645.

User-defined internal buffer size (samples)

Define the internal buffer size, or the size of the chunks of data sent by the block to the audio hardware device.

This parameter is only visible when **Automatically determine internal buffer size** is not selected.

Initial output delay (seconds)

Specify the amount of time by which to delay the initial output to the audio device. During this time data accumulates in the block's buffer. Any value less than or equal to the queue duration specifies the smallest possible initial delay, which is a single frame.

Use default audio device

Select to direct audio output to the system's default audio device.

Audio device

This parameter lists the names of the installed audio devices. Specify the name of the audio device to receive the audio output. Select **Use default audio device** when the system has only a single audio card installed.

This parameter is only enabled when the **Use default audio device** check box is not selected.

Enable 24-bit output for double and single precision input signals

Select to output 24-bit data when inputs are double- or single-precision. Otherwise, the block outputs 16-bit data for double- and single-precision inputs.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Signed fixed point with a word length of 16 and a fraction length of 15 • 16-bit signed integers • 8-bit unsigned integers

To Wave File (Obsolete)

Write audio data to file in Microsoft Wave (.wav) format

Library

dspwin32

Description

Note The To Wave File block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the To Multimedia File block.

The To Wave File block streams audio data to a Microsoft Wave (.wav) file in the uncompressed pulse code modulation (PCM) format. For compatibility reasons, the sample rate of the discrete-time input signal should typically be one of the standard Windows audio device rates (8000, 11025, 22050, or 44100 Hz), although the block supports arbitrary rates.

The input to the block, u , can contain audio data with one or more channels. A signal with C channels is represented as a sample-based length- C vector or a frame-based M -by- C matrix. The amplitude of the input should be in the range ± 1 . Values outside this range are clipped to the nearest allowable value.

```
wavwrite(u,Fs,bits,'filename')    % Equivalent MATLAB code
```

Note AVI files are the only supported file type for non-Windows platforms.

Parameters

File name

Specify the path and name of the file to write. Paths can be relative or absolute. You do not need to specify the `.wav` extension.

Sample width (bits)

Specify the number of bits used to represent the signal samples in the file. The higher sample width settings require more memory but yield better fidelity for double- and single-precision inputs:

- 8 — Allocates 8 bits to each sample, allowing a resolution of 256 levels
- 16 — Allocates 16 bits to each sample, allowing a resolution of 65536 levels
- 24 — Allocates 24 bits to each sample, allowing a resolution of 16777216 levels
- 32 — Allocates 32 bits to each sample, allowing a resolution of 2^{32} levels ranging from -1 to 1

The 8-, 16-, and 24-bit modes output integer data, while the 32-bit mode outputs single-precision floating-point data.

Minimum number of samples for each write to file

Specify the number of consecutive samples, L , to write with each file access. To reduce the required number of file accesses, the block writes L consecutive samples to the file during each access for $L \geq M$. For $L < M$, the block instead writes M consecutive samples during each access. Larger values of L result in fewer file accesses, which reduces run-time overhead.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Signed fixed point with a word length of 16 and a fraction length of 15 • 16-bit signed integers • 8-bit unsigned integers

Triggered Delay Line (Obsolete)

Buffer sequence of inputs into frame-based output

Library

dspobslib

Description

Note The Triggered Delay Line block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the Delay Line block.

The Triggered Delay Line block acquires a collection of M_0 input samples into a frame, where you specify M_0 in the **Delay line size** parameter. The block buffers a single sample from input 1 whenever it is triggered by the control signal at input 2 (⚡). When the next triggering event occurs, the newly acquired input sample is appended to the output frame so that the new output overlaps the previous output by M_0-1 samples. Between triggering events the block ignores input 1 and holds the output at its last value.

You specify the triggering event at input 2 in the **Trigger type** pop-up menu:

- **Rising edge** triggers execution of the block when the trigger input rises from a negative value to zero or a positive value, or from zero to a positive value.
- **Falling edge** triggers execution of the block when the trigger input falls from a positive value to zero or a negative value, or from zero to a negative value.
- **Either edge** triggers execution of the block when either a rising or falling edge (as described above) occurs.

The Triggered Delay Line block has zero latency, so the new input appears at the output in the same simulation time step. The output frame period is the same as the input sample period, $T_{fo}=T_{si}$.

Sample-Based Operation

In sample-based operation, the Triggered Delay Line block buffers a sequence of sample-based length- N vector inputs (1-D, row, or column) into a sequence of overlapping sample-based M_o -by- N matrix outputs, where you specify M_o in the **Delay line size** parameter ($M_o>1$). That is, each input vector becomes a *row* in the sample-based output matrix. When $M_o=1$, the input is simply passed through to the output, and retains the same dimension. Sample-based full-dimension matrix inputs are not accepted.

Frame-Based Operation

In frame-based operation, the Triggered Delay Line block rebuffers a sequence of frame-based M_i -by- N matrix inputs into an sequence of overlapping frame-based M_o -by- N matrix outputs, where M_o is the output frame size specified by the **Delay line size** parameter (that is, the number of consecutive samples from the input frame to rebuffer into the output frame). M_o can be greater or less than the input frame size, M_i . Each of the N input channels is rebuffered independently.

Initial Conditions

The Triggered Delay Line block's buffer is initialized to the value specified by the **Initial condition** parameter. The block always outputs this buffer at the first simulation step ($t=0$). When the block's output is a vector, the **Initial condition** can be a vector of the same size or a scalar value to be repeated across all elements of the initial output. When the block's output is a matrix, the **Initial condition** can be a matrix of the same size or a scalar to be repeated across all elements of the initial output.

Parameters

Trigger type

The type of event that triggers the block's execution.

Delay line size

The length of the output frame (number of rows in output matrix), M_o .

Initial condition

The value of the block's initial output, a scalar, vector, or matrix.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Trigger	<ul style="list-style-type: none"> • Any data type supported by the Trigger block
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Triggered Signal From Workspace

Import signal samples from MATLAB workspace when triggered

Library

Signal Operations

dspsigops

Description

The Triggered Signal From Workspace block imports signal samples from the MATLAB workspace into the Simulink model when triggered by the control signal at the input port (☞). The **Signal** parameter specifies the name of a MATLAB workspace variable containing the signal to import, or any valid MATLAB expression defining a matrix or 3-D array.

When the **Signal** parameter specifies an M-by-N matrix ($M \neq 1$), each of the N columns is treated as a distinct channel. You specify the frame size in the **Samples per frame** parameter, M_o , and the output when triggered is an M_o -by-N matrix containing M_o consecutive samples from each signal channel. For convenience, an imported row vector ($M=1$) is treated as a single channel, so the output dimension is M_o -by-1.

When the **Signal** parameter specifies an M-by-N-by-P array, the block generates a single page of the array (an M-by-N matrix) at each trigger time. The **Samples per frame** parameter must be set to 1.

Trigger Event

You specify the triggering event at the input port in the **Trigger type** pop-up menu:

- **Rising edge** triggers execution of the block when the trigger input rises from a negative value to zero or a positive value, or from zero to a positive value.

- `Falling edge` triggers execution of the block when the trigger input falls from a positive value to zero or a negative value, or from zero to a negative value.
- `Either edge` triggers execution of the block when either a rising or falling edge (as described above) occurs.

Initial and Final Conditions

The **Initial output** parameter specifies the output of the block from the start of the simulation until the first trigger event arrives. Between trigger events, the block holds the output value constant at its most recent value (that is, no linear interpolation takes place). For single-channel signals, the **Initial output** parameter value can be a vector of length M_0 or a scalar to repeat across the M_0 elements of the initial output frames. For matrix outputs (M_0 -by- N or M -by- N), the **Initial output** parameter value can be a matrix of the same size or a scalar to be repeated across all elements of the initial output.

When the block has output all of the available signal samples, it can start again at the beginning of the signal, or simply repeat the final value or generate zeros until the end of the simulation. (The block does not extrapolate the imported signal beyond the last sample.) The **Form output after final data value by** parameter controls this behavior:

- When you specify `Setting To Zero`, the block generates zero-valued outputs for the duration of the simulation after generating the last frame of the signal.
- When you specify `Holding Final Value`, the block repeats the final sample for the duration of the simulation after generating the last frame of the signal.
- When you specify `Cyclic Repetition`, the block repeats the signal from the beginning after generating the last frame. When there are not enough samples at the end of the signal to fill the final frame, the block zero-pads the final frame as necessary to ensure that the output for each cycle is identical (for example, the i th frame of one cycle contains the same samples as the i th frame of any other cycle).

Parameters

Signal

The name of the MATLAB workspace variable from which to import the signal, or a valid MATLAB expression specifying the signal.

Trigger type

The type of event that triggers the block's execution.

Initial output

The value to output until the first trigger event is received.

Samples per frame

The number of samples, M_o , to buffer into each output frame. This value must be 1 when you specify a 3-D array in the **Signal** parameter.

Form output after final data value by

Specifies the output after all of the specified signal samples have been generated. The block can output zeros for the duration of the simulation (**Setting to zero**), repeat the final data sample (**Holding Final Value**) or repeat the entire signal from the beginning (**Cyclic Repetition**).

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed and unsigned)
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

Triggered To Workspace

DSP System Toolbox

Simulink

DSP System Toolbox

Introduced before R2006a

Triggered To Workspace

Write input sample to MATLAB workspace when triggered

Library

Sinks

dspnks4

Description

The Triggered To Workspace block creates a matrix or array variable in the MATLAB workspace, where it stores the acquired inputs at the end of a simulation. The block overwrites an existing variable with the same name.

When you set the **Save 2-D signals as** parameter to 2-D array (concatenate along first dimension, the block saves an M -by- N input as a P -by- N matrix, where P is the **Maximum number of rows** parameter. When the simulation progresses long enough for the block to acquire more than P samples, the block stores only the most recent P samples. The **Decimation factor**, D , allows you to store only every D th input matrix.

When you set the **Save 2-D signals as** parameter to 3-D array (concatenate along third dimension, the block saves an M -by- N input as a three-dimensional array in which each M -by- N page represents a single sample from each of the $M*N$ channels (the most recent input matrix occupies the last page). The maximum size of this variable is limited to M -by- N -by- P , where P is the **Maximum number of rows** parameter. When the simulation progresses long enough for the block to acquire more than P inputs, it stores only the last P inputs. The **Decimation factor**, D , allows you to store only every D th input matrix.

The block acquires and buffers a single frame from input 1 whenever it is triggered by the control signal at input 2 (↑). At all other times, the block ignores input 1. You specify the triggering event at input 2 in the **Trigger type** pop-up menu:

- **Rising edge** triggers execution of the block when the trigger input rises from a negative value to zero or a positive value, or from zero to a positive value.
- **Falling edge** triggers execution of the block when the trigger input falls from a positive value to zero or a negative value, or from zero to a negative value.
- **Either edge** triggers execution of the block when either a rising or falling edge (as described above) occurs.

To save a record of the sample time corresponding to each sample value, open the Configuration Parameters dialog box. In the **Select** pane, click **Data Import/Export** and select the **Time** check box.

The nontriggered version of this block is the To Workspace block.

Parameters

Trigger type

The type of event that triggers the block's execution.

Variable name

The name of the workspace variable in which to store the data.

Maximum number of rows

The maximum number of rows (one row per time step) to be saved, P .

Decimation

The decimation factor, D .

Save 2-D signals as

Specify whether the block saves 2-D signals as a 2-D or 3-D array in the MATLAB workspace:

- **2-D array (concatenate along first dimension)** — When you select this option, the block vertically concatenates each M -by- N matrix input with the previous input to produce a 2-D output array.
- **3-D array (concatenate along third dimension)** — When you select this option, the block saves an M -by- N input signal as a 3-D array. The maximum

size of this 3-D array is limited to M -by- N -by- P , where P is the **Maximum number of rows** parameter. When the simulation progresses long enough for the block to acquire more than P inputs, the block stores only the last P inputs. The **Decimation factor**, D , allows you to store only every D th input matrix.

Log fixed-point data as a fi object

Select to log fixed-point data to the MATLAB workspace as a Fixed-Point Designer `fi` object. Otherwise, fixed-point data is logged to the workspace as `double`.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none">Any data type supported by the To Workspace block
Trigger	<ul style="list-style-type: none">Any data type supported by the Trigger block

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see Triggered To Workspace.

Two-Channel Analysis Subband Filter

Decompose signal into high-frequency and low-frequency subbands

Library

Filtering / Multirate Filters

`dspmlti4`

Description

The Two-Channel Analysis Subband Filter block decomposes the input into high-frequency and low-frequency subbands, each with half the bandwidth and half the sample rate of the input.

The block filters the input with a pair of highpass and lowpass FIR filters, and then downsamples the results by 2, as illustrated in the following figure.

The block implements the FIR filtering and downsampling steps together using a polyphase filter structure, which is more efficient than the straightforward filter-then-decimate algorithm shown in the preceding figure. Each subband is the first phase of the respective polyphase filter. You can implement a multilevel dyadic analysis filter bank by connecting multiple copies of this block or by using the Dyadic Analysis Filter Bank block. See “Creating Multilevel Dyadic Analysis Filter Banks” on page 2-1666 for more information.

You must provide a vector of filter coefficients for the lowpass and highpass FIR filters. Each filter should be a half-band filter that passes the frequency band that the other filter stops.

See the following topics for more information about this block:

- “Specifying the FIR Filters” on page 2-1664
- “Frame-Based Processing” on page 2-1664
- “Sample-Based Processing” on page 2-1665
- “Latency” on page 2-1665
- “Creating Multilevel Dyadic Analysis Filter Banks” on page 2-1666

Specifying the FIR Filters

You must provide the vector of numerator coefficients for the lowpass and highpass filters in the **Lowpass FIR filter coefficients** and **Highpass FIR filter coefficients** parameters.

For example, to specify a filter with the following transfer function, enter the vector $[b(1) \ b(2) \ \dots \ b(m)]$.

$$H(z) = B(z) = b_1 + b_2 z^{-1} + \dots + b_m z^{-(m-1)}$$

Each filter should be a half-band filter that passes the frequency band that the other filter stops. You can use the Two-Channel Synthesis Subband Filter block to reconstruct the input to this block. To do so, you must design perfect reconstruction filters to use in the synthesis subband filter.

The best way to design perfect reconstruction filters is to use the Wavelet Toolbox `wfilters` function in to design both the filters both in this block and in the Two-Channel Synthesis Subband Filter block. You can also use other DSP System Toolbox and Signal Processing Toolbox functions.

The Two-Channel Analysis Subband Filter block initializes all filter states to zero.

Frame-Based Processing

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block accepts an M -by- N matrix. The block treats each column of the input as the high- or low-frequency subbands of the corresponding output channel. You can use the **Rate options** parameter to specify how the block resamples the input:

- When you set the **Rate options** parameter to `Enforce single-rate processing`, the input to the block can be an M -by- N matrix, where M is a multiple of two. The block treats each column of the input as an independent channel and decomposes each channel over time. The block outputs two matrices, where each column of the output is the high- or low-frequency subband of the corresponding input column. To maintain the input sample rate, the block decreases the output frame size by a factor of two.
- When you set the **Rate options** parameter to `Allow multirate processing`, the block treats an M_i -by- N matrix input as N independent channels and decomposes each channel over time. The block outputs two M -by- N matrices, where each column of the output is the high- or low-frequency subband of the corresponding input column. The input and output frame *sizes* are the same, but the frame *rate* of the output is half that of the input. Thus, the overall sample rate of the output is half that of the input.

In this mode, the block has one frame of latency, as described in the “Latency” on page 2-1665 section.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats an M -by- N matrix input as $M \cdot N$ independent channels. The block decomposes each channel over time and outputs two M -by- N matrices whose sample rates are half the input sample rate. Each element in the output matrix is the high- or low-frequency subband output of the corresponding element of the input matrix.

Depending on the setting of your Simulink configuration parameters, the output may have one sample of latency, as described in the “Latency” on page 2-1665 section.

Latency

When you set the **Input processing** parameter to `Columns as channels (frame based)` and the **Rate options** parameter to `Enforce single-rate processing`, the Two-Channel Analysis Subband Filter block always has zero-tasking latency. Zero-tasking latency means that the block propagates the first input sample (received at time $t=0$) as the first output sample.

When you set the **Rate options** parameter to `Allow multirate processing`, the Two-Channel Analysis Subband Filter block may exhibit latency. The amount of latency

depends on the setting of the **Input processing** parameter of this block, and the setting of the Simulink **Treat each discrete rate as a separate task** configuration parameter. The following table summarizes the conditions that produce latency when the block is performing multirate processing.

Input processing	Treat each discrete rate as a separate task	Latency
Elements as channels (sample based)	Off	None.
	On	One sample. The first output sample in each channel always has a value of 0.
Columns as channels (frame based)	On or Off	One frame. All samples in the first output frame have a value of 0.

Note For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Creating Multilevel Dyadic Analysis Filter Banks

The Two-Channel Analysis Subband Filter block is the basic unit of a dyadic analysis filter bank. You can connect several of these blocks to implement an n -level filter bank, as illustrated in the following figure. For a review of dyadic analysis filter banks, see the Dyadic Analysis Filter Bank block reference page.

When you create a filter bank by connecting multiple copies of this block, the output values of the filter bank differ depending on whether there is latency. Though the output values differ, both sets of values are valid; the difference arises from changes in latency. See the “Latency” on page 2-1665 section for more information about when latency can occur in the Two-Channel Analysis Subband Filter block.

In some cases, rather than connecting several Two-Channel Analysis Subband Filter blocks, you can use the Dyadic Analysis Filter Bank block, which is faster and requires less memory. In particular, the Dyadic Analysis Filter Bank block is more efficient under the following conditions:

- The frame size of the signal you are decomposing is a multiple of 2^n .
- You are decomposing the signal into $n+1$ or 2^n subbands.

In all other cases, use Two-Channel Analysis Subband Filter blocks to implement your filter banks.

3-Level Dyadic Analysis Filter Banks

Conceptual illustration

Both implementations of the dyadic analysis filter bank decompose a frame-based signal with frame size a multiple of 2^n into $n+1$ subbands, where $n = 3$.

In this case, the Dyadic Analysis Filter Bank block's implementation is more efficient.

Use the Two-Channel Analysis Subband Filter block implementation for other cases, such as to handle sample-based inputs, or to handle frame-based inputs whose frame size is not a multiple of 2^n .

Two-Channel Analysis Subband Filter block implementation

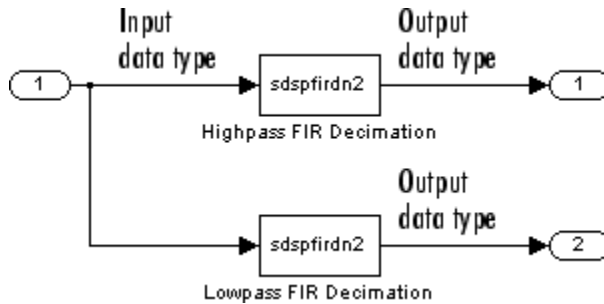

Dyadic Analysis Filter Bank block implementation

The Dyadic Analysis Filter Bank block allows you to specify the filter bank filters by providing vectors of filter coefficients, just as this block does. The Dyadic Analysis Filter Bank block provides an additional option of using wavelet-based filters that the block designs by using a wavelet you specify.

Fixed-Point Data Types

The Two-Channel Analysis Subband Filter Bank block is composed of two FIR Decimation blocks as shown in the following diagram.

For fixed-point signals, you can set the coefficient, product output, accumulator, and output data types of the FIR Decimation blocks as discussed in “Parameters” on page 2-1668. For a diagram showing the usage of these data types, see the FIR Decimation block reference page.

Parameters

Main Tab

Lowpass FIR filter coefficients

Specify a vector of lowpass FIR filter coefficients, in descending powers of z . The lowpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Highpass FIR filter coefficients** parameter. The default values of this parameter specify a filter based on a third-order Daubechies wavelet. When you use the Two-Channel Synthesis Subband Filter block to reconstruct the input to this block, you need to design perfect reconstruction filters to use in the synthesis subband filter. For more information, see “Specifying the FIR Filters” on page 2-1664.

Highpass FIR filter coefficients

Specify a vector of highpass FIR filter coefficients, in descending powers of z . The highpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Lowpass FIR filter coefficients** parameter. The default values of this parameter specify a filter based on a third-order Daubechies wavelet. When you use the Two-Channel Synthesis Subband Filter block to reconstruct the input to this block, you need to design perfect reconstruction filters to use in the synthesis subband filter. For more information, see “Specifying the FIR Filters” on page 2-1664.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` (default) — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Rate options

Specify the rate processing rule for the block. You can set this parameter to one of the following options:

- `Enforce single-rate processing` — When you select this option, the block treats each column of the input as an independent channel and decomposes each channel over time. The output has the same sample rate as the input, but the output frame size is half that of the input frame size. To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.
- `Allow multirate processing` — When you select this option, the input and output of the block are the same size, but the sample rate of the output is half that of the input.

Some settings of this parameter cause the block to have nonzero latency. See “Latency” on page 2-1665 for more information.

Data Types Tab

Rounding mode

Select the rounding mode for fixed-point operations. The filter coefficients do not obey this parameter; they are always rounded to `Nearest`.

Note The **Rounding mode** and **Saturate on integer overflow** settings have no effect on numerical results when all the following conditions exist:

- **Product output data type** is `Inherit`: Inherit via internal rule
- **Accumulator data type** is `Inherit`: Inherit via internal rule
- **Output data type** is `Inherit`: Same as accumulator

With these data type settings, the block is effectively operating in full precision mode.

Saturate on integer overflow

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see [overflow mode for fixed-point operations](#).

Note The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numeric results when all these conditions are met:

- **Product output** data type is `Inherit: Inherit` via internal rule.
- **Accumulator** data type is `Inherit: Inherit` via internal rule.

With these data type settings, the block operates in full-precision mode.

Coefficients data type

Specify the coefficients data type. See “Fixed-Point Data Types” on page 2-1667 and “Multiplication Data Types” for illustrations depicting the use of the coefficients data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Coefficients data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Coefficients Minimum

Specify the minimum value of the filter coefficients. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Automatic scaling of fixed-point data types

Coefficients Maximum

Specify the maximum value of the filter coefficients. The default value is [] (unspecified). Simulink software uses this value to perform:

- Automatic scaling of fixed-point data types

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 2-1667 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.

Note The actual product output word length may be equal to or greater than the calculated ideal product output word length, depending on the settings on the **Hardware Implementation** pane of the Configuration Parameters dialog box.

- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-1667 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 2-1667 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Output Minimum

Specify the minimum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Output Maximum

Specify the maximum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

- Double-precision floating point
- Single-precision floating point

- Fixed point (signed only)
- 8-, 16-, and 32-bit signed integers

Two-Channel Synthesis Subband Filter

Reconstruct signal from high-frequency and low-frequency subbands

Library

Filtering / Multirate Filters

`dspmlti4`

Description

The Two-Channel Synthesis Subband Filter block reconstructs a signal from its high-frequency and low-frequency subbands, each with half the bandwidth and half the sample rate of the original signal. Use this block to reconstruct signals decomposed by the Two-Channel Analysis Subband Filter block.

The block upsamples the high- and low-frequency subbands by 2, and then filters the results with a pair of highpass and lowpass FIR filters, as illustrated in the following figure.

The block implements the FIR filtering and downsampling steps together using a polyphase filter structure, which is more efficient than the straightforward interpolate-then-filter algorithm shown in the preceding figure. You can implement a multilevel dyadic synthesis filter bank by connecting multiple copies of this block or by using the Dyadic Synthesis Filter Bank block. For more information, see “Creating Multilevel Dyadic Synthesis Filter Banks” on page 2-1677.

You must provide a vector of filter coefficients for the lowpass and highpass FIR filters. Each filter should be a half-band filter that passes the frequency band that the other

filter stops. You can use this block to reconstruct the output of a Two-Channel Analysis Subband Filter block. To do so, you must design the filters in this block such that they perfectly reconstruct the outputs of the analysis filters.

See the following topics for more information about this block:

- “Specifying the FIR Filters” on page 2-1675
- “Frame-Based Processing” on page 2-1675
- “Sample-Based Processing” on page 2-1676
- “Latency” on page 2-1677
- “Creating Multilevel Dyadic Synthesis Filter Banks” on page 2-1677

Specifying the FIR Filters

You must provide the vector of numerator coefficients for the lowpass and highpass filters in the **Lowpass FIR filter coefficients** and **Highpass FIR filter coefficients** parameters.

For example, to specify a filter with the following transfer function, enter the vector $[b(1) \ b(2) \ \dots \ b(m)]$.

$$H(z) = B(z) = b_1 + b_2 z^{-1} + \dots + b_m z^{-(m-1)}$$

Each filter should be a half-band filter that passes the frequency band that the other filter stops. You can use this block to reconstruct the output of a Two-Channel Analysis Subband Filter block. To do so, you must design the filters in this block such that they perfectly reconstruct the outputs of the analysis filters.

The best way to design perfect reconstruction filters is to use the Wavelet Toolbox `wfilters` function for the filters in both this block *and* in the corresponding Two-Channel Analysis Subband Filter block. You can also use DSP System Toolbox and Signal Processing Toolbox functions.

The Two-Channel Synthesis Subband Filter block initializes all filter states to zero.

Frame-Based Processing

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block accepts any two M -by- N matrices with the same frame rates. The

block treats each column of the input as the high- or low-frequency subbands of the corresponding output channel. You can use the **Rate options** parameter to specify how the block resamples the input:

- When you set the **Rate options** parameter to `Enforce single-rate processing`, the input to the block can be any two M -by- N matrices with the same frame rate. The block treats each input column as the high- or low-frequency subbands of the corresponding output channel. The input to the topmost input port should contain the high-frequency subbands. The block outputs one matrix, where each column is reconstructed from the corresponding columns of each input matrix. The input and output frame *rates* are the same, but the frame *size* of the output is twice that of the input.
- When you set the **Rate options** parameter to `Allow multirate processing`, the block treats each column of the input as the high- or low-frequency subbands of the corresponding output channel. The input to the topmost input port should contain the high-frequency subbands. The block outputs one matrix, where each column is reconstructed from the corresponding columns of the input matrices. The input and output frame *sizes* are the same, but the frame *rate* of the output is twice that of the input. Thus, the overall sample rate of the output is twice that of the input sample rate.

In this mode, the block has one frame of latency, as described in the “Latency” on page 2-1677 section.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block accepts any two M -by- N matrices with the same sample rates. The block treats each M -by- N matrix as $M \cdot N$ independent subbands. Each element of the input matrices is the high- or low-frequency subband of the corresponding channel in the output matrix. The input to the topmost input port should contain the high-frequency subbands. The block outputs one matrix with the same dimensions as the input matrices, but a sample rate that is twice that of the input. The block reconstructs each element of the output from the corresponding elements in the input matrices.

Depending on the setting of your Simulink configuration parameters, the output may have one sample of latency, as described in the “Latency” on page 2-1677 section.

Latency

When you set the **Input processing** parameter to `Columns as channels` (frame based) and the **Rate options** parameter to `Enforce single-rate processing`, the Two-Channel Synthesis Subband Filter block always has zero-tasking latency. Zero-tasking latency means that the block propagates the first input sample (received at time $t=0$) as the first output sample.

When you set the **Rate options** parameter to `Allow multirate processing`, the Two-Channel Synthesis Subband Filter block may exhibit latency. The amount of latency depends on the setting of the **Input processing** parameter of this block and the setting of the Simulink **Treat each discrete rate as a separate task** configuration parameter. The following table summarizes the conditions that produce latency when the block is performing multirate processing.

Input processing	Treat each discrete rate as a separate task	Latency
Elements as channels (sample based)	Off	None.
	On	One sample. The first output sample in each channel always has a value of 0.
Columns as channels (frame based)	Off or On	One frame. All samples in the first output frame have a value of 0.

Note For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Creating Multilevel Dyadic Synthesis Filter Banks

The Two-Channel Synthesis Subband Filter block is the basic unit of a dyadic synthesis filter bank. You can connect several of these blocks to implement an n -level filter bank, as illustrated in the following figure. For a review of dyadic synthesis filter banks, see the Dyadic Synthesis Filter Bank block reference page.

When you create a filter bank by connecting multiple copies of this block, the output values of the filter bank differ depending on whether there is latency. Though the output values differ, both sets of values are valid; the difference arises from changes in latency.

See the “Latency” on page 2-1677 section for more information about when latency can occur in the Two-Channel Analysis Subband Filter block.

In some cases, rather than connecting several Two-Channel Analysis Subband Filter blocks, you can use the Dyadic Analysis Filter Bank block, which is faster and requires less memory. In particular, the Dyadic Analysis Filter Bank block is more efficient under the following conditions:

- You are reconstructing a signal from 2^n or $n+ 1$ subbands.
- The frame size of the signal you are reconstructing is a multiple of 2^n .
- The properties of the subbands you are working with match those of the outputs of the Dyadic Analysis Filter Bank block. These properties are described in the Dyadic Analysis Filter Bank reference page.

3-Level Dyadic Synthesis Filter Banks

Conceptual illustration

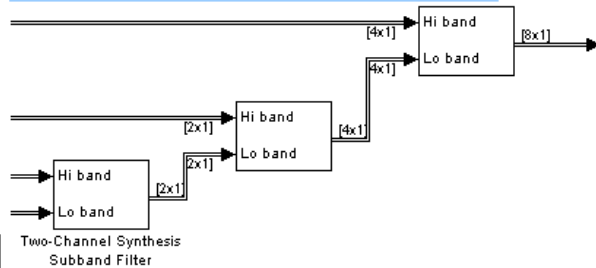

Both implementations of the dyadic analysis filter bank reconstruct a frame-based signal from $n+1$ subbands, where $n = 3$.

In this case, the Dyadic Synthesis Filter Bank block’s implementation is more efficient, since the input subbands have the properties of the outputs of a Dyadic Analysis Filter Bank block.

Use the Two-Channel Synthesis Subband Filter block implementation for other cases, such as to handle separate sample-based vectors or matrices of subbands (rather than a single sample-based vector or matrix of concatenated subbands), or to output sample-based signals.

Two-Channel Synthesis Subband Filter block implementation

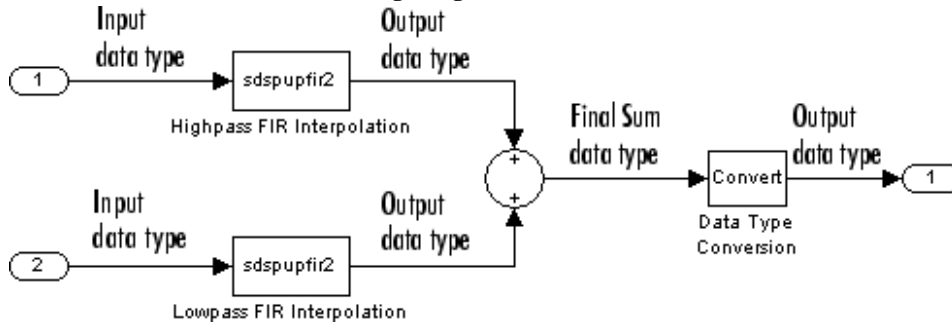

Dyadic Synthesis Filter Bank block implementation

The Dyadic Synthesis Filter Bank block allows you to specify the filter bank filters by providing vectors of filter coefficients, just as this block does. The Dyadic Synthesis Filter Bank block provides an additional option of using wavelet-based filters that the block designs by using a wavelet you specify.

Fixed-Point Data Types

The Two-Channel Synthesis Subband Filter block is composed of two FIR Interpolation blocks as shown in the following diagram.

For fixed-point signals, you can set the coefficient, product output, accumulator, and output data types used in the FIR Interpolation blocks as discussed in “Parameters” on page 2-1679. For a diagram showing the usage of these data types within the FIR blocks, see the FIR Interpolation block reference page.

In addition, the inputs to the Sum block shown in the previous diagram are accumulated using the accumulator data type. The output of the Sum block is then cast from the accumulator data type to the output data type. Therefore the output of the Two-Channel Synthesis Subband Filter block is in the output data type. You also set these data types in the block dialog box as discussed in the “Parameters” on page 2-1679 section.

Parameters

Main Tab

Lowpass FIR filter coefficients

A vector of lowpass FIR filter coefficients, in descending powers of z . The lowpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Highpass FIR filter coefficients** parameter. To use this block to reconstruct the output of a Two-Channel Analysis Subband Filter block, you must design the filters in this block to perfectly reconstruct the outputs of the analysis filters. For more information, see “Specifying the FIR Filters” on page 2-1675.

Highpass FIR filter coefficients

A vector of highpass FIR filter coefficients, in descending powers of z . The highpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Lowpass FIR filter coefficients** parameter. To use this block to reconstruct the output of a Two-Channel Analysis Subband Filter block, you must design the filters in this block to perfectly reconstruct the outputs of the analysis filters. For more information, see “Specifying the FIR Filters” on page 2-1675.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` (default) — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Rate options

Specify the rate processing rule for the block. You can set this parameter to one of the following options:

- `Enforce single-rate processing` — When you select this option, the block treats each column of the input as an independent channel and reconstructs each channel over time. The output has the same sample rate as the input, but the output frame size is twice that of the input frame size. To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.
- `Allow multirate processing` — When you select this option, the input and output of the block are the same size, but the sample rate of the output is twice that of the input.

Some settings of this parameter cause the block to have nonzero latency. See “Latency” on page 2-1677 for more information.

Data Types Tab

Rounding mode

Select the rounding mode for fixed-point operations. The filter coefficients do not obey this parameter; they always round to `Nearest`.

Note The **Rounding mode** and **Saturate on integer overflow** settings have no effect on numerical results when all the following conditions exist:

- **Product output data type** is `Inherit`: `Inherit via internal rule`
- **Accumulator data type** is `Inherit`: `Inherit via internal rule`
- **Output data type** is `Inherit`: `Same as accumulator`

With these data type settings, the block is effectively operating in full precision mode.

Saturate on integer overflow

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see `overflow mode for fixed-point operations`.

Note The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numeric results when all these conditions are met:

- **Product output data type** is `Inherit`: `Inherit via internal rule`.
- **Accumulator data type** is `Inherit`: `Inherit via internal rule`.

With these data type settings, the block operates in full-precision mode.

Coefficients data type

Specify the coefficients data type. See “Fixed-Point Data Types” on page 2-1679 and “Multiplication Data Types” for illustrations depicting the use of the coefficients data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit`: `Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Coefficients data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Coefficients Minimum

Specify the minimum value of the filter coefficients. The default value is [] (unspecified). Simulink software uses this value to perform:

- Automatic scaling of fixed-point data types

Coefficients Maximum

Specify the maximum value of the filter coefficients. The default value is [] (unspecified). Simulink software uses this value to perform:

- Automatic scaling of fixed-point data types

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 2-1679 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.

Note The actual product output word length may be equal to or greater than the calculated ideal product output word length, depending on the settings on the **Hardware Implementation** pane of the Configuration Parameters dialog box.

- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-1679 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 2-1679 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Output Minimum

Specify the minimum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Output Maximum

Specify the maximum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed only)
- 8-, 16-, and 32-bit signed integers

UDP Receive

Receive uint8 vector as UDP message

Library

Sources

dspsrcs4

Description

The UDP Receive block receives UDP packets from an IP network port and saves them to its buffer. With each sample, the block outputs the contents of a single UDP packet as a data vector. The local IP port number on which the block receives the UDP packets is tunable in the C/C++ generated code.

The generated code for this block relies on prebuilt `.dll` files. You can run this code outside the MATLAB environment, or redeploy it, but you must account for these extra `.dll` files when doing so. The `packNGo` function creates a single zip file containing all of the pieces required to run or rebuild this code. For more details, see “How To Run a Generated Executable Outside MATLAB”.

Parameters

Local IP port

Specify the IP port number on which to receive UDP packets. This parameter is tunable in the C/C++ generated code but not tunable during simulation. The default is 25000. The value can be in the range [1 65535].

Note On Linux, to set the IP port number below 1024, run MATLAB with root privileges. For example, at the Linux command line, enter:

```
sudo matlab
```

Remote IP address ('0.0.0.0' to accept all)

Specify the IP address from which to accept packets. Entering a specific IP address blocks UDP packets from other addresses. To accept packets from any IP address, enter '0.0.0.0'. This value defaults to '0.0.0.0'.

Receive buffer size (bytes)

Make the receive buffer large enough to avoid data loss caused by buffer overflows. This value defaults to 8192.

Maximum length for Message

Specify the maximum length, in vector elements, of the data output vector. Set this parameter to a value equal or greater than the data size of a UDP packet. The system truncates data that exceeds this length. This value defaults to 255.

If you disable **Output variable-size signal**, the block outputs a fixed-length output the same length as the **Maximum length for Message**.

Data type for Message

Set the data type of the vector elements in the Message output. Match the data type with the data input used to create the UDP packets. This option defaults to `uint8`.

Output variable-size signal

If your model supports signals of varying length, enable the **Output variable-size signal** parameter. This checkbox defaults to selected (enabled). In that case:

- The output vector varies in length, depending on the amount of data in the UDP packet.
- The block emits the data vector from a single unlabeled output.

If your model does not support signals of varying length, disable the **Output variable-size signal** parameter. In that case:

- The block emits a fixed-length output the same length as the **Maximum length for Message**.

- If the UDP packet contains less data than the fixed-length output, the difference contains invalid data.
- The block emits the data vector from the **Message** output.
- The block emits the length of the valid data from the **Length** output.
- The block dialog box displays the **Data type for Length** parameter.

In both cases, the block truncates data that exceeds the **Maximum length for Message**.

Data type for Length

Set the data type of the Length output. This option defaults to `double`.

Blocking time (seconds)

For each sample, wait this length of time for a UDP packet before returning control to the scheduler. This value defaults to `inf`, which indicates to wait indefinitely.

Note This parameter appears only in the Embedded Coder® UDP Receive block.

Sample time (seconds)

Specify how often the scheduler runs this block. Enter a value greater than zero. In real-time operation, setting this option to a smaller value reduces the likelihood of dropped UDP messages. This value defaults to a sample time of 0.01 s.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- The executable generated from this block relies on prebuilt dynamic library files (`.dll` files) included with MATLAB. Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development

environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

- The **Local IP port** parameter is tunable in the generated code, but not tunable during simulation. You can control the parameter tunability in the generated code through several ways. One of the ways is to configure the parameter as a tunable field of a global structure in the generated code. Other ways include applying a built-in storage class or custom storage class to a `Simulink.Parameter` object and using this object to set the value of the block parameter. For details, see “Block Parameter Representation in the Generated Code” (Simulink Coder).

Blocks

UDP Send

Introduced in R2010a

UDP Send

Send UDP message

Library

Sinks

dspnsks4

Description

The UDP Send block transmits an input vector as a UDP message over an IP network port. The remote IP port number to which the block sends the UDP packets is tunable in the C/C++ generated code.

Note Some Simulink blocks and .exe files built from models that contain those blocks require shared libraries, such as .dll files on Windows. The UDP Send block requires the networkdevice.dll library file. To meet this requirement, follow the example on the packNGo function page to package the code files for your model. The resulting compressed folder contains the .dll files that the model requires, including networkdevice.dll. To run this type of .exe file outside a MATLAB environment, place the required .dll files in the same folder as the .exe file, or place them in a folder on the Windows system path. For more details, see “How To Run a Generated Executable Outside MATLAB”.

Parameters

IP address ('255.255.255.255' for broadcast)

Specify the IP address or hostname to which the block sends the message. To broadcast the UDP message, retain the default value, '255.255.255.255'.

Remote IP port

Specify the port to which the block sends the message. This parameter is tunable in the C/C++ generated code but not tunable during simulation. The default is 25000. The value can be in the range [1 65535].

Note On Linux, to set the IP port number below 1024, run MATLAB with root privileges. For example, at the Linux command line, enter:

```
sudo matlab
```

Local IP port source

To let the system automatically assign the port number, select *Assign automatically*. To specify the IP port number using the **Local IP port** parameter, select *Specify*.

Local IP port

Specify the IP port number from which the block sends the message.

If the receiving address expects messages from a particular port number, enter that number here.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- The executable generated from this block relies on prebuilt dynamic library files (.dll files) included with MATLAB. Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.
- The **Remote IP port** parameter is tunable in the generated code, but not tunable during simulation. You can control the parameter tunability in the generated code through several ways. One of the ways is to configure the parameter as a tunable field of a global structure in the generated code. Other ways include applying a built-in storage class or custom storage class to a `Simulink.Parameter` object and using this object to set the value of the block parameter. For details, see “Block Parameter Representation in the Generated Code” (Simulink Coder).

Blocks

UDP Receive

Introduced in R2010a

Unbuffer

Unbuffer input frame into sequence of scalar outputs

Library

Signal Management / Buffers

`dspbuff3`

Description

The Unbuffer block unbuffers an M_i -by- N input into a 1-by- N output. That is, inputs are unbuffered *row-wise* so that each matrix row becomes an independent time-sample in the output. The rate at which the block receives inputs is generally less than the rate at which the block produces outputs.

The block adjusts the output rate so that the *sample period* is the same at both the input and output, $T_{so} = T_{si}$. Therefore, the output sample period for an input of frame size M_i and frame period T_{fi} is T_{fi}/M_i , which represents a *rate* M_i times higher than the input frame rate. In the example above, the block receives inputs only once every three sample periods, but produces an output once every sample period. To rebuffer inputs to a larger or smaller frame size, use the Buffer block.

In the model below, the block unbuffers a four-channel input with a frame size of three. The **Initial conditions** parameter is set to zero and the tasking mode is set to multitasking, so the first three outputs are zero vectors.

Zero Latency

The Unbuffer block has *zero-tasking latency* in Simulink single-tasking mode. Zero-tasking latency means that the first input sample (received at $t=0$) appears as the first output sample.

Nonzero Latency

For *multitasking* operation, the Unbuffer block's buffer is initialized with the value specified by the **Initial conditions** parameter, and the block begins unbuffering this frame at the start of the simulation. Inputs to the block are therefore delayed by one buffer length, or M_1 samples.

The **Initial conditions** parameter can be one of the following:

- A scalar to be repeated for the first M_i output samples of every channel
- A length- M_i vector containing the values of the first M_i output samples for every channel
- An M_i -by- N matrix containing the values of the first M_i output samples in each of N channels

Note For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Parameters

Initial conditions

The value of the block's initial output for cases of nonzero latency. You can specify a scalar, vector, or matrix.

`dspquant2`

Description

The Uniform Decoder block performs the inverse operation of the Uniform Encoder block, and reconstructs quantized floating-point values from encoded integer input. The block adheres to the definition for uniform decoding specified in ITU-T Recommendation G.701.

Inputs can be real or complex values of the following six integer data types: `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`.

The block first casts the integer input values to floating-point values, and then uniquely maps (decodes) them to one of 2^B uniformly spaced floating-point values in the range $[-V, (1-2^{1-B})V]$, where you specify B in the **Bits** parameter (as an integer between 2 and 32) and V is a floating-point value specified by the **Peak** parameter. The smallest input value representable by B bits (0 for an unsigned input data type; -2^{B-1} for a signed input data type) is mapped to the value $-V$. The largest input value representable by B bits (2^B-1 for an unsigned input data type; $2^{B-1}-1$ for a signed input data type) is mapped to the value $(1-2^{1-B})V$. Intermediate input values are linearly mapped to the intermediate values in the range $[-V, (1-2^{1-B})V]$.

To correctly decode values encoded by the Uniform Encoder block, the **Bits** and **Peak** parameters of the Uniform Decoder block should be set to the same values as the **Bits** and **Peak** parameters of the Uniform Encoder block. The **Overflow mode** parameter

specifies the Uniform Decoder block's behavior when the integer input is outside the range representable by B bits. When you select **Saturate**, *unsigned* input values greater than 2^B-1 saturate at 2^B-1 ; *signed* input values greater than $2^{B-1}-1$ or less than -2^{B-1} saturate at those limits. The real and imaginary components of complex inputs saturate independently.

When you select **Wrap**, *unsigned* input values, u , greater than 2^B-1 are wrapped back into the range $[0, 2^B-1]$ using mod- 2^B arithmetic.

$$u = \text{mod}(u, 2^B)$$

Signed input values, u , greater than $2^{B-1}-1$ or less than -2^{B-1} are wrapped back into that range using mod- 2^B arithmetic.

$$u = (\text{mod}(u+2^{B/2}, 2^B) - (2^{B/2}))$$

The real and imaginary components of complex inputs wrap independently.

The **Output type** parameter specifies whether the decoded floating-point output is single or double precision. Either level of output precision can be used with any of the six integer input data types.

Examples

See example model `ex_uniform_decoder`.

In this example, the input to the block is the `uint8` output of a Uniform Encoder block. This block has comparable settings: **Peak** = 2, **Bits** = 3, and **Output type** = `Unsigned`. (Comparable settings ensure that inputs to the Uniform Decoder block do not saturate or wrap. See the example on the Uniform Encoder block reference page for more about these settings.)

The real and complex components of each input are independently mapped to one of 2^3 distinct levels in the range $[-2.0, 1.5]$.

```
0 is mapped to -2.0
1 is mapped to -1.5
2 is mapped to -1.0
3 is mapped to -0.5
4 is mapped to  0.0
5 is mapped to  0.5
```

6 is mapped to 1.0
7 is mapped to 1.5

Parameters

Peak

Specify the largest amplitude represented in the encoded input. To correctly decode values encoded with the Uniform Encoder block, set the **Peak** parameters in both blocks to the same value.

Bits

Specify the number of input bits, *B*, used to encode the data. (This can be less than the total number of bits supplied by the input data type.) To correctly decode values encoded with the Uniform Encoder block, set the **Bits** parameters in both blocks to the same value.

Overflow mode

Specify the block's behavior when the integer input is outside the range representable by *B* bits. Out-of-range inputs can either saturate at the extreme value, or wrap back into range.

Output type

Specify the precision of the floating-point output, `single` or `double`.

Uniform Encoder

Quantize and encode floating-point input into integer output

Library

Quantizers

`dspquant2`

Description

The Uniform Encoder block performs the following two operations on each floating-point sample in the input vector or matrix:

- 1 Quantizes the value using the same precision
- 2 Encodes the quantized floating-point value to an integer value

In the first step, the block quantizes an input value to one of 2^B uniformly spaced levels in the range $[-V, (1-2^{1-B})V]$, where you specify B in the **Bits** parameter and you specify V in the **Peak** parameter. The quantization process rounds both positive and negative inputs *downward* to the nearest quantization level, with the exception of those that fall exactly on a quantization boundary. The real and imaginary components of complex inputs are quantized independently.

The number of bits, B , can be any integer value between 2 and 32, inclusive. Inputs greater than $(1-2^{1-B})V$ or less than $-V$ saturate at those respective values. The real and imaginary components of complex inputs saturate independently.

In the second step, the quantized floating-point value is uniquely mapped (encoded) to one of 2^B integer values. When the **Output type** is set to `Unsigned integer`, the smallest quantized floating-point value, $-V$, is mapped to the integer 0, and the largest quantized floating-point value, $(1-2^{1-B})V$, is mapped to the integer 2^B-1 . Intermediate

quantized floating-point values are linearly (uniformly) mapped to the intermediate integers in the range $[0, 2^B-1]$. For efficiency, the block automatically selects an *unsigned* output data type (uint8, uint16, or uint32) with the minimum number of bits equal to or greater than B .

When the **Output type** is set to Signed integer, the smallest quantized floating-point value, $-V$, is mapped to the integer -2^{B-1} , and the largest quantized floating-point value, $(1-2^{1-B})V$, is mapped to the integer $2^{B-1}-1$. Intermediate quantized floating-point values are linearly mapped to the intermediate integers in the range $[-2^{B-1}, 2^{B-1}-1]$. The block automatically selects a *signed* output data type (int8, int16, or int32) with the minimum number of bits equal to or greater than B .

Inputs can be real or complex, double or single precision. The output data types that the block uses are shown in the table below. Note that most of the DSP System Toolbox blocks accept only double-precision inputs. Use the Simulink Data Type Conversion block to convert integer data types to double precision. See “About Data Types in Simulink” (Simulink) for a complete discussion of data types, as well as a list of Simulink blocks capable of reduced-precision operations.

Bits	Unsigned Integer	Signed Integer
2 to 8	uint8	int8
9 to 16	uint16	int16
17 to 32	uint32	int32

The Uniform Encoder block operations adhere to the definition for uniform encoding specified in ITU-T Recommendation G.701.

Examples

See example model ex_uniform_encoder.

In this example, the following parameters are set:

- **Peak** = 2
- **Bits** = 3
- **Output type** = Unsigned

The following figure illustrates uniform encoding.

The real and complex components of each input (horizontal axis) are independently quantized to one of 2^3 distinct levels in the range $[-2, 1.5]$. These components are then mapped to one of 2^3 integer values in the range $[0, 7]$.

-2.0 is mapped to 0
 -1.5 is mapped to 1
 -1.0 is mapped to 2
 -0.5 is mapped to 3
 0.0 is mapped to 4
 0.5 is mapped to 5
 1.0 is mapped to 6
 1.5 is mapped to 7

This table shows the results for a few particular inputs.

Input	Quantized Input	Output	Notes
1.6	1.5+0.0i	7+4i	
-0.4	-0.5+0.0i	3+4i	
-3.2	-2.0+0.0i	4i	Saturation (real)
0.4-1.2i	0.0-1.5i	4+i	
0.4-6.0i	0.0-2.0i	4	Saturation (imaginary)
-4.2+3.5i	-2.0+2.0i	7i	Saturation (real and imaginary)

The output data type is automatically set to `uint8`, the most efficient format for this input range.

Parameters

Peak

The largest input amplitude to be encoded, V . Real or imaginary input values greater than $(1-2^{1-B})V$ or less than $-V$ saturate (independently for complex inputs) at those limits.

Bits

Specify the number of bits, B , needed to represent the integer output. The number of levels at which the block quantizes the floating-point input is 2^B .

Output type

The data type of the block's output, `Unsigned integer` or `Signed integer`. Unsigned outputs are `uint8`, `uint16`, or `uint32`, while signed outputs are `int8`, `int16`, or `int32`.

Unwrap

Unwrap signal phase

Library

Signal Operations

dspsigops

Description

The Unwrap block unwraps each channel of the input by adding or subtracting appropriate multiples of 2π to each channel element. The input can be a vector or matrix, and must have radian phase entries. The block recognizes phase discontinuities larger than the **Tolerance** parameter setting. For more information about phase unwrapping, see the “Definition of Phase Unwrap” on page 2-1709.

The block preserves the input size and dimension, and the output port rate equals the input port rate.

Unwrap Method

The Unwrap block unwraps each channel of its input matrix or input vector by adding $2\pi k$ to each successive channel element, and updating k at each *phase jump*. A phase jump occurs when the difference between two adjacent phase value entries exceeds the value of the **Tolerance** parameter.

The following code illustrates how the block unwraps the data in a given input channel u .

```
k=0; % initialize k to 0
i=1; % initialize the counter to 1
alpha=pi; % set alpha to the desired Tolerance. In this case, pi

for i = 1:(size(u)-1)
    yout(i,:) = u(i) + (2*pi*k); % add 2*pi*k to ui
```

```
if((abs(u(i+1)-u(i)))>(abs(alpha))) %if diff is greater than alpha, increment or decrement k
    if u(i+1)<u(i) % if the phase jump is negative, increment k
        k=k+1;
    else % if the phase jump is positive, decrement k
        k=k-1;
    end
end
end
yout((i+1),:)=u(i+1)+(2*pi*k); % add 2*pi*k to the last element of the input
```

Frame-Based Processing

When you configure the block to perform frame-based processing, the block supports two different unwrap modes. In both modes, the block adds $2\pi k$ to each input channel's elements, and updates k at each phase discontinuity. The difference between the two modes is how often the block resets the initial phase value (k) to zero. You can choose to unwrap data across frame boundaries (default), or to unwrap only within input frames, by resetting the initial phase value each time a new input frame is received.

In the default mode, the block ignores boundaries between input frames, and continues to unwrap the data in each channel without resetting the initial phase value to zero. To specify this mode, clear the **Do not unwrap phase discontinuities between successive frames** check box. The following figure illustrates how the block unwraps data in this mode.

Default Frame-Based Unwrap Mode

Do not unwrap phase discontinuities between successive frames

When you select the **Do not unwrap phase discontinuities between successive frames** check box, the block treats each frame of input data independently. In this mode, the block resets the initial phase value to zero each time a new input frame is received. The following figure illustrates how the block unwraps data in this mode.

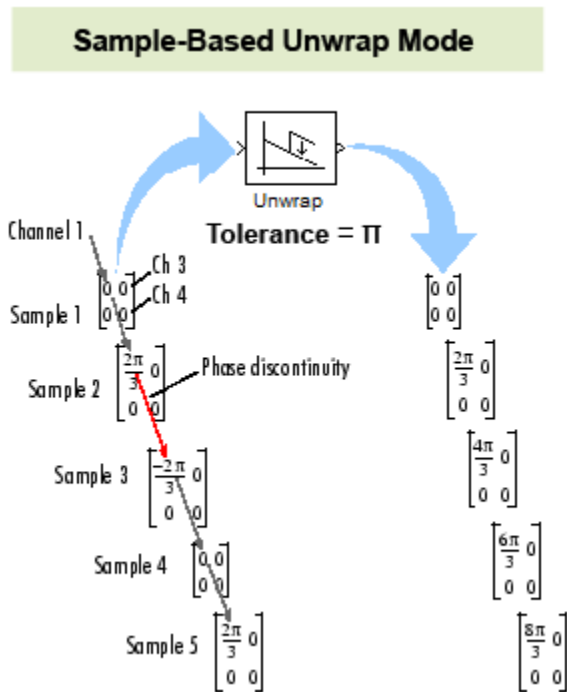

Nondefault Frame-Based Unwrap Mode

Do not unwrap phase discontinuities between successive frames

Sample-Based Processing

When you configure the block to perform sample-based processing, the block treats each element of the input as an individual channel. The block unwraps the data in each channel of the input, and does not reset the initial phase to zero each time a new input is received. The following figure illustrates how the block unwraps data when performing sample-based processing.

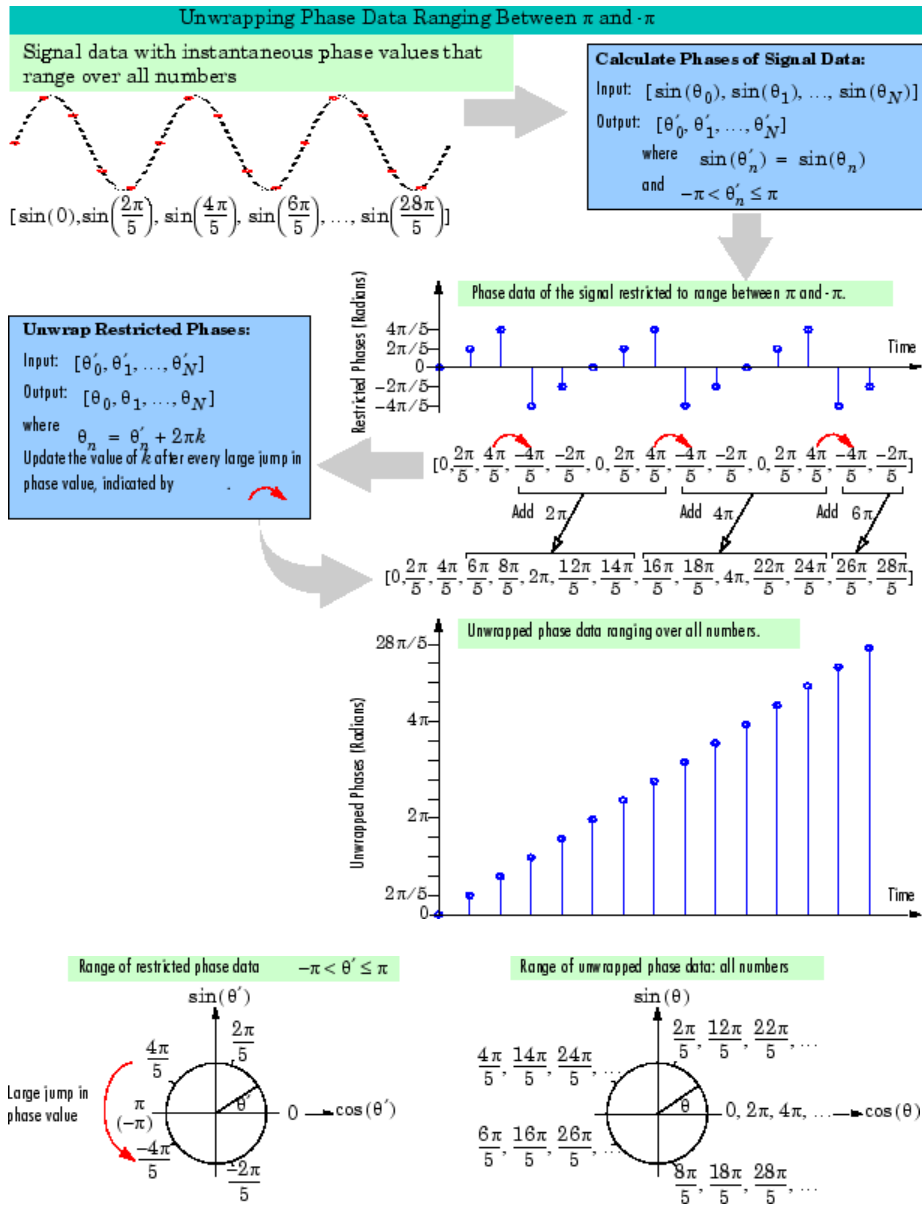

Definition of Phase Unwrap

Algorithms that compute the phase of a signal often only output phases between $-\pi$ and π . For instance, such algorithms compute the phase of $\sin(2\pi + 3)$ to be 3, since $\sin(3) = \sin(2\pi + 3)$, and since the actual phase, $2\pi + 3$, is not between $-\pi$ and π . Such algorithms compute the phases of $\sin(-4\pi + 3)$ and $\sin(16\pi + 3)$ to be 3 as well.

Phase unwrap or unwrap is a process often used to reconstruct a signal's original phase. Unwrap algorithms add appropriate multiples of 2π to each phase input to restore original phase values, as illustrated in the following diagram. See “Unwrap Method” on page 2-1705 for more information on the unwrap algorithm used by this block.

The following figure illustrates the concept of phase unwrapping.

Parameters

Tolerance

The jump size that the block recognizes as a true phase discontinuity. The default is set to π (rather than a smaller value) to avoid altering legitimate signal features. To increase the block's sensitivity, set the **Tolerance** to a value slightly less than π .

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` (default) — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Do not unwrap phase discontinuities between successive frames

When you clear this check box, the block ignores boundaries between input frames and does not reset the initial phase value to zero each time a new input is received. In this mode, the block continuously unwraps the data in each column of the input. When you select this check box, the block treats each frame of input data independently, and resets the initial phase value for each new input frame. See the “Frame-Based Processing” on page 2-1706 section for more information.

This parameter is available only when you configure the block to perform frame-based processing. In sample-based processing mode, the block does not reset the initial phase value to zero for each new input. See “Sample-Based Processing” on page 2-1708 for more information.

Supported Data Types

- Double-precision floating point
- Single-precision floating point

Upsample

Resample input at higher rate by inserting zeros

Library

Signal Operations

dspsigops

Description

The Upsample block resamples each channel of the M_1 -by- N input at a rate L times higher than the input sample rate by inserting $L-1$ zeros between consecutive samples. You specify the integer L in the **Upsample factor** parameter. The **Sample offset** parameter, D , allows you to delay the output samples by an integer number of sample periods. Doing so enables you to select any of the L possible output phases. The value you specify for the **Sample offset** parameter must be in the range $0 \leq D < (L-1)$.

You can use this block inside of triggered subsystems when you set the **Rate options** parameter to `Enforce single-rate processing`.

Frame-Based Processing

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block upsamples each column of the input over time. In this mode, the block can perform either single-rate or multirate processing. You can use the **Rate options** parameter to specify how the block upsamples the input:

- When you set the **Rate options** parameter to `Enforce single-rate processing`, the input and output of the block have the same sample rate. In this mode, the block outputs a signal with a proportionally larger frame *size* than the input. For

upsampling by a factor of L , the output frame size is L times larger than the input frame size ($M_o = M_i * L$), but the input and output frame rates are equal.

For an example of single-rate upsampling, see the **Single-Rate Processing** example.

- When you set the **Rate options** parameter to `Allow multirate processing`, the block treats an M_i -by- N matrix input as N independent channels. The block upsamples each column of the input over time by keeping the frame size constant ($M_i = M_o$), and making the output frame period (T_{fo}) L times shorter than the input frame period ($T_{fo} = T_{fi}/L$).

See the **Multirate, Frame-Based Processing** example to see the Upsample block in this mode.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats an M -by- N matrix input as $M * N$ independent channels, and upsamples each channel over time. In this mode, the block always performs multirate processing. The output sample rate is L times higher than the input sample rate ($T_{so} = T_{si}/L$), and the input and output sizes are identical.

Zero Latency

The Upsample block has *zero-tasking latency* for all single-rate operations. The block is in a single-rate mode if you set the **Upsample factor** parameter to 1 or if you set the **Input processing** parameter to `Columns as channels (frame based)` and the **Rate options** parameter to `Enforce single-rate processing`.

The Upsample block also has zero-tasking latency for multirate operations if you run your model in Simulink single-tasking mode.

Zero-tasking latency means that the block propagates the first input (received at $t=0$) immediately following the D consecutive zeros specified by the **Sample offset** parameter. This output ($D+1$) is followed in turn by the $L-1$ inserted zeros and the next input sample.

Nonzero Latency

The Upsample block has tasking latency for multirate, multitasking operation:

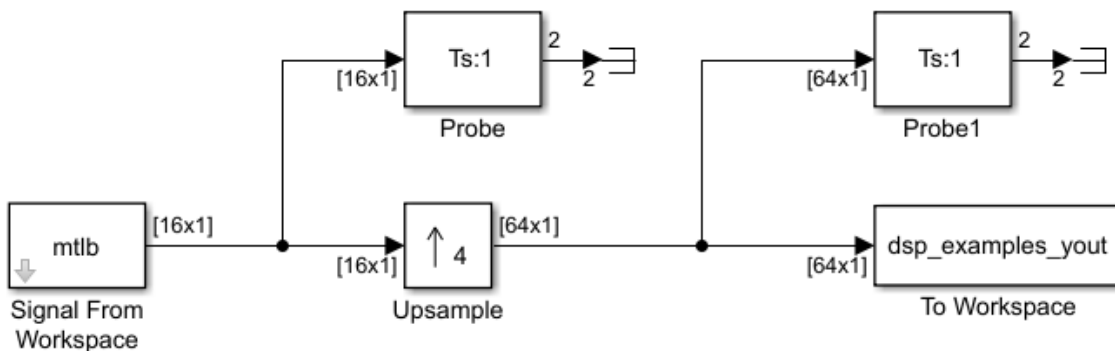

- In multirate, sample-based processing mode, the initial condition for each channel appears as output sample $D+1$, and is followed by $L-1$ inserted zeros. The channel's first input appears as output sample $D+L+1$. The **Initial conditions** parameter can be an M_i -by- N matrix containing one value for each channel, or a scalar to be applied to all signal channels.
- In multirate, frame-based processing mode, the first row of the initial condition matrix appears as output sample $D+1$, and is followed by $L-1$ inserted rows of zeros, the second row of the initial condition matrix, and so on. The first row of the first input matrix appears in the output as sample M_iL+D+1 . The **Initial conditions** parameter can be an M_i -by- N matrix, or a scalar to be repeated across all elements of the input matrix.

Note For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Examples

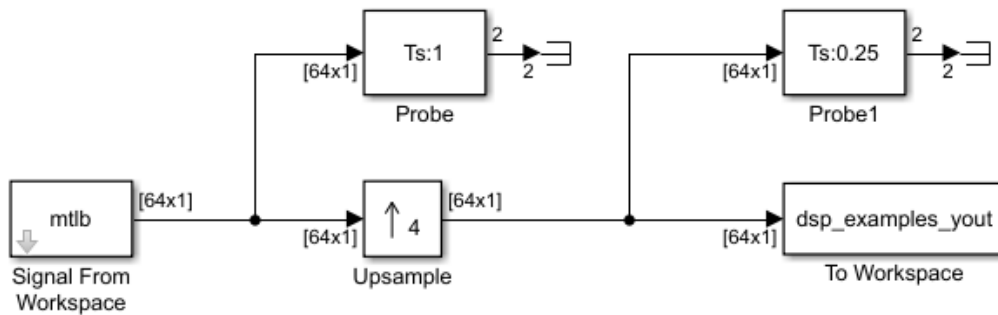

Example 2.5. Example: Single-Rate Processing

In the `ex_upsample_ref2` model, the Upsample block resamples a single-channel input with a frame size of 16. The block upsamples the input by a factor of 4. Thus, the output of the block has a frame size of 64. Because the block is in single-rate processing mode, the input and output frame rates are identical.

Example 2.6. Example: Multirate, Frame-Based Processing

In the `ex_upsample_ref1` model, the Upsample block resamples a single-channel input with a frame period of 1 second. The block upsamples the input by a factor of 4. Thus, the output of the block has a frame period of 0.25 seconds. Because the block is in multirate processing mode, the input and output frame sizes are identical.

Parameters

Upsample factor

The integer factor, L , by which to increase the input sample rate.

Sample offset

The sample offset, D , which must be an integer in the range $[0, L-1]$.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel. In this mode, the block can perform single-rate or multirate processing.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel. In this mode, the block always performs multirate processing.

Rate options

Specify the method by which the block upsamples the input. You can select one of the following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the input sample rate by increasing the output frame size by a factor of L . To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.
- `Allow multirate processing` — When you select this option, the block resamples the signal such that the output sample rate is L times faster than the input sample rate.

Initial conditions

The value with which the block is initialized for cases of nonzero latency, a scalar or matrix. This value appears in the output as sample $D+1$. This parameter appears only when you configure the block to perform multirate processing.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see Upsample.

Variable Bandwidth FIR Filter

Design tunable bandwidth FIR filter

Library

Filtering / Filter Designs

dspfdesign

Description

The Variable Bandwidth FIR Filter block filters each channel of the input signal over time using specified FIR filter specifications. This block offers tunable filter design parameters, which enable you to tune the filter characteristics while the simulation is running.

The block designs the FIR filter according to the filter parameters set in the block dialog box. The output port properties, such as datatype, complexity, and dimension, are identical to the input port properties.

Each column of the input signal is treated as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size) and the second dimension represents the number of channels. If the input is a one-dimensional signal, then it is interpreted as a single channel.

This block supports variable-size input, enabling you to change the channel length during simulation. To enable variable-size input, clear the **Inherit sample rate from input** check box. The number of channels must remain constant.

Algorithms

This block brings the capabilities of `dsp.VariableBandwidthFIRFilter` System object to the Simulink environment.

The FIR filter is designed using the window method. For information on the algorithms used by the Variable Bandwidth FIR Filter block, see the “Algorithms” on page 4-1781 section of `dsp.VariableBandwidthFIRFilter`.

Examples

- “System Identification Using RLS Adaptive Filtering”

Parameters

FIR filter order

Order of the FIR filter, specified as a positive integer scalar. The default is 30. This parameter is nontunable.

Filter type

Type of FIR filter. You can set this parameter to:

- Lowpass (default)
- Highpass
- Bandpass
- Bandstop

This parameter is nontunable.

Filter Cutoff frequency (Hz)

Cutoff frequency of the FIR filter, specified as a real positive scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter type** to Lowpass or Highpass. The default is 1000. This parameter is tunable.

Filter center frequency (Hz)

Center frequency of the FIR filter, specified as a real positive scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter type** to Bandpass or Bandstop. The default is 10000. This parameter is tunable.

Filter bandwidth (Hz)

Bandwidth of the FIR filter, specified as a real positive scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter type** to Bandpass or Bandstop. The default is 2000. This parameter is tunable.

Window function

Window function used to design the FIR filter. You can set this parameter to:

- Hann (default)
- Hamming
- Chebyshev
- Kaiser

This parameter is nontunable.

Chebyshev window sidelobe attenuation (dB)

Sidelobe attenuation of chebyshev window, specified as a real positive scalar. This parameter applies when you set **Window function** to Chebyshev. The default is 60. This parameter is nontunable.

Kaiser window parameter

Kaiser window parameter, specified as a real scalar. This parameter applies when you set **Window function** to Kaiser. The default is 0.5. This parameter is nontunable.

Inherit sample rate from input

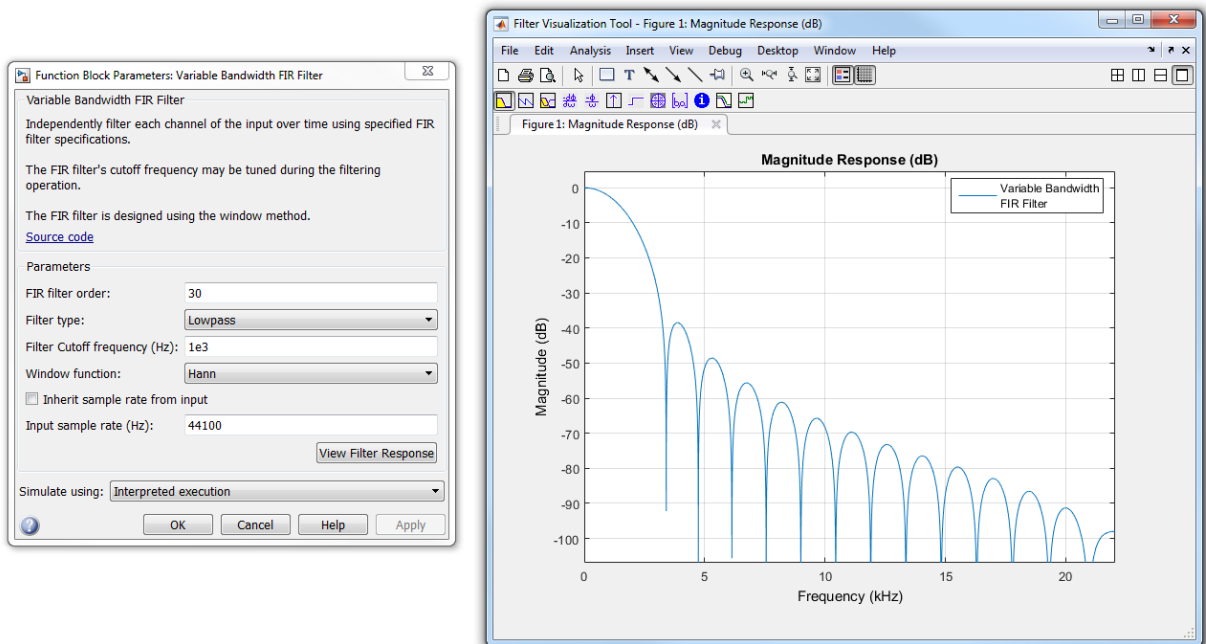

When you select this check box, the block's sample rate is computed as N / T_s , where N is the frame size of the input signal and T_s is the sample time of the input signal. When you clear this check box, the block's sample rate is the value specified in **Input sample rate (Hz)**. By default, this check box is selected.

Input sample rate (Hz)

Sample rate of the input signal, specified as a positive scalar. The default is 44100. This parameter applies when you clear the **Inherit sample rate from input** check box. This parameter is nontunable.

View Filter Response

Opens the Filter Visualization Tool FVTool and displays the magnitude/phase response of the Variable Bandwidth FIR Filter. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.

To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

Simulate using

Type of simulation to run. You can set this parameter to:

- Interpreted execution (default)

Simulate model using the MATLAB interpreter. This option has faster simulation speed compared to Code generation.

- Code generation

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time compared to Interpreted execution.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none">• Double-precision floating point• Single-precision floating point
Output	<ul style="list-style-type: none">• Double-precision floating point• Single-precision floating point

Variable Bandwidth IIR Filter

Design tunable bandwidth IIR filter

Library

Filtering / Filter Designs

`dspfdesign`

Description

The Variable Bandwidth IIR Filter block filters each channel of the input signal over time using specified IIR filter specifications. This block offers tunable filter design parameters, which enable you to tune the filter characteristics while the simulation is running.

The block designs the IIR filter according to the filter parameters set in the block dialog box. The output port properties, such as datatype, complexity, and dimension, are identical to the input port properties.

Each column of the input signal is treated as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size) and the second dimension represents the number of channels. If the input is a one-dimensional signal, then it is interpreted as a single channel.

This block supports variable-size input, enabling you to change the channel length during simulation. To enable variable-size input, clear the **Inherit sample rate from input** check box. The number of channels must remain constant.

Algorithms

This block brings the capabilities of `dsp.VariableBandwidthIIRFilter` System object to the Simulink environment.

The IIR filter is designed using the elliptical method. The IIR filter is tuned using IIR spectral transformations based on allpass filters. For more information on the algorithms used by the Variable Bandwidth IIR Filter block, see the “Algorithms” on page 4-1791 section of `dsp.VariableBandwidthIIRFilter`.

Examples

- “Tunable Lowpass Filtering of Noisy Input in Simulink”

Parameters

Filter type

Type of IIR filter. You can set this parameter to:

- Lowpass (default)
- Highpass
- Bandpass
- Bandstop

This parameter is nontunable.

IIR filter order

Order of the IIR filter, specified as a positive integer scalar. The default is 8. This parameter is nontunable.

Filter passband frequency (Hz)

Passband frequency of the IIR filter, specified as a real positive scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter type** to `Lowpass` or `Highpass`. The default is 1000. This parameter is tunable.

Filter center frequency (Hz)

Center frequency of the IIR filter, specified as a real positive scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter type** to Bandpass or Bandstop. The default is 10000. This parameter is tunable.

Filter bandwidth (Hz)

Bandwidth of the IIR filter, specified as a real positive scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter type** to Bandpass or Bandstop. The default is 2000. This parameter is tunable.

Filter passband ripple (dB)

Passband ripple of the IIR filter, specified as a real positive scalar. The default is 1. This parameter is nontunable.

Filter Stopband attenuation (dB)

Stopband attenuation of the IIR filter, specified as a real positive scalar. The default is 60. This parameter is nontunable.

Inherit sample rate from input

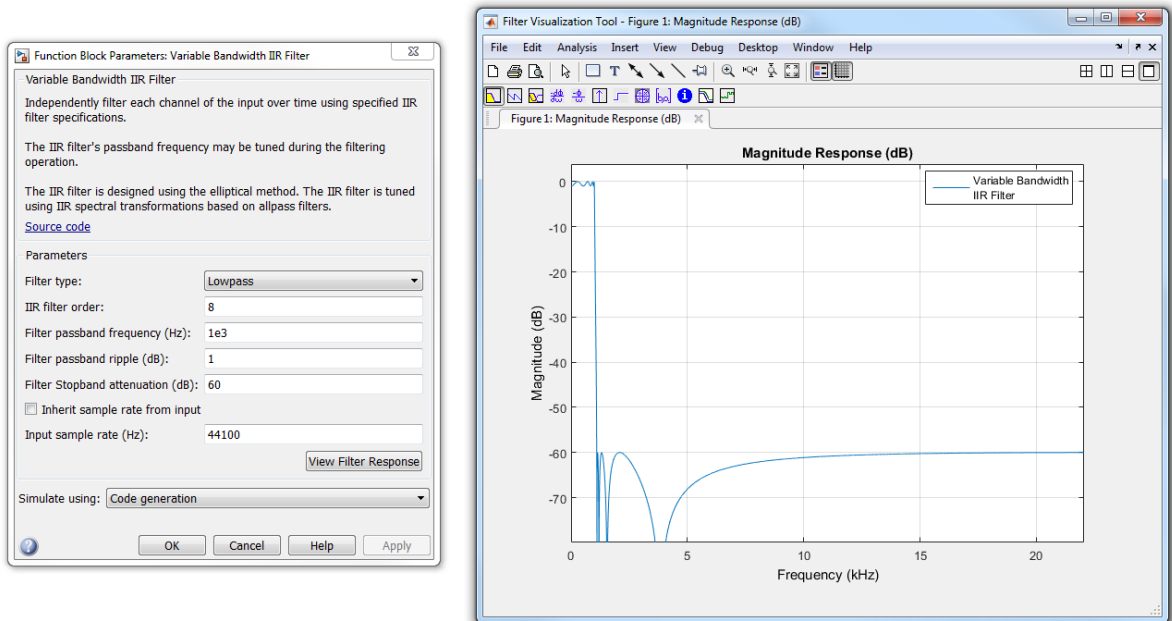

When you select this check box, the block's sample rate is computed as N / T_s , where N is the frame size of the input signal and T_s is the sample time of the input signal. When you clear this check box, the block's sample rate is the value specified in **Input sample rate (Hz)**. By default, this check box is selected.

Input sample rate (Hz)

Sample rate of the input signal, specified as a positive scalar. The default is 44100. This parameter applies when you clear the **Inherit sample rate from input** check box. This parameter is nontunable.

View Filter Response

Opens the Filter Visualization Tool FVTool and displays the magnitude/phase response of the Variable Bandwidth IIR Filter. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.

To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

Simulate using

Type of simulation to run. You can set this parameter to:

- Code generation (default)

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

- Interpreted execution

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none">• Double-precision floating point• Single-precision floating point
Output	<ul style="list-style-type: none">• Double-precision floating point• Single-precision floating point

Variable Fractional Delay

Delay input by time-varying fractional number of sample periods

Library: DSP System Toolbox / Signal Operations

Description

The Variable Fractional Delay block delays the input signal by a specified number of fractional samples along each channel of the input. The block can also concurrently compute multiple delayed versions (taps) of the same signal. For an example, see “Delay Signal Using Multitap Fractional Delay”.

When the delay has a fractional value, the block interpolates the input signal to obtain new samples at noninteger sampling intervals. You can set **Interpolation mode** parameter to one of `Linear`, `FIR`, or `Farrow`. The block supports time-varying delay values. That is, the delay value can vary within a frame from sample to sample.

The block assumes that the input values at the **Delay** port are between D_{min} and D_{max} , where D_{min} appears in the `Valid delay range` section on the **Main** tab of the block dialog, and D_{max} is the value of the **Maximum delay (Dmax) in samples** parameter. The block clips delay values less than D_{min} to D_{min} and delay values greater than D_{max} to D_{max} .

You must consider additional factors when selecting valid `Delay` values for the `FIR` and `Farrow` interpolation modes. For details, see “Algorithms” on page 2-1749.

Ports

Input

In — Data input
vector | matrix

Specify the data input as a vector or matrix. The data input must have the same data type as the delay input.

This block supports variable-size input signal. That is, you can change the number of input rows during the simulation. However, the number of channels must remain constant.

Example: [1 2 3 4;5 1 4 2;2 6 2 3;1 2 3 2;3 4 5 6;1 2 3 1]

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

Delay — Delay input

scalar | vector | matrix | *N*-D array

Specify the delay input as a scalar, vector, matrix, or *N*-D array. The delay can be an integer or a fractional value. The block interpolates the signal to obtain new samples at noninteger sampling intervals. The delay input must have the same data type as the data input.

This block supports variable-size delay signal. That is, you can change one or both of the dimensions of the delay signal during simulation. However, the block must make sure that the resulting number of output channels remains constant throughout the simulation.

When the **Input processing** parameter is set to `Columns as channels (frame based)`, the table below shows the effect of the dimension of the delay input on the data input. For an example, see “Delay Signal Using Multitap Fractional Delay”.

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
<i>N</i> (unoriented, one channel)	scalar	Unoriented (<i>N</i>)	One delay value applied to the input channel
<i>N</i> (unoriented, one channel)	Unoriented (<i>N</i>)	Unoriented (<i>N</i>)	Delay value varies within the frame from sample to sample

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N (unoriented, one channel)	1-by- P	N -by- P	P taps. Each column in the output is a delayed version of the input. The delay value is specified by the corresponding element in the delay input vector.
N (unoriented, one channel)	N -by- P	N -by- P	P taps. In addition, delay varies within each frame from sample to sample.
N -by-1 (one channel with frame size equal to N)	scalar	N -by-1	One delay value applied to the input channel
N -by-1 (one channel with frame size equal to N)	Unoriented (N)	N -by-1	Delay value varies within the frame from sample to sample
N -by-1 (one channel with frame size equal to N)	N -by-1	N -by-1	Delay value varies within the frame from sample to sample
N -by-1 (one channel with frame size equal to N)	1-by- P	N -by- P	P taps. Each column in the output is a delayed version of the input. The delay value is specified by the corresponding element in the delay input vector.
N -by-1 (one channel with frame size equal to N)	N -by- P	N -by- P	P taps. In addition, delay varies within each frame from sample to sample.

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N -by- L (L channels with frame size equal to N)	scalar	N -by- L	One delay value applied to all input channels
N -by- L (L channels with frame size equal to N)	1-by- L	N -by- L	Unique delay value for each input channel
N -by- L (L channels with frame size equal to N)	N -by-1	N -by- L	Delay value varies within the frame from sample to sample. Same set of delay values for all channels.
N -by- L (L channels with frame size equal to N)	N -by- L	N -by- L	Delay value varies within the frame from sample to sample. Different delay values for each input channel.
N -by- L (L channels with frame size equal to N)	1-by-1-by- P	N -by- L -by- P	L channels. P taps per channel. Same delay for all channels.
N -by- L (L channels with frame size equal to N)	1-by- L -by- P	N -by- L -by- P	L channels. P taps per channel. Taps vary across channels.
N -by- L (L channels with frame size equal to N)	N -by-1-by- P	N -by- L -by- P	L channels. P taps per channel. Delay varies within the frame from sample to sample. Same set of delay values for each channel.

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N -by- L (L channels with frame size equal to N)	N -by- L -by- P	N -by- L -by- P	L channels. P taps per channel. Delay varies within the frame from sample to sample. Different set of delay values for each channel.

When the **Input processing** parameter is set to `Elements as channels (sample based)`, the table below shows the effect of the dimension of the delay input on the data input.

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N (unoriented, one channel)	scalar	Unoriented (N)	One delay value applied to the input channel
N (unoriented, one channel)	Unoriented (N)	Unoriented (N)	Delay value varies within the frame from sample to sample
N -by-1 (one channel with frame size equal to N)	scalar	N -by-1	One delay value applied to the input channel
N -by-1 (one channel with frame size equal to N)	Unoriented (N)	N -by-1	Delay value varies within the frame from sample to sample
N -by-1 (one channel with frame size equal to N)	N -by-1	N -by-1	Delay value varies within the frame from sample to sample
N -by- L (L channels with N samples in each channel)	scalar	N -by- L	One delay value applied to all input channels

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N -by- L (L channels with N samples in each channel)	1-by- L	N -by- L	Unique delay value for each input channel
N -by- L (L channels with N samples in each channel)	N -by-1	N -by- L	Delay value varies within the frame from sample to sample. Same set of delay values for all channels.
N -by- L (L channels with N samples in each channel)	N -by- L	N -by- L	Delay value varies within the frame from sample to sample. Different delay values for each input channel.

Example: [2 3 4 5]

Example: [2.5]

Example: [5.6]

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

Port_1 — Delayed output

`vector` | `matrix`

Delayed output, returned as a vector or matrix. The data type and complexity of the output match the data type and complexity of the data input.

When the **Input processing** parameter is set to `Columns as channels` (frame based), the table below shows the effect of the dimension of the delay input on the data input.

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N (unoriented, one channel)	scalar	Unoriented (N)	One delay value applied to the input channel
N (unoriented, one channel)	Unoriented (N)	Unoriented (N)	Delay value varies within the frame from sample to sample
N (unoriented, one channel)	1-by- P	N -by- P	P taps. Each column in the output is a delayed version of the input. The delay value is specified by the corresponding element in the delay input vector.
N (unoriented, one channel)	N -by- P	N -by- P	P taps. In addition, delay varies within each frame from sample to sample.
N -by-1 (one channel with frame size equal to N)	scalar	N -by-1	One delay value applied to the input channel
N -by-1 (one channel with frame size equal to N)	Unoriented (N)	N -by-1	Delay value varies within the frame from sample to sample
N -by-1 (one channel with frame size equal to N)	N -by-1	N -by-1	Delay value varies within the frame from sample to sample

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N -by-1 (one channel with frame size equal to N)	1-by- P	N -by- P	P taps. Each column in the output is a delayed version of the input. The delay value is specified by the corresponding element in the delay input vector.
N -by-1 (one channel with frame size equal to N)	N -by- P	N -by- P	P taps. In addition, delay varies within each frame from sample to sample.
N -by- L (L channels with frame size equal to N)	scalar	N -by- L	One delay value applied to all input channels
N -by- L (L channels with frame size equal to N)	1-by- L	N -by- L	Unique delay value for each input channel
N -by- L (L channels with frame size equal to N)	N -by-1	N -by- L	Delay value varies within the frame from sample to sample. Same set of delay values for all channels.
N -by- L (L channels with frame size equal to N)	N -by- L	N -by- L	Delay value varies within the frame from sample to sample. Different delay values for each input channel.
N -by- L (L channels with frame size equal to N)	1-by-1-by- P	N -by- L -by- P	L channels. P taps per channel. Same delay for all channels.

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N -by- L (L channels with frame size equal to N)	1-by- L -by- P	N -by- L -by- P	L channels. P taps per channel. Taps vary across channels.
N -by- L (L channels with frame size equal to N)	N -by-1-by- P	N -by- L -by- P	L channels. P taps per channel. Delay varies within the frame from sample to sample. Same set of delay values for each channel.
N -by- L (L channels with frame size equal to N)	N -by- L -by- P	N -by- L -by- P	L channels. P taps per channel. Delay varies within the frame from sample to sample. Different set of delay values for each channel.

When the **Input processing** parameter is set to `Elements` as channels (sample based), the table below shows the effect of the dimension of the delay input on the data input.

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N (unoriented, one channel)	scalar	Unoriented (N)	One delay value applied to the input channel
N (unoriented, one channel)	Unoriented (N)	Unoriented (N)	Delay value varies within the frame from sample to sample
N -by-1 (one channel with frame size equal to N)	scalar	N -by-1	One delay value applied to the input channel

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N -by-1 (one channel with frame size equal to N)	Unoriented (N)	N -by-1	Delay value varies within the frame from sample to sample
N -by-1 (one channel with frame size equal to N)	N -by-1	N -by-1	Delay value varies within the frame from sample to sample
N -by- L (L channels with N samples in each channel)	scalar	N -by- L	One delay value applied to all input channels
N -by- L (L channels with N samples in each channel)	1-by- L	N -by- L	Unique delay value for each input channel
N -by- L (L channels with N samples in each channel)	N -by-1	N -by- L	Delay value varies within the frame from sample to sample. Same set of delay values for all channels.
N -by- L (L channels with N samples in each channel)	N -by- L	N -by- L	Delay value varies within the frame from sample to sample. Different delay values for each input channel.

Example: [0 0 0 0;0 0 0 0;1 0 0 0;5 2 0 0;2 1 3 0;1 6 4 4]

Example: [0 0 0 0;0 0 0 0;0.5 1.0 1.5 2.0;3 1.5 3.5 3.0;3.5 3.5 3.0 2.5;1.5 4.0 2.5 2.5]

Example: [0 0 0 0;0 0 0 0;0 0 0 0;0 0 0 0;0 0 0 0;0.4 0.8 1.2 1.6]

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

Parameters

Interpolation mode — Method of interpolation

Linear (default) | FIR | Farrow

Specify the method of interpolation. Using this method, the block interpolates the signal to obtain new samples at noninteger sampling intervals.

- **Linear** — Linear interpolation. In this mode, the block stores the $D_{\max}+1$ most recent samples the **In** port receives for each channel. D_{\max} is the value you specify in the **Maximum delay (Dmax) in samples** parameter.
- **FIR** — Polyphase FIR interpolation. In this mode, the block stores the $D_{\max}+P+1$ most recent samples the **In** port receives for each channel. P is the value you specify in the **Interpolation filter half-length (P)** parameter.
- **Farrow** — LaGrange method. In this mode, the block stores the $D_{\max} + \frac{N}{2} + 1$ most recent samples the **In** port receives for each channel. N is the value you specify in the **Farrow filter length (N)** parameter.

For more details on these methods, see “Algorithms” on page 2-1749.

Interpolation filter half-length (P) — Half length of interpolation filter

4 (default) | positive integer in the range [1 65535]

Half-length of the FIR interpolation filter. For periodic signals, a larger value of this property, which indicates a higher order filter, yields a better estimate of the delayed output sample. A property value of 4 to 6, which corresponds to a 7th-order to 11th-order filter, is usually adequate.

Example: 6

Example: 10

Dependencies

This parameter applies only when you set **Interpolation mode** to FIR.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point

Interpolation points per input sample — Number of interpolation points per input sample

10 (default) | positive integer in the range [2, 65,535]

Number of interpolation points per input sample at which a unique FIR interpolation filter is computed.

Example: 20

Example: 5

Dependencies

This parameter applies only when you set **Interpolation mode** to FIR.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Normalized input bandwidth (0 to 1) — Normalized input bandwidth

1 (default) | real scalar in the range (0, 1]

Normalized input bandwidth at which to constrain the interpolated output samples. A value of 1 equals the Nyquist frequency, or half the sampling frequency, F_s . Use this property to take advantage of the bandlimited frequency content of the input. For example, if the input signal does not have frequency content above $F_s/4$, you can specify a value of 0.5.

Example: 0.5

Example: 0.8

Dependencies

This parameter applies only when you set **Interpolation mode** to FIR.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point

Farrow filter length (N) — Length of Farrow filter

4 (default) | integer greater than or equal to 2

Length of the FIR filter implemented using the Farrow structure. If the length equals 2, the filter performs linear interpolation.

Example: 4

Example: 10

Dependencies

This parameter applies only when you set **Interpolation mode** to Farrow.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Maximum delay (Dmax) in samples — Maximum delay

100 (default) | integer in the range [0 65535]

Maximum delay the block can produce, D_{\max} . Input delay values exceeding this maximum are clipped to D_{\max} .

Example: 200

Example: 500

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Input processing — Method to process the input

`Columns as channels (frame based) (default)` | `Elements as channels (sample based)`

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based) (default)` — When you select this option, the block treats each column of the input as a separate channel. The block treats each of the R input columns as independent channels containing M_i sequential time samples.

The input to the **Delay** port, v , contains floating-point values that specify the number of sample intervals to delay the current input.

The input to the **Delay** port can be a scalar value to uniformly delay every sample in every channel. It can also be a length- M column vector, containing one delay for each sample in the input frame. The block applies the set of delays contained in the vector identically to every channel of a multichannel input. The **Delay** port entry can also be a length- R row vector, containing one delay for each channel. Finally, the **Delay** port entry can be an M -by- R matrix, containing a different delay for each corresponding element of the input.

For example, if v is the M_i -by-1 matrix $[v(1) \ v(2) \ \dots \ v(M_i)]'$, the earliest sample in the current frame is delayed by $v(1)$ fractional sample intervals, the

following sample in the frame is delayed by $v(2)$ fractional sample intervals, and so on. The block applies the set of fractional delays contained in v identically to every channel of a multichannel input.

- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel. The block treats each element of the N-D input array, u , as an independent channel. The input to the **Delay** port, v , must either be an N-D array of the same size and dimension as the input u , or be a scalar value, such that $D_{min} \leq v \leq D_{max}$.

For example, consider an M -by- R input matrix. The block treats each of the $M \times R$ matrix elements as independent channels. The input to the **Delay** port can be an M -by- R matrix of floating-point values in the range $D_{min} \leq v \leq D_{max}$ that specifies the number of sample intervals to delay each channel of the input, or it can be a scalar floating-point value, $D_{min} \leq v \leq D_{max}$, by which to equally delay all channels.

In sample-based processing mode, the block treats an unoriented vector input as an M -by-1 matrix. In this mode, the output is also an unoriented vector.

InitialConditions — Initial values in the memory

0 (default) | scalar | 1-by- R -by- D array | 1-by- R -by- $(D+L)$ array

Specify the values with in the block's memory at the start of the simulation. The dimensions of this parameter can vary depending on whether you want fixed or time-varying initial conditions. The block treats each of the R input columns as a frame containing M sequential time samples from an independent channel.

For an M -by- R input matrix, u , you can set this parameter as follows:

- To specify fixed initial conditions, set this parameter to a scalar value. The block initializes every sample of every channel in memory using the value you specify.
- The dimensions you specify for time-varying initial conditions depend on the interpolation method. To specify different time-varying initial conditions for each channel, set this parameter as follows:
 - If you set the **Interpolation mode** to `Linear`, set the **Initial conditions** to an array of size 1-by- R -by- D , where D is the value in **Maximum delay (Dmax) in samples** parameter.
 - If you set the **Interpolation mode** to `FIR` or `Farrow`, set the **Initial conditions** to an array of size 1-by- R -by- $(D+L)$, where D is the value of the maximum delay. For FIR interpolation, L is the value of the interpolation filter half length. For

Farrow interpolation, L equals `floor` of half the value of the farrow filter length (`floor(farrow filter length/2)`).

Example: 1

Example: `randn(1,3,104)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Disable direct feedthrough by increasing minimum possible delay by one — Disable direct feedthrough

`off` (default) | `on`

Select this box to disable direct feedthrough by increasing the minimum possible delay value. When you set the **Input processing** parameter to `Columns as channels` (frame based), the block increases the minimum possible delay value by `frame size - 1`. Similarly, when you set the **Input processing** parameter to `Elements as channels` (sample based), the block increases the minimum possible delay value by one sample.

Checking this box allows you to use the Variable Fractional Delay block in feedback loops.

For small input delay values — Action to take for small input delay values

`Clip to the minimum value necessary for centered kernel` (default) | `Use off-centered kernel` | `Switch to linear interpolation if kernel cannot be centered`

Specify the block's behavior when the input delay values are too small to center the kernel.

You can specify how the block handles input delay values that are too small for the kernel to be centered using one of the following choices:

- In both FIR and Farrow interpolation modes, you can select `Clip to the minimum value necessary for centered kernel`. This option forces the block to increase D_{min} to the smallest value necessary to keep the kernel centered.
- In FIR interpolation mode, you can select `Switch to linear interpolation if kernel cannot be centered`. This option forces the block to preserve the value of D_{min} and compute all interpolated values using `Linear interpolation`.

- In **Farrow** interpolation mode, you can select `Use off-centered kernel`. This option forces the block to preserve the value of D_{min} and compute the interpolated values using a farrow filter with an off-centered kernel.

Dependencies

This parameter applies only when **Interpolation mode** is set to `FIR` or `Farrow`.

Valid delay range (in samples) — Range of valid delay values

[0 100] (default) | [D_{min} D_{max}]

This property is read-only.

The delay range values [D_{min} D_{max}] are calculated (in samples) by the block based on the current parameter settings. D_{min} is the smallest possible valid delay value (in samples). The block clips all input delay values less than D_{min} to D_{min} . D_{max} is the maximum valid delay value (in samples). The block clips all input delay values greater than D_{max} to D_{max} .

When the **Interpolation mode** is set to one of the following:

- **Linear** — D_{min} equal 0. D_{max} equals the value you specify in the **Maximum delay (Dmax) in samples** parameter.
- **FIR** — D_{min} equals $P - 1$, where P is the value you specify in **Interpolation filter half-length (P)**. D_{max} equals the value you specify in the **Maximum delay (Dmax) in samples** parameter.
- **Farrow** — D_{min} equals $N/2 - 1$, where N is the value you specify in **Farrow filter length (N)**. D_{max} equals the value you specify in the **Maximum delay (Dmax) in samples** parameter.

Example: [1 100]

Example: [2 100]

Example: [3 100]

Fixed-Point Properties

Rounding mode — Rounding method for fixed-point operations

Zero (default) | Ceiling | Convergent | Floor | Nearest | Round | Simplest

Specify the rounding mode for fixed-point operations as one of the following:

- Zero
- Ceiling
- Convergent
- Floor
- Nearest
- Round
- Simplest

For more details, see rounding mode.

Overflow mode — Overflow action for fixed-point operations

`Wrap (default)` | `Saturate`

Specify the overflow action for fixed-point operations as one of the following:

- `Wrap` — The block wraps the result of its fixed-point operations.
- `Saturate` — The block saturates the result of its fixed-point operations.

For more details on overflow actions, see overflow mode for fixed-point operations.

Coefficients — Data type of the coefficients

`Same word length as input (default)` | `Specify word length`

Specify the data type of the filter coefficients as one of the following:

- `Same word length as input` — The word length of the filter coefficients matches that of the input to the block. The fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- `Specify word length` — Specify the word length of the coefficients, in bits. In this mode, the fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.

For more information on the coefficients data type this block uses, see the “Fixed Point” on page 2-0 section.

Product output — Data type of the product output

Same as first input (default) | Binary point scaling | Slope and bias scaling

Specify the data type of the product output as one of the following:

- Same as first input — The block specifies the product output data type to be the same as that of the data input.
- Binary point scaling — Specify the word length and the fraction length of the product output, in bits.
- Slope and bias scaling — Specify the word length, in bits, and the slope of the product output. This block requires power-of-two slope and a bias of zero.

For more information on the product output data type, see “Multiplication Data Types” and the “Fixed Point” on page 2-0 section.

Accumulator — Data type of accumulation operation

Same as product output (default) | Same as first input | Binary point scaling | Slope and bias scaling

Specify the data type of an accumulation operation as one of the following:

- Same as product output — The block specifies the accumulator data type to be the same as that of the product output data type.
- Same as first input — The block specifies the accumulator data type to be the same as that of the data input.
- Binary point scaling — Specify the word length and the fraction length of the accumulator output, in bits.
- Slope and bias scaling — Specify the word length, in bits, and the slope of the accumulator output. This block requires power-of-two slope and a bias of zero.

For more information on the accumulator data type this block uses, see the “Fixed Point” on page 2-0 .

Product output polyval — Data type of the product polynomial value

Same as first input (default) | Binary point scaling | Slope and bias scaling

Specify the data type of the product polynomial value as one of the following:

- `Same as first input` — The block specifies the product polynomial value data type to be the same as that of the data input.
- `Binary point scaling` — Specify the word length and the fraction length of the product output polynomial, in bits.
- `Slope and bias scaling` — Specify the word length, in bits, and the slope of the product output polynomial. This block requires power-of-two slope and a bias of zero.

For more information on the product polynomial value data type this block uses, see the “Fixed Point” on page 2-0 section.

Dependencies

This property applies when you set **Interpolation mode** to `Farrow`.

Accumulator polyval — Data type of the accumulator polynomial value

`Same as first input (default) | Binary point scaling | Slope and bias scaling`

Specify the data type of the accumulator polynomial value as one of the following:

- `Same as first input` — The block specifies the accumulator polynomial value data type to be the same as that of the data input.
- `Binary point scaling` — Specify the word length and the fraction length of the accumulator polynomial value, in bits.
- `Slope and bias scaling` — Specify the word length, in bits, and the slope of the accumulator polynomial value. This block requires power-of-two slope and a bias of zero.

For more information on the accumulator polynomial value data type that this block uses, see the “Fixed Point” on page 2-0 section.

Dependencies

This property applies when you set **Interpolation mode** to `Farrow`.

Multiplicand polyval — Data type of multiplicand polynomial value

`Same as first input (default) | Binary point scaling | Slope and bias scaling`

Specify the data type of the multiplicand polynomial value as one of the following:

- `Same as first input` — The block specifies the multiplicand polynomial value data type to be the same as that of the data input.
- `Binary point scaling` — Specify the word length and the fraction length of the multiplicand polynomial value, in bits.
- `Slope and bias scaling` — Specify the word length, in bits, and the slope of the multiplicand polynomial value. This block requires power-of-two slope and a bias of zero.

For more information on the multiplicand polynomial value data type this block uses, see the “Fixed Point” on page 2-0 section.

Dependencies

This property applies when you set **Interpolation mode** to `Farrow`.

Output — Data type of block output

`Same as accumulator (default) | Same as first input | Binary point scaling | Slope and bias scaling`

Specify the data type of the block output as one of the following:

- `Same as accumulator` — The block specifies the output data type to be the same as that of the accumulator output data type.
- `Same as first input` — The block specifies the output data type to be the same as that of the data input.
- `Binary point scaling` — Specify the word length and the fraction length of the block output, in bits.
- `Slope and bias scaling` — Specify the word length, in bits, and the slope of the block output. This block requires power-of-two slope and a bias of zero.

For more information on the output data type this block uses, see the “Fixed Point” on page 2-0 section.

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

`off (default) | on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block dialog box.

Model Examples

Algorithms

The delay value specified at the **Delay** port serves as an index into the block's memory, U , which stores, at a minimum, the $D_{\max}+1$ most recent samples received at the **In** port for each channel. For example, an integer delay of 5 on a scalar input sequence retrieves and outputs the fifth most recent input sample from the block's memory, $U(6)$. The block computes fractional delays by interpolating between stored samples. The block uses a linear, FIR, or farrow interpolation method to interpolate signal values at noninteger sample intervals.

Linear Interpolation Mode

For noninteger delays, at each sample time, the linear interpolation method uses the two samples in memory nearest to the specified delay to compute a value for the sample at that time.

For a vector data input, the output vector, y , is computed using the following relation:

$$\begin{aligned} v_i &= \text{floor}(v) \\ v_f &= v - v_i \\ y(i) &= U(i - v_i - 1) * v_f + U(i - v_i) * (1 - v_f) \end{aligned}$$

where,

- i — Index of the current sample
- v — Fractional delay
- v_i — Integer part of the delay
- v_f — Fractional part of the delay
- U — Input data vector
- y — Output data vector
- $U(i - v_i), U(i - v_i - 1)$ — Two samples in memory nearest to the specified delay
- $i - v_i$ — Distance, in samples, between the current index and the nearest point in the interpolation line.

The variable fractional delay stores the $D_{max}+1$ most recent samples received at the input for each channel, where D_{max} is the maximum delay specified. U represents the stored samples.

FIR Interpolation Mode

In the FIR interpolation mode, the block stores the $D_{max}+P+1$ most recent samples received at the input for each channel, where P is the specified interpolation filter half-length.

In this mode, the block provides a discrete set of fractional delays:

$$v + \frac{i}{L}, \quad v \geq P-1, \quad i = 0, 1, \dots, L-1$$

If v is less than $P-1$, the behavior depends on the **For small input delay values** parameter. You can specify the block's behavior when the input delay value is too small to center the kernel (less than $P-1$), by setting the **For small input delay values** parameter:

- Clip to the minimum value necessary for centered kernel — The FIR interpolation method remains in use. The small input delay values are clipped to the smallest value necessary to center the kernel.
- Switch to linear interpolation if kernel cannot be centered — Fractional delays are computed using linear interpolation when the input delay value is less than $P-1$.

In the FIR interpolation mode, the algorithm implements a polyphase structure to compute a value for each sample at the specified delay. Each arm of the structure corresponds to a different delay value. The output computed for each sample corresponds to the output of the arm with a delay value nearest to the specified input delay. Therefore, only a discrete set of delays is actually possible. The number of coefficients in each of the L filter arms of the polyphase structure is $2P$. In most cases, using values of P between 4 and 6 provides you with reasonably accurate interpolation values.

The `designMultirateFIR` function designs the FIR interpolation filter.

For example, when you set the following values:

- Interpolation filter half-length (P) to 4

- Interpolation points per input sample to 10
- Normalized input bandwidth to 1
- Stopband attenuation to 80 dB

The filter coefficients are given by:

```
b = designMultirateFIR(10,1,4,80);
```

The algorithm then implements this filter as a polyphase structure.

Increasing the filter half length (P) increases the accuracy of the interpolation, but also increases the number of computations performed per input sample. The amount of memory needed to store the filter coefficients increases too. Increasing the interpolation points per sample (L) increases the number of representable discrete delay points, but also increases the simulation's memory requirements. The computational load per sample is not affected.

The normalized input bandwidth from 0 to 1 allows you to take advantage of the bandlimited frequency content of the input. For example, if you know that the input signal does not have frequency content above $F_s/4$, you can specify 0.5 normalized bandwidth to constrain the frequency content of the output to that range.

Note You can consider each of the L interpolation filters to correspond to one output phase of an upsample-by- L FIR filter. Therefore, the normalized input value improves the stopband in critical regions and relaxes the stopband requirements in frequency regions without signal energy.

Farrow Interpolation Mode

In the farrow interpolation mode, the block stores the $D_{max}+N/2+1$ most recent samples received at the input for each channel, where N is the specified farrow filter length.

The algorithm uses the LaGrange method to interpolate values.

To increase the minimum possible delay value, select the **Disable direct feedthrough by increasing minimum possible delay by one** check box. Checking this box prevents algebraic loops from occurring when you use the block inside a feedback loop.

To specify the behavior when the input delay value is too small to center the kernel (less

than $\frac{N}{2} - 1$), use the Farrow small delay action setting.

- **Clip to the minimum value necessary for centered kernel** — The block clips small input delay values to the smallest value necessary to keep the kernel centered. This increases D_{min} but yields more accurate interpolation values.
- **Use off-centered kernel** — The fractional delays are computed using a Farrow filter with an off-centered kernel. This mode does not increase D_{min} , but the results for

input delay values less than $\frac{N}{2} - 1$ are less accurate than the results achieved by keeping the kernel centered.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Fixed-Point Conversion

Design and simulate fixed-point algorithms using Fixed-Point Designer™.

The diagrams in the following sections show the data types used within the Variable Fractional Delay for fixed-point signals.

Although you can specify most of these data types, the following data types are computed internally by the block and cannot be directly specified on the block dialog box.

Data Type	Word Length	Fraction Length
vf data type	Same word length as the coefficients	Same as the word length
HoldInteger data type	Same word length as the input delay value	0 bits

Data Type	Word Length	Fraction Length
Integer data type	32 bits	0 bits

Note When the input is fixed point, all internal data types are signed fixed point.

To compute the integer (v_i) and fractional (v_f) parts of the input delay value (v), the Variable Fractional Delay block uses the following equations:

$$D_{min} < v < D_{max} \Rightarrow \begin{cases} v_i = \text{floor}(v) \\ v_f = v - v_i \end{cases}$$

$$v \leq D_{min} \Rightarrow \begin{cases} v_i = D_{min} \\ v_f = 0 \end{cases}$$

$$v \geq D_{max} \Rightarrow \begin{cases} v_i = D_{max} \\ v_f = 0 \end{cases}$$

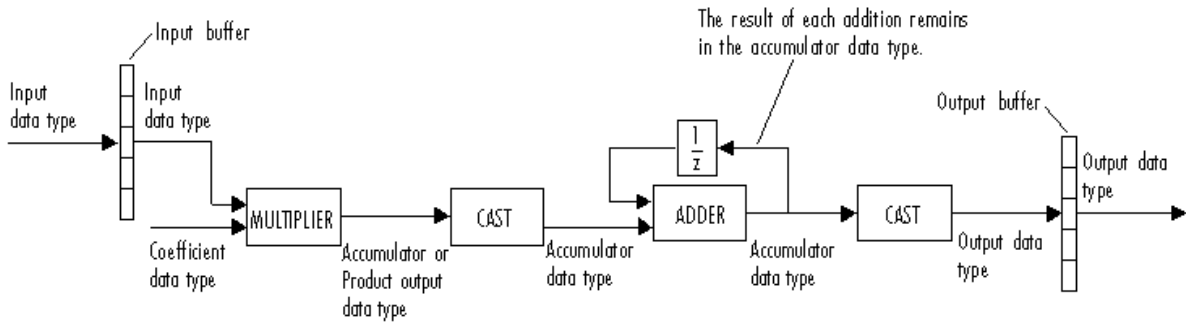

The following diagram shows the fixed-point data types used by the Linear interpolation mode of the Variable Fractional Delay block.

The following diagram illustrates how the Variable Fractional Delay block selects the arm of the polyphase filter structure that most closely matches the fractional delay value (v_f).

The following diagram shows the fixed-point data types used by the variable fractional delay algorithm in the FIR interpolation mode.

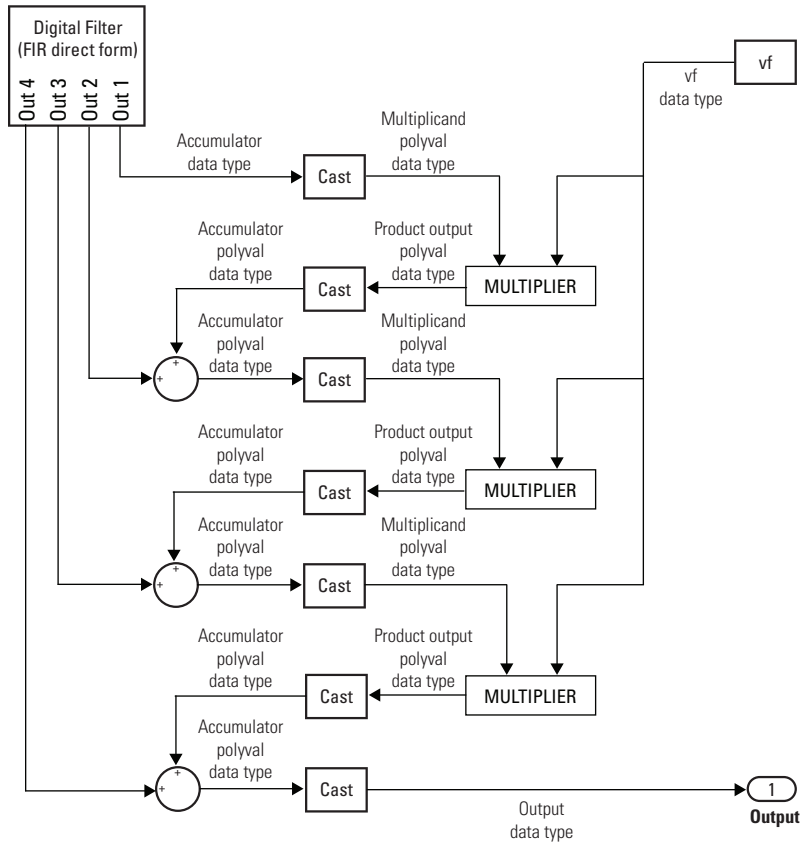

You can set the coefficient, product output, accumulator, and output data types in the block. This diagram shows that input data is stored in the input buffer with the same data type and scaling as the input. The block stores filtered data and any initial conditions in the output buffer using the output data type and scaling that you set.

When at least one of the inputs to the multiplier is real, the output of the multiplier is in the product output data type. When both inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication, see “Multiplication Data Types”.

The following diagram shows the fixed-point data types used by the Farrow interpolation mode when:

- Farrow filter length is set to 4
- Farrow small delay action is set to Clip to the minimum value necessary for centered kernel

The following diagram shows the fixed-point data types used by the Farrow interpolation mode when:

- Farrow filter length is set to 4.
- Farrow small delay action is set to Use off-centered kernel.

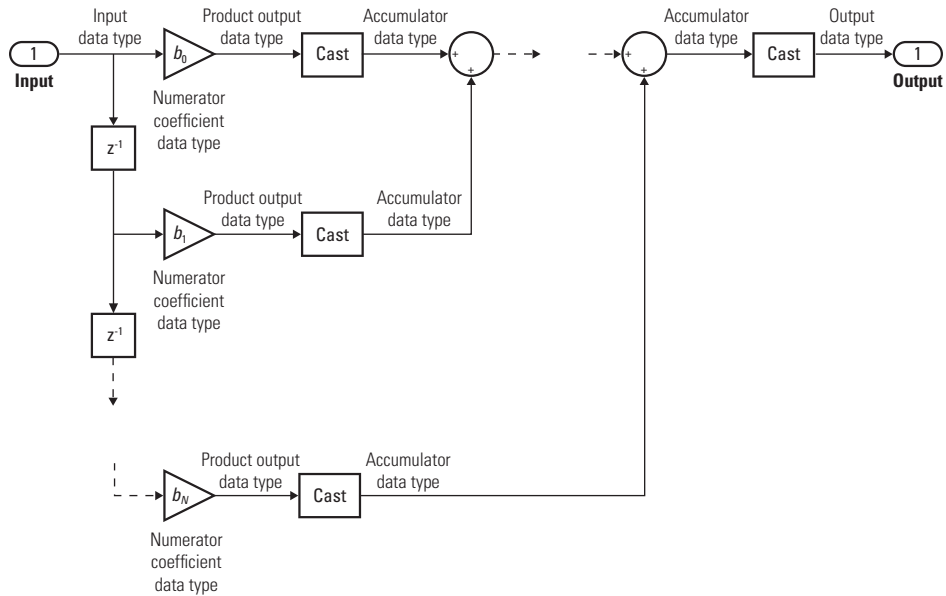

Diff is computed from the integer part of the delay value (v_i) and the farrow filter length (N) according to the following equation:

$$Diff = v_i - \left(\frac{N - 1}{2} \right)$$

$$Diff \geq 0 \Rightarrow Diff = 0$$

$$Diff < 0 \Rightarrow Diff = -Diff$$

The following diagram shows the fixed-point data types used by the Digital Filter's FIR direct form filter.

Variable Integer Delay (Obsolete)

Delay input by time-varying integer number of sample periods

Library

dspobslib

Description

Note The Variable Integer Delay block has been replaced with the Simulink Variable Integer Delay block. Existing instances of the DSP block will continue to operate, but certain functionality will be disabled in future releases. See “Functionality being removed or replaced for blocks and System objects”.

The Variable Integer Delay block delays the discrete-time input at the In port by the integer number of sample intervals specified by the input to the Delay port. The sample rate of the input signal at the Delay port must be the same as the sample rate of the input signal at the In port. When these sample rates are not the same, you need to insert a Zero-Order Hold or Rate Transition block in order to make the sample rates identical. When you set the **Input processing** parameter to `Elements as channels` (sample based), the delay for an N-D input can be a scalar value to uniformly delay every sample in every channel, or a matrix containing one delay value for each channel of the input. When you set the **Input processing** parameter to `Columns as channels` (frame based), the delay can be a scalar value to uniformly delay every sample in every channel, a vector containing one delay value for each sample in the input frame, or a vector containing one delay value for each channel in the input frame.

The delay values should be in the range of 0 to D , where D is the **Maximum delay**. Delay values greater than D or less than 0 are clipped to those respective values and noninteger delays are rounded to the nearest integer value.

The Variable Integer Delay block differs from the Delay block in the following ways.

Variable Integer Delay Block	Delay Block
The delay is provided as an input to the Delay port.	You specify the delay as a parameter setting in the dialog box.
Delay can vary with time; for example, when the block performs frame-based processing, the n th element's delay in the first input frame can differ from the n th element's delay in the second input frame.	Delay cannot vary with time; for example, when the block performs frame-based processing, the n th element's delay is the same for every input frame.
When you use the Variable Integer Delay block in a feedback loop, you must check the Disable direct feedthrough by increasing minimum possible delay by one check box. This prevents the occurrence of an algebraic loop when the delay of the Variable Integer Delay block is driven to zero.	You can use the Delay block to break an algebraic loop.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the Variable Integer Delay block supports N-D input arrays. When the input is an M -by- N -by- P array, the block treats each of the $M*N*P$ elements as independent channels, and applies the delay at the Delay port to each channel.

The Variable Integer Delay block stores the $D+1$ most recent samples received at the In port for each channel. At each sample time the block outputs the stored sample(s) indexed by the input to the Delay port.

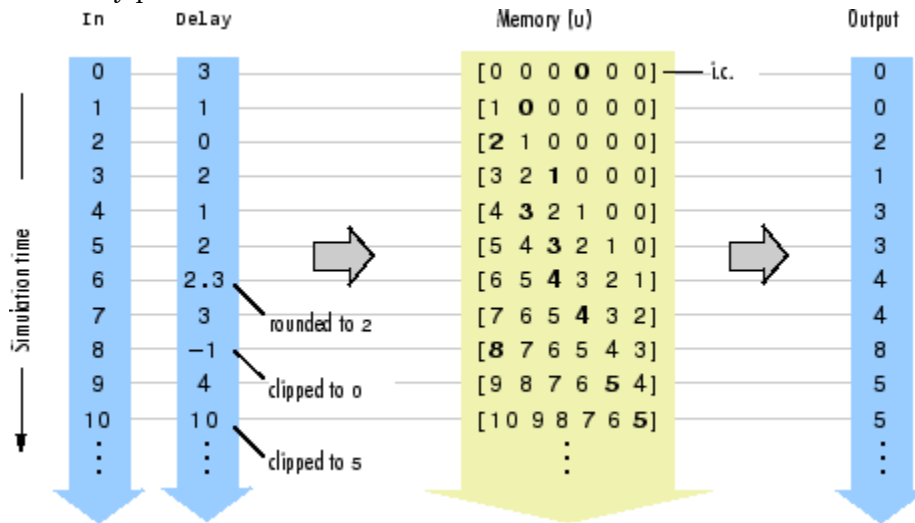

For example, when the input to the In port, u , is a scalar signal, the block stores a vector, U , of the $D+1$ most recent signal samples. When the current input sample is $U(1)$, the previous input sample is $U(2)$, and so on, then the block's output is

```
y = U(v+1); % Equivalent MATLAB code
```

where v is the input to the Delay port. A delay value of 0 ($v=0$) causes the block to pass through the sample at the In port in the same simulation step that it is received. The

block's memory is initialized to the **Initial conditions** value at the start of the simulation (see below).

The next figure shows the block output for a scalar ramp sequence at the In port, a **Maximum delay** of 5, an **Initial conditions** of 0, and a variety of different delays at the Delay port.

The current input at each time step is immediately stored in memory as $U(1)$. This allows the current input to be available at the output for a delay of 0 ($v=0$).

The **Initial conditions** parameter specifies the values in the block's memory at the start of the simulation. Unlike the Delay block, the Variable Integer Delay block does not have a fixed initial delay period during which the initial conditions appear at the output. Instead, the initial conditions are propagated to the output only when they are indexed in memory by the value at the Delay port. Both fixed and time-varying initial conditions can be specified in a variety of ways to suit the dimensions of the input sequence.

Fixed Initial Conditions

The settings in this section specify fixed initial conditions. For a fixed initial condition, the block initializes each of D samples in memory to the value entered in the **Initial conditions** parameter. A fixed initial condition in sample-based mode can be specified in one of the following ways:

- Scalar value with which to initialize every sample of every channel in memory. For a general M -by- N input and the parameter settings in this figure,

Maximum delay (samples):
100

Initial conditions:
0

the block initializes 100 M -by- N matrices in memory with zeros.

- Array of size M -by- N -by- D . In this case, you can specify different fixed initial conditions for each channel. See the Array bullet in “Time-Varying Initial Conditions” on page 2-1762 below for details.

Time-Varying Initial Conditions

The following settings specify time-varying initial conditions. For a time-varying initial condition, the block initializes each of D samples in memory to one of the values entered in the **Initial conditions** parameter. This allows you to specify a unique output value for each sample in memory. A time-varying initial condition in sample-based mode can be specified in one of the following ways:

- Vector containing D elements with which to initialize memory samples $U(2:D+1)$, where D is the **Maximum delay**. For a scalar input and the parameters in the next figure, the block initializes $U(2:6)$ with values $[-1, -1, -1, 0, 1]$.

Maximum delay (samples):
5

Initial conditions:
[-1 -1 -1 0 1]

- Array of dimension M -by- N -by- D with which to initialize memory samples $U(2:D+1)$, where D is the **Maximum delay** and M and N are the number of rows and columns, respectively, in the input matrix. For a 2-by-3 input and the following parameters, the block initializes memory locations $U(2:5)$ with values

$$\mathbf{U}(2) = \begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix}, \quad \mathbf{U}(3) = \begin{bmatrix} 2 & 2 & 2 \\ 2 & 2 & 2 \end{bmatrix}, \quad \mathbf{U}(4) = \begin{bmatrix} 3 & 3 & 3 \\ 3 & 3 & 3 \end{bmatrix}, \quad \mathbf{U}(5) = \begin{bmatrix} 4 & 4 & 4 \\ 4 & 4 & 4 \end{bmatrix}$$

Maximum delay (samples):
4

Initial conditions:
cat(3, [1 1 1; 1 1 1], [2 2 2; 2 2 2], [3 3 3; 3 3 3], [4 4 4; 4 4 4])

An M -by- N -by- P -by- D array can be entered for the **Initial Conditions** parameter when the input is an M -by- N -by- P array. The (M,N,P,T) th sample of the **Initial Conditions** matrix provides the initial condition value for the (M,N,P) th channel of the input matrix at delay = $D-t+1$ samples.

Frame-Based Processing

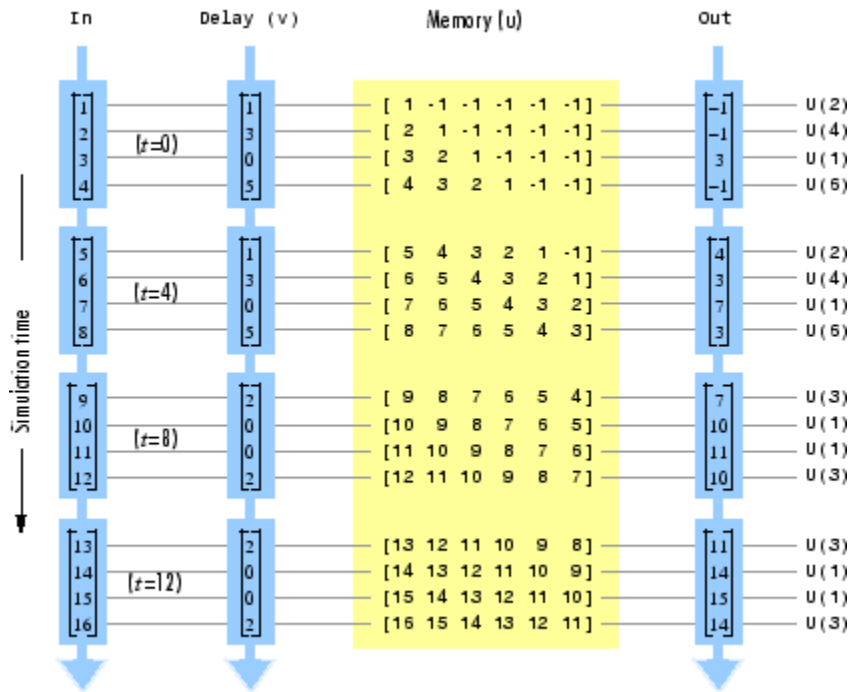

When you set the **Input processing** parameter to Columns as channels (frame based), the input can be an M -by- N matrix. The block treats each of the N input columns as independent channels containing M sequential time samples.

In this mode, the input at the Delay port can be a scalar value to uniformly delay every sample in every channel. It can also be a length- M column vector containing one delay value for each sample in the input frame(s). The set of delays contained in the vector is applied identically to every channel of a multichannel input. The Delay port entry can also be a length- N row vector, containing one delay for each channel. Finally, the Delay port entry can be an M -by- N matrix, containing a different delay for each corresponding element of the input.

Vector v does not specify when the samples in the current input frame will appear in the output. Rather, v indicates which previous input samples (stored in memory) should be included in the current output frame. The first sample in the current output frame is the input sample $v(1)$ intervals earlier in the sequence, the second sample in the current output frame is the input sample $v(2)$ intervals earlier in the sequence, and so on.

The illustration below shows how this works for an input with a sample period of 1 and frame size of 4. The **Maximum delay** (D_{\max}) is 5, and the **Initial conditions** parameter is set to -1. The delay input changes from [1 3 0 5] to [2 0 0 2] after the second input frame. The samples in each output frame are the values in memory indexed by the elements of v :

$$\begin{aligned} y(1) &= U(v(1)+1) \\ y(2) &= U(v(2)+1) \\ y(3) &= U(v(3)+1) \\ y(4) &= U(v(4)+1) \end{aligned}$$

The **Initial conditions** parameter specifies the values in the block's memory at the start of the simulation. Both fixed and time-varying initial conditions can be specified.

Fixed Initial Conditions

The settings shown in this section specify fixed initial conditions. For a fixed initial condition, the block initializes each of D samples in memory to the value entered in the **Initial conditions** parameter. A fixed initial condition in frame-based mode can be one of the following:

- Scalar value with which to initialize every sample of every channel in memory. For a general M -by- N input with the parameter settings below, the block initializes five samples in memory with zeros.

Maximum delay (samples):	5
Initial conditions:	0

- Array of size 1-by- N -by- D . In this case, you can specify different fixed initial conditions for each channel. See the Array bullet in “Time-Varying Initial Conditions” on page 2-1765 below for details.

Time-Varying Initial Conditions

The following setting specifies a time-varying initial condition. For a time-varying initial condition, the block initializes each of D samples in memory to one of the values entered in the **Initial conditions** parameter. This allows you to specify a unique output value for each sample in memory. When the block is performing frame-based processing, you can specify a time-varying initial condition in the following ways:

- Vector containing D elements. In this case, all channels have the same set of time-varying initial conditions specified by the entries of the vector. For the ramp input `[1:100; 1:100]'` with a frame size of 4, delay of 5, and the following parameter settings, the block outputs the following sequence of frames at the start of the simulation:

$$\begin{bmatrix} -1 & -1 \\ -2 & -2 \\ -3 & -3 \\ -4 & -4 \end{bmatrix}, \begin{bmatrix} -5 & -5 \\ 1 & 1 \\ 2 & 2 \\ 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 \\ 5 & 5 \\ 6 & 6 \\ 7 & 7 \end{bmatrix}, \dots$$

- Array of size 1-by- N -by- D . In this case, you can specify different time-varying initial conditions for each channel. For the ramp input `[1:100; 1:100]'` with a frame size of 4, delay of 5, and the following parameter settings, the block outputs the following sequence of frames at the start of the simulation:

$$\begin{bmatrix} -1 & -11 \\ -2 & -22 \\ -3 & -33 \\ -4 & -44 \end{bmatrix}, \begin{bmatrix} -5 & -55 \\ 1 & 1 \\ 2 & 2 \\ 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 \\ 5 & 5 \\ 6 & 6 \\ 7 & 7 \end{bmatrix}, \dots$$

By specifying a 1-by- N -by- D initial condition array such that each 1-by- N vector entry is identical, you can implement different fixed initial conditions for each channel.

Examples

See “Basic Algorithmic Delay” in the *DSP System Toolbox User's Guide*.

Parameters

Maximum delay

The maximum delay that the block can produce for any sample. Delay input values exceeding this maximum are clipped at the maximum.

Initial conditions

The values with which the block's memory is initialized.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note The `Inherited` (this choice will be removed - see release notes) option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

Disable direct feedthrough by increasing minimum possible delay by one

Select this box to disable direct feedthrough by adding one to the minimum possible delay value. When you set the **Input processing** parameter to `Columns as`

channels (frame based), the block increases the minimum possible delay value by $frame\ size - 1$. Similarly, when you set the **Input processing** parameter to Elements as channels (sample based), the block increases the minimum possible delay value by one sample.

Checking this box allows you to use the Variable Integer Delay block in feedback loops.

Supported Data Types

Port	Supported Data Types
In	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Variable Selector

Select subset of rows or columns from input

Library

Signal Management / Indexing

dspindex

Description

The Variable Selector block extracts a subset of rows or columns from the M -by- N input matrix u at each input port. You specify the number of input and output ports in the **Number of input signals** parameter.

When the **Select** parameter is set to `Rows`, the Variable Selector block extracts rows from each input matrix, while if the **Select** parameter is set to `Columns`, the block extracts columns.

When the **Selector mode** parameter is set to `Variable`, the length- L vector input to the `Idx` port selects L rows or columns of each input to pass through to the output. The elements of the indexing vector can be updated at each sample time, but the vector length must remain the same throughout the simulation.

When the **Selector mode** parameter is set to `Fixed`, the `Idx` port is disabled, and the length- L vector specified in the **Elements** parameter selects L rows or columns of each input to pass through to the output. The **Elements** parameter is tunable, so you can change the values of the indexing vector elements at any time during the simulation; however, the vector length must remain the same.

For both variable and fixed indexing modes, the row selection operation is equivalent to

```
y = u(idx,:) % Equivalent MATLAB code
```

and the column selection operation is equivalent to

```
y = u(:,idx) % Equivalent MATLAB code
```

where `idx` is the length- L indexing vector. The row selection output size is L -by- N and the column selection output size is M -by- L . Input rows or columns can appear any number of times in the output, or not at all.

When the input is an unoriented vector, the **Select** parameter is ignored; the output is a unoriented vector of length L containing those elements specified by the length- L indexing vector.

When an element of the indexing vector references a nonexistent row or column of the input, the block reacts with the action you specify using the **Invalid index** parameter.

When the indexing vector elements are of Boolean data type, the block performs logical indexing. Select **Fill empty spaces in outputs (for logical indexing)** to access the **Fill values** parameter. These values are appended to the output to make it as long as the input elements.

Note The Variable Selector block always copies the selected input rows to a contiguous block of memory (unlike the Simulink Selector block).

Parameters

Number of input signals

Specify the number of input signals. An input port is created on the block for each input signal.

Select

Specify the dimension of the input to select, `Rows` or `Columns`.

Selector mode

Specify the type of indexing operation to perform, `Variable` or `Fixed`. `Variable` indexing uses the input at the `Idx` port to select rows or columns from the input at

the **In** port. Fixed indexing uses the **Elements** parameter value to select rows from the input at the **In** port, and disables the **Idx** port.

Elements

Specify a vector containing the indices of the input rows or columns that will appear in the output matrix. This parameter appears only when you set the **Selector mode** to **Fixed**.

Index mode

When set to **One-based**, an index value of 1 refers to the first row or column of the input. When set to **Zero-based**, an index value of 0 refers to the first row or column of the input.

Invalid index

Specify how the block handles an invalid index value. You can select one of the following options:

- **Clip index** — Clip the index to the nearest valid value, and do not issue an alert.

For example, if the block receives a 64-by-4 input and the **Select** parameter is set to **Rows**, the block clips an index of 72 to 64. For the same input, if the **Select** parameter is set to **Columns**, the block clips an index of 72 to 4. In both cases, the block clips an index of -2 to 1.

- **Clip and warn** — Clip the index to the nearest valid value and display a warning message at the MATLAB command line.
- **Generate error** — Display an error dialog box and terminate the simulation.

This parameter is tunable (Simulink).

Fill empty spaces in outputs (for logical indexing)

When the indexing vector elements are of Boolean data type, the block performs logical indexing. This can cause empty spaces in the output. Select this parameter to designate values to be appended to the output in the **Fill values** parameter.

Fill values

Specify the fill values when the block performs logical indexing. This parameter appears only when you select the **Fill empty spaces in outputs (for logical indexing)** check box.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see Variable Selector.

Variance

Variance of input or sequence of inputs

Library: DSP System Toolbox / Statistics

Description

The Variance block computes the unbiased variance of each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the variance of the entire input. You can specify the dimension using the **Find the variance value over** parameter. The Variance block can also track the variance in a sequence of inputs over a period of time. To track the variance in a sequence of inputs, select the **Running variance** parameter.

Note The **Running** mode in the Variance block will be removed in a future release. To compute the running variance in Simulink, use the Moving Variance block instead.

Ports

Input

In — Data input

vector | matrix | N -D array

The block accepts real-valued or complex-valued multichannel and multidimensional inputs.

This port is unnamed until you select the **Running variance** parameter and set the **Reset port** parameter to any option other than None.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

Rst — Reset port

scalar

Specify the reset event that causes the block to reset the running variance. The sample time of the **Rst** input must be a positive integer multiple of the input sample time.

Dependencies

To enable this port, select the **Running variance** parameter and set the **Reset port** parameter to any option other than **None**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Output**Port_1** — Variance along the specified dimensionscalar | vector | matrix | N -D array

The data type of the output matches the data type of the input.

When you do not select the **Running variance** parameter, the block computes the variance in each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the variance of the entire input at each individual sample time. Each element in the output array y is the variance of the corresponding column, row, or entire input. The output array y depends on the setting of the **Find the variance value over** parameter. Consider a three-dimensional input signal of size M -by- N -by- P . When you set **Find the variance value over** to:

- `Entire input` — The output at each sample time is a scalar that contains the variance of the M -by- N -by- P input matrix.
- `Each row` — The output at each sample time consists of an M -by-1-by- P array, where each element contains the variance of each vector over the second dimension of the input. For an M -by- N matrix input, the output at each sample time is an M -by-1 column vector.
- `Each column` — The output at each sample time consists of a 1-by- N -by- P array, where each element contains the variance of each vector over the first dimension of the input. For an M -by- N matrix input, the output at each sample time is a 1-by- N row vector.

In this mode, the block treats length- M unoriented vector inputs as M -by-1 column vectors.

- **Specified dimension** — The output at each sample time depends on the value of the **Dimension** parameter. If you set the **Dimension** to 1, the output is the same as when you select `Each column`. If you set the **Dimension** to 2, the output is the same as when you select `Each row`. If you set the **Dimension** to 3, the output at each sample time is an M -by- N matrix containing the variance of each vector over the third dimension of the input.

When you select **Running variance**, the block tracks the variance of each channel in a time sequence of inputs. In this mode, you must also specify a value for the **Input processing** parameter.

- **Elements as channels (sample based)** — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size M -by- N -by- P , the block outputs an M -by- N -by- P array. Each element y_{ijk} of the output contains the variance of the element u_{ijk} for all inputs since the last reset.

When a reset event occurs, the running variance y_{ijk} in the current frame is reset to the element u_{ijk} .

- **Columns as channels (frame based)** — The block treats each column of the input as a separate channel. This option does not support input signals with more than two dimensions. For a two-dimensional input signal of size M -by- N , the block outputs an M -by- N matrix. Each element y_{ij} of the output contains the variance of the elements in the j th column of all inputs since the last reset, up to and including the element u_{ij} of the current input.

When a reset event occurs, the running variance for each channel becomes the variance of all the samples in the current input frame, up to and including the current input sample.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Parameters

Main Tab

Running variance — Option to select running variance

off (default) | on

When you select the **Running variance** parameter, the block tracks the variance value of each channel in a time sequence of inputs.

Find the variance value over — Dimension over which the block computes the variance

Each column (default) | Entire input | Each row | Specified dimension

- Each column — The block outputs the variance over each column.
- Each row — The block outputs the variance over each row.
- Entire input — The block outputs the variance over the entire input.
- Specified dimension — The block outputs the variance over the dimension specified in the **Dimension** parameter.

Dependencies

To enable this parameter, clear the **Running variance** parameter.

Dimension — Custom dimension

1 (default) | scalar

Specify the dimension (one-based value) of the input signal over which the variance is computed. The value of this parameter must be greater than 0 and less than the number of dimensions in the input signal.

Dependencies

To enable this parameter, set **Find the variance value over** to Specified dimension.

Input processing — Method to process the input in running mode

Columns as channels (frame based) (default) | Elements as channels (sample based)

- **Columns as channels (frame based)** — The block treats each column of the input as a separate channel. This option does not support input signals with more than two dimensions. For a two-dimensional input signal of size M -by- N , the block outputs an M -by- N matrix. Each element y_{ij} of the output contains the variance of the elements in the j th column of all inputs since the last reset, up to and including the element u_{ij} of the current input.

When a reset event occurs, the running variance for each channel becomes the variance of all the samples in the current input frame, up to and including the current input sample.

- **Elements as channels (sample based)** — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size M -by- N -by- P , the block outputs an M -by- N -by- P array. Each element y_{ijk} of the output contains the variance of the element u_{ijk} for all inputs since the last reset.

When a reset event occurs, the running variance y_{ijk} in the current frame is reset to the element u_{ijk} .

Variable-Size Inputs

When your inputs are of variable size, and you select the **Running variance** parameter, then:

- If you set the **Input processing** parameter to **Elements as channels (sample based)**, the state is reset.
- If you set the **Input processing** parameter to **Columns as channels (frame based)**, then:
 - When the input size difference is in the number of channels (number of columns), the state is reset.
 - When the input size difference is in the length of channels (number of rows), no reset occurs and the running operation is carried out as usual.

Dependencies

To enable this parameter, select the **Running variance** parameter.

Reset port — Reset event

None (default) | Rising edge | Falling edge | Either edge | Non-zero sample

The block resets the running variance whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer multiple of the input sample time.

When a reset event occurs while the **Input processing** parameter is set to `Elements as channels` (sample based), the running variance for each channel is initialized to the value in the corresponding channel of the current input. Similarly, when the **Input processing** parameter is set to `Columns as channels` (frame based), the running variance for each channel becomes the variance of all the samples in the current input frame, up to and including the current input sample.

Use this parameter to specify the reset event.

- `None` — Disables the **Rst** port.
- `Rising edge` — Triggers a reset operation when the **Rst** input does one of the following:
 - Rises from a negative value to either a positive value or zero.
 - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.

- `Falling edge` — Triggers a reset operation when the **Rst** input does one of the following:
 - Falls from a positive value to a negative value or zero.
 - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.

- **Either edge** — Triggers a reset operation when the **Rst** input is a Rising edge or Falling edge.
- **Non-zero sample** — Triggers a reset operation at each sample time, when the **Rst** input is not zero.

Note When running simulations in the Simulink multitasking mode, reset signals have a one-sample latency. Therefore, when the block detects a reset event, there is a one-sample delay at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Dependencies

To enable this parameter, select the **Running variance** parameter.

Data Types Tab

Note To use these parameters, the data input must be fixed point. For all other inputs, the parameters on the **Data Types** tab are ignored.

Rounding mode — Method of rounding operation

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

Overflow mode — Method of overflow action

Wrap (default) | Saturate

Specify the overflow action for fixed-point operations as one of the following:

- Wrap — The block wraps the result of its fixed-point operations.
- Saturate — The block saturates the result of its fixed-point operations.

For more details on overflow actions, see overflow mode for fixed-point operations.

Input-squared product — Data type that stores the input-squared term

Same as input (default) | Binary point scaling | Slope and bias scaling

The squares of the input elements are stored in the **Input-squared product** data type. If the input is complex, the squares of the real and imaginary parts of the input are stored in this data type. For more details, see “Fixed Point” on page 2-0 .

You can set this parameter to:

- **Inherit: Same as input** — The block specifies this data type to be the same as the input data type.
- **Binary point scaling** — The **Input-squared product** data type uses binary point scaling. If you select this option, the block displays the fields to specify the **Word length** and **Fraction length**. The **Signedness** is inherited from the input.
- **Slope and bias scaling** — The **Input-squared product** data type uses slope and bias scaling. If you select this option, the block displays the fields to specify the **Word length** and **Slope**. The **Signedness** is inherited from the input and **Bias** is specified to be 0.

Input-sum-squared product — Data type that stores the input-sum-squared term

Same as `input-squared product (default)` | `Binary point scaling` | `Slope and bias scaling`

The squares of the sum of the input elements are stored in the **Input-sum-squared product** data type. If the input is complex, the squares of the sum of the real parts and the squares of the sum of the imaginary parts are stored in this data type. For more details, see “Fixed Point” on page 2-0 .

You can set this parameter to:

- Same as `input-squared product` — The block specifies this data type to be the same as the `input squared-product` data type.
- `Binary point scaling` — The **Input-sum-squared product** data type uses binary point scaling. If you select this option, the block displays the fields to specify the **Word length** and **Fraction length**. The **Signedness** is inherited from the input.
- `Slope and bias scaling` — The **Input-sum-squared product** data type uses slope and bias scaling. If you select this option, the block displays the fields to specify the **Word length** and **Slope**. The **Signedness** is inherited from the input and **Bias** is specified to be 0.

Accumulator — Accumulator data type

Same as `input-squared product (default)` | Same as `input` | `Binary point scaling` | `Slope and bias scaling`

Accumulator specifies the data type of the output of an accumulation operation in the Variance block. See “Fixed Point” on page 2-0 for illustrations depicting the use of the accumulator data type in this block.

You can set this parameter to:

- Same as `input-squared product` — The block specifies the accumulator data type to be the same as the `input-squared product` data type.
- Same as `input` — The block specifies the accumulator data type to be the same as the `input` data type.
- `Binary point scaling` — The **Accumulator** data type uses binary point scaling. If you select this option, the block displays the fields to specify the **Word length** and **Fraction length**. The **Signedness** is inherited from the input.

- Slope and bias scaling — The **Accumulator** data type uses slope and bias scaling. If you select this option, the block displays the fields to specify the **Word length** and **Slope**. The **Signedness** is inherited from the input and **Bias** is specified to be 0.

Output — Output data type

Same as input-squared product (default) | Same as accumulator | Same as input | Binary point scaling | Slope and bias scaling

Output specifies the data type of the output of the Variance block. See “Fixed Point” on page 2-0 for illustrations depicting the use of the output data type in this block. You can set it to:

- Same as input-squared product — The block specifies the output data type to be the same as the input-squared product data type.
- Same as accumulator — The block specifies the output data type to be the same as the accumulator data type.
- Same as input — The block specifies the output data type to be the same as the input data type.
- Binary point scaling — The **Output** data type uses binary point scaling. If you select this option, the block displays the fields to specify the **Word length** and **Fraction length**. The **Signedness** is inherited from the input.
- Slope and bias scaling — The **Output** data type uses slope and bias scaling. If you select this option, the block displays the fields to specify the **Word length** and **Slope**. The **Signedness** is inherited from the input and **Bias** is specified to be 0.

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block.

Definitions

Variance

The variance of a discrete-time signal is the square of the standard deviation of the signal.

Variance gives a measure of deviation of the signal from its mean value.

For purely real or imaginary input, u , of size M -by- N , the variance is given by the following equation:

$$y = \sigma^2 = \frac{\sum_{i=1}^M \sum_{j=1}^N |u_{ij}|^2 - \frac{\left| \sum_{i=1}^M \sum_{j=1}^N u_{ij} \right|^2}{M * N}}{M * N - 1}$$

- u_{ij} is the input data element at indices i, j .
- M is the length of the j th column.
- N is the number of columns.

For complex inputs, the variance is given by the following equation:

$$\sigma^2 = \sigma_{Re}^2 + \sigma_{Im}^2$$

- σ_{Re}^2 is the variance of the real part of the complex input.
- σ_{Im}^2 is the variance of the imaginary part of the complex input.

Algorithms

Variance

When you clear the **Running variance** parameter in the block and specify a dimension, the block produces results identical to the MATLAB `var` function, when it is called as `y = var(u, 0, D)`.

- u is the data input.
- D is the dimension.
- y is the variance along the specified dimension.

The variance along the entire input is identical to calling the `var` function as $y = \text{var}(u(:))$.

For a complex input signal, the variance is the sum of the variances of the real and imaginary parts.

$$\sigma^2 = \sigma_{\text{Re}}^2 + \sigma_{\text{Im}}^2$$

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

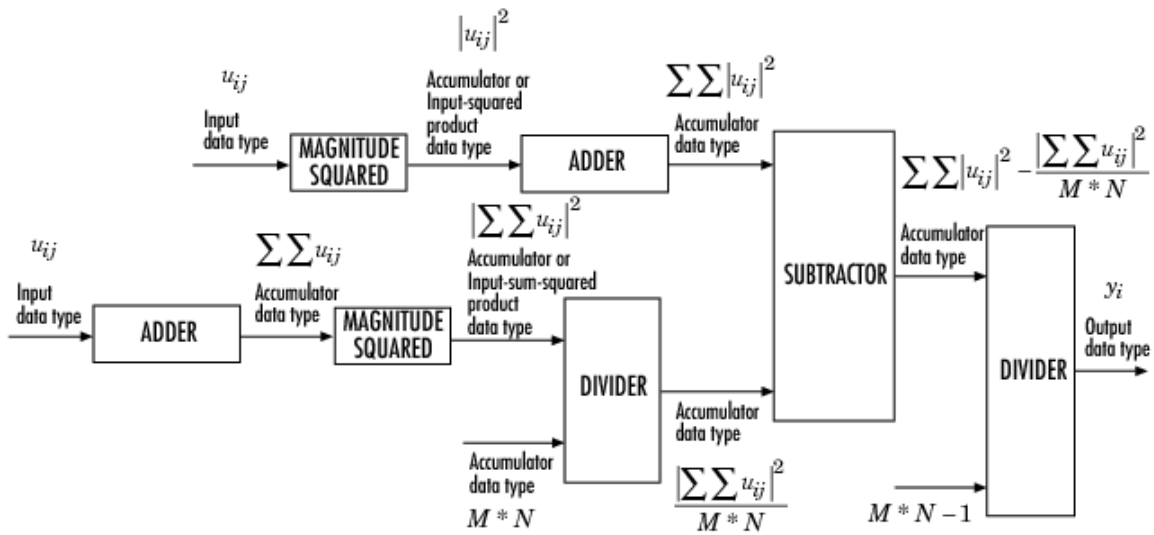

Fixed-Point Conversion

Design and simulate fixed-point algorithms using Fixed-Point Designer™.

For purely real or imaginary input, u of size M -by- N , the variance is given by the following equation.

$$y = \sigma^2 = \frac{\sum_{i=1}^M \sum_{j=1}^N |u_{ij}|^2 - \frac{\left| \sum_{i=1}^M \sum_{j=1}^N u_{ij} \right|^2}{M * N}}{M * N - 1}$$

The following diagram shows the data types used within the Variance block when the input is fixed-point.

For complex inputs, the variance is given by the following equation:

$$\sigma^2 = \sigma_{\text{Re}}^2 + \sigma_{\text{Im}}^2$$

Vector Quantizer Decoder

Find vector quantizer codeword that corresponds to given, zero-based index value

Library

Quantizers

dspquant2

Description

The Vector Quantizer Decoder block associates each input index value with a codeword, a column vector of quantized output values defined in the **Codebook values** parameter. When you input multiple index values into this block, the block outputs a matrix of quantized output vectors. This matrix is created by horizontally concatenating the codeword vectors that correspond to each index value.

You can select how you want to enter the codebook values using the **Source of codebook** parameter. When you select *Specify via dialog*, you can type the codebook values into the block parameters dialog box. Select *Input port* and port C appears on the block. The block uses the input to port C as the **Codebook values** parameter.

The **Codebook values** parameter is a k -by- N matrix of values, where $k \geq 1$ and $N \geq 1$. Each column of this matrix is a codeword vector, and each codeword vector corresponds to an index value. The index values are zero based; therefore, the first codeword vector corresponds to an index value of 0, the second codeword vector corresponds to an index value of 1, and so on.

The input to this block is a vector of index values, where $0 \leq \textit{index} < N$ and N is the number of columns of the codebook matrix. Use the **Action for out of range index value** parameter to determine how the block behaves when an input index value is out of this range. When you want any index values less than 0 to be set to 0 and any index values greater than or equal to N to be set to $N-1$, select `Clip`. When you want to be warned when any index values less than 0 are set to 0 and any index values greater than or equal to N are set to $N-1$, select `Clip` and `warn`. When you want the simulation to stop and display an error when the index values are out of range, select `Error`.

Data Type Support

The input to the block can be the index values and the codebook values. The data type of the index input to the block at port I can be `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`. The data type of the codebook values can be `double`, `single`, or `Fixed-point`.

The output of the block is the quantized output values. These quantized output values always have the same data type as the codebook values. When the codebook values are specified via an input port, the block assigns the same data type to the Q(U) output port. When the codebook values are specified via the dialog, use the **Codebook and output data type** parameter to specify the data type of the Q(U) output port. The data type of the codebook and quantized output can be `Same as input`, `double`, `single`, `Fixed-point`, `User-defined`, or `Inherit` via back propagation.

Dialog Box

The **Main** pane of the Vector Quantizer Decoder block dialog appears as follows.

Action for out of range index value

Choose the behavior of the block when an input index value is out of range, where $0 \leq \text{index} < N$ and N is the length of the codebook vector. Select **Clip** when you want any index values less than 0 to be set to 0 and any index values greater than or equal to N to be set to $N-1$. Select **Clip and warn** when you want to be warned when any index values less than 0 are set to 0 and any index values greater than or equal to N are set to $N-1$. Select **Error** when you want the simulation to stop and display an error when the index values are out of range.

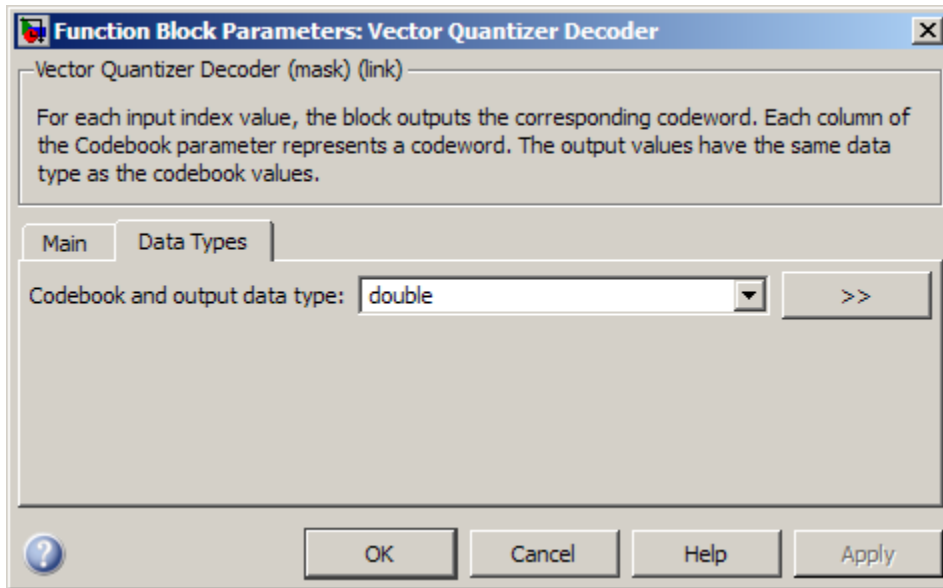

Source of codebook

Choose **Specify via dialog** to type the codebook values into the block parameters dialog box. Select **Input port** to specify the codebook values using the block's input port, C .

Codebook values

Enter a k -by- N matrix of quantized output values, where $1 \leq k$ and $1 \leq N$. Each column of your matrix corresponds to an index value. This parameter is visible if, from the **Source of codebook** list, you select **Specify via dialog**.

The **Data Types** pane of the Vector Quantizer Decoder block dialog appears as follows.

Codebook and output data type

Specify the data type of the codebook and quantized output values. You can select one of the following:

- A rule that inherits a data type, for example, `Inherit: Same as input`.
- A built in data type, such as `double`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

This parameter is available only when you set the **Source of codebook** parameter to `Specify via dialog`. If you set the **Source of codebook** parameter to `Input port`, the output values have the same data type as the input codebook values.

Vector Quantizer Design

Design vector quantizer using Vector Quantizer Design Tool (VQDTool)

Library

Quantizers

dspquant2

Description

Double-click on the Vector Quantizer Design block to start VQDTool, a GUI that allows you to design and implement a vector quantizer. You can also start VQDTool by typing `vqdttool` at the MATLAB command prompt. Based on your specifications, VQDTool iteratively calculates the codebook values that minimize the mean squared error between the training set and the codebook until the stopping criteria for the design process is satisfied. The block uses the resulting codebook values to implement your vector quantizer.

For the **Training Set** parameter, enter a k -by- M matrix of values you want to use to train the quantizer codebook. The variable k , where $k \geq 1$, is the length of each training vector. It also represents the dimension of your quantizer. The variable M , where $M \geq 2$, is the number of training vectors. This data can be created using a MATLAB function, such as the default value `randn(10,1000)`, or it can be any variable defined in the MATLAB workspace.

You have two choices for the **Source of initial codebook** parameter. Select `Auto-generate` to have the block choose the values of the initial codebook. In this case, the block picks N random training vectors as the initial codebook, where N is the **Number of**

levels parameter and $N \geq 2$. When you select `User defined`, enter the initial codebook values in the **Initial codebook** field. The initial codebook matrix must have the same number of rows as the training set. Each column of the codebook is a codeword, and your codebook must have at least two codewords.

For the given training set and initial codebook, the block performs an iterative process, using the Generalized Lloyd Algorithm (GLA), to design a final codebook. For each iteration of the GLA, the block first associates each training vector with its nearest codeword by calculating the distortion. You can specify one of the two possible methods for calculating distortion using the **Distortion measure** parameter.

When you select `Squared error` for the **Distortion measure** parameter, the block finds the nearest codeword by calculating the squared error (unweighted). Consider the codebook $CB = [CW_1 \quad CW_2 \quad \dots \quad CW_N]$. This codebook has N codewords; each codeword has k elements. The i -th codeword is defined as $CW_i = [a_{1i} \quad a_{2i} \quad \dots \quad a_{ki}]$. The training set has M columns and is defined as $U = [U_1 \quad U_2 \quad \dots \quad U_M]$, where the p -th training

vector is $U_p = [u_{1p} \quad u_{2p} \quad \dots \quad u_{kp}]'$. The squared error (unweighted) is calculated using the equation

$$D = \sum_{j=1}^k (a_{ji} - u_{jp})^2$$

When you select `Weighted squared error` for the **Distortion measure** parameter, enter a vector or matrix for the **Weighting factor** parameter. When the weighting factor is a vector, its length must be equal to the number of rows in the training set. This weighting factor is used for each training vector. When the weighting factor is a matrix, it must be the same size as the training set matrix. The block finds the nearest codeword by calculating the weighted squared error. If the weighting factor for the p -th column of

the training vector, U_p , is defined as $Wp = [w_{1p} \quad w_{2p} \quad \dots \quad w_{kp}]'$, then the weighted squared error is defined by the equation

$$D = \sum_{j=1}^k w_{jp} (a_{ji} - u_{jp})^2$$

Once the block has associated all the training vectors with their nearest codeword vectors, the block calculates the mean squared error for the codebook and checks to see if the stopping criteria for the process has been satisfied.

The two possible options for the **Stopping criteria** parameter are `Relative threshold` and `Maximum iteration`. When you want the design process to stop when the fractional drop in the squared error is below a certain value, select `Relative threshold`. Then, type the maximum acceptable fractional drop in the **Relative threshold** field. The fraction drop in the squared error is defined as

$$\frac{\text{error at previous iteration} - \text{error at current iteration}}{\text{error at previous iteration}}$$

When you want the design process to stop after a certain number of iterations, choose `Maximum iteration`. Then, enter the maximum number of iterations you want the block to perform in the **Maximum iteration** field. For **Stopping criteria**, you can also choose `Whichever comes first` and enter **Relative threshold** and **Maximum iteration** values. The block stops iterating as soon as one of these conditions is satisfied.

When a training vector has the same distortion for two different codeword vectors, the algorithm uses the **Tie-breaking rule** parameter to determine which codeword vector the training vector is associated with. When you want the training vector to be associated with the lower indexed codeword, select `Lower indexed codeword`. To associate the training vector with the higher indexed codeword, select `Higher indexed codeword`.

With each iteration, the block updates the codeword values in order to minimize the distortion. The **Codebook update method** parameter defines the way the block calculates these new codebook values.

Note If, for the **Distortion measure** parameter, you choose `Squared error`, the **Codebook update method** parameter is set to `Mean`.

If, for the **Distortion measure** parameter, you choose `Weighted squared error` and you choose `Mean` for the **Codebook update method** parameter, the new codeword vector is found as follows. Suppose there are three training vectors associated with one codeword vector. The training vectors are

$$TS_1 = \begin{bmatrix} 1 \\ 2 \end{bmatrix}, TS_3 = \begin{bmatrix} 10 \\ 12 \end{bmatrix}, \text{ and } TS_7 = \begin{bmatrix} 11 \\ 12 \end{bmatrix}.$$

$$CW_{new} = \begin{bmatrix} \frac{1+10+11}{3} \\ \frac{2+12+12}{3} \end{bmatrix}$$

The new codeword vector is calculated as

where the denominator is the number of training vectors associated with this codeword. If, for the **Codebook update method** parameter, you choose `Centroid` and you specify

the weighting factors $W_1 = \begin{bmatrix} 0.1 \\ 0.2 \end{bmatrix}$, $W_3 = \begin{bmatrix} 1 \\ 0.6 \end{bmatrix}$, and $W_7 = \begin{bmatrix} 0.3 \\ 0.4 \end{bmatrix}$, the new codeword vector is calculated as

$$CW_{new} = \begin{bmatrix} \frac{(0.1)(1) + (1)(10) + (0.3)(11)}{0.1 + 1 + 0.3} \\ \frac{(0.2)(2) + (0.6)(12) + (0.4)(12)}{0.2 + 0.6 + 0.4} \end{bmatrix}$$

Click **Design and Plot** to design the quantizer with the parameter values specified on the left side of the GUI. The performance curve and the entropy of the quantizer are updated and displayed in the figures on the right side of the GUI.

Note You must click **Design and Plot** to apply any changes you make to the parameter values in the VQDTool dialog box.

The following is an example of how the block calculates the entropy of the quantizer at each iteration. Suppose you have a codebook with four codewords and a training set with 200 training vectors. Also suppose that, at the i -th iteration, 40 training vectors are associated with the first codeword, 60 training vectors are associated with the second codeword, 20 training vectors are associated with the third codeword, and 80 training vectors are associated with the fourth codeword. The probability that a training vector is

associated with the first codeword is $\frac{40}{200}$. The probabilities that training vectors are

associated with the second, third, and fourth codewords are $\frac{60}{200}$, $\frac{20}{200}$, and $\frac{80}{200}$, respectively. The GUI uses these probabilities to calculate the entropy according to the equation

$$H = \sum_{i=1}^N -p_i \log_2 p_i$$

where N is the number of codewords. Based on these probabilities, the GUI calculates the entropy of the quantizer at the i -th iteration as

$$H = -\left(\frac{40}{200} \log_2 \frac{40}{200} + \frac{60}{200} \log_2 \frac{60}{200} + \frac{20}{200} \log_2 \frac{20}{200} + \frac{80}{200} \log_2 \frac{80}{200} \right)$$
$$H = 1.8464$$

VQDTool can export parameter values that correspond to the figures displayed in the GUI. Click the **Export Outputs** button, or press **Ctrl+E**, to export the **Final Codebook**, **Mean Square Error**, and **Entropy** values to the workspace, a text file, or a MAT-file.

In the **Model** section of the GUI, specify the destination of the block that will contain the parameters of your quantizer. For **Destination**, select `Current model` to create a block with your parameters in the model you most recently selected. Type `gcs` in the MATLAB Command Window to display the name of your current model. Select `New model` to create a block in a new model file.

From the **Block type** list, select `Encoder` to design a Vector Quantizer Encoder block. Select `Decoder` to design a Vector Quantizer Decoder block. Select `Both` to design a Vector Quantizer Encoder block and a Vector Quantizer Decoder block.

In the **Encoder block name** field, enter a name for the Vector Quantizer Encoder block. In the **Decoder block name** field, enter a name for the Vector Quantizer Decoder block. When you have a Vector Quantizer Encoder and/or Decoder block in your destination model with the same name, select the **Overwrite target block** check box to replace the block's parameters with the current parameters. When you do not select this check box, a new Vector Quantizer Encoder and/or Decoder block is created in your destination model.

Click **Generate Model**. VQDTool uses the parameters that correspond to the current plots to set the parameters of the Vector Quantizer Encoder and/or Decoder blocks.

Parameters

Training Set

Enter the samples of the signal you would like to quantize. This data set can be a MATLAB function or a variable defined in the MATLAB workspace. The typical length of this data vector is $1e5$.

Source of initial codebook

Select `Auto-generate` to have the block choose the initial codebook values. Choose `User defined` to enter your own initial codebook values.

Number of levels

Enter the number of codeword vectors, N , in your codebook matrix, where $N \geq 2$.

Initial codebook

Enter your initial codebook values. From the **Source of initial codebook** list, select `User defined` in order to activate this parameter. The codebook must have the same number of rows as the training set. You must provide at least two codeword vectors.

Distortion measure

When you select `Squared error`, the block finds the nearest codeword by calculating the squared error (unweighted). When you select `Weighted squared error`, the block finds the nearest codeword by calculating the weighted squared error.

Weighting factor

Enter a vector or matrix. The block uses these values to compute the weighted squared error. When the weighting factor is a vector, its length must be equal to the number of rows in the training set. This weighting factor is used for each training vector. When the weighting factor is a matrix, it must be the same size as the training set matrix. The individual weighting factors cannot be negative. The weighting factor vector or matrix cannot contain all zeros.

Stopping criteria

Choose `Relative threshold` to enter the maximum acceptable fractional drop in the squared quantization error. Choose `Maximum iteration` to specify the number of iterations at which to stop. Choose `Whichever comes first` and the block stops the iteration process as soon as the relative threshold or maximum iteration value is attained.

Relative threshold

This parameter is available when you choose `Relative threshold` or `Whichever comes first` for the **Stopping criteria** parameter. Enter the value that is the maximum acceptable fractional drop in the squared quantization error.

Maximum iteration

This parameter is available when you choose `Maximum iteration` or `Whichever comes first` for the **Stopping criteria** parameter. Enter the maximum number of iterations you want the block to perform.

Tie-breaking rules

When a training vector has the same distortion for two different codeword vectors, select `Lower indexed codeword` to associate the training vector with the lower indexed codeword. Select `Higher indexed codeword` to associate the training vector with the lower indexed codeword.

Codebook update method

When you choose `Mean`, the new codeword vector is calculated by taking the average of all the training vector values that were associated with the original codeword vector. When you choose `Centroid`, the block calculates the new codeword vector by taking the weighted average of all the training vector values that were associated with the original codeword vector. Note that if, for the **Distortion measure** parameter, you choose `Squared error`, the **Codebook update method** parameter is set to `Mean`.

Destination

Choose `Current model` to create a Vector Quantizer block in the model you most recently selected. Type `gcs` in the MATLAB Command Window to display the name of your current model. Choose `New model` to create a block in a new model file.

Block type

Select `Encoder` to design a Vector Quantizer Encoder block. Select `Decoder` to design a Vector Quantizer Decoder block. Select `Both` to design a Vector Quantizer Encoder block and a Vector Quantizer Decoder block.

Encoder block name

Enter a name for the Vector Quantizer Encoder block.

Decoder block name

Enter a name for the Vector Quantizer Decoder block.

Overwrite target block

When you do not select this check box and a Vector Quantizer Encoder and/or Decoder block with the same block name exists in the destination model, a new Vector Quantizer Encoder and/or Decoder block is created in the destination model. When you select this check box and a Vector Quantizer Encoder and/or Decoder block with the same block name exists in the destination model, the parameters of these blocks are overwritten by new parameters.

Generate Model

Click this button and VQDTool uses the parameters that correspond to the current plots to set the parameters of the Vector Quantizer Encoder and/or Decoder blocks.

Design and Plot

Click this button to design a quantizer using the parameters on the left side of the GUI and to update the performance curve and entropy plots on the right side of the GUI.

You must click **Design and Plot** to apply any changes you make to the parameter values in the VQDTool GUI.

Export Outputs

Click this button, or press **Ctrl+E**, to export the **Final Codebook**, **Mean Squared Error**, and **Entropy** values to the workspace, a text file, or a MAT-file.

Supported Data Types

- Double-precision floating point

Vector Quantizer Encoder

For given input, find index of nearest codeword based on Euclidean or weighted Euclidean distance measure

Library

Quantizers

dspquant2

Description

The Vector Quantizer Encoder block compares each input column vector to the codeword vectors in the codebook matrix. Each column of this codebook matrix is a codeword. The block finds the codeword vector nearest to the input column vector and returns its zero-based index. This block supports real floating-point and fixed-point signals on all input ports.

The block finds the nearest codeword by calculating the distortion. The block uses two methods for calculating distortion: Euclidean squared error (unweighted) and weighted

Euclidean squared error. Consider the codebook, $CB = [CW_1 \ CW_2 \ \dots \ CW_N]$. This codebook has N codewords; each codeword has k elements. The i -th codeword is defined

as a column vector, $CW_i = [a_{1i} \ a_{2i} \ \dots \ a_{ki}]$. The multichannel input has M columns

and is defined as $U = [U_1 \ U_2 \ \dots \ U_M]$, where the p -th input column vector is

$U_p = [u_{1p} \ u_{2p} \ \dots \ u_{kp}]'$. The squared error (unweighted) is calculated using the equation

$$D = \sum_{j=1}^k (a_{ji} - u_{jp})^2$$

The weighted squared error is calculated using the equation

$$D = \sum_{j=1}^k w_j (a_{ji} - u_{jp})^2$$

where the weighting factor is defined as $W = [w_1 \ w_2 \ \dots \ w_k]$. The index of the codeword that is associated with the minimum distortion is assigned to the input column vector.

You can select how you want to enter the codebook values using the **Source of codebook** parameter. When you select `Specify via dialog`, you can type the codebook values into the block parameters dialog box. Select `Input port` and port C appears on the block. The block uses the input to port C as the **Codebook** parameter.

The **Codebook** parameter is an k -by- N matrix of values, where $k \geq 1$ and $N \geq 1$. Each input column vector is compared to this codebook. Each column of the codebook matrix is a codeword, and each codeword has an index value. The first codeword vector corresponds to an index value of 0, the second codeword vector corresponds to an index value of 1, and so on. The codeword vectors must have the same number of rows as the input, U .

For the **Distortion measure** parameter, select `Squared error` when you want the block to calculate the distortion by evaluating the Euclidean distance between the input column vector and each codeword in the codebook. Select `Weighted squared error` when you want to use a weighting factor to emphasize or deemphasize certain input values.

For the **Source of weighting factor** parameter, select `Specify via dialog` to enter a weighting factor vector in the dialog box. Choose `Input port` to specify the weighting factor using port W.

Use the **Weighting factor** parameter to emphasize or deemphasize certain input values when calculating the distortion measure. For example, consider the p -th input column

vector, U_p , as previously defined. When you want to neglect the effect of the first element of this vector, enter `[0 1 1 ... 1]` as the **Weighting factor** parameter. This weighting factor is used to calculate the weighted squared error using the equation

$$D = \sum_{j=1}^k w_j (a_{ji} - u_{jp})^2$$

Because of the weighting factor used in this example, the weighted squared error is not affected by the first element of the input matrix. Therefore, the first element of the input column vector no longer impacts the choice of index value output by the Vector Quantizer Encoder block.

Use the **Index output data type** parameter to specify the data type of the index values output at port I. The data type of the index values can be `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32`.

When an input vector is equidistant from two codewords, the block uses the **Tie-breaking rule** parameter to determine which index value the block chooses. When you want the input vector to be represented by the lower index valued codeword, select `Choose the lower index`. To represent the input column vector by the higher index valued codeword, select `Choose the higher index`.

Select the **Output codeword** check box to output at port Q(U) the codeword vectors that correspond to each index value. When the input is a matrix, the corresponding codeword vectors are horizontally concatenated into a matrix.

Select the **Output quantization error** check box to output at port D the quantization error that results when the block represents the input column vector by its nearest codeword. When the input is a matrix, the quantization error values are horizontally concatenated.

The Vector Quantizer Encoder block accepts real floating-point and fixed-point inputs. For more information on the data types accepted by each port, see “Data Type Support” on page 2-1803 or “Supported Data Types” on page 2-1809.

Data Type Support

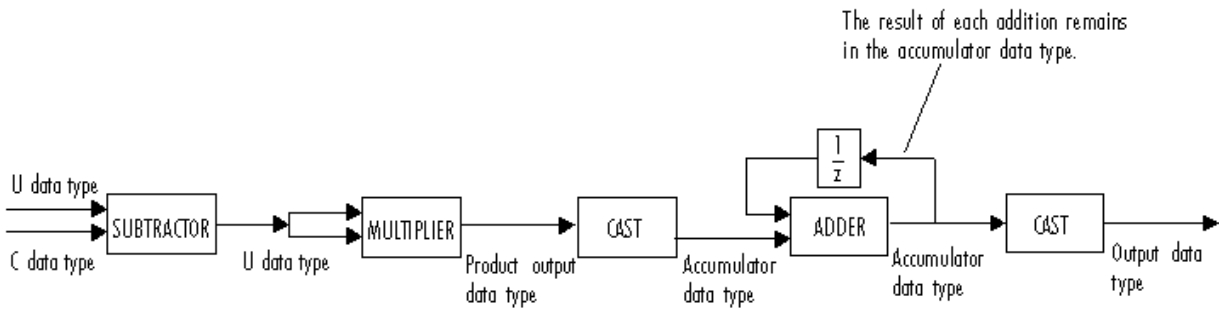

The input data values, codebook values, and weighting factor values are input to the block at ports U, C, and W, respectively. The data type of the input data values, codebook values, and weighting factor values can be `double`, `single`, or `Fixed-point`. The input data, codebook values, and weighting factor must be the same data type.

The outputs of the block are the index values, output codewords, and quantization error. Use the **Index output data type** parameter to specify the data type of the index output

from the block at port I. The data type of the index can be `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32`. The data type of the output codewords and the quantization error can be `double`, `single`, or `Fixed-point`. The block assigns the data type of the output codewords and the quantization error based on the data type of the input data.

Fixed-Point Data Types

The following diagram shows the data types used within the Vector Quantizer Encoder block for fixed-point signals.

You can set the product output, accumulator, and index output data types in the block dialog as discussed below.

Dialog Box

The **Main** pane of the Vector Quantizer Encoder block dialog appears as follows.

Source of codebook

Choose `Specify via dialog` to type the codebook values into the block parameters dialog box. Select `Input port` to specify the codebook values using the block's input port, `C`.

Codebook

Enter a k -by- N matrix of values, where $1 \leq k$ and $1 \leq N$, to which your input column vector or matrix is compared. This parameter is visible if, from the **Source of codebook** list, you select `Specify via dialog`.

Distortion measure

Select `Squared error` when you want the block to calculate the distortion by evaluating the Euclidean distance between the input column vector and each codeword in the codebook. Select `Weighted squared error` when you want the block to calculate the distortion by evaluating a weighted Euclidean distance using a weighting factor to emphasize or deemphasize certain input values.

Source of weighting factor

Select `Specify via dialog` to enter a value for the weighting factor in the dialog box. Choose `Input port` and specify the weighting factor using port W on the block. This parameter is visible if, for the **Distortion measure** parameter, you select `Weighted squared error`.

Weighting factor

Enter a vector of values. This vector must have length equal to the number of rows of the input, U . This parameter is visible if, for the **Source of weighting factor** parameter, you select `Specify via dialog`.

Tie-breaking rule

Set this parameter to determine the behavior of the block when an input column vector is equidistant from two codewords. When you want the input column vector to be represented by the lower index valued codeword, select `Choose the lower index`. To represent the input column vector by the higher index valued codeword, select `Choose the higher index`.

Output codeword

Select this check box to output the codeword vectors nearest to the input column vectors.

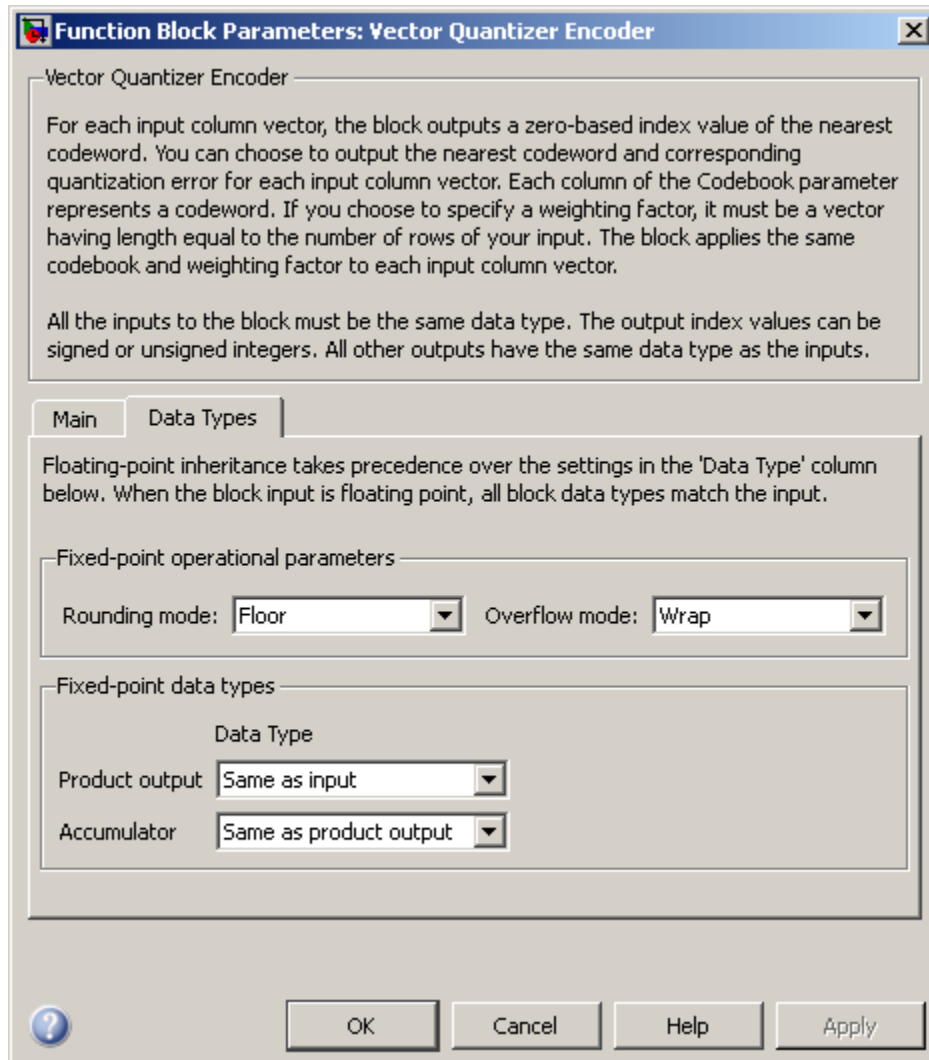

Output quantization error

Select this check box to output the quantization error value that results when the block represents the input column vector by the nearest codeword.

Index output data type

Select `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32` as the data type of the index output at port I .

The **Data Types** pane of the Vector Quantizer Encoder block dialog appears as follows.

Rounding mode

Select the rounding mode for fixed-point operations.

Overflow mode

Select the overflow mode to be used when block inputs are fixed point.

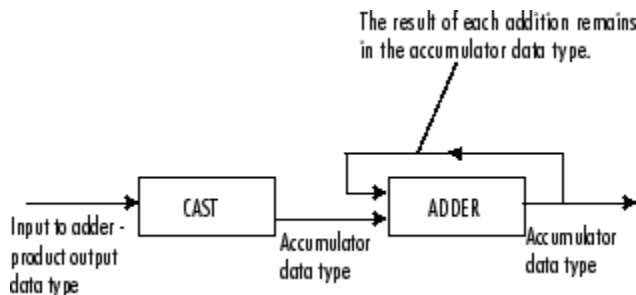

Product output

As depicted above, the output of the multiplier is placed into the product output data type and scaling. Use this parameter to specify how you would like to designate this product output word and fraction lengths.

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the product output, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the product output. This block requires power-of-two slope and zero bias.

Accumulator

As depicted above, inputs to the accumulator are cast to the accumulator data type. The output of the adder remains in the accumulator data type as each element of the input is added to it. Use this parameter to specify how you would like to designate the accumulator word and fraction lengths.

- When you select `Same as product output`, these characteristics match those of the product output.
- When you select `Same as input`, these characteristics match those of the input to the block.

- When you select `Binary point scaling`, you can enter the word length and the fraction length of the accumulator, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the accumulator. This block requires power-of-two slope and zero bias.

Vector Scope

Display vector or matrix of time-domain, frequency-domain, or user-defined data

Library

Sinks

dspsnks4

Description

Note Consider using the Array Plot block, which offers more features than the Vector Scope. Additional features supported by the Array Plot are:

- Multiple inputs
 - Cursors, Signal Statistics, and Peak Finder measurements
 - Magnitude-phase plot
 - Log x -axis scaling
 - Advanced panning, zooming, and autoscaling
 - Ability to customize the plot appearance, such as, figure and axes colors, line width, and legend text
-

The Vector Scope block is a comprehensive display tool similar to a digital oscilloscope. The block can display time-domain, frequency-domain, or user-defined signals. You can use the Vector Scope block to plot consecutive time samples from a vector, or to plot vectors containing data such as filter coefficients or spectral magnitudes. To compute and plot the periodogram of a signal with a single block, use the Spectrum Analyzer block.

The input to the Vector Scope block can be any real-valued matrix or vector. The block treats each column of an M -by- N matrix input as an independent channel of data with M consecutive samples.

The block plots each sample of each input channel sequentially across the horizontal axis of the plot.

Scope Properties Pane

The **Scope Properties** pane enables you to plot time-domain, frequency-domain, or user-defined data, and adjust the horizontal display span of the plot. The scope displays frames of data, and updates the display for each new input frame.

The **Input domain** parameter specifies the domain of the input data. If you select `Time`, for M -by- N inputs containing time-domain data, the block treats each of the N input frames (columns) as a succession of M consecutive samples taken from a time series. That is, each data point in the input frame is assumed to correspond to a unique time value. Also, the **Time display span (number of frames)** parameter appears on the pane. Enter a scalar value greater than or equal to one that corresponds to the number of frames to be displayed across the width of the scope window.

If you select `Frequency` for the **Input domain** parameter, for M -by- N inputs containing frequency-domain data, the block treats each of the N input frames (columns) as a vector of spectral magnitude data corresponding to M consecutive ascending frequency indices. That is, when the input is a single column vector, u , each value in the input frame, $u(i)$, is assumed to correspond to a unique frequency value, $f(i)$, where $f(i+1) > f(i)$.

If you select `User-defined` for the **Input domain** parameter, the block does not assume that the input frame data is time-domain or frequency-domain data. You can plot the data in the appropriate manner. Also, the **Horizontal display span (number of frames)** parameter appears on the pane. Enter a scalar value greater than or equal to one that corresponds to the number of frames to be displayed across the width of the scope window.

Display Properties Pane

The **Display Properties** pane enables you to control how the block displays your data.

The **Show grid** parameter toggles the background grid on and off.

If you select the **Frame number** check box, the block displays the number of the current frame in the input sequence on the scope window, and the block increments the count as each new input is received. Counting starts at 1 with the first input frame, and continues until the simulation stops.

If you select the **Channel legend** check box, a legend indicating the line color, style, and marker of each channel's data is added. When the input signal is labeled, that label appears in the channel legend. When the input signal is not labeled, but comes from a Concatenate block or a Mux block with labeled inputs, those labels appear in the channel legend. Otherwise, each channel in the legend is labeled with the channel number (CH 1, CH 2, etc.). Click and drag the legend to reposition it in the scope window; double-click on the line label to edit the text. If you rerun the simulation, the labels revert to the defaults.

If you select the **Compact display** check box, the scope completely fills the figure window. The scope does not display menus and axis titles, but it does show the numerical

axis labels within the axes. If you clear the **Compact display** check box, the scope displays the axis labels and titles in a gray border surrounding the scope axes, and the window's menus and toolbar become visible.

If you select the **Open scope at start of simulation** check box, the scope opens at the start of the simulation. If you clear this parameter, the scope does not open automatically during the simulation. You can use this feature when you have several scope blocks in a model, and you do not want to view all the associated scopes during the simulation.

Note Before running a model that contains a Vector Scope block in Accelerator, Rapid Accelerator, or External mode, you must select the **Open scope at start of simulation** check box. If you do not select this check box before running your model for the first time, the scope will not display your simulation data.

If you want to view a scope window that is not open during simulation, click **Open scope immediately** on the **Display Properties** pane of the desired Scope block.

The **Scope position** parameter specifies a four-element vector of the form

```
[left bottom width height]
```

specifying the position of the scope window on the screen, where (0,0) is the lower-left corner of the display. See the MATLAB `figure` function for more information.

Axis Properties Pane

The parameters that are available on the **Axis Properties** pane depend on the setting of the **Input domain** parameter on the **Scope Properties** pane.

Time Domain Inputs

When **Time display limits** is set to `Auto`, the block scales the horizontal axis of time-

domain signals automatically. The range of the time axis is $[0, S * T_{fi}]$, where T_{fi} is the input frame period, and S is the **Time display span (number of frames)** parameter on

the **Scope Properties** pane. The spacing between time points is $T_{fi} / (M - 1)$, where M is the number of samples in each consecutive input frame.

When **Time display limits** is set to User-defined, the **Minimum X-limit (s)** and **Maximum X-limit (s)** parameters set the range of the horizontal axis.

Minimum Y-limit and **Maximum Y-limit** parameters set the range of the vertical axis. Setting these parameters is analogous to setting the `ymin` and `ymax` values of the MATLAB axis function.

The **Y-axis label** is the text displayed to the left of the y -axis.

Frequency Domain Inputs

The **Frequency units** parameter specifies whether the frequency axis values should be in units of Hertz or rad/sec. When the **Frequency units** parameter is set to Hertz, the spacing between frequency points is $1/(M * T_s)$, where T_s is the sample time of the original time-domain signal. When the **Frequency units** parameter is set to rad/sec, the spacing between frequency points is $2\pi/(M * T_s)$.

The **Frequency range** parameter specifies the range of frequencies over which the magnitudes in the input should be plotted. The available options are $[0 \dots Fs/2]$, $[-Fs/2 \dots Fs/2]$, and $[0 \dots Fs]$, where F_s is the original time-domain signal's sample frequency. The Vector Scope block assumes that the input data spans the range $[0, F_s)$, which is the same as the output from an FFT. To plot over the range $[0 \dots Fs/2]$ the scope truncates the input vector, leaving only the first half of the data, then plots these remaining samples over half the frequency range. To plot over the range $[-Fs/2 \dots Fs/2]$, the scope reorders the input vector elements such that the last half of the data becomes the first half, and vice versa; then it relabels the x -axis accordingly.

If you select the **Inherit sample time from input** check box for frequency domain inputs, the block scales the frequency axis by reconstructing the frequency data from the frame-period of the frequency-domain input. This is valid when the following conditions hold:

- Each frame of frequency-domain data shares the same length as the frame of time-domain data from which it was generated; for example, when the FFT is computed on the same number of points as are contained in the time-domain input.
- The sample period of the time-domain signal in the simulation is equal to the period with which the physical signal was originally sampled.
- Consecutive frames containing the time-domain signal do not overlap each other; that is, a particular signal sample does not appear in more than one sequential frame.

In cases where not all of these conditions hold, specify the appropriate value for the **Sample time of original time series** parameter.

When **Frequency display limits** is set to `Auto`, the block scales the horizontal axis of frequency-domain signals automatically. To do this, the Vector Scope block needs to know the sample period of the original time-domain sequence represented by the frequency-domain data. Specify this period by entering a value for the **Sample time of original time series** parameter.

When **Frequency display limits** is set to `User-defined`, the **Minimum frequency** and **Maximum frequency** parameters set the range of the horizontal axis.

The **Y-axis scaling** parameter allows you to select `Magnitude` or `dB` scaling along the y -axis.

Minimum Y-limit and **Maximum Y-limit** parameters set the range of the vertical axis. Setting these parameters is analogous to setting the `ymin` and `ymax` values of the MATLAB axis function.

The **Y-axis label** is the text displayed to the left of the y -axis.

User-Defined Inputs

If you select the **Inherit sample increment from input** check box for user-defined input domains, the block scales the horizontal axis by computing the horizontal interval between samples in the input frame from the frame period of the input. For example, when the input frame period is 1, and there are 64 samples per input frame, the interval between samples is computed to be $1/64$. Computing the interval this way is usually only valid when the following conditions hold:

- The input is a nonoverlapping time series; the x -axis on the scope represents time.
- The input sample period ($1/64$ in the above example) is equal to the period with which the physical signal was originally sampled.

In cases where not all of these conditions hold, use the **X display offset (samples)** and **Increment per sample in input** parameters.

The **X-axis title** is the text displayed below the x -axis.

When **X display limits** is set to `Auto`, the block scales the horizontal axis of user-defined domain signals automatically. To do this, the Vector Scope block needs to know the

spacing of the input data. Specify this spacing using the **Increment per sample in input** parameter, I_s . This parameter represents the numerical interval between adjacent x -axis points corresponding to the input data. The range of the horizontal axis is

$[0, M * I_s * S]$, where M is the number of samples in each consecutive input frame, and S is the **Horizontal display span (number of frames)** parameter that you specify in the **Scope Properties** pane.

When **X display limits** is set to *User-defined*, the **Minimum X-limit (samples)** and **Maximum X-limit (samples)** parameters set the range of the horizontal axis.

Minimum Y-limit and **Maximum Y-limit** parameters set the range of the vertical axis. Setting these parameters is analogous to setting the `ymin` and `ymax` values of the MATLAB `axis` function.

The **Y-axis label** is the text displayed to the left of the y -axis.

Line Properties Pane

Use the parameters on the **Line Properties** pane to help you distinguish between two or more independent channels of data on the scope.

The **Line visibilities** parameter specifies which channel's data is displayed on the scope, and which is hidden. The syntax specifies the visibilities in list form, where the term `on` or `off` as a list entry specifies the visibility of the corresponding channel's data. The list entries are separated by the pipe symbol, `|`.

For example, a five-channel signal would ordinarily generate five distinct plots on the scope. To disable plotting of the third and fifth lines, enter the following visibility specification in the **Line visibilities** parameter.

```
on | on | off | on | off
ch 1 ch 2 ch 3 ch 4 ch 5
```

Note that the first (leftmost) list item corresponds to the first signal channel (leftmost column of the input matrix).

The **Line styles** parameter specifies the line style with which each channel's data is displayed on the scope. The syntax specifies the channel line styles in list form, with each list entry specifying a style for the corresponding channel's data. The list entries are separated by the pipe symbol, `|`.

For example, a five-channel signal would ordinarily generate all five plots with a solid line style. To plot each line with a different style, enter

```
- | -- | : | -. | -
ch 1 ch 2 ch 3 ch 4 ch 5
```

These settings plot the signal channels with the following styles.

Line Style	Command to Type in Line Style Parameter	Appearance
Solid	-	
Dashed	--	
Dotted	:	
Dash-dot	-.	
No line	none	No line appears

Note that the first (leftmost) list item, '-', corresponds to the first signal channel (leftmost column of the input matrix). See the `LineStyle` property of the MATLAB `line` function for more information about the style syntax.

The **Line markers** parameter specifies the marker style with which each channel's samples are represented on the scope. The syntax specifies the channels' marker styles in list form, with each list entry specifying a marker for the corresponding channel's data. The list entries are separated by the pipe symbol, |.

For example, a five-channel signal would ordinarily generate all five plots with no marker symbol (that is, the individual sample points are not marked on the scope). To instead plot each line with a different marker style, you could enter

```
* | . | x | s | d
ch 1 ch 2 ch 3 ch 4 ch 5
```

These settings plot the signal channels with the following styles.

Marker Style	Command to Type in Marker Style Parameter	Appearance
Asterisk	*	
Point	.	
Cross	x	

Marker Style	Command to Type in Marker Style Parameter	Appearance
Square	s	
Diamond	d	

Note that the leftmost list item, '*', corresponds to the first signal channel or leftmost column of the input matrix. See the `LineStyle` (Line Specification) property of the MATLAB `line` function for more information about the available markers.

To produce a stem plot for the data in a particular channel, type the word `stem` instead of one of the basic marker shapes.

The **Line colors** parameter specifies the color in which each channel's data is displayed on the scope. The syntax specifies the channel colors in list form, with each list entry specifying a color (in one of the MATLAB `ColorSpec` formats) for the corresponding channel's data. The list entries are separated by the pipe symbol, |.

For example, a five-channel signal would ordinarily generate all five plots in the color black. To instead plot the lines with the color order below, enter

```
[0 0 0] | [0 0 1] | [1 0 0] | [0 1 0] | [.7529 0 .7529]
  ch 1   ch 2   ch 3   ch 4   ch 5
```

or

```
'k' | 'b' | 'r' | 'g' | [.7529 0 .7529]
ch 1 ch 2 ch 3 ch 4   ch 5
```

These settings plot the signal channels in the following colors (8-bit RGB equivalents shown in the center column).

Color	RGB Equivalent	Appearance
Black	(0,0,0)	
Blue	(0,0,255)	
Red	(255,0,0)	
Green	(0,255,0)	
Dark purple	(192,0,192)	

Note that the leftmost list item, 'k', corresponds to the first signal channel or leftmost column of the input matrix. See the MATLAB function `ColorSpec` for more information about the color syntax.

Vector Scope Window

The title that appears in the title bar of the scope window is the same as the block title. In addition to the standard MATLAB figure window menus such as **File**, **Window**, and **Help**, the Vector Scope window contains **View**, **Axes**, and **Channels** menus.

The options in the **View** menu allow you to zoom in and out of the scope window:

- To zoom in on the scope window, you must first select **View > Zoom In** or click the corresponding `Zoom In` toolbar button (). You can then zoom in by clicking in the center of your area of interest, or by clicking and dragging your cursor to draw a rectangular area of interest inside of the scope window.
- To zoom in on the x -axis of the scope window, you must first select **View > Zoom X**, or click the corresponding `Zoom X-Axis` toolbar button (). You can then zoom in on the x -axis with a single click inside the scope window or by clicking and dragging the cursor along the x -axis over your area of interest.
- To zoom in on the y -axis of the scope window, you must first select **View > Zoom Y** or click the corresponding `Zoom Y-Axis` toolbar button (). You can then zoom in on the y -axis with a single click inside the scope window or by clicking and dragging the cursor along the y -axis over your area of interest.
- To return to the original view of the scope window, you have the following options:
 - Select **Full View** from the **View** menu .
 - Click the `Restore default view` toolbar button () on the Vector Scope window.
 - Right-click inside the scope window, and select `Reset to Original View`.

Note To zoom out in smaller increments, you can right-click inside of the scope window and select `Zoom Out`. You can also zoom out by holding down the **Shift** key and clicking the left mouse button inside the scope window.

The parameters that you set using the **Axes** menu apply to all channels. Many of the parameters in this menu are also accessible through the block parameters dialog box. For descriptions of these parameters, see “Display Properties Pane” on page 2-1813. Below are descriptions of other parameters in the **Axes** menu:

- **Refresh** erases all data on the scope display, except for the most recent trace.
- **Autoscale** resizes the *y*-axis to best fit the vertical range of the data.

Note The **Minimum Y-limit** and **Maximum Y-limit** parameters on the **Axis properties** pane of the block dialog are not updated to display the numerical limits selected by the autoscale feature.

- **Save Axes Settings** allows you to save the current axes settings. When you select this option, the **Minimum Y-limit** and **Maximum Y-limit** parameters of the **Axes Properties** pane update with the current *y*-axes limits. The **Time display limits** (or **Frequency display limits**) parameter is set to *User-defined*, and the current *x*-axes limits are saved in the **Minimum X-limit** and **Maximum X-limit** (or **Minimum Frequency** and **Maximum Frequency**) parameters. To save these axes settings for your next MATLAB session, you need to resave your model.
- **Save Scope Position** updates the **Scope position** parameter on the **Display Properties** pane of the block dialog to reflect the scope window's current position and size. To make the scope window open at a particular location on the screen when the simulation runs, drag the window to the desired location, resize it, and select **Save Scope Position** from the **Axes** menu.

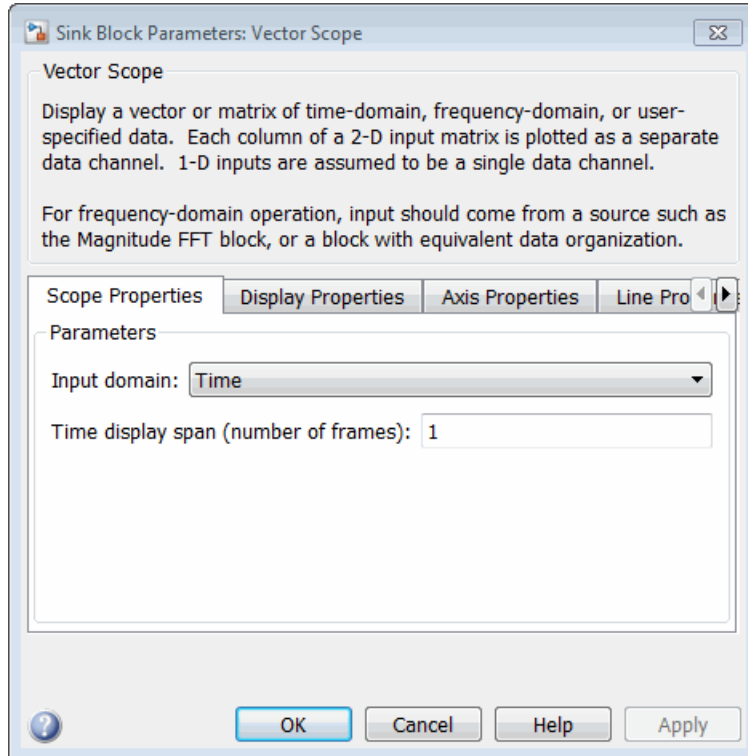

The properties listed in the **Channels** menu apply to a particular channel. All of the parameters in this menu are also accessible through the block parameters dialog box. For descriptions of these parameters, see “Line Properties Pane” on page 2-1817.

Many of these options can also be accessed by right-clicking with the mouse anywhere on the scope display. The menu that is displayed contains a combination of the options available in the **View**, **Axes** and **Channels** menus.

Note When you select **Compact Display** from the **Axes** menu, the scope window menus are no longer visible. Right-click in the Vector Scope window and click **Compact Display** in order to make the menus reappear.

Dialog Box

Scope Properties Pane

Input domain

Select the domain of the input. Your choices are **Time**, **Frequency**, or **User-defined**. Tunable (Simulink).

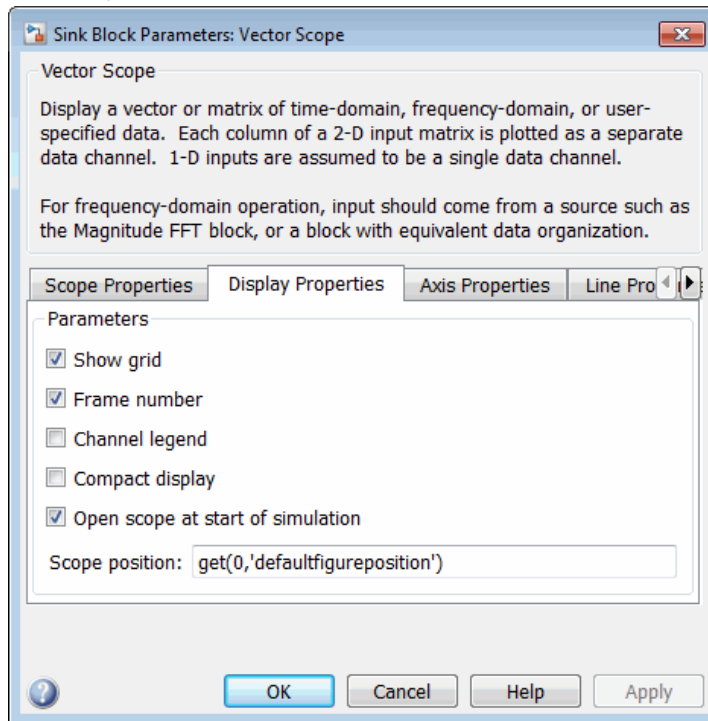

Time display span (number of frames)

The number of consecutive frames to display (horizontally) on the scope at any one time. This parameter is visible when the **Input domain** parameter is set to **Time**.

Horizontal display span (number of frames)

The number of consecutive frames to display (horizontally) on the scope at any one time. This parameter is visible when the **Input domain** parameter is set to **User-defined**.

Display Properties Pane

Show grid

Toggle the scope grid on and off. Tunable (Simulink).

Frame number

If you select this check box, the number of the current frame in the input sequence appears in the Vector Scope window. Tunable (Simulink).

Channel legend

Toggles the legend on and off. Tunable (Simulink).

Compact display

Resizes the scope to fill the window. Tunable (Simulink).

Open scope at start of simulation

Select this check box to open the scope at the start of the simulation. When this parameter is cleared, the scope does not open automatically during the simulation. Tunable (Simulink).

Note Before running a model that contains a Vector Scope block in Accelerator, Rapid Accelerator, or External mode, you must select the **Open scope at start of simulation** check box. If you do not select this check box before running your model for the first time, the scope will not display your simulation data.

Open scope immediately

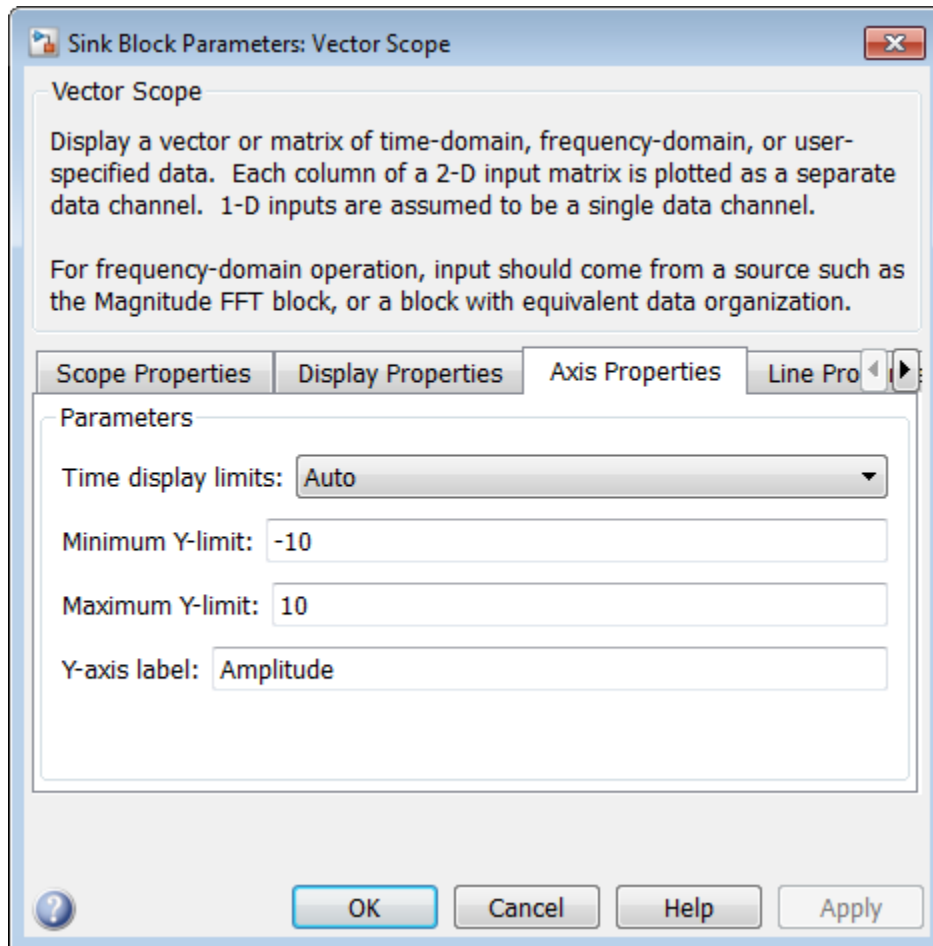

If the scope is not open during simulation, select this check box to open it. This parameter is visible only while the simulation is running.

Scope position

A four-element vector of the form `[left bottom width height]` specifying the position of the scope window. $(0, 0)$ is the lower-left corner of the display. Tunable (Simulink).

Axis Properties Pane

The parameters that are available on the **Axis Properties** pane depend on the setting of the **Input domain** parameter on the **Scope Properties** pane. When `Time` is selected for the **Input domain** parameter, the following parameters are available on the **Axis Properties** pane:

Time display limits

Select **Auto** to have the limits of the x -axis set for you automatically, or **User-defined** to set the limits yourself in the **Minimum X-limit (s)** and **Maximum X-limit (s)** parameters.

Minimum X-limit (s)

Specify the minimum value of the x -axis in seconds. This parameter is only visible if the **Time display limits** parameter is set to **User-defined**. Tunable (Simulink).

Maximum X-limit (s)

Specify the maximum value of the x -axis in seconds. This parameter is only visible if the **Time display limits** parameter is set to `User-defined`. Tunable (Simulink).

Minimum Y-limit

Specify the minimum value of the y -axis. Setting this parameter is analogous to setting the `ymin` value of the MATLAB `axis` function. Tunable (Simulink).

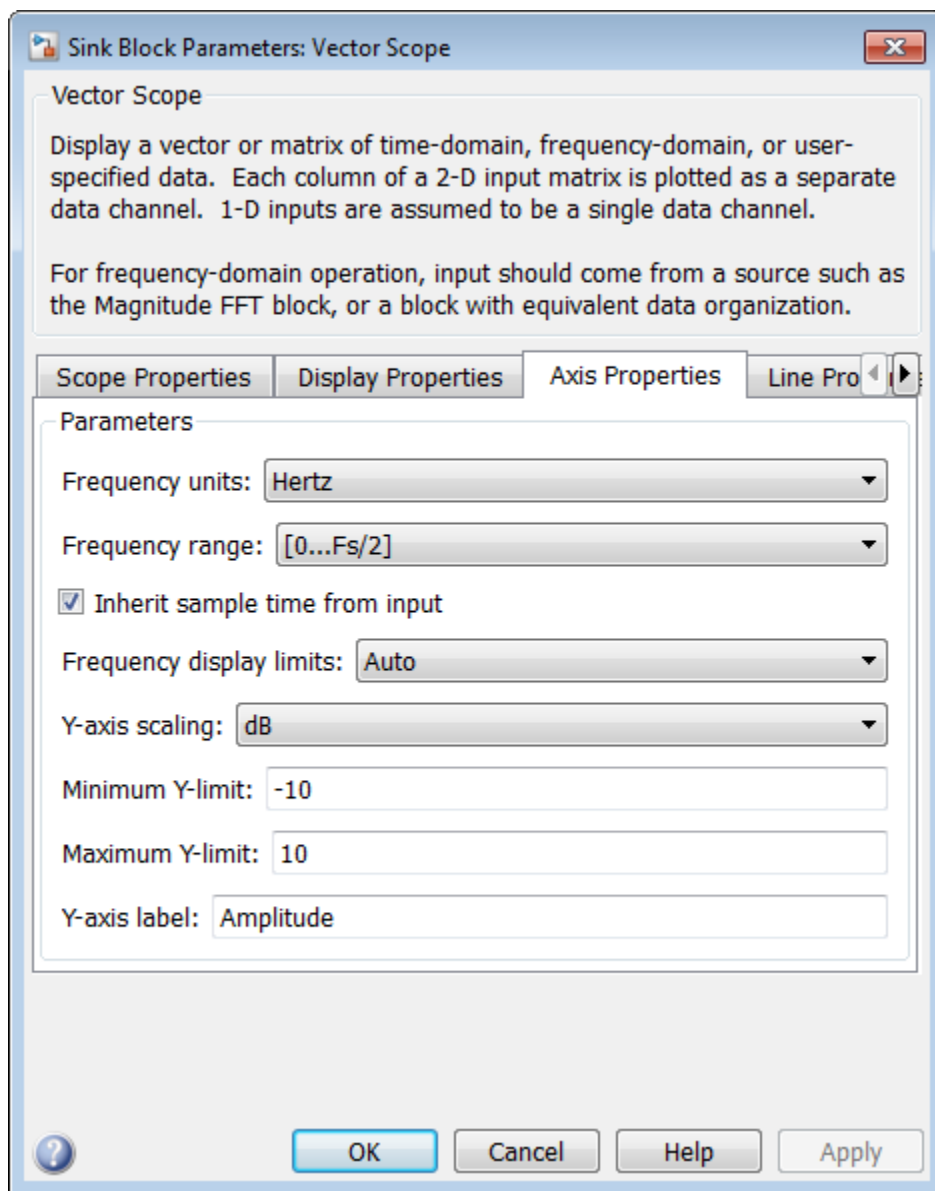

Maximum Y-limit

Specify the maximum value of the y -axis. Setting this parameter is analogous to setting the `ymax` value of the MATLAB `axis` function. Tunable (Simulink).

Y-axis label

Specify text to be displayed to the left of the y -axis. Tunable (Simulink).

When `Frequency` is selected for the **Input domain** parameter, the following parameters are available on the **Axis Properties** pane:

Frequency units

Choose the frequency units for the x -axis, Hertz or rad/sec. Tunable (Simulink).

Frequency range

Specify the frequency range over which to plot the data. Tunable (Simulink).

Inherit sample time from input

If you select this check box, the block computes the time-domain sample period from the frame period and frame size of the frequency-domain input. Use this parameter only when the length of the each frame of frequency-domain data is the same as the length of the frame of time-domain data from which it was generated. Tunable (Simulink).

Sample time of original time series

Enter the sample period, T_s , of the original time-domain signal. This parameter is only visible when the **Inherit sample time from input** check box is not selected. Tunable (Simulink).

Frequency display limits

Select `Auto` to have the limits of the x -axis set for you automatically, or `User-defined` to set the limits yourself in the **Minimum frequency** and **Maximum frequency** parameters.

Minimum frequency

Specify the minimum frequency value of the x -axis in Hertz or rad/sec. This parameter is only visible if the **Frequency display limits** parameter is set to `User-defined`. Tunable (Simulink).

Maximum frequency

Specify the maximum frequency value of the x -axis in Hertz or rad/sec. This parameter is only visible if the **Frequency display limits** parameter is set to `User-defined`. Tunable (Simulink).

Y-axis scaling

Choose either `dB` (decibel) or `Magnitude` scaling for the y -axis. Tunable (Simulink).

Minimum Y-limit

Specify the minimum value of the y -axis. Setting this parameter is analogous to setting the `ymin` value of the MATLAB `axis` function. Tunable (Simulink).

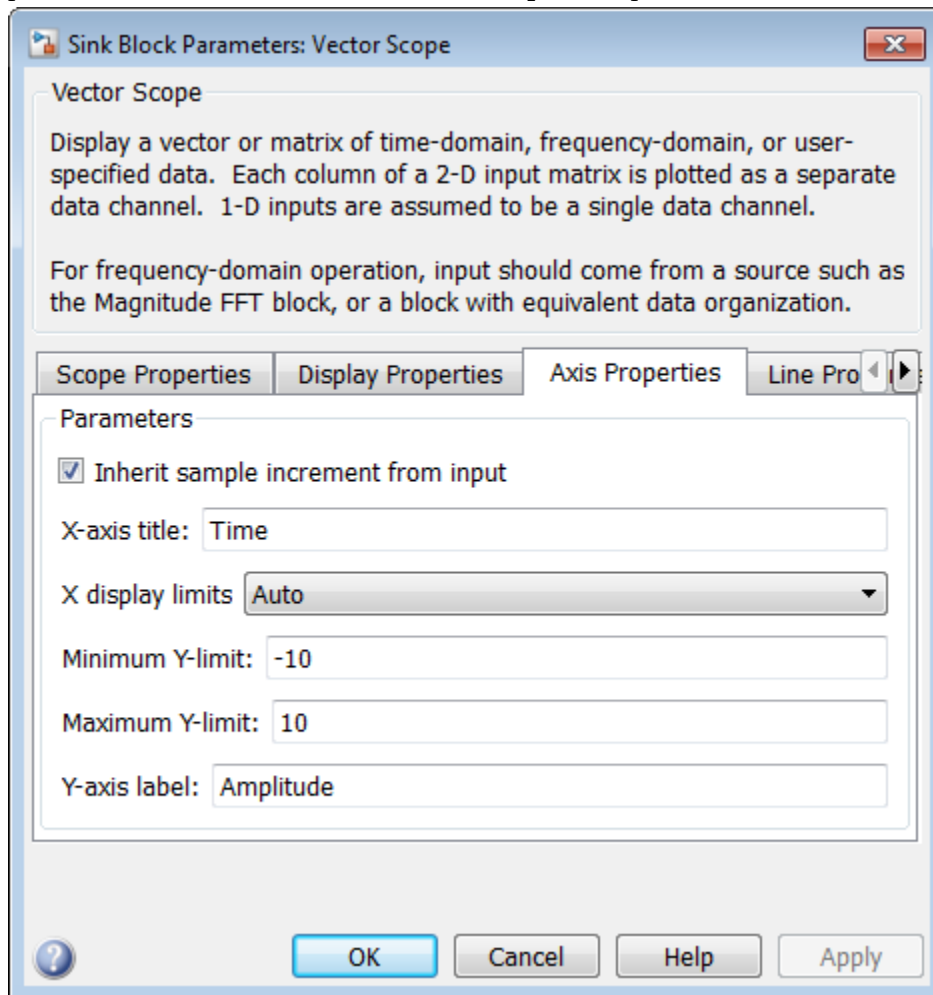

Maximum Y-limit

Specify the maximum value of the y -axis. Setting this parameter is analogous to setting the `ymax` value of the MATLAB `axis` function. Tunable (Simulink).

Y-axis label

Specify text to be displayed to the left of the y -axis. Tunable (Simulink).

When User-defined is selected for the **Input domain** parameter, the following parameters are available on the **Axis Properties** pane:

Inherit sample increment from input

When you select this check box, the block scales the horizontal axis by computing the horizontal interval between samples in the input frame from the frame period of the input. Use this parameter only when the input's sample period is equal to the period with which the physical signal was originally sampled. Tunable (Simulink).

Increment per sample in input

Enter the numerical interval between adjacent x -axis points corresponding to the user-defined input data. This parameter is only visible when the **Inherit sample increment from input** check box is not selected. Tunable (Simulink).

X display offset (samples)

Specify an offset for the x -axis display in samples. This parameter is only visible when the **Inherit sample increment from input** check box is not selected. Tunable (Simulink).

X-axis title

Enter the text to be displayed below the x -axis. Tunable (Simulink).

X display limits

Select `Auto` to have the limits of the x -axis set for you automatically, or `User-defined` to set the limits yourself in the **Minimum X-limit (samples)** and **Maximum X-limit (samples)** parameters.

Minimum X-limit (samples)

Specify the minimum value of the x -axis in samples. This parameter is only visible if the **X display limits** parameter is set to `User-defined`. Tunable (Simulink).

Maximum X-limit (samples)

Specify the maximum value of the x -axis in samples. This parameter is only visible if the **X display limits** parameter is set to `User-defined`. Tunable (Simulink).

Minimum Y-limit

Specify the minimum value of the y -axis. Setting this parameter is analogous to setting the `ymin` value of the MATLAB `axis` function. Tunable (Simulink).

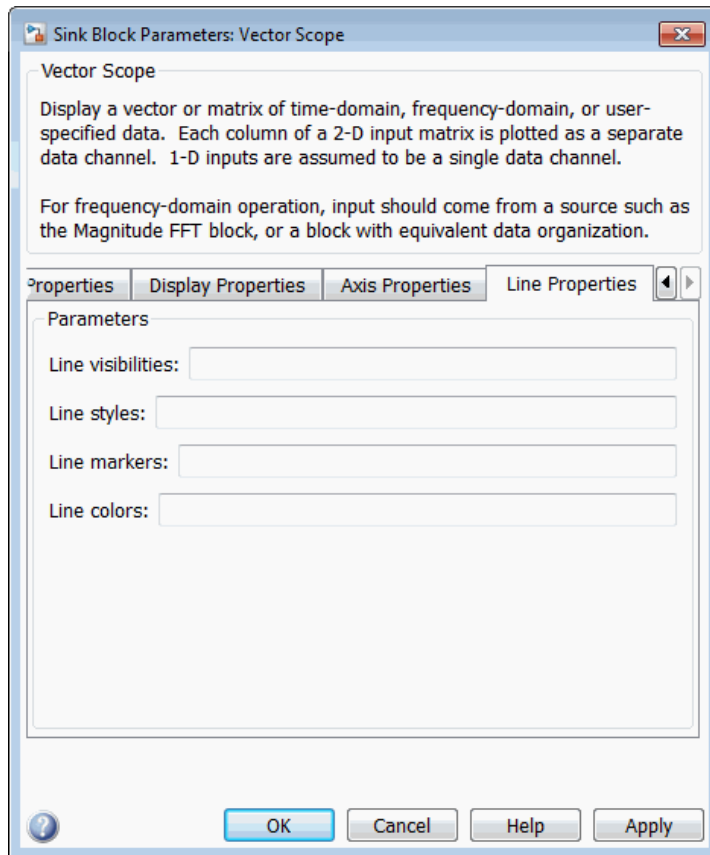

Maximum Y-limit

Specify the maximum value of the y -axis. Setting this parameter is analogous to setting the `ymax` value of the MATLAB `axis` function. Tunable (Simulink).

Y-axis label

Specify text to be displayed to the left of the y -axis. Tunable (Simulink).

Line Properties Pane

Line visibilities

Enter `on` or `off` to specify the visibility of the various channels' scope traces. Separate your choices for each channel with by a pipe (`|`) symbol. Tunable (Simulink).

Line styles

Enter the line styles of the various channels' scope traces. Separate your choices for each channel with by a pipe (`|`) symbol. Tunable (Simulink).

Line markers

Enter the line markers of the various channels' scope traces. Separate your choices for each channel with by a pipe (|) symbol. Tunable (Simulink).

Line colors

Enter the colors of the various channels' scope traces using the ColorSpec formats. Separate your choices for each channel with by a pipe (|) symbol. Tunable (Simulink).

Description

The Waterfall block displays multiple vectors of data at one time. These vectors represent the input data at consecutive sample times. The input to the block can be real or complex-valued data vectors of any data type including fixed-point data types. However, the input is converted to double-precision before the block processes the data. The Waterfall block displays only real-valued, double-precision vectors of data.

The data is displayed in a three-dimensional axis in the Waterfall window. By default, the x -axis represents amplitude, the y -axis represents samples, and the z -axis represents time. You can adjust the number of sample vectors that the block displays, move and resize the Waterfall window, and modify block parameter values during the simulation. The Waterfall window has toolbar buttons that enable you to zoom in on displayed data, suspend data capture, freeze the scope's display, save the scope position, and export data to the workspace. The toolbar buttons are labeled in the following figure, which shows the Waterfall window as it appears when you double-click a Waterfall block.

Sections of This Reference Page

Waterfall Parameters

You can control the display and behavior of the Waterfall window using the Parameters dialog box.

Note You can alter the Waterfall parameters while the simulation is running. However, when you make changes to values in text boxes, you must click **Enter** or click outside the text box before the block accepts your changes.

- 1 To open the Parameters dialog box, click the **Scope parameters** button.

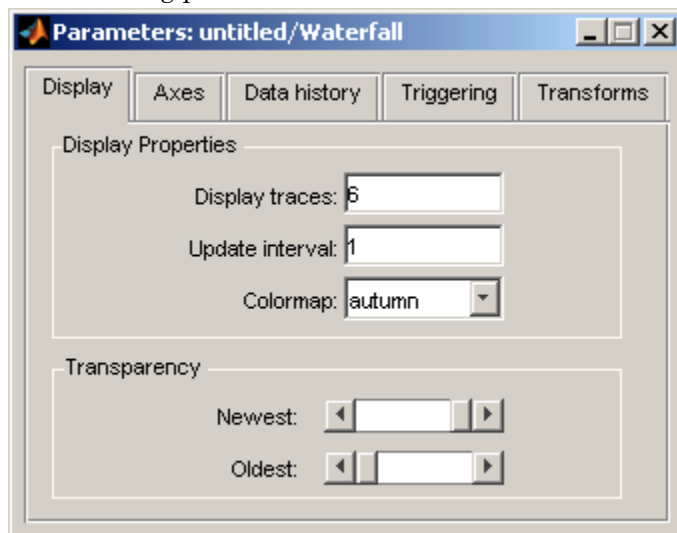

The Parameters dialog box appears.

- 2 Click on the different panes to enter parameter settings.

Display Parameters

The following parameters control the Waterfall window's display.

Display traces

Enter the number of vectors of data to be displayed in the Waterfall window.

Update interval

Enter the number of vectors the block should store before it displays them to the window.

Colormap

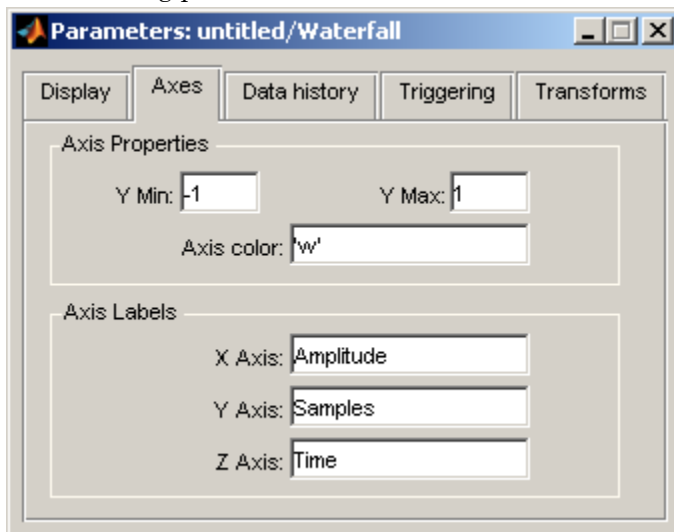

Choose a colormap for the displayed data.

Transparency

Specify the transparency of the newest and oldest data vectors. Placing the slider in the left-most position tells the block to make the data vector transparent. Placing the slider in the right-most position tells the block to make the data vector opaque. The intermediate data vectors transition between the two chosen transparency values.

Axes Parameters

The following parameters control the axes in the Waterfall window.

Y Min

Enter the minimum value of the y -axis.

Y Max

Enter the maximum value of the y -axis.

Axis color

Enter a background color for the axes. Specify the color using a character vector. For example, to specify black, enter 'k'.

X Axis

Enter the x -axis label.

Y Axis

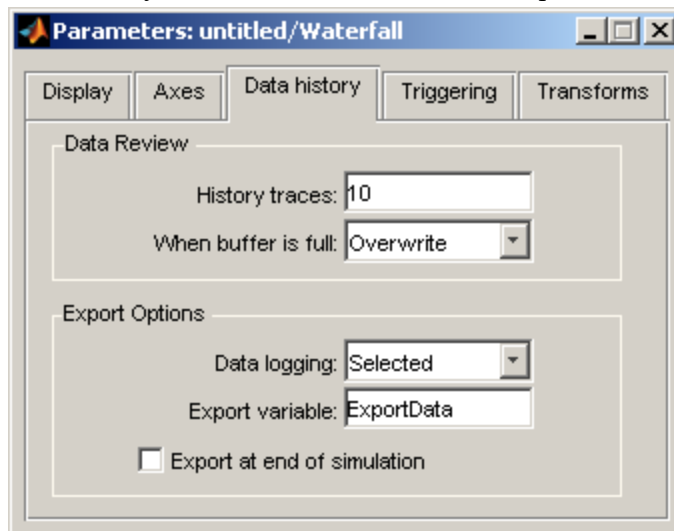

Enter the y -axis label.

Z Axis

Enter the z -axis label.

Data History Parameters

The following parameters control how many input data vectors the Waterfall block stores. They also control how the data is exported to the MATLAB workspace or SPTool.

**History traces**

Enter the number of vectors (traces) that you want the block to store.

When the buffer is full

Use this parameter to control the behavior of the block when the buffer is filled:

- `Overwrite` — The old data is replaced with the new data.
- `Suspend` — The block stops storing data in the buffer; however, the simulation continues to run.
- `Extend` — The block extends the buffer so that it can continue to store all the input data.

Data logging

Use this parameter to control which data is exported from the block:

- `Selected` — The selected data vector is exported.
- `All visible` — All of the data vectors displayed in the Waterfall window are exported.
- `All history` — All of the data vectors stored in the block's history buffer are exported.

Export variable

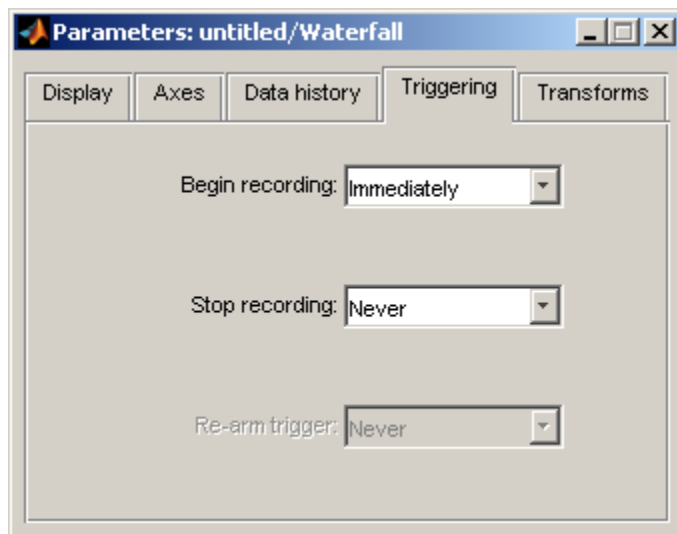

Enter the name of the variable that represents your data in the MATLAB workspace or SPTool. The default variable name is `ExportData`.

Export at end of simulation

Select this check box to automatically export the data to the MATLAB workspace when the simulation stops.

Triggering Parameters

The following parameters control when the Waterfall block starts and stops capturing data.

Begin recording

This parameter controls when the Waterfall block starts capturing data:

- **Immediately** — The Waterfall window captures the input data as soon as the simulation starts.
- **After T seconds** — The **Time, T** parameter appears in the dialog box. Enter the number of seconds the block should wait before it begins capturing data.
- **After N inputs** — The **Count, N** parameter appears in the dialog box. Enter the number of inputs the block should receive before it begins capturing data.
- **User-defined** — The **Function name** parameter appears in the dialog box. Enter the name of a MATLAB function that defines when the block should begin capturing data. For more information about how you define this function, see “Scope Trigger Function” on page 2-1843.

Stop recording

This parameter controls when the Waterfall block stops capturing data:

- **Never** — The block captures the input data as long as the simulation is running.
- **After T seconds** — The **Time, T** parameter appears in the dialog box. Enter the number of seconds the block should wait before it stops capturing data.

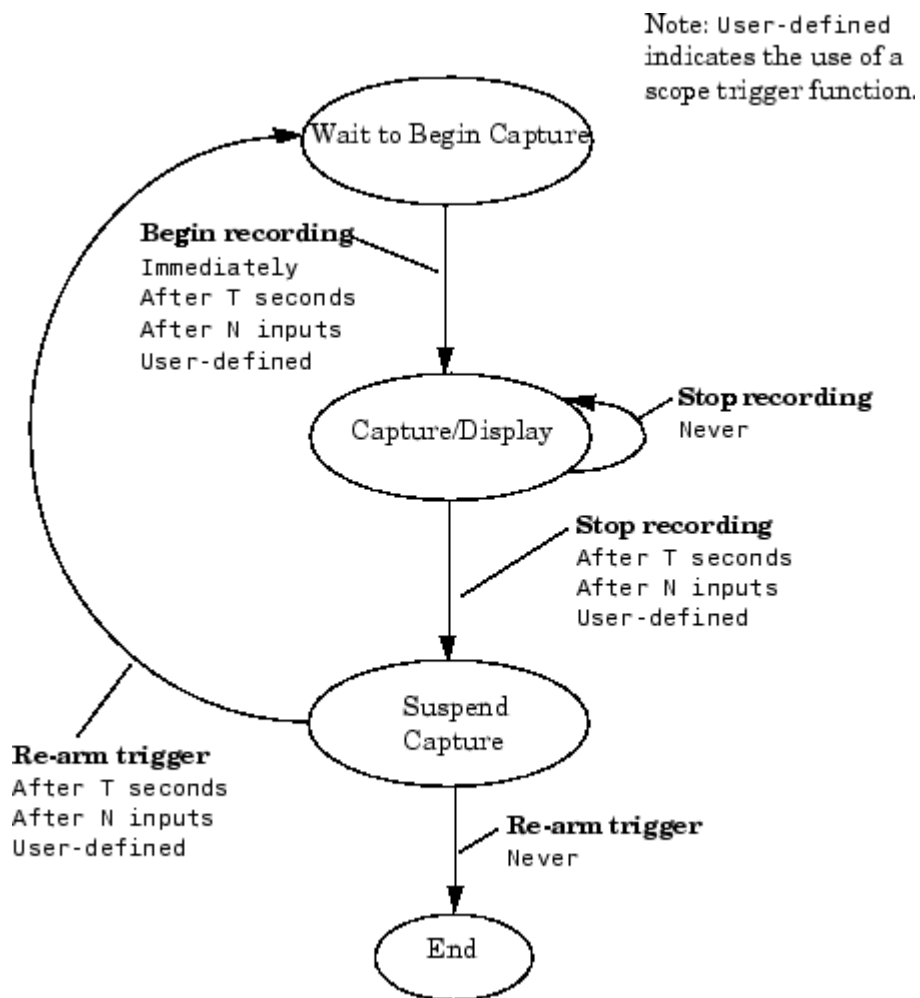

- *After N inputs* — The **Count, N** parameter appears in the dialog box. Enter the number of inputs the block should receive before it stops capturing data.
- *User-defined* — The **Function name** parameter appears in the dialog box. Enter the name of a MATLAB function that defines when the block should stop capturing data. For more information about how you define this function, see “Scope Trigger Function” on page 2-1843.

Re-arm trigger

This parameter controls when the Waterfall block begins waiting to capture data. It is available only when you select *After T seconds*, *After N inputs*, or *User-defined* for the **Stop recording** parameter:

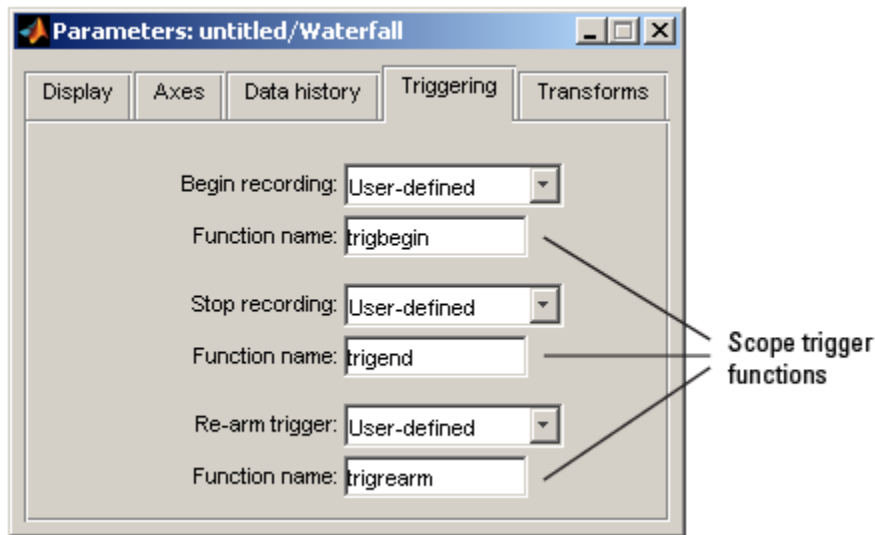

- *Never* — The Waterfall Scope block starts and stops capturing data as defined by the **Begin recording** and **Stop recording** parameters.
- *After T seconds* — The **Time, T** parameter appears in the dialog box. Enter the number of seconds the block should wait before it begins waiting to capture data.
- *After N inputs* — The **Count, N** parameter appears in the dialog box. Enter the number of inputs the block should receive before it begins waiting to capture data.
- *User-defined* — The **Function name** parameter appears in the dialog box. Enter the name of a MATLAB function that defines when the block should begin waiting to capture data. For more information about how you define this function, see “Scope Trigger Function” on page 2-1843.

The triggering process is illustrated in the state diagram below.

Scope Trigger Function

You can create custom scope trigger functions to control when the scope starts, stops, or begins waiting to capture data.

These functions must be valid MATLAB functions and be located either in the current folder or on the MATLAB path.

Each scope trigger function must have the following form

```
y = functionname(blk,t,u),
```

where `functionname` refers to the name you give your scope trigger function. The variable `blk` is the Simulink block handle. When the scope trigger function is called by the block, Simulink automatically populates this variable with the handle of the Waterfall block. The variable `t` is the current simulation time, represented by a real, double-precision, scalar value. The variable `u` is the vector input to the block. The output of the scope trigger function, `y`, is interpreted as a logical signal. It is either true or false:

- Begin recording scope trigger function
 - When the output of this scope trigger function is true, the Waterfall block starts capturing data.
 - When the output is false, the block remains in its current state.
- Stop recording scope trigger function
 - When the output of this scope trigger function is true, the block stops capturing data.

- When the output is false, the block remains in its current state.
- Re-arm trigger scope trigger function
 - When the output of this scope trigger function is true, the block waits for a begin recording event.
 - When the output is false, the block remains in its current state.

Note The Waterfall block passes its input data directly to the scope trigger functions. These functions do not use the transformed data defined by the Transform parameters.

The following is an example of a scope trigger function. This function, called `trigPower` detects when the energy in `u` exceeds a certain threshold.

```
function y = trigPower(blk, t, u)

y = (u'*u > 2300);
```

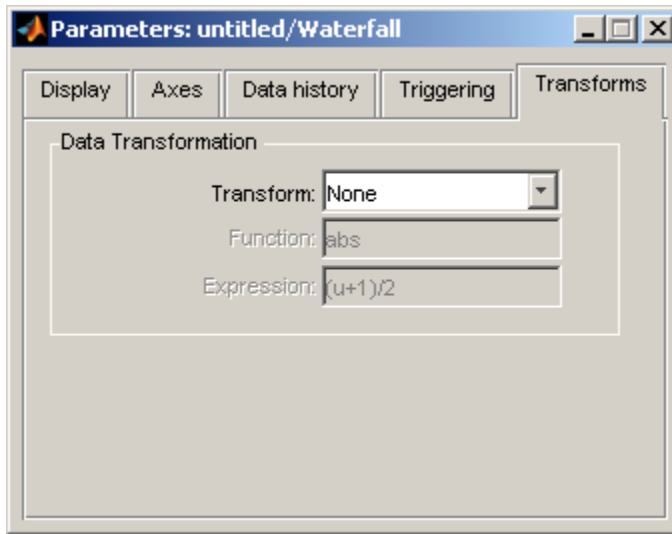

The following is another example of a scope trigger function. This function, called `count3`, triggers the scope once three vectors with positive means are input to the block. Then, the function resets itself and begins searching for the next three input vectors with positive means. This scope trigger function is valid only when one Waterfall block is present in your model.

```
function y = count3(blk, t, u)

persistent state;
if isempty(state); state = 0; end
if mean(u)>0; state = state+1; end
y = (state>=3);
if y; state = 0; end
```

Transform Parameters

The following parameters transform the input data to the Waterfall block. The result of the transform is displayed in the Waterfall window.

Note The block assumes that the input to the block corresponds to the **Transform** parameter you select. For example, when you choose `Complex-> Angle`, the block assumes that the input is complex. The block does not produce an error when the input is not complex. Therefore, you must verify the format of your input data to guarantee that a meaningful result is displayed in the Waterfall window.

Transform

Choose a transform that you would like to apply to the input of the Waterfall block:

- `None` — The input is displayed as it is received by the block.
- `Amplitude-> dB` — The block converts the input amplitude into decibels.
- `Complex-> Mag Lin` — The block converts the complex input into linear magnitude.
- `Complex-> Mag dB` — The block converts the complex input into magnitude in decibels.
- `Complex-> Angle` — The block converts the complex input into phase.
- `FFT-> Mag Lin Fs/2` — The block takes the linear magnitude of the FFT input and plots it from 0 to the Nyquist frequency.

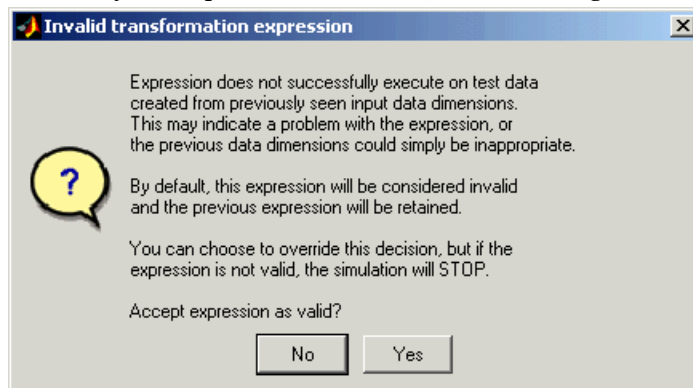

- **FFT-> Mag dB Fs/2** — The block takes the magnitude of the FFT input, converts it to decibels, and plots it from 0 to the Nyquist frequency.
- **FFT-> Angle Fs/2** — The block converts the FFT input into phase and plots it from 0 to the Nyquist frequency.
- **Power-> dB** — The block converts the input power into decibels.

Function

This parameter is only available when you select `User-defined fcn` for the **Transform** parameter. Enter a function that you would like to apply to the input of the Waterfall block. For more information about how you define this function, see “Scope Transform Function” on page 2-1848.

Expression

This parameter is only available when you select `User-defined expr` for the **Transform** parameter. Enter an expression that you would like to apply to the input of the Waterfall block. The result of this expression must be real-valued. When you write the expression, be sure to include only one unknown variable. The block assumes this unknown variable represents the input to the block. When the block believes your expression is invalid, the following window appears.

When you click **No**, your expression is not applied to the input. When you click **Yes** and your expression is invalid, your simulation stops and Simulink displays an error.

Scope Transform Function

You can create a scope transform function to control how the Waterfall block transforms your input data. This function must have a valid MATLAB function name and be located either in the current folder or on the MATLAB path.

Your scope transform function must have the following form

```
y = functionname(u),
```

where `functionname` refers to the name you give your function. The variable `u` is the real or complex vector input to the block. The output of the scope transform function, `y`, must be a double-precision, real-valued vector. When it is not, the simulation stops and Simulink displays an error. Note that the output vector does not need to be the same size as the input vector.

Examples

The following examples illustrate some capabilities of the Waterfall block.

- “Exporting Data” on page 2-1848
- “Capturing Data” on page 2-1849
- “Linking Scopes” on page 2-1849
- “Selecting Data” on page 2-1851
- “Zooming” on page 2-1852
- “Rotating the Display” on page 2-1853
- “Scaling the Axes” on page 2-1853
- “Saving Scope Settings” on page 2-1853

Exporting Data

You can use the Waterfall block to export data to the MATLAB workspace or to SPTool:

- 1 Open and run the `dspanc` example.
- 2 While the simulation is running, click the **Export to Workspace** button.
- 3 Type `whos` at the MATLAB command line.

The variable `ExportData` appears in your MATLAB workspace. `ExportData` is a 40-by-6 matrix. This matrix represents the six data vectors that were present in the Waterfall window at the time you clicked the **Export to Workspace** button. Each column of this matrix contains 40 filter coefficients. The columns of data were captured at six consecutive instants in time.

You can control what data is exported using the **Data logging** parameter in **Data history** pane of the Parameters dialog box. For more information, see “Data History Parameters” on page 2-1839.

- 4 While the simulation is running, click the **Export to SPTool** button.

The SPTool GUI opens and the variable `ExportData` is displayed in the **Signals** list.

For more information about SPTool, see the Signal Processing Toolbox documentation.

Capturing Data

You can use the Waterfall block to interact with your data while it is being captured:

- 1 Open and run the `dspanc` example.
- 2 While the simulation is running, click the **Suspend data capture** button.

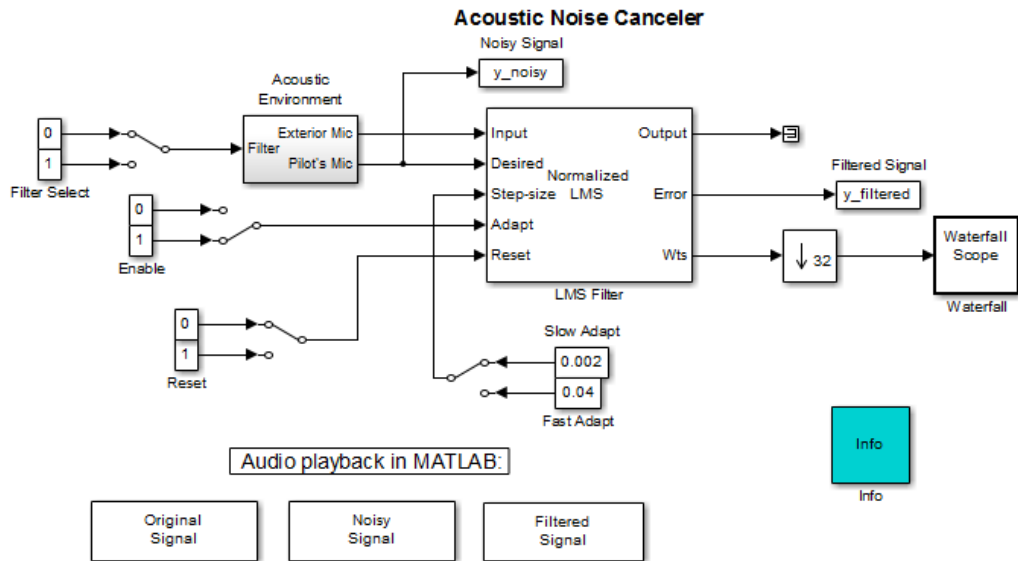

The Waterfall block no longer captures or displays the data coming from the Downsample block.
- 3 To continue capturing data, click the **Resume data capture** button.
- 4 To freeze the data display while continuing to capture data, click the **Snapshot display** button.
- 5 To view the Waterfall block that the data is coming from, click the **Go to scope block** button.

In the Simulink model window, the Waterfall block that corresponds to the active Waterfall window flashes. This feature is helpful when you have more than one Waterfall block in a model and you want to clarify which data is being displayed.

Linking Scopes

You can link several Waterfall blocks together in order to capture the effect of a model event in all of the Waterfall windows in the model:

- 1 Open the `dspanc` example.
- 2 Drag a second Waterfall block into the example model.
- 3 Connect this block to the Output port of the LMS Filter block as shown in the figure below.

- 4 Run the model and view the model behavior in both Waterfall windows.
- 5 In the `dspanc`/Waterfall window, click the **Link scopes** button.
- 6 In the same window, click the **Suspend data capture** button.

The data capture is suspended in both scope windows.

- 7 Click the **Resume data capture** button.

The data capture resumes in both scope windows.

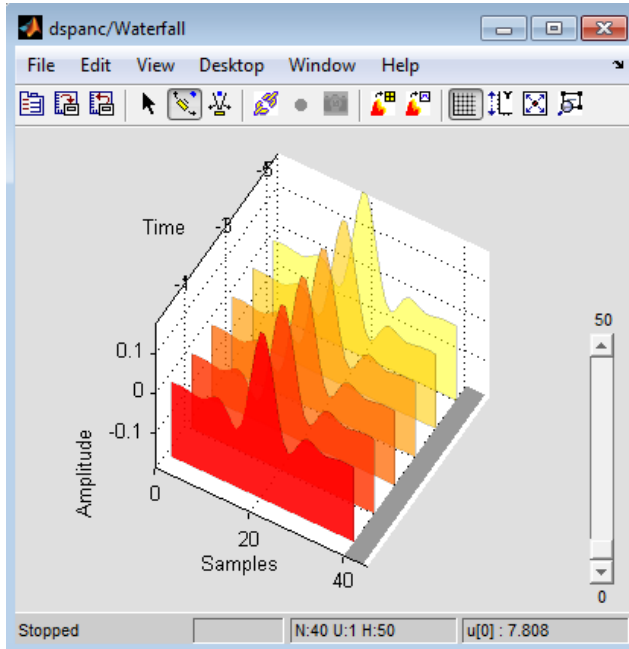

- 8 In the `dspanc`/Waterfall window, click the **Snapshot display** button.

In both scope windows, the data display freezes while the block continues to capture data.

- 9 To continue displaying the captured data, click the **Resume display** button.

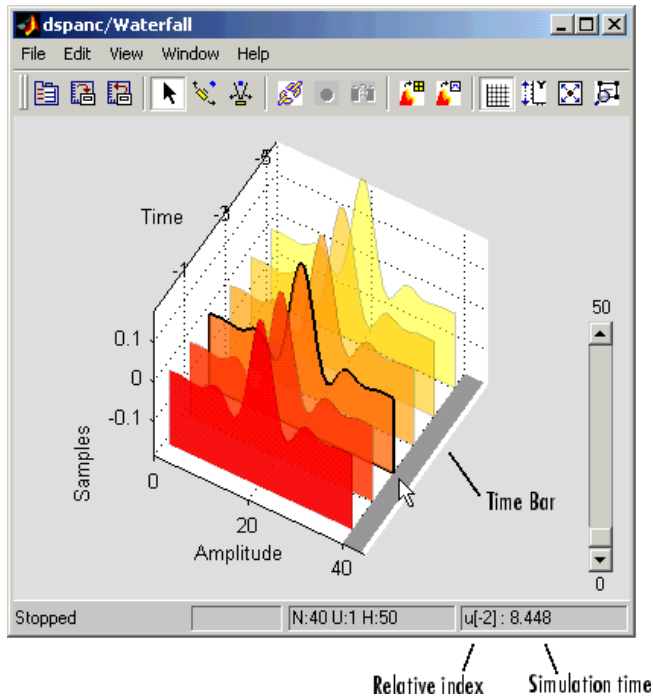

Selecting Data

The following figure shows the Waterfall window displaying the output of the `dspanc` example:

- 1 To select a particular set of data, click the **Select** button.
- 2 Click on the Time Bar at the bottom right of the axes to select a vector of data.

The Waterfall block highlights the selected trace.

While the simulation is running, in the bottom right corner, the Waterfall window displays the relative index of the selected trace. For example, in the previous figure, the selected vector is two sample times away from the most current data vector. When the simulation is stopped, the Waterfall window displays both the relative index and the simulation time associated with the selected trace.

- 3 To deselect the data vector, click it again.
- 4 Click-and-drag along the Time Bar.

Your selection follows the movement of the pointer.

You can use this feature to choose a particular vector to export to the MATLAB workspace or SPTool. For more information, see “Data History Parameters” on page 2-1839.

Zooming

You can use the Waterfall window to zoom in on data:

- 1 Click the **Zoom camera** button.
- 2 In the Waterfall window, click and hold down the left mouse button.
- 3 Move the mouse up and down and side-to-side to move closer and farther away from the axes.
- 4 To resize the axes to fit the Waterfall window, click the **Fit to view** button.

Rotating the Display

You can rotate the data displayed in the Waterfall window:

- 1 Click on the **Orbit camera** button.
- 2 In the Waterfall window, click and hold down the left mouse button.
- 3 Move the mouse in a circular motion to rotate the axes.
- 4 To return to the position of the original axes, click the **Restore scope position and view** button.

Scaling the Axes

You can use the Waterfall window to rescale the y -axis values:

- 1 Open and run the `dspanc` example.
- 2 Click the **Rescale amplitude** button.

The y -axis changes so that its minimum value is zero. The maximum value is scaled to fit the data displayed.

Alternatively, you can scale the y -axis using the **Y Min** and **Y Max** parameters in the **Axes** pane of the Parameters dialog box. This is helpful when you want to undo the effects of rescaling the amplitude. For more information, see “Axes Parameters” on page 2-1838.

Saving Scope Settings

The Waterfall block can save the screen position and viewpoint of the Waterfall window:

- 1 Click the **Save scope position and view** button.
- 2 Close the Waterfall window.

- 3 Reopen the Waterfall window.

It reopens at the same place on your screen. The viewpoint of the axes also remains the same.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none">• Double-precision floating point• Single-precision floating point• Fixed point (signed and unsigned)• 8-, 16-, and 32-bit signed integers• 8-, 16-, and 32-bit unsigned integers

The Waterfall block accepts any of these data types as input. However, the input is converted to double-precision before the block processes the data. The Waterfall block displays only real-valued, double-precision vectors of data.

Wavelet Analysis (Obsolete)

Decompose signal into components of logarithmically decreasing frequency intervals and sample rates (requires the Wavelet Toolbox product)

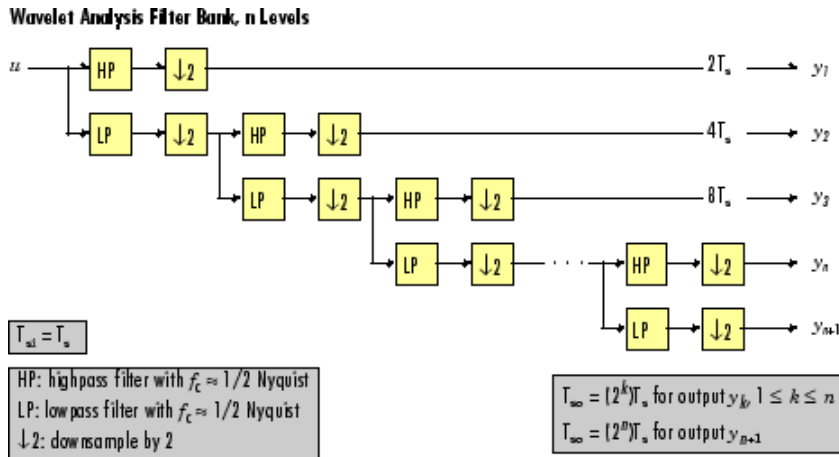

Library

dspobslib

Description

Note The Wavelet Analysis block will be removed from the product in a future release. We strongly recommend replacing this block with the DWT block.

The Wavelet Analysis block uses the Wavelet Toolbox `wfilters` function to construct a dyadic analysis filter bank that decomposes a broadband signal into a collection of successively more bandlimited components. An n -level filter bank structure is shown below, where n is specified by the **Number of levels** parameter.

At each level, the low-frequency output of the previous level is decomposed into adjacent high- and low-frequency subbands by a highpass (HP) and lowpass (LP) filter pair. Each of the two output subbands is half the bandwidth of the input to that level. The bandlimited output of each filter is maximally decimated by a factor of 2 to preserve the bit rate of the original signal.

Filter Coefficients

The filter coefficients for the highpass and lowpass filters are computed by the Wavelet Toolbox function `wfilters`, based on the wavelet specified in the **Wavelet name** parameter. The table below lists the available options.

Wavelet Name	Sample Wavelet Function Syntax
Haar	<code>wfilters('haar')</code>
Daubechies	<code>wfilters('db4')</code>
Symlets	<code>wfilters('sym3')</code>
Coiflets	<code>wfilters('coif1')</code>
Biorthogonal	<code>wfilters('bior3.1')</code>
Reverse Biorthogonal	<code>wfilters('rbio3.1')</code>
Discrete Meyer	<code>wfilters('dmey')</code>

The **Daubechies**, **Symlets**, and **Coiflets** options enable a secondary **Wavelet order** parameter that allows you to specify the wavelet order. For example, if you specify a

Daubechies wavelet with **Wavelet order** equal to 6, the Wavelet Analysis block calls the `wfilters` function with input argument `'db6'`.

The **Biorthogonal** and **Reverse Biorthogonal** options enable a secondary **Filter order [synthesis / analysis]** parameter that allows you to independently specify the wavelet order for the analysis and synthesis filter stages. For example, if you specify a **Biorthogonal** wavelet with **Filter order [synthesis / analysis]** equal to `[2 / 6]`, the Wavelet Analysis block calls the `wfilters` function with input argument `'bior2.6'`.

See the Wavelet Toolbox documentation for more information about the `wfilters` function. If you want to explicitly specify the FIR coefficients for the analysis filter bank, use the Dyadic Analysis Filter bank block.

Tree Structure

The wavelet tree structure has $n+1$ outputs, where n is the number of levels. The sample rate and bandwidth of the top output are half the input sample rate and bandwidth. The sample rate and bandwidth of each additional output (except the last) are half that of the output from the previous level. In general, for an input with sample period $T_{si} = T_s$, and bandwidth BW , output y_k has sample period $T_{so,k}$ and bandwidth BW_k .

$$T_{so,k} = \begin{cases} (2^k) T_s & (1 \leq k \leq n) \\ (2^n) T_s & (k = n + 1) \end{cases}$$

$$BW_k = \begin{cases} \frac{BW}{2^k} & (1 \leq k \leq n) \\ \frac{BW}{2^n} & (k = n + 1) \end{cases}$$

Note that in frame-based mode, the change in the sample period of output y_k is reflected by its frame size $M_{o,k}$, rather than by its frame rate.

$$M_{o,k} = \begin{cases} \frac{M_i}{2^k} & (1 \leq k \leq n) \\ \frac{M_i}{2^n} & (k = n + 1) \end{cases}$$

The bottom two outputs (y_n and y_{n+1}) share the same sample period, bandwidth, and frame size because they originate at the same tree level.

Sample-Based Operation

An M -by- N sample-based matrix input is treated as $M*N$ independent channels, and the block filters each channel independently over time. The output at each port is the same size as the input, one output channel for each input channel. As described earlier, each output port has a different sample period.

The figure below shows the input and output sample periods for a 64-channel sample-based input to a three-level filter bank. The input has a period of 1, so the fastest output has a period of 2.

Frame-Based Operation

An M_i -by- N frame-based matrix input is treated as N independent channels, and the block filters each channel independently over time. The input frame size M_i must be a multiple of 2^n , and n is the number of filter bank levels. For example, a frame size of 8 would be appropriate for a three-level tree ($2^3=8$). The number of columns in each output is the same as the number of columns in the input.

Each output port has the same frame period as the input. The reduction in the output sample rates results from the smaller output frame sizes, as shown in the example below for a four-channel input to a three-level filter bank.

Zero Latency

The Wavelet Analysis block has no tasking latency for frame-based operation, which is always single-rate. The block therefore analyzes the first input sample (received at $t=0$) to produce the first output sample at each port.

Nonzero Latency

For sample-based operation, the Wavelet Analysis block is multirate and has 2^{n-1} samples of latency in both Simulink tasking modes. As a result, the block repeats a zero initial condition in each channel for the first 2^{n-1} output samples, before propagating the first analyzed input sample (computed from the input received at $t=0$).

Note For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Parameters

Wavelet name

The wavelet used in the analysis.

Wavelet order

The order for the **Daubechies**, **Symlets**, and **Coiflets** wavelets. This parameter is available only when one of these wavelets is selected in the **Wavelet name** menu.

Filter order [synthesis / analysis]

The filter orders for the synthesis and analysis stages of the **Biorthogonal** and **Reverse Biorthogonal** wavelets. For example, [2 / 6] selects a second-order

synthesis stage and a sixth-order analysis stage. The **Filter order** parameter is available only when one of the above wavelets is selected in the **Wavelet name** menu.

Number of levels

The number of filter bank levels. An n -level structure has $n+1$ outputs.

`wfilters` Wavelet Toolbox

Introduced in R2008b

Wavelet Synthesis (Obsolete)

Reconstruct signal from its multirate bandlimited components (requires the Wavelet Toolbox product)

Library

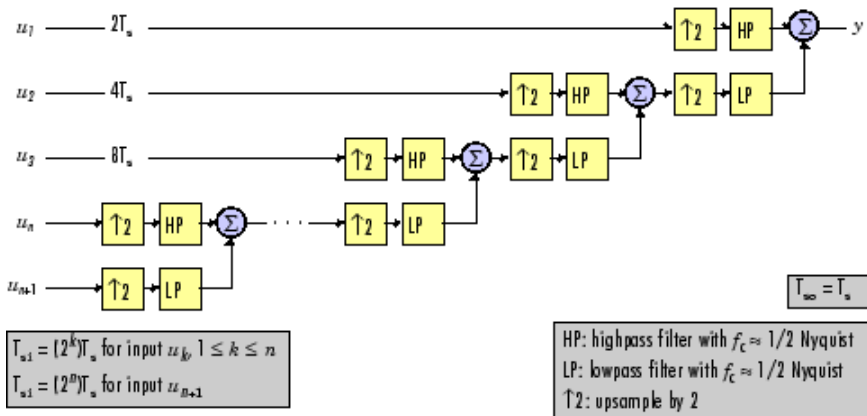

dspobslib

Description

Note The Wavelet Synthesis block will be removed from the product in a future release. We strongly recommend replacing this block with the IDWT block.

The Wavelet Synthesis block uses the Wavelet Toolbox `wfilters` function to reconstruct a signal that was decomposed by the Wavelet Analysis (Obsolete) block. The reconstruction or synthesis process is the inverse of the analysis process, and restores the original signal by upsampling, filtering, and summing the bandlimited inputs in stages corresponding to the analysis process. An n -level synthesis filter bank structure is shown below, where n is specified by the **Number of levels** parameter.

Wavelet Synthesis Filter Bank, n Levels

At each level, the two bandlimited inputs (one low-frequency, one high-frequency, both with the same sample rate) are upsampled by a factor of 2 to match the sample rate of the input to the next stage. They are then filtered by a highpass (HP) and lowpass (LP) filter pair with coefficients calculated to cancel (in the subsequent summation) the aliasing introduced in the corresponding analysis filter stage. The output from each (upsample-filter-sum) level has twice the bandwidth and twice the sample rate of the input to that level.

For perfect reconstruction, the Wavelet Synthesis and Wavelet Analysis blocks must have the same parameter settings.

Filter Coefficients

The filter coefficients for the highpass and lowpass filters are computed by the Wavelet Toolbox function `wfilters`, based on the wavelet specified in the **Wavelet name** parameter. The table below lists the available options.

Wavelet Name	Sample Wavelet Function Syntax
Haar	<code>wfilters('haar')</code>
Daubechies	<code>wfilters('db4')</code>
Symlets	<code>wfilters('sym3')</code>
Coiflets	<code>wfilters('coif1')</code>
Biorthogonal	<code>wfilters('bior3.1')</code>

Wavelet Name	Sample Wavelet Function Syntax
Reverse Biorthogonal	wfilters('rbio3.1')
Discrete Meyer	wfilters('dmey')

The **Daubechies**, **Symlets**, and **Coiflets** options enable a secondary **Wavelet order** parameter that allows you to specify the wavelet order. For example, if you specify a **Daubechies** wavelet with **Wavelet order** equal to 6, the Wavelet Synthesis block calls the `wfilters` function with input argument `'db6'`.

The **Biorthogonal** and **Reverse Biorthogonal** options enable a secondary **Filter order [synthesis / analysis]** parameter that allows you to independently specify the wavelet order for the analysis and synthesis filter stages. For example, if you specify a **Biorthogonal** wavelet with **Filter order [synthesis / analysis]** equal to [2 / 6], the Wavelet Synthesis block calls the `wfilters` function with input argument `'bior2.6'`.

See the Wavelet Toolbox documentation for more information about the `wfilters` function. If you want to explicitly specify the FIR coefficients for the synthesis filter bank, use the Dyadic Synthesis Filter bank block.

Tree Structure

The wavelet tree structure has $n+1$ inputs, where n is the number of levels. The sample rate and bandwidth of the output are twice the sample rate and bandwidth of the top input. The sample rate and bandwidth of each additional input (except the last) are half that of the input to the previous level.

$$T_{si,k+1} = 2T_{si,k} \quad 1 \leq k < n$$

$$BW_{k+1} = \frac{BW_k}{2} \quad 1 \leq k < n$$

The bottom two inputs (u_n and u_{n+1}) should have the same sample rate and bandwidth since they are processed by the same level.

$$T_{si,n+1} = T_{si,n}$$

$$BW_{n+1} = BW_n$$

Note that in frame-based mode, the sample period of input u_k is reflected by its frame size $M_{i,k}$, rather than by its frame rate.

$$M_{i,k+1} = \frac{M_{i,k}}{2} \quad 1 \leq k < n$$

$$M_{i,n+1} = M_{i,n}$$

Sample-Based Operation

An M -by- N sample-based matrix input is treated as $M \times N$ independent channels, and the block filters each channel independently over time. The output is the same size as the input at each port, one output channel for each input channel. As described earlier, each input port has a different sample period.

The figure below shows the input and output sample periods for the four 64-channel sample-based inputs to a three-level filter bank. The fastest input has a period of 2, so the output period is 1.

Frame-Based Operation

An M_i -by- N frame-based matrix input is treated as N independent channels, and the block filters each channel independently over time. The number of columns in the output is the same as the number of columns in the input.

All inputs must have the same frame period, which is also the output frame period. The different input sample rates should be represented by the input frame sizes: If the input to the top port has frame size M_i , the input to the second-from-top port should have frame size $M_i/2$, the input to the third-from-top port should have frame size $M_i/4$, and so on. The input to the bottom port should have the same frame size as the second-from-bottom port. The increase in the sample rate of the output is also represented by its frame size, which is twice the largest input frame size.

The relationship between sample periods, frame periods, and frame sizes is shown below for a four-channel frame-based input to a 3-level filter bank.

Zero Latency

The Wavelet Synthesis block has no tasking latency for frame-based operation, which is always single-rate. The block therefore uses the first input samples (received at $t=0$) to synthesize the first output sample.

Nonzero Latency

For sample-based operation, the Wavelet Synthesis block is multirate and has the following tasking latencies:

- $2^n - 2$ samples in Simulink's single-tasking mode
- 2^n samples in Simulink's multitasking mode

In the above cases, the block repeats a zero initial condition in each channel for the first D output samples, where D is the latency shown above. For example, in single-tasking mode the block generates $2^n - 2$ zero-valued output samples in each channel before propagating the first synthesized output sample (computed from the inputs received at $t=0$).

Note For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Parameters

Wavelet name

The wavelet used in the synthesis.

Wavelet order

The order for the **Daubechies**, **Symlets**, and **Coiflets** wavelets. This parameter is available only when one of these wavelets is selected in the **Wavelet name** menu.

Filter order [synthesis / analysis]

The filter orders for the synthesis and analysis stages of the **Biorthogonal** and **Reverse Biorthogonal** wavelets. For example, [2 / 6] selects a second-order synthesis stage and a sixth-order analysis stage. The **Filter order** parameter is available only when one of the above wavelets is selected in the **Wavelet name** menu.

Number of levels

The number of filter bank levels. An n -level structure has $n+1$ outputs.

Window Function

Compute and/or apply window to input signal

Library

Signal Operations

`dpsigops`

Description

The Window Function block computes a window and/or applies a window to an input signal. The input signal can be a matrix or an N-D array.

Operation Modes

The Window Function block has three modes of operation that you can select via the **Operation** parameter. In each mode, the block first creates a window vector w by sampling the window specified in the **Window type** parameter at M discrete points. The operation modes are:

- Apply window to input

In this mode, the block computes an M -by-1 window vector w and applies it to the input. The output y always has the same dimension as the input.

When the input is an M -by- N matrix u , the window is multiplied element-wise with each of the N channels in the input matrix u . This is equivalent to the following MATLAB code:

```
y = repmat(w,1,N) .* u % Equivalent MATLAB code
```

The window is always applied to the first dimension:

$$y(i, j, \dots, k) = w(i) * u(i, j, \dots, k) \quad i = 1, \dots, M, \quad j = 1, \dots, N, \quad \dots, \quad k = 1, \dots, P$$

A length- M unoriented vector input is treated as an M -by-1 matrix.

- Generate window

In this mode, the block generates an unoriented window vector w with length M specified by the **Window length** parameter. The In port is disabled for this mode.

- Generate and apply window

In this mode, the block generates an M -by-1 window vector w and applies it to the input. The block produces two outputs:

- At the Out port, the block produces the result of the multiplication y , which has the same dimension as the input.
- At the Win port, the block produces the M -by-1 window vector w .

When the input is an M -by- N matrix u , the window is multiplied element-wise with each of the N channels in the input matrix u . This is equivalent to the following MATLAB code:

```
y = repmat(w,1,N) .* u % Equivalent MATLAB code
```

The window is always applied to the first dimension:

$$y(i, j, \dots, k) = w(i) * u(i, j, \dots, k) \quad i = 1, \dots, M, \quad j = 1, \dots, N, \quad \dots, \quad k = 1, \dots, P$$

A length- M 1-D vector input is treated as an M -by-1 matrix.

Window Type

The following table lists the available window types. For complete information about the window functions, consult the Signal Processing Toolbox documentation.

Window Type	Description
Bartlett	Computes a Bartlett window. <code>w = bartlett(M)</code>
Blackman	Computes a Blackman window. <code>w = blackman(M)</code>
Boxcar	Computes a rectangular window. <code>w = rectwin(M)</code>
Chebyshev	Computes a Chebyshev window with stopband ripple R . <code>w = chebwin(M,R)</code>
Hamming	Computes a Hamming window. <code>w = hamming(M)</code>
Hann	Computes a Hann window (also known as a Hanning window). <code>w = hann(M)</code>
Hanning	Obsolete. This window type is included only for compatibility with older models. Use the Hann Window type instead of Hanning whenever possible.
Kaiser	Computes a Kaiser window with the Kaiser parameter β . <code>w = kaiser(M,beta)</code>
Taylor	Computes a Taylor window. <code>w = taylorwin(M)</code>
Triang	Computes a triangular window. <code>w = triang(M)</code>

Window Type	Description
User Defined	<p>Computes the user-defined window function specified by the entry in the Window function name parameter, <code>usrwin</code>.</p> <pre>w = usrwin(M) % Window takes no extra parameters w = usrwin(M, x₁, ..., x_n) % Window takes extra parameters {x₁ ... x_n}</pre>

Window Sampling

For the generalized-cosine windows (Blackman, Hamming, Hann, and Hanning), the **Sampling** parameter determines whether the window samples are computed in a periodic or a symmetric manner. For example, when **Sampling** is set to `Symmetric`, a Hamming window of length M is computed as

```
w = hamming(M) % Symmetric (aperiodic) window
```

When **Sampling** is set to `Periodic`, the same window is computed as

```
w = hamming(M+1) % Periodic (asymmetric) window
w = w(1:M)
```

Fixed-Point Data Types

The following diagram shows the data types used within the Window Function block for fixed-point signals for each of the three operating modes.

Apply window to input

The input data type comes from the driving block. You can set the window, product output, and output data types in the block dialog. In this mode, the window vector is not output from the block.

Generate window

In this mode, the block acts as a source. The window vector is output in the window data type you specify in the block dialog.

Generate and apply window

The input data type comes from the driving block. You can set the window, product output, and output data types in the block dialog. In this mode, the window vector is output from the block.

You can set the window, product output, and output data types in the block dialog box. For more information see the “Dialog Box” on page 2-1873 section.

Examples

The following model uses the Window Function block to generate and apply a Hamming window to a 3-dimensional input array.

In this example, set the **Operation** mode of the Window Function block to `Generate and apply window`, so the block provides two outputs: the window vector *Window* at the Win port, and the result of the multiplication *simout* at the Out port.

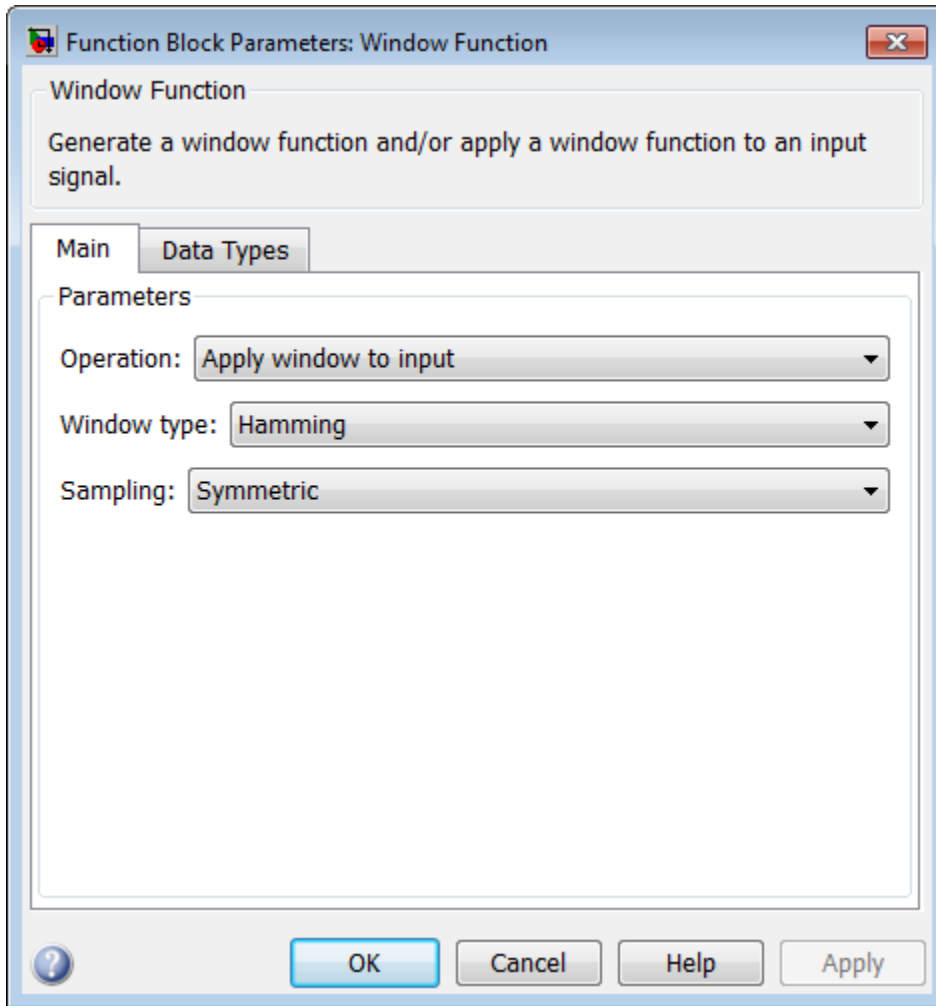

Open the model by typing `ex_windowfunction_ref` at the MATLAB command line, and run it.

- The length of the first dimension of the input array is 10, so the Window Function block generates and outputs a Hamming window vector of length 10. To see the window vector generated by the Window Function block, type `Window` at the MATLAB command line.
- To see the result of the multiplication, type `simout` at the MATLAB command line.

Dialog Box

The **Main** pane of the Window Function block dialog appears as follows.

Operation

Specify the block's operation, as discussed in “Operation Modes” on page 2-1868. The port configuration of the block is updated to match the setting of this parameter.

Window type

Specify the window type to apply, as listed in “Window Type” on page 2-1870. Tunable (Simulink) in simulation only.

Sampling

Specify the window sampling for generalized-cosine windows. This parameter is only visible when you select Blackman, Hamming, Hann, or Hanning for the **Window type** parameter. Tunable (Simulink) in simulation only.

Sample Mode

Specify the sample mode for the block, Continuous or Discrete, when it is in Generate Window mode. In the Apply window to output and Generate and apply window modes, the block inherits the sample time from its driving block. Therefore, this parameter is only visible when you select Generate window for the **Operation** parameter.

Sample time

Specify the sample time for the block when it is in Generate window and Discrete modes. In Apply window to output and Generate and apply window modes, the block inherits the sample time from its driving block. This parameter is only visible when you select Discrete for the **Sample Mode** parameter.

Window length

Specify the length of the window to apply. This parameter is only visible when you select Generate window for the **Operation** parameter. Otherwise, the window vector length is computed to match the length of the first dimension of the input.

Stopband attenuation in dB

Specify the level of stopband attenuation, R_s , in decibels. This parameter is only visible when you select Chebyshev for the **Window type** parameter. Tunable (Simulink) in simulation only.

Beta

Specify the Kaiser window β parameter. Increasing β widens the mainlobe and decreases the amplitude of the window sidelobes in the window's frequency magnitude response. This parameter is only visible when you select Kaiser for the **Window type** parameter. Tunable (Simulink) in simulation only.

Number of sidelobes

Specify the number of sidelobes as a scalar integer value greater than zero. This parameter is only visible when you select Taylor for the **Window type** parameter.

Maximum sidelobe level relative to mainlobe (dB)

Specify, in decibels, the maximum sidelobe level relative to the mainlobe. This parameter must be a scalar less than or equal to zero. The default value of -30

produces sidelobes with peaks 30 dB down from the mainlobe peak. This parameter is only visible when you select `Taylor` for the **Window type** parameter.

Window function name

Specify the name of the user-defined window function to be calculated by the block. This parameter is only visible when you select `User defined` for the **Window type** parameter.

Specify additional arguments to the hamming function

Select to enable the **Cell array of additional arguments** parameter, when the user-defined window requires parameters other than the window length. This parameter is only visible when you select `User defined` for the **Window type** parameter.

Cell array of additional arguments

Specify the extra parameters required by the user-defined window function, besides the window length. This parameter is only available when you select the **Specify additional arguments to the hamming function** parameter. The entry must be a cell array.

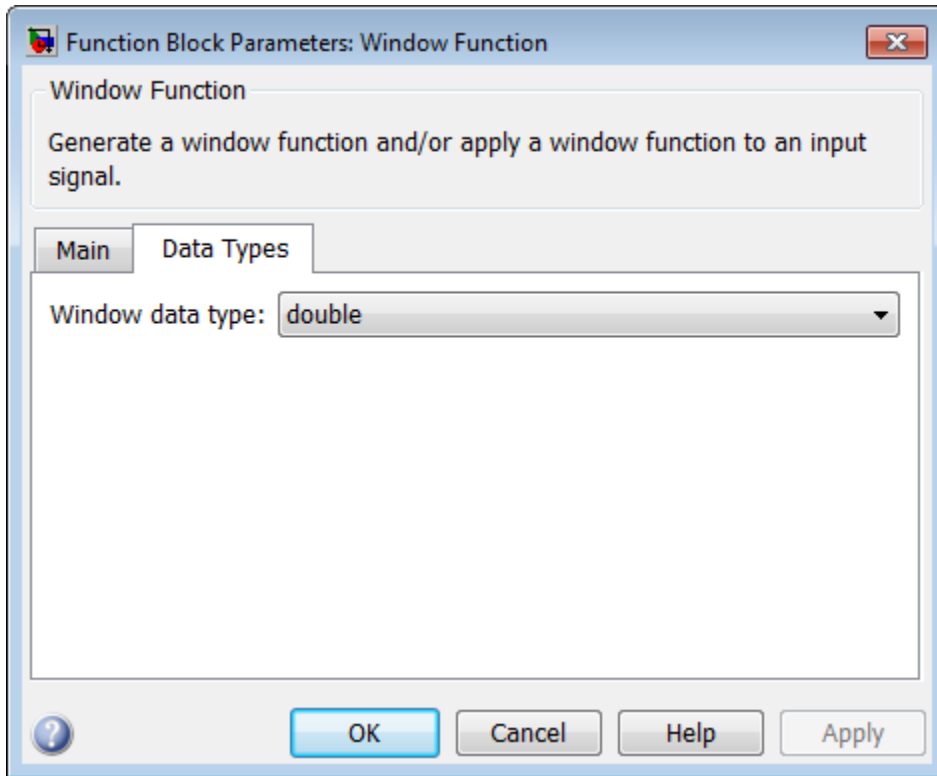

The **Data Types** pane of the Window Function block dialog is discussed in the following sections:

“Parameters for Generate Window Only Mode” on page 2-1876

“Parameters for Apply Window Modes” on page 2-1878

Parameters for Generate Window Only Mode

The **Data Types** pane of the Window Function block dialog appears as follows when the **Operation** parameter is set to `Generate window`.

Window data type

Specify the window data type in one of the following ways:

- Choose `double` or `single` from the list.
- Choose `Fixed-point` to specify the window data type and scaling in the **Signed**, **Word length**, **Set fraction length in output to**, and **Fraction length** parameters.
- Choose `User-defined` to specify the window data type and scaling in the **User-defined data type**, **Set fraction length in output to**, and **Fraction length** parameters.
- Choose `Inherit via back propagation` to set the window data type and scaling to match the following block.

Signed

Select to output a signed fixed-point signal. Otherwise, the signal is unsigned.

Word length

Specify the word length, in bits, of the fixed-point window data type. This parameter is only visible when you select `Fixed-point` for the **Window data type** parameter.

User-defined data type

Specify any built-in or fixed-point data type. You can specify fixed-point data types using the Fixed-Point Designer functions `sfix`, `ufix`, `sint`, `uint`, `sfrac`, and `ufrac`. This parameter is only visible when you select `User-defined` for the **Window data type** parameter.

Set fraction length in output to

Specify the scaling of the fixed-point window data type by either of the following two methods:

- Choose `Best precision` to have the window data type scaling automatically set such that the output signal has the best possible precision.
- Choose `User-defined` to specify the window data type scaling in the **Fraction length** parameter.

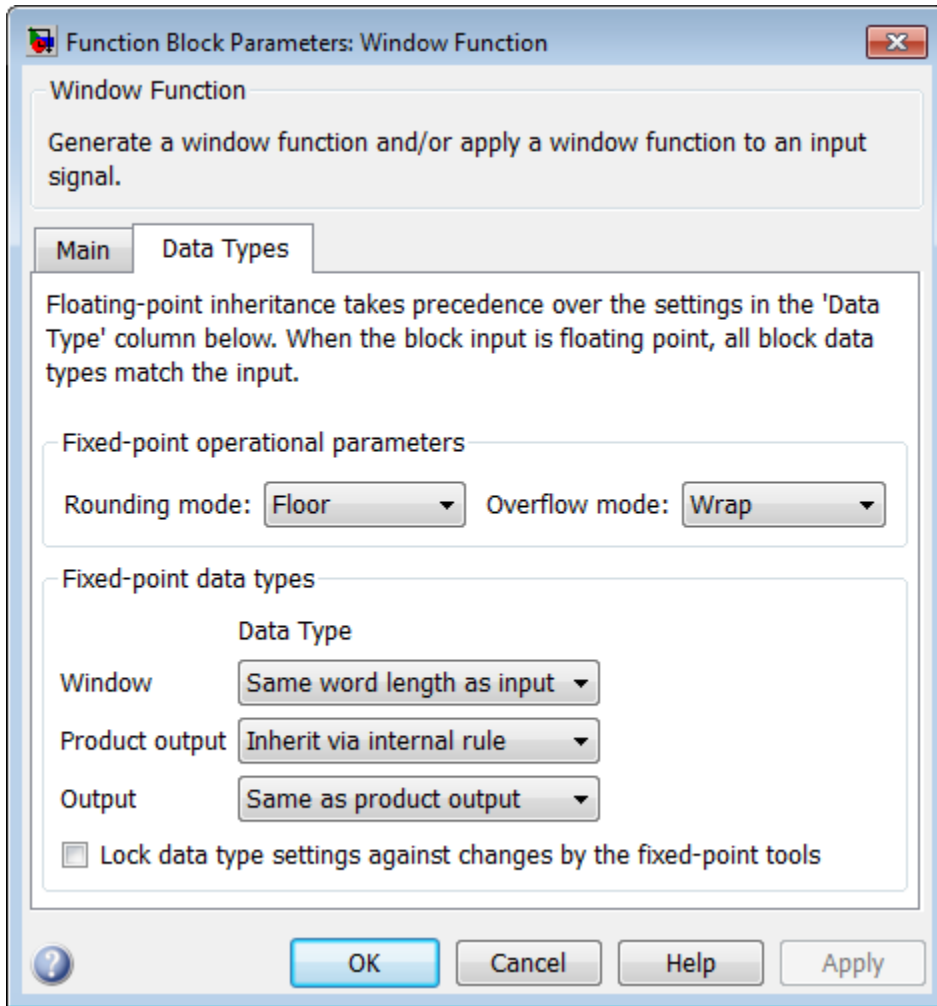

This parameter is only visible when you select `Fixed-point` or `User-defined` for the **Window data type** parameter, and when the specified window data type is a fixed-point data type.

Fraction length

Specify the fraction length, in bits, of the fixed-point window data type. This parameter is only visible when you select `Fixed-point` or `User-defined` for the **Window data type** parameter and `User-defined` for the **Set fraction length in output to** parameter.

Parameters for Apply Window Modes

The **Data Types** pane of the Window Function block dialog appears as follows when the **Operation** parameter is set to either `Apply window to input` or `Generate and apply window`.

Rounding mode

Select the rounding mode for fixed-point operations.

The window vector w does not obey this parameter; it always rounds to Nearest.

Note The **Rounding mode** and **Overflow mode** settings have no effect on numerical results when both of the following conditions exist:

- **Product output data type** is `Inherit` via internal rule
- **Output data type** is `Same` as product output

With these data type settings, the block is effectively operating in full precision mode.

Overflow mode

Select the overflow mode for fixed-point operations.

The window vector w does not obey this parameter; it is always saturated.

Window

Choose how you specify the word length and fraction length of the window vector w .

When you select `Same word length as input`, the word length of the window vector elements is the same as the word length of the input. The fraction length is automatically set to the best precision possible.

When you select `Specify word length`, you can enter the word length of the window vector elements in bits. The fraction length is automatically set to the best precision possible.

When you select `Binary point scaling`, you can enter the word length and the fraction length of the window vector elements in bits.

When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the window vector elements. This block requires power-of-two slope and a bias of zero.

The window vector does not obey the **Rounding mode** and **Overflow mode** parameters; it is always saturated and rounded to `Nearest`.

Product output

Use this parameter to specify how you want to designate the product output word and fraction lengths.

- When you select `Inherit via internal rule`, the product output word length and fraction length are calculated automatically. For information about how the product output word and fraction lengths are calculated when an internal rule is used, see “Inherit via Internal Rule”.

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the product output, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the product output. This block requires power-of-two slope and a bias of zero.

Output

Choose how you specify the word length and fraction length of the output of the block:

- When you select `Same as product output`, these characteristics match those of the product output.
- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the output, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the output. This block requires power-of-two slope and a bias of zero.

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Yule-Walker AR Estimator

Compute estimate of autoregressive (AR) model parameters using Yule-Walker method

Library

Estimation / Parametric Estimation

dspparest3

Description

The Yule-Walker AR Estimator block uses the Yule-Walker AR method, also called the autocorrelation method, to fit an autoregressive (AR) model to the windowed input data by minimizing the forward prediction error in the least squares sense. This formulation leads to the Yule-Walker equations, which are solved by the Levinson-Durbin recursion. Block outputs are always nonsingular.

The Yule-Walker AR Estimator block can output the AR model coefficients as polynomial coefficients, reflection coefficients, or both. The input can be a row vector, a column vector, or an unoriented vector which is assumed to be the output of an AR system driven by white noise. The block accepts matrices, and treats each column of the matrix as a channel. If the input is a row vector of length N , the input is treated as N different channels. If the input is an unoriented vector, the input is treated as a single channel. The block computes the normalized estimate of the AR system parameters, $A(z)$, independently for each successive input frame.

$$H(z) = \frac{\sqrt{G}}{A(z)} = \frac{\sqrt{G}}{1 + a(2)z^{-1} + \dots + a(p+1)z^{-p}}$$

When you select **Inherit estimation order from input dimensions**, the order p of the all-pole model is one less than the length of each input channel. Otherwise, the order is the value specified by the **Estimation order** parameter. To guarantee a valid output, you must set the **Estimation order** parameter to be a scalar less than or equal to half the input channel length. The Yule-Walker AR Estimator and Burg AR Estimator blocks return similar results for large frame sizes.

When **Output(s)** is set to **A**, port A is enabled. For each channel, port A outputs a column of length $p+1$ that contains the normalized estimate of the AR model coefficients in descending powers of z

```
[1 a(2) ... a(p+1)]
```

When **Output(s)** is set to **K**, port K is enabled. For each channel, port K outputs a length- p column whose elements are the AR model reflection coefficients. When **Output(s)** is set to **A** and **K**, both port A and K are enabled, and each port outputs the respective AR model coefficients for each channel.

The square of the model gain, G , is provided at port G. G is a scalar for each channel.

See the Burg AR Estimator block reference page for a comparison of the Burg AR Estimator, Covariance AR Estimator, Modified Covariance AR Estimator, and Yule-Walker AR Estimator blocks.

Parameters

Output(s)

The type of AR model coefficients output by the block. The block can output polynomial coefficients (**A**), reflection coefficients (**K**), or both (**A** and **K**).

Inherit estimation order from input dimensions

When selected, sets the estimation order p to one less than the length of each input channel.

Estimation order

The order of the AR model, p . This parameter is enabled when you do not select **Inherit estimation order from input dimensions**.

Yule-Walker Method

Power spectral density estimate using Yule-Walker method

Library

Estimation / Power Spectrum Estimation

dspspect3

Description

The Yule-Walker Method block estimates the power spectral density (PSD) of the input using the Yule-Walker AR method. This method, also called the autocorrelation method, fits an autoregressive (AR) model to the windowed input data. It does so by minimizing the forward prediction error in the least squares sense. This formulation leads to the Yule-Walker equations, which the Levinson-Durbin recursion solves. Block outputs are always nonsingular.

The input must be a column vector. This input represents a frame of consecutive time samples from a single-channel signal. The block outputs a column vector containing the estimate of the power spectral density of the signal at N_{fft} equally spaced frequency points. The frequency points are in the range $[0, F_s)$, where F_s is the sampling frequency of the signal.

When you select **Inherit estimation order from input dimensions**, the order of the all-pole model is one less than the input frame size. Otherwise, the **Estimation order** parameter value specifies the order. To guarantee a valid output, the **Estimation order** parameter must be less than or equal to half the input vector length. The block computes the spectrum from the FFT of the estimated AR model parameters.

Selecting the **Inherit FFT length from estimation order** parameter specifies that N_{fft} is one greater than the estimation order. Clearing the **Inherit FFT length from**

estimation order check box allows you to use the **FFT length** parameter to specify N_{fft} as a power of 2. The block zero-pads or wraps the input to N_{fft} before computing the FFT.

When you select the **Inherit sample time from input** check box, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time using the **Sample time of original time series** parameter.

See the Burg Method block reference for a comparison of the Burg Method, Covariance Method, Modified Covariance Method, and Yule-Walker AR Estimator blocks. The Yule-Walker AR Estimator and Burg Method blocks return similar results for large buffer lengths.

Parameters

Inherit estimation order from input dimensions

When you select this option, it sets the estimation order to one less than the length of the input vector.

Estimation order

Specify the order of the AR model. This parameter is only visible when you clear the **Inherit estimation order from input dimensions** check box.

Inherit FFT length from estimation order

When you select the **Inherit FFT length from estimation order** check box, the FFT length is one greater than the estimation order. To specify the number of points on which to perform the FFT, clear the **Inherit FFT length from estimation order** check box. You can then specify a power-of-two FFT length using the **FFT length** parameter.

FFT length

Enter the number of data points on which to perform the FFT, N_{fft} . When N_{fft} is larger than the input frame size, the block zero-pads each frame as needed. When N_{fft}

is smaller than the input frame size, the block wraps each frame as needed. This parameter becomes visible only when you clear the **Inherit FFT length from input dimensions** check box.

Inherit sample time from input

When you select the **Inherit sample time from input** check box, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time using the **Sample time of original time series** parameter.

Sample time of original time series

Specify the sample time of the original time-domain signal. This parameter becomes visible only when you clear the **Inherit sample time from input** check box.

Zero Crossing

Count number of times signal crosses zero in single time step

Library

Signal Operations

dspsigops

Description

The Zero Crossing block concludes that a signal in a given channel has passed through zero if it meets any of the following criteria, where x_i is the current signal value, x_{i-1} is the previous signal value, and so on:

- $x_i < 0$ and $x_{i-1} > 0$
- $x_i > 0$ and $x_{i-1} < 0$
- For some positive integer L , $x_i < 0$, $x_{i-l} = 0$, and $x_{i-L-l} > 0$, where $0 \leq l \leq L$.
- For some positive integer L , $x_i > 0$, $x_{i-l} = 0$, and $x_{i-L-l} < 0$, where $0 \leq l \leq L$.

For the first input value, x_{i-1} and x_{i-2} are zero. The block outputs the number of times the signal crosses zero in a single time step at the Cnt port.

The input to this block must be a real-valued fixed-point or floating-point signal. If you set the **Input processing** parameter to Elements as channels (sample based), the block treats each element of the input as a time-varying channel. If you set the **Input processing** parameter to Columns as channels (frame based), the block treats each column of the input as an independent channel.

Examples

The following example, `ex_zero_crossing` illustrates the behavior of the Zero Crossing block.

To run the model for one time step, the **Stop time** is set to 0.

- 1 Run the model.

Because the signal passes through zero once during the first time step, the Zero Crossing block finds one zero crossing. The number of detected zero crossings in the first time step is shown in the Display block in the following figure.

- 2 To run the model for two time steps, change the simulation **Stop time** to 1. To do so, open the Configuration Parameters dialog box by selecting **Model Configuration Parameters** from the **Simulation** menu. In the **Solver** pane, set **Stop time** to 1.
- 3 Run the model.

The Zero Crossing block remembers that the last value of the last frame was 3. Therefore, the signal passes through zero twice during the second time step. It passes through zero while going from 3 to -3, and it passes through zero again while going from -3 to 3. The Zero Crossing block finds two zero crossings in the second time step as shown in the Display block in the following figure.

Parameters

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` (default) — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Supported Data Types

Port	Supported Data Types

Zoom FFT

High-resolution FFT of a portion of a spectrum

Library: DSP System Toolbox / Transforms

Description

The Zoom FFT block computes the fast Fourier Transform (FFT) of a signal over a portion of frequencies in the Nyquist interval. By setting an appropriate decimation factor D , and sampling rate F_s , you can choose the bandwidth of frequencies to analyze BW , where $BW = F_s/D$. You can also select a specific range of frequencies to analyze in the Nyquist interval by choosing the center frequency of the desired band.

The resolution of a signal is the ratio of F_s and the FFT length (L). Using zoom FFT, you can retain the same resolution you would achieve with a full-size FFT on your original signal by computing a small FFT on a shorter signal. The shorter signal comes from decimating the original signal. The savings come from being able to compute a much shorter FFT while achieving the same resolution. For a decimation factor of D , the new sampling rate, F_{sd} , is F_s/D , and the new frame size (and FFT length) is $L_d = L/D$. The resolution of the decimated signal is $F_{sd}/L_d = F_s/L$. To achieve a higher resolution of the shorter band, use the original FFT length, L , instead of the decimated FFT length, L_d .

Ports

Input

x — Data input

vector | matrix

Data input whose zoom FFT the block computes, specified as a vector or a matrix. The number of input rows must be a multiple of the decimation factor.

This block supports variable-size input signals, as long as the input frame size is a multiple of the decimation factor. That is, you can change the input frame size (number

of rows) during the simulation. However, the number of channels (number of columns) must remain constant.

This port is unnamed until you select the **Specify center frequency from input port** parameter and click **Apply**.

Example: `randn(22,2)`

Data Types: `single` | `double`

Fc — Center frequency input

real scalar

Center frequency of the desired band in Hz, passed through this input port as a real scalar in the range $(-SampleRate/2, SampleRate/2)$. *SampleRate* is the input sample rate either inherited from the input signal or specified through the **Input sample rate (Hz)** parameter. This port appears only when you select the **Specify center frequency from input port** check box.

This port appears only when you select the **Specify center frequency from input port** check box and click **Apply**.

Example: 0

Example: 1200

Data Types: `single` | `double`

Output Arguments

Port_1 — Zoom FFT output

vector | matrix

Zoom FFT output, returned as a vector or matrix. If you select the **Inherit FFT Length from input dimensions** check box, the output frame size equals the input frame size divided by the decimation factor. If you clear the **Inherit FFT Length from input dimensions** check box and specify the FFT length, the output frame size equals the specified FFT length. The output data type matches the input data type.

Example: `randn(11,2)`

Data Types: `single` | `double`

Parameters

Decimation factor — Decimation factor

2 (default) | positive integer

Decimation factor, specified as a positive integer. This value specifies the factor by which the block reduces the bandwidth of the input signal. The number of rows in the input signal must be a multiple of the decimation factor.

Example: 4

Example: 8

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Specify center frequency from input port — Flag to specify center frequency from input port

'off' (default) | 'on'

When you select this option and click **Apply**, the input port **Fc** appears on the block icon. You can pass the center frequency through this input port as a scalar.

Center frequency (Hz) — Center frequency

0 (default) | real scalar

Center frequency of the desired band in Hz, specified as a real scalar in the range ($-SampleRate/2$, $SampleRate/2$). *SampleRate* is the input sample rate either inherited from the input or specified through the **Input sample rate (Hz)** parameter.

Example: 0.5

Example: 10

Dependencies

This parameter applies when you clear the **Specify center frequency from input port** check box.

Data Types: `single` | `double`

Inherit FFT Length from input dimensions — Flag to inherit FFT length from input dimensions

'on' (default) | 'off'

When you select this option, the FFT length is the ratio of the input frame size (number of rows in the input) and the **Decimation factor**.

FFT length — FFT length

64 (default) | positive scalar

FFT length, specified as a positive integer. The FFT length must be greater than or equal to the ratio of the frame size (number of input rows) and the **Decimation factor**.

Example: 24

Example: 52

Dependencies

This parameter applies when you clear the **Inherit FFT Length from input dimensions** check box.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Inherit Sample rate from input — Flag to inherit sample rate from input

'off' (default) | 'on'

When you clear this check box, the block inherits the sample rate from the input signal.

Input sample rate (Hz) — Input sample rate

44100 (default) | positive real scalar

Input sample rate in Hz, specified as positive real scalar.

Example: 44100

Example: 48000

Simulate using — Type of simulation to run

Interpreted execution (default) | Code generation

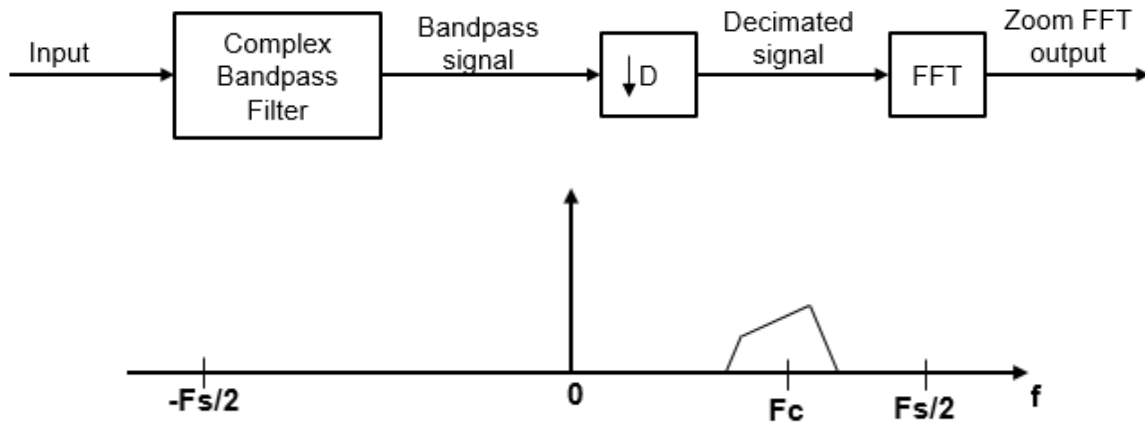

- `Interpreted execution` — Simulate model using the MATLAB interpreter. This option shortens startup time and has faster simulation speed than `Code generation`.
- `Code generation` — Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for

subsequent simulations, as long as the model does not change. This option requires additional startup time and provides slower simulation speed than Interpreted execution.

Model Examples

Algorithms

The zoom FFT algorithm leverages bandpass filtering before computing the FFT of the signal. The concept of bandpass filtering is that suppose you are interested in the band $[F1, F2]$ of the original input signal, sampled at the rate F_s Hz. If you pass this signal through a complex (one-sided) bandpass filter centered at $F_c = (F1+F2)/2$, with the bandwidth $BW = F2 - F1$, and then downsample the signal by a factor of $D = \text{floor}(F_s/BW)$, the desired band comes down to the baseband.

If F_c cannot be expressed in the form of $k \times F_s / D$, where k is an integer, then the shifted, decimated spectrum is not centered at DC. In this case, the center frequency gets translated to F_d .

$$F_d = F_c - (F_s / D) \times \text{floor}((D \times F_c + F_s / 2) / F_s)$$

The complex bandpass filter is obtained by first designing a lowpass filter prototype and then multiplying the lowpass coefficients with a complex exponential. This algorithm uses a multirate, multistage FIR filter as the lowpass filter prototype. To obtain the bandpass filter, the coefficients of each stage are frequency shifted. The decimation factor is the cumulative decimation factor of each stage. The complex bandpass filter followed by the decimator are implemented using an efficient polyphase structure. For more details on the design of the complex bandpass filter from the multirate multistage FIR filter prototype, see “Zoom FFT” and “Complex Bandpass Filter Design”.

dsp.AdaptiveLatticeFilter System object

Package: dsp

Adaptive lattice filter

Description

The `dsp.AdaptiveLatticeFilter` computes output, error, and coefficients using a Lattice based FIR adaptive filter.

To implement the adaptive FIR filter object:

- 1 Define and set up your adaptive FIR filter object. See “Construction” on page 4-2.
- 2 Call `step` to implement the filter according to the properties of `dsp.AdaptiveLatticeFilter`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`alf = dsp.AdaptiveLatticeFilter` returns a Lattice based FIR adaptive filter System object, `alf`. This System object is used to compute the filtered output and the filter error for a given input and desired signal.

`alf = dsp.AdaptiveLatticeFilter('PropertyName', PropertyValue,...)` returns an `AdaptiveLatticeFilter` System object, `alf`, with each specified property set to the specified value.

`alf = dsp.AdaptiveLatticeFilter(LEN, 'PropertyName', PropertyValue,...)`

returns an `AdaptiveLatticeFilter` System object, `alf`, with the `Length` property set to `LEN` and other specified properties set to the specified values.

Properties

Method

Method to calculate filter coefficients

Specify the method used to calculate filter coefficients as one of `'Least-squares Lattice'` | `'QR-decomposition Least-squares Lattice'` | `'Gradient Adaptive Lattice'`. The default value is `'Least-squares Lattice'`. For algorithms used to implement these three different methods, refer to [1] [2]. This property is nontunable.

Length

Length of the filter coefficients vector

Specify the length of the FIR filter coefficients vector as a positive integer value. This property is nontunable.

The default value is 32.

ForgettingFactor

Least-squares lattice forgetting factor

Specify the Least-squares lattice forgetting factor as a scalar positive numeric value less than or equal to 1. Setting this value to 1 denotes infinite memory during adaptation. This property applies only if the `Method` property is set to `'Least-squares Lattice'` or `'QR-decomposition Least-squares Lattice'`. The default value is 1.

This property is tunable.

StepSize

Joint process step size of the gradient adaptive filter

Specify the joint process step size of the gradient adaptive lattice filter as a positive numeric scalar less than or equal to 1. This property applies only if the `Method` property is set to `'Gradient Adaptive Lattice'`. The default value is 0.1.

This property is tunable.

Offset

Offset for denominator of StepSize normalization term

Specify an offset value for the denominator of the StepSize normalization term as a nonnegative numeric scalar. A nonzero offset helps avoid a divide-by-near-zero condition when the input signal amplitude is very small. This property applies only if the Method property is set to 'Gradient Adaptive Lattice'. The default value is 1.

This property is tunable.

ReflectionStepSize

Reflection process step size

Specify the reflection process step size of the gradient adaptive lattice filter as a scalar numeric value between 0 and 1, both inclusive. Use this property only if the Method property is set to 'Gradient Adaptive Lattice'. The default value is the StepSize property value.

This property is tunable.

AveragingFactor

Averaging factor of the energy estimator

Specify the averaging factor as a positive numeric scalar less than 1. Use this property to compute the exponentially windowed forward and backward prediction error powers for the coefficient updates. This property applies only if the Method property is set to 'Gradient Adaptive Lattice'. The default is the value of $1 - \text{StepSize}$.

This property is tunable.

InitialPredictionErrorPower

Initial prediction error power

Specify the initial values for the prediction error vectors as a scalar positive numeric value.

If the `Method` property is set to 'Least-squares Lattice' or 'QR-decomposition Least-squares Lattice', the default value is 1.0. If the `Method` property is set to 'Gradient Adaptive Lattice', the default value is 0.1.

This property is tunable.

InitialCoefficients

Initial coefficients of the filter

Specify the initial values of the FIR adaptive filter coefficients as a scalar or a vector of length equal to the value of the `Length` property. The default value is 0.

This property is tunable.

LockCoefficients

Locked status of the coefficient updates

Specify whether to lock the filter coefficient values. By default, the value of this property is `false`, and the object continuously updates the filter coefficients. If this property is set to `true`, the filter coefficients do not update and their values remain the same.

This property is applicable only if the `Method` property is set to 'Gradient Adaptive Lattice'.

This property is tunable.

Methods

<code>mssim</code>	Mean-square error for Adaptive Lattice filter
<code>reset</code>	Reset filter states for Adaptive Lattice filter
<code>step</code>	Apply Adaptive Lattice filter to input

<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object

Common to All System Objects	
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

QPSK adaptive equalization Using Adaptive Lattice Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Create the QPSK signal and the noise, filter them to obtain the received signal, and delay the received signal to obtain the desired signal.

```
D = 16;
b = exp(1i*pi/4)*[-0.7 1];
a = [1 -0.7];
ntr = 1000;
s = sign(randn(1,ntr+D)) + 1i*sign(randn(1,ntr+D));
n = 0.1*(randn(1,ntr+D) + 1i*randn(1,ntr+D));
r = filter(b,a,s) + n;
x = r(1+D:ntr+D);
d = s(1:ntr);
```

Use the Adaptive Lattice Filter to compute the filtered output and the filter error for the input and desired signal.

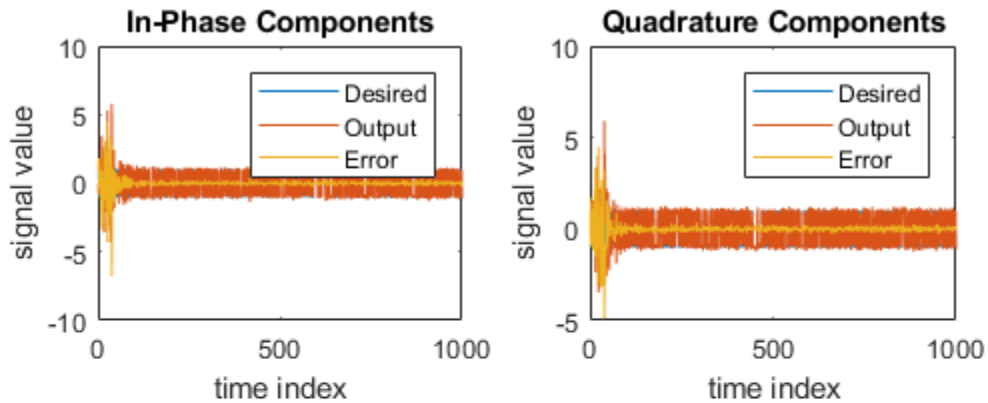

```
lam = 0.995;
del = 1;
alf = dsp.AdaptiveLatticeFilter('Length', 32, ...
    'ForgettingFactor', lam, 'InitialPredictionErrorPower', del);
[y,e] = alf(x,d);
```

Plot the In-Phase and the Quadrature components of the desired, output, and the error signals.

```

subplot(2,2,1); plot(1:ntr,real([d;y;e]));
title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('time index'); ylabel('signal value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('time index'); ylabel('signal value');

```

Plot the received and equalized signals' scatter plots.

```

subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;

```

```
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

msesim

System object: dsp.AdaptiveLatticeFilter

Package: dsp

Mean-square error for Adaptive Lattice filter

Syntax

```
MSE = msesim(sysObj,X,D)
[MSE,MEANW,W,TRACEK] = msesim(sysObj,X,D)
[...] = msesim(sysObj,X,D,M)
```

Description

`MSE = msesim(sysObj,X,D)` returns a sequence of mean-square errors. This column vector contains estimates of the mean-square error of the adaptive filter at each time instant. The length of `MSE` is equal to `SIZE(X,1)`. The columns of the matrix `X` contain individual input signal sequences, and the columns of the matrix `D` contain corresponding desired response signal sequences.

`[MSE,MEANW,W,TRACEK] = msesim(sysObj,X,D)` calculates three parameters corresponding to the simulated behavior of the adaptive filter defined by `sysObj`. `MEANW` is a sequence of coefficient vector means. The columns of this matrix contain estimates of the mean values of the adaptive filter coefficients at each time instant. The dimensions of `MEANW` are `(SIZE(X,1))` by `(sysObj.length)`. `W` is an estimate of the final values of the adaptive filter coefficients for the algorithm corresponding to `sysObj`. `TRACEK` is a sequence of total coefficient error powers. This column vector contains estimates of the total coefficient error power of the adaptive filter at each time instant. The length of `TRACEK` is equal to `SIZE(X,1)`.

`[...] = msesim(sysObj,X,D,M)` specifies an optional decimation factor for computing `MSE`, `MEANW`, and `TRACEK`. If `M > 1`, every `Mth` predicted value of each of these sequences is saved. If omitted, the value of `M` is the default, which is 1.

System identification of an FIR filter Using Adaptive Lattice Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent step syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
ha = fir1(31,0.5);
fir = dsp.FIRFilter('Numerator',ha); % FIR system to be identified
iir = dsp.IIRFilter('Numerator',sqrt(0.75),...
    'Denominator',[1 -0.5]);
x = iir(sign(randn(2000,25)));
n = 0.1*randn(size(x));           % Observation noise signal
d = fir(x)+n;                     % Desired signal
l = 32;                           % Filter length
m = 5;                             % Decimation factor for analysis
                                % and simulation results

ha = dsp.AdaptiveLatticeFilter(l);
[simmse,meanWsim,Wsim,traceKsim] = mzesim(ha,x,d,m);
plot(m*(1:length(simmse)),10*log10(simmse));
xlabel('Iteration'); ylabel('MSE (dB)');
title('Learning curve for Adaptive Lattice filter used in system identification')
```

reset

System object: dsp.AdaptiveLatticeFilter

Package: dsp

Reset filter states for Adaptive Lattice filter

Syntax

```
reset(alf)
```

Description

`reset(alf)` resets the internal states of the System object, `alf`, to their initial values. The reset method is always a no-op for unlocked System objects, as the states may not be allocated when the object is not locked.

step

System object: dsp.AdaptiveLatticeFilter

Package: dsp

Apply Adaptive Lattice filter to input

Syntax

```
[Y, ERR] = step(sysObj, x, D)
Y = step(sysObj, x)
[Y1, ..., YN] = step(sysObj, x)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

`[Y, ERR] = step(sysObj, x, D)` filters the input `x`, using `D` as the desired signal, and returns the filtered output in `Y` and the filter error in `ERR`. The System object estimates the filter weights needed to minimize the error between the output signal and the desired signal.

`Y = step(sysObj, x)` processes the input data, `x`, to produce the output, `Y`, from the System object, `sysObj`. `[Y1, ..., YN] = step(sysObj, x)` produces `N` outputs.

Every System object has a `step` method. The `step` method processes the input data according to the object algorithm. The number of input and output arguments depends on the algorithm, and may depend also on one or more property settings. The `step` method for some objects accepts fixed-point (fi) inputs.

Calling `step` on an object puts that object into a locked state. When locked, you cannot change nontunable properties or any input characteristics (size, data type and complexity) without reinitializing (unlocking and relocking) the object.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.AffineProjectionFilter System object

Package: dsp

Compute output, error and coefficients using Affine Projection (AP) Algorithm

Description

The `AffineProjectionFilter` object filters each channel of the input using AP filter implementations.

To filter each channel of the input:

- 1 Define and set up your AP filter. See “Construction” on page 4-16.
- 2 Call `step` to filter each channel of the input according to the properties of `dsp.AffineProjectionFilter`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`apf = dsp.AffineProjectionFilter` returns an adaptive FIR filter System object, `apf`. This System object computes the filtered output and the filter error for a given input and desired signal using the Affine Projection (AP) algorithm.

`apf = dsp.AffineProjectionFilter('PropertyName', PropertyValue, ...)` returns an AP filter System object, `apf`, with each specified property set to the specified value.

`apf = dsp.AffineProjectionFilter(LEN, 'PropertyName', PropertyValue, ...)` returns an AP filter System object, `apf`. This System object has the `Length` property set to `LEN`, and other specified properties set to the specified values.

Properties

Method

Method to calculate the filter coefficients

Specify the method used to calculate filter coefficients as one of | Direct Matrix Inversion | Recursive Matrix Update | Block Direct Matrix Inversion. The default value is Direct Matrix Inversion. This property is nontunable.

Length

Length of filter coefficients vector

Specify the length of the FIR filter coefficients vector as a scalar positive integer value. The default value is 32. This property is nontunable.

ProjectionOrder

Projection order of the affine projection algorithm

Specify the projection order of the affine projection algorithm as a scalar positive integer value greater than or equal to 2. This property defines the size of the input signal covariance matrix. The default value is 2. This property is nontunable.

StepSize

Affine projection step size

Specify the affine projection step size factor as a scalar non-negative numeric value between 0 and 1, both inclusive. Setting step equal to one provides the fastest convergence during adaptation. The default value is 1. This property is tunable.

InitialCoefficients

Initial coefficients of the filter

Specify the initial values of the FIR adaptive filter coefficients as a scalar or a vector of length equal to the Length property value. The default value is 0. This property is tunable.

InitialOffsetCovariance

Initial values of the offset input covariance matrix

Specify the initial values for the offset input covariance matrix. This property must be either a scalar positive numeric value or a positive-definite square matrix with each dimension equal to the `ProjectionOrder` property value. If it is a scalar value, the `OffsetCovariance` property is initialized to a diagonal matrix with the diagonal elements equal to that scalar value. If it is a square matrix, the `OffsetCovariance` property is initialized to the value of that square matrix. This property is applicable only if the `Method` property is set to `Direct Matrix Inversion` or `Block Direct Matrix Inversion`. The default value is 1. This property is tunable.

InitialInverseOffsetCovariance

Initial values of the offset input covariance matrix inverse

Specify the initial values for the offset input covariance matrix inverse. This property must be either a scalar positive numeric value or a positive-definite square matrix with each dimension equal to the `ProjectionOrder` property value. If it is a scalar value, the `InverseOffsetCovariance` property is initialized to a diagonal matrix with each diagonal element equal to that scalar value. If it is a square matrix, the `InverseOffsetCovariance` property is initialized to the values of that square matrix. This property is applicable only if the `Method` property is set to `Recursive Matrix Update`. The default value is 20. This property is tunable.

InitialCorrelationCoefficients

Initial correlation coefficients

Specify the initial values of the correlation coefficients of the FIR filter as a scalar or a vector of length equal to `ProjectionOrder - 1`. This property is applicable only if the `Method` property is set to `Recursive Matrix Update`. The default value is 0. This property is tunable.

LockCoefficients

Lock coefficient updates

Specify whether the filter coefficient values should be locked. When you set this property to `true`, the filter coefficients are not updated and their values remain the same. The

default value is `false` (filter coefficients are continuously updated). This property is tunable.

Methods

<code>mseSim</code>	Mean-square error for Affine Projection filter
<code>reset</code>	Reset the internal states of a System object
<code>step</code>	Process inputs using the affine projection filter algorithm

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

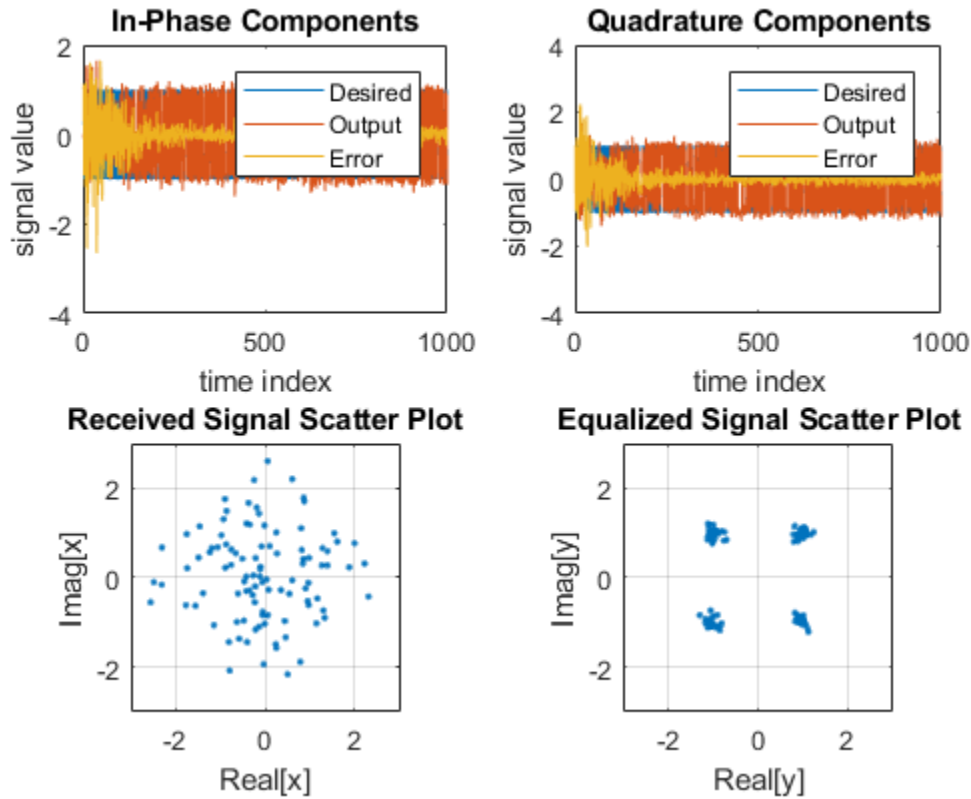

QPSK Adaptive Equalization

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

QPSK Adaptive Equalization Using a 32-Coefficient FIR Filter (1000 Iterations)

```
D = 16; % Number of samples of delay
b = exp(1i*pi/4)*[-0.7 1]; % Numerator coefficients of channel
a = [1 -0.7]; % Denominator coefficients of channel
ntr = 1000; % Number of iterations
s = sign(randn(1,ntr+D)) + 1i*sign(randn(1,ntr+D)); % Baseband signal
n = 0.1*(randn(1,ntr+D) + 1i*randn(1,ntr+D)); % Noise signal
r = filter(b,a,s)+n; % Received signal
```

```
x = r(1+D:ntr+D);           % Input signal (received signal)
d = s(1:ntr);               % Desired signal (delayed QPSK signal)
mu = 0.1;                   % Step size
po = 4;                     % Projection order
offset = 0.05;              % Offset for covariance matrix
apf = dsp.AffineProjectionFilter('Length', 32, ...
    'StepSize', mu, 'ProjectionOrder', po, ...
    'InitialOffsetCovariance', offset);
[y,e] = apf(x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e]));
title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('time index'); ylabel('signal value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('time index'); ylabel('signal value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

Algorithms

The affine projection algorithm (APA), is an adaptive scheme that estimates an unknown system based on multiple input vectors [1]. It is designed to improve the performance of other adaptive algorithms, mainly those that are LMS-based. The affine projection algorithm reuses old data resulting in fast convergence when the input signal is highly correlated, leading to a family of algorithms that can make trade-offs between computation complexity with convergence speed [2].

The following equations describe the conceptual algorithm used in designing AP filters:

$$\mathbf{U}_{ap}(n) = \begin{pmatrix} u(n) & \dots & u(n-L) \\ \vdots & \ddots & \vdots \\ u(n-N) & \dots & u(n-L-N) \end{pmatrix} = (\mathbf{u}(n) \quad \mathbf{u}(n-1) \quad \dots \quad \mathbf{u}(n-L))$$

$$\mathbf{y}_{ap}(n) = \mathbf{U}_{ap}^T(n)\mathbf{w}(n) = \begin{pmatrix} y(n) \\ \bullet \\ \bullet \\ \bullet \\ y(n-L) \end{pmatrix}$$

$$\mathbf{d}_{ap}(n) = \begin{pmatrix} d(n) \\ \bullet \\ \bullet \\ \bullet \\ d(n-L) \end{pmatrix}$$

$$\mathbf{e}_{ap}(n) = \mathbf{d}_{ap}(n) - \mathbf{y}_{ap}(n) = \begin{pmatrix} e(n) \\ \bullet \\ \bullet \\ \bullet \\ e(n-L) \end{pmatrix}$$

$$\mathbf{w}(n) = \mathbf{w}(n-1) + \mu \mathbf{U}_{ap}(n)(\mathbf{U}_{ap}^H(n)\mathbf{U}_{ap}(n) + \mathbf{C})^{-1} \mathbf{e}_{ap}$$

where \mathbf{C} is either $\varepsilon\mathbf{I}$ if the initial offset covariance is a scalar ε , or \mathbf{R} if the initial offset covariance is a matrix \mathbf{R} . The variables are as follows:

Variable	Description
n	The current time index
$u(n)$	The input sample at step n
$\mathbf{U}_{ap}(n)$	The matrix of the last $L+1$ input signal vectors

Variable	Description
$\mathbf{w}(n)$	The adaptive filter coefficients vector
$y(n)$	The adaptive filter output
$d(n)$	The desired signal
$e(n)$	The error at step n
L	The projection order
N	The filter order (i.e., filter length = $N+1$)
μ	The step size

`dsp.FIRFilter` | `dsp.LMSFilter` | `dsp.RLSFilter`

Introduced in R2013a

msesim

System object: dsp.AffineProjectionFilter

Package: dsp

Mean-square error for Affine Projection filter

Syntax

```
MSE = msesim(sysObj,X,D)
[MSE,MEANW,W,TRACEK] = msesim(sysObj,X,D)
[...] = msesim(sysObj,X,D,M)
```

Description

`MSE = msesim(sysObj,X,D)` returns a sequence of mean-square errors. This column vector contains estimates of the mean-square error of the adaptive filter at each time instant. The length of `MSE` is equal to `SIZE(X,1)`. The columns of the matrix `X` contain individual input signal sequences, and the columns of the matrix `D` contain corresponding desired response signal sequences.

`[MSE,MEANW,W,TRACEK] = msesim(sysObj,X,D)` calculates three parameters corresponding to the simulated behavior of the adaptive filter defined by `sysObj`. `MEANW` is a sequence of coefficient vector means. The columns of this matrix contain estimates of the mean values of the adaptive filter coefficients at each time instant. The dimensions of `MEANW` are `(SIZE(X,1))` by `(sysObj.length)`. `W` is an estimate of the final values of the adaptive filter coefficients for the algorithm corresponding to `sysObj`. `TRACEK` is a sequence of total coefficient error powers. This column vector contains estimates of the total coefficient error power of the adaptive filter at each time instant. The length of `TRACEK` is equal to `SIZE(X,1)`.

`[...] = msesim(sysObj,X,D,M)` specifies an optional decimation factor for computing `MSE`, `MEANW`, and `TRACEK`. If `M > 1`, every `Mth` predicted value of each of these sequences is saved. If omitted, the value of `M` is the default, which is 1.

System Identification of an FIR Filter Using Affine Projection Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent step syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```

ha = fir1(31,0.5);
fir = dsp.FIRFilter('Numerator',ha); % FIR system to be identified
iir = dsp.IIRFilter('Numerator',sqrt(0.75),...
    'Denominator',[1 -0.5]);
x = iir(sign(randn(2000,25)));
n = 0.1*randn(size(x));           % Observation noise signal
d = fir(x)+n;                     % Desired signal
l = 32;                           % Filter length
mu = 0.008;                       % Affine Projection filter Step size.
m = 5;                            % Decimation factor for analysis
                                % and simulation results

apf = dsp.AffineProjectionFilter(l,'StepSize',mu);
[simmse,meanWsim,Wsim,traceKsim] = msesim(apf,x,d,m);
plot(m*(1:length(simmse)),10*log10(simmse));
xlabel('Iteration'); ylabel('MSE (dB)');
title('Learning curve for Affine Projection filter used in system identification')

```

reset

System object: dsp.AffineProjectionFilter

Package: dsp

Reset the internal states of a System object

Syntax

```
reset(apf)
```

Description

`reset(apf)` resets the internal states of the System object, `apf`, to their initial values.

For many System objects, this method is nonoperational. Objects that have internal states describe in their **help** what the reset method does for that object. The `reset` method is always nonoperational for unlocked System objects, as states may not be allocated when the object is not locked.

step

System object: `dsp.AffineProjectionFilter`

Package: `dsp`

Process inputs using the affine projection filter algorithm

Syntax

```
Y = step(apf,x)
[Y1,...,YN] = step(apf,x)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(apf,x)` processes the input data, `x`, to produce the output, `Y`, for the System object, `apf`. `[Y1,...,YN] = step(apf,x)` produces `N` outputs.

Every System object has a `step` method. The `step` method processes the input data according to the object algorithm. The number of the input and the output arguments depends on the algorithm, and may depend also on one or more property settings. The `step` method for some objects accepts fixed-point (fi) inputs.

Calling `step` on an object puts that object into a locked state. When locked, you cannot change nontunable properties or any input characteristics (size, data type and complexity) without reinitializing (unlocking and relocking) the object.

dsp.AllpassFilter System object

Package: dsp

Single section or cascaded allpass filter

Note MATLAB code with `LatticeCoefficients`, `AllpassCoefficients`, and `WDFCoefficients` properties set to cell arrays will error in a future release. Set these properties to array values instead.

Description

The `AllpassFilter` object filters each channel of the input using Allpass filter implementations. This System object supports code generation. To import this object into Simulink, use the MATLAB System block.

To filter each channel of the input:

- 1 Define and set up your Allpass filter. See “Construction” on page 4-29.
- 2 Call `step` to filter each channel of the input according to the properties of `dsp.AllpassFilter`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`Allpass = dsp.AllpassFilter` returns an Allpass filter System object, `Allpass`, that filters each channel of the input signal independently using an allpass filter, with the default structure and coefficients.

`Allpass = dsp.AllpassFilter('PropertyName',PropertyValue, ...)` returns an Allpass filter System object, `Allpass`, with each property set to the specified value.

Properties

Structure

Internal allpass filter structure

You can specify the internal allpass filter implementation structure as one of | `Minimum multiplier` | `Lattice` | `Wave Digital Filter`. The default is `Minimum multiplier`. Each structure uses a different set of coefficients, independently stored in the corresponding object property.

AllpassCoefficients

Allpass polynomial coefficients

Specify the real allpass polynomial filter coefficients. This property is applicable only when the `Structure` property is set to `Minimum multiplier`. Specify this property as either an N -by-1 or N -by-2 matrix of N first-order or second-order allpass sections. The default value of this property is $[-2^{(-1/2)} \ 0.5]$. The default value defines a stable second-order allpass filter with poles and zeros located at $\pm\pi/3$ in the Z plane. This property is tunable.

WDFCoefficients

Wave Digital Filter allpass coefficients

Specify the real allpass coefficients in the Wave Digital Filter form. This property is only applicable when the `Structure` property is set to `Wave Digital Filter`. Specify this property as either an N -by-1 or N -by-2 matrix of N first-order or second-order allpass sections. All elements must have absolute values less than or equal to 1. The default value for this property is $[1/2, -2^{(1/2)}/3]$. This value is a transformed version of the default value of `AllpassCoefficients`, computed using `allpass2wdf(AllpassCoefficients)`. These coefficients define the same stable second-order allpass filter as when `Structure` is set to `'Minimum multiplier'`. This property is tunable.

LatticeCoefficients

Lattice allpass coefficients

Specify the real or complex allpass coefficients as lattice reflection coefficients. This property is applicable only if the `Structure` property is set to `Lattice`. Specify this property as either a row vector (single-section configuration) or a column vector. The default is $[-2^{(1/2)}/3, 1/2]$. This value is a transformed and transposed version of the default value of `AllpassCoefficients`, computed using `transpose(tf2latc([1 h.AllpassCoefficients]))`. These coefficients define the same stable second-order allpass filter as when `Structure` is set to `'Lattice'`. This property is tunable.

TrailingFirstOrderSection

Indicate if last section is first order

Indicate if last section is first order or second order. When you set `TrailingFirstOrderSection` to `true`, the last section is considered to be first-order, and the second element of the last row of the N -by-2 matrix is ignored. When you set `TrailingFirstOrderSection` to `false`, the last section is considered to be second-order. The default is `false`.

Methods

`reset` Reset internal states of a System object
`step` Process inputs using allpass filter

For additional methods, see “Analysis Methods for Filter System Objects” on page 3-2.

For a complete list of analysis methods supported for the `dsp.AllpassFilter` object, enter `dsp.AllpassFilter.helpFilterAnalysis` at the MATLAB command prompt.

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object

Common to All System Objects	
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Lowpass Filtering using Two Allpass Filters

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Construct the Allpass Filters

```
Fs = 48000;    % in Hz
FL = 1024;
APF1 = dsp.AllpassFilter('AllpassCoefficients',...
    [-0.710525516540603  0.208818210000029]);
APF2 = dsp.AllpassFilter('AllpassCoefficients',...
    [-0.940456403667957  0.6;...
    -0.324919696232907  0],...
    'TrailingFirstOrderSection',true);
```

Construct the Transfer Function Estimator to estimate the transfer function between the random input and the Allpass filtered output

```
TFE = dsp.TransferFunctionEstimator('FrequencyRange',...
    'onesided', 'SpectralAverages',2);
```

Construct the ArrayPlot to plot the magnitude response

```
AP = dsp.ArrayPlot('PlotType','Line','YLimits', [-80 5],...
    'YLabel','Magnitude (dB)','SampleIncrement', Fs/FL,...
    'XLabel','Frequency (Hz)','Title','Magnitude Response',...
    'ShowLegend', true, 'ChannelNames',{'Magnitude Response'});
```

Filter the Input and show the magnitude response of the estimated transfer function between the input and the filtered output

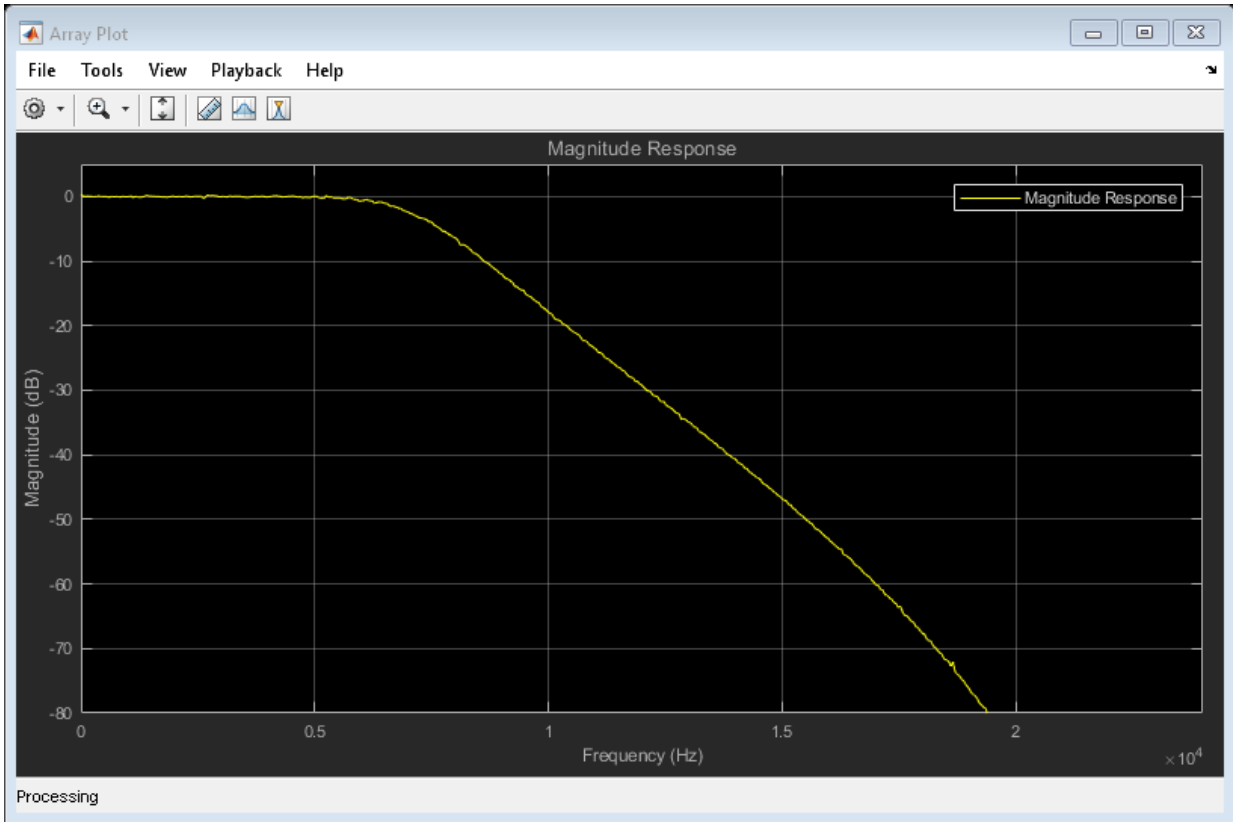

```
tic;
while toc < 5
```

```

in = randn(FL,1);
out = 0.5.*(APF1(in) + APF2(in));
A = TFE(in, out);
AP(db(A));
end

```

Algorithms

The transfer function of an allpass filter is given by

$$H(z) = \frac{c(n) + c(n-1)z^{-1} + \dots + z^{-n}}{1 + c(1)z^{-1} + \dots + c(n)z^{-n}}$$

c is allpass polynomial coefficients vector. The order, n , of the transfer function is the length of vector c .

In the minimum multiplier form and wave digital form, the allpass filter is implemented as a cascade of either second-order (biquad) sections or first-order sections. When the coefficients are specified as an N -by-2 matrix, each row of the matrix specifies the coefficients of a second-order filter. The last element of the last row can be ignored based on the trailing first-order setting. When the coefficients are specified as an N -by-1 matrix, each element in the matrix specifies the coefficient of a first-order filter. The cascade of all the filter sections forms the allpass filter.

In the lattice form, the coefficients are specified as a vector.

These structures are computationally more economical and structurally more stable compared to the generic IIR filters, such as `df1`, `df1t`, `df2`, `df2t`. For all structures, the allpass filter can be a single-section or a multiple-section (cascaded) filter. The different sections can have different orders, but they are all implemented according to the same structure.

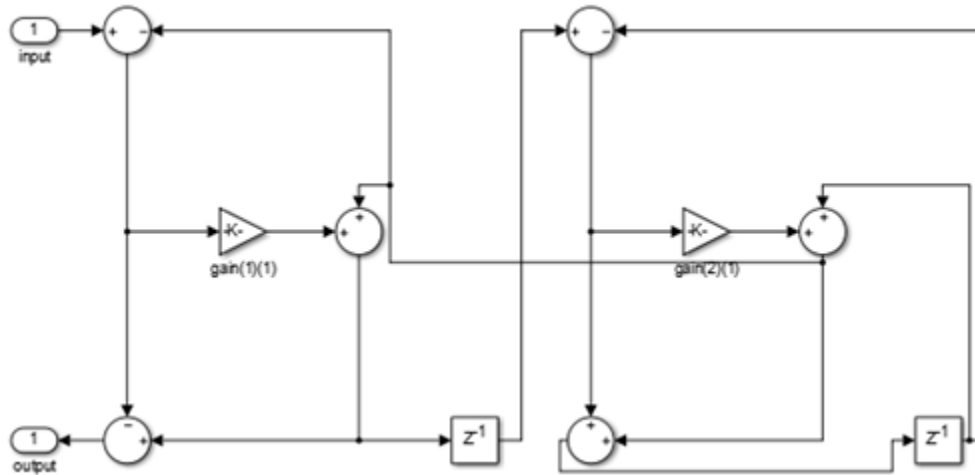

Minimum Multiplier

This structure realizes the allpass filter with the minimum number of required multipliers, equal to the order n . It also uses $2n$ delay units and $2n$ adders. The multipliers uses the specified coefficients, which are equal to the polynomial vector c in the allpass transfer function. In this second-order section of the minimum multiplier structure, the coefficients vector, c , is equal to `[0.1 -0.7]`.

Wave Digital Filter

This structure uses n multipliers, but only n delay units, at the expense of requiring $3n$ adders. To use this structure, specify the coefficients in wave digital filter (WDF) form. Obtain the WDF equivalent of the conventional allpass coefficients using `allpass2wdf(allpass_coefficients)`. To convert WDF coefficients into the equivalent allpass polynomial form, use `wdf2allpass(WDF_coefficients)`. In this second-order section of the WDF structure, the coefficients vector w is equal to `allpass2wdf([0.1 -0.7])`.

Lattice

This lattice structure uses $2n$ multipliers, n delay units, and $2n$ adders. To use this structure, specify the coefficients as a vector.

You can obtain the lattice equivalent of the conventional allpass coefficients using `transpose(tf2latc(1, [1 allpass_coefficients]))`. In the following second-order section of the lattice structure, the coefficients vector is computed using `transpose(tf2latc(1, [1 0.1 -0.7]))`. Use these coefficients for a filter that is functionally equivalent to the minimum multiplier structure with coefficients [0.1 -0.7].

reset

System object: dsp.AllpassFilter

Package: dsp

Reset internal states of a System object

Syntax

`reset (OBJ)`

Description

`reset (OBJ)` resets the internal states of the System object, `OBJ`, to their initial values.

For many System objects, this method is equivalent to no operation being executed. The `reset` method is always nonoperational for unlocked System objects, as states may not be allocated when the object is not locked.

step

System object: dsp.AllpassFilter

Package: dsp

Process inputs using allpass filter

Syntax

```
Y = step(OBJ,x)
```

```
[Y1,...,YN] = step(OBJ,x)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(OBJ,x)` processes the input data, `x`, to produce the output, `Y`, for the System object, `OBJ`. `[Y1,...,YN] = step(OBJ,x)` produces `N` outputs.

Every System object has a `step` method. The `step` method processes the input data according to the object algorithm. The number of the input and the output arguments depends on the algorithm, and may depend also on one or more property settings. The `step` method for some objects accepts fixed-point (fi) inputs.

Calling `step` on an object puts that object into a locked state. When locked, you cannot change nontunable properties or any input characteristics (size, data type and complexity) without reinitializing (unlocking and relocking) the object.

dsp.AllpoleFilter System object

Package: dsp

IIR Filter with no zeros

Description

The `AllpoleFilter` object filters each channel of the input using Allpole filter implementations.

To filter each channel of the input:

- 1 Define and set up your Allpole filter. See “Construction” on page 4-41.
- 2 Call `step` to filter each channel of the input according to the properties of `dsp.AllpoleFilter`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`allpole = dsp.AllpoleFilter` returns an Allpole filter System object, `allpole`, which independently filters each channel of the input over successive calls to the `step` method. This System object uses a specified Allpole filter implementation, and it supports variable-size input.

`allpole = dsp.AllpoleFilter('PropertyName',PropertyValue, ...)` returns an Allpole filter System object, `allpole`, with each property set to the specified value.

Properties

Structure

Filter structure

Specify the filter structure.

You can specify the filter structure as one of `Direct form` | `Direct form transposed` | `Lattice AR`. The default is `Direct form`. Analysis methods are not supported for fixed-point processing if the structure is `Direct form` or `Direct form transposed`. This property is nontunable.

Denominator

Filter denominator coefficients

Specify the denominator coefficients as a real or complex numeric row vector. This property is applicable when the `Structure` property is set to one of `Direct form` | `Direct form transposed`. The default value of this property is `[1 0.1]`. This property is tunable.

ReflectionCoefficients

Lattice filter coefficients

Specify the lattice filter coefficients as a real or complex numeric row vector. This property is applicable when the `Structure` property is set to `Lattice AR`. The default value of this property is `[0.2 0.4]`. This property is tunable.

InitialConditions

Initial conditions for the filter states

Specify the initial conditions of the filter states. The default value is 0.

You can specify the initial conditions as a scalar, vector, or matrix. If you specify a scalar value, this System object initializes all delay elements in the filter to that value. You can also specify a vector whose length equals the number of delay elements in the filter. When you do so, each vector element specifies a unique initial condition for the corresponding delay element. The object applies the same vector of initial conditions to each channel of the input signal.

You can also specify a matrix with the same number of rows as the number of delay elements in the filter and one column for each channel of the input signal. In this case, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel. This property is tunable.

CoefficientsDataType

Denominator coefficients word- and fraction-length designations

Specify the denominator coefficients fixed-point data type as one of Same word length as input | Custom. The default is Same word length as input. This property is nontunable.

ReflectionCoefficientsDataType

Reflection coefficients word- and fraction-length designations

Specify the reflection coefficients fixed-point data type as one of Same word length as input | Custom. The default is Same word length as input. This property is nontunable.

Fixed-Point Properties**ProductDataType**

Product word- and fraction-length designations

Specify the product fixed-point data type as one of | Full precision | Same as input | Custom |. The default is Full precision. This property is nontunable.

AccumulatorDataType

Accumulator word- and fraction-length designations

Specify the accumulator fixed-point data type to one of | Full precision | Same as input | Same as product | Custom |. The default is Full precision. This property is nontunable.

OutputDataType

Output word- and fraction-length designations

Specify the output fixed-point data type as one of | Same as accumulator | Same as input | Custom |. The default is Same as input. This property is nontunable.

StateDataType

State word- and fraction-length designations

Specify the state fixed-point data type as one of | Same as input | Same as accumulator | Custom. The default is Same as accumulator. This property is nontunable.

CustomCoefficientsDataType

Custom denominator word- and fraction-lengths

Specify the denominator coefficients fixed-point type as an autosigned `numericType` object. This property is applicable when the `CoefficientsDataType` property is `Custom`. The default value of this property is `numericType ([],16,15)`. This property is nontunable.

CustomReflectionCoefficientsDataType

Custom reflection coefficients word- and fraction-lengths

Specify the denominator coefficients fixed-point type as an autosigned `numericType` object. This property is applicable when the `ReflectionCoefficientsDataType` property is `Custom`. The default value of this property is `numericType ([],16,15)`. This property is nontunable.

CustomProductDataType

Custom Product word- and fraction-lengths

Specify the product fixed-point type as an autosigned scaled `numericType` object. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numericType ([],32,30)`. This property is nontunable.

CustomAccumulatorDataType

Custom accumulator word- and fraction-lengths

Specify the accumulator fixed-point type as an autosigned scaled `numericType` object. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([], 32, 30)`. This property is nontunable.

CustomStateDataType

Custom state word- and fraction-lengths

Specify the state fixed-point type as an autosigned scaled `numericType` object. This property applies when you set the `StateDataType` property to `Custom`. The default is `numericType([], 16, 15)`. This property is nontunable.

CustomOutputDataType

Custom output word- and fraction-lengths

Specify the output fixed-point type as an autosigned scaled `numericType` object. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numericType([], 16, 15)`. This property is nontunable.

Methods

<code>freqz</code>	Frequency response
<code>fvtool</code>	Open filter visualization tool
<code>impz</code>	Impulse response
<code>phasez</code>	Unwrapped phase response
<code>reset</code>	Reset internal states of Allpole filter
<code>step</code>	Filter input with Allpole filter object

More “Analysis Methods for Filter System Objects” on page 3-2.

Note In `AllpoleFilter`, analysis methods are not supported for fixed-point processing if the structure is `Direct form` or `Direct form transposed`.

Common to All System Objects	
clone	Create System object with same property values
getNumInputs	Expected number of inputs to a System object
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Lowpass filtering a waveform with two frequencies

Use an Allpole filter to apply a lowpass filter to a waveform with two sinusoidal frequencies.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
t = (0:1000)./8e3;
xin = sin(2*pi*1e3*t)+sin(2*pi*3e3*t);

src = dsp.SignalSource(xin', 4);
sink = dsp.SignalSink;
allpole = dsp.AllpoleFilter;
tt = (-25:25)';
xsinc = 0.4*sinc(0.4*tt);
asinc = lpc(xsinc,51);
allpole.Denominator = asinc;

sa = dsp.SpectrumAnalyzer('SampleRate',8e3,...
    'PlotAsTwoSidedSpectrum',false,...
    'OverlapPercent', 80,'PowerUnits','dBW',...
    'YLimits', [-150 50]);

while ~isDone(src)
    input = src();
```

```
filteredOutput = allpole(input);  
sink(filteredOutput);  
sa(filteredOutput)  
  
end  
  
filteredResult = sink.Buffer;  
fvtool(allpole, 'Fs', 8000)
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Allpole Filter block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Only the `Denominator` property is tunable for code generation.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

See Also

`dsp.BiquadFilter` | `dsp.FIRFilter` | `dsp.IIRFilter`

Introduced in R2012b

freqz

System object: dsp.AllpoleFilter

Package: dsp

Frequency response

Syntax

```
[h,w] = freqz(allpole)
[h,w] = freqz(allpole,n)
[h,w] = freqz(allpole,Name,Value)
freqz(allpole)
```

Description

`[h,w] = freqz(allpole)` returns the complex, 8192–element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample.

`[h,w] = freqz(allpole,n)` returns the complex, `n`-element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[h,w] = freqz(allpole,Name,Value)` returns the frequency response and the corresponding frequencies, with additional options specified by one or more `Name, Value` pair arguments.

`freqz(allpole)` uses `FVTool` to plot the magnitude and unwrapped phase of the frequency response of the filter System object `allpole`.

fvtool

System object: dsp.AllpoleFilter

Package: dsp

Open filter visualization tool

Syntax

```
fvtool(allpole)
fvtool(allpole, 'Arithmetic', ARITH, ...)
```

Description

`fvtool(allpole)` performs an analysis and computes the magnitude response of the filter System object `allpole`.

`fvtool(allpole, 'Arithmetic', ARITH, ...)` analyzes the filter System object `allpole`, based on the arithmetic specified in the `ARITH` input. `ARITH` can be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The 'Arithmetic' input is only relevant for the analysis of filter System objects.

impz

System object: dsp.AllpoleFilter

Package: dsp

Impulse response

Syntax

```
[h,t] = impz(allpole)
[h,t] = impz(allpole,Name,Value)
impz(allpole)
```

Description

`[h,t] = impz(allpole)` returns the impulse response `h`, and the corresponding time points `t` at which the impulse response of `allpole` is computed.

`[h,t] = impz(allpole,Name,Value)` returns the impulse response `h`, and the corresponding time points `t`, with additional options specified by one or more `Name, Value` pair arguments.

`impz(allpole)` uses `FVTool` to plot the impulse response of the filter System object `allpole`.

Note You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

phasez

System object: dsp.AllpoleFilter

Package: dsp

Unwrapped phase response

Syntax

```
[phi,w] = phasez(allpole)
[phi,w] = phasez(allpole,n)
[phi,w] = phasez(allpole,Name,Value)
phasez(allpole)
```

Description

`[phi,w] = phasez(allpole)` returns the 8192–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample.

`[phi,w] = phasez(allpole,n)` returns the `n`-element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[phi,w] = phasez(allpole,Name,Value)` returns the phase response and the corresponding frequencies, with additional options specified by one or more `Name, Value` pair arguments.

`phasez(allpole)` uses `FVTool` to plot the phase response of the filter System object `allpole`.

reset

System object: dsp.AllpoleFilter

Package: dsp

Reset internal states of Allpole filter

Syntax

```
reset(allpole)
```

Description

`reset(allpole)` resets the filter states of the Allpole filter object, `allpole`, to their initial values of 0. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the `step` method applies the allpole filter object to nonzero input data, the states may be nonzero. Invoking the `step` method again without first invoking the `reset` method may produce different outputs for an identical input.

Reset an Allpole Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
n = 0:100;  
x = cos(0.2*pi*n)+sin(0.8*pi*n);  
allpole = dsp.AllpoleFilter;  
a = lpc(x,20);  
allpole.Denominator = a;  
y = allpole(x);
```

Filter states are nonzero. Filter the input again without resetting the filter states.

```
y1 = allpole(x);  
isequal(y,y1)
```

```
ans =  
    logical  
     0
```

Now reset filter states to 0.

```
reset(allpole)
```

Filter the input.

```
y2 = allpole(x);  
isequal(y,y2)
```

```
ans =  
    logical  
     1
```

step

System object: `dsp.AllpoleFilter`

Package: `dsp`

Filter input with Allpole filter object

Syntax

```
Y = step(allpole,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(allpole,X)` filters the real or complex input signal `X` using the Allpole filter, `allpole`, to produce the output `Y`. When the input data is of a fixed-point type, it must be signed. The Allpole filter object operates on each channel of the input signal independently over successive calls to `step` method.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.AnalyticSignal System object

Package: dsp

Analytic signals of discrete-time inputs

Description

The `AnalyticSignal` object computes analytic signals of discrete-time inputs. The real part of the analytic signal in each channel is a replica of the real input in that channel, and the imaginary part is the Hilbert transform of the input. In the frequency domain, the analytic signal doubles the positive frequency content of the original signal while zeroing-out negative frequencies and retaining the DC component. The object computes the Hilbert transform using an equiripple FIR filter.

To compute the analytic signal of a discrete-time input:

- 1 Define and set up your analytic signal calculation. See “Construction” on page 4-57.
- 2 Call `step` to compute the analytic signal according to the properties of `dsp.AnalyticSignal`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`anaSig = dsp.AnalyticSignal` returns an analytic signal object, `anaSig`, that computes the complex analytic signal corresponding to each channel of a real M -by- N input matrix.

`anaSig = dsp.AnalyticSignal('PropertyName',PropertyValue,...)` returns an analytic signal object, `anaSig`, with each specified property set to the specified value.

`anaSig = dsp.AnalyticSignal(order, 'PropertyName', PropertyValue, ...)`
returns an analytic signal object, `anaSig`, with the “FilterOrder” on page 4-0 property set to `order` and other specified properties set to the specified values.

Properties

FilterOrder

Filter order used to compute Hilbert transform

Specify the order of the equiripple FIR filter used in computing the Hilbert transform as an even integer scalar. The default is 100.

Methods

`reset` Reset internal states of analytic signal object
`step` Analytic signal

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

Compute The Analytic Signal

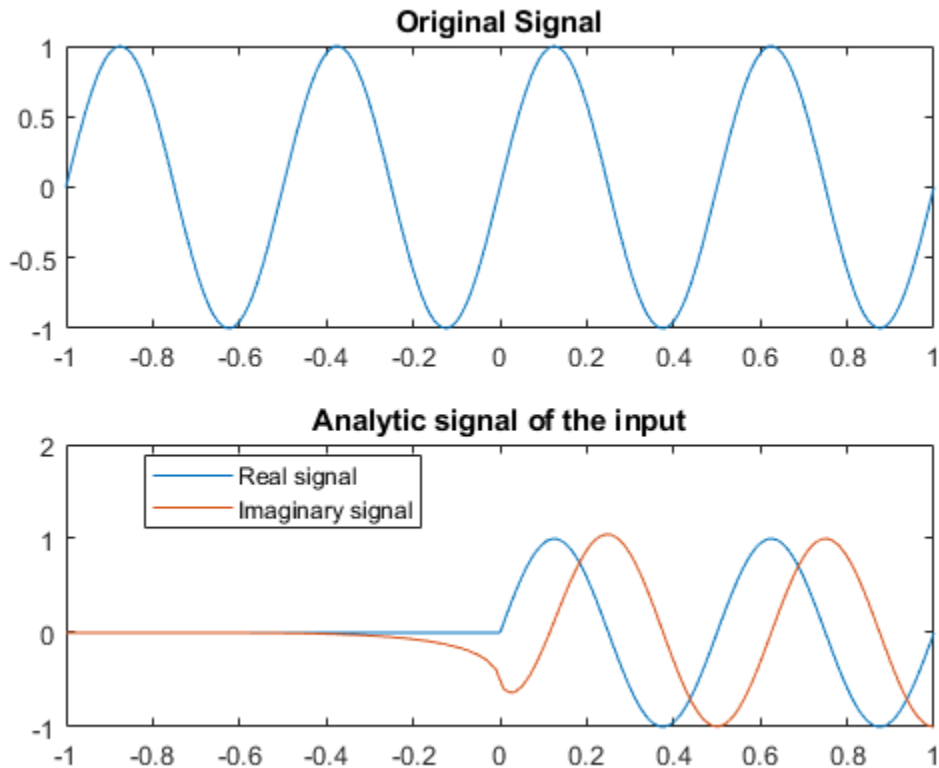

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Compute the analytic signal of a sinusoidal input.

```
t = (-1:0.01:1)';  
x = sin(4*pi*t);  
anaSig = dsp.AnalyticSignal(200);  
y = anaSig(x);
```

View the analytic signal.

```
subplot(2,1,1), plot(t, x);  
title('Original Signal');  
subplot(2,1,2), plot(t, [real(y) imag(y)]);  
title('Analytic signal of the input')  
legend('Real signal', 'Imaginary signal', ...  
       'Location', 'best');
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Analytic Signal block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

See Also

`dsp.FFT` | `dsp.IFFT`

Introduced in R2012a

reset

System object: dsp.AnalyticSignal

Package: dsp

Reset internal states of analytic signal object

Syntax

```
reset(anaSig)
```

Description

`reset(anaSig)` sets the internal states of the `AnalyticSignal` object `anaSig` to their initial values.

step

System object: dsp.AnalyticSignal

Package: dsp

Analytic signal

Syntax

```
Y = step(anaSig,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(anaSig,X)` computes the analytic signal, Y , of the M -by- N input matrix X , according to the equation

$$\mathbf{Y} = \mathbf{X} + jH\{\mathbf{X}\}$$

where j is the imaginary unit and $H\{\mathbf{X}\}$ denotes the Hilbert transform.

Each of the N columns in X contains M sequential time samples from an independent channel. The method computes the analytic signal for each channel.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.ArrayPlot System object

Package: dsp

Display vectors or arrays

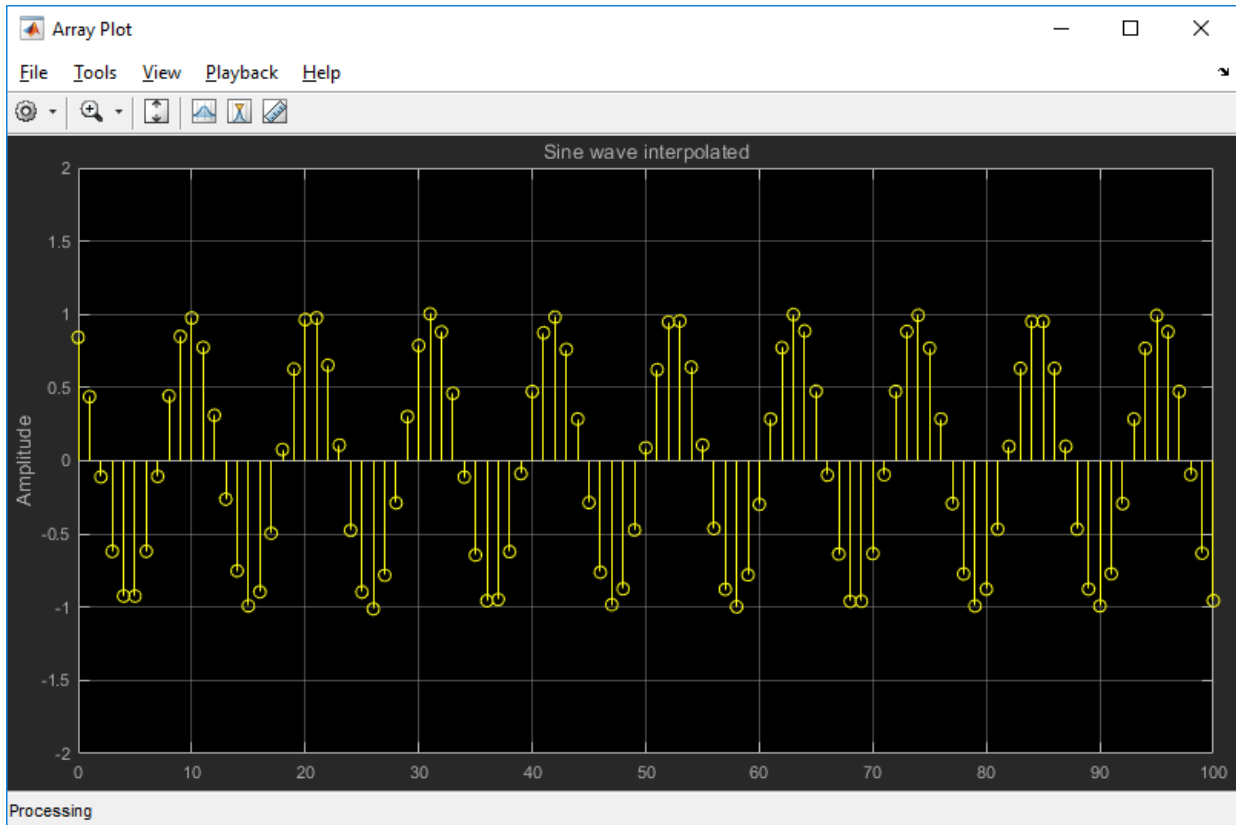

Description

The dsp.ArrayPlot System object displays vectors or arrays.

To display vectors or array on the Array Plot:

- 1 Create the dsp.ArrayPlot object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#) (MATLAB).

Creation

Syntax

```
scope = dsp.ArrayPlot  
scope = dsp.ArrayPlot(Name,Value)
```

Description

`scope = dsp.ArrayPlot` creates an Array Plot System object, `scope`.

`scope = dsp.ArrayPlot(Name, Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes. For example, `scope = dsp.ArrayPlot('NumInputPorts', 3)`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects \(MATLAB\)](#).

Plot Configuration

NumInputPorts — Number of input ports

1 (default) | integer between [1, 96]

Number of input ports, specified as a positive integer. Each signal coming through an input port becomes a separate channel in the scope. You must invoke the scope with the same number of inputs as the value of this property.

XDataMode — Source of the x-data spacing

'SampleIncrement and XOffset' (default) | 'Custom'

Specify whether to use the `SampleIncrement` and `XOffset` property values to determine spacing, or specify your own custom spacing. If you specify 'Custom', you also must specify the `CustomXData` property values.

UI Use

Open the **Configuration Properties**. On the **Main** tab, set **X-data mode**.

CustomXData — X-data values

empty vector (default) | vector

Specify the desired x -data values as a row or column vector of length equal to the frame length of the inputs. If you use the default (empty vector) value, the x -data is uniformly spaced and set to $(0:L-1)$, where L is the frame length.

```
Example: scope = dsp.ArrayPlot('XDataMode','Custom',  
'CustomXData',logspace(0,log10(44100/2),1024))
```

UI Use

Open the **Configuration Properties**. On the **Main** tab, set **Custom X-Data**.

Dependency

To use this property, set `XDataMode` to 'Custom'.

SampleIncrement — Sample increment of input

1 (default) | finite numeric scalar

Specify the spacing between samples along the x -axis as a finite numeric scalar. The input signal is only y -axis data. x -axis data is set automatically based on the `XOffset` and `SampleIncrement` properties. For example, when `Xoffset` is 0 and `SampleIncrement` is 1, the x -data for the input signal is set to 0, 1, 2, 3, 4, etc. If you set `SampleIncrement` to 0.25, the x -axis data becomes 0, 0.25, 0.5, 0.75, 1, etc.

Tunable: Yes

UI Use

Open the **Configuration Properties**. On the **Main** tab, set **Sample increment**.

xoffset — Display offset of x-axis

0 (default) | scalar

Specify the offset to display on the x -axis. This property is a scalar

Tunable: Yes

UI Use

Open the **Configuration Properties**. On the **Main** tab, set **X-offset**.

xScale — Scale of x-axis

'Linear' (default) | 'Log'

Specify whether the scale of the x -axis is 'Linear' or 'Log'. If XOffset is a negative value, you cannot set this property to 'Log'.

Tunable: Yes

UI Use

Open the **Configuration Properties**. On the **Main** tab, set **X-axis scale**.

PlotType — Control type of plot

'Stem' (default) | 'Line' | 'Stairs'

Specify the type of plot to use for all the input signals displayed in the scope window:

- 'Stem' – The scope displays the input signal as circles with vertical lines extending down to the x -axis at each of the sampled values. This option is similar to the `stem` function.
- 'Line' – The scope displays the input signal as lines connecting each of the sampled values. This option is similar to the `line` or `plot` functions.
- 'Stairs' – The scope displays the input signal as a staircase graph. A staircase graph is made up of only horizontal lines and vertical lines. Each horizontal line represents the signal value for a discrete sample period and is connected to two vertical lines. Each vertical line represents a change in values occurring at a sample. This option is similar to the `stairs` function. Stairstep graphs are useful for drawing time history graphs of digitally sampled data.

UI Use

Open the **Style** dialog box and set **Plot type**.

AxisScaling — Axes scaling mode

'OnceAtStop' (default) | 'Auto' | 'Manual' | 'Updates'

Specify when the scope scales the axes. Valid values are:

- 'Auto' — The scope scales the axes as needed to fit the data, both during and after simulation.
- 'Manual' — The scope does not scale the axes automatically.
- 'OnceAtStop' — The scope scales the axes when the simulation stops.
- 'Updates' — The scope scales the axes once and only once after 10 updates.

UI Use

Select **Tools > Axes Scaling**.

Visualization

Name — Window name

'Array Plot' (default) | character vector | string

Specify the name of the scope as a character vector. This name appears as the title of the scope's figure window. To specify a title of a scope plot, use the Title property.

Data Types: char | string

Position — Scope window position in pixels

screen center (default) | [left bottom width height]

Specify, in pixels, the size and location of the scope window as a four-element vector of the form [left bottom width height]. By default, the scope window appears in the center of your screen with a width of 800 pixels and height of 450 pixels. The default values for this property may change depending on your screen resolution.

ReduceUpdates — Reduce updates to improve performance

true (default) | false

- true — The scope logs data for later use and updates the window periodically.
- false — The scope updates every time the scope is called.

The simulation speed is faster when this property is set to true.

Tunable: Yes

UI Use

Select **Simulation > Reduce Updates to Improve Performance**.

MaximizeAxes — Maximize axes control

'Auto' (default) | 'On' | 'Off'

Specify whether to display the scope in maximized-axes mode. In this mode, the axes are expanded to fit into the entire display. To conserve space, labels do not appear in each

display. Instead, tick-mark values appear on top of the plotted data. You can select one of the following options:

- 'Auto' — The axes appear maximized in all displays only if the `Title` and `YLabel` properties are empty for every display. If you enter any value in any display for either of these properties, the axes are not maximized.
- 'On' — The axes appear maximized in all displays. Any values entered into the `Title` and `YLabel` properties are hidden.
- 'Off' — None of the axes appear maximized.

Tunable: Yes

UI Use

Open the **Configuration Properties**. On the **Main** tab, set **Maximize axes**.

Title — Display title

' ' (default) | character vector | string

Specify the display title as a character vector or string. Enter %<SignalLabel> to use the signal labels as the axes titles.

Tunable: Yes

UI Use

Open the **Configuration Properties**. On the **Display** tab, set **Title**.

ShowLegend — Show legend

false (default) | true

To show a legend with the input names, set this property to `true`.

From the legend, you can control which signals are visible. This control is equivalent to changing the visibility in the **Style** dialog box. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again. To show only one signal, right-click the signal name. To show all signals, press **Esc**.

Tunable: Yes

UI Use

Open the **Configuration Properties**. On the **Display** tab, select **Show legend**.

ChannelNames — Channel names

empty cell (default) | cell array of character vectors | cell array of strings

Specify the input channel names as a cell array of character vectors or strings. The names appear in the legend, **Style** dialog box, and **Measurements** panels. If you do not specify names, the channels are labeled as Channel 1, Channel 2, etc.

Tunable: Yes

Dependency

To see channel names, set `ShowLegend` to `true`.

UI Use

Show the legend and double-click the channel name.

ShowGrid — Display grid

`true` (default) | `false`

Set this property to `true` to show gridlines on the plot.

Tunable: Yes

UI Use

Open the **Configuration Properties**. On the **Display** tab, set **Show grid**.

PlotAsMagnitudePhase — Plot signal as magnitude and phase

`false` (default) | `true`

When you set this property to `true`, the scope plots the magnitude and phase of the input signal on two separate axes within the same active display. When you set this property to `false`, the scope plots the real and imaginary parts of the input signal on two separate axes within the same active display.

This property is useful for complex-valued input signals. Turning on this property affects the phase for real-valued input signals. When the amplitude of the input signal is nonnegative, the phase is 0 degrees. When the amplitude of the input signal is negative, the phase is 180 degrees.

Tunable: Yes

UI Use

Open the **Configuration Properties**. On the **Display** tab, select **Plot signals as magnitude and phase**.

XLabel — X-axis label

' ' (default) | character vector

Specify the text for the scope to display below the *x*-axis.

Tunable: Yes

UI Use

Open the **Configuration Properties**. On the **Display** tab, set **X-label**.

YLabel — Y-axis label

'Amplitude' (default) | character vector | string

Specify the text for the scope to display to the left of the *y*-axis.

Tunable: Yes

Dependencies

This property applies only when `PlotAsMagnitudePhase` is `false`. When `PlotAsMagnitudePhase` is `true`, the two *y*-axis labels are read-only values. The *y*-axis labels are set to 'Magnitude' and 'Phase' for the magnitude plot and the phase plot, respectively.

UI Use

Open the **Configuration Properties**. On the **Display** tab, set **Y-Label**.

Data Types: char | string

YLimits — Y-axis limits

[-10,10] (default) | [ymin, ymax]

Specify the *y*-axis limits as a two-element numeric vector, [ymin, ymax].

If `PlotAsMagnitudePhase` is `false`, the default is [-10,10]. If `PlotAsMagnitudePhase` is `true`, the default is [0,10].

Tunable: Yes

Dependencies

When `PlotAsMagnitudePhase` is `true`, this property specifies the y -axis limits of only the magnitude plot. The y -axis limits of the phase plot are always `[-180, 180]`.

UI Use

Open the **Configuration Properties**. On the **Display** tab, set **Y-limits (Minimum)** and **Y-limits (Maximum)**.

Usage

Note For versions earlier than R2016b, use the `step` function to run the System object™ algorithm. The arguments to `step` are the object you created, followed by the arguments shown in this section.

For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Syntax

```
scope(signal)
scope(signal1, signal2, ..., signalN)
```

Description

`scope(signal)` displays the signal in the Array Plot.

`scope(signal1, signal2, ..., signalN)` displays multiple signals in the Array Plot. The signals must have the same frame length, but can vary in number of channels. You must set the `NumInputPorts` property to enable multiple input signals.

Input Arguments

signal — Input signal or signals to visualize
scalar | vector | matrix

Specify one or more input signals to visualize in the `dsp.ArrayPlot`. Signals can have a different number of channels, but they must have the same frame length.

Example: `scope(signal1, signal2)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `string` | `struct` | `table` | `cell` | `categorical` | `datetime` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to Scopes

`show` Display scope window
`hide` Hide scope window

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>clone</code>	Create duplicate System object
<code>getNumInputs</code>	Number of inputs required to call the System object
<code>getNumOutputs</code>	Number of outputs from calling the System object
<code>isLocked</code>	Determine if System object is locked
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Plot a Gaussian Distribution

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Create a new Array Plot object.

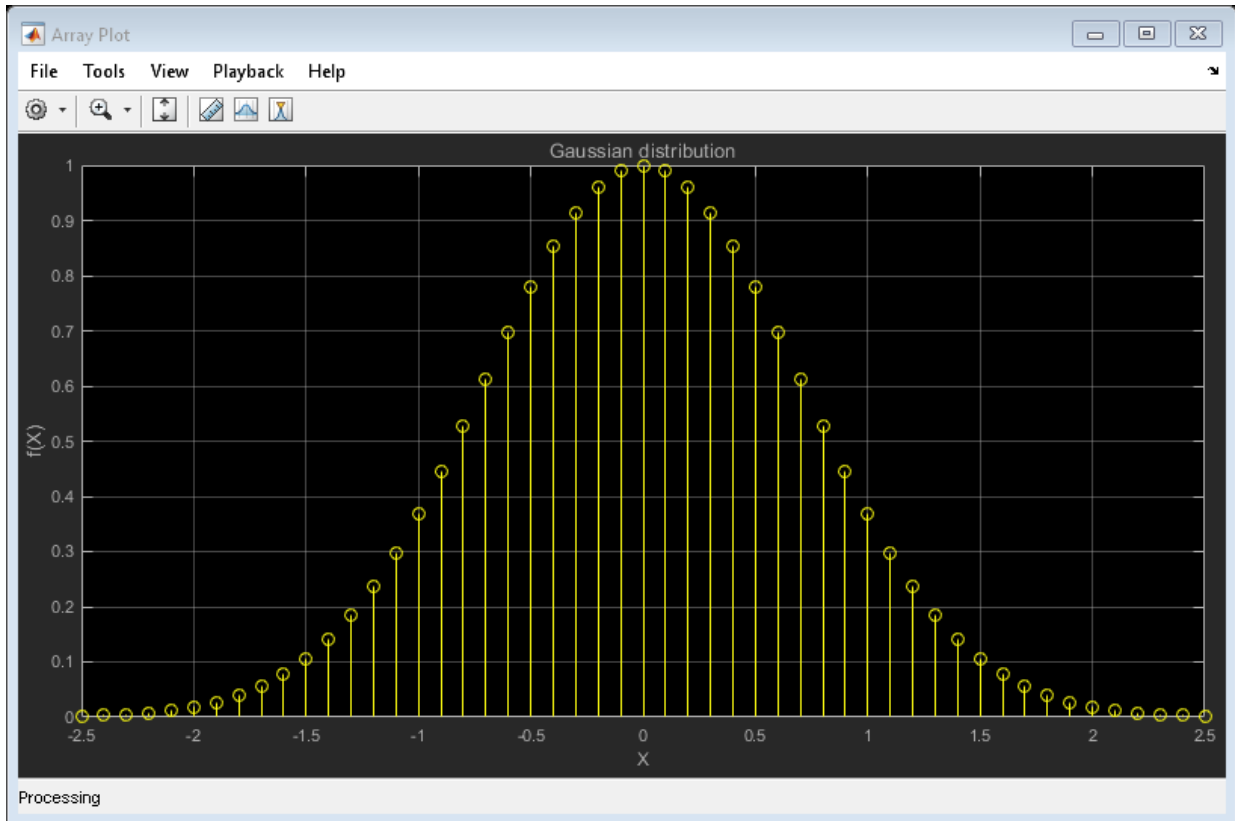

```
scope = dsp.ArrayPlot;
```

Configure the properties of the Array Plot object for a Gaussian distribution.

```
scope.YLimits = [0 1];  
scope.XOffset = -2.5;  
scope.SampleIncrement = 0.1;  
scope.Title = 'Gaussian distribution';  
scope.XLabel = 'X';  
scope.YLabel = 'f(X)';
```

Call the Array Plot object to plot a Gaussian distribution.

```
scope(exp(-(-2.5:.1:2.5).*(-2.5:.1:2.5))')
```

Plot Changing Filter Weights

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

View least mean squares (LMS) adaptive filter weights on the Array Plot figure. Watch the filter weights change as they adapt to filter a noisy input signal.

Create an LMS adaptive filter System object.

```
lmsFilter = dsp.LMSFilter(40,'Method','Normalized LMS','StepSize',0.002);
```

Create and configure a `dsp.AudioFileReader` System object to read the input signal from the specified audio file.

```
signalSource = dsp.AudioFileReader('dspafx_8000.wav', ...  
    'SamplesPerFrame', 40, ...  
    'PlayCount', Inf, ...  
    'OutputDataType', 'double');
```

Create and configure a `dsp.FIRFilter` System object to filter random white noise, creating colored noise.

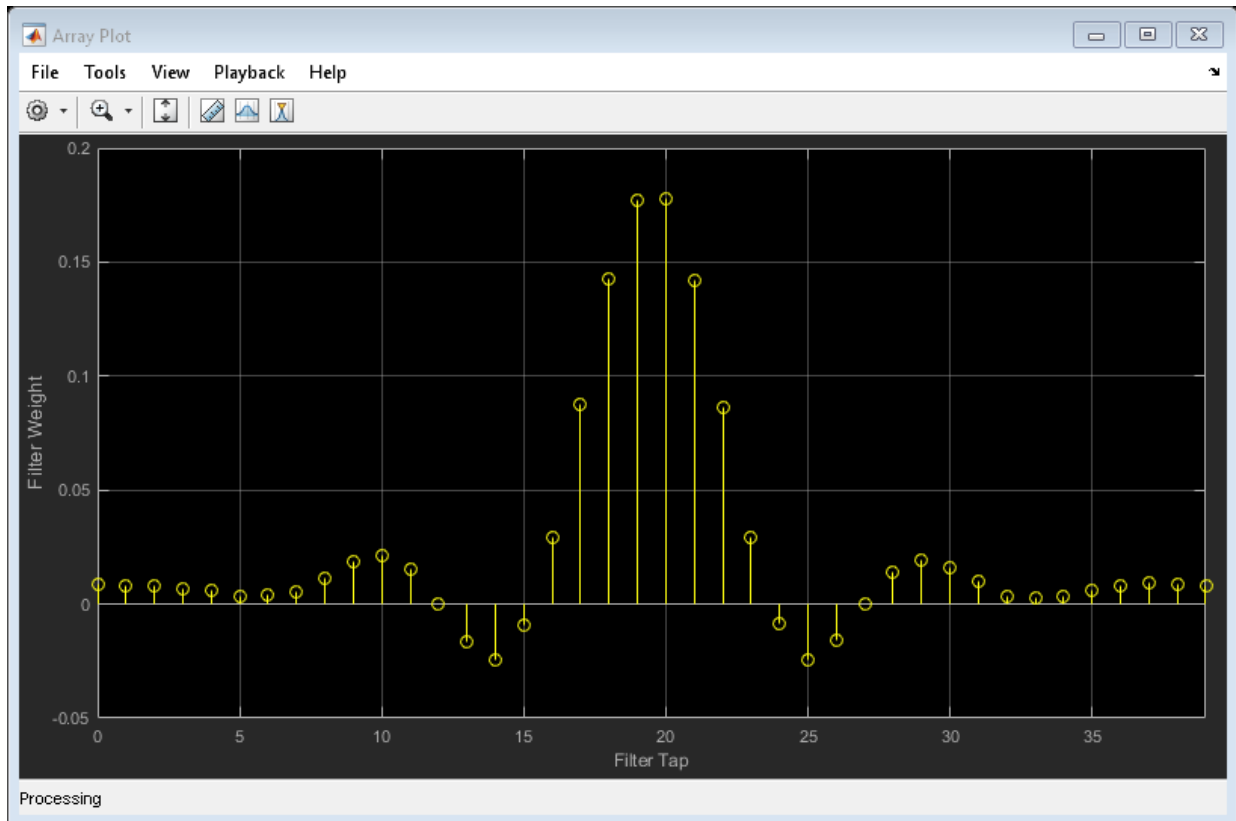

```
firFilter = dsp.FIRFilter('Numerator', fir1(39, 0.25));
```

Create and configure an Array Plot System object to display the adaptive filter weights.

```
scope = dsp.ArrayPlot('XLabel', 'Filter Tap', ...  
    'YLabel', 'Filter Weight', ...  
    'YLimits', [-0.05 0.2]');
```

Plot the LMS filter weights as they adapt to a desired signal. Read from the audio file, produce random data, and filter the random data. Update the filter weights and plot the filter weights.

```
numplays = 0;  
while numplays < 3  
    [y, eof] = signalSource();  
    noise = rand(40, 1);  
    noisefilt = firFilter(noise);  
    desired = y + noisefilt;  
    [~, ~, wts] = lmsFilter(noise, desired);  
    scope(wts);  
    numplays = numplays + eof;  
end
```

- “Visualize Central Limit Theorem in Array Plot”

Tips

- To close the Array Plot window and clear its associated data, use the MATLAB `clear` function.
- To hide or show the Array Plot window, use the `hide` and `show` functions.
- Use the MATLAB `mcc` function to compile code containing an Array Plot.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Supports MEX code generation by treating the calls to the object as extrinsic. Does not support code generation for standalone applications.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

dsp.ArrayVectorAdder System object

Package: dsp

Add array to vector along specified dimension

Description

The `ArrayVectorAdder` object adds an N-D array to a vector along a specified dimension. The length of the vector must equal the size of the N-D array along the specified dimension.

To add an N-D array to a vector along a specified dimension:

- 1 Define and set up your array-vector addition object. See “Construction” on page 4-81.
- 2 Call `step` to add the N-D array according to the properties of `dsp.ArrayVectorAdder`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`ava = dsp.ArrayVectorAdder` returns an array-vector addition object, `ava`, that adds a vector to an N-D array along the first dimension.

`ava = dsp.ArrayVectorAdder('PropertyName',PropertyValue, ...)` returns an array-vector addition object, `ava`, with each property set to the specified value.

Properties

Dimension

Dimension along which to add vector elements to input

Specify the dimension along which to add the input array to the elements of the vector as a positive integer. The length of the vector must match the size of the N-D array along the specified dimension. The default is 1.

VectorSource

Source of vector

Specify the source of the vector values as `| Input port | Property |`. The default is `Input port`.

Vector

Vector values

Specify the vector values. This property applies only when you set the `VectorSource` property to `Property`. The default is `[0.5 0.25]`. This property is tunable.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as | Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |. The default is Floor. This property applies only if the object is not in full precision mode.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as | Wrap | Saturate |. The default is Wrap. This property applies only if the object is not in full precision mode.

VectorDataType

Vector word and fraction lengths

Specify the vector fixed-point data type as | Same word length as input | Custom |. This property applies when you set the VectorSource property to Property. The default is Same word length as input.

CustomVectorDataType

Vector word and fraction lengths

Specify the vector fixed-point type as a numeric type object with a Signedness of Auto. This property applies when you set the VectorSource property to Property and the VectorDataType property to Custom. The default is numeric type ([], 16, 15).

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as | Full precision | Same as first input | Custom |. The default is Full precision.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when the `AccumulatorDataType` property is `Custom`. The default is `numericType([], 32, 30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as | Same as accumulator | Same as first input | Custom |.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when the “OutputDataType” on page 4-0 property is `Custom`. The default is `numericType([], 16, 15)`.

Methods

`step` Add vector to N-D array

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

Add a Vector To a Matrix

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Add a 2-by-1 vector to a 2-by-2 matrix along the first dimension of the array.

```
ava = dsp.ArrayVectorAdder;  
a = ones(2);  
x = [1 2]';  
y = ava(a, x);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Array-Vector Add block reference page. The object properties correspond to the block parameters, except:

The array-vector addition object does not have **Minimum** or **Maximum** options for data output.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

`dsp.ArrayVectorDivider` | `dsp.ArrayVectorMultiplier` |
`dsp.ArrayVectorSubtractor`

Introduced in R2012a

step

System object: dsp.ArrayVectorAdder

Package: dsp

Add vector to N-D array

Syntax

$Y = \text{step}(\text{ava}, A)$

$Y = \text{step}(\text{ava}, A, V)$

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

$Y = \text{step}(\text{ava}, A)$ returns Y , the result of adding the input array A to the elements of the vector specified in the `Vector` property along the specified dimension when the `VectorSource` property is `Property`. The length of the vector specified in the `Vector` property must equal the length of the specified dimension of A .

$Y = \text{step}(\text{ava}, A, V)$ returns Y , the result of adding the input array A to the elements of the input vector V along the specified dimension when the `VectorSource` property is `Input port`. The length of the input V must equal the length of the specified dimension of A .

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as

dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.ArrayVectorDivider System object

Package: dsp

Divide array by vector along specified dimension

Description

The `ArrayVectorDivider` object divides an array by a vector along a specified dimension.

To divide an array by a vector along a specified dimension:

- 1 Define and set up your array-vector division object. See “Construction” on page 4-89.
- 2 Call `step` to divide the array according to the properties of `dsp.ArrayVectorDivider`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`avd = dsp.ArrayVectorDivider` returns an array-vector division object, `avd`, that divides an input array by the elements of a vector along the first dimension of the array.

`avd = dsp.ArrayVectorDivider('PropertyName', PropertyValue, ...)` returns an array-vector division object, `avd`, with each property set to the specified value.

Properties

Dimension

Dimension along which to divide input by vector elements

Specify the dimension along which to divide the input array by the elements of a vector as a positive integer. The default is 1.

VectorSource

Source of vector

Specify the source of the vector values as | `Input port` | `Property` |. The default is `Input port`.

Vector

Vector values

Specify the vector values. This property applies when you set the `VectorSource` property to `Property`. The default is `[0.5 0.25]`. This property is tunable.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as | `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as | `Wrap` | `Saturate` |. The default is `Wrap`.

VectorDataType

Vector word and fraction lengths

Specify the vector fixed-point mode as | Same word length as input | Custom |. This property applies when you set the `VectorSource` property to `Property`. The default is `Same word length as input`.

CustomVectorDataType

Vector word and fraction lengths

Specify the vector fixed-point data type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `VectorSource` property to `Property` and the `VectorDataType` property to `Custom`. The default is `numerictype([],16,15)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as | Same as first input | Custom |. The default is `Same as first input`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the “`OutputDataType`” on page 4-0 property to `Custom`. The default is `numerictype([],16,15)`.

Methods

`step` Divide array by vector

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object

Common to All System Objects	
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Divide a Matrix By a Vector

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
avd = dsp.ArrayVectorDivider;  
a = ones(2)
```

```
a =
```

```
    1    1  
    1    1
```

```
x = [2 3]'
```

```
x =
```

```
    2  
    3
```

```
y = avd(a, x)
```

```
y =
```

```
    0.5000    0.5000  
    0.3333    0.3333
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Array-Vector Divide block reference page. The object properties correspond to the block parameters, except:

The array-vector division object does not have **Minimum** or **Maximum** options for data output.

dsp.ArrayVectorMultiplier System object

Package: dsp

Multiply array by vector along specified dimension

Description

The `ArrayVectorMultiplier` object multiplies an array by a vector along a specified dimension.

To multiply an array by a vector along a specified:

- 1 Define and set up your array-vector multiplication object. See “Construction” on page 4-96.
- 2 Call `step` to multiply the array according to the properties of `dsp.ArrayVectorMultiplier`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`avm = dsp.ArrayVectorMultiplier` returns an array-vector multiplication object, `avm`, that multiplies an input N-D array by the elements of a vector along the second dimension.

`avm = dsp.ArrayVectorMultiplier('PropertyName',PropertyValue,...)` returns an array-vector multiplication object, `avm`, with each property set to the specified value.

Properties

Dimension

Dimension along which to multiply input by vector elements

Specify the dimension along which to multiply the input array by the elements of vector as a positive integer. The default is 2.

VectorSource

Source of vector

Specify the source of the vector values as one of `Input port` or `Property`. The default is `Input port`.

Vector

Vector to multiply array

Specify the vector by which to multiply the array. This property applies when you set the `VectorSource` property to `Property`. The default is `[0.5 0.25]`. This property is tunable.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, `Zero`. The default is `floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

VectorDataType

Vector word and fraction lengths

Specify the vector fixed-point data type as `Same word length as input`, `Custom`. This property applies when you set the `VectorSource` property to `Property`. The default is `Same word length as input`.

CustomVectorDataType

Vector word and fraction lengths

Specify the vector fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `VectorSource` property to `Property` and the `VectorDataType` property to `Custom`. The default is `numericType([], 16, 15)`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as `Full precision`, `Same as first input`, or `Custom`. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as `Full precision`, `Same as product`, `Same as first input`, or `Custom`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as `Same as product`, `Same as first input`, or `Custom`. The default is `Same as product`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numericType([],16,15)`.

Methods

`step` Multiply array by vector

Common to All System Objects	
<code>clone</code>	Create System object with same property values

dsp.ArrayVectorSubtractor System object

Package: dsp

Subtract vector from array along specified dimension

Description

The `ArrayVectorSubtractor` object subtracts a vector from an N-D array along a specified dimension.

To subtract a vector from an N-D array along a specified dimension:

- 1 Define and set up your array-vector subtraction object. See “Construction” on page 4-103.
- 2 Call `step` to subtract the vector according to the properties of `dsp.ArrayVectorSubtractor`. The behavior of `step` is specified to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`avs = dsp.ArrayVectorSubtractor` returns an array-vector subtraction object, `avs`, that subtracts the elements of a vector from an N-D input array along the first dimension.

`avs = dsp.ArrayVectorSubtractor('PropertyName',PropertyValue,...)` returns an array-vector subtraction object, `avs`, with each property set to the specified value.

Properties

Dimension

Dimension along which to subtract vector elements from input

Specify the dimension along which to subtract the elements of the vector from the input array as an integer-valued scalar greater than 0. The default is 1.

VectorSource

Source of vector

Specify the source of the vector values as one of `Input port` or `Property`. The default is `Input port`.

Vector

Vector values

Specify the vector values. This property applies when you set the `VectorSource` property to `Property`. The default is `[0.5 0.25]`. This property is tunable.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. This property applies only if the object is not in full precision mode.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

VectorDataType

Vector word and fraction lengths

Specify the vector fixed-point data type as `Same word length as input` or `Custom`. This property applies when you set the `VectorSource` property to `Property`. The default is `Same word length as input`.

CustomVectorDataType

Vector word and fraction lengths

Specify the vector fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `VectorSource` property to `Property` and the `VectorDataType` property to `Custom`. The default is `numericType([],16,15)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `Full precision`, `Same as first input`, or `Custom`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as `Same as accumulator`, `Same as first input`, or `Custom`. The default is `Same as accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the “OutputDataType” on page 4-0 property to `Custom`. The default is `numericType([], 16, 15)`.

Methods

`step` Subtract vector from array along specified dimension

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

Subtract Vector From Matrix

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
avs = dsp.ArrayVectorSubtractor;  
a = ones(2);  
x = [1 2]';  
y = avs(a, x)  
  
y =  
  
     0     0  
    -1    -1
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Array-Vector Subtract block reference page. The object properties correspond to the block parameters, except:

The array-vector subtraction object does not have **Minimum** or **Maximum** options for data output.

Extended Capabilities

Package: `dsp`

Subtract vector from array along specified dimension

Syntax

`Y = step(avs, A, V)`

`Y = step(avs, A)`

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

`Y = step(avs, A, V)` returns `Y`. The value of `Y` results from subtracting the elements of input vector `V` from the input array `A` along the specified dimension when the `VectorSource` property is `Input port`. The length of the input `V` must equal the length of the specified dimension of `A`.

`Y = step(avs, A)` returns `Y`. The value of `Y` results from subtracting the elements of the vector specified in the `Vector` property from the input array `A` along the specified dimension when the `VectorSource` property is `Property`. The length of the vector specified in the `Vector` property must equal the length of the specified dimension of `A`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as

dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.AsyncBuffer System object

Package: dsp

FIFO buffer

Description

The `dsp.AsyncBuffer` System object writes samples to and reads samples from a first-in, first-out (FIFO) buffer. The `write` method writes data to the buffer and the `read` method reads data from the buffer. When creating the object, you can set the number of samples (rows) of the buffer using the `Capacity` property. The number of channels (columns) is set during the first call to `write`. Initialize the buffer by calling `write` or `setup` before the first call to `read`.

The data that you write occupies the next available space in the buffer. If the buffer is full and all the data within it is unread, that is, if `asyncBuff.NumUnreadSamples == asyncBuff.Capacity`, the object overwrites the oldest data with any new data that comes in. The buffer removes data only when the data is overwritten, so you can reread data from the past. The `dsp.AsyncBuffer` object supports writing and reading variable frame size signals. For examples, see “Read Variable Frame Sizes from Buffer” on page 4-112 and “Write Variable Frame Sizes to Buffer” on page 4-114.

To write and read samples from a FIFO buffer:

- 1 Create a `dsp.AsyncBuffer` object and set the properties of the object.
- 2 Call `write` to write samples to the buffer.
- 3 Call `read` to read samples from the buffer.

Construction

`asyncBuff = dsp.AsyncBuffer` returns an `AsyncBuffer` object, `asyncBuff`, using the default properties.

`asyncBuff = dsp.AsyncBuffer(cap)` sets the `Capacity` property to `cap`.

`asyncBuff = dsp.AsyncBuffer(Name, Value)` specifies properties using `Name, Value` pairs. Unspecified properties have default values.

Example:

```
asyncBuff = dsp.AsyncBuffer(200000);
```

Properties

Capacity — Number of writable/readable rows in buffer

192000 (default) | positive integer greater than or equal to 2

Number of writable/readable rows in buffer. The number of rows during each write to the buffer must not exceed the capacity of the buffer. If the buffer is full and all the data within is unread, the object overwrites the oldest data with any new data that comes in. The `CumulativeOverrun` property returned by the `info` method gives the number of samples overrun per channel since the last call to `reset`. The number of samples overrun is the number of unread samples overwritten.

By default, this property is of data type `int32`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

NumUnreadSamples — Number of unread samples in each channel

0 (default) | scalar greater than or equal to 0

This property is read-only.

Number of unread samples in each channel (column) of the buffer. The total number of unread samples in the buffer is `NumUnreadSamples × numChann`, where `numChann` is the number of channels in the buffer.

The `CumulativeUnderrun` property returned by the `info` method gives the number of samples underrun per channel since the last call to `reset`. Underrun occurs if you attempt to read more samples than available.

Data Types: `int32`

Limitations

Before calling the `read` method, you must initialize the buffer by calling either the `write` or `setup` method. For an example, see “Why Does the `dsp.AsyncBuffer` Object Error When You Call `read` Before `write`?”

Methods

<code>info</code>	Get cumulative overrun and underrun
<code>read</code>	Read data from buffer
<code>reset</code>	Reset internal states of System object
<code>write</code>	Write data to buffer

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

Read Variable Frame Sizes from Buffer

The `dsp.AsyncBuffer` System object™ supports reading variable frame sizes from the buffer.

Create a `dsp.AsyncBuffer` System object. The input is white Gaussian noise with zero mean, a standard deviation of 1, and a frame size of 512 samples. Write the input to the buffer using the `write` method. Store the data that is read from the buffer in `outTotal`.

```
asyncBuff = dsp.AsyncBuffer;  
input = randn(512,1);  
write(asyncBuff,input);  
  
outTotal = [];  
plot(input)  
hold on
```

Plot the input signal and data that is read from the buffer in the same plot. Read data from the buffer until all samples are read. In each loop of iteration, `randi` determines the number of samples to read. Therefore, the signal is read in as a variable-size signal.

```
while asyncBuff.NumUnreadSamples ~= 0  
    numToRead = randi([1,64]);
```

```
    out = read(asyncBuff,numToRead);  
    outTotal = [outTotal;out];  
    plot(outTotal,'r');  
    pause(0.2)  
end  
hold off
```

Write Variable Frame Sizes to Buffer

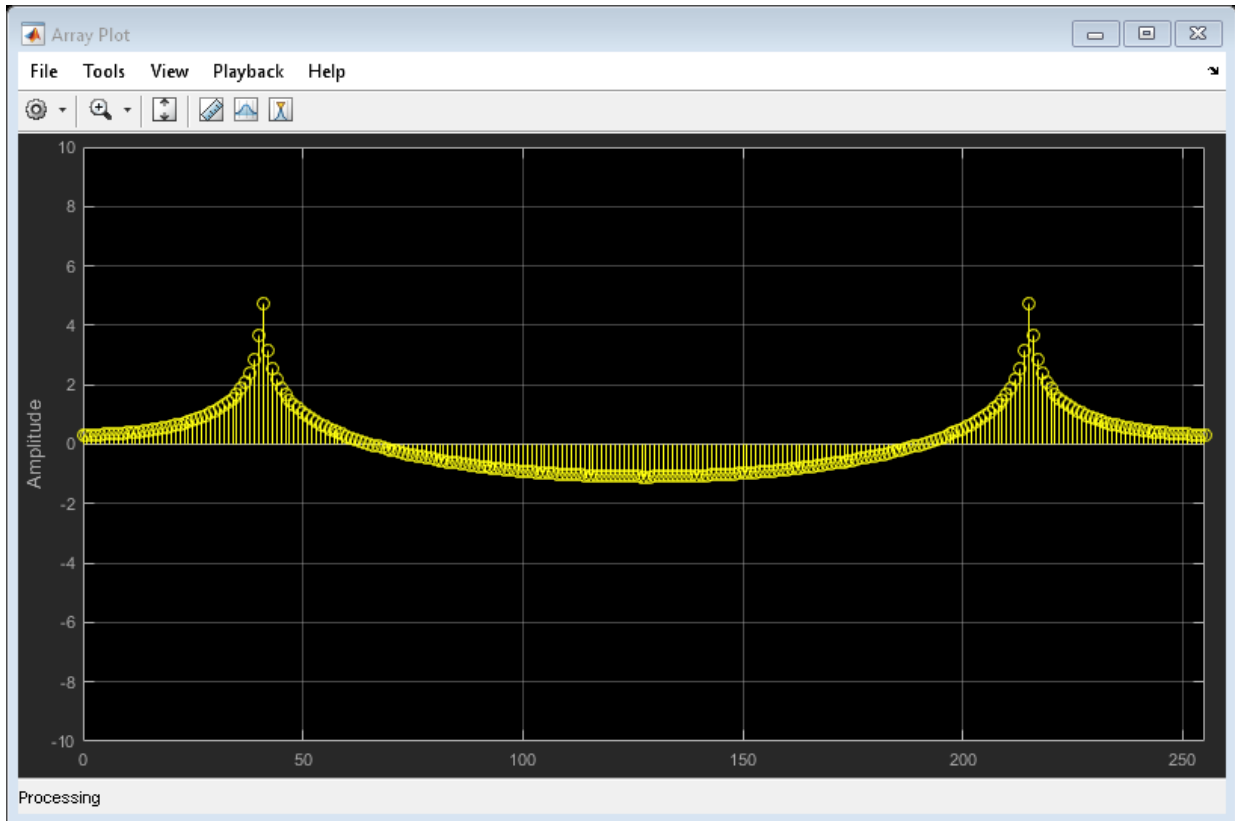

Write a sine wave of variable frame size to the buffer. Compute the FFT of the sine wave and visualize the result on an array plot.

Initialize the `dsp.AsyncBuffer`, `dsp.ArrayPlot`, and `dsp.FFT` System objects.

```
asynBuff = dsp.AsyncBuffer;  
plotter = dsp.ArrayPlot;  
fftObj = dsp.FFT('FFTLengthSource','Property','FFTLength',256);
```

The sine wave is generated using the `sin` function in MATLAB®. The `start` and `finish` variables mark the start and finish indices of each frame. If enough data is cached, read from the buffer and perform the FFT. View the FFT on an array plot.

```
start = 1;  
  
for Iter = 1 : 2000  
    numToWrite = randi([200,800]);  
    finish = start + numToWrite;  
  
    inputData = sin(start:finish)';  
    start = finish + 1;  
  
    write(asynBuff,inputData);  
    while asynBuff.NumUnreadSamples >= 256  
        x = read(asynBuff,256);  
        X = abs(fftObj(x));  
        plotter(log(X));  
    end  
end
```

Introduced in R2017a

info

System object: dsp.AsyncBuffer

Package: dsp

Get cumulative overrun and underrun

Syntax

```
S = info(asyncBuff)
```

Description

`S = info(asyncBuff)` returns a structure, `S`, containing the cumulative overrun and underrun information of the `dsp.AsyncBuffer` System object, `asyncBuff`.

The `CumulativeOverrun` property gives the number of samples overrun per channel since the last call to `reset`. The number of samples overrun is the number of unread samples overwritten. The `CumulativeUnderrun` property gives the number of samples underrun per channel since the last call to `reset`. Underrun occurs if you attempt to read more samples than available. The `CumulativeOverrun` and `CumulativeUnderrun` properties are of data type `int32`.

Introduced in R2017a

read

System object: dsp.AsyncBuffer

Package: dsp

Read data from buffer

Syntax

```
out = read(asyncBuff)
out = read(asyncBuff, NumRows)
out = read(asyncBuff, NumRows, Overlap)
[out, nUnderrun] = read(asyncBuff, ___)
```

Description

`out = read(asyncBuff)` returns all unread samples from the buffer, `asyncBuff`.

`out = read(asyncBuff, NumRows)` returns `NumRows` samples from each channel (column) of the buffer. If the requested number of samples is greater than the number of unread samples, the output is zero-padded.

`out = read(asyncBuff, NumRows, Overlap)` returns `NumRows` samples from each channel and overlaps previously read samples by `Overlap`. The total number of samples read is $\text{NumRows} \times \text{NumChann}$, where `NumChann` is the number of channels in the buffer. The total number of new samples read is $(\text{NumRows} - \text{Overlap}) \times \text{NumChann}$. If the overlap portion contains samples that are overwritten, and are therefore not contiguously written, the output is zero-padded.

`[out, nUnderrun] = read(asyncBuff, ___)` additionally returns the number of rows zero-padded if underrun occurred, using any of the previous arguments. Underrun occurs if you attempt to read more samples than available. Samples that are zero-padded in overlapped portions are not counted as underrun. `nUnderrun` is of data type `int32`.

Introduced in R2017a

reset

System object: dsp.AsyncBuffer

Package: dsp

Reset internal states of System object

Syntax

```
reset(asyncBuff)
```

Description

`reset(asyncBuff)` returns the buffer to its initial condition, and resets the `CumulativeOverrun` and `CumulativeUnderrun` properties.

Introduced in R2017a

write

System object: dsp.AsyncBuffer

Package: dsp

Write data to buffer

Syntax

```
nOverrun = write(asyncBuff,x)
```

Description

`nOverrun = write(asyncBuff,x)` writes the input array, `x`, to the buffering object, `asyncBuff`. The object returns the number of samples overrun in the current call to `write`. The number of samples overrun is the number of unread samples overwritten. If `x` is a multichannel input, then `nOverrun` is the number of rows of data overrun. `nOverrun` is of data type `int32`.

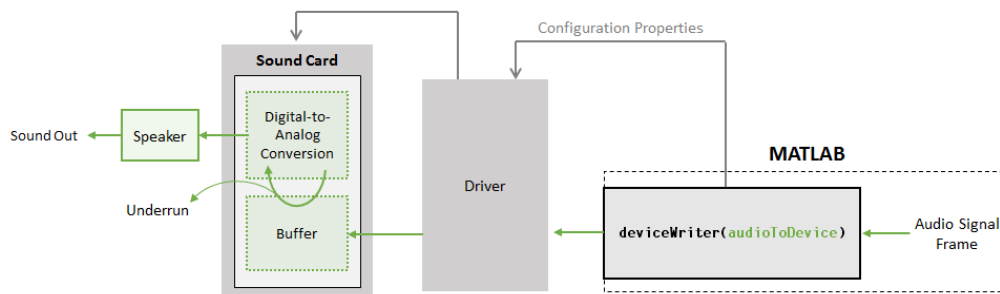

Introduced in R2017a

audioDeviceWriter System object

Play to sound card

Description

The `audioDeviceWriter` System object writes audio samples to an audio output device. Properties of the audio device writer specify the driver, the device, and device attributes such as sample rate, bit depth, and buffer size.

Data Flow of Audio Device Writer

- Call the object to input an audio signal frame to the `audioDeviceWriter`.
- The `audioDeviceWriter` uses the specified driver to pass the frame (device input) to the buffer of your specified audio device.
- The audio device performs digital-to-analog conversion at the specified sample rate and bit depth.
- The audio device outputs an analog chunk to your speaker.

To stream data to an audio device:

- 1 Create the `audioDeviceWriter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

Creation

Syntax

```
deviceWriter = audioDeviceWriter  
deviceWriter = audioDeviceWriter(sampleRateValue)  
deviceWriter = audioDeviceWriter(____, Name, Value)
```

Description

`deviceWriter = audioDeviceWriter` returns a System object, `deviceWriter`, that writes audio samples to an audio output device in real time.

`deviceWriter = audioDeviceWriter(sampleRateValue)` sets the `SampleRate` property to `sampleRateValue`.

`deviceWriter = audioDeviceWriter(____, Name, Value)` sets each property `Name` to the specified `Value`. Unspecified properties have default values.

Example: `deviceWriter = audioDeviceWriter(48000, 'BitDepth', '8-bit integer')` creates a System object, `deviceWriter`, that operates at a 48 kHz sample rate and an 8-bit integer bit depth.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects \(MATLAB\)](#).

Driver — Driver used to access audio device (Windows only)

'DirectSound' (default) | 'ASIO' | 'WASAPI'

Driver used to access your audio device, specified as 'DirectSound', 'ASIO', or 'WASAPI'.

- ASIO drivers do not come pre-installed on Windows machines. To use the 'ASIO' driver option, install an ASIO driver outside of MATLAB.

Note If `Driver` is specified as 'ASIO', use `asiosettings` to set the sound card buffer size to the buffer size of your `audioDeviceWriter` System object.

- WASAPI drivers are supported for exclusive-mode only.

ASIO and WASAPI drivers do not provide sample rate conversion. For ASIO and WASAPI drivers, set `SampleRate` to a sample rate supported by your audio device.

This property applies only on Windows machines. Linux machines always use the ALSA driver. Mac machines always use the CoreAudio driver.

To specify nondefault `Driver` values, you must have an Audio System Toolbox licence. If the toolbox is not installed, specifying nondefault `Driver` values returns an error.

Data Types: `char`

Device — Device used to play audio samples

default audio device (default) | character vector

Device used to play audio samples, specified as a character vector. Use `getAudioDevices` to list available devices for the selected driver.

Data Types: `char`

SampleRate — Sample rate of signal sent to audio device (Hz)

44100 (default) | positive integer

Sample rate of signal sent to audio device, in Hz, specified as a positive integer. The range of `SampleRate` depends on your audio hardware.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

BitDepth — Data type used by the device

'16-bit integer' (default) | '8-bit integer' | '24-bit integer' | '32-bit float'

Data type used by the device, specified as a character vector. Before performing digital-to-analog conversion, the input data is cast to a data type specified by `BitDepth`.

To specify a nondefault `BitDepth`, you must have an Audio System Toolbox licence. If the toolbox is not installed, specifying a nondefault `BitDepth` returns an error.

Data Types: char

SupportVariableSizeInput — Support variable frame size

false (default) | true

Option to support variable frame size, specified as `true` or `false`.

- `false` — If the `audioDeviceWriter` object is locked, the input must have the same frame size at each call. The buffer size of your audio device is the same as the input frame size.
- `true` — If the `audioDeviceWriter` object is locked, the input frame size can change at each call. The buffer size of your audio device is specified through the `BufferSize` property.

Data Types: char

BufferSize — Buffer size of audio device

4096 (default) | positive integer

Buffer size of audio device, specified as a positive integer.

Note If `Driver` is specified as 'ASIO', open the ASIO UI to set the sound card buffer size to the `BufferSize` value of your `audioDeviceWriter` System object.

Dependencies

To enable this property, set `SupportVariableSizeInput` to `true`.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

ChannelMappingSource — Source of mapping between input matrix and device channels

'Auto' (default) | 'Property'

Source of mapping between columns of input matrix and channels of audio output device, specified as 'Auto' or 'Property'.

- 'Auto' — Default settings determine the mapping between columns of input matrix and channels of audio output device. For example, suppose that your input is a matrix with four columns, and your audio device has four channels available. Column 1 of your input data writes to channel 1 of your device, column 2 of your input data writes to channel 2 of your device, and so on.
- 'Property' — The ChannelMapping property determines the mapping between columns of input matrix and channels of audio output device.

Data Types: char

ChannelMapping — Nondefault mapping between input matrix and device channels

[1:MaximumOutputChannels] (default) | scalar | vector

Nondefault mapping between columns of input matrix and channels of output device, specified as a scalar or vector of valid channel indices.

To selectively map between columns of the input matrix and your sound card's output channels, you must have an Audio System Toolbox licence. If the toolbox is not installed, specifying a nondefault ChannelMapping returns an error.

Dependencies

To enable this property, set ChannelMappingSource to 'Property'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Usage

Note For versions earlier than R2016b, use the `step` function to run the System object™ algorithm. The arguments to `step` are the object you created, followed by the arguments shown in this section.

For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Syntax

```
numUnderrun = deviceWriter(audioToDevice)
```

Description

`numUnderrun = deviceWriter(audioToDevice)` writes one frame of audio samples, `audioToDevice`, to the selected audio device and returns the number of audio samples underrun since the last call to `deviceWriter`.

Note: When you call the `audioDeviceWriter` System object, the audio device specified by the `Device` property is locked. An audio device can be locked by only one `audioDeviceWriter` at a time. To release the audio device, call `release` on your `audioDeviceWriter` System object.

Input Arguments

audioToDevice — Audio to device

matrix

Audio signal to write to device, specified as a matrix. The columns of the matrix are treated as independent audio channels.

If `audioToDevice` is of data type `'double'` or `'single'`, the audio device writer clips values outside the range `[-1, 1]`. For other data types, the allowed input range is `[min, max]` of the specified data type.

Data Types: `single` | `double` | `int16` | `int32` | `uint8`

Output Arguments

numUnderrun — Number of samples underrun

scalar

Number of samples by which the audio device writer queue was underrun since the last call to `deviceWriter`.

Data Types: `uint32`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `audioDeviceWriter`

`getAudioDevices` List available audio devices
`info` Characteristic information about System object

Common to All System Objects

`clone` Create duplicate System object
`isLocked` Determine if System object is locked
`release` Release resources and allow changes to System object property values and input characteristics
`reset` Reset internal states of System object
`step` Run System object algorithm

Examples

Read from File and Write to Audio Device

Read an MP3 audio file and play it through your default audio output device.

Create a `dsp.AudioFileReader` System object™ with default settings. Use the `audioinfo` function to return a structure containing information about the audio file.

```
fileReader = dsp.AudioFileReader('speech_dft.mp3');  
fileInfo = audioinfo('speech_dft.mp3');
```

Create an `audioDeviceWriter` System object and specify the sample rate. Call `setup` to reduce the computational load of initialization in an audio stream loop.

```
deviceWriter = audioDeviceWriter(...  
    'SampleRate', fileInfo.SampleRate);  
setup(deviceWriter, ...  
    zeros(fileReader.SamplesPerFrame, fileInfo.NumChannels));
```

In an audio stream loop, read an audio signal frame from the file, and write the frame to your device.

```
while ~isDone(fileReader)
    audioData = fileReader();
    deviceWriter(audioData);
end
```

Close the input file and release the device.

```
release(fileReader);
release(deviceWriter);
```

Reduce Latency due to Output Device Buffer

Latency due to the output device buffer is the time delay of writing one frame of data. Modify default properties of your `audioDeviceWriter` System object™ to reduce latency due to device buffer size.

Create a `dsp.AudioFileReader` System object to read an audio file with default settings.

```
fileReader = dsp.AudioFileReader('speech_dft.mp3');
```

Create an `audioDeviceWriter` System object and specify the sample rate to match that of the audio file reader.

```
deviceWriter = audioDeviceWriter(...
    'SampleRate',fileReader.SampleRate);
```

Calculate the latency due to your device buffer, in seconds.

```
bufferLatency = fileReader.SamplesPerFrame/deviceWriter.SampleRate
bufferLatency = 0.0464
```

Set the `SamplesPerFrame` property of your `dsp.AudioFileReader` System object to 256. Calculate the buffer latency in seconds.

```
fileReader.SamplesPerFrame = 256;
bufferLatency = fileReader.SamplesPerFrame/deviceWriter.SampleRate
```

```
bufferLatency = 0.0116
```

Determine and Decrease Underrun

Underrun refers to output signal silence, which occurs when the audio stream loop does not keep pace with the output device. Determine the underrun of an audio stream loop, add artificial computational load to the audio stream loop, and then modify properties of your `audioDeviceWriter` System object™ to decrease underrun. Your results depend on your computer.

Create a `dsp.AudioFileReader` System object, and specify the file to read. Use the `audioinfo` function to return a structure containing information about the audio file.

```
fileReader = dsp.AudioFileReader('speech_dft.mp3');  
fileInfo = audioinfo('speech_dft.mp3');
```

Create an `audioDeviceWriter` System object. Use the `SampleRate` of the file reader as the `SampleRate` of the device writer. Call `setup` to reduce the computational load of initialization in an audio stream loop.

```
deviceWriter = audioDeviceWriter( ...  
    'SampleRate',fileReader.SampleRate);  
setup(deviceWriter, ...  
    zeros(fileReader.SamplesPerFrame,fileInfo.NumChannels));
```

Run your audio stream loop with input from file and output to device. Print the total samples underrun and the underrun in seconds.

```
totalUnderrun = 0;  
while ~isDone(fileReader)  
    input = fileReader();  
    numUnderrun = deviceWriter(input);  
    totalUnderrun = totalUnderrun + numUnderrun;  
end  
fprintf('Total samples underrun: %d.\n', ...  
    totalUnderrun);  
fprintf('Total seconds underrun: %d.\n', ...  
    double(totalUnderrun)/double(deviceWriter.SampleRate));  
  
Total samples underrun: 0.  
Total seconds underrun: 0.
```

Release your `dsp.AudioFileReader` and `audioDeviceWriter` System objects and set your counter variable to zero.

```
release(fileReader);
release(deviceWriter);
totalUnderrun = 0;
```

Use `pause` to mimic an algorithm that takes 0.075 seconds to process. The pause causes the audio stream loop to go slower than the device, which results in periods of silence in the output audio signal.

```
while ~isDone(fileReader)
    input = fileReader();
    numUnderrun = deviceWriter(input);
    totalUnderrun = totalUnderrun + numUnderrun;
    pause(0.075)
end
fprintf('Total samples underrun: %d.\n', ...
    totalUnderrun);
fprintf('Total seconds underrun: %d.\n', ...
    double(totalUnderrun)/double(deviceWriter.SampleRate));
```

```
Total samples underrun: 69632.
Total seconds underrun: 3.157914e+00.
```

Release your `audioDeviceReader` and `dsp.AudioFileWriter` and set the counter variable to zero.

```
release(fileReader);
release(deviceWriter);
totalUnderrun = 0;
```

Set the frame size of your audio stream loop to 2048. Because the `SupportVariableSizeInput` property of your `audioDeviceWriter` System object is set to `false`, the buffer size of your audio device is the same size as the input frame size. Increasing your device buffer size decreases underrun.

```
fileReader = dsp.AudioFileReader('speech_dft.mp3');
fileReader.SamplesPerFrame = 2048;
fileInfo = audioinfo('speech_dft.mp3');

deviceWriter = audioDeviceWriter( ...
    'SampleRate',fileReader.SampleRate);
setup(deviceWriter, ...
    zeros(fileReader.SamplesPerFrame,fileInfo.NumChannels));
```

Calculate the total underrun.

```
while ~isDone(fileReader)
    input = fileReader();
    numUnderrun = deviceWriter(input);
    totalUnderrun = totalUnderrun + numUnderrun;
    pause(0.075)
end
fprintf('Total samples underrun: %d.\n', ...
        totalUnderrun);
fprintf('Total seconds underrun: %d.\n', ...
        double(totalUnderrun)/double(deviceWriter.SampleRate));

Total samples underrun: 0.
Total seconds underrun: 0.
```

The increased frame size reduces the total underrun of your audio stream loop. However, increasing the frame size also increases latency. Other approaches to reduce underrun include:

- Increasing the buffer size independent of input frame size. To increase buffer size independent of input frame size, you must first set `SupportVariableSizeInput` to `true`. This approach also increases latency.
- Decreasing the sample rate. Decreasing the sample rate reduces both latency and underrun at the cost of signal resolution.
- Choosing an optimal driver and device for your system.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- “System Objects in MATLAB Code Generation” (MATLAB Coder)
- The executable generated from this System object relies on prebuilt dynamic library files (.dll files) included with MATLAB. Use the `packNGo` function to package the

code generated from this object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

dsp.AudioFileReader System object

Package: dsp

Stream from audio file

Description

The `AudioFileReader` object reads audio samples from an audio file.

To read audio samples from an audio file:

- 1 Define and set up your audio file reader object. See “Construction” on page 4-138.
- 2 Call `step` to read audio samples according to the properties of `dsp.AudioFileReader`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

Construction

`afr = dsp.AudioFileReader` returns an audio file reader System object, `afr` that reads audio from an audio file.

`afr = dsp.AudioFileReader('PropertyName', PropertyValue, ...)` returns an audio file reader System object, `afr`, with each specified property set to the specified value.

`afr = dsp.AudioFileReader(FileName, 'PropertyName', PropertyValue, ...)` returns an audio file reader object, `afr`, with `FileName` property set to `FILENAME` and other specified properties set to the specified values.

Properties

Filename

Name of audio file from which to read

Specify the name of an audio file as a character vector. Specify the full path for the file only if the file is not on the MATLAB path. The default is `speech_dft.mp3`.

PlayCount

Number of times to play file

Specify a positive integer as the number of times to play the file. The default is 1.

SampleRate

Sampling rate of the audio file

This read-only property displays the sampling rate, in Hz, of the audio file.

SamplesPerFrame

Number of samples in audio frame

Specify the number of samples in an audio frame as a positive, scalar integer value. The default value is 1024.

OutputDataType

Data type of output

Set the data type of the audio data output from the audio file reader object. Specify the data type as `double` | `single` | `int16` | `uint8`. The default is `double`.

Supported Platforms and File Types

The following table lists the supported audio file formats:

Platforms	File Name Extensions
Windows	.wav, .wma, .avi, .aif, .aifc, .aiff, .mp3, .au, .snd, .mp4, .m4a, .flac, .ogg, .mov
Non-Windows	.avi, .mp3, .mp4, .m4a, .wav, .flac, .ogg, .aif, .aifc, .aiff, .au, .snd, .mov

Methods

- info Information about specific audio file
- isDone End-of-file status (logical)
- reset Reset internal states of audio file reader to read from beginning of file
- step Read audio samples from audio file

Common to All System Objects	
clone	Create System object with same property values
getNumInputs	Expected number of inputs to a System object
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Read and Play back an Audio File

This example shows how to read and play back an audio file using the standard audio output device.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For `dsp.AudioFileReader` System object™, `myObject()` becomes `step(myObject)`. For all other objects, `myObject(x)` becomes `step(myObject,x)`.

```
afr = dsp.AudioFileReader('speech_dft.mp3');
adw = audioDeviceWriter('SampleRate', afr.SampleRate);

while ~isDone(afr)
    audio = afr();
    adw(audio);
end
release(afr);
release(adw);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the From Multimedia File block reference page. The object properties correspond to the block parameters, except:

- The object has no corresponding property for the **Inherit sample time from file** block parameter. The object always inherits the sample time from the file.
- The object has no corresponding property for the **Output end-of-file indicator** parameter. The object always outputs EOF as the last output.
- The object has no corresponding property for the **Multimedia Outputs** parameter because audio is the only supported output.
- The object has no corresponding property for the **Image signal** block parameter.
- The object has no corresponding property for the **Output color format** parameter.
- The object has no corresponding property for the **Video output data type** parameter.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- See “System Objects in MATLAB Code Generation” (MATLAB Coder).
- The executable generated from this System object relies on prebuilt dynamic library files (.dll files) included with MATLAB. Use the `packNGo` function to package the code generated from this object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

System Objects

`dsp.AudioFileWriter`

Topics

“How To Run a Generated Executable Outside MATLAB”

Introduced in R2012a

info

System object: dsp.AudioFileReader

Package: dsp

Information about specific audio file

Syntax

```
S = info(afr)
```

Description

`S = info(afr)` returns a MATLAB structure, `S`, with information about the audio file specified in the `Filename` property. The number of fields in `S` varies depending on the audio content of the file. For possible fields and values for the structure `S`, see the following table.

Field	Value
SampleRate	Audio sampling rate of the audio file in Hz.
NumBits	Number of bits used to encode the audio stream.
NumChannels	Number of audio channels.

isDone

System object: dsp.AudioFileReader

Package: dsp

End-of-file status (logical)

Syntax

```
STATUS = isDone(afr)
```

Description

`STATUS = isDone(afr)` returns a logical value, `STATUS`, when the file is read `PlayCount` number of times. If you set the `PlayCount` property to a value greater than 1, `STATUS` is true when EOF is reached `PlayCount` number of times, and it is false otherwise. `STATUS` is the same as the `PlayCount` output value in the `step` method syntax.

reset

System object: dsp.AudioFileReader

Package: dsp

Reset internal states of audio file reader to read from beginning of file

Syntax

```
reset(afr)
```

Description

`reset(afr)` resets the `AudioFileReader` object to read from the beginning of the file.

step

System object: dsp.AudioFileReader

Package: dsp

Read audio samples from audio file

Syntax

```
AUDIO = step(afr)
[AUDIO,EOF] = step(afr)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

`AUDIO = step(afr)` outputs one frame of audio samples, `AUDIO`. You can specify the number of times to play the file using the `PlayCount` property. After playing the file for the number of times you specify, `AUDIO` contains silence.

`[AUDIO,EOF] = step(afr)` returns an end-of-file indicator, `EOF`. `EOF` is true each time the output `AUDIO` contains the last audio sample in the file.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.AudioFileWriter System object

Package: dsp

Stream to audio file

Description

The `AudioFileWriter` object writes audio samples to an audio file.

To write audio samples to an audio file:

- 1 Define and set up your audio file writer object. See “Construction” on page 4-147.
- 2 Call `step` to write audio samples according to the properties of `dsp.AudioFileWriter`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`afw = dsp.AudioFileWriter` returns an audio file writer System object, `afw`. This object writes audio samples to an audio file.

The following platform-specific restrictions apply when writing these files:

Windows 7	macOS
<ul style="list-style-type: none"> • Only sample rates of 44,100 Hz and 48,000 Hz are supported for MPEG-4 AAC file format. For other file formats, there is no restriction on the sample rate. 	<ul style="list-style-type: none"> • Only mono or stereo outputs are allowed for MPEG-4 AAC file format. For all other formats, more than two audio output channels are allowed.

Windows 7	macOS
<ul style="list-style-type: none"> Only mono or stereo outputs are allowed for MPEG-4 AAC file format. For all other formats, more than two audio output channels are allowed. 	
<ul style="list-style-type: none"> The output data is padded on both the front and back of the signal, with extra samples of silence. <p>Windows AAC encoder places sharp fade-in and fade-out on audio signal, causing signal to be slightly longer in samples when written to disk.</p>	<ul style="list-style-type: none"> Not all sampling rates are supported, although the Mac Audio Toolbox API do not explicitly specify a restriction.
<ul style="list-style-type: none"> A minimum of 1025 samples per channel must be written to the MPEG-4 AAC file. 	

`afw = dsp.AudioFileWriter('PropertyName', PropertyValue, ...)` returns an audio file writer System object, `afw`, with each specified property set to the specified value.

`afw = dsp.AudioFileWriter(FILENAME, 'PropertyName', PropertyValue, ...)` returns an audio file writer System object, `afw`. This object has the `Filename` property set to `FILENAME` and other specified properties set to the specified values.

Properties

Filename

Name of audio file to which to write

Specify the name of the audio file as a character vector. The default is `output.wav`.

FileFormat

Audio file format

Specify which audio file format the object writes. On Microsoft platforms, select one of AVI | WAV | FLAC | OGG | MPEG4 | WMA. On Linux platforms, select one of AVI | WAV |

FLAC | OGG. On macOS platforms, select one of AVI | WAV | FLAC | OGG | MPEG4. These abbreviations correspond to the following file formats:

- AVI: Audio-Video Interleave
- WAV: Microsoft WAVE Files
- WMA: Windows Media Audio
- FLAC: Free Lossless Audio Codec
- OGG: Ogg/Vorbis Compressed Audio File
- MPEG4: MPEG-4 AAC File — You can use both `.m4a` and `.mp4` extensions

The default is WAV.

SampleRate

Sampling rate of audio data stream

Specify the sampling rate of the input audio data as a positive, numeric scalar value. The default is 44100.

Compressor

Algorithm that compresses audio data

Specify the type of compression algorithm the audio file writer uses to compress the audio data. Compression reduces the size of the audio file. Select `None` (uncompressed) to save uncompressed audio data to the file. The other options available reflect the audio compression algorithms installed on your system. You can use tab completion to query valid `Compressor` options for your computer by typing `H.Compressor = '` and then pressing the tab key. This property applies when writing WAV or AVI files on Windows platforms.

DataType

Data type of the uncompressed audio

Specify the type of uncompressed audio data written to the file as one of `inherit`, `int16`, `int24`, `single`, or `uint8`. This property only applies when writing uncompressed WAV files. The default value of this property is `int16`.

Methods

step Write one frame of audio output samples

Common to All System Objects	
clone	Create System object with same property values
getNumInputs	Expected number of inputs to a System object
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Write an Audio Signal to a WAV File

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Decimate an audio signal, and write it to disk as a WAV file.

```
afr = dsp.AudioFileReader('OutputDataType',...  
    'double');  
firdec = dsp.FIRDecimator; % decimate by 2  
afw = dsp.AudioFileWriter...  
    ('speech_dft.wav', ...  
    'SampleRate', afr.SampleRate/2);  
  
while ~isDone(afr)  
    audio = afr();  
    audiod = firdec(audio);  
    afw(audiod);  
end
```

```
release(afr);  
release(afw);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the To Multimedia File block reference page. The object properties correspond to the block parameters, except:

- The object `FileFormat` property does not support video-only file formats.
- The object has no corresponding property for the **Write** parameter. The object writes only audio content to files.
- The object has no corresponding property for the **Video compressor** parameter.
- The object has no corresponding property for the **File color format** parameter.
- The object has no corresponding property for the **Image signal** parameter.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- See “System Objects in MATLAB Code Generation” (MATLAB Coder).
- The executable generated from this System object relies on prebuilt dynamic library files (.dll files) included with MATLAB. Use the `packNGo` function to package the code generated from this object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. System Objects

`dsp.AudioFileReader`

Topics

“How To Run a Generated Executable Outside MATLAB”

Introduced in R2012a

step

System object: dsp.AudioFileWriter

Package: dsp

Write one frame of audio output samples

Syntax

```
step(afw,AUDIO)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`step(afw,AUDIO)` writes one frame of audio samples, `AUDIO`, to the output file. `AUDIO` is either a vector or an M-by-N matrix for mono or N-channel audio inputs respectively.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.AudioPlayer System object

Package: dsp

Play audio data using computer's audio device

Note The `dsp.AudioPlayer` object will be removed in a future release. Existing instances of the object continue to run. For new code, use the `audioDeviceWriter` object instead.

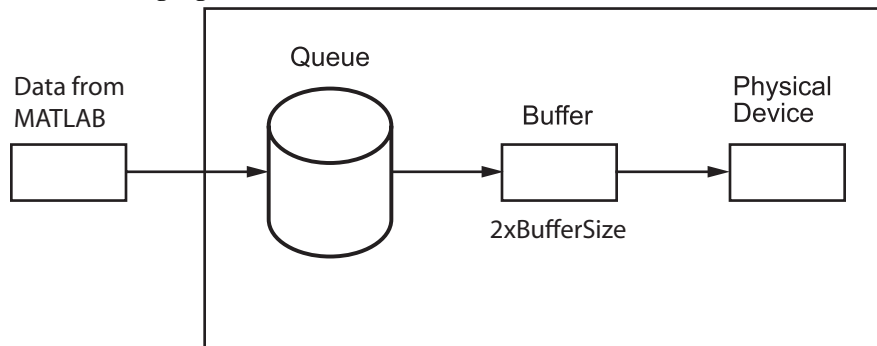

Description

The `AudioPlayer` object plays audio data using the computer's audio device.

To play audio data using the computer's audio device:

- 1 Define and set up your audio player object. See “Construction” on page 4-155.
- 2 Call `step` to play audio data according to the properties of `dsp.AudioPlayer`. The behavior of `step` is specific to each object in the toolbox.

This System object buffers the data from the audio device using the process illustrated by the following figure.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = dsp.AudioPlayer` returns an audio player object, `H`, that plays audio samples using an audio output device in real-time.

`H = dsp.AudioPlayer('PropertyName', PropertyValue, ...)` returns an audio player object, `H`, with each property set to the specified value.

`H = dsp.AudioPlayer(SAMPLERATE, 'PropertyName', PropertyValue, ...)` returns an audio player object, `H`, with the `SampleRate` property set to `SAMPLERATE` and other specified properties set to the specified values. This System object supports variable-size input. If you use variable-size signals with this System object, you may experience sound dropouts when the size of the input frame increases. To avoid this behavior, use a signal of maximum expected size when you first call `step` to start running through this System object.

Properties

DeviceName

Device to which to send audio data

Specify the device to which to send the audio data. The default is `Default`, which is the computer's standard output device. You can use tab completion to query valid `DeviceName` assignments for your computer by typing `H.DeviceName = '` and then pressing the tab key.

SampleRate

Number of samples per second sent to audio device

Specify the number of samples per second in the signal as an integer. The default is 44100. This property is tunable.

DeviceDataType

Data type used by device

Specify the data type used by the audio device to acquire audio data as `Determine` from input data type, 8-bit integer, 16-bit integer, 24-bit integer, or 32-bit float. The default is `Determine` from input data type.

BufferSizeSource

Source of Buffer Size

Specify how to determine the buffer size as `Auto` or `Property`. The default is `Auto`. When this property is set to `Auto`, an appropriate buffer size based on the `SampleRate` gets computed.

BufferSize

Buffer size

Specify the size of the buffer that the audio player object uses to communicate with the audio device as an integer. `BufferSize` is half the size of the sound card buffer. A frame of data cannot be passed to the queue until the device empties the buffer, which introduces latency. Latency is the time it takes the device to empty the queue and the buffer. `BufferSize` has to be smaller than the effective queue duration. This property is tunable. Tuning this property involves a balance between device latency and the possibility of dropping data (buffer underrun).

This property applies when you set the `BufferSizeSource` property to `Property`. The default is 4096. To set the `BufferSize` to a value other than the default, first change the `BufferSizeSource` to `'Property'`. You can select `BufferSize` in the list of properties.

QueueDuration

Size of queue in seconds

Specify the length of the audio queue, in seconds. The default is 1.0. This property is tunable. The purpose of the queue is to control the trade-off between latency and data dropout. Latency is calculated by the following equation:

$$latency = \frac{QueueDuration \times SampleRate + 2 \times BufferSize}{SampleRate} .$$

To minimize latency, lower the `QueueDuration` or set it to 0. However, be aware that data dropouts or loss of system robustness may result. The `QueueDuration` property specifies the duration of the signal, in seconds, that can be buffered during the simulation. This value is the maximum length of time that the System object's data supply can lag the device's data demand. If the MATLAB data throughput rate is lower than the device throughput rate, a buffer underrun occurs. You can use `OutputNumUnderrunSamples` to monitor underrun. To correct the underrun, make the queue duration larger than the buffer. If the MATLAB data throughput rate is higher than the device throughput rate, a buffer overrun occurs, causing the System object to wait before writing data to the queue. To minimize the chance of dropouts, the System object checks to verify the queue duration is at least as large as the maximum of the buffer size and the frame size. If it is not, the queue duration is automatically set to this maximum value. At the start of the simulation, the queue is filled with silence. At each time step, the System object sends a buffer of samples from the top of the queue to the audio device. If the queue does not contain enough data to completely fill the buffer, the System object fills the remaining portion of the buffer with zeros.

OutputNumUnderrunSamples

Enable output of underrun count

Set to `true` to output the number of zero samples inserted due to queue underrun since the last call to the `step` method. The default is `false`.

ChannelMappingSource

Source of device channel mapping

Specify whether to determine the channel mapping as 'Auto' or as 'Property'. If you set the value of `ChannelMappingSource` to 'Auto', the `ChannelMapping` field is rendered inactive. If you set this property to 'Property', the vector specified in the `ChannelMapping` field is used to route the output.

ChannelMapping

Data-to-device channel mapping

Vector of valid channel indices to represent the mapping between data and device output channels. The term Channel Mapping refer to a 1-to-1 mapping that associates channels on the selected audio device to channels of the data. When you play audio, channel mapping allows you to specify which channel of the audio data to output a specific

channel of audio data. By default, the ChannelMapping field is [1:MAXOUTPUTCHANNELS], where MAXOUTPUTCHANNELS depends upon the selected device.

Methods

step Write audio to audio output device

Common to All System Objects	
clone	Create System object with same property values
getNumInputs	Expected number of inputs to a System object
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Read and Play an Audio File

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent step syntax. For example, myObject(x) becomes step(myObject,x).

Read in an AVI audio file, and play the file back using the standard audio output device.

```
AFR = dsp.AudioFileReader; % points to a default audio file
AP = audioDeviceWriter('SampleRate',AFR.SampleRate);
while ~isDone(AFR)
    audio = AFR();
    nUnderrun = AP(audio);
    if nUnderrun > 0
        fprintf('Audio player queue underrun by %d samples.\n'...
            ,nUnderrun);
    end
end
```

```

end
end
release(AFR);           % close the input file
release(AP);           % close the audio output device

```

Troubleshooting

Running an Executable Outside MATLAB

To run your generated standalone executable application in Shell, you need to set your environment to the following:

Platform	Command
Mac	<pre> setenv DYLD_LIBRARY_PATH \$LD_LIBRARY_PATH: \$MATLABROOT/bin/maci64 (csh/tcsh) export DYLD_LIBRARY_PATH \$LD_LIBRARY_PATH: \$MATLABROOT/bin/maci64 (Bash) </pre>
Linux	<pre> setenv LD_LIBRARY_PATH \$LD_LIBRARY_PATH: \$MATLABROOT/bin/glnxa64 (csh/ tcsh) export LD_LIBRARY_PATH \$LD_LIBRARY_PATH: \$MATLABROOT/bin/glnxa64 (Bash) </pre>
Windows	<pre> set PATH = \$MATLABROOT\bin \win64;%PATH% </pre>

Algorithms

This object implements the algorithm, inputs, and outputs described on the To Audio Device block reference page. The object properties correspond to the block parameters.

`dsp.AudioFileReader` | `dsp.AudioRecorder`

Topics

Set the Audio Hardware API on page 2-1632

Introduced in R2012a

step

System object: dsp.AudioPlayer

Package: dsp

Write audio to audio output device

Note The `dsp.AudioPlayer` object will be removed in a future release. Existing instances of the object continue to run. For new code, use the `audioDeviceWriter` object instead.

Syntax

```
step(H,AUDIO)
Underrun = step(H,AUDIO)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`step(H,AUDIO)` writes one frame of AUDIO samples to the audio output device.

`Underrun = step(H,AUDIO)` writes one frame of AUDIO samples to the audio output device. The output `Underrun` indicates the number of zero samples inserted due to queue underrun since the last call to the `step` method. This syntax applies when you set the `OutputNumUnderrunSamples` property to `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.AudioRecorder System object

Package: dsp

Record audio data using computer's audio device

Note The `dsp.AudioRecorder` object will be removed in a future release. Existing instances of the object continue to run. For new code, use the `audioDeviceReader` object from Audio System Toolbox instead.

Description

The `AudioRecorder` object records audio data using the computer's audio device.

To record audio data using the computer's audio device:

- 1 Define and set up your audio recorder object. See “Construction” on page 4-164.
- 2 Call `step` to record audio data according to the properties of `dsp.AudioRecorder`. The behavior of `step` is specific to each object in the toolbox.

This System object buffers the data from a frame of data using the process illustrated by the following figure.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = dsp.AudioRecorder` returns an audio recorder object, `H`, that records audio samples using an audio input device in real-time.

`H = dsp.AudioRecorder('PropertyName', PropertyValue, ...)` returns an audio recorder object, `H`, with each property set to the specified value.

Properties

DeviceName

Device from which to acquire audio data

Specify the device from which to acquire audio data. The default is `Default`, which is the computer's standard input device. You can use tab completion to query valid `DeviceName` assignments for your computer by typing `H.DeviceName = '` and then pressing the tab key. The tab completion functionality shows all valid audio device names for your computer.

SampleRate

Number of samples per second read from audio device

Specify the number of samples per second in the signal as an integer. The default is 44100. This property is tunable.

NumChannels

Number of audio channels

Specify the number of audio channels as an integer. The default is 2.

DeviceDataType

Data type used by device

Specify the data type used by the device to acquire audio data as `Determine` from output data type, 8-bit integer, 16-bit integer, 24-bit integer, or 32-bit float. The default is `Determine` from output data type.

BufferSizeSource

Source of Buffer Size

Specify how to determine the buffer size as `Auto` or `Property`. The default is `Auto`.

BufferSize

Buffer size

Specify as an integer the size of the buffer that the audio recorder object uses to communicate with the audio device. This property applies when you set the `BufferSizeSource` property to `Property`. The default is 4096. This property is tunable. Tuning this property involves a balance between device latency and the possibility of dropping data (buffer underrun). The instant you receive the buffer from a device, you have samples that are relatively new and samples that are at least as old as the size of the buffer. Therefore, the buffer size introduces latency, which is the time required for the device to fill the queue and the buffer. `BufferSize` is half the size of the sound card buffer. The size of the buffer processed in each interrupt from the audio device affects the performance of the system. A frame of data cannot pass through the queue until the buffer is filled by the device, thus introducing latency. `BufferSize` has to be smaller than the effective queue duration. To set the `BufferSize` to a value other than the default, first change the `BufferSizeSource` to 'Property'. You can select `BufferSize` from the list of properties.

QueueDuration

Size of queue in seconds

Specify the length of the audio queue, in seconds. The default is 1.0. This property is tunable. The purpose of the queue is to control the trade-off between latency and data dropout. Latency is calculated by the following equation:

$$latency = \frac{QueueDuration \times SampleRate + 2 \times BufferSize}{SampleRate} .$$

To minimize latency, lower the `QueueDuration` or set it to 0. However, be aware that data dropouts or loss of system robustness may result. The `QueueDuration` property specifies the duration of the signal, in seconds, that can be buffered during the simulation. This value is the maximum length of time that the System object's data supply can lag the device's data demand. If the MATLAB data throughput rate is lower than the device throughput rate, a buffer overrun occurs. You can use `OutputNumOverrunSamples` to monitor overrun. To correct the overrun, make the queue duration larger than the buffer. If the MATLAB data throughput rate is higher than the device throughput rate, a buffer underrun occurs, causing the System object to wait for new samples to become available. To minimize the chance of dropouts, the System object checks to verify the queue duration is at least as large as the maximum of the buffer size and the frame size. If it is not, the queue duration is automatically set to this maximum value. At the start of the simulation, the queue is filled with silence. At each time step, the audio device sends a buffer of samples to the top of the queue.

SamplesPerFrame

Number of samples in the output signal

Specify the number of samples in the audio recorder's output as an integer. The default is 1024.

OutputDataType

Data type of the output

Select the output data type as `uint8`, `int16`, `int32`, `single`, or `double`. The default is `double`.

OutputNumOverrunSamples

Enable output of overrun count

Set to `true` to output the number of samples dropped due to queue overrun since the last call to the `step` method. The default is `false`.

ChannelMappingSource

Source of device channel mapping

Specify whether to determine the channel mapping as `'Auto'` or as `'Property'`. If you set the value of `ChannelMappingSource` to `'Auto'`, the `ChannelMapping` field is

rendered inactive. If you set this property to 'Property', the vector specified in the ChannelMapping field is used to route the input. Additionally, the NumChannels field is rendered inactive, because the channel map contains information about the number of data channels that the user is attempting to read.

ChannelMapping

Device-to-data channel mapping

Vector of valid channel indices to represent the mapping between device input channels and the data. The term Channel Mapping refers to a 1-to-1 mapping that associates channels on the selected audio device to channels of the data. When you record audio, channel mapping allows you to specify which channel of the audio data directs input to a specific channel of audio. By default, the ChannelMapping field is [1:MAXNUMINPUTCHANNELS], where MAXNUMINPUTCHANNELS depends upon the selected device.

Methods

step Record audio from recording device

Common to All System Objects	
clone	Create System object with same property values
getNumInputs	Expected number of inputs to a System object
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Package: `dsp`

Record audio from recording device

Note The `dsp.AudioRecorder` object will be removed in a future release. Existing instances of the object continue to run. For new code, use the `audioDeviceReader` object from Audio System Toolbox instead.

Syntax

```
AUDIO = step(H)
[AUDIO,Overrun] = step(H)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`AUDIO = step(H)` reads one frame of audio samples from the selected audio input device.

`[AUDIO,Overrun] = step(H)` reads one frame of audio samples from the selected audio input device. The output `Overrun` indicates the number of samples dropped due to queue overrun since the last call to the `step` method. This syntax applies when you set the “OutputNumOverrunSamples” on page 4-0 property to `true`.

dsp.Autocorrelator System object

Package: dsp

Autocorrelation sequence

Description

The `Autocorrelator` object returns the autocorrelation sequence for a discrete-time, deterministic input, or the autocorrelation sequence estimate for a discrete-time, wide-sense stationary (WSS) random process at positive lags.

To obtain the autocorrelation sequence:

- 1 Define and set up your autocorrelator. See “Construction” on page 4-171.
- 2 Call `step` to compute the autocorrelation sequence according to the properties of `dsp.Autocorrelator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`ac = dsp.Autocorrelator` returns an autocorrelator, `ac`, that computes the autocorrelation along the first dimension of an N-D array. By default, the autocorrelator computes the autocorrelation at lags from zero to $N - 1$, where N is the length of the input vector or the row dimension of the input matrix. Inputting a row vector results in a row of zero-lag autocorrelation sequence values, one for each column of the row vector. The default autocorrelator returns the unscaled autocorrelation and performs the computation in the time domain.

`ac = dsp.Autocorrelator('PropertyName', PropertyValue, ...)` returns an autocorrelator, `ac`, with each property set to the specified value.

Properties

MaximumLagSource

Source of maximum lag

Specify how to determine the range of lags for the autocorrelation as `Auto` or `Property`. If the value of `MaximumLagSource` is `Auto`, the autocorrelator computes the autocorrelation over all nonnegative lags in the interval $[0, N-1]$, where N is the length of the first dimension of the input. Otherwise, the object computes the autocorrelation using lags in the range $[0, \text{MaximumLag}]$. The default is `Auto`.

MaximumLag

Maximum positive lag

Specify the maximum lag as a positive integer. This property applies only when the `MaximumLagSource` property is `Property`. The `MaximumLag` must be less than the length of the input data. The default is 1.

Scaling

Autocorrelation function scaling

Specify the scaling to apply to the output as `None`, `Biased`, `Unbiased`, or `Unity` at zero-lag. Set this property to `None` to generate the autocorrelation function without scaling. This option is appropriate if you are computing the autocorrelation of a nonrandom (deterministic) input.

The `Biased` option scales the autocorrelation by $1/N$, where N is the length of the input data. Scaling by $1/N$ yields a biased, finite-sample approximation to the theoretical autocorrelation of a WSS random process. In spite of the bias, scaling by $1/N$ has the desirable property that the sample autocorrelation matrix is nonnegative definite, a property possessed by the theoretical autocorrelation matrices of all wide-sense stationary random processes. The Fourier transform of the biased autocorrelation estimate is the *periodogram*, a widely used estimate of the power spectral density of a WSS process.

The `Unbiased` option scales the estimate of the autocorrelation by $1/(N-1)$. Scaling by $1/(N-1)$ produces an unbiased estimate of the theoretical autocorrelation. However, using the

unbiased option, you can obtain an estimate of the autocorrelation function that fails to have the nonnegative definite property.

Use the `Unity at zero-lag` option to normalize the autocorrelation estimate as identically one at lag zero. The default is `None`.

Method

Domain for computing autocorrelations

Specify the domain for computing autocorrelations as `Time Domain` or `Frequency Domain`. You must set this property to `Time Domain` for fixed-point signals. The default is `Time Domain`.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. This property applies only when you set the `Method` property to `Time Domain`. The default is `Floor`. This property applies only if the object is not in full precision mode.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. This property applies only when you set the `Method` property to `Time Domain`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of `Full precision`, `Same as input`, or `Custom`. This property applies only when you set the `Method` property to `Time Domain`. The default is `Full precision`

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `Method` property to `Time Domain` and the `ProductDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `Full precision`, `Same as product`, `Same as input`, or `Custom`. This property applies only when the `Method` property is `Time Domain`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `Method` property to `Time Domain` and the `AccumulatorDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as `Same as accumulator`, `Same as product`, `Same as input`, or `Custom`. This property applies only when the `Method` property is `Time Domain`. The default is `Same as accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `Method` property to `Time Domain` and the `OutputDataType` property to `Custom`. The default is `numerictype([], 16, 15)`.

Methods

`step` Autocorrelation sequence

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

Autocorrelation Of a Number Sequence

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

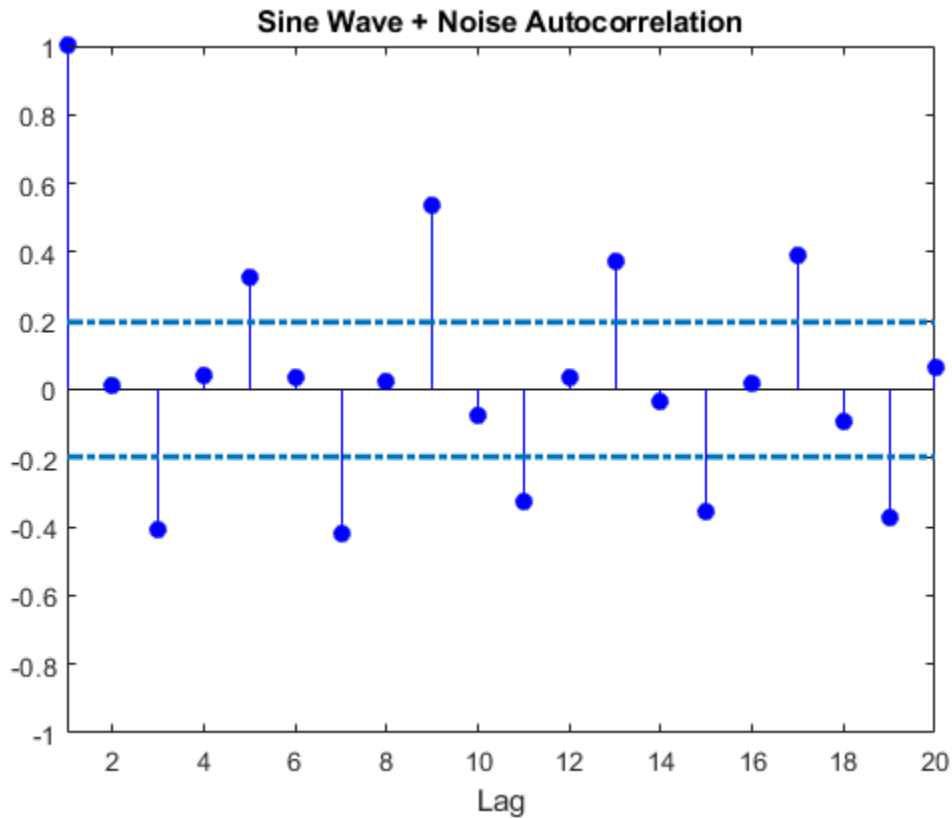

```
ac1 = dsp.Autocorrelator;
% x is a column vector
x = (1:100)';
y = ac1(x);
```

Autocorrelation of a Noisy Sine Wave

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Compute the autocorrelation of a sine wave in white Gaussian noise with approximate 95% upper and lower confidence limits.

```
S = rng('default');
% Sine wave with period N=4
x = 1.4*cos(pi/2*(1:100))'+randn(100,1);
MaxLag = 20;
ac = dsp.Autocorrelator('MaximumLagSource',...
'Property','MaximumLag',MaxLag,'Scaling','Unity at zero-lag');
SigAutocorr = ac(x);
stem(SigAutocorr,'b','markerfacecolor',[0 0 1]);
line(1:MaxLag+1,1.96/sqrt(100)*ones(MaxLag+1,1),...
'linestyle','-','linewidth',2);
line(1:MaxLag+1,-1.96/sqrt(100)*ones(MaxLag+1,1),...
'linestyle','-','linewidth',2);
axis([1 20 -1 1]);
title('Sine Wave + Noise Autocorrelation'); xlabel('Lag');
```

As this figure shows, the autocorrelation estimate demonstrates the four sample periodic sine wave with excursions outside the 95% white Gaussian noise confidence limits every two samples.

Definitions

Autocorrelation

Autocorrelation is the correlation of a signal with itself at different points in time.

For a deterministic discrete-time sequence, $x(n)$, the autocorrelation is computed using the following relationship:

$$r_x(h) = \sum_{n=0}^{N-h-1} x^*(n)x(n+h) \quad h = 0, 1, \dots, N-1$$

where h is the lag and $*$ denotes the complex conjugate. If the input is a length N realization of a WSS stationary random process, $r_x(h)$ is an estimate of the theoretical autocorrelation:

$$\rho_x(h) = E\{x^*(n)x(n+h)\}$$

where $E\{\}$ is the expectation operator. The Unity at zero-lag normalization divides each sequence value by the autocorrelation or autocorrelation estimate at zero lag.

$$\frac{\rho_x(h)}{\rho_x(0)} = \frac{E\{x^*(n)x(n+h)\}}{E\{|x(0)|^2\}}$$

The most commonly used estimate of the theoretical autocorrelation of a WSS random process is the biased estimate:

$$\hat{\rho}_x(h) = \frac{1}{N} \sum_{k=0}^{N-h-1} x^*(k)x(k+h)$$

Algorithms

Time-Domain Computation

When you set the computation domain to time, the algorithm computes the autocorrelation of the input signal in the time domain. The input signal can be a fixed-point signal in this domain.

The autocorrelation sequence, y , is computed using this equation:

$$y_{i,j} = \sum_{k=0}^{M-l-1} u_{k,j}^* u_{(k+i),j} \quad 0 \leq i \leq l$$

- y_{0j} is the zero-lag element in the j th column of the input.
- i is the index of the lag.

- j is the index of the input data column.
- $*$ denotes the complex conjugate.
- M is the number of elements in each column.
- l is the maximum positive lag for autocorrelation. When you choose to compute the autocorrelation with all nonnegative lags, $l=M-1$. Otherwise, l is the maximum nonnegative integer lag value specified.
- u is an M -by- N input matrix.

Frequency-Domain Computation

When you set the computation domain to frequency, the algorithm computes the autocorrelation in the frequency domain.

In this domain, the algorithm computes the autocorrelation sequence by taking the Fourier transform of the input signal, multiplying the Fourier transform with its complex conjugate, and taking the inverse Fourier transform of the product. In this domain, depending on the input length, the algorithm can require fewer computations.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

`dsp.Crosscorrelator`

Introduced in R2012a

step

System object: dsp.Autocorrelator

Package: dsp

Autocorrelation sequence

Syntax

$Y = \text{step}(ac, X)$

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

$Y = \text{step}(ac, X)$ computes the autocorrelation sequence Y for the columns of the input X .

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.BinaryFileReader System object

Package: dsp

Read data from binary file

Description

The `dsp.BinaryFileReader` System object reads multichannel signal data from a binary file. If the header is not empty, then the header precedes the signal data. The System object specifies the prototype of the header, and the type, size, and complexity of the data. The first time you read the file, the reader reads the header, followed by the data. On subsequent calls, the reader reads the remaining data. Once the end of file is reached, the reader returns zeros of the specified data type, size, and complexity. The reader can read signal data from a binary file that is not created by the `dsp.BinaryFileWriter` System object.

The object accepts floating-point data or integer data. To read character data and fixed-point data, see the “Write and Read Character Data” on page 4-192 and “Write and Read Fixed-Point Data” on page 4-191 examples. The input data can be real or complex. When the data is complex, the object reads the data as interleaved real and imaginary components. For an example, see “Read Complex Data” on page 4-190. The reader assumes the default endianness of the host machine. To change the endianness, you can use the `swapbytes` function. For an example, see “Change the Endianness of the Data” on page 4-193.

This object supports C and C++ code generation.

To read data from a binary file:

- 1 Create a `dsp.BinaryFileReader` object and set the properties of the object.
- 2 Call `step` to read the binary file.

Note Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

Construction

`reader = dsp.BinaryFileReader` creates a binary file reader object, `reader`, using the default properties.

`reader = dsp.BinaryFileReader(fname)` sets the `Filename` property to `fname`.

`reader = dsp.BinaryFileReader(fname, Name, Value, ...)` with `Filename` set to `fname`, and each property `Name` set to the specified `Value`. Unspecified properties have default values.

Example:

```
reader = dsp.BinaryFileReader('myFilename.bin', 'SamplesPerFrame', 1000, 'NumChannels', 2);
```

Properties

Filename — Name of the file

'Untitled.bin' (default) | character vector

Name of the file from which the object reads the data, specified as a character vector. If the file is not on the MATLAB path, then specify the full path for the file.

HeaderStructure — Size of the header

struct('Field1', []) (default) | structure

Size of the structure, specified as a structure. The structure specifies the prototype of the file header, that is, the size of the header and the data type of the field values. The structure can have an arbitrary number of fields. Each field of the structure must be a real matrix of a built-in type. For example, if `HeaderStructure` is set to `struct('field1', 1:10, 'field2', single(1))`, the object assumes that the header is formed by 10 real double-precision values followed by 1 single-precision value. If the file contains no header, you can set this property to an empty structure, `struct([])`. To retrieve the file header, call the `readHeader` method on the reader object.

SamplesPerFrame — Number of samples per output frame

1024 (default) | positive integer

Number of samples per output frame, specified as a positive integer. `SamplesPerFrame` specifies the number of rows of the output matrix that the object returns. The size of the

data is `SamplesPerFrame-by-NumChannels`. Once the end of file is reached, the reader returns zeros of the specified data type, size, and complexity.

NumChannels — Number of channels

1 (default) | positive integer

Number of channels, specified as a positive integer. `NumChannels` specifies the number of columns of the output matrix that the object returns. This property defines the number of consecutive interleaved data samples stored in the file for each time instant. The size of the data is `SamplesPerFrame-by-NumChannels`. Once the end of file is reached, if the output matrix is not full, the object fills the matrix with zeros to make it a full-sized matrix.

DataType — Storage class of data in file

'double' (default) | 'single' | 'int8' | 'int16' | 'int32' | 'int64' | 'uint8' | 'uint16' | 'uint32' | 'uint64'

Storage class of data in file, specified as a character vector. This property defines the data type of the matrix returned by the `step` method.

IsDataComplex — Specify data complexity

false (default) | true

Option to specify data complexity, specified as false or true. When this property is set to true, the reader treats the data as being complex. The object reads the data as interleaved real and imaginary components. Consider a reader object configured to read the data as a 2-by-2 matrix. The object reads [1 5 2 6 3 7 4 8] as [1 2; 3 4]+1j*[5 6; 7 8]. If this property is set to false, the same object reads the data as [1 5; 2 6].

Methods

<code>isdone</code>	End-of-file status (logical)
<code>readheader</code>	Read file header
<code>reset</code>	Reset internal states of System object
<code>step</code>	Read data from binary file

Common to All System Objects	
clone	Create System object with same property values
getNumInputs	Expected number of inputs to a System object
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Write and Read Binary Files

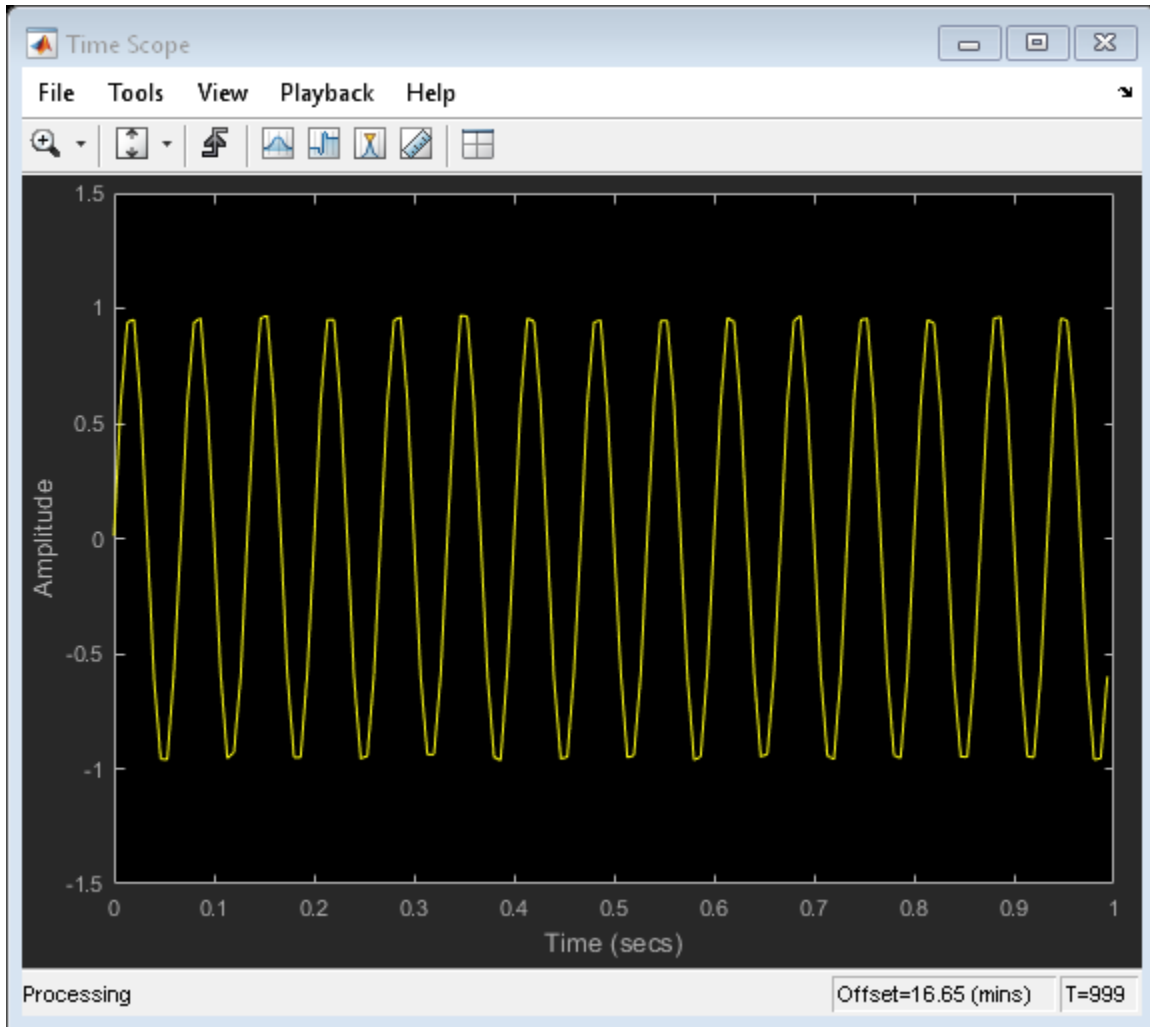

Create a binary file with a custom header using the `dsp.BinaryFileWriter` System object™. Write data to this file. Read the header and data using the `dsp.BinaryFileReader` System object.

Write the Data

Specify the file header and create a `dsp.BinaryFileWriter` object. The object writes the header first, followed by the data, to the `ex_file.bin` file. The data is a noisy sine wave signal. View the data in a time scope.

```
header = struct('A', [1 2 3 4], 'B', 'x7');
writer = dsp.BinaryFileWriter('ex_file.bin', 'HeaderStructure', header);
L = 150;
sine = dsp.SineWave('SamplesPerFrame', L);
scopewriter = dsp.TimeScope(1, 'YLimits', [-1.5 1.5], 'SampleRate', ...
    L, 'TimeSpan', 1);

for i = 1:1000
    data = sine()+0.01*randn(L,1);
    writer(data);
    scopewriter(data);
end
```

Release the writer so that the reader can access the data from this file.

```
release(writer);
```

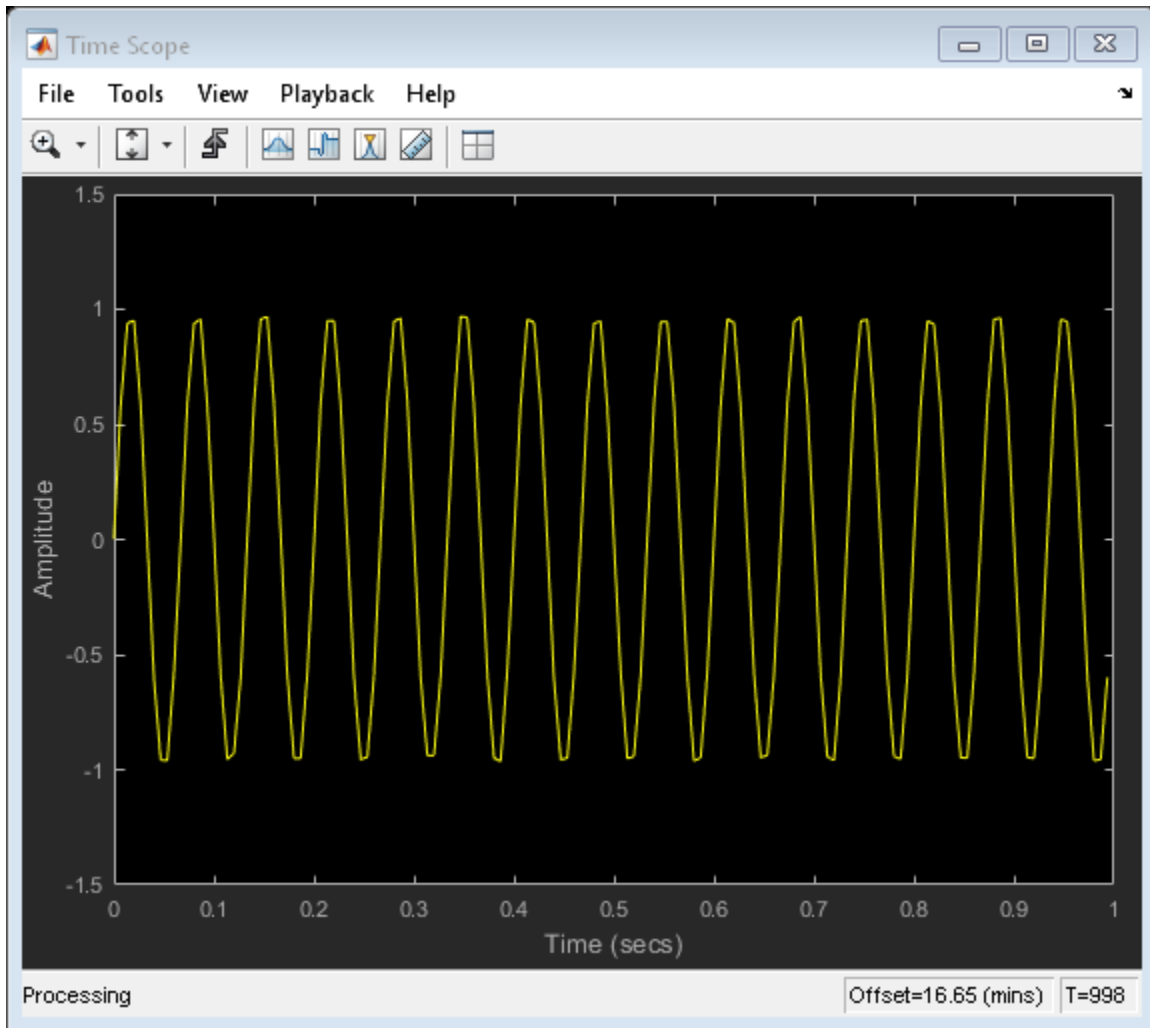

Read the Data

Specify the header using the `HeaderStructure` property of the reader object. If the exact header is not known, you must at least specify the prototype of the header, that is,

its size and data type. The `dsp.BinaryFileReader` object reads the binary data from `ex_file.bin` until the end of file is reached. The data is read into a single channel (column) containing multiple frames, where each frame has 300 samples. View the data in a time scope.

```
headerPrototype = struct('A',[0 0 0 0], 'B','-0');

reader = dsp.BinaryFileReader(...
    'ex_file.bin',...
    'HeaderStructure',headerPrototype,...
    'NumChannels',1, 'SamplesPerFrame',300);
scopereader = dsp.TimeScope(1, 'YLimits', [-1.5 1.5], 'SampleRate',...
    L, 'TimeSpan',1);
while ~isDone(reader)
    out = reader();
    scopereader(out);
end
release(reader);
```

Even when the reader reads data with a different frame size, the output in both time scopes matches exactly.

Write and Read Matrix Data

Use a `dsp.BinaryFileReader` System object™ to read data from a binary file in a row-major format.

Write the Data

Write the matrix `A` to the binary file `Matdata.bin` using a `dsp.BinaryFileWriter` object. The object writes the specified header followed by the data.

```
A = [1 2 3 8; 4 5 6 10; 7 8 9 11];
header = struct('A',[1 2], 'B','x7');
writer = dsp.BinaryFileWriter('Matdata.bin','HeaderStructure',header);
writer(A);
```

Release the writer so that the reader can access the data.

```
release(writer);
```

Read the Data

Specify the header using the `HeaderStructure` property of the reader object. If the exact header is not known, you must at least specify the prototype of the header, that is, its size and data type. The `dsp.BinaryFileReader` object reads the binary file `Matdata.bin` until the end of file is reached. Specify the System object to read the data into 4 channels, with each channel containing 5 samples. Each loop of the iteration reads a channel (or frame) of data.

```
headerPrototype = struct('A',[0 0], 'B','-0');
reader = dsp.BinaryFileReader('Matdata.bin','HeaderStructure',header,...
    'NumChannels',4,'SamplesPerFrame',5);
while ~isDone(reader)
    out = reader();
    display(out)
end

out =
```

```
1     2     3     8
4     5     6    10
7     8     9    11
0     0     0     0
0     0     0     0
```

Each frame of `out` contains frames of the matrix `A`, followed by zeros to complete the frame. The original matrix `A` contains 4 channels with 3 samples in each channel. The reader is specified to read data into 4 channels, with each channel containing 5 samples. Because there are not enough samples to complete the frame, the reader object appends zeros at the end of each frame.

Read Header Data

Read the header data from a binary file using the `readHeader` method.

Write a header, followed by the data to a binary file named `myfile.dat`. The header is a 1-by-4 matrix of double precision values, followed by a 5-by-1 vector of single-precision values. The data is a sequence of 1000 double-precision values.

```
fid = fopen('myfile.dat','w');
fwrite(fid,[1 2 3 4],'double');
fwrite(fid,single((1:5).'),'single');
fwrite(fid,(1:1000).','double');
fclose(fid);
```

Read the header using a `dsp.BinaryFileReader` object. Specify the expected header structure. This structure specifies only the format of the expected binary file header and does not contain the exact values.

```
reader = dsp.BinaryFileReader('myfile.dat');
s = struct('A',zeros(1,4),'B',ones(5,1,'single'));
reader.HeaderStructure = s;
```

Read the header using the `readHeader` method of the `dsp.BinaryFileReader` object.

```
H = readHeader(reader);
fprintf('H.A: ')

H.A:

fprintf('%d ',H.A);

1 2 3 4

fprintf('\nH.A datatype: %s\n',class(H.A))

H.A datatype: double
```

```
fprintf('H.B: ')
H.B:
fprintf('%d ',H.B);
1 2 3 4 5
fprintf('\nH.B datatype: %s\n',class(H.B))
H.B datatype: single
```

Read Complex Data

Read complex data from a binary file using the `dsp.BinaryFileReader` object.

Write a sequence of numbers to a binary file named `myfile.dat`. There is no header. The data is a 2-by-4 matrix of double-precision values. `fwrite` writes the data in a column-major format. That is, the 2-by-4 matrix `[1 2 3 4; 9 10 11 12]` is written as `[1 9 2 10 3 11 4 12]` in the binary file.

```
fid = fopen('myfile.dat','w');
fwrite(fid,[1 2 3 4; 9 10 11 12],'double');
fclose(fid);
```

Specify the data to be complex using the `IsDataComplex` property. The object reads the data as interleaved real and imaginary components. The `SamplesPerFrame` and `NumChannel` properties specify the number of rows and columns of the output data. The header structure is specified as empty.

```
reader = dsp.BinaryFileReader('myfile.dat','SamplesPerFrame',2,...
    'NumChannels',2, 'IsDataComplex',true);
s = struct([]);
reader.HeaderStructure = s;
data = reader();
display(data);

data =
    1.0000 + 9.0000i    2.0000 +10.0000i
    3.0000 +11.0000i    4.0000 +12.0000i
```

```
release(reader);
```

Alternatively, if you do not specify the data to be complex, the reader reads the data as a `SamplesPerFrame-by-NumChannel` matrix of real values.

```
reader.IsDataComplex = false;
data = reader();
display(data);
```

```
data =
```

```
     1     9
     2    10
```

```
release(reader);
```

Write and Read Fixed-Point Data

The `dsp.BinaryFileWriter` and `dsp.BinaryFileReader` System objects do not support writing and reading fixed-point data. As a workaround, you can write the stored integer portion of the `fi` data, read the data, and use this value to reconstruct the `fi` data.

Write the Fixed-Point Data

Create a `fi` object to represent 100 signed random numbers with a word length of 14 and a fraction length of 12. Write the stored integer portion of the `fi` object to the data file `myFile.dat`. The built-in data type is `int16`, which can be computed using `class(storeIntData)`.

```
data = randn(100,1);
fiDataWriter = fi(data,1,14,12);
storeIntData = storedInteger(fiDataWriter);
```

```
writer = dsp.BinaryFileWriter('myFile.dat');
writer(storeIntData);
```

Release the writer so that the reader can access the data.

```
release(writer);
```

Read the Fixed-Point Data

Specify the reader to read the stored integer data as `int16` data with 100 samples per data frame. The real-world value of the fixed-point number can be represented using $2^{(-fractionLength)} * (storedInteger)$. If you know the signedness, word length, and fraction length of the fixed-point data, you can reconstruct the `fi` data using `fi(realValue, signedness, wordLength, fractionLength)`. In this example, the data is signed with a word length of 14 and a fraction length of 12.

```
reader = dsp.BinaryFileReader('Filename', 'myFile.dat', 'SamplesPerFrame', 100, ...
    'DataType', 'int16');
data = reader();
fractionLength = 12;
wordLength = 14;
realValue = 2^(-fractionLength)*double(data);

fiDataReader = fi(realValue, 1, wordLength, fractionLength);
```

Verify that the writer data is the same as the reader data.

```
isequal(fiDataWriter, fiDataReader)

ans =

    logical

     1
```

Write and Read Character Data

The `dsp.BinaryFileWriter` and `dsp.BinaryFileReader` System objects do not support writing and reading characters. As a workaround, cast character data to one of the built-in data types and write the integer data. After the reader reads the data, convert the data to a character using the `char` function.

Write the Character Data

Cast a character into `uint8` using the `cast` function. Write the cast data to the data file `myFile.dat`.

```
data = 'binary_file';
castData = cast(data, 'uint8');
writer = dsp.BinaryFileWriter('myFile.dat');
writer(castData);
```

Release the writer so that the reader can access the data.

```
release(writer);
```

Read the uint8 Data

Specify the reader to read the cast data as uint8 data.

```
reader = dsp.BinaryFileReader('myFile.dat', 'DataType', 'uint8', 'SamplesPerFrame', 11);
readerData = reader();
charData = char(readerData);
```

Verify that the writer data is the same as the reader data. By default, the reader returns the data in a column-major format.

```
strcmp(data, charData.')
```

```
ans =
    logical
     1
```

Change the Endianness of the Data

By default, the dsp.BinaryFileReader System object™ uses the endianness of the host machine. To change the endianness, such as when the host machine that writes the data does not have the same endianness as the host machine that reads the data, use the swapbytes function.

Write a numeric array into myfile.dat in big endian format. Read the data using the dsp.BinaryFileReader object. The reader object reads the data in little endian format.

```
fid = fopen('myfile.dat', 'w', 'b');
fwrite(fid, [1 2 3 4 5 6 7 8], 'double');
```

```
fclose(fid);  
reader = dsp.BinaryFileReader('myfile.dat','SamplesPerFrame',8);  
x = reader();  
display(x);
```

x =

```
1.0e-318 *  
  
0.3039  
0.0003  
0.0104  
0.0206  
0.0256  
0.0307  
0.0357  
0.0408
```

x does not match the original data. Change the endianness of x using the `swapbytes` function.

```
y = swapbytes(x);  
display(y);
```

y =

```
1  
2  
3  
4  
5  
6  
7  
8
```

y matches the original data.

System Objects

`dsp.BinaryFileWriter`

Blocks

Binary File Reader | Binary File Writer

Introduced in R2016b

isdone

System object: dsp.BinaryFileReader

Package: dsp

End-of-file status (logical)

Syntax

```
status = isDone(reader)
```

Description

`status = isDone(reader)` returns true if the source System object, `obj`, has reached the end of the file.

Introduced in R2016b

readheader

System object: dsp.BinaryFileReader

Package: dsp

Read file header

Syntax

```
header = readHeader(reader)
```

Description

`header = readHeader(reader)` returns the header structure, `header`, from the file specified by the binary file reader, `reader`.

Introduced in R2016b

reset

System object: dsp.BinaryFileReader

Package: dsp

Reset internal states of System object

Syntax

```
reset(reader)
```

Description

`reset(reader)` resets to the beginning of the file and skips the header bytes.

Introduced in R2016b

step

System object: dsp.BinaryFileReader

Package: dsp

Read data from binary file

Syntax

```
data = step(reader)
```

Description

Note Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

`data = step(reader)` reads data from the binary file in row-major format. The data type, size, and complexity of the data are determined by the properties of the `reader` object. Once end of file is reached, the `step` method returns zeros of the specified data type, size, and complexity.

Introduced in R2016b

dsp.BinaryFileWriter System object

Package: dsp

Write data to binary files

Description

The `dsp.BinaryFileWriter` System object writes multichannel signal data to a binary file. If the header is not empty, then the header precedes the signal data. The object specifies the file name and the structure of the header. The first time you write to the file, the object writes the header, followed by the data. On subsequent calls, the object writes the remaining data. If the header is empty, then no header is written.

The object can write floating-point data and integer data. To write character data and fixed-point data, see “Write and Read Character Data” on page 4-209 and “Write and Read Fixed-Point Data” on page 4-207. The input data can be real or complex. When the data is complex, the object writes the data as interleaved real and imaginary components. For an example, see “Write and Read Fixed-Point Data” on page 4-207. The writer assumes the default endianness of the host machine. To change the endianness, you can use the `swapbytes` function. For an example, see “Change the Endianness of the Data Before Writing the Data” on page 4-210 .

The object writes the data in row-major format. For example if the input array is `[1 2 4 5; 8 7 9 2]`, the object writes the data as `[1 2 4 5 8 7 9 2]`.

The object supports C and C++ code generation.

To write data to a binary file:

- 1 Create a `dsp.BinaryFileWriter` object and set the properties of the object.
- 2 Call `step` to write to the binary file. In the first call to `step`, the object writes the header before the data. In subsequent calls, the object writes the data to the end of the file.

Note Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

Construction

`writer = dsp.BinaryFileWriter` creates a binary file writer object, `writer`, using the default properties.

`writer = dsp.BinaryFileWriter(fname)` sets the `Filename` property to `fname`.

`writer = dsp.BinaryFileWriter(fname, Name, Value, ...)` with `Filename` set to `fname`, and each property `Name` set to the specified `Value`. Unspecified properties have default values.

Example:

```
writer = dsp.BinaryFileWriter('myFilename.bin', 'HeaderStructure', ...
struct('field1', 1:10, 'field2', single(1)));
```

Properties

Filename — Name of the file

'untitled.bin' (default) | character vector

Name of the file to which the object writes the data, specified as a character vector. You must specify the full path for the file.

HeaderStructure — Header to write at the beginning of the file

struct([]) (default) | structure

Header to write at the beginning of the file, specified as a structure. The structure can have an arbitrary number of fields. Each field of the structure must be a real matrix of a built-in type. For example, if `HeaderStructure` is set to `struct('field1', 1:10, 'field2', single(1))`, the object writes a header formed by 10 double-precision values, `(1:10)`, followed by one single precision value, `single(1)`. If you do not specify a header, the object sets this property to an empty structure, `struct([])`.

Methods

reset Reset internal states of System object
 step Write data to the binary file

Common to All System Objects	
clone	Create System object with same property values
getNumInputs	Expected number of inputs to a System object
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Write and Read Binary Files

Create a binary file with a custom header using the `dsp.BinaryFileWriter` System object™. Write data to this file. Read the header and data using the `dsp.BinaryFileReader` System object.

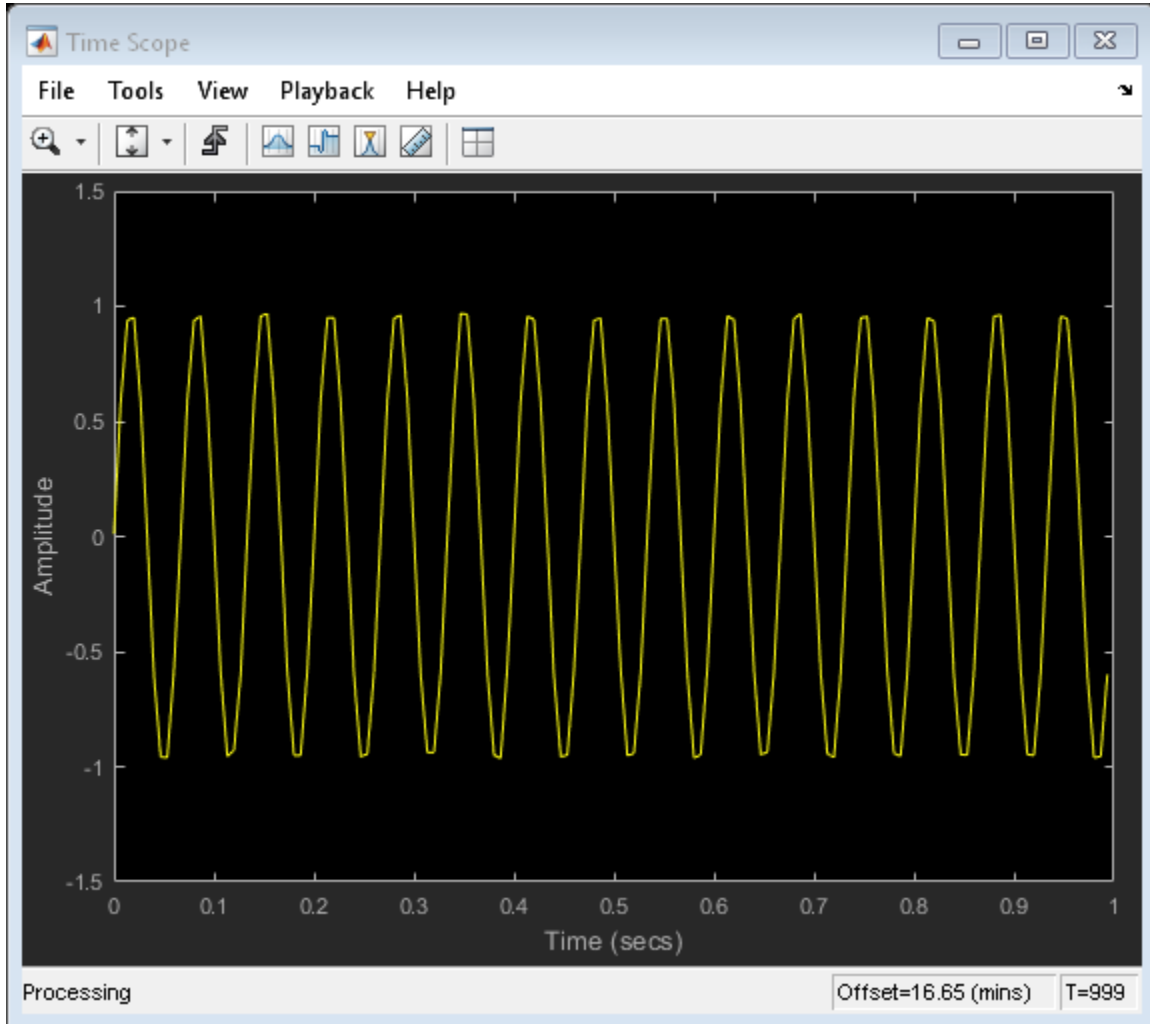

Write the Data

Specify the file header and create a `dsp.BinaryFileWriter` object. The object writes the header first, followed by the data, to the `ex_file.bin` file. The data is a noisy sine wave signal. View the data in a time scope.

```
header = struct('A',[1 2 3 4],'B','x7');
writer = dsp.BinaryFileWriter('ex_file.bin','HeaderStructure',header);
L = 150;
sine = dsp.SineWave('SamplesPerFrame',L);
scopewriter = dsp.TimeScope(1,'YLimits',[-1.5 1.5],'SampleRate',...
    L,'TimeSpan',1);

for i = 1:1000
```

```
data = sine()+0.01*randn(L,1);  
writer(data);  
scopewriter(data);  
end
```

Release the writer so that the reader can access the data from this file.

```
release(writer);
```

Read the Data

Specify the header using the `HeaderStructure` property of the reader object. If the exact header is not known, you must at least specify the prototype of the header, that is, its size and data type. The `dsp.BinaryFileReader` object reads the binary data from `ex_file.bin` until the end of file is reached. The data is read into a single channel (column) containing multiple frames, where each frame has 300 samples. View the data in a time scope.

```
headerPrototype = struct('A',[0 0 0 0], 'B', '-0');

reader = dsp.BinaryFileReader(...
    'ex_file.bin',...
    'HeaderStructure',headerPrototype,...
    'NumChannels',1, 'SamplesPerFrame',300);
scopereader = dsp.TimeScope(1, 'YLimits', [-1.5 1.5], 'SampleRate',...
    L, 'TimeSpan', 1);
while ~isDone(reader)
    out = reader();
    scopereader(out);
end
release(reader);
```

Even when the reader reads data with a different frame size, the output in both time scopes matches exactly.

Write and Read Matrix Data

Use a `dsp.BinaryFileReader` System object™ to read data from a binary file in a row-major format.

Write the Data

Write the matrix `A` to the binary file `Matdata.bin` using a `dsp.BinaryFileWriter` object. The object writes the specified header followed by the data.

```
A = [1 2 3 8; 4 5 6 10; 7 8 9 11];
header = struct('A', [1 2], 'B', 'x7');
writer = dsp.BinaryFileWriter('Matdata.bin', 'HeaderStructure', header);
writer(A);
```

Release the writer so that the reader can access the data.

```
release(writer);
```

Read the Data

Specify the header using the `HeaderStructure` property of the reader object. If the exact header is not known, you must at least specify the prototype of the header, that is, its size and data type. The `dsp.BinaryFileReader` object reads the binary file `Matdata.bin` until the end of file is reached. Specify the System object to read the data into 4 channels, with each channel containing 5 samples. Each loop of the iteration reads a channel (or frame) of data.

```
headerPrototype = struct('A', [0 0], 'B', '-0');
reader = dsp.BinaryFileReader('Matdata.bin', 'HeaderStructure', header, ...
    'NumChannels', 4, 'SamplesPerFrame', 5);
while ~isDone(reader)
    out = reader();
    display(out)
end

out =
```

```
1     2     3     8
4     5     6    10
7     8     9    11
0     0     0     0
0     0     0     0
```

Each frame of `out` contains frames of the matrix `A`, followed by zeros to complete the frame. The original matrix `A` contains 4 channels with 3 samples in each channel. The reader is specified to read data into 4 channels, with each channel containing 5 samples. Because there are not enough samples to complete the frame, the reader object appends zeros at the end of each frame.

Write Complex Data

This example shows how the `dsp.BinaryFileWriter` object writes complex data.

Create a `dsp.BinaryFileWriter` object which writes to a file named 'myfile.dat'. There is no header. The data is complex.

```
writer = dsp.BinaryFileWriter('myfile.dat');
data = [1 2 3 4]+1i*[5 6 7 8];
writer(data);
release(writer);
```

Read the data using the `dsp.BinaryFileReader` System object™. To view data in the format it is written to the file, set the `IsDataComplex` property to `false`. The reader object reads the data as a sequence of numbers in a row major format. Set `SamplesPerFrame` to 1 and `NumChannels` to 8.

```
reader = dsp.BinaryFileReader('myfile.dat','SamplesPerFrame',1,...
    'NumChannels',8);
s = struct([]);
reader.HeaderStructure = s;
dataRead = reader();
```

You can see that the real and imaginary components of the original data are sample interleaved.

```
display(dataRead);

dataRead =

    1     5     2     6     3     7     4     8
```

Write and Read Fixed-Point Data

The `dsp.BinaryFileWriter` and `dsp.BinaryFileReader` System objects do not support writing and reading fixed-point data. As a workaround, you can write the stored integer portion of the `fi` data, read the data, and use this value to reconstruct the `fi` data.

Write the Fixed-Point Data

Create a `fi` object to represent 100 signed random numbers with a word length of 14 and a fraction length of 12. Write the stored integer portion of the `fi` object to the data file `myFile.dat`. The built-in data type is `int16`, which can be computed using `class(storeIntData)`.

```
data = randn(100,1);
fiDataWriter = fi(data,1,14,12);
storeIntData = storedInteger(fiDataWriter);

writer = dsp.BinaryFileWriter('myFile.dat');
writer(storeIntData);
```

Release the writer so that the reader can access the data.

```
release(writer);
```

Read the Fixed-Point Data

Specify the reader to read the stored integer data as `int16` data with 100 samples per data frame. The real-world value of the fixed-point number can be represented using $2^{(-fractionLength) * (storedInteger)}$. If you know the signedness, word length, and fraction length of the fixed-point data, you can reconstruct the `fi` data using `fi(realValue, signedness, wordLength, fractionLength)`. In this example, the data is signed with a word length of 14 and a fraction length of 12.

```
reader = dsp.BinaryFileReader('Filename', 'myFile.dat', 'SamplesPerFrame', 100, ...
    'DataType', 'int16');
data = reader();
fractionLength = 12;
wordLength = 14;
realValue = 2^(-fractionLength) * double(data);

fiDataReader = fi(realValue, 1, wordLength, fractionLength);
```

Verify that the writer data is the same as the reader data.

```
isequal(fiDataWriter,fiDataReader)
```

```
ans =
```

```
logical
```

```
1
```

Write and Read Character Data

The `dsp.BinaryFileWriter` and `dsp.BinaryFileReader` System objects do not support writing and reading characters. As a workaround, cast character data to one of the built-in data types and write the integer data. After the reader reads the data, convert the data to a character using the `char` function.

Write the Character Data

Cast a character into `uint8` using the `cast` function. Write the cast data to the data file `myFile.dat`.

```
data = 'binary_file';  
castData = cast(data,'uint8');  
writer = dsp.BinaryFileWriter('myFile.dat');  
writer(castData);
```

Release the writer so that the reader can access the data.

```
release(writer);
```

Read the `uint8` Data

Specify the reader to read the cast data as `uint8` data.

```
reader = dsp.BinaryFileReader('myFile.dat','DataType','uint8','SamplesPerFrame',11);  
readerData = reader();  
charData = char(readerData);
```

Verify that the writer data is the same as the reader data. By default, the reader returns the data in a column-major format.

```
strcmp(data, charData.')
```

```
ans =
```

```
    logical
```

```
     1
```

Change the Endianness of the Data Before Writing the Data

By default, the `dsp.BinaryFileWriter` System object™ uses the endianness of the host machine. To change the endianness, use the `swapbytes` function.

Write a numeric array into `myfile.dat` using the `dsp.BinaryFileWriter` object. Before writing the data, change the endianness of the data using the `swapbytes` function.

```
data = [1 2 3 4 2 2];  
swapData = swapbytes(data);  
writer = dsp.BinaryFileWriter('myfile.dat');  
writer(swapData);
```

System Objects

`dsp.BinaryFileReader`

Blocks

Binary File Reader | Binary File Writer

Introduced in R2016b

reset

System object: dsp.BinaryFileWriter

Package: dsp

Reset internal states of System object

Syntax

```
reset(writer)
```

Description

`reset(writer)` resets the position in the file at which the writer object writes the data. Upon calling `reset`, the writer object starts writing the data where the header data ends.

Introduced in R2016b

step

System object: dsp.BinaryFileWriter

Package: dsp

Write data to the binary file

Syntax

```
step(writer,data)
```

Description

Note Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

`step(writer,data)` writes data to the binary file in row-major format. Each call to `step` writes the elements of `data` at the end of the file. At the first call to `step`, the object writes the header first, followed by the data. If the header is empty, then no header is written.

The input data can be real or complex. For complex data, real and imaginary parts are interleaved. For example, if `data = [1 2; 3 4]+1j*[5 6; 7 8]`, then the object writes the elements as 1 5 2 6 3 7 4 8.

Introduced in R2016b

dsp.BiquadFilter System object

Package: dsp

IIR filter using biquadratic structures

Description

The `BiquadFilter` object implements an IIR filter structure using biquadratic or second-order sections (SOS).

To implement an IIR filter structure using biquadratic or SOS:

- 1 Define and set up your biquadratic IIR filter. See “Construction” on page 4-214.
- 2 Call `step` to implement the IIR filter according to the properties of `dsp.BiquadFilter`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`biquad = dsp.BiquadFilter` returns a biquadratic IIR (SOS) filter System object, `biquad`, which independently filters each channel of the input over time using the SOS section `[1 0.3 0.4 1 0.1 0.2]` with a direct-form II transposed structure.

`biquad = dsp.BiquadFilter('PropertyName', PropertyValue, ...)` returns a biquadratic filter object, `biquad`, with each property set to the specified value.

`biquad = dsp.BiquadFilter(sosmatrix, scalevalues, ... 'PropertyName', PropertyValue, ...)` returns a biquadratic filter object, with the `SOSMatrix` property set to `sosmatrix`, the `ScaleValues` property set to `scalevalues`, and other specified properties set to the specified values.

Properties

Structure

Filter structure

Specify the filter structure as one of | Direct form I | Direct form I transposed | Direct form II | Direct form II transposed |. The default is Direct form II transposed.

SOSMatrixSource

SOS matrix source

Specify the source of the SOS matrix as one of | Property | Input port |. The default is Property.

SOSMatrix

SOS matrix

Specify the second-order section (SOS) matrix as an N-by-6 matrix, where N is the number of sections in the filter. The default is [1 0.3 0.4 1 0.1 0.2]. Each row of the SOS matrix contains the numerator and denominator coefficients of the corresponding section of the filter. The system function, $H(z)$, of a biquad filter is:

$$H(z) = \frac{\sum_{k=0}^2 b_k z^{-k}}{1 - \sum_{l=1}^2 a_l z^{-l}}$$

The coefficients are ordered in the rows of the SOS matrix as $(b_0, b_1, b_2, 1, -a_1, -a_2)$. You can use coefficients of real or complex values. This property applies only when you set the `SOSMatrixSource` property to `Property`. The leading denominator coefficient of the biquad filter, a_0 , equals 1 for each filter section, regardless of the specified value.

ScaleValues

Scale values for each biquad section

Specify the scale values to apply before and after each section of a biquad filter. `ScaleValues` must be either a scalar or a vector of length $N+1$, where N is the number of

sections. If you set this property to a scalar, the scalar value is used as the gain value only before the first filter section. The remaining gain values are set to 1. If you set this property to a vector of $N+1$ values, each value is used for a separate section of the filter.

This property applies only when you set the `SOSMatrixSource` property to `Property`. The default is 1.

InitialConditions

Initial conditions for direct form II structures

Specify the initial conditions of the filter states when the `Structure` property is one of `Direct form II` | `Direct form II transposed` |. The number of states or delay elements (zeros and poles) in a direct-form II biquad filter equals twice the number of filter sections. You can specify the initial conditions as a scalar, vector, or matrix.

When you specify a scalar value, the biquad filter initializes all delay elements in the filter to that value. When you specify a vector of length equal to the number of delay elements in the filter, each vector element specifies a unique initial condition for the corresponding delay element.

The biquad filter applies the same vector of initial conditions to each channel of the input signal. When you specify a vector of length equal to the product of the number of input channels and the number of delay elements in the filter, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel. When you specify a matrix with the same number of rows as the number of delay elements in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel. The default is the scalar 0.

NumeratorInitialConditions

Initial conditions on zeros side

Specify the initial conditions of the filter states on the side of the filter structure with the zeros. This property applies only when you set the `Structure` property to one of `Direct form I` | `Direct form I transposed` |. The number of states or delay elements in the numerator of a direct-form I biquad filter equals twice the number of filter sections. You can specify the initial conditions as a scalar, vector, or matrix. When you specify a scalar, the biquad filter initializes all delay elements on the zeros side in the filter to that value. When you specify a vector of length equal to the number of delay

elements on the zeros side in the filter, each vector element specifies a unique initial condition for the corresponding delay element on the zeros side.

The biquad filter applies the same vector of initial conditions to each channel of the input signal. When you specify a vector of length equal to the product of the number of input channels and the number of delay elements on the zeros side in the filter, each element specifies a unique initial condition for the corresponding delay element on the zeros side in the corresponding channel. When you specify a matrix with the same number of rows as the number of delay elements on the zeros side in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element on the zeros side in the corresponding channel. The default is the scalar 0.

DenominatorInitialConditions

Initial conditions on poles side

Specify the initial conditions of the filter states on the side of the filter structure with the poles. This property only applies when you set the `Structure` property to one of `| Direct form I | Direct form I transposed |`. The number of denominator states, or delay elements, in a direct-form I (noncanonic) biquad filter equals twice the number of filter sections. You can specify the initial conditions as a scalar, vector, or matrix. When you specify a scalar, the biquad filter initializes all delay elements on the poles side of the filter to that value. When you specify a vector of length equal to the number of delay elements on the poles side in the filter, each vector element specifies a unique initial condition for the corresponding delay element on the poles side.

The object applies the same vector of initial conditions to each channel of the input signal. When you specify a vector of length equal to the product of the number of input channels and the number of delay elements on the poles side in the filter, each element specifies a unique initial condition for the corresponding delay element on the poles side in the corresponding channel. When you specify a matrix with the same number of rows as the number of delay elements on the poles side in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element on the poles side in the corresponding channel. The default is the scalar 0.

OptimizeUnityScaleValues

Optimize unity scale values

When this Boolean property is set to `true`, the biquad filter removes all unity scale gain computations. This reduces the number of computations and increases the fixed-point accuracy. This property applies only when you set the `SOSMatrixSource` property to `Property`. The default is `true`.

ScaleValuesInputPort

How to specify scale values

Select how to specify scale values. This property applies only when the `SOSMatrixSource` property is `Input port`. By default, this property is `true`, and the scale values are specified via the input port. When this property is `false`, all scale values are 1.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `| Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `| Wrap | Saturate |`. The default is `Wrap`.

MultiplicandDataType

Multiplicand word and fraction lengths

Specify the multiplicand fixed-point data type as one of `| Same as output | Custom |`. This property applies only when you set the `Structure` property to `Direct form I transposed`. The default is `Same as output`.

CustomMultiplicandDataType

Custom multiplicand word and fraction lengths

Specify the multiplicand fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `MultiplicandDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

SectionInputDataType

Section input word and fraction lengths

Specify the section input fixed-point data type as one of `| Same as input | Custom |`. The default is `Same as input`.

CustomSectionInputDataType

Custom section input word and fraction lengths

Specify the section input fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `SectionInputDataType` property to `Custom`. The default is `numericType([], 16, 15)`.

SectionOutputDataType

Section output word and fraction lengths

Specify the section output fixed-point data type as one of `| Same as section input | Custom |`. The default is `Same as section input`.

CustomSectionOutputDataType

Custom section output word and fraction lengths

Specify the section output fixed-point type as a signed, scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `SectionOutputDataType` property to `Custom`. The default is `numericType([], 16, 15)`.

NumeratorCoefficientsDataType

Numerator coefficients word and fraction lengths

Specify the numerator coefficients fixed-point data type as one of `| Same word length as input | Custom |`. This property applies only when you set the `SOSMatrixSource` property to `Property`. Setting this property also sets the

`DenominatorCoefficientsDataType` and `ScaleValuesDataType` properties to the same value. The default is Same word length as input.

CustomNumeratorCoefficientsDataType

Custom numerator coefficients word and fraction lengths

Specify the numerator coefficients fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `SOSMatrixSource` property to `Property` and the `NumeratorCoefficientsDataType` property to `Custom`. The word length of the `CustomNumeratorCoefficientsDataType`, `CustomDenominatorCoefficientsDataType`, and `CustomScaleValuesDataType` properties must be the same. The default is `numericType([],16,15)`.

DenominatorCoefficientsDataType

Denominator coefficients word and fraction lengths

Specify the denominator coefficients fixed-point data type as one of `| Same word length as input | Custom |`. This property applies only when you set the `SOSMatrixSource` property to `Property`. Setting this property also sets the `NumeratorCoefficientsDataType` and `ScaleValuesDataType` properties to the same value. The default is Same word length as input.

CustomDenominatorCoefficientsDataType

Custom denominator coefficients word and fraction lengths

Specify the denominator coefficients fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `SOSMatrixSource` property to `Property` and the `DenominatorCoefficientsDataType` property to `Custom`. The `CustomNumeratorCoefficientsDataType`, `CustomDenominatorCoefficientsDataType`, and `CustomScaleValuesDataType` properties must have the same word lengths. The default is `numericType([],16,15)`.

ScaleValuesDataType

Scale values word and fraction lengths

Specify the scale values fixed-point data type as one of `| Same word length as input | Custom |`. This property applies only when you set the `SOSMatrixSource` property to

Property. Setting this property also sets the `NumeratorCoefficientsDataType` and `DenominatorCoefficientsDataType` properties to the same value. The default is Same word length as input.

CustomScaleValuesDataType

Custom scale values word and fraction lengths

Specify the scale values fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `SOSMatrixSource` property to `Property` and the `ScaleValuesDataType` property to `Custom`. The `CustomNumeratorCoefficientsDataType`, `CustomDenominatorCoefficientsDataType`, and `CustomScaleValuesDataType` properties must have the same word lengths. The default is `numericType([], 16, 15)`.

NumeratorProductDataType

Numerator product word and fraction lengths

Specify the mode to determine the numerator product fixed-point data type as:

- Same as input (default) — The numerator product word and fraction lengths are same as that of the input.
- Custom — Enables the `CustomNumeratorProductDataType` property, which you can use to specify the custom numerator product data type. Specify the data type as a `numericType` object.
- Full precision — Use full-precision rules to specify the data type. These rules provide the most accurate fixed-point numerics. The rules prevent quantization from occurring within the object. Bits are added, as needed, so that no roundoff or overflow occurs. For more information, see “Full Precision for Fixed-Point System Objects”.

Setting this property also sets the `DenominatorProductDataType` property to the same value.

CustomNumeratorProductDataType

Custom numerator product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `NumeratorProductDataType` property to `Custom`. The `CustomNumeratorProductDataType` and

`CustomDenominatorProductDataType` properties must have the same word lengths. The default is `numerictype([], 32, 30)`.

DenominatorProductDataType

Denominator product word and fraction lengths

Specify the mode to determine the denominator product fixed-point data type as:

- `Same as input` (default) — The denominator product word and fraction lengths are same as that of the input.
- `Custom` — Enables the `CustomDenominatorProductDataType` property, which you can use to specify the custom denominator product data type. Specify the data type as a `numerictype` object.
- `Full precision` — Use full-precision rules to specify the data type. These rules provide the most accurate fixed-point numerics. The rules prevent quantization from occurring within the object. Bits are added, as needed, so that no roundoff or overflow occurs. For more information, see “Full Precision for Fixed-Point System Objects”.

Setting this property also sets the `NumeratorProductDataType` property to the same value.

CustomDenominatorProductDataType

Custom denominator product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `DenominatorProductDataType` to `Custom`. The `CustomNumeratorProductDataType` and `CustomDenominatorProductDataType` properties must have the same word lengths. The default is `numerictype([], 32, 30)`.

NumeratorAccumulatorDataType

Numerator accumulator word and fraction lengths

Specify the numerator accumulator fixed-point data type as one of `| Same as input | Same as product | Custom |`. Setting this property also sets the `DenominatorAccumulatorDataType` property to the same value. The default is `Same as product`.

CustomNumeratorAccumulatorDataType

Custom numerator accumulator word and fraction lengths

Specify the numerator accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `NumeratorAccumulatorDataType` property to `Custom`. The `CustomNumeratorAccumulatorDataType` and `CustomDenominatorAccumulatorDataType` properties must have the same word lengths. The default is `numericType([], 32, 30)`.

DenominatorAccumulatorDataType

Denominator accumulator word and fraction lengths

Specify the denominator accumulator fixed-point data type as one of `| Same as input | Same as product | Custom|`. Setting this property also sets the `NumeratorAccumulatorDataType` property to the same value. The default is `Same as product`.

CustomDenominatorAccumulatorDataType

Custom denominator accumulator word and fraction lengths

Specify the denominator accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `DenominatorAccumulatorDataType` property to `Custom`. The `CustomNumeratorAccumulatorDataType` and `CustomDenominatorAccumulatorDataType` properties must have the same word lengths. The default is `numericType([], 32, 30)`.

StateDataType

State word and fraction lengths

Specify the state fixed-point data type as one of `| Same as input | Same as accumulator | Custom|`. This property applies when you set the “Structure” on page 4-0 property to `Direct form II` or `Direct form II transposed`. The default is `Same as accumulator`.

CustomStateDataType

Custom state word and fraction lengths

Specify the state fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `StateDataType` property to `Custom`. The default is `numericType([],16,15)`.

NumeratorStateDataType

Numerator state word and fraction lengths

Specify the numerator state fixed-point data type as one of `| Same as input | Same as accumulator | Custom |`. Setting this property also sets the `DenominatorStateDataType` property to the same value. This property applies only when you set the “Structure” on page 4-0 property to `Direct form I transposed`. The default is `Same as accumulator`.

CustomNumeratorStateDataType

Custom numerator state word and fraction lengths

Specify the numerator state fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `StateDataType` property to `Custom`. The `CustomNumeratorProductDataType` and `CustomDenominatorProductDataType` properties must have the same word lengths. The default is `numericType([],16,15)`.

DenominatorStateDataType

Denominator state word and fraction lengths

Specify the denominator state fixed-point data type as one of `| Same as input | Same as accumulator | Custom |`. Setting this property also sets the `NumeratorStateDataType` property to the same value. This property applies only when you set the “Structure” on page 4-0 property to `Direct form I transposed`. The default is `Same as accumulator`.

CustomDenominatorStateDataType

Custom denominator state word and fraction lengths

Specify the denominator state fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `StateDataType` property to `Custom`. The `CustomNumeratorStateDataType` and `CustomDenominatorStateDataType` properties must have the same word lengths. The default is `numericType([],16,15)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of `| Same as input | Same as accumulator | Custom |`. The default is `Same as accumulator`.

CustomOutputDataType

Custom output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the “`OutputDataType`” on page 4-0 property to `Custom`. The default is `numericType([],16,15)`.

Examples

Filter a Signal Using Biquadratic Filter

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Use a fourth order, lowpass biquadratic filter object with a normalized cutoff frequency of 0.4 to filter high frequencies from an input signal. Display the result as a power spectrum using the Spectrum Analyzer.

```
t = (0:1000)'/8e3;
xin = sin(2*pi*0.3e3*t)+sin(2*pi*3e3*t); % Input is 0.3 &
                                         % 3kHz sinusoids

src = dsp.SignalSource(xin, 100);
sink = dsp.SignalSink;

[z,p,k] = ellip(4,1,60,.4); % Set up the filter
[s,g] = zp2sos(z,p,k);
biquad = dsp.BiquadFilter(s,g,'Structure','Direct form I');

sa = dsp.SpectrumAnalyzer('SampleRate',8e3,...
    'PlotAsTwoSidedSpectrum',false,...
    'OverlapPercent', 80,'PowerUnits','dBW',...
    'YLimits', [-160 -10]);

while ~isDone(src)
    input = src();
    filteredOutput = biquad(input);
    sink(filteredOutput);
    sa(filteredOutput)
end
```

```
filteredResult = sink.Buffer;  
fvtool(biquad, 'Fs', 8000)
```

Design and apply a lowpass biquad filter System object™ using the design function.

```
lpSpec = fdesign.lowpass('Fp,Fst,Ap,Ast',500,550,0.5,60,10000);
lpfilter = design(lpSpec,'butter','systemobject',true)
fvtool(lpfilter);
```

```
lpfilter =
```

```
    dsp.BiquadFilter with properties:
```

```
        Structure: 'Direct form II'
    SOSMatrixSource: 'Property'
        SOSMatrix: [42x6 double]
```

```
ScaleValues: [43x1 double]  
InitialConditions: 0  
OptimizeUnityScaleValues: true
```

Use `get` to show all properties

Algorithms

This object implements the algorithm, inputs, and outputs described on the Biquad Filter block reference page. The object properties correspond to the block parameters, except:

- **Coefficient source**
- **Action when the `a0` values of the SOS matrix are not one** – the biquad filter object assumes the zero-th-order denominator coefficient equals 1 regardless of the specified value. The biquad filter object does not support the `Error` or `Warn` options found in the corresponding block.

Both this object and its corresponding block support variable-size input. This means that the `step` method can handle an input which is changing in size.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

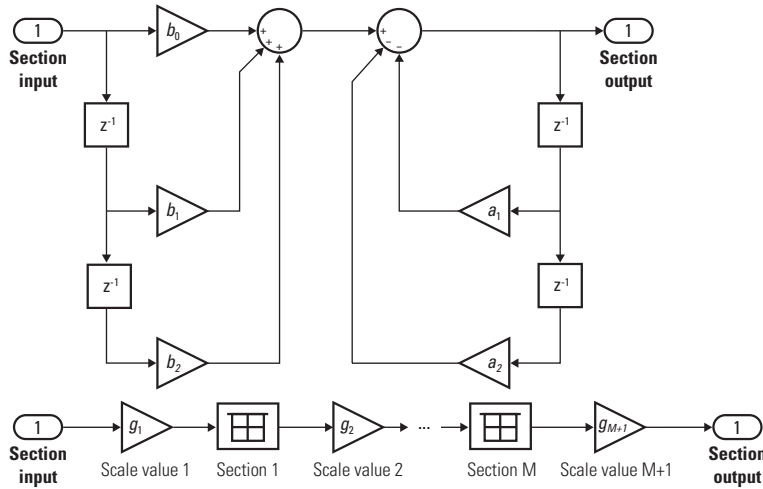

This object supports HDL code generation if you have the HDL Coder installed. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

Fixed-Point Conversion

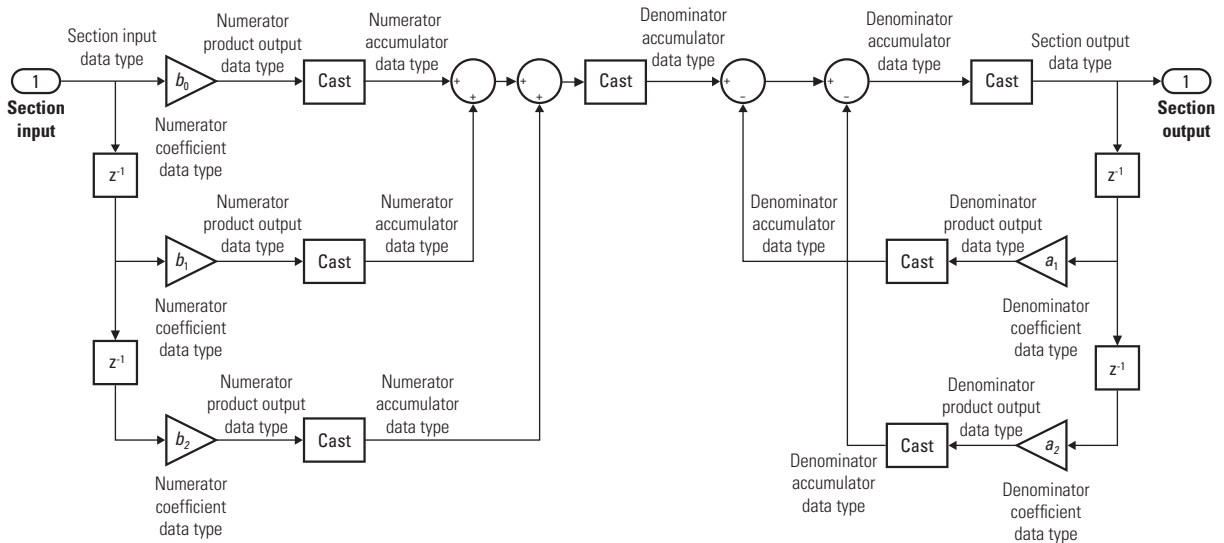

Design and simulate fixed-point algorithms using Fixed-Point Designer™.

The following diagrams show the data types used in the `dsp.BiquadFilter` object when the input is fixed-point. For each filter structure the object supports, the data types shown in the diagrams can be set through the respective fixed-point properties of the object.

Direct Form I

The following diagram shows the data types for one section of the filter for fixed-point signals.

The following diagrams show the fixed-point data types between filter sections.

System Objects

`dsp.FIRFilter` | `dsp.IIRFilter`

Blocks

Biquad Filter

Introduced in R2012a

freqz

System object: dsp.BiquadFilter

Package: dsp

Frequency response

Syntax

```
[h,w] = freqz(biquad)
[h,w] = freqz(biquad,n)
[h,w] = freqz(biquad,Name,Value)
freqz(biquad)
```

Description

`[h,w] = freqz(biquad)` returns the complex, 8192–element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample.

`[h,w] = freqz(biquad,n)` returns the complex, `n`–element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[h,w] = freqz(biquad,Name,Value)` returns the frequency response and the corresponding frequencies, with additional options specified by one or more `Name, Value` pair arguments.

`freqz(biquad)` uses `FVTool` to plot the magnitude and unwrapped phase of the frequency response of the filter System object `biquad`.

fvtool

System object: dsp.BiquadFilter

Package: dsp

Open filter visualization tool

Syntax

```
fvtool(biquad)
fvtool(biquad, 'Arithmetic', ARITH, ...)
```

Description

`fvtool(biquad)` performs an analysis and computes the magnitude response of the filter System object `biquad`.

`fvtool(biquad, 'Arithmetic', ARITH, ...)` analyzes the filter System object `biquad`, based on the arithmetic specified in the `ARITH` input. `ARITH` can be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The 'Arithmetic' input is only relevant for the analysis of filter System objects.

impz

System object: dsp.BiquadFilter

Package: dsp

Impulse response

Syntax

```
[h,t] = impz(biquad)
[h,t] = impz(biquad,Name,Value)
impz(biquad)
```

Description

`[h,t] = impz(biquad)` returns the impulse response `h`, and the corresponding time points `t` at which the impulse response of `biquad` is computed.

`[h,t] = impz(biquad,Name,Value)` returns the impulse response `h`, and the corresponding time points `t`, with additional options specified by one or more `Name, Value` pair arguments.

`impz(biquad)` uses `FVTool` to plot the impulse response of the filter System object `biquad`.

Note You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

phasez

System object: dsp.BiquadFilter

Package: dsp

Unwrapped phase response

Syntax

```
[phi,w] = phasez(biquad)
[phi,w] = phasez(biquad,n)
[phi,w] = phasez(biquad,Name,Value)
phasez(biquad)
```

Description

`[phi,w] = phasez(biquad)` returns the 8192–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample.

`[phi,w] = phasez(biquad,n)` returns the `n`–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[phi,w] = phasez(biquad,Name,Value)` returns the phase response and the corresponding frequencies, with additional options specified by one or more `Name, Value` pair arguments.

`phasez(biquad)` uses `FVTool` to plot the phase response of the filter System object `biquad`.

reset

System object: dsp.BiquadFilter

Package: dsp

Reset states of biquad filter object

Syntax

```
reset(biquad)
```

Description

`reset(biquad)` resets the filter states of the biquad filter object, `biquad`, to the specified initial conditions. After the `step` method applies the biquad filter object to nonzero input data, the states may change. Invoking the `step` method again without first invoking the `reset` method may produce different outputs for an identical input.

Reset a Biquad Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
n = 0:20;  
x = cos(pi/4*n) + sin(pi/2*n);  
biquad = dsp.BiquadFilter;  
y = biquad(x');
```

Call the biquad filter without invoking `reset`.

```
y1 = biquad(x');  
isequal(y, y1)
```

```
ans =
```

```
logical
```

```
0
```

Reset filter states to zero.

```
reset(biquad);
```

Call the biquad filter again.

```
y2 = biquad(x');  
isequal(y,y2)
```

```
ans =
```

```
logical
```

```
1
```

step

System object: dsp.BiquadFilter

Package: dsp

Filter input with biquad filter object

Syntax

```
Y = step(biquad, X)
```

```
Y = step(biquad, X, NUM, DEN)
```

```
Y = step(biquad, X, NUM, DEN, G)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

`Y = step(biquad, X)` filters the real or complex input signal `X`, and outputs the filtered values, `Y`. The biquad filter object filters each channel of the input signal over successive calls to the `step` method.

`Y = step(biquad, X, NUM, DEN)` filters the input using `NUM` as the numerator coefficients, and `DEN` as the denominator coefficients of the biquad filter. `NUM` must be a 3-by- N numeric matrix and `DEN` must be a 2-by- N numeric matrix, where N is the number of biquad filter sections. The object assumes that the first denominator coefficient of each section is 1. This configuration applies when the `SOSMatrixSource` property is `InputPort` and the `ScaleValuesInputPort` property is `false`.

`Y = step(biquad, X, NUM, DEN, G)` specifies the scale values, `G`, of the biquad filter. `G` must be a 1-by- $(N+1)$ numeric vector, where N is the number of biquad filter sections. This configuration applies when the `SOSMatrixSource` property is `InputPort` and the `ScaleValuesInputPort` property is `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.BlockLMSFilter System object

Package: dsp

Compute output, error, and weights using Block LMS adaptive algorithm

Description

The `BlockLMSFilter` object computes output, error, and weights using the Block LMS adaptive algorithm.

To compute the output, error, and weights:

- 1 Define and set up your adaptive FIR filter. See “Construction” on page 4-247.
- 2 Call `step` to compute the output, error, and weights according to the properties of `dsp.BlockLMSFilter`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`blms = dsp.BlockLMSFilter` returns an adaptive FIR filter, `blms`, that filters the input signal and computes filter weights based on the Block Least Mean Squares (LMS) algorithm.

`blsm = dsp.BlockLMSFilter('PropertyName', PropertyValue, ...)` returns an adaptive FIR filter, `blms`, with each specified property set to the specified value.

`blms = dsp.BlockLMSFilter(length,blocksize,'PropertyName',... PropertyValue, ...)` returns an adaptive FIR filter, `blms`, with the `Length` property set to `length`, the `BlockSize` property set to `blocksize`, and other specified properties set to the specified values.

Properties

Length

Length of FIR filter weights vector

Specify the length of the FIR filter weights vector as a positive integer scalar. The default is 32.

BlockSize

Number of samples acquired before weight adaptation

Specify the number of samples of the input signal to acquire before the object updates the filter weights. The input frame length must be an integer multiple of the block size. The default is 32.

StepSizeSource

Source of adaptation step size

Choose to specify the adaptation step size factor as `Property` or `Input port`. The default is `Property`.

StepSize

Adaptation step size

Specify the adaptation step size factor as a scalar, nonnegative numeric value. The default is 0.1. This property applies only when you set the “StepSizeSource” on page 4-0 property to 'Property'. This property is tunable.

LeakageFactor

Leakage factor used in Leaky LMS algorithm

Specify the leakage factor used in Leaky LMS algorithm as a scalar numeric value between 0 and 1, both inclusive. When the value is less than 1, the System object implements a leaky LMS algorithm. The default is 1, providing no leakage in the adapting algorithm. This property is tunable.

InitialWeights

Initial values of filter weights

Specify the initial values of the filter weights as a scalar or a vector of length equal to the “Length” on page 4-0 property value. The default is 0.

AdaptInputPort

Additional input to enable adaptation of filter weights.

Specify when the object should adapt the filter weights. By default, the value of this property is `false`, and the filter continuously updates the filter weights. When this property is set to `true`, an adaptation control input is provided to the `step` method. If the value of this input is nonzero, the filter continuously updates the filter weights. If the input is zero, the filter weights remain at their current value.

WeightsResetInputPort

Additional input to enable weights reset

Specify whether the FIR filter can reset the filter weights. By default, the value of this property is `false`, and the object does not reset the weights. When this property is set to `true`, a reset control input is provided to the `step` method, and the `WeightsResetCondition` property applies. The object resets the filter weights based on the values of the `WeightsResetCondition` property and the reset input to the `step` method.

WeightsResetCondition

Condition that triggers the resetting of filter weights

Specify the event to reset the filter weights as one of `Rising edge`, `Falling edge`, `Either edge`, or `Non-zero`. The object resets the filter weights based on the values of this property and the reset input to the `step` method. This property applies only when you set the `WeightsResetInputPort` property to `true`. The default is `Non-zero`.

WeightsOutputPort

Output filter weights

Set this property to `true` to output the adapted filter weights. The default is `true`.

Methods

msesim	Mean-square error for Block LMS filter
reset	Reset internal states of adaptive FIR filter object
step	Filter inputs using Block LMS algorithm

Common to All System Objects	
clone	Create System object with same property values
getNumInputs	Expected number of inputs to a System object
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Remove Noise Using Block LMS Adaptive Algorithm

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
blms = dsp.BlockLMSFilter(10,5);
blms.StepSize = 0.01;
blms.WeightsOutputPort = false;
filt = dsp.FIRFilter;
filt.Numerator = fir1(10,[.5, .75]);
x = randn(1000,1); % Noise
d = filt(x) + sin(0:.05:49.95)'; % Noise + Signal
[y, err] = blms(x, d);
subplot(2,1,1);
plot(d);
title('Noise + Signal');
subplot(2,1,2);
```

```
plot(err);  
title('Signal');
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Block LMS Filter block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

See Also

`dsp.FIRFilter` | `dsp.LMSFilter`

Introduced in R2012a

mstesim

System object: dsp.BlockLMSFilter

Package: dsp

Mean-square error for Block LMS filter

Syntax

```
MSE = mstesim(sysObj, X, D)
[MSE, MEANW, W, TRACEK] = mstesim(sysObj, X, D)
[...] = mstesim(sysObj, X, D, M)
```

Description

`MSE = mstesim(sysObj, X, D)` returns a sequence of mean-square errors. This column vector contains estimates of the mean-square error of the adaptive filter at each time instant. The length of `MSE` is equal to `SIZE(X, 1)`. The columns of the matrix `X` contain individual input signal sequences, and the columns of the matrix `D` contain corresponding desired response signal sequences.

`[MSE, MEANW, W, TRACEK] = mstesim(sysObj, X, D)` calculates three parameters corresponding to the simulated behavior of the adaptive filter defined by `sysObj`. `MEANW` is a sequence of coefficient vector means. The columns of this matrix contain estimates of the mean values of the adaptive filter coefficients at each time instant. The dimensions of `MEANW` are `(SIZE(X, 1))` by `(sysObj.length)`. `W` is an estimate of the final values of the adaptive filter coefficients for the algorithm corresponding to `sysObj`. `TRACEK` is a sequence of total coefficient error powers. This column vector contains estimates of the total coefficient error power of the adaptive filter at each time instant. The length of `TRACEK` is equal to `SIZE(X, 1)`.

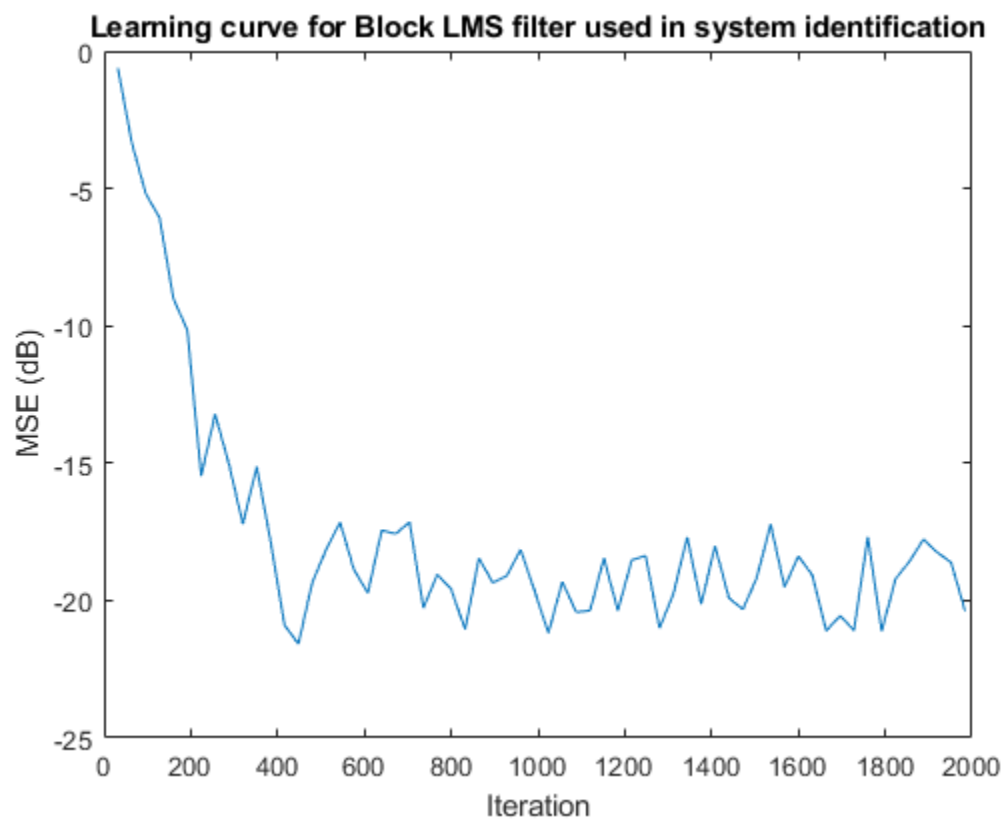

`[...] = mstesim(sysObj, X, D, M)` specifies an optional decimation factor for computing `MSE`, `MEANW`, and `TRACEK`. If `M > 1`, every `Mth` predicted value of each of these sequences is saved. If omitted, the value of `M` is the default, which is 1.

System Identification of an FIR Filter Using Block LMS Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent step syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
fir = fir1(31,0.5);
firFilter = dsp.FIRFilter('Numerator',fir); % FIR system to be identified
iirFilter = dsp.IIRFilter('Numerator',sqrt(0.75),...
    'Denominator',[1 -0.5]);
x = iirFilter(sign(randn(2000,25)));
n = 0.1*randn(size(x)); % Observation noise signal
d = firFilter(x)+n; % Desired signal
l = 32; % Filter length
mu = 0.008; % Block LMS Step size.
m = 32; % Decimation factor for analysis
% and simulation results

fir = dsp.BlockLMSFilter(l,'StepSize',mu);
[simmse,meanWsim,Wsim,traceKsim] = msesim(fir,x,d,m);
plot(m*(1:length(simmse)),10*log10(simmse));
xlabel('Iteration'); ylabel('MSE (dB)');
title('Learning curve for Block LMS filter used in system identification')
```

reset

System object: dsp.BlockLMSFilter

Package: dsp

Reset internal states of adaptive FIR filter object

Syntax

```
reset(blms)
```

Description

`reset(blms)` sets the internal states of the `BlockLMSFilter` object `blms` to their initial values.

step

System object: dsp.BlockLMSFilter

Package: dsp

Filter inputs using Block LMS algorithm

Syntax

```
[Y,ERR,WTS] = step(blms,X,D)
[Y,ERR] = step(blms,X,D)
[...] = step(blms,X,D,MU)
[...] = step(blms,X,D,A)
[...] = step(blms,X,D,R)
[Y,ERR,WTS] = step(blms,X,D,MU,A,R)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[Y,ERR,WTS] = step(blms,X,D)` filters the input `X`, using `D` as the desired signal, and returns the filtered output in `Y`. The filter error is in `ERR`, and the estimated filter weights is in `WTS`. The filter weights update once for every block of data that the object processes.

`[Y,ERR] = step(blms,X,D)` returns only the filtered output in `Y` and the filter error in `ERR`, when the `WeightsOutputPort` property is `false`.

`[...] = step(blms,X,D,MU)` uses `MU` as the step size, when you set the `StepSizeSource` property to `Input port`.

[...] = `step(blms, X, D, A)` uses `A` as the adaptation control, when you set the `AdaptInputPort` property to `true`. When `A` is nonzero, the filter continuously updates the filter weights. When `A` is zero, the filter weights remain constant.

[...] = `step(blms, X, D, R)` uses `R` as a reset signal, when you set the `WeightsResetInputPort` property to `true`. Use the `WeightsResetCondition` property to set the reset trigger condition. If a reset event occurs, the filter resets the filter weights to their initial values.

[`Y, ERR, WTS`] = `step(blms, X, D, MU, A, R)` filters input `X`, using `D` as the desired signal, `MU` as the step size, `A` as the adaptation control, and `R` as the reset signal. The object returns the filtered output in `Y`, the filter error in `ERR`, and the adapted filter weights in `WTS`. Set the properties appropriately to provide all possible inputs.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.Buffer System object

Package: dsp

Buffer input signal

Description

The `Buffer` object buffers an input signal. The number of samples per channel in the input must equal the difference between the output buffer size and buffer overlap (i.e., `Length - OverlapLength`).

To buffer an input signal:

- 1 Define and set up your buffer System object. See “Construction” on page 4-259.
- 2 Call `step` to buffer the input according to the properties of `dsp.Buffer`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`buff = dsp.Buffer` returns a buffer System object, `buff`, used to buffer input signals with overlap.

`buff = dsp.Buffer('PropertyName', PropertyValue, ...)` returns a buffer object, `buff`, with each specified property set to the specified value.

`buff = dsp.Buffer(LEN, OVLAP, ICS, 'PropertyName', ... PropertyValue, ...)` returns a buffer object, `buff`, with “Length” on page 4-0 property set to `LEN`, `OverlapLength` property set to `OVLAP`, “InitialConditions” on page 4-0 property set to `ICS` and other specified properties set to the specified values.

Properties

Length

Number of samples to buffer

Specify the number of consecutive samples from each input channel to buffer. You can set this property to any scalar integer greater than 0 of MATLAB built-in numeric data type. The default is 64.

OverlapLength

Amount of overlap between outputs

Specify the number of samples by which consecutive output frames overlap. You can set this property to any scalar integer greater than or equal to 0 of MATLAB built-in numeric data type. The default is 0.

InitialConditions

Initial output

Specify the value of the object's initial output for cases of nonzero latency as a scalar, vector, or matrix. The default is 0.

Methods

`reset` Reset the internal states of a System object

`step` Buffer input signal based on past values

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)

Common to All System Objects

release	Allow System object property value changes
---------	--

Examples

Create a Buffer

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Create a buffer of 256 samples with 128 sample overlap.

```
reader = dsp.SignalSource(randn(1024,1),128);
buff = dsp.Buffer(256,128);

for i = 1:8
    y = buff(reader());
end
```

`y` is of length 256 with 128 samples from previous input.

Algorithms

This object implements the algorithm, inputs, and outputs described on the Buffer block reference page. The object properties correspond to the block properties, except as noted.

See Also

`dsp.Delay` | `dsp.DelayLine`

Introduced in R2012a

reset

System object: dsp.Buffer

Package: dsp

Reset the internal states of a System object

Syntax

```
reset(buff)
```

Description

`reset(buff)` resets the internal states of buffer to their initial values.

For many System objects, this method is a no-op. Objects that have internal states will describe in their help what the reset method does for that object.

The reset method is always a no-op for unlocked System objects, as the states may not be allocated when the object is not locked.

step

System object: dsp.Buffer

Package: dsp

Buffer input signal based on past values

Syntax

`Y = step(buff,X)`

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(buff,X)` creates output `Y` based on current input and stored past values of `X`. Output length equals the `Length` property.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.BurgAREstimator System object

Package: dsp

Estimate of autoregressive (AR) model parameters using Burg method

Description

The `BurgAREstimator` object computes the estimate of the autoregressive (AR) model parameters using the Burg method.

To compute the estimate of the AR model parameters:

- 1 Define and set up your System object. See “Construction” on page 4-264.
- 2 Call `step` to compute the estimate according to the properties of `dsp.BurgAREstimator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`burgarest = dsp.BurgAREstimator` returns a Burg `BurgAREstimator` System object, `burgarest`, that performs parametric AR estimation using the Burg maximum entropy method.

`burgarest = dsp.BurgAREstimator('PropertyName',PropertyValue,...)` returns a Burg AR estimator object, `burgarest`, with each specified property set to the specified value.

Properties

AOutputPort

Enable output of polynomial coefficients

Set this property to `true` to output the polynomial coefficients, A , of the AR model the object computes. The default is `true`. Either the `AOutputPort` property, the `KOutputPort` property, or both must be `true`.

KOutputPort

Enable output of reflection coefficients

Set this property to `true` to output the reflection coefficients, K , for the AR model that the object computes. The default is `false`. Either the `AOutputPort` property, the `KOutputPort` property, or both must be `true`.

EstimationOrderSource

Source of estimation order

Specify how to determine estimator order as `Auto` or `Property`. When you set this property to `Auto`, the object assumes the estimation order is one less than the length of the input vector. When you set this property to `Property`, the value in `EstimationOrder` is used. The default is `Auto`.

EstimationOrder

Order of AR model

Set the AR model estimation order to a real positive integer. This property applies when you set the `EstimationOrderSource` to `Property`. The default is 4.

Methods

`step` Normalized estimate of AR model parameter

Common to All System Objects	
clone	Create System object with same property values
getNumInputs	Expected number of inputs to a System object
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

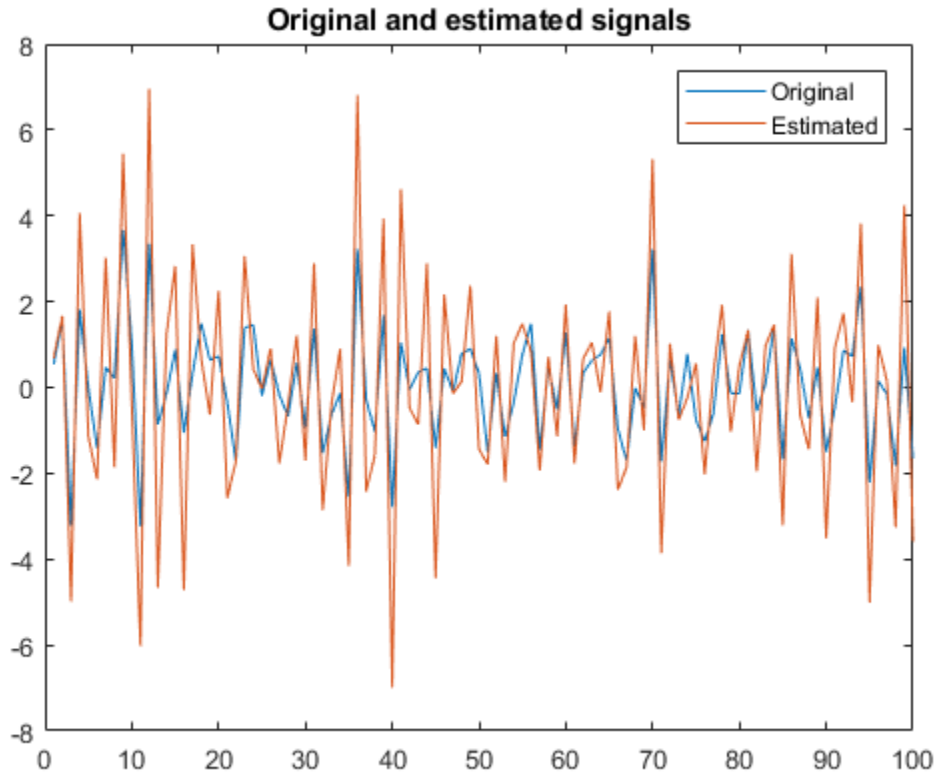

Examples

Estimate the parameters of an AR model

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Use the `dsp.BurgAREstimator` System object™ to estimate the parameters of an AR model.

```
rng default; % Use default random number generator and seed
noise = randn(100,1); % Normalized white Gaussian noise
x = filter(1,[1 1/2 1/3 1/4 1/5],noise);
burgarest = dsp.BurgAREstimator(...
    'EstimationOrderSource', 'Property', ...
    'EstimationOrder', 4);
[a, g] = burgarest(x);
x_est = filter(g, a, x);
plot(1:100,[x x_est]);
title('Original and estimated signals');
legend('Original', 'Estimated');
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Burg AR Estimator block reference page. The object properties correspond to the block parameters, except:

Output(s) block parameter corresponds to the `AOutputPort` and the `KOutputPort` object properties.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

`dsp.LevinsonSolver`

Introduced in R2012a

step

System object: dsp.BurgAREstimator

Package: dsp

Normalized estimate of AR model parameter

Syntax

```
[A,G] = step(burgarest,X)
[K,G] = step(burgarest,X)
[A,K,G] = step(burgarest,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[A,G] = step(burgarest,X)` computes the normalized estimate of the AR model parameters to fit the input, `X`, in the least square sense. The input `X` must be a column vector. Output `A` is a column vector that contains the normalized estimate of the AR model polynomial coefficients in descending powers of z . The scalar `G` is the AR model gain.

`[K,G] = step(burgarest,X)` returns `K`, a column vector containing the AR model reflection coefficients when you set the `KOutputPort` property to `true` and the `AOutputPort` property to `false`.

`[A,K,G] = step(burgarest,X)` returns the AR model polynomial coefficients `A`, reflection coefficients `K`, and the scalar gain `G` when the `AOutputPort` and `KOutputPort` properties are both `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.BurgSpectrumEstimator System object

Package: dsp

Parametric spectral estimate using Burg method

Description

The `BurgSpectrumEstimator` object computes a parametric spectral estimate of the input using the Burg method. The object fits an autoregressive (AR) model to the signal by minimizing the forward and backward prediction errors (via least-squares). The AR parameters are constrained to satisfy the Levinson-Durbin recursion.

To compute the parametric spectral estimate of the input:

- 1 Define and set up your System object. See “Construction” on page 4-271.
- 2 Call `step` to compute the estimate according to the properties of `dsp.BurgSpectrumEstimator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`burgspecest = dsp.BurgSpectrumEstimator` returns an object, `burgspecest`, that estimates the power spectral density (PSD) of the input frame using the Burg method.

`burgspecest = dsp.BurgSpectrumEstimator('PropertyName', PropertyValue, ...)` returns a spectrum estimator, `burgspecest`, with each specified property set to the specified value.

Properties

EstimationOrderSource

Source of estimation order

Specify the source of the estimation order as `Auto` or `Property`. If you set this property to `Auto`, the object assumes the estimation order is one less than the length of the input vector. The default value is `Property`.

EstimationOrder

Order of AR model

Specify the order of AR model as a real positive integer. This property applies only when you set the `EstimationOrderSource` property to `Property`. The default value is 6.

FFTLengthSource

Source of FFT length

Specify the source of the FFT length as `Auto` or `Property`. When you set this property to `Auto`, the objects assumes the FFT length is one more than the estimation order. When you set this property to `Property`, the “`FFTLength`” on page 4-0 property value must be an integer power of two.

FFTLength

FFT length as power-of-two integer value

Specify the FFT length as a power-of-two numeric scalar. This property applies when you set the `FFTLengthSource` property to `Property`. The default value is 256.

SampleRate

Sample rate of input time series

Specify the sampling rate of the original input time series as a positive numeric scalar in hertz. The default value is 1.

Methods

step Estimate of power spectral density

Common to All System Objects	
clone	Create System object with same property values
getNumInputs	Expected number of inputs to a System object
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

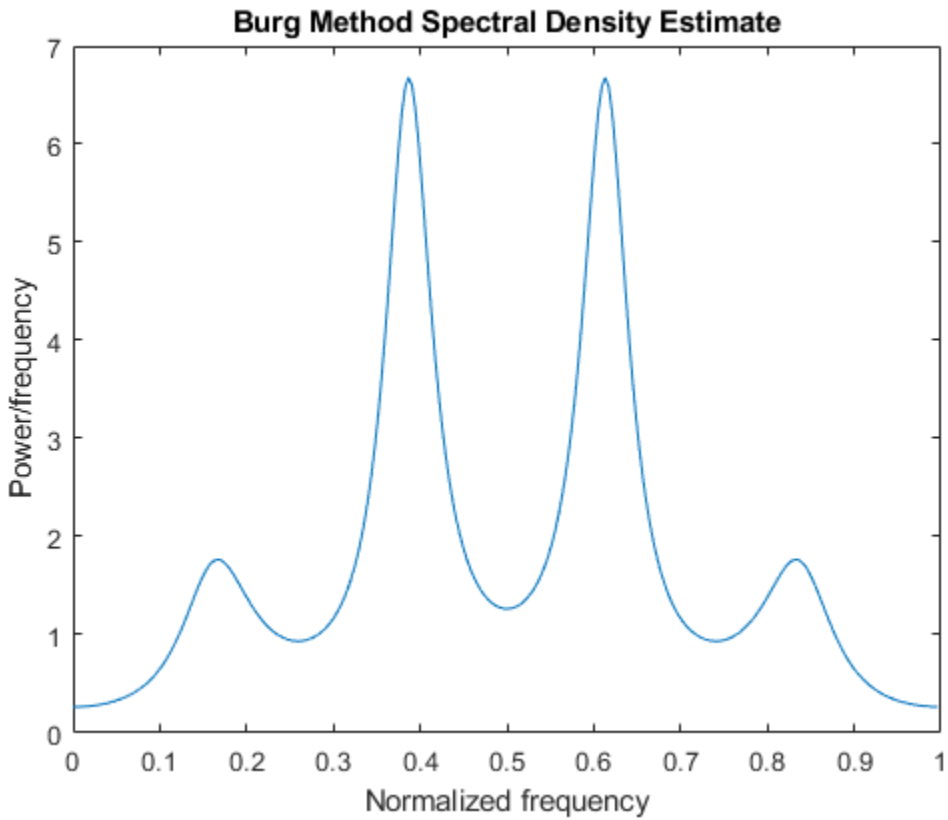

Examples

Estimate PSD Using the Burg Method

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
x = randn(100,1);
burgspecest = dsp.BurgSpectrumEstimator('EstimationOrder', 4);
y = filter(1,[1 1/2 1/3 1/4 1/5],x); % Fourth order AR filter
p = burgspecest(y); % Uses default FFT length of 256

plot((0:255)/256, p);
title('Burg Method Spectral Density Estimate');
xlabel('Normalized frequency'); ylabel('Power/frequency');
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Burg Method block reference page. The object properties correspond to the block properties.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- “System Objects in MATLAB Code Generation” (MATLAB Coder)
- When the FFT length is not a power of two, the executable generated from this System object relies on prebuilt dynamic library files (.dll files) included with MATLAB. Use the `packNGo` function to package the code generated from this object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.
- When the FFT length is a power of two, you can generate standalone C and C++ code from this System object.

Package: dsp

Estimate of power spectral density

Syntax

`Y = step(burgspecest,X)`

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(burgspecest,X)` outputs `Y`, a spectral estimate of input `X`, using the Burg method.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.CepstralToLPC System object

Package: dsp

Convert cepstral coefficients to linear prediction coefficients

Description

The `CepstralToLPC` object converts cepstral coefficients to linear prediction coefficients (LPC).

To convert cepstral coefficients to LPC:

- 1 Define and set up your System object. See “Construction” on page 4-277.
- 2 Call `step` to convert the coefficients according to the properties of `dsp.CepstralToLPC`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`cc2lpc = dsp.CepstralToLPC` returns a System object, `cc2lpc`, that converts the cepstral coefficients (CCs) to linear prediction coefficients (LPCs).

`cc2lpc = dsp.CepstralToLPC('PropertyName', PropertyValue, ...)` returns a Cepstral to LPC object, `cc2lpc`, with each specified property set to the specified value.

Properties

PredictionErrorOutputPort

Enable prediction error power output

Set this property to `true` to output the prediction error power. The prediction error power is the power of the error output of an FIR analysis filter represented by the LPCs for a given input signal. The default is `false`.

Methods

`step` LPC coefficients from column of cepstral coefficients

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object

step

System object: dsp.CepstralToLPC

Package: dsp

LPC coefficients from column of cepstral coefficients

Syntax

```
A = step(cc2lpc,CC)
[A,P]=step(cc2lpc,CC)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`A = step(cc2lpc,CC)` computes the linear prediction coefficients (LPC) coefficients, `A`, from the columns of cepstral coefficients, `CC`.

`[A,P]=step(cc2lpc,CC)` converts the columns of the cepstral coefficients `CC` to the LPCs and returns the prediction error power `P` when the `PredictionErrorOutputPort` property is `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.Channelizer System object

Package: dsp

Polyphase FFT analysis filter bank

Description

The `dsp.Channelizer` System object separates a broadband input signal into multiple narrow subbands using a fast Fourier transform (FFT)-based analysis filter bank. The filter bank uses a prototype lowpass filter and is implemented using a polyphase structure. You can specify the filter coefficients directly or through design parameters.

To separate a broadband signal into multiple narrow subbands:

- 1 Create the `dsp.Channelizer` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#) (MATLAB).

Creation

Syntax

```
channelizer = dsp.Channelizer
channelizer = dsp.Channelizer(M)
channelizer = dsp.Channelizer(Name, Value)
```

Description

`channelizer = dsp.Channelizer` creates a polyphase FFT analysis filter bank System object that separates a broadband input signal into multiple narrowband output signals. This object implements the inverse operation of the `dsp.ChannelSynthesizer` System object.

`channelizer = dsp.Channelizer(M)` creates an M -band polyphase FFT analysis filter bank, with the “NumFrequencyBands” on page 4-0 property set to M .

Example: `channelizer = dsp.Channelizer(16);`

`channelizer = dsp.Channelizer(Name, Value)` creates a polyphase FFT analysis filter bank with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `channelizer = dsp.Channelizer('NumTapsPerBand',20,'StopbandAttenuation',140);`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects \(MATLAB\)](#).

NumFrequencyBands — Number of frequency bands

8 (default) | positive integer greater than 1

Number of frequency bands into which the object separates the input broadband signal, specified as a positive integer greater than 1. This property corresponds to the number of polyphase branches and the FFT length used in the filter bank.

Example: 16

Example: 64

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Specification — Filter design parameters or coefficients

'Number of taps per band and stopband attenuation' (default) |
'Coefficients'

Filter design parameters or filter coefficients, specified as one of these options:

- 'Number of taps per band and stopband attenuation' — Specify the filter design parameters through the NumTapsPerBand and “Stopband attenuation (dB)” on page 2-0 properties.
- 'Coefficients' — Specify the filter coefficients directly using the “LowpassCoefficients” on page 4-0 property.

NumTapsPerBand — Number of filter coefficients per frequency band

12 (default) | positive integer

Number of filter coefficients each polyphase branch uses, specified as a positive integer. The number of polyphase branches matches the number of frequency bands. The total number of filter coefficients for the prototype lowpass filter is given by $\text{NumFrequencyBands} \times \text{NumTapsPerBand}$. For a given stopband attenuation, increasing the number of taps per band narrows the transition width of the filter. As a result, there is more usable bandwidth for each frequency band at the expense of increased computation.

Example: 8

Example: 16

Dependencies

This property applies when you set Specification to 'Number of taps per band and stopband attenuation'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

StopbandAttenuation — Stopband attenuation

80 (default) | positive real scalar

Stopband attenuation of the lowpass filter, specified as a positive real scalar in dB. This value controls the maximum amount of aliasing from one frequency band to the next. When the stopband attenuation increases, the passband ripple decreases. For a given stopband attenuation, increasing the number of taps per band narrows the transition width of the filter. As a result, there is more usable bandwidth for each frequency band at the expense of increased computation.

Example: 80

Dependencies

This property applies when you set `Specification` to 'Number of taps per band and stopband attenuation'.

Data Types: `single` | `double`

LowpassCoefficients — Coefficients of prototype lowpass filter

[1×49 `double`] (default) | row vector

Coefficients of the prototype lowpass filter, specified as a row vector. There must be at least one coefficient per frequency band. If the length of the lowpass filter is less than the number of frequency bands, the object zero-pads the coefficients.

Tunable: Yes

Dependencies

This property applies when you set `Specification` to 'Coefficients'.

Data Types: `single` | `double`

Usage

Syntax

```
channOut = channelizer(input)
```

Description

`channOut = channelizer(input)` separates the broadband input signal into a number of narrow band signals contained in the columns of the channelizer output.

Input Arguments

input — Data input

vector | matrix

Data input, specified as a vector or a matrix. The number of rows in the input signal must be a multiple of the number of frequency bands of the filter bank. Each column of

the input corresponds to a separate channel. If M is the number of frequency bands, and the input is an L -by-1 matrix, then the output signal has dimensions L/M -by- M . Each narrowband signal forms a column in the output. If the input has more than one channel, that is, it has dimensions L -by- N with $N > 1$, then the output has dimensions L/M -by- M -by- N .

This object supports variable-size input signals. You can change the input frame size (number of rows) even after calling the algorithm. However, the number of channels (number of columns) must remain constant.

Example: `randn(64,4)`

Data Types: `single` | `double`

Output Arguments

channOut — Channelizer output

matrix | 3-D array

Channelizer output, returned as a matrix or a 3-D array. If the input is an L -by-1 matrix, then the output signal has dimensions L/M -by- M , where M is the number of frequency bands. Each narrowband signal forms a column in the output. If the input has more than one channel, that is, it has dimensions L -by- N with $N > 1$, then the output has dimensions L/M -by- M -by- N .

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.Channelizer

<code>coeffs</code>	Coefficients of prototype lowpass filter
<code>tf</code>	Return transfer function of overall prototype lowpass filter
<code>polyphase</code>	Return polyphase matrix
<code>freqz</code>	Frequency response of filters in channelizer

<code>fvtool</code>	Visualize the filters in the channelizer
<code>bandedgeFrequencies</code>	Compute the bandedge frequencies
<code>centerFrequencies</code>	Compute center frequencies
<code>getFilters</code>	Return matrix of channelizer FIR filters

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>clone</code>	Create duplicate System object
<code>getNumInputs</code>	Number of inputs required to call the System object
<code>getNumOutputs</code>	Number of outputs from calling the System object
<code>isLocked</code>	Determine if System object is locked
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Quadrature Mirror Filter Bank

The quadrature mirror filter bank (QMF) contains an analysis filter bank section and a synthesis filter bank section. `dsp.Channelizer` implements the analysis filter bank. `dsp.ChannelSynthesizer` implements the synthesis filter bank using the efficient polyphase implementation based on a prototype lowpass filter.

Initialization

Initialize the `dsp.Channelizer` and `dsp.ChannelSynthesizer` System objects. Each object is set up with 8 frequency bands, 8 polyphase branches in each filter, 12 coefficients per polyphase branch, and a stopband attenuation of 140 dB. Use a sine wave with multiple frequencies as the input signal. View the input spectrum and the output spectrum using a spectrum analyzer.

```
offsets = [-40,-30,-20,10,15,25,35,-15];
sinewave = dsp.SineWave('ComplexOutput',true,'Frequency',...
    offsets+(-375:125:500),'SamplesPerFrame',800);

channelizer = dsp.Channelizer('StopbandAttenuation',140);
synthesizer = dsp.ChannelSynthesizer('StopbandAttenuation',140);
```

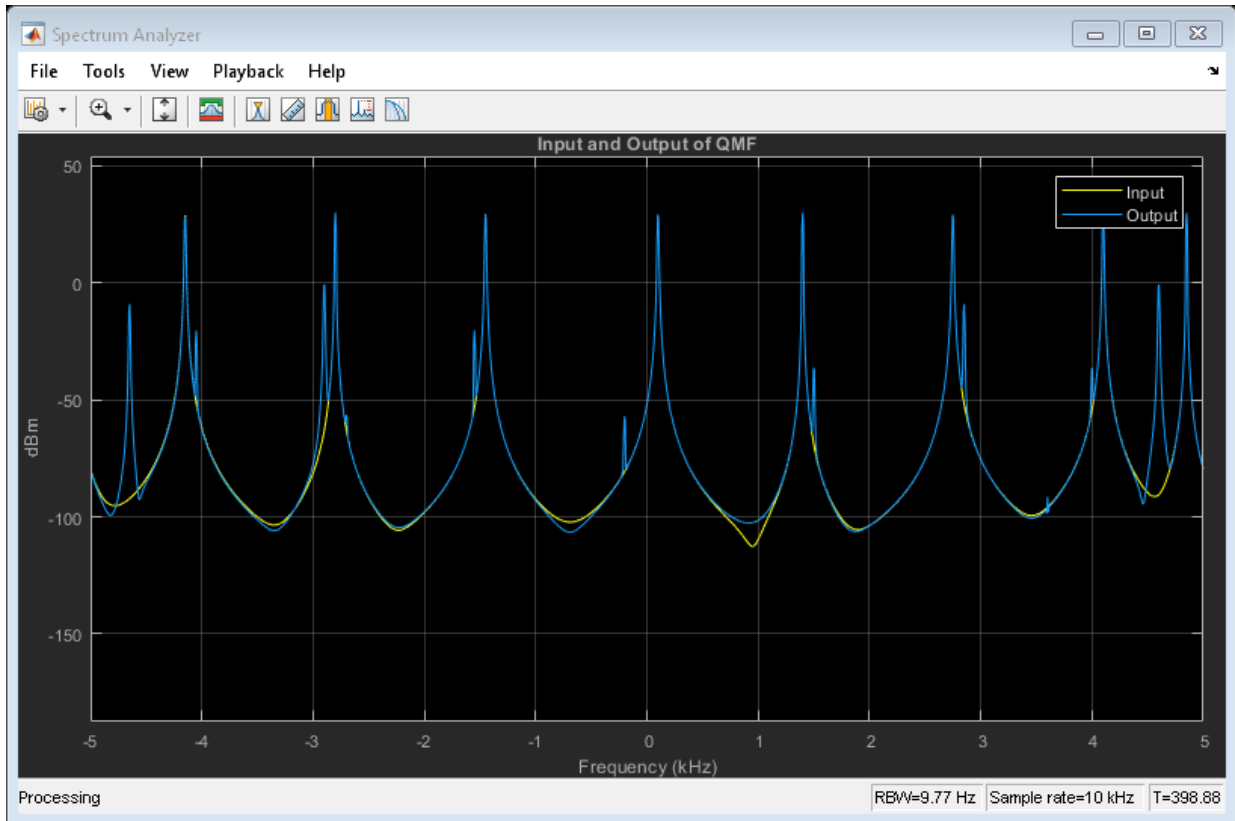

```
spectrumAnalyzer = dsp.SpectrumAnalyzer('ShowLegend',true,'NumInputPorts',...  
    2,'ChannelNames',{'Input','Output'},'Title','Input and Output of QMF');
```

Streaming

Use the channelizer to split the broadband input signal into multiple narrow bands. Then pass the multiple narrowband signals into the synthesizer, which merges these signals to form the broadband signal. Compare the spectra of the input and output signals. The input and output spectra match very closely.

```
for i = 1:5000  
    x = sum(sinewave(),2);  
    y = channelizer(x);  
    v = synthesizer(y);  
    spectrumAnalyzer(x,v)  
end
```

Definitions

Analysis Filter Bank

The analysis filter bank consists of a series of parallel bandpass filters that split an input broadband signal, $x(n)$, into a series of narrow subbands. Each bandpass filter retains a different portion of the input signal. After the bandwidth is reduced by one of the bandpass filters, the signal is downsampled to a lower sampling rate commensurate with the new bandwidth.

Prototype Lowpass Filter

To implement the analysis filter bank efficiently, the channelizer uses a prototype lowpass filter. This filter has an impulse response of $h[n]$, a normalized two-sided bandwidth of $2\pi/M$, and a cutoff frequency of π/M . M is the number of frequency bands, that is, the branches of the analysis filter bank. This value corresponds to the FFT length that the filter bank uses. M can be high on the order of 2048 or more. The stopband attenuation determines the minimum level of interference (aliasing) from one frequency band to another. The passband ripple must be small so that the input signal is not distorted in the passband.

The prototype lowpass filter models the first branch of the filter bank. The other $M - 1$ branches are modeled by filters that are modulated versions of the prototype filter. The modulation factor is given by the following equation:

$$e^{-jw_k n}, \quad w_k = 2\pi k / M, \quad k = 0, 1, \dots, M - 1$$

Using the Prototype Lowpass Filter

The transfer function of the modulated k th bandpass filter is given by:

$$H_k(z) = H_0(z e^{-jw_k}), \quad w_k = 2\pi k / M, \quad k = 1, 2, \dots, M - 1$$

This figure shows the frequency response of M filters.

To obtain the frequency response characteristics of the filter $H_k(z)$, where $k = 1, \dots, M-1$, uniformly shift the frequency response of the prototype filter, $H_0(z)$, by multiples of $2\pi/M$. Each subband filter, $H_k(z)$, $\{k = 1, \dots, M-1\}$, is derived from the prototype filter.

Shift Narrow Subbands to Baseband

The frequency components in the input signal, $x(n)$, are translated in frequency to baseband by multiplying $x(n)$ with the complex exponentials,

$e^{-jw_k n}$, where $w_k = 2\pi k / M$, and $k = 1, 2, \dots, M-1$, where, $w_k = 2\pi k / M$, and

$k = 1, 2, \dots, M-1$. The resulting product signals are passed through the lowpass filters, $H_0(z)$. The output of the lowpass filter is relatively narrow in bandwidth. Downsample the signal commensurate with the new bandwidth. Choose a decimation factor, $D \leq M$, where M is the number of branches of the analysis filter bank.

The figure shows an analysis filter bank that uses the prototype lowpass filter.

$y_1(n), y_2(n), \dots, y_{M-1}(n)$ are narrow subband signals translated into baseband.

Algorithms

Polyphase Implementation

The analysis filter bank can be implemented efficiently using the polyphase structure. To derive the polyphase structure, start with the transfer function of the prototype lowpass filter:

$$H_0(z) = b_0 + b_1 z^{-1} + \dots + b_N z^{-N}$$

$N+1$ is the length of the prototype filter.

You can rearrange this equation as follows:

$$\begin{aligned}
 H_0(z) = & z^{-1} \left(b_0 + b_M z^{-M} + b_{2M} z^{-2M} + \dots + b_{N-M+1} z^{-(N-M+1)} \right) + \\
 & z^{-1} \left(b_1 + b_{M+1} z^{-M} + b_{2M+1} z^{-2M} + \dots + b_{N-M+2} z^{-(N-M+1)} \right) + \\
 & \vdots \\
 & z^{-(M-1)} \left(b_{M-1} + b_{2M-1} z^{-M} + b_{3M-1} z^{-2M} + \dots + b_N z^{-(N-M+1)} \right)
 \end{aligned}$$

M is the number of polyphase components.

You can write this equation as:

$$H_0(z) = E_0(z^M) + z^{-1} E_1(z^M) + \dots + z^{-(M-1)} E_{M-1}(z^M)$$

$E_0(z^M), E_1(z^M), \dots, E_{M-1}(z^M)$ are polyphase components of the prototype lowpass filter, $H_0(z)$.

The other filters in the filter bank, $H_k(z)$, where $k = 1, \dots, M-1$, are modulated versions of this prototype filter.

You can write the transfer function of the k th modulated bandpass filter as

$$H_k(z) = H_0(z e^{-jw_k})$$

Replacing z with $z e^{jw_k}$,

$$H_k(z) = h_0 + h_1 e^{-jw_k} z^{-1} + h_2 e^{-j2w_k} z^{-2} \dots + h_N e^{-jNw_k} z^{-N}$$

$N+1$ is the length of the k th filter.

In polyphase form, the equation is as follows:

$$H_k(z) = \begin{bmatrix} 1 & e^{-jw_k} & e^{-j2w_k} & \dots & e^{-j(M-1)w_k} \end{bmatrix} \begin{bmatrix} E_0(z^M) \\ z^{-1} E_1(z^M) \\ \vdots \\ z^{-(M-1)} E_{M-1}(z^M) \end{bmatrix}$$

For all M channels in the filter bank, the MIMO transfer function, $H(z)$, is given by:

$$H(z) = \begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & e^{-j\omega_1} & e^{-j2\omega_1} & \dots & e^{-j(M-1)\omega_1} \\ & & \vdots & & \\ 1 & e^{-j\omega_{M-1}} & e^{-j2\omega_{M-1}} & \dots & e^{-j(M-1)\omega_{M-1}} \end{bmatrix} \begin{bmatrix} E_0(z^M) \\ z^{-1}E_1(z^M) \\ \vdots \\ z^{-(M-1)}E_{M-1}(z^M) \end{bmatrix}$$

Here is the multirate noble identity for decimation.

For illustration, consider the first branch of the filter bank that contains the lowpass filter.

Replace $H_0(z)$ with its polyphase representation.

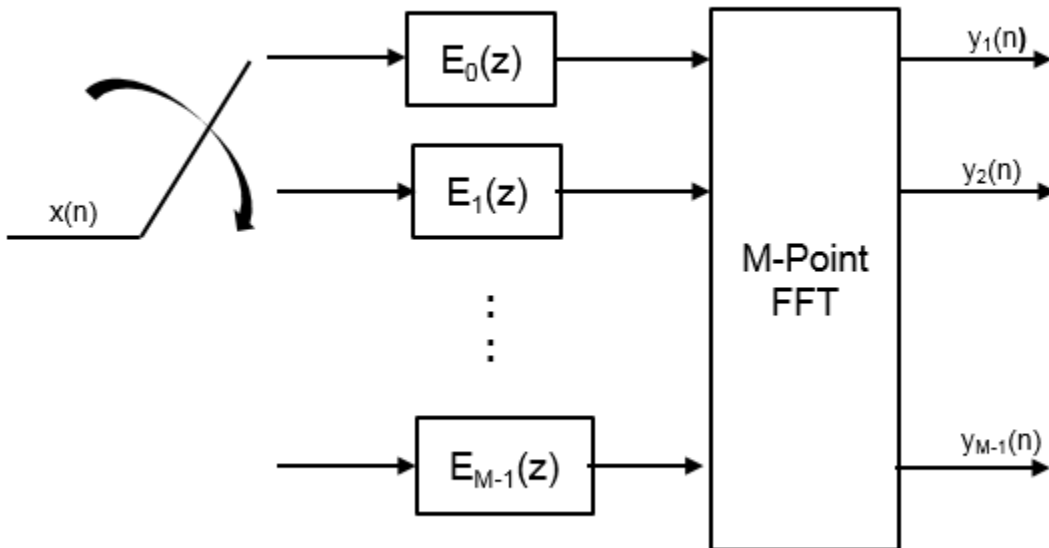

After applying the noble identity for decimation, you can replace the delays and the decimation factor with a commutator switch.

For all M channels in the filter bank, the MIMO transfer function, $H(z)$, is given by:

$$H(z) = \begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & e^{-j\omega_1} & e^{-j2\omega_1} & \dots & e^{-j(M-1)\omega_1} \\ & & \vdots & & \\ 1 & e^{-j\omega_{M-1}} & e^{-j2\omega_{M-1}} & \dots & e^{-j(M-1)\omega_{M-1}} \end{bmatrix} \begin{bmatrix} E_0(z) \\ E_1(z) \\ \vdots \\ E_{M-1}(z) \end{bmatrix}$$

The matrix on the left is a discrete Fourier transform (DFT) matrix. With the DFT matrix, the efficient implementation of the lowpass prototype based filter bank looks like the following.

dsp.ChannelSynthesizer System object

Package: dsp

Polyphase FFT synthesis filter bank

Description

The `dsp.ChannelSynthesizer` System object merges multiple narrowband signals into a broadband signal by using an FFT based synthesis filter bank. The filter bank uses a prototype lowpass filter and is implemented using a polyphase structure. You can specify the filter coefficients directly or through design parameters.

Each narrowband signal is stored as a column in the input signal, x . The number of columns in x corresponds to the number of frequency bands of the filter bank. If x is three-dimensional, each matrix corresponds to a separate channel. If M is the number of frequency bands, and x is an L -by- M matrix, then the output signal, y , has dimensions $L \times M$ -by-1. If x has more than one channel, that is, it has dimensions L -by- M -by- N , then y has dimensions $L \times M$ -by- N . The input x can be complex and supports single and double data types.

This object also accepts variable-size inputs. That is, once the object is locked, you can change the size of each input channel. The number of channels cannot change. This object supports C and C++ code generation.

To merge multiple narrowband signals into a broadband signal:

- 1 Create a `dsp.ChannelSynthesizer` object and set the properties of the object.
- 2 Call `step` to synthesize the signal.

Note Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Construction

`synthesizer = dsp.ChannelSynthesizer` creates a synthesizer object, using the default properties.

`synthesizer = dsp.ChannelSynthesizer(Name, Value)` specifies additional properties using `Name, Value` pairs. Unspecified properties have default values.

Example:

```
synthesizer = dsp.ChannelSynthesizer('NumTapsPerBand',20,'StopbandAttenuation',140);
```

Properties

Specification — Filter design parameters or coefficients

'Number of taps per band and stopband attenuation' (default) |
'Coefficients'

Filter design parameters or filter coefficients, specified as one of these options:

- 'Number of taps per band and stopband attenuation' — Specify the filter design parameters through the `NumTapsPerBand` and `StopbandAttenuation` properties.
- 'Coefficients' — Specify the filter coefficients directly using `LowpassCoefficients`.

NumTapsPerBand — Number of filter coefficients per frequency band

12 (default) | positive integer

Number of filter coefficients each polyphase branch uses, specified as a positive integer. The number of polyphase branches matches the number of frequency bands. The total number of filter coefficients for the prototype lowpass filter is given by product of the number of frequency bands and `NumTapsPerBand`. For a given stopband attenuation, increasing the number of taps per band narrows the transition width of the filter. As a result, there is more usable bandwidth for each frequency band at the expense of increased computation.

This property applies when you set `Specification` to 'Number of taps per band and stopband attenuation'.

StopbandAttenuation — Stopband attenuation

80 (default) | positive real scalar

Stopband attenuation of the lowpass filter, specified as a positive real scalar in dB. This value controls the maximum amount of aliasing from one frequency band to the next. Larger is the stopband attenuation, smaller is the passband ripple.

This property applies when you set `Specification` to 'Number of taps per band and stopband attenuation'.

LowpassCoefficients — Coefficients of the prototype lowpass filter

[1×49 double] (default) | row vector

Coefficients of the prototype lowpass filter, specified as a row vector. There must be at least one coefficient per frequency band. If the length of the lowpass filter is less than the number of frequency bands, the object zero-pads the coefficients.

This property applies when you set `Specification` to 'Coefficients'.

This property is tunable. You can change its value even after the object is locked.

Examples

Quadrature Mirror Filter Bank

The quadrature mirror filter bank (QMF) contains an analysis filter bank section and a synthesis filter bank section. `dsp.Channelizer` implements the analysis filter bank. `dsp.ChannelSynthesizer` implements the synthesis filter bank using the efficient polyphase implementation based on a prototype lowpass filter.

Initialization

Initialize the `dsp.Channelizer` and `dsp.ChannelSynthesizer` System objects. Each object is set up with 8 frequency bands, 8 polyphase branches in each filter, 12 coefficients per polyphase branch, and a stopband attenuation of 140 dB. Use a sine wave with multiple frequencies as the input signal. View the input spectrum and the output spectrum using a spectrum analyzer.

```
offsets = [-40,-30,-20,10,15,25,35,-15];
sinewave = dsp.SineWave('ComplexOutput',true,'Frequency',...
    offsets+(-375:125:500),'SamplesPerFrame',800);

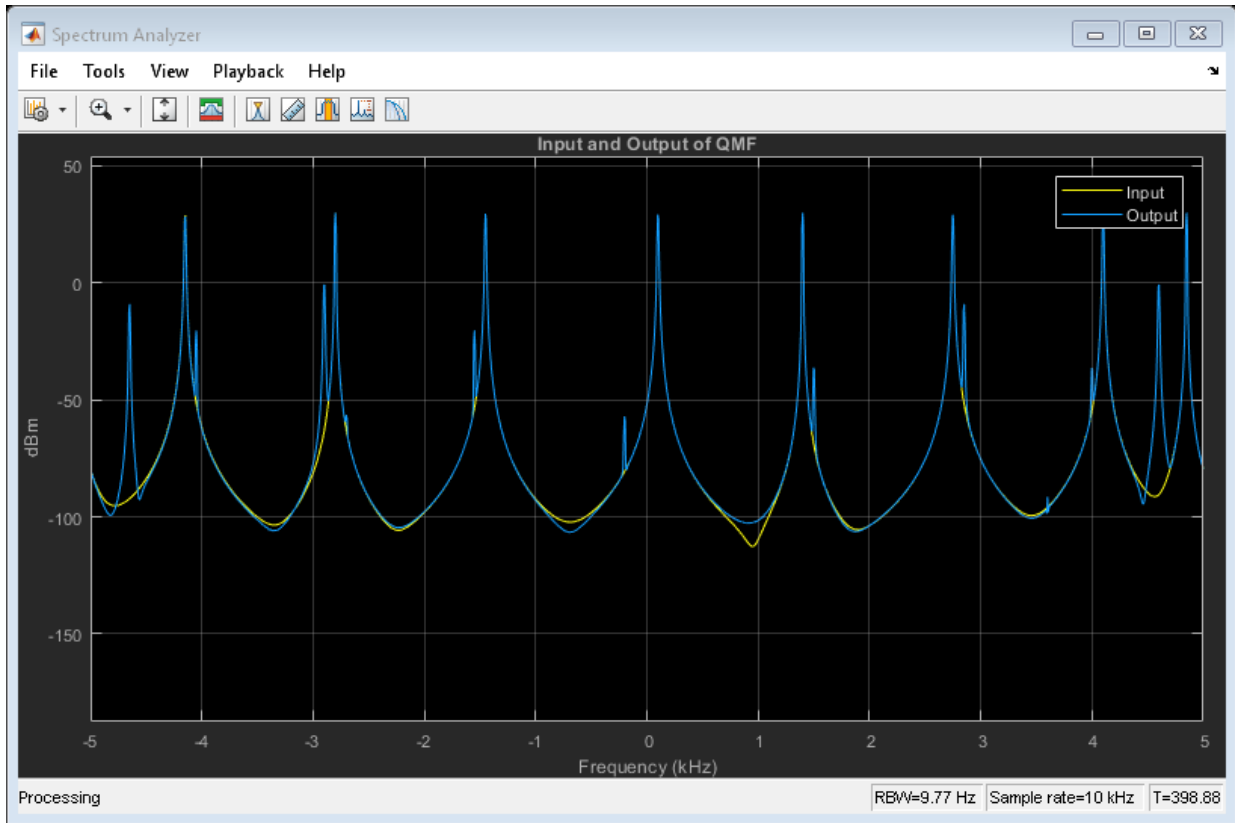

channelizer = dsp.Channelizer('StopbandAttenuation',140);
synthesizer = dsp.ChannelSynthesizer('StopbandAttenuation',140);
spectrumAnalyzer = dsp.SpectrumAnalyzer('ShowLegend',true,'NumInputPorts',...
    2,'ChannelNames',{'Input','Output'},'Title','Input and Output of QMF');
```

Streaming

Use the channelizer to split the broadband input signal into multiple narrow bands. Then pass the multiple narrowband signals into the synthesizer, which merges these signals to form the broadband signal. Compare the spectra of the input and output signals. The input and output spectra match very closely.

```
for i = 1:5000
    x = sum(sinewave(),2);
    y = channelizer(x);
    v = synthesizer(y);
```

```
spectrumAnalyzer(x,v)
end
```

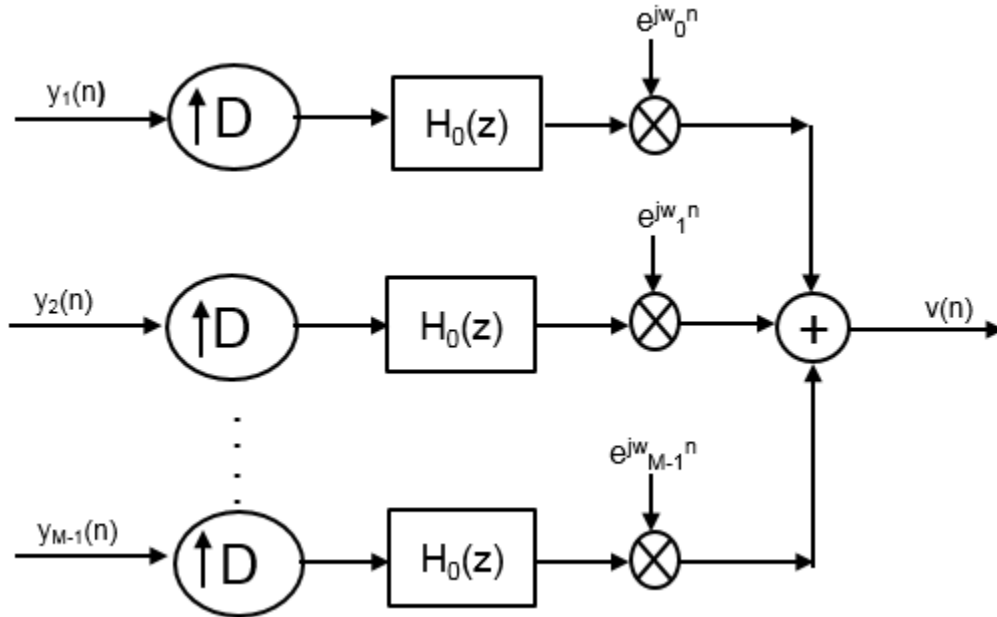

Definitions

Synthesis Filter Bank

The synthesis filter bank consists of a set of parallel bandpass filters that merge multiple input narrowband signals, $y_1(n)$, $y_2(n)$, ..., $y_{M-1}(n)$ into a single broadband signal, $v(n)$. The input narrowband signals are in the baseband. Each narrowband signal is interpolated to a higher sampling rate by using the upsampler, and then filtered by the lowpass filter. A

complex exponential that follows the lowpass filter centers the baseband signal around ω_k .

Prototype Lowpass Filter

To implement the synthesis filter bank efficiently, the synthesizer uses a prototype lowpass filter. This filter has an impulse response of $h[n]$, a normalized two-sided bandwidth of $2\pi/M$, and a cutoff frequency of π/M . M is the number of frequency bands, that is, the branches of the synthesis filter bank. This value corresponds to the FFT length that the filter bank uses. M can be high, in the order of 2048 or more. The stopband attenuation determines the minimum level of interference (aliasing) from one frequency band to another. The passband ripple must be small so that the input signal is not distorted in the passband.

The prototype lowpass filter models the first branch of the filter bank. The other $M - 1$ branches are modeled by filters that are modulated versions of the prototype filter. The modulation factor is given by $e^{j\omega_k n}$, $\omega_k = 2\pi k / M$, $k = 0, 1, \dots, M - 1$.

The output of each bandpass filter forms a specific portion of the broadband signal. The output of all the branches are added to form the broadband signal, $v(n)$.

Algorithms

Polyphase Implementation

The synthesis filter bank can be implemented efficiently using the polyphase structure.

To derive the polyphase structure, start with the transfer function of the prototype lowpass filter.

$$H_0(z) = b_0 + b_1 z^{-1} + \dots + b_N z^{-N}$$

$N+1$ is the length of the prototype filter.

You can rearrange this equation as follows:

$$\begin{aligned} & (b_0 + b_M z^{-M} + b_{2M} z^{-2M} + \dots + b_{N-M+1} z^{-(N-M+1)}) + \\ H_0(z) = & z^{-1} (b_1 + b_{M+1} z^{-M} + b_{2M+1} z^{-2M} + \dots + b_{N-M+2} z^{-(N-M+1)}) + \\ & \vdots \\ & z^{-(M-1)} (b_{M-1} + b_{2M-1} z^{-M} + b_{3M-1} z^{-2M} + \dots + b_N z^{-(N-M+1)}) \end{aligned}$$

M is the number of polyphase components.

You can write this equation as:

$$H_0(z) = E_0(z^M) + z^{-1} E_1(z^M) + \dots + z^{-(M-1)} E_{M-1}(z^M)$$

$E_0(z^M), E_1(z^M), \dots, E_{M-1}(z^M)$ are polyphase components of the prototype lowpass filter, $H_0(z)$.

The other filters in the filter bank, $H_k(z)$, where $k = 1, \dots, M-1$, are modulated versions of this prototype filter.

You can write the transfer function of the k th modulated bandpass filter as

$$\begin{aligned} H_k(z) &= H_0(z e^{jw_k}) \text{ . Replacing } z \text{ with } z e^{jw_k}, \\ H_k(z) &= h_0 + h_1 e^{jwk} z^{-1} + h_2 e^{j2wk} z^{-2} \dots + h_N e^{jNwk} z^{-N} \end{aligned}$$

$N+1$ is the length of the k th filter.

In polyphase form, the equation is as follows:

$$H_k(z) = \begin{bmatrix} 1 & e^{jw_k} & e^{j2w_k} & \dots & e^{j(M-1)w_k} \end{bmatrix} \begin{bmatrix} E_0(z^M) \\ z^{-1}E_1(z^M) \\ \vdots \\ z^{-(M-1)}E_{M-1}(z^M) \end{bmatrix}$$

For all M channels in the filter bank, the MIMO transfer function, $H(z)$, is given by:

$$H(z) = \begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & e^{jw_1} & e^{j2w_1} & \dots & e^{j(M-1)w_1} \\ & & \vdots & & \\ 1 & e^{jw_{M-1}} & e^{j2w_{M-1}} & \dots & e^{j(M-1)w_{M-1}} \end{bmatrix} \begin{bmatrix} E_0(z^M) \\ z^{-1}E_1(z^M) \\ \vdots \\ z^{-(M-1)}E_{M-1}(z^M) \end{bmatrix}$$

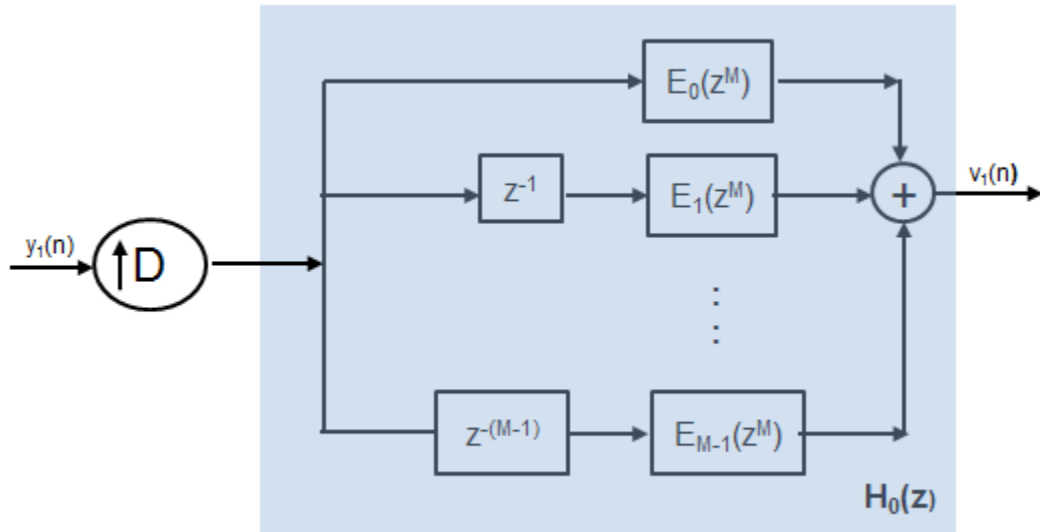

Here is the multirate noble identity for interpolation:

For illustration, consider the first branch of the filter bank that contains the lowpass filter.

Replace $H_0(z)$ with its polyphase representation.

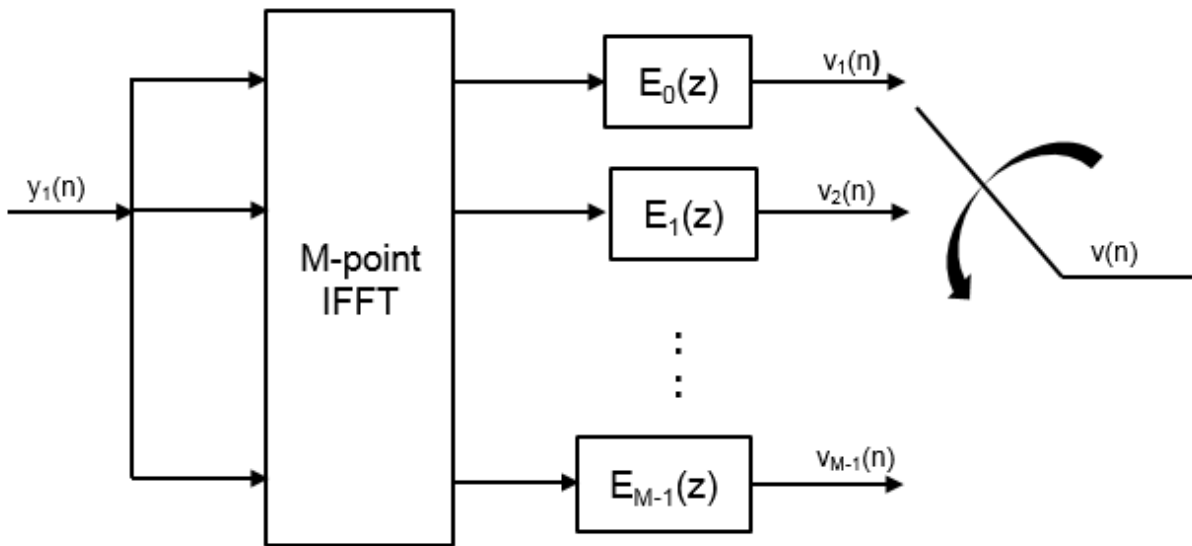

After applying the noble identity for interpolation, you can replace the delays, interpolation factor, and the adder with a commutator switch.

For all the M channels in the filter bank, the MIMO transfer function, $H(z)$, is given by:

$$H(z) = \begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & e^{jw_1} & e^{j2w_1} & \dots & e^{j(M-1)w_1} \\ & & & \vdots & \\ 1 & e^{jw_{M-1}} & e^{j2w_{M-1}} & \dots & e^{j(M-1)w_{M-1}} \end{bmatrix} \begin{bmatrix} E_0(z) \\ E_1(z) \\ \vdots \\ E_{M-1}(z) \end{bmatrix}$$

The matrix on the left is an IDFT matrix. With the IDFT matrix, the efficient implementation of the lowpass prototype based filter bank looks like the following.

coeffs

System object: dsp.ChannelSynthesizer

Package: dsp

Coefficients of prototype lowpass filter

Syntax

```
c = coeffs(synthesizer)
```

Description

`c = coeffs(synthesizer)` returns a structure that contains the coefficients of the prototype lowpass filter. This value is equal to the number of frequency bands times the number of coefficients per band. Number of frequency bands or the number of narrow band signals is given by the number of columns in the input signal. You can run `coeffs` on the synthesizer object only after the object is locked, that is, after you pass the input signal to the object.

Introduced in R2016b

polyphase

System object: dsp.ChannelSynthesizer

Package: dsp

Polyphase matrix

Syntax

```
p = polyphase(synthesizer)
```

Description

`p = polyphase(synthesizer)` returns the polyphase matrix used by the filter bank. Each row in the matrix corresponds to a polyphase branch. The number of columns in p corresponds to the number of filter taps per polyphase branch.

Introduced in R2016b

reset

System object: dsp.ChannelSynthesizer

Package: dsp

Reset internal states of System object

Syntax

```
reset(synthesizer)
```

Description

`reset(synthesizer)` resets the states of the input object to their initial values. The initial state values correspond to the initial conditions for the difference equation defining the object. After you call the object using nonzero input data, the filter might have nonzero states. If you continue to pass nonzero input data to the object without first calling `reset`, the object might produce different outputs for an identical input.

Introduced in R2016b

step

System object: dsp.ChannelSynthesizer

Package: dsp

Merge narrowband signals into a broadband signal

Syntax

```
y = step(synthesizer,x)
```

Description

Note Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`y = step(synthesizer,x)` merges the narrowband input signals contained as columns in `x` into broadband signal, `y`. The number of columns in `x` corresponds to the number of frequency bands. If `x` is three dimensional, each matrix corresponds to a separate channel. If M is the number of frequency bands, and `x` is a L -by- M matrix, then `y` has dimensions, $L*M$ -by-1. If `x` has more than one channel, that is, L -by- M -by- N , then `y` has dimensions $L*M$ -by- N . The input `x` can be complex and supports single and double data types.

Introduced in R2016b

tf

System object: dsp.ChannelSynthesizer

Package: dsp

Transfer function

Syntax

```
[b,a] = tf(synthesizer)
```

Description

`[b,a] = tf(synthesizer)` returns the vector of numerator coefficients, `b`, and the vector of denominator coefficients, `a`, of the prototype lowpass filter.

Introduced in R2016b

dsp.Chirp System object

Package: dsp

Generate swept-frequency cosine (chirp) signal

Description

The `Chirp` object generates a swept-frequency cosine (chirp) signal.

To generate the chirp signal:

- 1 Define and set up your chirp signal. See “Construction” on page 4-316.
- 2 Call `step` to generate the signal according to the properties of `dsp.Chirp`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

Construction

`chirp = dsp.Chirp` returns a chirp signal, `chirp`, with unity amplitude.

`chirp = dsp.Chirp('PropertyName', PropertyValue, ...)` returns a chirp signal, `chirp`, with each specified property set to the specified value.

Properties

Type

Frequency sweep type

Specify the frequency sweep type as `Swept cosine`, `Linear`, `Logarithmic`, or `Quadratic`. This property specifies how the output instantaneous frequency sweep varies over time. The default value is `Linear`.

SweepDirection

Sweep direction

Specify the sweep direction as either `Unidirectional` or `Bidirectional`. The default value is `Unidirectional`.

InitialFrequency

Initial frequency (hertz)

When you set the `Type` property to `Linear`, `Quadratic`, or `Logarithmic`, this property specifies the initial instantaneous frequency in hertz of the output chirp signal. When you set the `Type` property to `Logarithmic`, the value of this property is one less than the actual initial frequency of the sweep. Also, when the sweep is logarithmic, the initial frequency must be less than the target frequency, specified by the `TargetFrequency` property. This property is tunable. The default value is 1000.

TargetFrequency

Target frequency (hertz)

When you set the `Type` property to `Linear`, `Quadratic`, or `Logarithmic`, this property specifies the instantaneous frequency of the output signal in hertz at the target time. When you set the `Type` property to `Swept Cosine`, the target frequency is the instantaneous frequency of the output at half the target time. Also, when the sweep is logarithmic, the target frequency must be greater than the initial frequency, specified by the `InitialFrequency` property. This property is tunable. The default value is 4000.

TargetTime

Target time

When you set the `Type` property to `Linear`, `Quadratic`, or `Logarithmic`, this property specifies the target time in seconds at which the target frequency is reached. When you set the `Type` property to `Swept cosine`, this property specifies the time at which the sweep reaches $2f_{tgt} - f_{init}$ Hz, where f_{tgt} is the `TargetFrequency` and f_{init} is the

`InitialFrequency`. The target time should not be greater than the sweep time, specified by the `SweepTime` property. This property is tunable. The default value is 1.

SweepTime

Sweep time

When you set the `SweepDirection` property to `Unidirectional`, the sweep time in seconds is the period of the output frequency sweep. When you set the `SweepDirection` property to `Bidirectional`, the sweep time is half the period of the output frequency sweep. The sweep time should be no less than the target time, specified by the `TargetTime`. This property must be a positive numeric scalar and is tunable. The default value is 1.

InitialPhase

Initial phase

Specify initial phase of the output in radians at time $t = 0$. This property is tunable. The default value is 0.

SampleRate

Sample rate

Specify the sampling rate of the output in hertz as a positive numeric scalar. The default value is 8000.

SamplesPerFrame

Samples per output frame

Specify the number of samples to buffer into each output as a positive integer. The default value is 1.

OutputDataType

Output data type

Specify the output data type as `double` or `single`. The default value is `double`.

Methods

reset Reset internal states of chirp object
 step Generate chirp signal

Common to All System Objects	
clone	Create System object with same property values
getNumInputs	Expected number of inputs to a System object
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Generate a Bidirectional Swept Chirp Signal

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject()` becomes `step(myObject)`.

```
chirp = dsp.Chirp(...
    'SweepDirection', 'Bidirectional', ...
    'TargetFrequency', 25, ...
    'InitialFrequency', 0, ...
    'TargetTime', 1, ...
    'SweepTime', 1, ...
    'SamplesPerFrame', 400, ...
    'SampleRate', 400);
plot(chirp());
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Chirp block reference page. The object properties correspond to the block parameters.

See Also

`dsp.SineWave`

Introduced in R2012a

reset

System object: dsp.Chirp

Package: dsp

Reset internal states of chirp object

Syntax

```
reset(chirp)
```

Description

`reset(chirp)` sets the internal states of the Chirp object `chirp` to their initial values. After you reset `chirp`, the frequency sweep restarts from the beginning.

step

System object: dsp.Chirp

Package: dsp

Generate chirp signal

Syntax

```
Y = step(chirp)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

`Y = step(chirp)` returns a swept-frequency cosine output, `Y`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.CICCompensationDecimator System object

Package: dsp

Compensate for CIC decimation filter using FIR decimator

Description

You can compensate for the shortcomings of a CIC decimator, namely its passband droop and wide transition region, by following it with a compensation decimator. This System object lets you design and use such a filter. `dsp.CICCompensationDecimator` supports fixed-point operations and ARM Cortex code generation.

To compensate for the shortcomings of a CIC filter using an FIR decimator:

- 1 Define and set up your CIC compensation decimator. See “Construction” on page 4-324.
- 2 Call `step` to compensate for the passband droop and wide transition region of the CIC filter according to the properties of `dsp.CICCompensationDecimator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Construction

`ciccompdec = dsp.CICCompensationDecimator` returns a System object, `ciccompdec`, that applies an FIR decimator to each channel of an input signal. Using the properties of the object, the decimation filter can be designed to compensate for a preceding CIC filter.

`ciccompdec = dsp.CICCompensationDecimator(Name, Value)` returns a CIC compensation decimator System object, `ciccompdec`, with properties and options specified by one or more `Name, Value` pair arguments.

`ciccompdec = dsp.CICCompensationDecimator(decim, Name, Value)` returns a CIC compensation decimator System object, `ciccompdec`, with the `DecimationFactor` property set to `decim` and additional properties and options specified by one or more `Name, Value` pair arguments.

`ciccompdec = dsp.CICCompensationDecimator(cic, Name, Value)` returns a CIC compensation decimator System object, `ciccompdec`, with the `CICRateChangeFactor`, `CICNumSections`, and `CICDifferentialDelay` properties specified in the `dsp.CICDecimator` System object `cic` and additional properties and options specified by one or more `Name, Value` pair arguments.

`ciccompdec = dsp.CICCompensationDecimator(cic, decim, Name, Value)` returns a CIC compensation decimator System object, `ciccompdec`, with the `CICRateChangeFactor`, `CICNumSections`, and `CICDifferentialDelay` properties specified in the `dsp.CICDecimator` System object `cic`, the `DecimationFactor` property set to `decim`, and additional properties and options specified by one or more `Name, Value` pair arguments.

Properties

CICDifferentialDelay — Differential delay of the CIC filter being compensated

1 (default) | positive integer scalar

Specify the differential delay of the CIC filter being compensated as a positive integer scalar. The default is 1.

CICNumSections — Number of sections of the CIC filter being compensated

2 (default) | positive integer scalar

Specify the number of sections of the CIC filter being compensated as a positive integer scalar. The default is 2.

CICRateChangeFactor — Rate-change factor of the CIC filter being compensated

2 (default) | positive integer scalar

Specify the rate-change factor of the CIC filter being compensated as a positive integer scalar. The default is 2.

DecimationFactor — Decimation factor of compensator

2 (default) | positive integer scalar

Specify the decimation factor of the compensator System object as a positive integer scalar. The default is 2.

DesignForMinimumOrder — Design filter of minimum order or of specified order

true (default) | logical value

Specify whether to design a filter of minimum order or a filter of specified order as a logical scalar. The default is true, which corresponds to a filter of minimum order.

FilterOrder — Order of decimation compensator filter

12 (default) | positive integer scalar

Specify the order of the decimation compensator filter as a positive integer scalar. This property applies only when you set the DesignForMinimumOrder property to false. The default is 12.

PassbandFrequency — Passband edge frequency in hertz

100 kHz (default) | positive real scalar

Specify the passband edge frequency as a positive real scalar expressed in hertz. PassbandFrequency must be less than $F_s/2$, where F_s is the input sample rate. The default is 100 kHz.

PassbandRipple — Filter passband ripple in decibels

0.1 dB (default) | positive real scalar

Specify the filter passband ripple as a positive real scalar expressed in decibels. The default is 0.1 dB.

SampleRate — Input sample rate in hertz

600 kHz (default) | positive real scalar

Specify the input sample rate as a positive real scalar expressed in hertz. The default is 1200 kHz.

StopbandAttenuation — Filter stopband attenuation in decibels

60 dB (default) | positive real scalar

Specify the filter stopband attenuation as a positive real scalar expressed in decibels. The default is 60 dB

StopbandFrequency — Stopband edge frequency in hertz

400 kHz (default) | positive real scalar

Specify the stopband edge frequency as a positive real scalar expressed in hertz. StopbandFrequency must be less than $F_s/2$, where F_s is the input sample rate. The default is 400 kHz.

Fixed-Point Properties**CoefficientsDataType — Word and fraction lengths of coefficients**

numericType(1,16) (default) | numericType object

Word and fraction lengths of coefficients, specified as a signed or unsigned numericType object. The default, numericType(1,16) corresponds to a signed numeric type object with 16-bit coefficients and a fraction length determined based on the coefficient values, to give the best possible precision.

This property is not tunable.

Word length of the output is same as the word length of the input. Fraction length of the output is computed such that the entire dynamic range of the output can be represented without overflow. For details on how the fraction length of the output is computed, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

RoundingMethod — Rounding method for output fixed-point operations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see “Precision and Range”.

Examples

Impulse and Frequency Response of CIC Compensation Decimator

Design an CIC compensation decimator. Specify the decimation factor to be 2, passband frequency to be 4 kHz, stopband frequency to be 4.5 kHz, and the input sample rate to be 16 kHz.

```
fs = 16e3;
fPass = 4e3;
fStop = 4.5e3;
```

```
CICCompDecim = dsp.CICCompensationDecimator('DecimationFactor',2,'PassbandFrequency',fPass, 'StopbandFrequency',fStop,'SampleRate',fs);
```

Plot the impulse response. The group delay of the filter is 45.5.

```
fvtool(CICCompDecim,'Analysis','impulse')
```

Plot the magnitude and Phase response.

```
fvtool(CICCompDecim, 'Analysis', 'freq')
```

Compensation Decimator Design

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Design a compensation decimator for an existing CIC decimator having six sections and a decimation factor of 6.

```
CICDecim = dsp.CICDecimator('DecimationFactor',6, ...
    'NumSections',6);
```

Construct the compensation decimator. Specify a decimation factor of 2, an input sample rate of 16 kHz, a passband frequency of 4 kHz, and a stopband frequency of 4.5 kHz.

```
fs = 16e3;
fPass = 4e3;
fStop = 4.5e3;

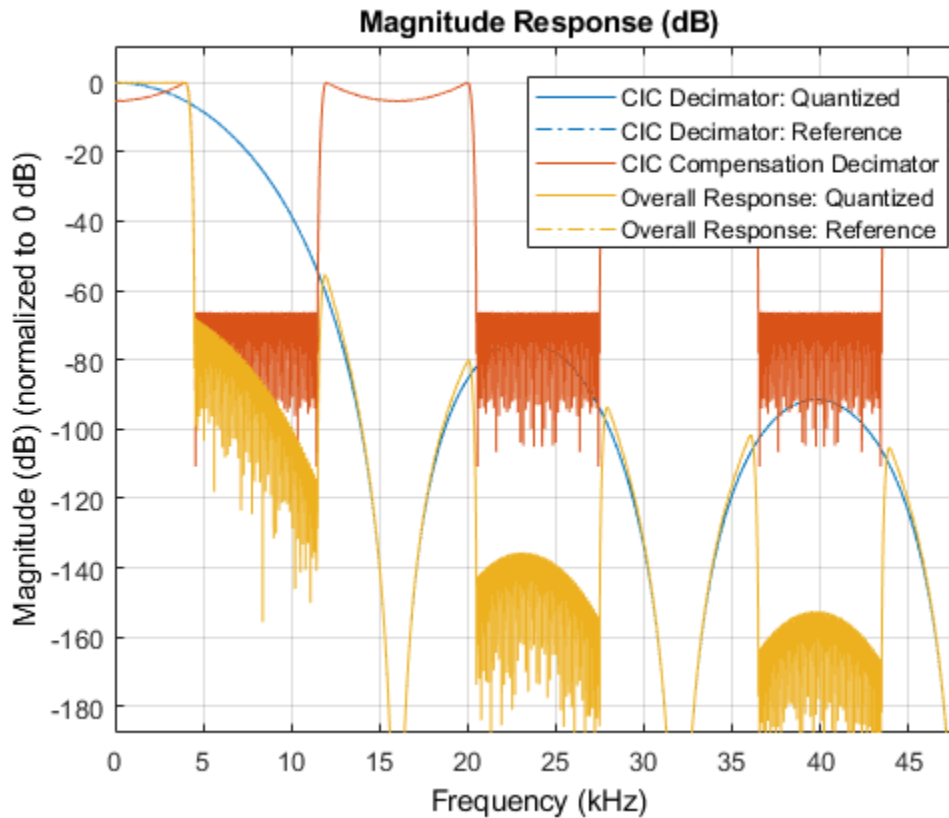

CICCompDecim = dsp.CICCompensationDecimator(CICDecim, ...
    'DecimationFactor',2,'PassbandFrequency',fPass, ...
    'StopbandFrequency',fStop,'SampleRate',fs);
```

Visualize the frequency response of the cascade. Normalize all magnitude responses to 0 dB.

```
filtCasc = dsp.FilterCascade(CICDecim,CICCompDecim);

f = fvtool(CICDecim, CICCompDecim, filtCasc, ...
    'Fs', [fs*6 fs fs*6]);

f.NormalizeMagnitudetol = 'on';
legend(f,'CIC Decimator','CIC Compensation Decimator', ...
    'Overall Response');
```

Apply the design to a 1200-sample random input signal.

```
x = dsp.SignalSource(fi(rand(1200,1),1,16,15),'SamplesPerFrame',120);

y = fi(zeros(0,1),1,32,20);
for ind = 1:10
    x2 = CICDecim(x());
```

```
y = [y;CICCompDecim(x2)];  
end
```

`dsp.CICCompensationInterpolator` | `dsp.CICDecimator` |
`dsp.CICInterpolator`

Introduced in R2014b

reset

System object: dsp.CICCompensationDecimator

Package: dsp

Reset internal states of CIC compensation decimator

Syntax

```
reset(ciccompdec)
```

Description

`reset(ciccompdec)` resets the internal states of a `CICCompensationDecimator` System object, `ciccompdec`, to their initial values.

Input Arguments

ciccompdec — CIC compensation decimator

`CICCompensationDecimator` System object

CIC compensation decimator, specified as a `CICCompensationDecimator` System object.

step

System object: dsp.CICCompensationDecimator

Package: dsp

Compensate for preceding CIC filter

Syntax

```
y = step(ciccompdec,x)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`y = step(ciccompdec,x)` returns the filtered and downsampled values, y , of the input signal, x . The System object treats a $K_i \times N$ input matrix as N independent channels, decimating each channel over the first dimension. The result is a $K_o \times N$ output matrix, where $K_o = K_i / M$ and M is the decimation factor. The object supports any real or complex floating-point or fixed-point input, with the exception of complex unsigned fixed-point data.

Input Arguments

ciccompdec — CIC compensation decimator

CICCompensationDecimator System object

CIC compensation decimator, specified as a CICCompensationDecimator System object.

x — Input signal

vector | matrix

Input signal, specified as a vector or matrix.

Output Arguments

y — Filtered and downsampled signal

vector | matrix

Filtered and downsampled signal, returned as a vector or matrix.

`dsp.CICCompensationInterpolator`

dsp.CICCompensationInterpolator System object

Package: dsp

Compensate for CIC interpolation filter using FIR interpolator

Description

You can compensate for the shortcomings of a CIC interpolator, namely its passband droop and wide transition region, by preceding it with a compensation interpolator. This System object lets you design and use such a filter.

`dsp.CICCompensationInterpolator` supports fixed-point operations and ARM Cortex code generation.

To compensate for the shortcomings of a CIC filter using an FIR interpolator:

- 1 Define and set up your CIC compensation interpolator. See “Construction” on page 4-337.
- 2 Call `step` to compensate for the passband droop and wide transition region of the CIC filter according to the properties of `dsp.CICCompensationInterpolator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`ciccompint = dsp.CICCompensationInterpolator` returns a System object, `ciccompint`, that applies an FIR interpolator to each channel of an input signal. Using the properties of the object, the interpolation filter can be designed to compensate for a subsequent CIC filter.

`ciccompint = dsp.CICCompensationInterpolator(Name, Value)` returns a CIC compensation interpolator System object, `ciccompint`, with properties and options specified by one or more `Name, Value` pair arguments.

`ciccompint = dsp.CICCompensationInterpolator(interp, Name, Value)` returns a CIC compensation interpolator System object, `ciccompint`, with the `InterpolationFactor` property set to `interp` and additional properties and options specified by one or more `Name, Value` pair arguments.

`ciccompint = dsp.CICCompensationInterpolator(cic, Name, Value)` returns a CIC compensation interpolator System object, `ciccompint`, with the `CICRateChangeFactor`, `CICNumSections`, and `CICDifferentialDelay` properties specified in the `dsp.CICInterpolator` System object `cic` and additional properties and options specified by one or more `Name, Value` pair arguments.

`ciccompint = dsp.CICCompensationInterpolator(cic, interp, Name, Value)` returns a CIC compensation interpolator System object, `ciccompint`, with the `CICRateChangeFactor`, `CICNumSections`, and `CICDifferentialDelay` properties specified in the `dsp.CICInterpolator` System object `cic`, the `InterpolationFactor` property set to `interp`, and additional properties and options specified by one or more `Name, Value` pair arguments.

Properties

CICDifferentialDelay — Differential delay of the CIC filter being compensated

1 (default) | positive integer scalar

Specify the differential delay of the CIC filter being compensated as a positive integer scalar. The default is 1.

CICNumSections — Number of sections of the CIC filter being compensated

2 (default) | positive integer scalar

Specify the number of sections of the CIC filter being compensated as a positive integer scalar. The default is 2.

CICRateChangeFactor — Rate-change factor of the CIC filter being compensated

2 (default) | positive integer scalar

Specify the rate-change factor of the CIC filter being compensated as a positive integer scalar. The default is 2.

DesignForMinimumOrder — Design filter of minimum order or of specified order

true (default) | logical value

Specify whether to design a filter of minimum order or a filter of specified order as a logical scalar. The default is true, which corresponds to a filter of minimum order.

FilterOrder — Order of interpolation compensator filter

12 (default) | positive integer scalar

Specify the order of the interpolation compensator filter as a positive integer scalar. This property applies only when you set the DesignForMinimumOrder property to false. The default is 12.

InterpolationFactor — Interpolation factor of compensator

2 (default) | positive integer scalar

Specify the interpolation factor of the compensator System object as a positive integer scalar. The default is 2.

PassbandFrequency — Passband edge frequency in hertz

100 kHz (default) | positive real scalar

Specify the passband edge frequency as a positive real scalar expressed in hertz. PassbandFrequency must be less than $F_s/2$, where F_s is the output sample rate. The default is 100 kHz.

PassbandRipple — Filter passband ripple in decibels

0.1 dB (default) | positive real scalar

Specify the filter passband ripple as a positive real scalar expressed in decibels. The default is 0.1 dB.

SampleRate — Input sample rate in hertz

600 kHz (default) | positive real scalar

Specify the input sample rate as a positive real scalar expressed in hertz. The default is 600 kHz.

StopbandAttenuation — Filter stopband attenuation in decibels

60 dB (default) | positive real scalar

Specify the filter stopband attenuation as a positive real scalar expressed in decibels. The default is 60 dB

StopbandFrequency — Stopband edge frequency in hertz

400 kHz (default) | positive real scalar

Specify the stopband edge frequency as a positive real scalar expressed in hertz. StopbandFrequency must be less than $F_s/2$, where F_s is the output sample rate. The default is 400 kHz.

Fixed-Point Properties

CoefficientsDataType — Word and fraction lengths of coefficients

numericType(1,16) (default) | numericType object

Word and fraction lengths of coefficients, specified as a signed or unsigned numericType object. The default, numericType(1,16) corresponds to a signed numeric type object with 16-bit coefficients and a fraction length determined based on the coefficient values, to give the best possible precision.

This property is not tunable.

Word length of the output is same as the word length of the input. Fraction length of the output is computed such that the entire dynamic range of the output can be represented without overflow. For details on how the fraction length of the output is computed, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

RoundingMethod — Rounding method for output fixed-point operations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see “Precision and Range”.

Methods

reset Reset internal states of CIC compensation interpolator
 step Compensate for subsequent CIC filter

More “Analysis Methods for Filter System Objects” on page 3-2.

Examples

Impulse and Frequency Response of CIC Compensation Interpolator

Design an CIC compensation interpolator. Specify the interpolation factor to be 2, passband frequency to be 200 Hz, stopband frequency to be 500 Hz, and the input sample rate to be 600 Hz.

```
fs = 600;
fPass = 200;
fStop = 500;
```

```
CICCompInterp = dsp.CICCompensationInterpolator('InterpolationFactor',2,'PassbandFrequency',fPass,'StopbandFrequency',fStop,'SampleRate',fs);
```

Plot the impulse response. The zeroth order coefficient is delayed 6 samples, which is equal to the group delay of the filter.

```
fvtool(CICCompInterp, 'Analysis', 'impulse')
```

Plot the magnitude and Phase response.

```
fvtool(CICCompInterp, 'Analysis', 'freq')
```

Compensation Interpolator Design

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent step syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Design a compensation interpolator for an existing CIC interpolator having six sections and an interpolation factor of 16.

```
CICInterp = dsp.CICInterpolator('InterpolationFactor',16, ...
    'NumSections',6);
```

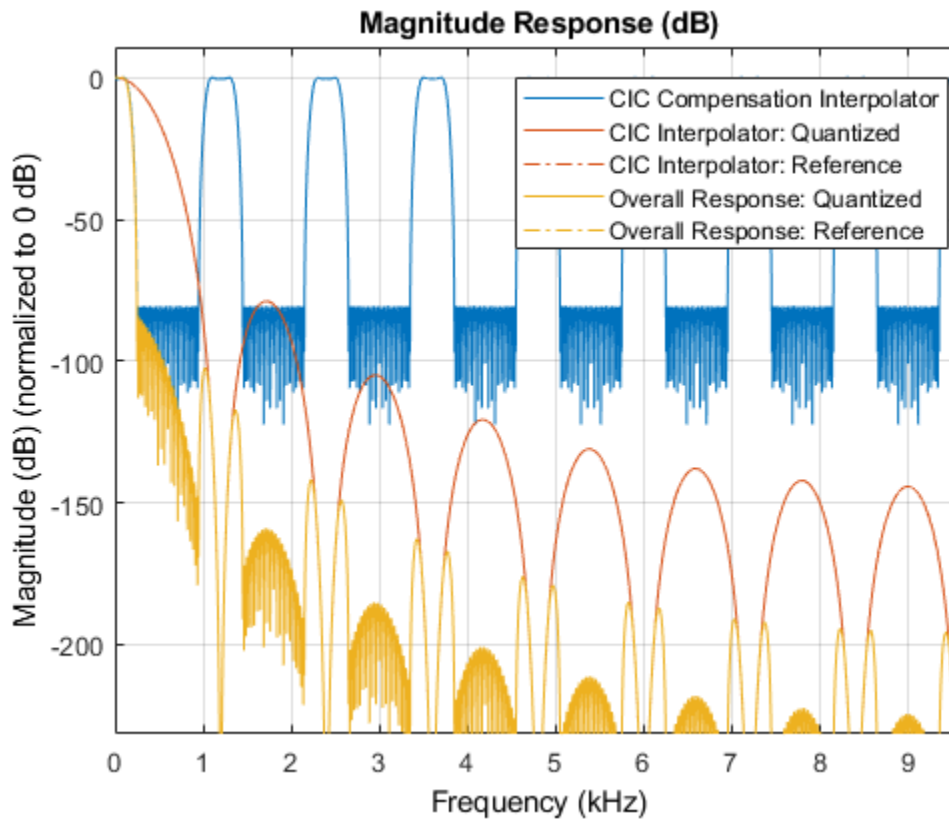

Construct the compensation interpolator. Specify an interpolation factor of 2, an input sample rate of 600 Hz, a passband frequency of 100 Hz, and a stopband frequency of 250 Hz. Set the minimum attenuation of alias components in the stopband to be at least 80 dB.

```
fs = 600;  
fPass = 100;  
fStop = 250;  
ast = 80;
```

```
CICCompInterp = dsp.CICCompensationInterpolator(CICInterp, ...  
    'InterpolationFactor',2, 'PassbandFrequency',fPass, ...  
    'StopbandFrequency',fStop, 'StopbandAttenuation',ast, ...  
    'SampleRate',fs);
```

Visualize the frequency response of the cascade. Normalize all magnitude responses to 0 dB.

```
FC = dsp.FilterCascade(CICCompInterp, CICInterp);  
  
f = fvtool(CICCompInterp,CICInterp,FC, ...  
    'Fs', [fs*2 fs*16*2 fs*16*2]);  
  
f.NormalizeMagnitudetol = 'on';  
legend(f, 'CIC Compensation Interpolator', 'CIC Interpolator', ...  
    'Overall Response');
```

Apply the design to a 1000-sample random input signal.

```
x = dsp.SignalSource(fi(rand(1000,1),1,16,15),'SamplesPerFrame',100);

y = fi(zeros(0,1),1,32,20);
for ind = 1:10
    x2 = CICCompInterp(x());
```

```
y = [y;CICInterp(x2)];  
end
```

dsp.CICDecimator System object

Package: dsp

Decimate input using Cascaded Integrator-Comb filter

Description

The `CICDecimator` object decimates inputs using a Cascaded Integrator-Comb filter. Fixed-point inputs and outputs to the object have signed fixed-point data types. To use fixed-point data types, you must have a Fixed-Point Designer license. Inputs and outputs to the System object can be single or double data types, in addition to the fixed-point data type. Property settings related to fixed-point data types are ignored for single or double data types.

Note To use the filter analysis methods on `dsp.CICDecimator` System object, you must have the Fixed-Point Designer license. To get a list of the filter analysis methods this object supports, type `dsp.CICDecimator.helpFilterAnalysis` in the MATLAB command prompt.

To decimate inputs using a CIC filter:

- 1 Define and set up your System object. See “Construction” on page 4-351.
- 2 Call `step` to decimate the input according to the properties of `dsp.CICDecimator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Construction

`cicdecim = dsp.CICDecimator` returns a `CICDecimator` System object, `cicdecim`, that you can use to decimate the input with a cascaded integrator-comb (CIC) decimation filter.

`cicdecim = dsp.CICDecimator('PropertyName', PropertyValue, ...)` returns a `CICDecimator` object, `cicdecim`, with each specified property set to the value you specify.

`cicdecim = dsp.CICDecimator(R, M, N, 'PropertyName', PropertyValue, ...)` returns a `CICDecimator` object, `cicdecim`, with the “DecimationFactor” on page 4-0 property set to R , the `DifferentialDelay` property set to M , the `NumSections` property set to N , and any other specified properties set to the values you specify.

Properties

DecimationFactor

Decimation factor of filter

Specify a positive integer amount by which the object decimates the input. The default is 2.

DifferentialDelay

Differential delay of filter comb sections

Specify a positive integer delay value for the object to use in each comb section of the filter. The default is 1.

NumSections

Number of integrator and comb sections

Specify the number of integrator and comb sections in the CIC filter as a positive integer value. The default is 2.

FixedPointDataType

Fixed-point property setting

Specify the fixed-point data type as one of | Full precision | Minimum section word lengths | Specify word lengths | Specify word and fraction lengths |. The default is Full precision. When you set this property to:

- Full precision – the CICDecimator object automatically determines the word and fraction lengths of the filter sections and output.
- Minimum section word length – the object automatically determines the word and fraction lengths of the filter sections and the fraction length of the output. You must specify the OutputWordLength.
- Specify word lengths – the object automatically determines the fraction lengths of the filter sections and the output. You must specify values for the OutputWordLength and the SectionWordLengths properties.
- Specify word and fraction lengths – the object does not automatically determine word and fraction lengths for the filter sections or the output. You must specify them using the OutputFractionLength, OutputWordLength, SectionFractionLengths, and SectionWordLengths properties.

SectionWordLengths

Word length of each filter section

Specify the fixed-point word length for each section of the CIC filter as a scalar or a vector of length $2 * \text{NumSections}$. This property applies only when you set the FixedPointDataType property to either Specify word lengths or Specify word and fraction lengths. The default is [16 16 16 16].

SectionFractionLengths

Fraction length of each filter section

Specify the fixed-point fraction length for each section of the CIC filter as a scalar or a vector of length $2 * \text{NumSections}$. This property applies only when you set the FixedPointDataType property to Specify word and fraction lengths. The default is 0.

OutputWordLength

Word length of filter output

Specify the fixed-point word length for the filter output. This property applies only when you set the `FixedPointDataType` property to `Minimum` section word lengths, `Specify word lengths`, or `Specify word and fraction lengths`. The default is 32.

OutputFractionLength

Fraction length of filter output

Specify the fixed-point fraction length for the output of the CIC filter. This property applies only when you set the `FixedPointDataType` property to `Specify word and fraction lengths`. The default is 0.

Methods

Examples

Decimate a Signal Using CICDecimator Object

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Decimate signal by a factor of 4 (i.e., downsample the signal from 44.1 kHz to 11.025 kHz).

```
cicdec = dsp.CICDecimator(4);
cicdec.FixedPointDataType = 'Minimum section word lengths';
cicdec.OutputWordLength = 16;
```

Create fixed-point sinusoidal input signal

```
Fs = 44.1e3; % Original sampling frequency
n = (0:1023)'; % 1024 samples, 0.0232 sec signal
x = fi(sin(2*pi*1e3/Fs*n),true,16,15);
```

Create SignalSource System object

```
src = dsp.SignalSource(x, 64);
```

Decimate output with 16 samples per frame

```
y = zeros(16,16);
for ii=1:16
    y(ii,:) = cicdec(src());
end
```

Plot first frame of original and decimated signals. Output latency is 2 samples.

```
gainCIC = ...
    (cicdec.DecimationFactor*cicdec.DifferentialDelay)^cicdec.NumSections;
stem(n(1:56)/Fs, double(x(4:59))); hold on;
stem(n(1:14)/(Fs/cicdec.DecimationFactor),double(y(1,3:end))/gainCIC,'r','filled');
xlabel('Time (sec)');ylabel('Signal Amplitude');
legend('Original signal', 'Decimated signal', 'location', 'north');
hold off;
```

Algorithms

A Cascaded Integrator-Comb (CIC) decimation filter with comb and integrator sections is implemented when the input is fixed-point data type. When the input data type is double or single the `dsp.CICDecimator` object implements an N -section CIC interpolation filter as an FIR filter with a response that corresponds to a cascade of N boxcar filters.

This object implements the algorithm, inputs, and outputs described on the CIC Decimation block reference page. The object properties correspond to the block properties, except:

- The **Rate options** block parameter is not supported by the `dsp.CICDecimator` object.

System object: dsp.CICDecimator

Package: dsp

Open filter visualization tool

Syntax

```
fvtool(cicdecim)
fvtool(cicdecim, 'Arithmetic', ARITH, ...)
```

Description

`fvtool(cicdecim)` performs an analysis and computes the magnitude response of the filter System object `cicdecim`.

`fvtool(cicdecim, 'Arithmetic', ARITH, ...)` analyzes the filter System object `cicdecim`, based on the arithmetic specified in the `ARITH` input. `ARITH` can be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The 'Arithmetic' input is only relevant for the analysis of filter System objects.

impz

System object: dsp.CICDecimator

Package: dsp

Impulse response

Syntax

```
[h,t] = impz(cicdecim)
[h,t] = impz(cicdecim,Name,Value)
impz(cicdecim)
```

Description

`[h,t] = impz(cicdecim)` returns the impulse response `h`, and the corresponding time points `t` at which the impulse response of `cicdecim` is computed.

`[h,t] = impz(cicdecim,Name,Value)` returns the impulse response `h`, and the corresponding time points `t`, with additional options specified by one or more `Name, Value` pair arguments.

`impz(cicdecim)` uses FVTool to plot the impulse response of the filter System object `cicdecim`.

Note You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

phasez

System object: dsp.CICDecimator

Package: dsp

Unwrapped phase response

Syntax

```
[phi,w] = phasez(cicdecim)
[phi,w] = phasez(cicdecim,n)
[phi,w] = phasez(cicdecim,Name,Value)
phasez(cicdecim)
```

Description

`[phi,w] = phasez(cicdecim)` returns the 8192–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample.

`[phi,w] = phasez(cicdecim,n)` returns the `n`–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[phi,w] = phasez(cicdecim,Name,Value)` returns the phase response and the corresponding frequencies, with additional options specified by one or more `Name, Value` pair arguments.

`phasez(cicdecim)` uses FVTool to plot the phase response of the filter System object `cicdecim`.

reset

System object: dsp.CICDecimator

Package: dsp

Reset filter states of CIC decimator object

Syntax

```
reset(cicdecim)
```

Description

`reset(cicdecim)` resets the filter states of the `CICDecimator` System object `cicdecim` to zero.

step

System object: dsp.CICDecimator

Package: dsp

Decimate input using Cascaded Integrator-Comb filter

Syntax

```
Y = step(cicdecim,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(cicdecim,X)` decimates the fixed-point input `X` to produce a fixed-point output `Y` using the `CICDecimator` System object `cicdecim`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.CICInterpolator System object

Package: dsp

Interpolate signal using Cascaded Integrator-Comb filter

Description

The `CICInterpolator` object interpolates inputs using a Cascaded Integrator-Comb filter. Fixed-point inputs and outputs to the object have signed fixed-point data types. To use fixed-point data types, you must have a Fixed-Point Designer license. Inputs and outputs to the System object can be single or double data types, in addition to the fixed-point data type. Property settings related to fixed-point data types are ignored for single or double data types.

Note To use the filter analysis methods on `dsp.CICInterpolator` System object, you must have the Fixed-Point Designer license. To get a list of the filter analysis methods this object supports, type `dsp.CICInterpolator.helpFilterAnalysis` in the MATLAB command prompt.

To interpolate inputs using a CIC filter:

- 1 Define and set up your System object. See “Construction” on page 4-364.
- 2 Call `step` to interpolate the input according to the properties of `dsp.CICInterpolator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`cicinterp = dsp.CICInterpolator` returns a System object, `cicinterp`, that you can use to interpolate the input with a cascaded integrator-comb (CIC) interpolation filter.

`cicinterp = dsp.CICInterpolator('PropertyName', PropertyValue, ...)` returns a CIC interpolation object, `cicinterp`, with each specified property set to the value you specify.

`cicinterp = dsp.CICInterpolator(R, M, N, 'PropertyName', PropertyValue, ...)` returns a `CICInterpolator` object, `cicinterp`, with the “InterpolationFactor” on page 4-0 property set to R , the `DifferentialDelay` property set to M , the `NumSections` property set to N , and other specified properties set to the values you specify.

Properties

InterpolationFactor

Interpolation factor of filter

Specify a positive integer amount by which the object interpolates the input signal. The default is 2.

DifferentialDelay

Differential delay of filter comb sections

Specify a positive integer delay value for the object to use in each comb section of the filter. The default is 1.

NumSections

Number of integrator and comb sections

Specify the number of integrator and comb sections in the CIC filter as a positive integer value. The default is 2.

FixedPointDataType

Fixed-point property setting

Specify the fixed-point data type as one of | Full precision | Minimum section word lengths | Specify word lengths | Specify word and fraction lengths |. The default is Full precision. When you set this property to:

- Full precision – the CICInterpolator object automatically determines the word and fraction lengths of the filter sections and output.
- Minimum section word length – the object automatically determines the word and fraction lengths of the filter sections and the fraction length of the output. You must specify the OutputWordLength.
- Specify word lengths – the object automatically determines the fraction lengths of the filter sections and the output. You must specify values for the OutputWordLength and the SectionWordLengths properties.
- Specify word and fraction lengths – the object does not automatically determine word and fraction lengths for the filter sections or the output. You must specify them using the OutputFractionLength, OutputWordLength, SectionFractionLengths, and SectionWordLengths properties.

SectionWordLengths

Word length of each filter section

Specify the fixed-point word length for each section of the CIC filter as a scalar or a vector of length $2 \times \text{NumSections}$. This property applies only when you set the FixedPointDataType property to Specify word lengths or Specify word and fraction lengths. The default is [16 16 16 16].

SectionFractionLengths

Fraction length of each filter section

Specify the fixed-point fraction length for each section of the CIC filter as a scalar or a vector of length $2 \times \text{NumSections}$. This property applies only when you set the FixedPointDataType property to Specify word and fraction lengths. The default is 0.

OutputWordLength

Word length of filter output

Specify the fixed-point word length for the filter output. This property applies only when you set the `FixedPointDataType` property to `Minimum` section word lengths, `Specify word lengths`, or `Specify word and fraction lengths`. The default is 32.

OutputFractionLength

Fraction length of filter output

Specify the fixed-point fraction length for the output of the CIC filter. This property applies only when you set the `FixedPointDataType` property to `Specify word and fraction lengths`. The default is 0.

Methods

- freqz Frequency response
- fvtool Open filter visualization tool
- impz Impulse response
- phasez Unwrapped phase response
- reset Reset internal states of CIC Interpolator object
- step Interpolate signal using Cascaded Integrator-Comb filter

More “Analysis Methods for Filter System Objects” on page 3-2.

Common to All System Objects	
clone	Create System object with same property values
getNumInputs	Expected number of inputs to a System object
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Interpolate a Signal Using CICInterpolator Object

Interpolate signal by a factor of 2 (upsample the signal from 22.05 kHz to 44.1 kHz).

```
cicint = dsp.CICInterpolator(2);
```

Create fixed-point sinusoidal input signal

```
Fs = 22.05e3;           % Original sampling frequency
n = (0:511)';          % 512 samples, 0.0113 sec signal
x = fi(sin(2*pi*1e3/Fs*n), true, 16, 15);
```

Create SignalSource System object (TM).

```
src = dsp.SignalSource(x, 32);
```

Interpolate output with 64 samples per frame

```
y = zeros(16, 64);
for ii=1:16
    y(ii, :) = cicint(src());
end
```

Plot first frame of original and interpolated signals. Output latency is 2 samples.

```
gainCIC = ...
    (cicint.InterpolationFactor*cicint.DifferentialDelay)...
    ^cicint.NumSections/cicint.InterpolationFactor;
stem(n(1:31)/Fs, double(x(1:31)), 'r', 'filled'); hold on;
stem(n(1:61)/(Fs*cicint.InterpolationFactor), ...
    double(y(1, 4:end))/gainCIC, 'b');
xlabel('Time (sec)'); ylabel('Signal Amplitude');
legend('Original signal', 'Interpolated signal', ...
    'location', 'north');
hold off;
```

Algorithms

A Cascaded Integrator-Comb (CIC) interpolation filter with comb and integrator sections is implemented when the input is fixed-point data type. When the input data type is double or single the `dsp.CICInterpolator` object implements an N -section CIC interpolation filter as an FIR filter with a response that corresponds to a cascade of N boxcar filters.

This object implements the algorithm, inputs, and outputs described on the CIC Interpolation block reference page. The object properties correspond to the block properties, except:

- The **Framing** block parameter is not supported by the `dsp.CICInterpolation` object. The object always maintains the input frame rate.
- The **Rate options** block parameter is not supported by the `dsp.CICInterpolation` object.
- The **Input processing** block parameter is not supported by the `dsp.CICInterpolation` object.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

`dsp.CICDecimator` | `dsp.FIRInterpolator`

Introduced in R2012a

freqz

System object: dsp.CICInterpolator

Package: dsp

Frequency response

Syntax

```
[h,w] = freqz(cicinterp)
[h,w] = freqz(cicinterp,n)
[h,w] = freqz(cicinterp,Name,Value)
freqz(cicinterp)
```

Description

`[h,w] = freqz(cicinterp)` returns the complex, 8192–element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample.

`[h,w] = freqz(cicinterp,n)` returns the complex, `n`-element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[h,w] = freqz(cicinterp,Name,Value)` returns the frequency response and the corresponding frequencies, with additional options specified by one or more `Name, Value` pair arguments.

`freqz(cicinterp)` uses FVTool to plot the magnitude and unwrapped phase of the frequency response of the filter System object `cicinterp`.

fvtool

System object: dsp.CICInterpolator

Package: dsp

Open filter visualization tool

Syntax

```
fvtool(cicinterp)
fvtool(cicinterp, 'Arithmetic', ARITH, ...)
```

Description

`fvtool(cicinterp)` performs an analysis and computes the magnitude response of the filter System object `cicinterp`.

`fvtool(cicinterp, 'Arithmetic', ARITH, ...)` analyzes the filter System object `cicinterp`, based on the arithmetic specified in the `ARITH` input. `ARITH` can be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The 'Arithmetic' input is only relevant for the analysis of filter System objects.

impz

System object: dsp.CICInterpolator

Package: dsp

Impulse response

Syntax

```
[h,t] = impz(cicinterp)
[h,t] = impz(cicinterp,Name,Value)
impz(cicinterp)
```

Description

`[h,t] = impz(cicinterp)` returns the impulse response `h`, and the corresponding time points `t` at which the impulse response of `cicinterp` is computed.

`[h,t] = impz(cicinterp,Name,Value)` returns the impulse response `h`, and the corresponding time points `t`, with additional options specified by one or more `Name, Value` pair arguments.

`impz(cicinterp)` uses `FVTool` to plot the impulse response of the filter System object `cicinterp`.

Note You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

phasez

System object: dsp.CICInterpolator

Package: dsp

Unwrapped phase response

Syntax

```
[phi,w] = phasez(cicinterp)
[phi,w] = phasez(cicinterp,n)
[phi,w] = phasez(cicinterp,Name,Value)
phasez(cicinterp)
```

Description

`[phi,w] = phasez(cicinterp)` returns the 8192–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample.

`[phi,w] = phasez(cicinterp,n)` returns the `n`-element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[phi,w] = phasez(cicinterp,Name,Value)` returns the phase response and the corresponding frequencies, with additional options specified by one or more `Name, Value` pair arguments.

`phasez(cicinterp)` uses `FVTool` to plot the phase response of the filter System object `cicinterp`.

reset

System object: dsp.CICInterpolator

Package: dsp

Reset internal states of CIC Interpolator object

Syntax

```
reset(cicinterp)
```

Description

`reset(cicinterp)` resets the internal states of the `CICInterpolator` System object `cicinterp` to zero.

step

System object: dsp.CICInterpolator

Package: dsp

Interpolate signal using Cascaded Integrator-Comb filter

Syntax

```
Y = step(cicinterp,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(cicinterp,X)` interpolates the fixed-point input `X` to produce a fixed-point output `Y` using the `CICInterpolator` System object `cicinterp`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.ColoredNoise System object

Package: dsp

Generate colored noise signal

Description

The `dsp.ColoredNoise` System object generates a colored noise signal with a power spectral density (PSD) of $1/|f|^a$ over its entire frequency range. The inverse frequency power, a , can be any value in the interval $[-2 \ 2]$. The type of colored noise the object generates depends on the “Color” on page 4-0 you choose. When you set `Color` to 'custom', you can specify the power density of the noise through the “InverseFrequencyPower” on page 4-0 property.

The size and data type properties of the generated signal depend on “SamplesPerFrame” on page 4-0, “NumChannels” on page 4-0, and the “OutputDataType” on page 4-0 properties.

This object uses the default MATLAB random stream, `RandStream`. Reset the default stream for repeatable simulations.

To generate colored noise signal:

- 1 Create the `dsp.ColoredNoise` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#) (MATLAB).

Creation

Syntax

```
cn = dsp.ColoredNoise
```

```
cn = dsp.ColoredNoise(Name,Value)
cn = dsp.ColoredNoise(pow,samp,numChan,Name,Value)
```

Description

`cn = dsp.ColoredNoise` creates a colored noise object, `cn`, that outputs a noise signal one sample or frame at a time, with a $1/|f|^a$ spectral characteristic over its entire frequency range. Typical values for a are $a = 1$ (pink noise) and $a = 2$ (brownian noise).

`cn = dsp.ColoredNoise(Name,Value)` creates a colored noise object with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `dsp.ColoredNoise('Color','pink');`

`cn = dsp.ColoredNoise(pow,samp,numChan,Name,Value)` creates a colored noise object with the `InverseFrequencyPower` property set to `pow`, the `SamplesPerFrame` property set to `samp`, and the `NumChannels` property set to `numChan`.

Example: `dsp.ColoredNoise(1,44.1e3,1,'OutputDataType','single');`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects \(MATLAB\)](#).

Color — Noise color

'custom' (default) | 'pink' | 'white' | 'brown' | 'blue' | 'purple'

Noise color, specified as one of the following. Each color is associated with a specific inverse frequency power of the generated noise sequence.

- 'pink' — The inverse frequency power, a equals 1.
- 'white' — $a = 0$.

- 'brown' — $a = 2$. Also known as red or Brownian noise.
- 'blue' — $a = -1$. Also known as azure noise.
- 'purple' — $a = -2$. Also known as violet noise.
- 'custom' — For noise with a custom inverse frequency power, a equals the value of the “InverseFrequencyPower” on page 4-0 property.

InverseFrequencyPower, a can be any value in the interval $[-2, 2]$.

InverseFrequencyPower — Inverse frequency power

1 (default) | real scalar in $[-2, 2]$

Inverse frequency power, a , specified as a real scalar in the interval $[-2, 2]$. The inverse exponent defines the PSD of the random process as $1/|f|^a$. Values of “InverseFrequencyPower” on page 4-0 greater than 0 generate lowpass noise with a singularity (pole) at $f = 0$. These processes exhibit long memory. Values of InverseFrequencyPower less than 0 generate highpass noise with increments that are negatively correlated. These processes are referred to as anti-persistent. Special cases include:

- 1 — Pink noise
- 2 — Brown, red, or Brownian noise
- 0 — White noise process with a flat PSD
- -1 — Blue or azure noise
- -2 — Purple or violet noise

In a log-log plot of power as a function of frequency, processes generated by this object exhibit an approximate linear relationship with slope equal to $-a$.

Example: 1.2

Example: -1.4

Dependencies

This property applies only when you set “Color” on page 4-0 to 'custom'.

SamplesPerFrame — Number of samples per output channel

1024 (default) | positive integer

Number of samples per output channel, specified as a positive integer. This property determines the number of rows of the signal.

Example: 512

NumChannels — Number of output channels

1 (default) | positive integer

Number of output channels, specified as an integer. This property determines the number of columns of the signal.

Example: 5

Example: 25

RandomStream — Source of random number stream

'Global stream' (default) | 'mt19937ar with seed'

Source of the random number stream, specified as one of the following:

- 'Global stream' — The current global random number stream is used for normally distributed random number generation.
- 'mt19937ar with seed' — The mt19937ar algorithm is used for normally distributed random number generation. The `reset` function reinitializes the random number stream to the value of the `Seed` property.

Seed — Initial seed

67 (default) | nonnegative integer

Initial seed of mt19937ar random number stream generator algorithm, specified as a nonnegative integer. The `reset` function reinitializes the random number stream to the value of the `Seed` property.

Example: 3

Example: 34

Dependencies

This property applies only when you set the `RandomStream` property to 'mt19937ar with seed'.

Data Types: double

OutputDataType — Output data type

'double' (default) | 'single'

Output data type, specified as either 'double' or 'single'.

Usage

Syntax

```
noiseOut = cn()
```

Description

`noiseOut = cn()` outputs one sample or one frame of colored noise data.

Output Arguments

noiseOut — Colored noise output

vector | matrix

Colored noise output, returned as a vector or matrix. The “SamplesPerFrame” on page 4-0 , “NumChannels” on page 4-0 , and the “OutputDataType” on page 4-0 properties specify the size and data type of the output.

Example:

```
[0.5377;2.1027;-1.1403;0.5885;0.6229;-0.8971;-0.7435;-0.0588;3.458;4.4537]
```

Note For versions earlier than R2016b, use the `step` function to run the System object™ algorithm. The arguments to `step` are the object you created, followed by the arguments shown in this section.

For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>clone</code>	Create duplicate System object
<code>getNumInputs</code>	Number of inputs required to call the System object
<code>getNumOutputs</code>	Number of outputs from calling the System object
<code>isLocked</code>	Determine if System object is locked
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Measure Pink Noise Power in Octave Bands

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

The output from this example shows that pink noise has approximately equal power in octave bands.

Generate a single-channel signal of pink noise that is 44,100 samples in length. Set the random number generator to the default settings for reproducible results.

```
pinkNoise = dsp.ColoredNoise(1,44.1e3,1);
rng default;
x = pinkNoise();
```

Set the sampling frequency to 44.1 kHz. Measure the power in octave bands beginning with 100-200 Hz and ending with 6.400-12.8 kHz. Display the results in a table.

```
beginfreq = 100;
endfreq = 200;
```

```

count = 1;
while(endfreq<=44.1e3/2)
    freqinterval(count,:) = [beginfreq endfreq];
    Pwr(count) = bandpower(x,44.1e3,[beginfreq endfreq]);
    beginfreq = endfreq;
    endfreq = 2*endfreq;
    count = count+1;
end
Pwr = Pwr(:);
table(freqinterval,Pwr)

```

```
ans =
```

```
7x2 table
```

freqinterval		Pwr
-----		-----
100	200	0.19436
200	400	0.18472
400	800	0.20873
800	1600	0.2177
1600	3200	0.21887
3200	6400	0.23617
6400	12800	0.23526

The pink noise has roughly equal power in octave bands.

Rerun the preceding code with 'InverseFrequencyPower' equal to 0, which generates a white noise signal. A white noise signal has a flat power spectral density, or equal power per unit frequency. Set the random number generator to the default settings for reproducible results.

```

whiteNoise = dsp.ColoredNoise(0,44.1e3,1);
rng default;
x = whiteNoise();

```

Set the sampling frequency is 44.1 kHz. Measure the power in octave bands beginning with 100-200 Hz and ending with 6.400-12.8 kHz. Display the results in a table.

```

beginfreq = 100;
endfreq = 200;
count = 1;

```

```

while(endfreq<=44.1e3/2)
    freqinterval(count,:) = [beginfreq endfreq];
    Pwr(count) = bandpower(x,44.1e3,[beginfreq endfreq]);
    beginfreq = endfreq;
    endfreq = 2*endfreq;
    count = count+1;
end
Pwr = Pwr(:);
table(freqinterval,Pwr)

```

```
ans =
```

```
7x2 table
```

freqinterval		Pwr
-----		-----
100	200	0.0031417
200	400	0.0073833
400	800	0.017421
800	1600	0.035926
1600	3200	0.071139
3200	6400	0.15183
6400	12800	0.28611

White noise has approximately equal power per unit frequency, so octave bands have an unequal distribution of power. Because the width of an octave band increases with increasing frequency, the power per octave band increases for white noise.

PSD of Pink Noise Realization

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Generate a pink noise signal 2048 samples in length. The sampling frequency is 1 Hz. Obtain an estimate of the power spectral density using Welch's overlapped segment averaging.

```

cn = dsp.ColoredNoise('Color','pink','SamplesPerFrame',2048);
x = cn();

```

```
Fs = 1;  
[Pxx,F] = pwelch(x,hamming(128),[],[],Fs,'psd');
```

Construct the theoretical PSD of the pink noise process.

```
PSDPink = 1./F(2:end);
```

Display the Welch PSD estimate of the noise along with the theoretical PSD on a log-log plot. Plot the frequency axis with a base-2 logarithmic scale to clearly show the octaves.

Plot the PSD estimate in dB, $10\log_{10}$.

```
plot(log2(F(2:end)),10*log10(Pxx(2:end)))  
hold on  
plot(log2(F(2:end)),10*log10(PSDPink),'r','linewidth',2)  
xlabel('log_2(Hz)')  
ylabel('dB')  
title('Pink Noise')  
grid on  
legend('PSD estimate','Theoretical pink noise PSD')  
hold off
```

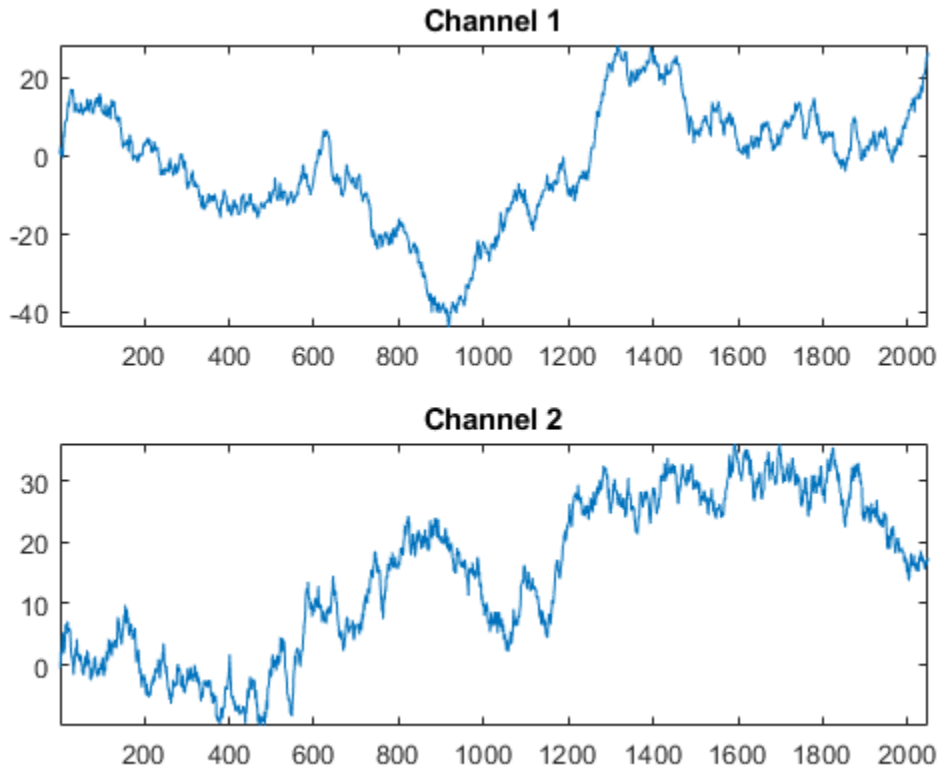

Two-Channel Brownian Noise

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Generate two channels of Brownian noise by setting `Color` to 'brown' and `NumChannels` to 2.

```
cn = dsp.ColoredNoise('Color','brown','SamplesPerFrame',2048,...
    'NumChannels',2);
x = cn();
```

```
subplot(2,1,1)
plot(x(:,1)); title('Channel 1'); axis tight;
subplot(2,1,2)
plot(x(:,2)); title('Channel 2'); axis tight;
```

The sampling frequency is 1 Hz. Obtain Welch PSD estimates for both channels.

```
Fs = 1;
for nn = 1:size(x,2)
[Pxx(:,nn),F] = pwelch(x(:,nn),hamming(128),[],[],Fs,'psd');
end
```

Construct the theoretical PSD of a Brownian process. Plot the theoretical PSD along with both realizations on a log-log plot. Use a base-2 logarithmic scale for the frequency axis and plot the power spectral densities in dB.

```
PSDBrownian = 1./F(2:end).^2;  
figure;  
plot(log2(F(2:end)),10*log10(PSDBrownian),'k-.','linewidth',2);  
hold on;  
plot(log2(F(2:end)),10*log10(Pxx(2:end,:)));  
xlabel('log_2(Hz)'); ylabel('dB');  
grid on;  
legend('Theoretical PSD','Channel 1', 'Channel 2');
```

Add Pink Noise at 0 dB SNR

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

This example shows how to stream in an audio file and add pink noise at a 0 dB signal-to-noise ratio (SNR). The example reads in frames of an audio file 1024 samples in length, measures the root mean square (RMS) value of the audio frame, and adds pink noise with the same RMS value as the audio frame.

Set up the System objects. Set 'SamplesPerFrame' for both the file reader and the colored noise generator to 1024 samples. Set Color to 'pink' to generate pink noise with a $1/|f|$ power spectral density.

```
N = 1024;
afr = dsp.AudioFileReader('Filename','speech_dft.mp3','SamplesPerFrame',N);
adw = audioDeviceWriter('SampleRate',afr.SampleRate);
cn = dsp.ColoredNoise('Color','pink','SamplesPerFrame',N);
rms = dsp.RMS;
```

Stream the audio file in 1024 samples at a time. Measure the signal RMS value for each frame, generate a frame of pink noise equal in length, and scale the RMS value of the pink noise to match the signal. Add the scaled noise to the signal and play the output.

```
while ~isDone(afr)
    audio = afr();
    speechRMS = rms(audio);
    noise = cn();
    noiseRMS = rms(noise);
    noise = noise*(speechRMS/noiseRMS);
    sigPlusNoise = audio+noise;
    adw(sigPlusNoise);
end

release(afr);
release(adw);
```

Averaged Power Spectrum of Pink Noise

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Generate two-channels of pink noise and compute the power spectrum based on a running average of 50 PSD estimates.

Set up the colored noise generator to generate two-channels of pink noise with 1024 samples. Set up the spectrum analyzer to compute modified periodograms using a Hamming window and 50% overlap. Obtain a running average of the PSD using 50 spectral averages.

```
pinkNoise = dsp.ColoredNoise(1,1024,2);  
sa = dsp.SpectrumAnalyzer('SpectrumType','Power density', ...  
    'OverlapPercent',50,'Window','Hamming', ...  
    'SpectralAverages',50,'PlotAsTwoSidedSpectrum',false, ...  
    'FrequencyScale','log','YLimits',[-50 20]);
```

Run the simulation for 30 seconds.

```
tic  
while toc < 30  
    pink = pinkNoise();  
    sa(pink);  
end
```

Definitions

Colored Noise Processes

Many phenomena in diverse fields, such as hydrology and finance, produce time series with PSD functions that follow a power law of the form

$$S(f) = \frac{L(f)}{|f|^a}$$

where a is a real number in the interval $[-2,2]$ and $L(f)$ is a positive, slowly-varying or constant function. Plotting the PSD of such processes on a log-log plot displays an

approximate linear relationship between the log frequency and log PSD with slope equal to $-\alpha$

$$\ln S(f) = -\alpha \ln |f| + \ln L(f).$$

It is often convenient to plot the PSD in dB as a function of the frequency on a base-2 logarithmic scale. The slope of the plot is then dB/octave. Rewriting the preceding equation, you obtain

$$10 \log S(f) = -10\alpha \frac{\ln(2) \log_2(f)}{\ln(10)} + 10 \frac{\ln(L(f))}{\ln(10)}$$

with the slope in dB/octave given by

$$-10\alpha \frac{\ln(2) \log_2(f)}{\ln(10)}$$

If $\alpha > 0$, $S(f)$ goes to infinity as the frequency, f , approaches 0. Stochastic processes with PSDs of this form exhibit long memory. Long-memory processes have autocorrelations that persist for a long time as opposed to decaying exponentially like many common time-series models. If $\alpha < 0$, the process is antipersistent and exhibits negative correlation between increments [1].

Special examples of $\frac{1}{|f|^\alpha}$ processes include:

- $\alpha = 0$ — White noise, where $L(f)$ is a constant proportional to the process variance.
- $\alpha = 1$ — Pink, or flicker noise. Pink noise has equal energy per octave. See “Measure Pink Noise Power in Octave Bands” on page 4-381 for a demonstration. The power spectral density of pink noise decreases 3 dB per octave.
- $\alpha = 2$ — brown noise, or Brownian motion. Brownian motion is a nonstationary process with stationary increments. You can think of Brownian motion as the integral of a white noise process. Even though Brownian motion is nonstationary, you can still

define a generalized power spectrum, which behaves like $\frac{1}{|f|^2}$. Accordingly, power in a brown noise decreases 6 dB per octave.

- $\alpha = -1$ — blue noise. The power spectral density of blue noise increases 3 dB per octave.

- $\alpha = -2$ — violet, or purple noise. The power spectral density of violet noise increases 6 dB per octave. You can think of violet noise as the derivative of white noise process.

Algorithms

AR Generation Method

`dsp.ColoredNoise` generates colored noise using a white noise input in an autoregressive model (AR) of order 63:

$$\sum_{k=0}^{63} a_k y(n-k) = w(n)$$

where $a_0 = 1$ and $w(n)$ is a zero-mean white noise process.

The AR coefficients for $k \geq 1$ are generated according to the following recursive formula with α the inverse PSD exponent:

$$a_k = \left(k - 1 - \frac{\alpha}{2}\right) \frac{a_{k-1}}{k} \quad k = 1, 2, \dots$$

The AR method used in `dsp.ColoredNoise` is detailed on pp. 820–822 in [2].

dsp.Convolver System object

Package: dsp

Convolution of two signals

Description

The `dsp.Convolver` System object convolves the first dimension of an N -D input array, u , with the first dimension of an N -D input array, v . You can convolve the inputs in the time domain or frequency domain. In the time domain, the object convolves the first input with the second input. In the frequency domain, the object multiplies the Fourier transforms of both the inputs, and computes the inverse Fourier transform of the product. In this domain, depending on the input length, the object can require fewer computations. For more information on the two computation methods, see “Algorithms” on page 4-403.

To convolve two inputs:

- 1 Create the `dsp.Convolver` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#) (MATLAB).

Creation

Syntax

```
cnv = dsp.Convolver  
cnv = dsp.Convolver(Name, Value)
```

Description

`cnv = dsp.Convolver` creates a convolution System object, `cnv`, to convolve two inputs in the time domain or frequency domain.

`cnv = dsp.Convolver(Name, Value)` creates a convolution System object, `cnv`, with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `cnv = dsp.Convolver('Method','Frequency Domain')`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects \(MATLAB\)](#).

Method — Domain for computing convolutions

'Time Domain' (default) | 'Frequency Domain' | 'Fastest'

Domain in which the System object computes convolutions, specified as one of the following:

- 'Time Domain' — Computes the convolutions in the time domain, which minimizes memory usage. For more information, see “Time-Domain Computation” on page 4-403.
- 'Frequency Domain' — Computes the convolutions in the frequency domain, which can require fewer computations depending on the input length. For more information, see “Frequency-Domain Computation” on page 4-403.
- 'Fastest' — Computes the convolutions in the domain that minimizes the number of computations.

Note Fixed-point signals are supported for the time domain only. To use the following fixed-point properties, set `Method` to 'Time Domain'.

Fixed-Point Properties

FullPrecisionOverride — Full-precision override for fixed-point arithmetic

`true` (default) | `false`

Flag to use full-precision rules for fixed-point arithmetic, specified as one of the following:

- `true` — The object computes all internal arithmetic and output data types using the full-precision rules. These rules provide the most accurate fixed-point numerics. In this mode, other fixed-point properties do not apply. No quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- `false` — Fixed-point data types are controlled through individual fixed-point property settings.

For more information, see “Full Precision for Fixed-Point System Objects” and “Set System Object Fixed-Point Properties”.

RoundingMethod — Rounding method

`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Select the rounding mode for fixed-point operations.

Dependencies

This property applies when you set the `FullprecisionOverride` property to `false` and at least one of the `ProductDataType`, `AccumulatorDataType`, and `OutputDataType` properties to any option other than `'Full precision'`.

OverflowAction — Overflow action

`'Wrap'` (default) | `'Saturate'`

The overflow action for fixed-point operations, specified as one of the following:

- `'Wrap'` — The object wraps the result of its fixed-point operations.
- `'Saturate'` — The object saturates the result of its fixed-point operations.

For more details on overflow actions, see overflow mode for fixed-point operations.

Dependencies

This property applies when you set the `FullprecisionOverride` property to `false` and at least one of the `ProductDataType`, `AccumulatorDataType`, and `OutputDataType` properties to any option other than `'Full precision'`.

ProductDataType — Product output data type

`'Full precision'` (default) | `'Custom'` | `'Same as first input'`

Data type of the output of a product operation in the `dsp.Convolver` object, specified as one of the following:

- `'Full precision'` — The object computes the product output data type using the full-precision rules. These rules provide the most accurate fixed-point numerics. No quantization occurs. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- `'Custom'` — The product output data type is specified as a custom numeric type through the `CustomProductDataType` property. The rounding method and the overflow action are specified through the `RoundingMethod` and `OverflowAction` properties.
- `'Same as first input'` — The object specifies the product output data type to be the same as the first input data type.

For more information on the product output data type, see the “Fixed Point” on page 4-0 section.

CustomProductDataType — Product word and fraction lengths

`numericType([],32,30)` (default)

The product output data type, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set `ProductDataType` to `'Custom'`.

AccumulatorDataType — Accumulator data type

`'Full precision'` (default) | `'Custom'` | `'Same as first input'` | `'Same as product'`

Data type of the output of an accumulation operation in the `dsp.Convolver` object, specified as one of the following:

- `'Full precision'` — The object computes the accumulator data type using the full precision rules. These rules provide the most accurate fixed-point numerics. No quantization occurs. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- `'Custom'` — The accumulator data type is specified as a custom numeric type through the `CustomAccumulatorDataType` property. The rounding method and the overflow action are specified through the `RoundingMethod` and the `OverflowAction` properties.
- `'Same as first input'` — The object specifies the accumulator data type to be the same as the first input data type.
- `'Same as product'` — The object specifies the accumulator data type to be the same as the product data type.

For more information on the accumulator data type, see the “Fixed Point” on page 4-0 section.

CustomAccumulatorDataType — Accumulator word and fraction lengths

`numericType([],32,30)` (default)

The accumulator data type, specified as an auto signed numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set `AccumulatorDataType` to `'Custom'`.

OutputDataType — Output data type

`'Same as accumulator'` (default) | `'Custom'` | `'Same as first input'` | `'Same as product'`

Data type of the output of the `dsp.Convolver` object, specified as one of the following:

- `'Same as accumulator'` — The object specifies the output data type to be the same as the accumulator data type. For more details on the accumulator data type, see the “AccumulatorDataType” on page 4-0 property.

- 'Custom' — The output data type is specified as a custom numeric type through the `CustomOutputDataType` property. The rounding method and the overflow action are specified through the `RoundingMethod` and the `OverflowAction` properties.
- 'Same as first input' — The object specifies the output data type to be the same as the first input data type.
- 'Same as product' — The object specifies the output data type to be the same as the product data type.

For more information on the output data type, see the “Fixed Point” on page 4-0 section.

CustomOutputDataType — Output word and fraction lengths

`numericType([],16,15)` (default)

The output data type, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Dependencies

This property applies only when you set `OutputDataType` to 'Custom'.

Usage

Syntax

```
cnvOut = cnv(input1, input2)
```

Description

`cnvOut = cnv(input1, input2)` convolves the two inputs, `input1` and `input2`, along their first dimensions, and returns the convolved output, `cnvOut`.

Input Arguments

input1 — First data input

vector | matrix | *N*-D array

First data input, specified as a vector, matrix, or N -D array. If the input is a matrix or an array, all the dimensions of both the inputs, except for the first dimension, must be the same.

Example: `ones(10,3,2)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

input2 — Second data input

vector | matrix | N -D array

Second data input, specified as a vector, matrix, or N -D array. If the input is a matrix or an array, all the dimensions of both the inputs, except for the first dimension, must be the same.

Example: `randn(4,3,2)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

Output Arguments

cnvOut — Convolved output

vector | matrix | N -D array

The convolved output of the two inputs, returned as a vector, matrix, or N -D array.

- When both inputs are N -D arrays, the size of their first dimension can differ, but the size of all other dimensions must be equal. For example, when u is an M_u -by- N -by- P array, and v is an M_v -by- N -by- P array, the output is an (M_u+M_v-1) -by- N -by- P array.
- When one input is a column vector and the other is an N -D array, the object independently convolves the vector with the first dimension of the N -D input array. For example, when u is an M_u -by-1 column vector and v is an M_v -by- N matrix, the output is an (M_u+M_v-1) -by- N matrix.
- When u and v are column vectors with lengths M_u and M_v , the object performs the vector convolution. The output is an (M_u+M_v-1) -by-1 column vector.

When both the inputs are real, the output is real. When one or both inputs are complex, the output is complex.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

Note For versions earlier than R2016b, use the `step` function to run the System object™ algorithm. The arguments to `step` are the object you created, followed by the arguments shown in this section.

For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>clone</code>	Create duplicate System object
<code>getNumInputs</code>	Number of inputs required to call the System object
<code>getNumOutputs</code>	Number of outputs from calling the System object
<code>isLocked</code>	Determine if System object is locked
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Convolve Two Rectangular Sequences

Note: If you are using R2016a or earlier, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Create a `dsp.Convolver` object. Convolve two rectangular sequences.

```
conv = dsp.Convolver;
x = ones(10,1);
y = conv(x,x);
```

Plot the resulting convolved sequence, which is a triangular sequence.

`plot(y)`

Definitions

Convolution

The convolution of two signals is the integral that measures the amount of overlap of one signal as it is shifted over another signal.

The convolution of two discrete time sequences, $u[n]$ and $v[n]$, is given by the following equation:

$$y(k) = \sum_n u(n-k)v(k)$$

Algorithms

Time-Domain Computation

When you set the computation domain to *time*, the algorithm computes the convolution of the two inputs in the time domain.

When the two inputs, u and v , are of size M_u -by- N and M_v -by- N respectively, the j th column of the convolution output is given by the following equation:

$$y_{i,j} = \sum_{k=0}^{\max(M_u, M_v)-1} u_{k,j} v_{(i-k),j} \quad 0 \leq i \leq (M_u + M_v - 2)$$

Inputs u and v are zero when they are indexed outside their valid ranges.

When u is an M_u -by-1 column and v an M_v -by- N matrix, the output is an (M_u+M_v-1) -by- N matrix whose j th column is computed using the following equation:

$$y_{i,j} = \sum_{k=0}^{\max(M_u, M_v)-1} u_k v_{(i-k),j} \quad 0 \leq i \leq (M_u + M_v - 2)$$

When both the inputs are column vectors with lengths M_u and M_v , the object performs the vector convolution given by the following equation:

$$y_i = \sum_{k=0}^{\max(M_u, M_v)-1} u_k v_{(i-k)} \quad 0 \leq i \leq (M_u + M_v - 2)$$

The output is an (M_u+M_v-1) -by-1 column vector.

Frequency-Domain Computation

When you set the computation domain to *frequency*, the algorithm computes the convolution in the frequency domain.

In this domain, the algorithm computes the convolution sequence by taking the Fourier transform of both the input signals, multiplying the Fourier transforms, and taking the inverse Fourier transform of the product. In this domain, depending on the input length, the algorithm can require fewer computations.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Fixed-Point Conversion

Design and simulate fixed-point algorithms using Fixed-Point Designer™.

The following diagram shows the data types used within the `dsp.Convolver` System object for fixed-point signals.

Fixed-point signals are supported for the time domain only.

The output of the multiplier is in the product output data type when the input is real. When the input is complex, the result of the multiplication is in the accumulator data

type. For details on the complex multiplication performed, see “Multiplication Data Types”.

When one or both of the inputs are signed fixed-point signals, all internal object data types are signed fixed point. The internal data types are unsigned fixed point only when *both* inputs are unsigned fixed-point signals.

dsp.Counter System object

Package: dsp

Count up or down through specified range of numbers

Description

The `Counter` object counts up or down through a specified range of numbers.

To count up or down through a specified range of numbers:

- 1 Define and set up your counter. See “Construction” on page 4-406.
- 2 Call `step` to count up or down according to the properties of `dsp.Counter`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`count = dsp.Counter` returns a counter System object, `count`, that counts up when the input is nonzero.

`count = dsp.Counter('PropertyName', PropertyValue, ...)` returns a counter System object, `count`, with each specified property set to the specified value.

Properties

Direction

Count up or down

Specify the counter direction as `Up` or `Down`. The default is `Up`. This property is tunable.

CountEventInputPort

Add input to specify a count event

Set this property to `true` to enable a count event input for the internal counter. The internal counter increments or decrements whenever the count event input satisfies the condition you specify in the `CountEventCondition` property. When you set this property to `false`, the internal counter is free running, that is, the counter increments or decrements on every call to the `step` method. The default is `true`.

CountEventCondition

Condition that increments, decrements, or resets internal counter

Specify the event at the count event input that increments or decrements the counter as `Rising edge`, `Falling edge`, `Either edge` or `Non-zero`.

If you set the `ResetInputPort` and `CountEventInputPort` properties to `true`, the counter is reset when the event you specify for the `CountEventCondition` occurs. This property applies only when you set the `CountEventInputPort` property to `true`.

CounterSizeSource

Source of counter size data type

Specify the source of the counter size data type as `Property` or `Input port`. The default is `Property`.

CounterSize

Range of integer values to count through

Specify the range of integer values to count through before recycling to zero as `8 bits`, `16 bits`, `32 bits` or `Maximum`. The default is `Maximum`.

MaximumCount

Counter's maximum value

Specify the counter's maximum value as a numeric scalar value. This property applies only when you set the `CounterSizeSource` property to `Property` and the `CounterSize` property to `Maximum`. The default is 255. This property is tunable.

InitialCount

Counter initial value

Specify the initial value for the counter. The default is 0. This property is tunable.

CountOutputPort

Output count

Set this property to `true` to enable output of the internal count. The default is `true`. You cannot set both `CountOutputPort` and `HitOutputPort` to `false` at the same time.

HitOutputPort

Output hit events

Set this property to `true` to enable output of the hit events. You cannot set both `CountOutputPort` and `HitOutputPort` to `false` at the same time. The default is `true`.

HitValues

Values whose occurrence in count produce a true hit output

Specify an integer scalar or a vector of integers, whose occurrences in the count you want flagged as a hit. This property applies only when you set the `HitOutputPort` property to `true`.

ResetInputPort

Add input to enable internal counter reset

When you set this property to `true`, specify a reset input to the `step` method. When the reset input receives the event you specify for the `CountEventCondition` property, the counter resets. If you set the `CountEventInputPort` property to `false`, the counter resets whenever the reset input is not zero.

SamplesPerFrame

Number of samples in each output frame

Specify the number of samples in each output frame. This property applies only when you set the `CountEventInputPort` property to `false`, indicating a free-running counter. The default is 1.

CountOutputDataType

Data type of count output

Specify the data type of the count output, `CNT`, as `double`, `single`, `int8`, `uint8`, `int16`, `uint16`, `int32` or `uint32`. This property applies when you set the `CountOutputPort` property to `true`. The default is `double`.

Methods

`reset` Reset internal states of Counter object
`step` Increment or decrement the internal counter

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

Count the Rising Edges

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Use `dsp.Counter` System object™ to count at every rising edge of the input signal.

```
count = dsp.Counter('MaximumCount', 5, ...
    'CountOutputPort', true, ...
    'HitOutputPort', false, ...
    'ResetInputPort', false);
sgnl = [0 1 0 1 0 1 0 1 0 1 0 1 ];
for ii = 1:length(sgnl)
    cnt(ii) = count(sgnl(ii));
end
display(cnt);

cnt =

     0     1     1     2     2     3     3     4     4     5     5     0
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Counter block reference page. The object properties correspond to the block parameters.

- The `CountEventCondition` object property does not have a free-running option. Set the `CountEventInputPort` property to `false` to obtain the free-running option.
- The `CounterSizeSource` and `CounterSize` object properties correspond to the **Counter size** block parameter.
- The `CountOutputPort` and `HitOutputPort` correspond to the **Output** block parameter.
- There is no object property that corresponds to the **Hit data type** block parameter. The output type is logical in MATLAB. (This logical is different from the popup logical in the block. For the object, logical corresponds to Boolean in the block.)

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Introduced in R2012a

reset

System object: dsp.Counter

Package: dsp

Reset internal states of Counter object

Syntax

```
reset(count)
```

Description

`reset(count)` resets the internal states of the counter object `count` to their initial values.

step

System object: dsp.Counter

Package: dsp

Increment or decrement the internal counter

Syntax

```
[CNT,HIT] = step(count,EVENT,RESET)
CNT = step(count,EVENT,RESET)
HIT = step(count,EVENT,RESET)
[...] = step(count)
[...] = step(count,EVENT)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[CNT,HIT] = step(count,EVENT,RESET)` increments, decrements, or resets the internal counter as specified by the values of the `EVENT` and `RESET` inputs. The output argument `CNT` denotes the present value of the counter. A trigger event at the `EVENT` input causes the counter to increment or decrement. A trigger event at the `RESET` input resets the counter to its initial state.

`CNT = step(count,EVENT,RESET)` returns the current value of the count when you set the `CountOutputPort` property to `true`, and the `HitOutputPort` property to `false`.

`HIT = step(count,EVENT,RESET)` returns a Boolean value indicating whether the count has reached any of the values specified by the `HitValues` property. This condition

applies when you set the `HitOutputPort` property to `true` and the `CountOutputPort` property to `false`.

`[...] = step(count)` increments or decrements the free-running internal counter when you set the `CountEventInputPort` property to `false` and the `ResetInputPort` property to `false`.

`[...] = step(count, EVENT)` increments or decrements the internal counter when the `EVENT` input matches the event you specify for the `CountEventCondition` property and you set the `ResetInputPort` property to `false`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.CoupledAllpassFilter System object

Package: dsp

Coupled allpass IIR filter

Description

The `CoupledAllpassFilter` object implements a coupled allpass filter structure composed of two allpass filters connected in parallel. Each allpass branch can contain multiple sections. The overall filter output is computed by adding the output of the two respective branches. An optional second output can also be returned, which is power complementary to the first. For example, from the frequency domain perspective, if the first output implements a lowpass filter, the second output implements the power complementary highpass filter. For real signals, the power complementary output is computed by subtracting the output of the second branch from the first.

`CoupledAllpassFilter` supports double- and single-precision floating point and allows you to choose between different realization structures. This System object also supports complex coefficients, multichannel variable length input, and tunable filter coefficient values.

To filter each channel of the input:

- 1 Define and set up your Coupled Allpass Filter. See “Construction” on page 4-416.
- 2 Call `step` to filter each channel of the input according to the properties of `dsp.CoupledAllpassFilter`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`caf = dsp.CoupledAllpassFilter` returns a coupled allpass filter System object, `caf`, that filters each channel of the input signal independently. The coupled allpass filter uses the default inner structures and coefficients.

`caf = dsp.CoupledAllpassFilter('PropertyName',PropertyValue, ...)` returns a Coupled allpass filter System object, `caf`, with each property set to the specified value.

`caf = CoupledAllpassFilter(AllpassCoefficients1,AllpassCoefficients2)` returns a coupled allpass filter System object, `caf`, with `Structure` set to 'Minimum multiplier'. The allpass coefficients for each of the two branches are set to their two corresponding specified values.

`caf = CoupledAllpassFilter(Structure,AllpassCoefficients1,AllpassCoefficients2)` returns a coupled allpass filter System object, `caf`, with `Structure` set to a specified value. This value can be 'Minimum multiplier' | 'Wave Digital Filter' | 'Lattice'. The coefficients relevant to the specified structure are set to the values provided.

Properties

Structure

Internal structure of allpass branches

Specify the internal structure of allpass branches as one of 'Minimum multiplier' | 'Wave Digital Filter' | 'Lattice'. Each structure uses a different pair of coefficient values, independently stored in the relevant object property.

AllpassCoefficients1

Allpass polynomial coefficients of branch 1

Specify the polynomial filter coefficients for the first allpass branch. This property is applicable only if you set the `Structure` property to 'Minimum multiplier'. This

property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections. The default value is `[0 0.5]`. This property is tunable.

WDFCoefficients1

Wave Digital Filter coefficients of branch 1

Specify the Wave Digital Filter coefficients for the first allpass branch. This property is applicable only if you set the `Structure` property to `'Wave Digital Filter'`. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections. The default value is `[0.5 0]`. This property is tunable.

LatticeCoefficients1

Lattice coefficients of branch 1

Specify the allpass lattice coefficients for the first allpass branch. This property is applicable only if you set the `Structure` property to `'Lattice'`. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections. The default value is `[0.5 0]`. This property is tunable.

Delay

length in samples for branch 1

`Delay` is the integer number of the delay taps in the top branch. This property is applicable only if you set the `PureDelayBranch` property to `true`. This property is a scalar positive integer, and is tunable.

Gain1

Independent Branch 1 Phase Gain

`Gain1` is the individual branch phase gain. This property can accept only values equal to `'1'`, `'-1'`, `'0+i'`, or `'0-i'`. The default value is 1. This property is nontunable.

AllpassCoefficients2

Allpass polynomial coefficients of branch 2

Specify the polynomial filter coefficients for the second allpass branch. This property is applicable only if you set the `Structure` property to `'Minimum Multiplier'`. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections. The default value is `[]`. This property is tunable.

WDFCoefficients2

Wave Digital Filter coefficients of branch 2

This property is applicable only if you set the `Structure` property to `'Wave Digital Filter'`. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections. The default value is `[]`. This property is tunable.

LatticeCoefficients2

Lattice coefficients of branch 2

Specify the allpass lattice coefficients for the second allpass branch. This property is applicable only if you set the `Structure` property to `'Lattice'`. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections. The default value is `[]`. This property is tunable.

Gain2

Independent Branch 2 Phase Gain

Specify the value of the independent phase gain applied to branch 2. This property can accept only values equal to `'1'`, `'-1'`, `'0+1i'` or `'0-1i'`. The default value is 1. This property is nontunable.

Beta

Coupled phase gain

Specify the value of the phasor gain in complex conjugate form, in each of the two branches, and in complex coefficient configuration. This property is applicable only when the selected `Structure` property supports complex coefficients. The absolute value of this property should be 1 and its default value is 1. This property is tunable.

PureDelayBranch

Replace allpass filter in first branch with pure delay

If you set `PureDelayBranch` to true, the property holding the coefficients for the first allpass branch is disabled and `Delay` becomes enabled. You can use this property to improve performance, when one of the two allpass branches is known to be a pure delay (e.g. for halfband filter designs)

ComplexConjugateCoefficients

Allow inferring coefficients of second allpass branch as complex conjugate of first

When the input signal is real, this property triggers the use of an optimized structural realization. This property is only enabled if the currently selected structure supports complex coefficients. Use it only if the filter coefficients are actually complex.

Methods

<code>getBranches</code>	Return internal allpass branches
<code>reset</code>	Reset internal states of Coupled Allpass filter
<code>step</code>	Filter input with CoupledAllpas filter object

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

Allpass Realization of a Butterworth Lowpass Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Realize a Butterworth lowpass filter of order 3. Use a coupled allpass structure with inner minimum multiplier structure.

```
Fs = 48000;      % in Hz
Fc = 12000;     % in Hz
frameLength = 1024;
[b, a] = butter(3,2*Fc/Fs);
AExp = [freqz(b,a,frameLength/2); NaN];
[c1, c2] = tf2ca(b,a);
caf = dsp.CoupledAllpassFilter(c1(2:end),c2(2:end));
tfe = dsp.TransferFunctionEstimator('FrequencyRange', 'onesided',...
    'SpectralAverages', 2);
aplot = dsp.ArrayPlot('PlotType', 'Line',...
    'YLimits', [-40 5],...
    'YLabel', 'Magnitude (dB)',...
    'SampleIncrement', Fs/frameLength,...
    'XLabel', 'Frequency (Hz)',...
    'Title', 'Magnitude Response',...
    'ShowLegend', true, 'ChannelNames',{'Actual','Expected'});
Niter = 200;
for k = 1:Niter
    in = randn(frameLength,1);
    out = caf(in);
    A = tfe(in,out);
    aplot(db([A,AExp]));
end
```

Allpass Realization of an Elliptic Highpass Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Remove a low-frequency sinusoid using an elliptic highpass filter design implemented through a coupled allpass structure.

Initialize

```
Fs = 1000;
f1 = 50; f2 = 100;
```

```
Fpass = 70; Apass = 1;
Fstop = 60; Astop = 80;
filtSpecs = fdesign.highpass(Fstop,Fpass,Astop,Apass,Fs);
hpSpec = design(filtSpecs,'ellip','FilterStructure','cascadeallpass',...
    'SystemObject',true);
frameLength = 1000;
nFrames = 100;
sine = dsp.SineWave('Frequency',[f1,f2],'SampleRate',Fs,...
    'SamplesPerFrame',frameLength); % Input composed of two sinusoids.
sa = dsp.SpectrumAnalyzer('SampleRate',Fs,'YLimits',[-150 30],...
    'PlotAsTwoSidedSpectrum',false,'ShowLegend',true,...
    'FrequencyResolutionMethod', 'WindowLength','WindowLength',1000,...
    'FFTLengthSource', 'Property','FFTLength', 1000,...
    'Title','Original (Channel 1) Filtered (Channel 2)',...
    'ChannelNames',{'Original','Filtered'});
```

Simulate

```
for k = 1:nFrames
    original = sum(sine(),2); % Add the two sinusoids together
    filtered = hpSpec(original);
    sa([original,filtered]);
end
```

View the Power Complementary Output of the Coupled Allpass Filter

Realize a Butterworth lowpass filter of order 3. Use a coupled allpass structure with inner minimum multiplier structure.

```

Fs = 48000;    % in Hz
Fc = 12000;   % in Hz
frameLength = 1024;
[b, a] = butter(3, 2*Fc/Fs);
AExp = [freqz(b, a, frameLength/2); NaN];
[c1, c2] = tf2ca(b, a);
caf = dsp.CoupledAllpassFilter(c1(2:end), c2(2:end));

```

Using the 'SubbandView' option of the `dsp.CoupledAllpassFilter`, you can visualize the lowpass filter output, power complimentary high pass filter output, or both using the `fvtool`.

To view the lowpass filter output, set 'SubbandView' to 1.

```
fvtool(caf, 'SubbandView', 1, 'Fs', Fs);
```

To view the highpass filter output, set 'SubbandView' to 2.

```
fvtool(caf, 'SubbandView', 2, 'Fs', Fs);
```

To view both the outputs, set 'SubbandView' to 'all', [1 2] or [1;2].

```
fvtool(caf, 'SubbandView', 'all', 'Fs', Fs);
```

Filter Analysis

`dsp.CoupledAllpassFilter` supports the filter analysis methods. To get a list of all the analysis methods the object supports, type `dsp.CoupledAllpassFilter.helpFilterAnalysis` in the MATLAB command prompt.

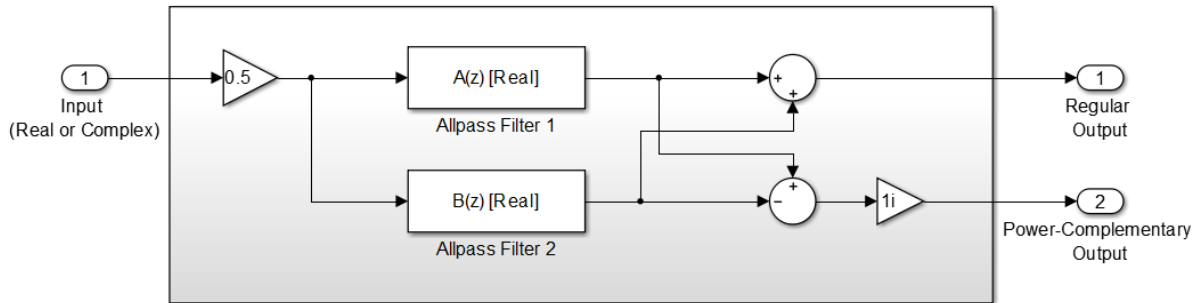

The `fvtool` method can display both the lowpass filter output and the power complimentary highpass filter output by setting the appropriate value of the 'SubbandView' option. To display the lowpass filter output, set this option to 1. To

display the power complementary output, set this option to 2. To view both the outputs, set this option to 'all', [1 2], or [1;2].

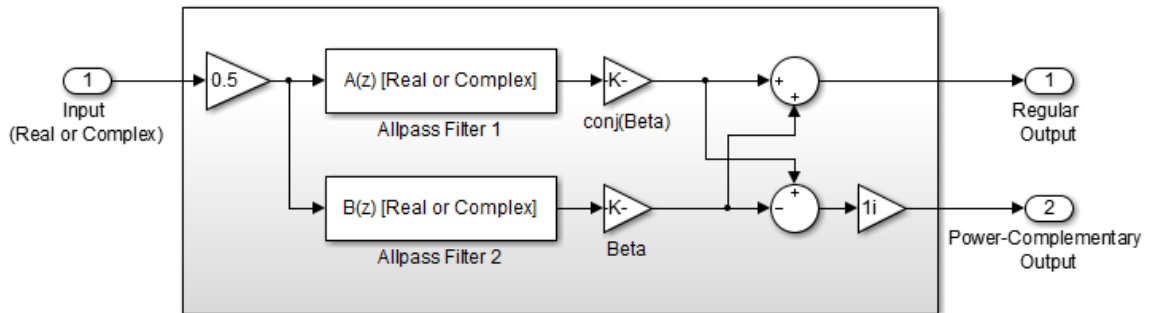

Algorithms

The following three figures summarize the main structures supported by `dsp.CoupledAllpassFilter`.

- Minimum Multiplier and WDF

- Lattice

- Lattice with Complex Conjugate Coefficients

Introduced in R2013b

getBranches

System object: dsp.CoupledAllpassFilter

Package: dsp

Return internal allpass branches

Syntax

`getBranches(caf)`

Description

`getBranches(caf)` returns copies of the internal allpass branches, as a two-field structure. Each branch is an instance of `dsp.AllpassFilter`.

reset

System object: dsp.CoupledAllpassFilter

Package: dsp

Reset internal states of Coupled Allpass filter

Syntax

```
reset (caf)
```

Description

`reset (caf)` resets the internal states of the Coupled Allpass filter object, `caf`, to their initial values. The reset method is always a no-op for unlocked System objects, as the states may not be allocated when the object is not locked.

step

System object: dsp.CoupledAllpassFilter

Package: dsp

Filter input with CoupledAllpas filter object

Syntax

```
Y = step(caf,X)
[Y1,...,YN] = step(caf,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(caf,X)` processes the input data, `X` to produce the output, `Y`, for System object, `caf`.

`[Y1,...,YN] = step(caf,X)` produces `N` outputs.

Every System object has a `step` method. The `step` method processes the input data according to the object algorithm. The number of input and output arguments depends on the algorithm, and may depend also on one or more property settings. The `step` method for some objects accepts fixed-point (fi) inputs (but not for this object).

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable

property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.CrossSpectrumEstimator System object

Package: dsp

Estimate cross-spectral density

Description

The `dsp.CrossSpectrumEstimator` computes the cross-spectrum density of a signal, using the Welch algorithm and the Periodogram method.

To implement the cross-spectrum estimation object:

- 1 Define and set up your cross-spectrum estimator object. See “Construction” on page 4-433.
- 2 Call `step` to implement the estimator according to the properties of `dsp.CrossSpectrumEstimator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`cse = dsp.CrossSpectrumEstimator` returns a System object, `cse`, that computes the cross-power spectrum of real or complex signals using the periodogram method and Welch’s averaged, modified periodogram method.

`cse = dsp.CrossSpectrumEstimator('PropertyName', PropertyValue,...)` returns a Cross-Spectrum Estimator System object, `cse`, with each specified property name set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

Properties

SampleRate

Sample rate of input

Specify the sample rate of the input, in hertz, as a finite numeric scalar. The default value is 1 Hz. The sample rate is the rate at which the signal is sampled in time.

SpectralAverages

Number of spectral averages

Specify the number of spectral averages as a positive, integer scalar. The Cross-Spectrum Estimator computes the current cross-spectral estimate by averaging the last N estimates. N is the number of spectral averages defined in the SpectralAverages property. The default is 8.

FFTLengthSource

Source of the FFT length value

Specify the source of the FFT length value as one of 'Auto' | 'Property'. The default is 'Auto'. If you set this property to 'Auto', the Cross-Spectrum Estimator sets the FFT length to the input frame size. If you set this property to 'Property', then you specify the number of FFT points using the FFTLength property.

FFTLength

FFT Length

Specify the length of the FFT that the Cross-Spectrum Estimator uses to compute cross-spectral estimates as a positive, integer scalar. This property applies when you set the FFTLengthSource property to 'Property'. The default value is 128.

Window

Window function

Specify a window function for the cross-spectral estimator as one of 'Rectangular' | 'Chebyshev' | 'Flat Top' | 'Hamming' | 'Hann' | 'Kaiser'. The default value is 'Hann'.

SidelobeAttenuation

Side lobe attenuation of window

Specify the side lobe attenuation of the window as a real, positive scalar, in decibels (dB). This property applies when you set the `Window` property to `'Chebyshev'` or `'Kaiser'`. The default is 60 dB.

FrequencyRange

Frequency range of the cross-spectrum estimate

Specify the frequency range of the cross-spectrum estimator as one of `'twosided'` | `'onesided'` | `'centered'`.

If you set the `FrequencyRange` to `'onesided'`, the cross-spectrum estimator computes the onesided spectrum of real input signals, x and y . If the FFT length, `NFFT`, is even, the length of the cross-spectrum estimate is $NFFT/2+1$ and is computed over the interval $[0, SampleRate/2]$. If `NFFT` is odd, the length of the cross-spectrum estimate is equal to $(NFFT+1)/2$ and the interval is $[0, SampleRate/2]$.

If you set the `FrequencyRange` to `'twosided'`, the cross-spectrum estimator computes the twosided spectrum of complex or real input signals, x and y . The length of the cross-spectrum estimate is equal to `NFFT`. This value is computed over $[0, SampleRate]$.

If you set the `FrequencyRange` to `'centered'`, the cross-spectrum estimator computes the centered twosided spectrum of complex or real input signals, x and y . The length of the cross-spectrum estimate is equal to `NFFT` and it is computed between $[-SampleRate/2, SampleRate/2]$ and $(-SampleRate/2, SampleRate/2)$ for even and odd lengths, respectively. The default value is `'Twosided'`.

Methods

<code>getFrequencyVector</code>	Get the vector of frequencies at which the cross-spectrum is estimated
<code>getRBW</code>	Get the resolution bandwidth of the cross-spectrum
<code>reset</code>	Reset the internal states of the cross-spectrum estimator
<code>step</code>	Estimate the cross-spectrum of a signal

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

Compute the Cross-Power Spectrum of Two Noisy Sine Waves

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Generate two sine waves.

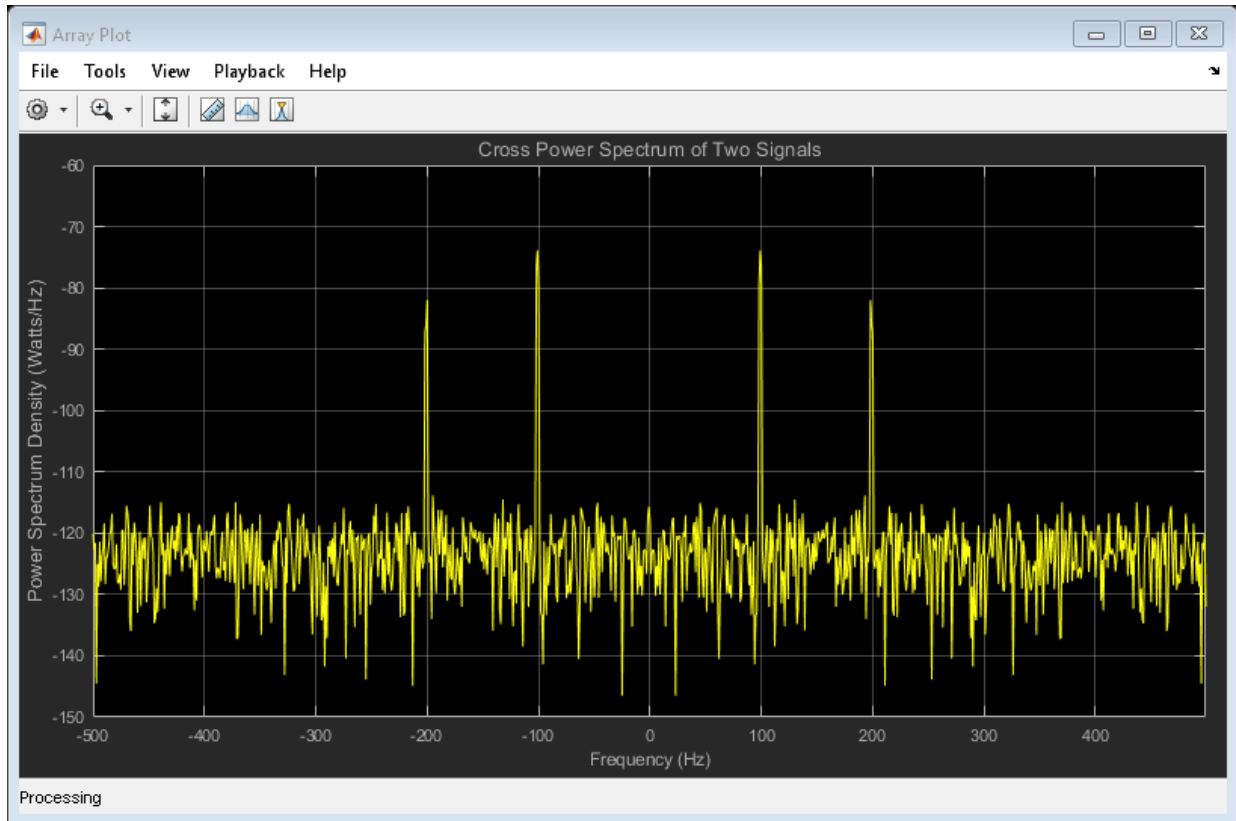

```
sin1 = dsp.SineWave('Frequency',200, 'SampleRate', 1000);  
sin1.SamplesPerFrame = 1000;  
sin2 = dsp.SineWave('Frequency',100, 'SampleRate', 1000);  
sin2.SamplesPerFrame = 1000;
```

Use the Cross-Spectrum Estimator to compute the cross-spectrum of the signals. Also, use the Array Plot to display the spectra.

```
cse = dsp.CrossSpectrumEstimator('SampleRate', sin1.SampleRate,...  
    'FrequencyRange','centered');  
aplot = dsp.ArrayPlot('PlotType','Line','XOffset',-500,'YLimits',...  
    [-150 -60],'YLabel','Power Spectrum Density (Watts/Hz)',...  
    'XLabel','Frequency (Hz)',...  
    'Title','Cross Power Spectrum of Two Signals');
```

Add random noise to the sine waves. Stream in the data, and plot the cross-power spectrum of the two signals.

```
for ii = 1:10  
    x = sin1() + 0.05*randn(1000,1);  
    y = sin2() + 0.05*randn(1000,1);  
    Pxy = cse(x, y);  
    aplot(20*log10(abs(Pxy)));  
end
```

Algorithms

Given two signals x and y as inputs. We first window the two inputs, and scale them by the window power. We then take FFT of the signals, calling them X and Y . This is followed by taking the cross correlation of the FFT, i.e., $Z = X \cdot \text{conj}(Y)$. We average the last N number of Z 's, and scale the answer by the sample rate.

For further information, refer to the "Algorithms" on page 4-1612 section in Spectrum Analyzer, which uses the same algorithm.

Blocks

Cross Spectrum Estimator

Introduced in R2013b

getFrequencyVector

System object: dsp.CrossSpectrumEstimator

Package: dsp

Get the vector of frequencies at which the cross-spectrum is estimated

Syntax

```
getFrequencyVector(cse)
```

Description

`getFrequencyVector(cse)` returns the vector of frequencies at which the cross-spectrum is estimated.

If you set the `FrequencyRange` to 'onesided' and the FFT length, `NFFT`, is even, the frequency vector is of length $NFFT/2+1$, and covers the interval $[0, SampleRate/2]$. If you set the `FrequencyRange` to 'onesided' and `NFFT` is odd, the frequency vector is of length $(NFFT+1)/2$ and covers the interval $[0, SampleRate/2]$. If you set the `FrequencyRange` to 'twosided', the frequency vector is of length `NFFT` and covers the interval $[0, SampleRate]$. If you set the `FrequencyRange` to 'centered', the frequency vector is of length `NFFT` and covers the range $[-SampleRate/2, SampleRate/2]$ and $[-SampleRate/2, SampleRate/2]$ for even and odd length `NFFT`, respectively.

getRBW

System object: dsp.CrossSpectrumEstimator

Package: dsp

Get the resolution bandwidth of the cross-spectrum

Syntax

```
getRBW(cse)
```

Description

`getRBW(cse)` returns the resolution bandwidth of the cross-spectrum.

The resolution bandwidth, RBW , is the smallest positive frequency, or frequency interval, that can be resolved. It is equal to $ENBW * \text{SampleRate} / L$, where L is the input length, and $ENBW$ is the two-sided equivalent noise bandwidth of the window (in Hz). For example, if `SampleRate=100`, `L=1024`, and `Window='Hann'`, $RBW = \text{enbw}(\text{hann}(1024)) * 100 / 1024$.

reset

System object: dsp.CrossSpectrumEstimator

Package: dsp

Reset the internal states of the cross-spectrum estimator

Syntax

```
reset(sysObj)
```

Description

`reset(sysObj)` resets the internal states of the System object, `sysObj`, to their initial values. The reset method is always a no-op for unlocked System objects, as the states may not be allocated when the object is not locked.

step

System object: dsp.CrossSpectrumEstimator

Package: dsp

Estimate the cross-spectrum of a signal

Syntax

```
Y = step(sysObj,x)
[Y1,...,YN] = step(sysObj,x)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(sysObj,x)` processes the input data, `x`, to produce the output, `Y`, from the System object, `sysObj`. `[Y1,...,YN] = step(sysObj,x)` produces `N` outputs.

The columns of `x` are treated as independent channels.

Every System object has a `step` method. The `step` method processes the input data according to the object algorithm. The number of input and output arguments depends on the algorithm, and may depend also on one or more property settings. The `step` method for some objects accepts fixed-point (fi) inputs.

Calling `step` on an object puts that object into a locked state. When locked, you cannot change nontunable properties or any input characteristics (size, data type and complexity) without reinitializing (unlocking and relocking) the object.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.Crosscorrelator System object

Package: dsp

Cross-correlation of two inputs

Description

The `Crosscorrelator` returns the cross-correlation sequence for two discrete-time deterministic inputs. This object can also return the cross-correlation sequence estimate for two discrete-time, jointly wide-sense stationary (WSS), random processes.

To obtain the cross-correlation for two discrete-time deterministic inputs:

- 1 Define and set up your cross-correlator. See “Construction” on page 4-445.
- 2 Call `step` to compute the cross-correlation according to the properties of `dsp.Crosscorrelator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`xcorr = dsp.Crosscorrelator` returns a cross-correlator object, `xcorr`, that computes the cross-correlation of two inputs. For N-D arrays, the cross-correlator computes the correlation column-wise. The inputs must have an equal number of columns. If one input is a vector and the other is an N-D array, the cross-correlator computes the cross-correlation of the vector with each column of the N-D array. Cross correlating inputs of length N and M results in a cross-correlation sequence of length $N + M - 1$. Cross correlating matrices of size M -by- N and P -by- N results in a matrix of cross-correlation sequences of size $M+P-1$ -by- N .

`xcorr = dsp.Crosscorrelator('PropertyName', PropertyValue, ...)` returns a cross-correlator, `xcorr`, with each property set to the specified value.

Properties

Method

Domain for computing correlations

Specify the domain for computing correlation as `Time Domain`, `Frequency Domain`, or `Fastest`. Computing correlations in the time domain minimizes memory use. Computing correlations in the frequency domain may require fewer computations than computing in the time domain depending on the input length. If the value of this property is `Fastest`, the cross-correlator operates in the domain which minimizes the number of computations. The default is `Time Domain`.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`. This property applies only if the object is not in full precision mode.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of `Full Precision`, `Same as first input`, or `Custom`. The default is `Full Precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when the `ProductDataType` property is `Custom`. The default is `numericType([], 32, 30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as `Full Precision`, `Same as product`, `Same as first input`, or `Custom`. The default is `Full Precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when the `AccumulatorDataType` property is `Custom`. The default is `numericType([], 32, 30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of `Same as accumulator`, `Same as product`, `Same as first input`, or `Custom`. The default is `Same as accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the “`OutputDataType`” on page 4-0 property is `Custom`. The default is `numerictype([],16,15)`.

Methods

`step` Cross-correlation sequence

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples**Compute Correlation Between Two Signals**

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
xcorr = dsp.Crosscorrelator;
t = 0:0.001:1;
x1 = sin(2*pi*2*t)+0.05*sin(2*pi*50*t);
x2 = sin(2*pi*2*t);
y = xcorr(x1,x2); %computes cross-correlation of x1 and x2
figure,plot(t,x1,'b',t, x2, 'g');
legend('Input signal 1',' Input signal 2')
```

```
figure, plot(y); title('Correlated output')
```

Cross-Correlation of Input Noise and Delayed Version

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Use cross-correlation to detect delay in jointly stationary white Gaussian noise inputs.

```
S = rng('default');
```

white Gaussian noise input

```
x = randn(100,1);
```

Create copy delayed by 10 samples $x_1[n] = x[n-10]$

```
delay = dsp.Delay(10);  
x1 = delay(x);  
xcorr = dsp.Crosscorrelator;  
y = xcorr(x1,x);  
lags = 0:99; %Positive lags  
stem(lags,y(100:end),'markerfacecolor',[0 0 1]);  
axis([0 99 -125 125]);  
xlabel('Lags');  
title('Cross-Correlation of Input Noise and Delayed Version');
```

The theoretical cross-correlation sequence is identically zero except at lag 10. Note this is not true in the sample cross-correlation sequence, but the estimate demonstrates a peak at the correct lag.

Definitions

Cross-Correlation

Cross-correlation is the measure of similarity of two discrete-time sequences as a function of the lag of one relative to the other.

For two length N deterministic inputs, or realizations of jointly WSS random processes, x and y , the cross-correlation is computed using the following relationship:

$$r_{xy}(h) = \begin{cases} \sum_{n=0}^{N-h-1} x(n+h)y^*(n) & 0 \leq h \leq N-1 \\ r_{yx}^*(h) & -(N-1) \leq h \leq 0 \end{cases}$$

where h is the lag and $*$ denotes the complex conjugate. If the inputs are realizations of jointly WSS stationary random processes, $r_{xy}(h)$ is an unnormalized estimate of the theoretical cross-correlation:

$$\rho_{xy}(h) = E\{x(n+h)y^*(n)\}$$

where $E\{\}$ is the expectation operator.

Algorithms

Time-Domain Computation

When you set the computation domain to time, the algorithm computes the cross-correlation of two signals in the time domain. The input signals can be fixed-point signals in this domain.

Correlate Two 2-D Arrays

When the inputs are two 2-D arrays, the j th column of the output, $y_{u,v}$, has these elements:

$$y_{uw(i,j)} = \sum_{k=0}^{\max(M_u, M_v)-1} u_{k,j}^* v_{(k+i),j} \quad 0 \leq i < M_v$$

$$y_{uw(i,j)} = y_{vu(-i,j)}^* \quad -M_u < i < 0$$

- $*$ denotes the complex conjugate.
- u is an M_u -by- N input matrix.
- v is an M_v -by- N input matrix.
- $y_{u,v}$ is an $(M_u + M_v - 1)$ -by- N matrix.

Inputs u and v are zero when indexed outside their valid ranges.

Correlate a Column Vector with a 2-D Array

When one input is a column vector and the other input is a 2-D array, the algorithm independently cross-correlates the input vector with each column of the 2-D array. The j th column of the output, $y_{u,v}$, has these elements:

$$y_{uw(i,j)} = \sum_{k=0}^{\max(M_u, M_v)-1} u_k^* v_{(k+i),j} \quad 0 \leq i < M_v$$

$$y_{uw(i,j)} = y_{vu(-i,j)}^* \quad -M_u < i < 0$$

- $*$ denotes the complex conjugate.
- u is an M_u -by-1 column vector.
- v is an M_v -by- N matrix.
- $y_{u,v}$ is an $(M_u + M_v - 1)$ -by- N matrix.

Inputs u and v are zero when indexed outside their valid ranges.

Correlate Two Column Vectors

When the inputs are two column vectors, the j th column of the output, $y_{u,v}$, has these elements:

$$y_{uw(i)} = \sum_{k=0}^{\max(M_u, M_v)-1} u_k v_{(k+i)}^* \quad 0 \leq i < M_v$$

$$y_{uw(i)} = y_{vu(-i)}^* \quad -M_u < i < 0$$

- * denotes the complex conjugate.
- u is an M_u -by-1 column vector.
- v is an M_v -by-1 column vector.
- $y_{u,v}$ is an $(M_u + M_v - 1)$ -by-1 column vector.

Inputs u and v are zero when indexed outside their valid ranges.

Frequency-Domain Computation

When you set the computation domain to frequency, the algorithm computes the cross-correlation in the frequency domain.

To compute the cross-correlation, the algorithm:

- 1 Takes the Fourier transform of both input signals, U and V .
- 2 Multiplies U and V^* , where * denotes the complex conjugate.
- 3 Computes the inverse Fourier transform of the product.

In this domain, depending on the input length, the algorithm can require fewer computations.

Extended Capabilities

C/C++ Code Generation

`dsp.Autocorrelator` | `dsp.Convolver`

Introduced in R2012a

step

System object: dsp.Crosscorrelator

Package: dsp

Cross-correlation sequence

Syntax

```
Y = step(xcorr,A,B)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(xcorr,A,B)` computes the cross-correlation of A and B and returns the result in Y.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.CumulativeProduct System object

Package: dsp

Cumulative product of channel, column, or row elements

Description

The `CumulativeProduct` object computes the cumulative product of channel, column, or row elements.

To compute the cumulative product of channel, column, or row elements:

- 1 Define and set up your cumulative product object. See “Construction” on page 4-457.
- 2 Call `step` to compute the cumulative product according to the properties of `dsp.CumulativeProduct`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`cprod = dsp.CumulativeProduct` returns a cumulative product object, `cprod`, that computes the cumulative product of input matrix or input vector elements along the default “Dimension” on page 4-0 .

`cprod = dsp.CumulativeProduct('PropertyName',PropertyValue,...)` returns a cumulative product object, `cprod`, with each specified property set to the specified value.

Properties

Dimension

Computation dimension for cumulative product

Specify the computation dimension as one of | Channels (running product) | Rows | Columns |. The default is Channels (running product).

ResetInputPort

Enable resetting cumulative product via input port

Set this property to `true` to enable resetting the cumulative product. When you set this property to `true`, specify a reset signal to the `step` method to reset the cumulative product. You can access this property when the “Dimension” on page 4-0 property is set to Channels (running product). The default is `false`.

ResetCondition

Reset condition for cumulative product

Specify the event on the reset input port that causes resetting the cumulative product to one of | Rising edge | Falling edge | Either edge | Non-zero |. This property applies when you set the “ResetInputPort” on page 4-0 property to `true` and the “Dimension” on page 4-0 property to Channels (running product). The default is Rising edge.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | Ceiling | Convergent | Floor | Nearest, | Round | Simplest | Zero |. The default is Floor.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of | Wrap | Saturate |. The default is Wrap.

IntermediateProductDataType

Intermediate product word and fraction lengths

Specify the intermediate product fixed-point data type as one of | Same as input | Custom |. The default is Same as input.

CustomIntermediateProductDataType

Intermediate product word and fraction lengths

Specify the intermediate product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `IntermediateProductDataType` property to `Custom`. The default is `numericType([], 16, 15)`.

ProductDataType

Product output word and fraction lengths

Specify the product output fixed-point data type as one of | Same as input | Custom |. The default is Same as input.

CustomProductDataType

Custom product output word and fraction lengths

Specify the product output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of | Same as product output | Same as input | Custom |. The default is Same as input.

CustomAccumulatorDataType

Custom accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of `| Same as product output | Same as input | Custom |`. The default is `Same as input`.

CustomOutputDataType

Custom output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the “`OutputDataType`” on page 4-0 property to `Custom`. The default is `numericType([], 16, 15)`.

Methods

`reset` Reset running cumulative product

`step` Cumulative product of input along specified dimension for input

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

Cumulative Product of a Matrix

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Use the `dsp.CumulativeProduct` object to compute the cumulative product of a matrix.

```
cprod = dsp.CumulativeProduct;  
x = magic(2)
```

```
x =
```

```
    1    3  
    4    2
```

```
y = cprod(x)
```

```
y =
```

```
    1    3  
    4    6
```

The cumulative product is computed column-wise along each channel.

Algorithms

This object implements the algorithm, inputs, and outputs described on the Cumulative Product block reference page. The object properties correspond to the block parameters, except:

The **Reset port** block parameter corresponds to both the `ResetCondition` and `ResetInputPort` object properties.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

`dsp.CumulativeSum`

Introduced in R2012a

reset

System object: dsp.CumulativeProduct

Package: dsp

Reset running cumulative product

Syntax

```
reset(cprod)
```

Description

`reset(cprod)` resets the running cumulative product for object `cprod` to zero.

step

System object: dsp.CumulativeProduct

Package: dsp

Cumulative product of input along specified dimension for input

Syntax

`Y = step(cprod, X)`

`Y = step(cprod, X, R)`

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

`Y = step(cprod, X)` computes the cumulative product along the specified dimension for the input `X`.

`Y = step(cprod, X, R)` resets the cumulative product object's state based on the `ResetCondition` property value and the value of the reset signal, `R` when the `ResetInputPort` property is `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.CumulativeSum System object

Package: dsp

Cumulative sum of channel, column, or row elements

Description

The `CumulativeSum` object computes the cumulative sum of channel, column, or row elements.

To compute the cumulative sum of channel, column, or row elements:

- 1 Define and set up your cumulative sum object. See “Construction” on page 4-466.
- 2 Call `step` to compute the cumulative sum according to the properties of `dsp.CumulativeSum`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`csum = dsp.CumulativeSum` returns a cumulative sum System object, `csum`, which computes the running cumulative sum for each channel in the input.

`csum = dsp.CumulativeSum('PropertyName', PropertyValue, ...)` returns a cumulative sum object, `csum`, with each specified property set to the specified value.

Properties

Dimension

Computation dimension for cumulative sum

Specify the computation dimension as one of | Channels (running sum) | Rows | Columns |. The default is Channels (running sum).

ResetInputPort

Enable resetting cumulative sum via input port.

Set this property to `true` to enable resetting the cumulative sum. When you set this property to `true`, you also specify a reset input to the `step` method to reset the cumulative sum. The default is `false`.

ResetCondition

Reset condition for cumulative sum

Specify the event on the reset input port that resets the cumulative sum as one of | Rising edge | Falling edge | Either edge | Non-zero |. This property applies when you set the “ResetInputPort” on page 4-0 property to `true`. The default is Rising edge.

Fixed-Point Properties**RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as one of | Ceiling | Convergent | Floor, Nearest, Round, Simplest | Zero |. The default is Floor.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of | Wrap | Saturate |. The default is Wrap.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of | Same as input | Custom |. The default is Same as input.

CustomAccumulatorDataType

Custom accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of one of `| Same as accumulator | Same as input | Custom |`. The default is `Same as accumulator`.

CustomOutputDataType

Custom output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the “`OutputDataType`” on page 4-0 property to `Custom`. The default is `numericType([], 16, 15)`.

Methods

- `reset` Reset internal states of cumulative sum object to zero
- `step` Cumulative sum along specified dimension for input

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

Cumulative Sum of a Matrix

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Use the `dsp.CumulativeSum` object to compute the cumulative sum of a matrix.

```
csum = dsp.CumulativeSum;  
x = magic(2)
```

```
x =
```

```
     1     3  
     4     2
```

```
y = csum(x)
```

```
y =
```

```
     1     3  
     5     5
```

The cumulative sum is computed column-wise along each channel.

Algorithms

This object implements the algorithm, inputs, and outputs described on the Cumulative Sum block reference page. The object properties correspond to the block properties, except:

The **Reset port** block parameter corresponds to both the `ResetCondition` and the `ResetInputPort` object properties

Extended Capabilities

`dsp.CumulativeProduct`

Introduced in R2012a

reset

System object: dsp.CumulativeSum

Package: dsp

Reset internal states of cumulative sum object to zero

Syntax

```
reset(csum)
```

Description

`reset(csum)` sets the states for the running cumulative sum object, `csum`, to zero when the `Dimension` property is set to `Channels` (`running sum`).

step

System object: dsp.CumulativeSum

Package: dsp

Cumulative sum along specified dimension for input

Syntax

$Y = \text{step}(\text{csum}, X)$

$Y = \text{step}(\text{csum}, X, R)$

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

$Y = \text{step}(\text{csum}, X)$ computes the cumulative sum along the specified dimension for the input X .

$Y = \text{step}(\text{csum}, X, R)$ resets the System object state based on the `ResetCondition` property value and the value of the reset signal, R . You can only reset the state if the `ResetInputPort` property is `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.DCBlocker System object

Package: dsp

Block DC component (offset) from input signal

Description

The `dsp.DCBlocker` System object removes the DC offset from each channel (column) of the input signal. The operation runs over time to continually estimate and remove the DC offset.

To block the DC component of the input signal:

- 1 Create the `dsp.DCBlocker` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#) (MATLAB).

Creation

Syntax

```
dcblk = dsp.DCBlocker
dcblk = dsp.DCBlocker(Name,Value)
```

Description

`dcblk = dsp.DCBlocker` creates a DC blocker System object, `dcblk`, to block the DC component from each channel (column) of the input signal.

`dcblk = dsp.DCBlocker(Name,Value)` creates a DC blocker System object, `dcblk`, with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `dcblkcr = dsp.DCBlocker('Algorithm','FIR')`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects (MATLAB)*.

Algorithm — Algorithm for estimating DC offset

'IIR' (default) | 'FIR' | 'CIC' | 'Subtract mean'

Algorithm for estimating DC offset, specified as one of the following:

- 'IIR' — The object uses a recursive estimate based on a narrow, lowpass elliptic filter. The “Order” on page 4-0 property sets the order of the filter, and the “NormalizedBandwidth” on page 4-0 property sets its bandwidth. This algorithm typically uses less memory than the FIR algorithm and is more efficient.
- 'FIR' — The object uses a nonrecursive, moving average estimate based on a finite number of past input samples. The “Length” on page 4-0 property sets the number of samples. The FIR filter has a linear phase response and does not cause any phase distortion to the signal. The IIR filter requires less memory and is more efficient to implement.
- 'CIC' — The object uses a CIC decimator, with a decimation factor of 1, whose differential delay is calculated using the NormalizedBandwidth property. It uses two sections to ensure that the first sidelobe attenuation is at least 25 dB below the main lobe of the filter. This algorithm requires fixed-point inputs and can be used for HDL code generation. For more details, see “HDL Code Generation” on page 4-0 .
- 'Subtract mean' — The object computes the means of the columns of the input matrix, and subtracts the means from the input. This method does not retain state between inputs.

You can visualize the IIR, FIR, and CIC responses by using the `fvtool` function.

NormalizedBandwidth — Normalized bandwidth of lowpass IIR or CIC filter

0.001 (default) | real scalar greater than 0 and less than 1

Normalized bandwidth of the IIR or CIC filter, specified as a real scalar greater than 0 or less than 1. The normalized bandwidth is used to estimate the DC component of the input signal.

Dependencies

This property applies only when you set the “Algorithm” on page 4-0 property to 'IIR' or 'CIC'.

Order — Order of lowpass IIR elliptic filter

6 (default) | integer greater than 3

Order of the lowpass IIR elliptic filter that is used to estimate the DC level, specified as an integer greater than 3.

Dependencies

This property applies only when you set the “Algorithm” on page 4-0 property to 'IIR'.

Length — Number of past input samples used in FIR algorithm

50 (default) | positive integer

Number of past input samples used in the FIR algorithm to estimate the running mean, specified as a positive integer.

Dependencies

This property applies only when you set the “Algorithm” on page 4-0 property to 'FIR'.

Usage

Syntax

```
dcblkkerOut = dcblkker(input)
```

Description

`dcblkOut = dcblk(input)` removes the DC component from each channel (column) of the input and returns the output.

Input Arguments

input — Input signal

vector | matrix | *N*-D array

Data input to the DC blocker object, specified as a vector, matrix, or *N*-D array.

Example: `t = (0:0.001:100)'; x = sin(30*pi*t) + 1;`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fi`

Output Arguments

dcblkOut — Signal with DC component removed

vector | matrix | *N*-D array

Signal with DC component removed, returned as a vector, matrix, or *N*-D array. The output dimensions match the input dimensions.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fi`

Note For versions earlier than R2016b, use the `step` function to run the System object™ algorithm. The arguments to `step` are the object you created, followed by the arguments shown in this section.

For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Visualization Specific to DSP System Toolbox

fvtool Visualize frequency response of DSP filters

Common to All System Objects

step	Run System object algorithm
clone	Create duplicate System object
getNumInputs	Number of inputs required to call the System object
getNumOutputs	Number of outputs from calling the System object
isLocked	Determine if System object is locked
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Remove DC Component and Display Results

Note: If you are using R2016a or earlier, replace each call to the object with the equivalent step syntax. For example, obj(x) becomes step(obj,x).

Remove the DC component of an input signal using the IIR, FIR, and subtract mean estimation algorithms.

Create a signal composed of a 15 Hz tone, a 25 Hz tone, and a DC offset.

```
t = (0:0.001:100)';  
x = sin(30*pi*t) + 0.33*cos(50*pi*t) + 1;
```

Create three DC blocker objects for the three estimation algorithms.

```
dc1 = dsp.DCBlocker('Algorithm','IIR','Order', 6);  
dc2 = dsp.DCBlocker('Algorithm','FIR','Length', 100);  
dc3 = dsp.DCBlocker('Algorithm','Subtract mean');
```

For each second of time, pass the input signal through the DC blockers. By implementing the DC blockers in 1-second increments, you can observe differences in the convergence times.

```
for idx = 1 : 100  
    range = (1:1000) + 1000*(idx-1);
```

```
y1 = dc1(x(range));           % IIR estimate
y2 = dc2(x(range));           % FIR estimate
y3 = dc3(x(range));           % Subtract mean
end
```

Plot the input and output data for the three DC blockers for the first second of time, and show the mean value for each signal. The mean values for the three algorithm types show that the FIR and Subtract mean algorithms converge more quickly.

```
plot(t(1:1000),x(1:1000), ...
     t(1:1000),y1, ...
     t(1:1000),y2, ...
     t(1:1000),y3);
xlabel('Time (sec)')
ylabel('Amplitude')
legend(sprintf('Input DC:%.3f',mean(x)), ...
        sprintf('IIR DC:%.3f',mean(y1)), ...
        sprintf('FIR DC:%.3f',mean(y2)), ...
        sprintf('Subtract mean DC:%.3f',mean(y3)));
```

Frequency Response Before and After DC Blocker

Note: If you are using R2016a or earlier, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Compare the spectrum of an input signal with a DC offset to the spectrum of the same signal after applying a DC blocker. Enable the DC blocker to use the FIR estimation algorithm.

Create an input signal composed of three tones and that has a DC offset of 1. Set the sampling frequency to 1 kHz and set the signal duration to 100 seconds.

```
fs = 1000;
t = (0:1/fs:100)';
x = sin(30*pi*t) + 0.67*sin(40*pi*t) + 0.33*sin(50*pi*t) + 1;
```

Create a DC blocker object that uses the FIR algorithm to estimate the DC offset.

```
dcblkcr = dsp.DCBlocker('Algorithm','FIR','Length',100);
```

Create a spectrum analyzer with power units set to dBW and a frequency range of [-30 30] to display the frequency response of the input signal. Using the `clone` function, create a second spectrum analyzer to display the response of the output. Then, use the `Title` property of the spectrum analyzers to label them.

```
hsa = dsp.SpectrumAnalyzer('SampleRate',fs, ...
    'PowerUnits','dBW','FrequencySpan','Start and stop frequencies',...
    'StartFrequency',-30,'StopFrequency',30,'YLimits',[-200 20],...
    'Title','Signal Spectrum');

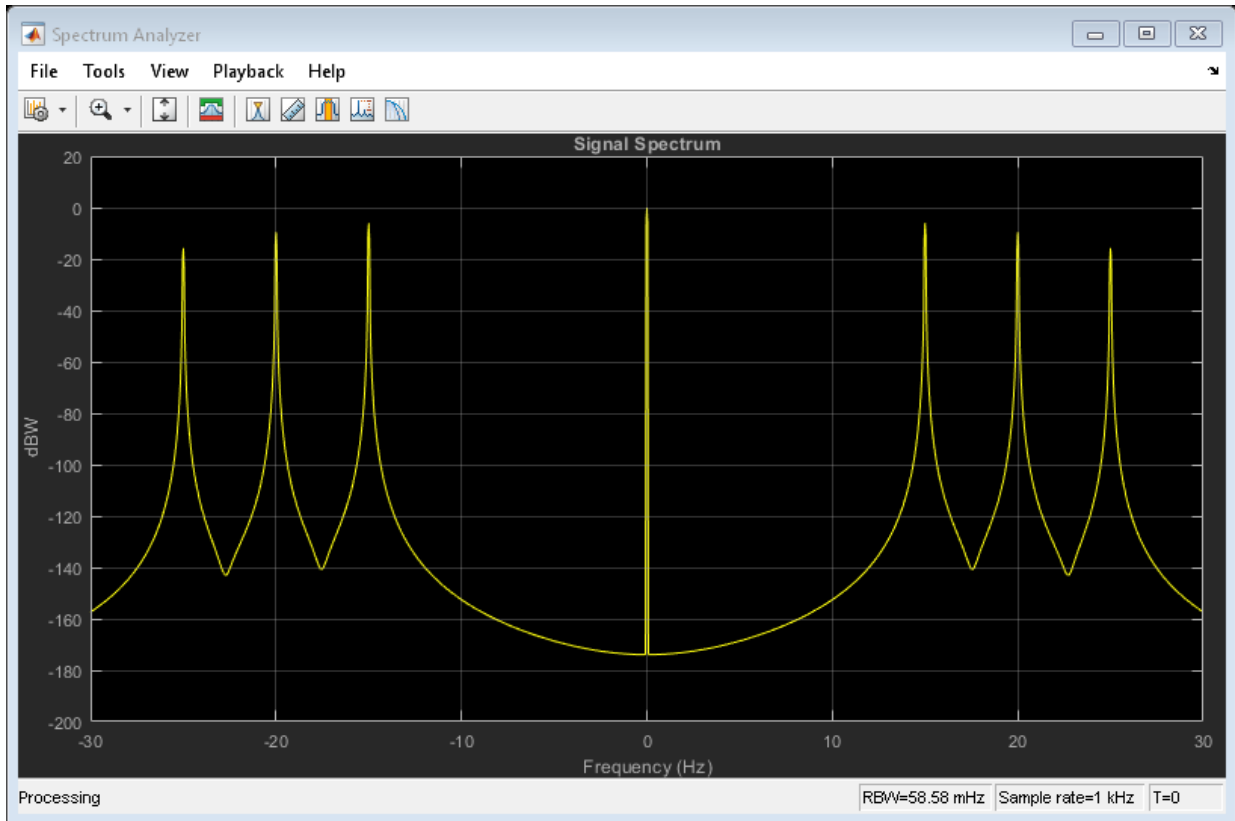

hsb = clone(hsa);
hsb.Title = 'Signal Spectrum After DC Blocker';
```

Pass the input signal, `x`, through the DC blocker to generate the output signal, `y`.

```
y = dcblkcr(x);
```

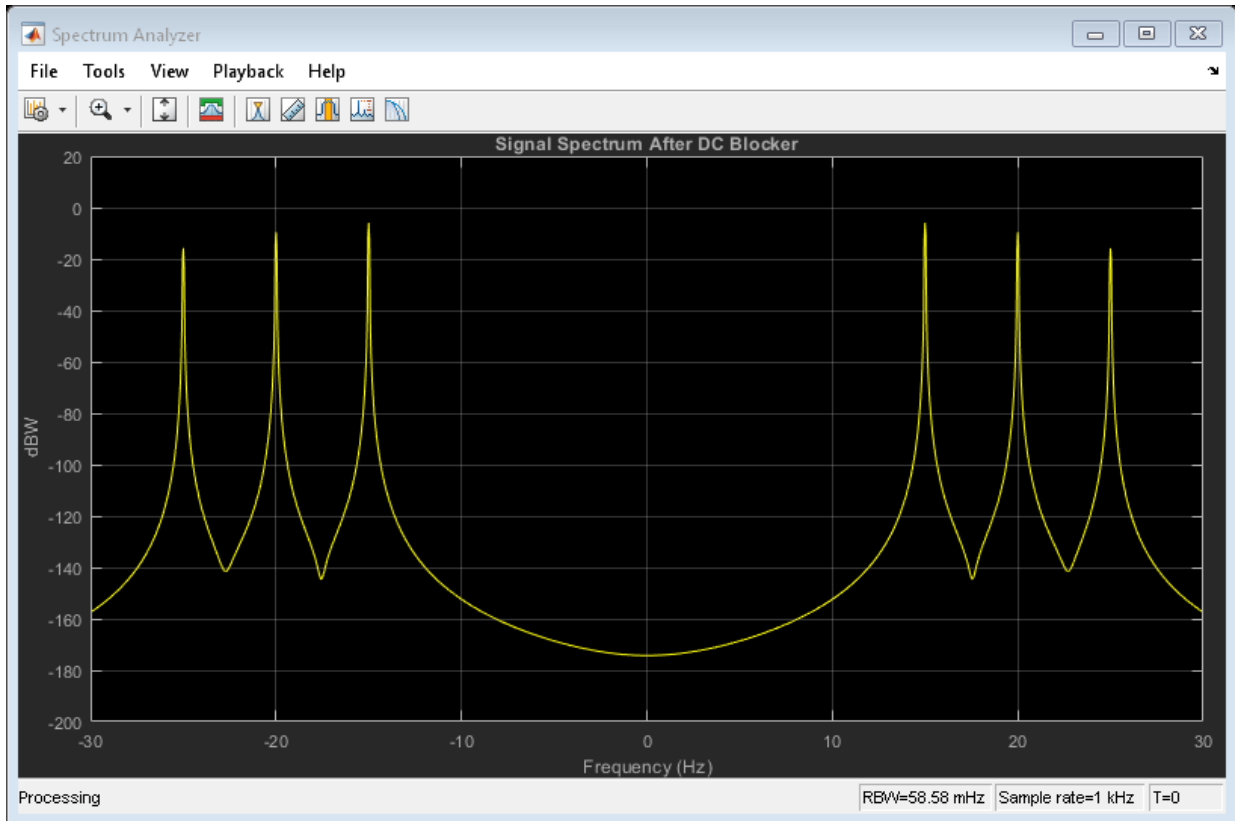

Use the first spectrum analyzer to display the frequency characteristics of the input signal. The tones at 15, 20, and 25 Hz, and the DC component, are clearly visible.

```
hsa(x)
```

Use the second spectrum analyzer to display the frequency characteristics of the output signal. The DC component has been removed.

`hsb(y)`

Remove DC Offset from Fixed-Point Data

Note: If you are using R2016a or earlier, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Remove a DC offset from a fixed-point signal by using a DC blocker. The DC blocker uses the CIC lowpass filtering method to estimate the DC offset.

Generate random binary data.

```
data = randi([0 1],1.2e5,1);
```

Create a 64-QAM modulator System object and modulate the data by running its algorithm.

```
mod = comm.RectangularQAMModulator('ModulationOrder',64, ...  
                                   'BitInput',true);  
modOut = mod(data);
```

Determine the constellation reference points for the modulator.

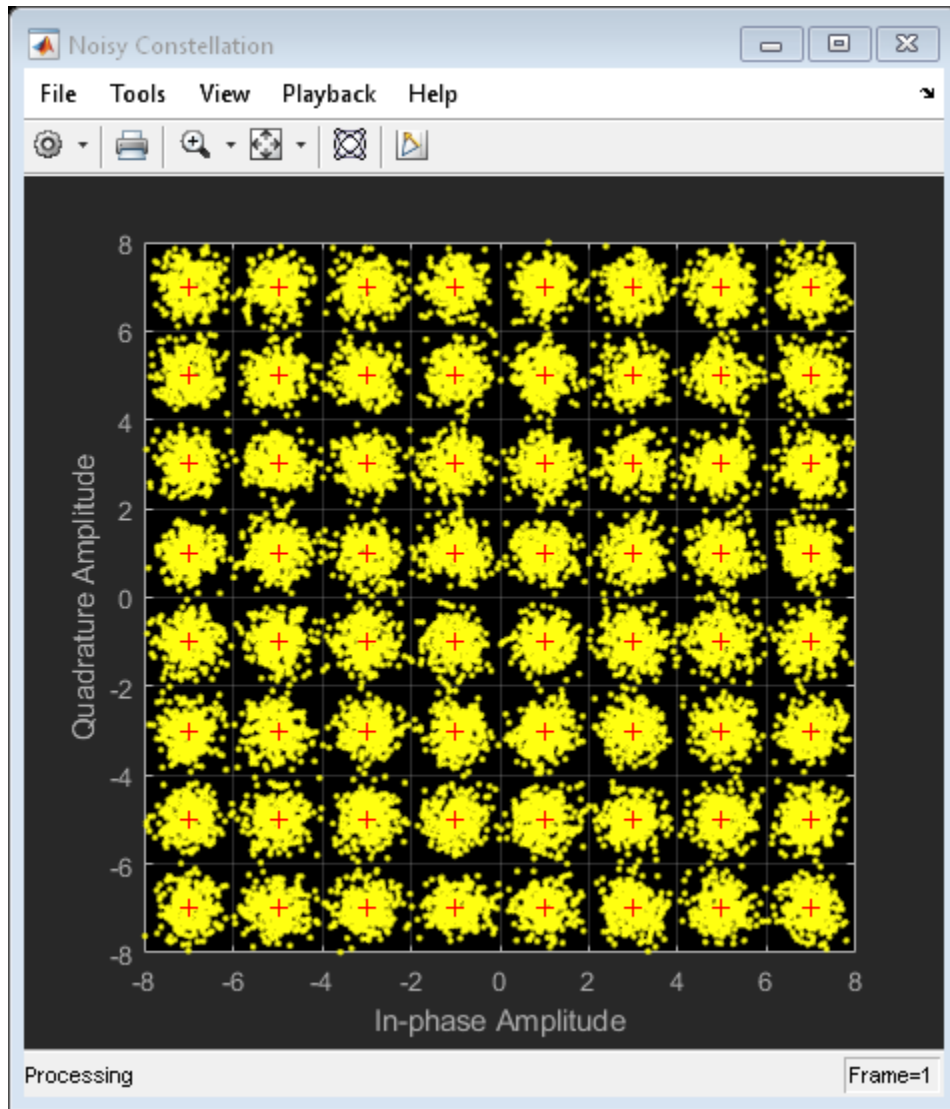

```
cRefPts = constellation(mod);
```

Add AWGN to the modulated signal by using the appropriate System object and running its algorithm.

```
noise = comm.AWGNChannel('EbNo', 14.75, ...  
                         'BitsPerSymbol', 6, ...  
                         'SignalPower', 42, ...  
                         'SamplesPerSymbol', 1);  
noisyOut = noise(modOut);
```

Display the scatter plot of the noisy signal by using a constellation diagram object. The red plus markers show the ideal symbol locations.

```
constDiag = comm.ConstellationDiagram('Name','Noisy Constellation',...  
                                       'ReferenceConstellation',cRefPts, ...  
                                       'XLimits',[-8 8],'YLimits',[-8 8]);  
constDiag(noisyOut)
```

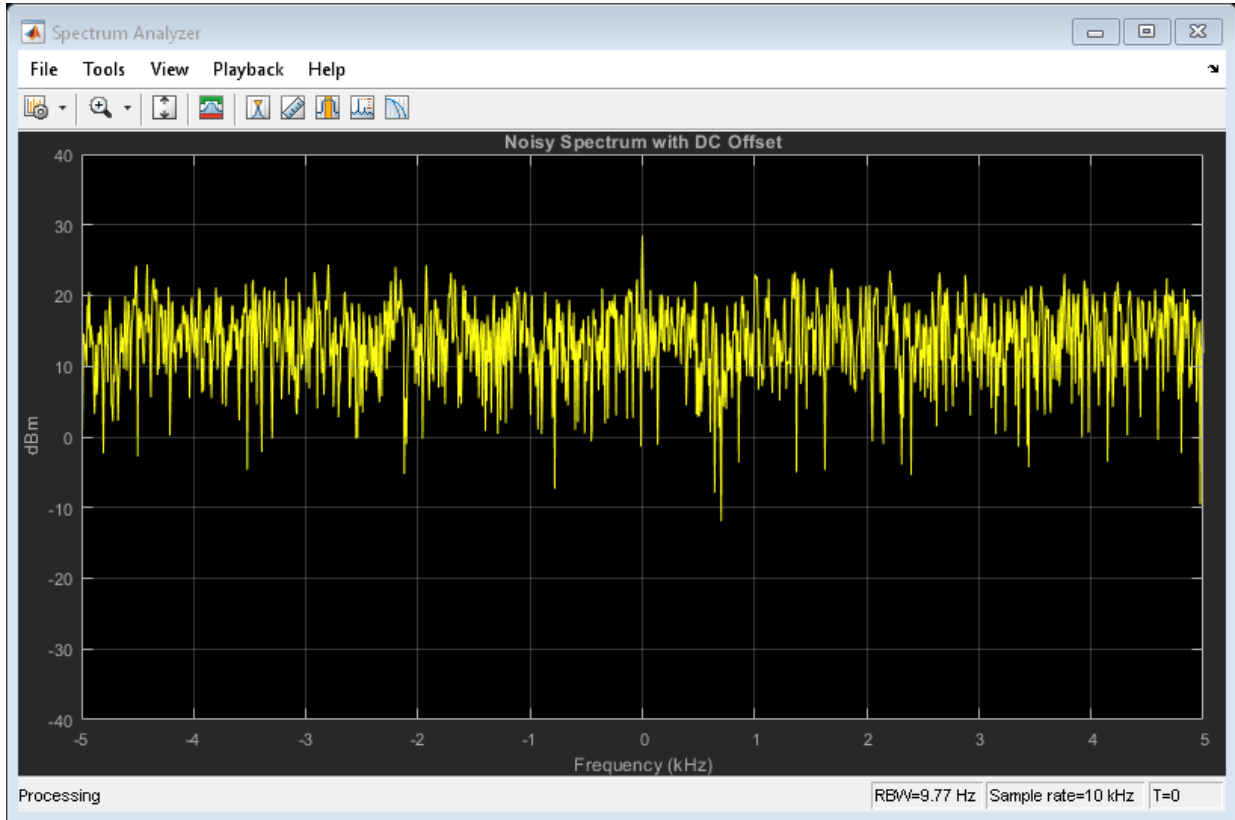

Add a DC offset of 1 to the modulated signal.

```
noisyOut = noisyOut + 1;
```

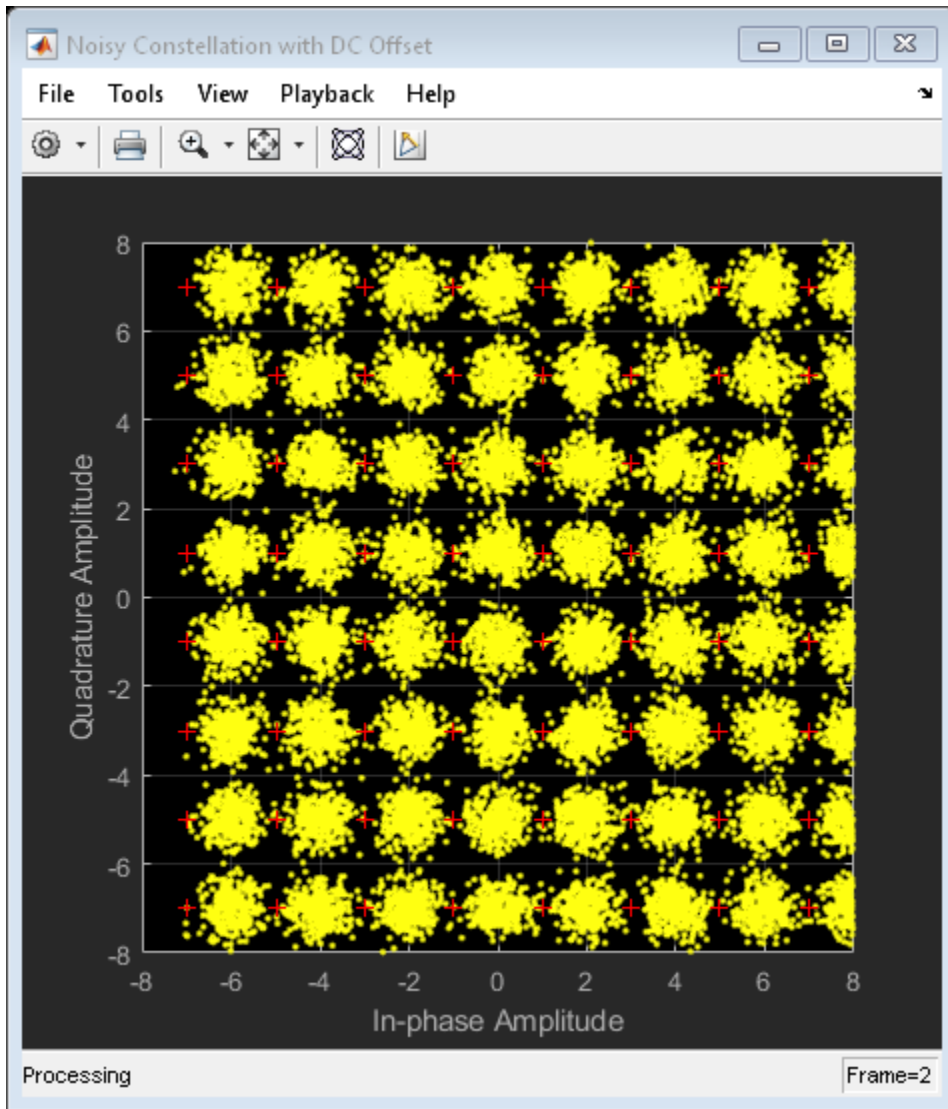

Display the spectrum of the signal. The spike at 0 kHz is due to the introduced offset.

```
specAna = dsp.SpectrumAnalyzer(...  
    'YLimits', [-40,40], ...  
    'Title', 'Noisy Spectrum with DC Offset');  
specAna(noisyOut);
```

View the effect of the DC offset on the constellation. The constellation has shifted one unit to the right.

```
constDiag(noisyOut)  
constDiag.Name = 'Noisy Constellation with DC Offset';
```

Convert the noisy signal to a signed, fixed-point object that has a 16-bit word length and an 11-bit fraction length.

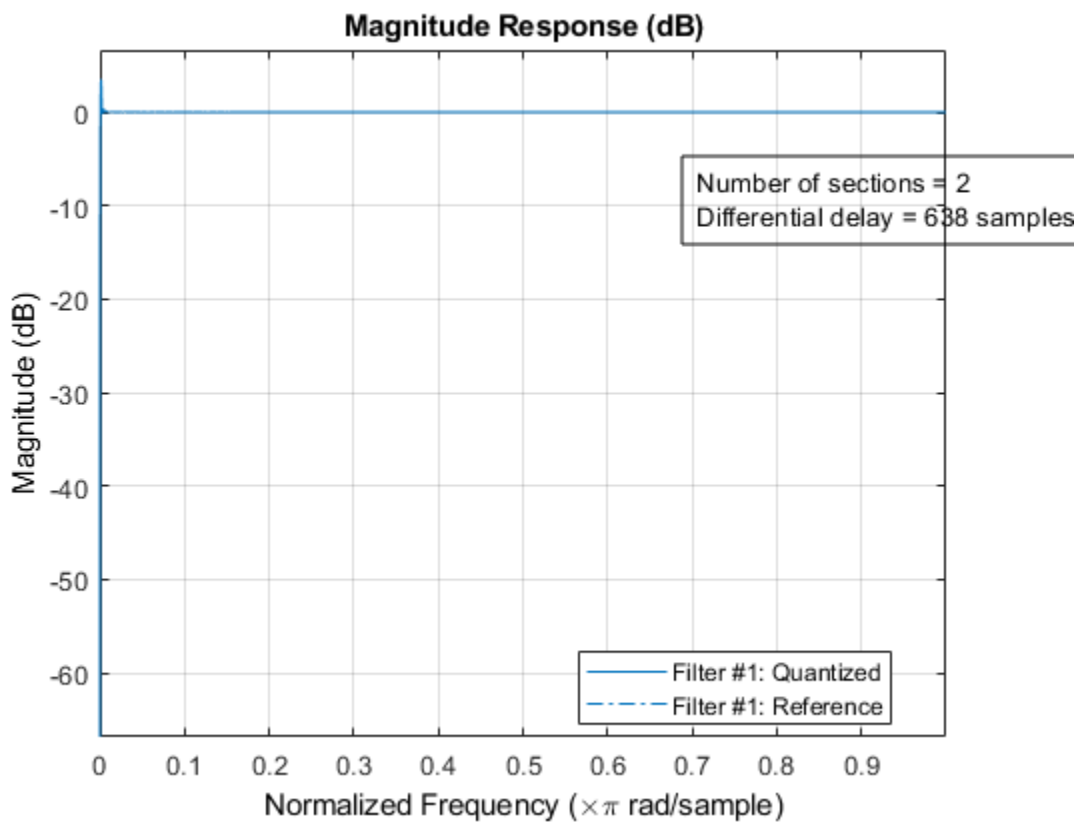

```
noisyOut = fi(noisyOut,1,16,11);
```

Remove the offset by creating a DC blocker object. The object uses the CIC algorithm to estimate the DC offset.

```
dcblker = dsp.DCBlocker('Algorithm','CIC');
```

Visualize the frequency response of the CIC estimating filter.

```
fvtool(dcblker)
```

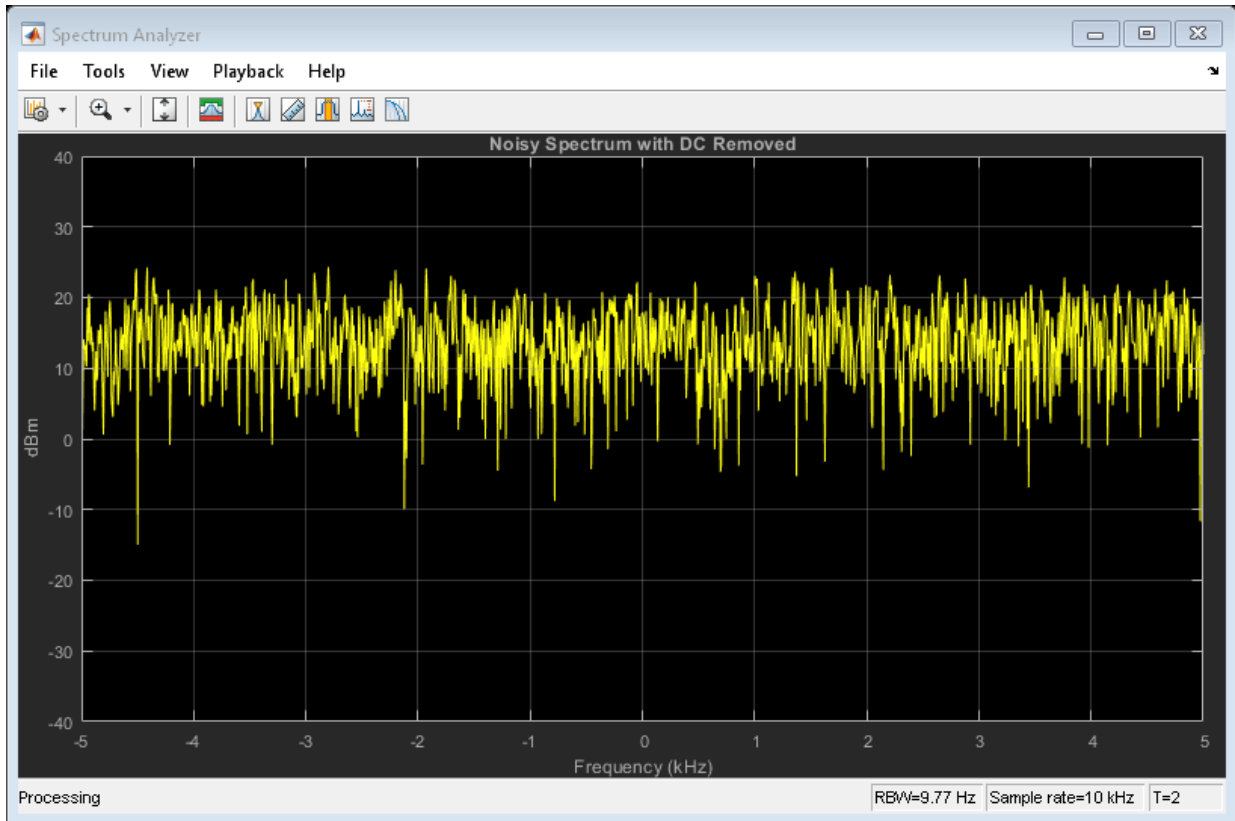

Pass the offset, noisy signal through the DC blocker and convert its output to a double.

```
dcBlockerOutFxp = dcblker(noisyOut);  
dcBlockerOut = double(dcBlockerOutFxp);
```

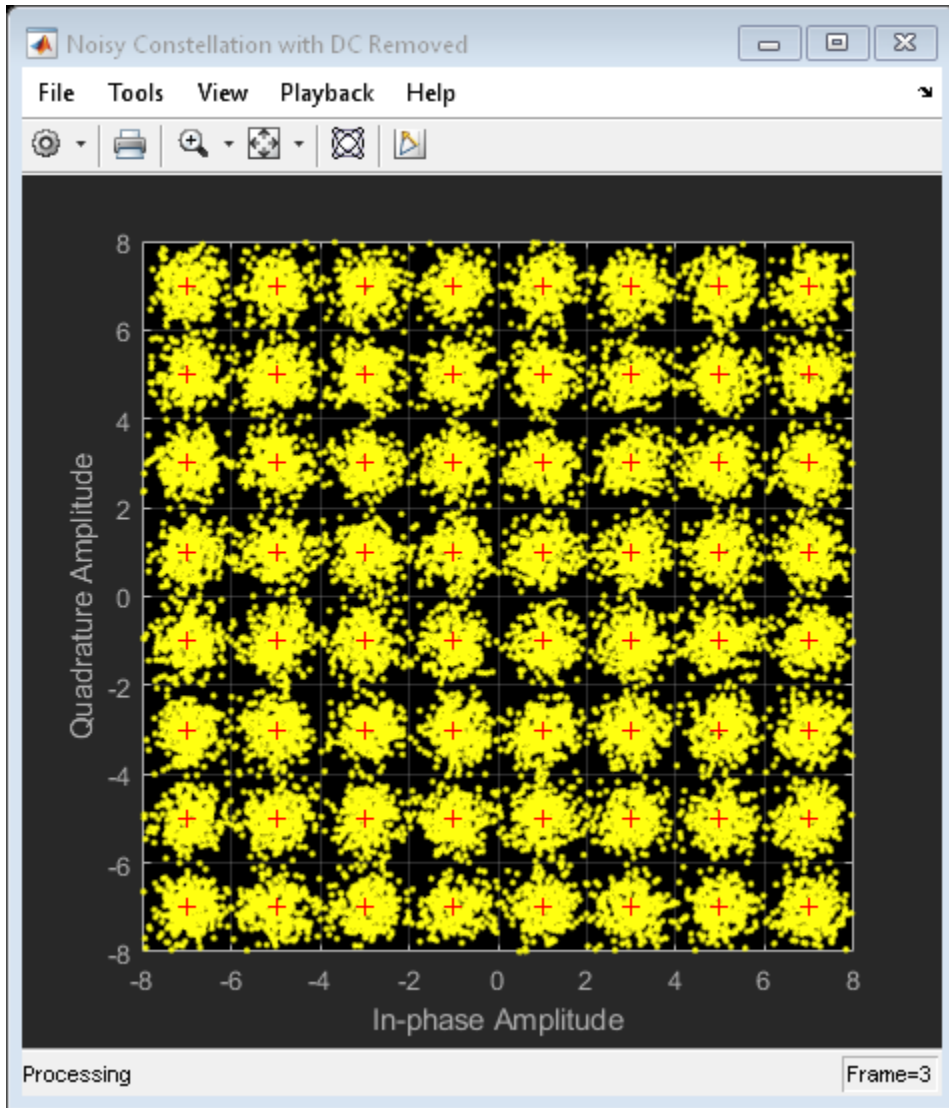

Plot the signal spectrum to show the effect of removing the DC offset. The spike at 0 kHz has been removed.

```
specAna(dcBlockerOut);  
specAna.Title = 'Noisy Spectrum with DC Removed';
```

Plot the constellation and verify that the signal shifted back to the left.

```
constDiag(dcBlockerOut)  
constDiag.Name = 'Noisy Constellation with DC Removed';
```

To see the effects of removing a DC offset, vary the value of the `NormalizedBandwidth` property in the DC blocker object.

Algorithms

The DC blocker subtracts the DC component from the input signal. You can estimate the DC component by using the IIR, FIR, CIC, or subtract mean algorithm.

IIR

Pass the input signal through an IIR lowpass elliptical filter.

The elliptical IIR filter has a passband ripple of 0.1 dB and a stopband attenuation of 60 dB. You specify the normalized bandwidth and the filter order.

FIR

Pass the input signal through an FIR filter that uses a nonrecursive moving average from a finite number of past input samples.

The FIR filter coefficients are given as $\text{ones}(1, \text{Length}) / \text{Length}$, where you specify the `Length`. The FIR filter structure is a direct form I transposed structure.

CIC

Pass the input signal through a CIC filter. Because the CIC filter amplifies the signal, the filter gain is estimated and subtracted from the DC estimate.

The Cascaded Integrator-Comb (CIC) filter consists of two integrator-comb pairs. These pairs help to ensure that the peak of the first sidelobe of the filter response is attenuated by at least 25 dB relative to the peak of the main lobe. The normalized 3-dB bandwidth is used to calculate the differential delay. The delay is used to determine the gain of the CIC filter. The inverse of the filter gain is used as a multiplier, which is applied to the output of the CIC filter. This ensures that the aggregate gain of the DC estimate is 0 dB.

The following equation characterizes the aggregate magnitude response of the filter and the multiplier:

$$|H(e^{j\omega})| = \left| \frac{\sin(M \frac{\pi}{2} B_{norm})}{M \sin(\frac{\pi}{2} B_{norm})} \right|^N$$

- B_{norm} is the normalized bandwidth such that $0 < B_{norm} < 1$.
- M is the differential delay in samples.
- N is the number of sections, equal to 2.

Set the differential delay, M , to the smallest integer such that $|H(e^{j\omega})| < 1/\sqrt{2}$. Once M is known, the gain of the CIC filter is calculated as M^N . Therefore, to precisely compensate for the filter gain, the multiplier is set to $(1/M)^N$.

Subtract Mean

Compute the mean value of each column of the input signal and subtract the mean from the input. For example, if the input is [1 2 3 4; 3 4 5 6], then a DC Blocker set to this mode outputs [-1 -1 -1 -1; 1 1 1 1].

dsp.DCT System object

Package: dsp

Discrete cosine transform (DCT)

Description

The `DCT` object computes the discrete cosine transform (DCT) of input.

To compute the DCT of input:

- 1 Define and set up your DCT object. See “Construction” on page 4-494.
- 2 Call `step` to compute the DCT according to the properties of `dsp.DCT`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`dct = dsp.DCT` returns a discrete cosine transform (DCT) object, `dct`, used to compute the DCT of a real or complex input signal.

`dct = dsp.DCT('PropertyName',PropertyValue, ...)` returns a DCT object, `dct`, with each property set to the specified value.

Properties

SineComputation

Method to compute sines and cosines

Specify how the DCT object computes the trigonometric values as `Trigonometric` function or `Table` lookup. This property must be set to `Table` lookup for fixed-point inputs. The default is `Table` lookup.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. This property applies when you set the `SineComputation` property to `Table` lookup.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. This property applies when you set the `SineComputation` property to `Table` lookup.

SineTableDataType

Sine table word-length designation

Specify the sine table fixed-point data type as one of `Same word length as input` or `Custom`. This property applies when you set the `SineComputation` property to `Table` lookup.

CustomSineTableDataType

Sine table word length

Specify the sine table fixed-point type as an `unscaled numeric type` object with a `Signedness` of `Auto`. This property applies when you set the `SineComputation` property to `Table` lookup and the `SineTableDataType` property to `Custom`. The default is `numeric type ([], 16)`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of `Full precision`, `Same as input`, `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `SineComputation` property to `Table lookup` and the `ProductDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `Full precision`, `Same as input`, `Same as product`, or `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `SineComputation` property to `Table lookup` and the `AccumulatorDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of `Full precision`, `Same as input`, `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`. The default is `Full precision`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `SineComputation` property to `Table` lookup and the “`OutputDataType`” on page 4-0 property to `Custom`. The default is `numericType([],16,15)`.

Methods

`step` Discrete cosine transform (DCT) of input

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

Analyze the Energy Content in a Sequence

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Use DCT to analyze the energy content in a sequence:

```
x = (1:128).' + 50*cos((1:128).'*2*pi/40);
dct = dsp.DCT;
X = dct(x);
```

Set the DCT coefficients which represent less than 0.1% of the total energy to 0 and reconstruct the sequence using IDCT.

```
[XX, ind] = sort(abs(X),1,'descend');
ii = 1;
while (norm([XX(1:ii);zeros(128-ii,1)]) <= 0.999*norm(XX))
    ii = ii+1;
end
disp(['Number of DCT coefficients that represent 99.9%',...
     'of the total energy in the sequence: ',num2str(ii)]);
```

Number of DCT coefficients that represent 99.9%of the total energy in the sequence: 10

```
XXt = zeros(128,1);
XXt(ind(1:ii)) = X(ind(1:ii));
idct = dsp.IDCT;
xt = idct(XXt);
plot(1:128,[x xt]);
legend('Original signal','Reconstructed signal',...
      'location','best');
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the DCT block reference page. The object properties correspond to the block parameters.

Extended Capabilities

`dsp.FFT` | `dsp.IDCT` | `dsp.IFFT`

Introduced in R2012a

step

System object: dsp.DCT

Package: dsp

Discrete cosine transform (DCT) of input

Syntax

```
Y = step(dct,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(dct,X)` computes the DCT of the input `X`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.Delay System object

Package: dsp

Delay input signal by fixed samples

Description

The `dsp.Delay` System object delays the input by a specified number of samples along each channel (column) of the input. You can specify the initial output of the object through the “InitialConditions” on page 4-0 property. To reset the delay, enable the “ResetCondition” on page 4-0 through the “ResetInputPort” on page 4-0 .

To delay the input:

- 1 Create the `dsp.Delay` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

Creation

Syntax

```
delay = dsp.Delay
delay = dsp.Delay(Name,Value)
delay = dsp.Delay(len,Name,Value)
```

Description

`delay = dsp.Delay` creates a System object that delays the input by 1 sample.

`delay = dsp.Delay(Name,Value)` creates a delay System object with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `delay = dsp.Delay('InitialConditionsPerChannel',true);`

`delay = dsp.Delay(len,Name,Value)` creates a delay System object, `delay`, with the `Length` property set to `len`, and other specified properties set to the specified values. Enclose each property name in single quotes.

Example: `delay = dsp.Delay(10,'ResetInputPort',true,'ResetCondition','Rising edge');`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects \(MATLAB\)](#).

Units — Units of delay

'Samples' (default) | 'Frames'

Units of delay, specified as 'Samples' or 'Frames'.

Length — Amount of delay to apply to input signal

1 (default) | scalar positive integer | vector of positive integers

Amount of delay to apply to the input signal, specified as one of the following:

- **Scalar positive integer** — The object applies equal delay to all the channels.
- **Vector of positive integers** — The length of the vector must equal the number of input channels (columns). The object delays each channel by the amount specified by the respective element in the delay vector.

InitialConditionsPerChannel — Enable different initial conditions per channel

false (default) | true

Enable different initial conditions per channel, specified as either:

- `false` — The object applies the same initial conditions for all channels.

- `true` — The object applies different initial conditions for each channel.

The value of this property determines the size of the initial conditions array. For more details, see the “InitialConditions” on page 4-0 property.

InitialConditionsPerSample — Enables different initial conditions per sample

`false` (default) | `true`

Different initial conditions per sample, specified as either:

- `false` — The object applies the same initial conditions for all samples.
- `true` — The object applies different initial conditions for each sample.

The value of this property determines the size of the initial conditions array, specified in the “InitialConditions” on page 4-0 property.

InitialConditions — Initial output of the object

0 (default) | scalar | vector | matrix | cell array

Initial output of System object, specified as a scalar, vector, matrix, or a cell array of MATLAB built-in numeric data type. The size of the initial conditions depends on the values of the “InitialConditionsPerChannel” on page 4-0 , “InitialConditionsPerSample” on page 4-0 , and “Units” on page 4-0 .

If the input is an M -by- N matrix, the dimensions of the InitialConditions property value must be as follows:

InitialConditionsPerChannel	InitialConditionsPerSample	Units	InitialConditions
false	false	'Samples' or 'Frames'	scalar
true	false	'Samples' or 'Frames'	vector of length N
false	true	'Frames'	vector of length equal to the product of M and Length property value

InputConditionsPerChannel	InputConditionsPerSample	Units	InitialConditions
false	true	'Samples'	vector of length equal to the Length property value
true	true	'Frames'	Cell array of size N . Each cell must be a vector of length equal to the product of M and the Length property value.
true	true	'Samples'	Cell array of size N . Each cell must be a vector of length equal to the Length property value.

ResetInputPort — Enable reset condition

false (default) | true

Enable the reset condition so that you can pass the reset control input to the object, specified as either:

- false — The object does not reset the delay states.
- true — You must pass a reset control input to the object by using the “ResetCondition” on page 4-0 property. The object resets the delay states based on the values of the ResetCondition property and the reset control that is input to the object.

ResetCondition — Event that triggers reset of delay

'Non-zero' (default) | 'Rising edge' | 'Falling edge' | 'Either edge'

Event that triggers the reset of the delay, specified as one of the following. The object resets the delay whenever a reset event is detected in its reset input.

- 'Non-zero' — Triggers a reset operation at each sample, when the reset input is not zero.
- 'Rising edge' — Triggers a reset operation when the reset input does one of the following:

- Rises from a negative value to either a positive value or zero.
- Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.

- 'Falling edge' — Triggers a reset operation when the reset input does one of the following:

- Falls from a positive value to a negative value or zero.
- Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.

- 'Either edge' — Triggers a reset operation when the reset input is a rising edge or a falling edge.

Dependencies

This property applies only when you set the `ResetInputPort` property to `true`.

Usage

Syntax

```
delayOut = delay(dataInput)
delayOut = delay(dataInput, resetInput)
```

Description

`delayOut = delay(dataInput)` adds delay to the data input and returns the delayed output. Each column of the input is treated as an independent channel.

`delayOut = delay(dataInput, resetInput)` adds delay to the data input and selectively resets the state of the System object based on the value of the reset input and the value of the “ResetCondition” on page 4-0 property.

To pass the reset input, set “ResetInputPort” on page 4-0 property to `true`.

```
delay = dsp.Delay('ResetInputPort', true);
...
delayOut = delay(dataInput, resetInput);
```

Input Arguments

dataInput — Data input

vector | matrix

Data input that is delayed by the object, specified as a vector or a matrix.

Example: `[1;2;3;4;5]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`

resetInput — Reset input

scalar

Reset input, specified as a scalar.

Example: `2`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

Output Arguments

delayOut — Delayed output

`vector` | `matrix`

Delayed output, returned as a vector or matrix. The size and data type of the output match the size and data type of the data input.

Example: `[0;0;1;2;3]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`

Note For versions earlier than R2016b, use the `step` function to run the System object™ algorithm. The arguments to `step` are the object you created, followed by the arguments shown in this section.

For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>clone</code>	Create duplicate System object
<code>getNumInputs</code>	Number of inputs required to call the System object
<code>getNumOutputs</code>	Number of outputs from calling the System object
<code>isLocked</code>	Determine if System object is locked
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Delay Input

Delay input by five samples by using the `dsp.Delay System` object™. By default, the initial conditions are 0.

Note: If you are using R2016a or earlier, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Delay input by 4 samples.

```
delay = dsp.Delay(4);
input = [(1:10)' (11:20)'];
delayOut = delay(input)
```

```
delayOut =
```

```

0     0
0     0
0     0
0     0
1    11
2    12
3    13
4    14
5    15
6    16
```

```
release(delay);
```

Specify initial conditions for each channel and for each sample. The `InitialConditions` property must be a (*Length*)-by-(*NumChannels*) matrix.

```
delay.InitialConditionsPerChannel = true;
delay.InitialConditionsPerSample = true;
delay.InitialConditions = [(0.1:0.1:0.4)' (0.5:0.1:0.8)'];
delayOut = delay(input)
```

```
delayOut =
```

```

0.1000    0.5000
```

```
0.2000    0.6000
0.3000    0.7000
0.4000    0.8000
1.0000   11.0000
2.0000   12.0000
3.0000   13.0000
4.0000   14.0000
5.0000   15.0000
6.0000   16.0000
```

```
release(delay);
```

Reset the delay by setting the reset event to 'Rising edge'. In this mode, a reset event occurs when the reset input:

- Rises from a negative value to 0.
- Rises from a negative value to a positive value.
- Rises from 0 to a positive value, where the rise is not a continuation from a negative value to 0.

Pass an initial reset input of 0.

```
delay.ResetInputPort = true;
delay.ResetCondition = 'Rising edge';
delayOut = delay(input,0)
```

```
delayOut =
```

```
0.1000    0.5000
0.2000    0.6000
0.3000    0.7000
0.4000    0.8000
1.0000   11.0000
2.0000   12.0000
3.0000   13.0000
4.0000   14.0000
5.0000   15.0000
6.0000   16.0000
```

Continue to run the delay. The delay samples now contain the rest of the input vector.

```
delayOut = delay(input,0)
```

```
delayOut =  
  
    7    17  
    8    18  
    9    19  
   10    20  
    1    11  
    2    12  
    3    13  
    4    14  
    5    15  
    6    16
```

Change the reset input to 2, indicating a rising edge.

```
delayOut = delay(input,2)
```

```
delayOut =  
  
    0.1000    0.5000  
    0.2000    0.6000  
    0.3000    0.7000  
    0.4000    0.8000  
    1.0000   11.0000  
    2.0000   12.0000  
    3.0000   13.0000  
    4.0000   14.0000  
    5.0000   15.0000  
    6.0000   16.0000
```

The delay values are reset to the initial conditions.

Package: dsp

Rebuffer sequence of inputs with one-sample shift

Description

The `DelayLine` object rebuffers a sequence of inputs with one-sample shift.

To rebuffer a sequence of inputs with one-sample shift:

- 1 Define and set up your delay line object. See “Construction” on page 4-513.
- 2 Call `step` to rebuffer the sequence of inputs according to the properties of `dsp.DelayLine`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`dline = dsp.DelayLine` returns a delay line System object, `dline`, that buffers the input samples into a sequence of overlapping or underlapping matrix outputs.

`dline = dsp.DelayLine('PropertyName', PropertyValue, ...)` returns a delay line System object, `dline`, with each specified property set to the specified value.

`dline = dsp.DelayLine(DELAYSIZE, INITIAL, 'PropertyName', PropertyValue, ...)` returns a delay line System object, `dline`, with the `Length` property set to `DELAYSIZE`, `InitialConditions` property set to `INITIAL` and other specified properties set to the specified values.

Properties

Length

Number of rows in output matrix

Specify the number of rows in the output matrix as a scalar positive integer. The default is 64.

InitialConditions

Initial delay line output

Set the value of the object's initial output as one of | scalar | vector | matrix |.

For vector outputs, the following selections apply for the `InitialConditions` property:

- A vector of the same size
- A scalar value that you want repeated across all elements of the initial output

For matrix outputs, the following selections apply for the `InitialConditions` property:

- A matrix of the same size
- A vector (equal to the length of the number of matrix rows) that repeats across all columns of the initial output
- A scalar that repeats across all elements of the initial output

The default is 0.

DirectFeedthrough

Enable passing input data to output without extra frame delay

When you set this property to `true`, there is no input data delay by an extra frame before it is available at the output buffer. Instead, the input data is available immediately at the output. When you set this property to `false`, there is one frame delay on the output. The default is `false`.

EnableOutputInputPort

Enable selective output linearization

The object internally uses a circular buffer, even though the output is linear. To obtain a valid output, the object must linearize the circular buffer. When this property is `true`, the object uses an additional Boolean input to determine if a valid output calculation is needed. If Boolean the input value is 1, the object's output is linearized and thus valid. If Boolean the input value is 0, the output is not linearized and is invalid. This allows the object to be more efficient when each step does not require the tapped delay line output. When you set this property to `false`, the output is always linearized and valid. The default is `false`.

HoldPreviousValue

Hold previous valid value for invalid output

If you set this property to `true`, the most recent, valid value is held on the output. If you set this property to `false`, the signal on the output is invalid data. This property applies only when you set the `EnableOutputInputPort` property to `true`. The default is `false`.

Methods

`reset` Reset internal states of delay line object
`step` Delayed version of input

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

Delay Line

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Use a delay line object with a delay line size of 4 samples.

```
delayline = dsp.DelayLine( ...
    'Length', 4, ...
    'DirectFeedthrough', true, ...
    'InitialConditions', -2, ...
    'EnableOutputInputPort', true, ...
    'HoldPreviousValue', true);
en = logical([1 1 0 1 0]);
y = zeros(4,5);
for ii = 1:5
    y(:,ii) = delayline(ii, en(ii));
end
display(y);
```

y =

```
-2    -2    -2     1     1
-2    -2    -2     2     2
-2     1     1     3     3
 1     2     2     4     4
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Delay Line block reference page. The object properties correspond to the block properties, except as noted.

This object processes inputs as separate channels (frames). The corresponding block has a temporary **Treat Mx1 and unoriented sample-based signals as** parameter with a `One channel` option for frame-based behavior and an `M channels` option for sample-based behavior. See the Delay Line block reference page for more information.

`dsp.Delay`

Introduced in R2012a

reset

System object: dsp.DelayLine

Package: dsp

Reset internal states of delay line object

Syntax

```
reset(dline)
```

Description

`reset(dline)` sets the internal delay buffers of the DelayLine object `dline` to their initial conditions.

step

System object: dsp.DelayLine

Package: dsp

Delayed version of input

Syntax

```
Y = step(dline,X)
Y = step(dline,X,EN)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(dline,X)` returns the delayed version of input `X`. `Y` is an output matrix with the same number of rows as the delay line size. Each column of `X` is treated as a separate channel.

The System object rebuffers a sequence of M_i -by- N matrix inputs into a sequence of M_o -by- N matrix outputs, where M_o is the output frame size specified by the `Length` property. Depending on whether M_o is greater than, less than, or equal to the input frame size, M_i , the output frames can be underlapped or overlapped. Each of the N input channels is rebuffered independently:

- When $M_o > M_i$, the output frame overlap is the difference between the output and input frame size, $M_o - M_i$.
- When $M_o < M_i$, the output is underlapped; the object discards the first $M_i - M_o$ samples of each input frame so that only the last M_o samples are buffered into the corresponding output frame.

- When $M_o = M_i$, the output data is identical to the input data, but is delayed by the latency of the object.

`Y = step(dline, X, EN)` selectively outputs the delayed version of input `X` depending on the Boolean input `EN`. This occurs only when you set the `EnableOutputInputPort` property to `true`. If `EN` is `false`, use the `HoldPreviousValue` property to specify if the object should hold the previous output value(s).

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.Differentiator System object

Package: dsp

Direct form FIR fullband differentiator filter

Description

`dsp.Differentiator` applies a fullband differentiator filter on the input signal to differentiate all its frequency components. This object uses an FIR equiripple filter design to design the differentiator filter. The ideal frequency response of the

differentiator is $D(\omega) = j\omega$ for $-\pi \leq \omega \leq \pi$. You can design the filter with minimum order with a specified order. This object supports fixed-point operations.

To filter each channel of your input:

- 1 Define and set up your differentiator. See “Construction” on page 4-522.
- 2 Call `step` to filter each channel of the input signal according to the properties of `dsp.Differentiator`. The input signal can be a real-valued or complex-valued column vector or matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel. The number of rows in the input signal denotes the channel length. The data type of the input can be double, single, or fixed-point data type. The number of channels cannot change between calls to the `step` method. The data type characteristics (double, single, or fixed-point) and the real-complex characteristics (real or complex valued) must be the same for the input data and output data.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`DF = dsp.Differentiator` returns a differentiator, `DF`, with the default settings. Calling `step` with the default property settings filters the input data with a minimum-order filter that has a passband ripple of 0.1 dB.

`DF = dsp.Differentiator(Name, Value)` sets each property `Name` to the specified `Value`. Unspecified properties have default values.

Properties

DesignForMinimumOrder — Design minimum order filter

`true` (default) | `false`

Option to design a minimum-order filter, specified as a logical scalar. The filter has 2 degrees of freedom. When you set this property to

- `true` — The object designs the filter with the minimum order that meets the `PassbandRipple` value.
- `false` — The object designs the filter with order that you specify in the `FilterOrder` property.

This property is not tunable.

FilterOrder — Order of the filter

31 (default) | odd positive integer

Order of the filter, specified as an odd positive integer. You can specify the filter order only when `'DesignForMinimumOrder'` is set to `false`.

This property is not tunable.

PassbandRipple — Maximum passband ripple

0.1 (default) | positive real scalar

Maximum passband ripple in dB, specified as a positive real scalar. You can specify the passband ripple only when `'DesignForMinimumOrder'` is set to `true`.

This property is not tunable.

ScaleCoefficients — Scale filter coefficients

false (default) | true

Option to scale the filter coefficients, specified as a logical scalar. When you set this property to true, the object scales the filter coefficients to preserve the input dynamic range.

This property is not tunable.

Fixed-Point Properties**CoefficientsDataType — Word and fraction lengths of coefficients**

numericType(1,16) (default) | numericType object

Word and fraction lengths of coefficients, specified as a signed or unsigned numericType object. The default, numericType(1,16), corresponds to a signed numeric type object with 16-bit coefficients. To give the best possible precision, the fraction length is computed based on the coefficient values.

This property is not tunable.

The word length of the output is the same as the word length of the input. The object computes the fraction length of the output such that the entire dynamic range of the output can be represented without overflow. For details on how the object computes the fraction length of the output, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

RoundingMethod — Rounding method for output fixed-point operations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see “Precision and Range”.

This property is not tunable.

Examples

Group Delay Estimation

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Estimate the group delay of a linear phase FIR filter using a `dsp.TransferFunctionEstimator` object followed by `dsp.PhaseExtractor` and `dsp.Differentiator` objects. The group delay of a linear phase FIR filter is given by $GD = -\frac{d\theta(\omega)}{d\omega} = -\frac{N}{2}$, where $\theta(\omega)$ is the phase information of the filter, ω is the frequency vector, and N is the order of the filter.

Set Up the Objects

Create a linear phase FIR lowpass filter. Set the order to 200, the passband frequency to 255 Hz, the passband ripple to 0.1 dB, and the stopband attenuation to 80 dB. Specify a sample rate of 512 Hz.

```
Fs = 512;  
LPF = dsp.LowpassFilter('SampleRate',Fs,'PassbandFrequency',255,...  
    'DesignForMinimumOrder',false,'FilterOrder',200);
```

To estimate the transfer function of the lowpass filter, create a transfer function estimator. Specify the window to be Hann. Set the FFT length to 1024 and the number of spectral averages to 200.

```
TFE = dsp.TransferFunctionEstimator('FrequencyRange','twosided',...  
    'SpectralAverages',200,'FFTLengthSource','Property',...  
    'FFTLength',1024);
```

To extract the unwrapped phase from the frequency response of the filter, create a phase extractor.

```
PE = dsp.PhaseExtractor;
```

To differentiate the phase θ , create a differentiator filter. This value is used in computing the group delay.

```
DF = dsp.Differentiator;
```

To smoothen the inputm create a variable bandwidth FIR filter.

```
Gain1 = 512/pi;  
Gain2 = -1;
```

```
VBFilter = dsp.VariableBandwidthFIRFilter('CutoffFrequency',10,...
    'SampleRate',Fs);
```

To view the group delay of the filter, create an array plot object.

```
AP = dsp.ArrayPlot('PlotType','Line','YLimits',[-500 400],...
    'YLabel','Amplitude','XLabel','Number of samples');
```

Run the Algorithm

The `for`-loop is the streaming loop that estimates the group delay of the filter. In the loop, the algorithm filters the input signal, estimates the transfer function of the filter, and differentiates the phase of the filter to compute the group delay.

```
Niter = 1000; % Number of iterations
for k = 1:Niter
    x = randn(512,1); % Input signal = white Gaussian noise
    y = LPF(x); % Filter noise with Lowpass FIR filter
    H = TFE(x,y); % Compute transfer function estimate
    Phase = PE(H); % Extract the Unwrapped phase
    phaseaftergain1 = Gain1*Phase;
    DiffOut = DF(phaseaftergain1); % Differentiate the phase
    phaseaftergain2 = Gain2 * DiffOut;
    VBFOut = VBFilter(phaseaftergain2); % Smooth the group delay
    AP(VBFOut); % Display the group delay
end
```

As you can see, the group delay of the lowpass filter is 100.

Algorithms

Differentiator Filter

Differentiator computes the derivative of a signal. The frequency response of an ideal differentiator filter is given by $D(\omega) = j\omega$, defined over the Nyquist interval $-\pi \leq \omega \leq \pi$.

The frequency response is antisymmetric and is linearly proportional to the frequency.

`dsp.Differentiator` object acts as a differentiator filter. This object condenses the two-step process into one. For the minimum order design, the object uses generalized Remez FIR filter design algorithm. For the specified order design, the object uses the

Parks-McClellan optimal equiripple FIR filter design algorithm. The filter is designed as a linear phase Type-IV FIR filter with a Direct form structure.

The ideal differentiator has an antisymmetric impulse response given by $d(n) = -d(-n)$. Hence $d(0) = 0$. The differentiator must have zero response at zero frequency.

Linear-Phase FIR Differentiator Filter

The impulse response of an antisymmetric linear-phase FIR filter is given by $h(n) = -h(M-1-n)$, where M is the length of the filter. Because the filter is antisymmetric, you can use this type of FIR filter to design the linear-phase FIR differentiators.

Consider the design of linear-phase FIR differentiators based on the Chebyshev approximation criterion.

If M is odd, the real-valued frequency response of the FIR filter, $H_r(\omega)$, has the characteristics that $H_r(0) = 0$ and $H_r(\pi) = 0$. This filter satisfies the condition of zero response at zero frequency. However, it is not fullband because $H_r(\pi) = 0$. This differentiator has a linear response over the limited frequency range $[0, 2\pi f_p]$, where f_p is the bandwidth of the differentiator. The absolute error between the desired response and the Chebyshev approximation increases as ω increases from 0 to $2\pi f_p$.

If M is even, the real-valued frequency response of the FIR filter, $H_r(\omega)$, has the characteristics that $H_r(0) = 0$ and $H_r(\pi) \neq 0$. This filter satisfies the condition of zero response at zero frequency. It is fullband and this design results in a significantly smaller approximation error than comparable odd-length differentiators. Hence, even-length (odd order) differentiators are preferred in practical systems.

Introduced in R2016a

step

System object: `dsp.Differentiator`

Package: `dsp`

Differentiate input signal with respect to time

Syntax

```
Y = step(DF,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(DF,X)` filters the real or complex input signal, `X`, using the differentiator filter, `DF`. `Y` is a differentiated version of `X`. The input `X` must be a column vector or matrix. If `X` is a matrix, each column is treated as an independent channel. `X` can be a floating point or a fixed-point input.

Input Arguments

DF — Differentiator filter

`dsp.Differentiator` System object

Differentiator filter, specified as a `dsp.Differentiator` System object.

x — Input signal

vector | matrix

Input signal, specified as a vector or matrix with floating point or fixed-point precision. The row length of X is the frame size, that is, the channel length. Each column of X is treated as a separate channel. The column length of X is the number of channels.

Output Arguments

y — Differentiated signal

vector | matrix

Differentiated signal, returned as a vector or matrix of the same size, data type, and complexity as the input signal, X .

Examples

Convert FM Signal to AM Signal

Create an FM wave on a 100 Hz carrier signal sampled at 1.5 kHz.

```
Fc = 1e2;    % Carrier
Fs = 1.5e3; % Sample rate
sinewave = dsp.SineWave('Frequency',10,...
                        'SamplesPerFrame',1e3,...
                        'SampleRate',Fs);
```

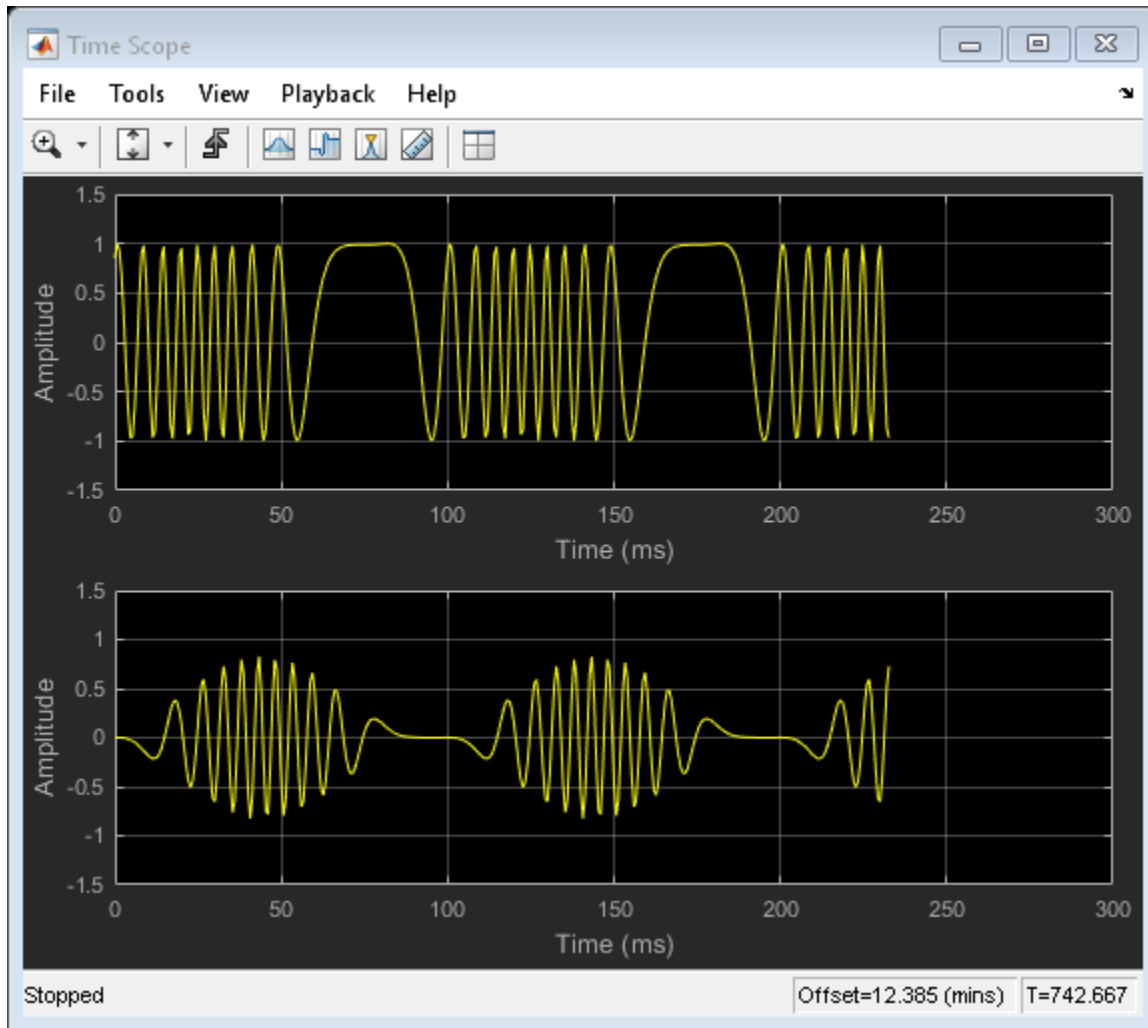

Convert the FM signal to an AM signal.

```
ts = dsp.TimeScope(2,...
                  'TimeSpan',0.3,...
                  'BufferLength',10*Fs,...
                  'SampleRate',Fs,...
                  'ShowGrid',true,...
                  'YLimits',[-1.5 1.5],...
                  'LayoutDimensions',[2 1]);

df = dsp.Differentiator;

tic
while toc<2.2
    x = step(sinewave);
```

```
    fm_y = modulate(x, Fc, Fs, 'fm');  
    am_y = step(df, fm_y);  
    step(ts, fm_y, am_y);  
end  
  
release(df);  
release(ts);
```

Introduced in R2016a

getFilter

System object: `dsp.Differentiator`

Package: `dsp`

Get underlying FIR filter

Syntax

```
filter = getFilter(DF)
```

Description

`filter = getFilter(DF)` returns the underlying FIR filter, `filter`, used to implement the differentiator, `DF`.

Input Arguments

DF — Differentiator filter

`dsp.Differentiator` System object

Differentiator filter, specified as a `dsp.Differentiator` System object.

Examples

Get the Underlying FIR Filter of the Differentiator

Create a `dsp.Differentiator` System object with default properties.

```
DF = dsp.Differentiator;
```

Use `getFilter` to get the underlying FIR filter, `filter`, which implements the differentiator, `DF`.

```
filter = getFilter(DF)

filter =
    dsp.FIRFilter with properties:

        Structure: 'Direct form'
        NumeratorSource: 'Property'
        Numerator: [1x60 double]
        InitialConditions: 0

    Show all properties
```

Introduced in R2016a

reset

System object: `dsp.Differentiator`

Package: `dsp`

Reset internal states of differentiator

Syntax

```
reset(DF)
```

Description

`reset(DF)` resets the filter states of the differentiator, `DF`, to their initial values. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the `step` method applies the differentiator to nonzero input data, the filter might have nonzero states. If you call `step` again without first calling `reset`, the object might produce different outputs for an identical input.

Input Arguments

DF — Differentiator filter

`dsp.Differentiator` System object

Differentiator filter, specified as a `dsp.Differentiator` System object.

Examples

Reset Differentiator

Create a differentiator with default properties.

```
DF = dsp.Differentiator;
```

Create a two-channel random signal. Call the `step` method twice on the signal.

```
x = randn(10,2);  
  
y1 = step(DF,x);  
y2 = step(DF,x);  
  
no = all(y2==y1)
```

```
no =  
  
    1x2 logical array  
  
    0    0
```

The output is different because the internal states of `DF` have changed. Use `reset` to reset the differentiator. Call `step` again, and verify that the output is unchanged.

```
reset(DF)  
  
y3 = step(DF,x);  
  
yes = all(y3==y1)
```

```
yes =  
  
    1x2 logical array  
  
    1    1
```

Introduced in R2016a

dsp.DigitalDownConverter System object

Package: dsp

Translate digital signal from Intermediate Frequency (IF) band to baseband and decimate it

Description

The `DigitalDownConverter` object translates digital signal from Intermediate Frequency (IF) band to baseband, and decimates it.

To digitally downconvert the input signal:

- 1 Define and set up your digital down converter. See “Construction” on page 4-538.
- 2 Call `step` to downconvert the input according to the properties of `dsp.DigitalDownConverter`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

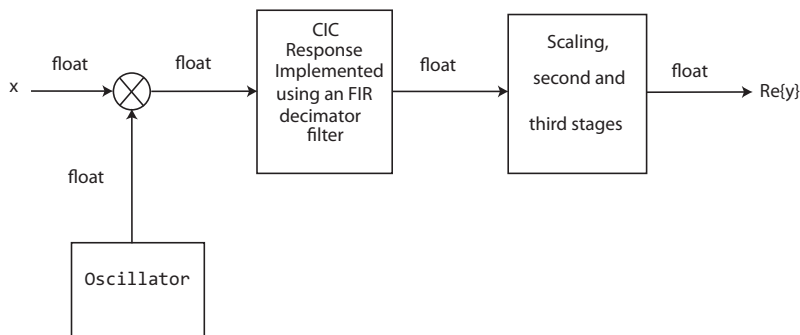

Construction

`dwnConv = dsp.DigitalDownConverter` returns a digital down-converter (DDC) System object, `dwnConv`. The object downconverts the input signal by multiplying it with a complex exponential with center frequency equal to the value in the `CenterFrequency` property. The object downsamples the frequency down-converted signal using a cascade of three decimation filters. In this case, the filter cascade consists of a CIC decimator, a CIC compensator, and a third FIR decimation stage. The following block diagram shows the architecture of the digital down converter.

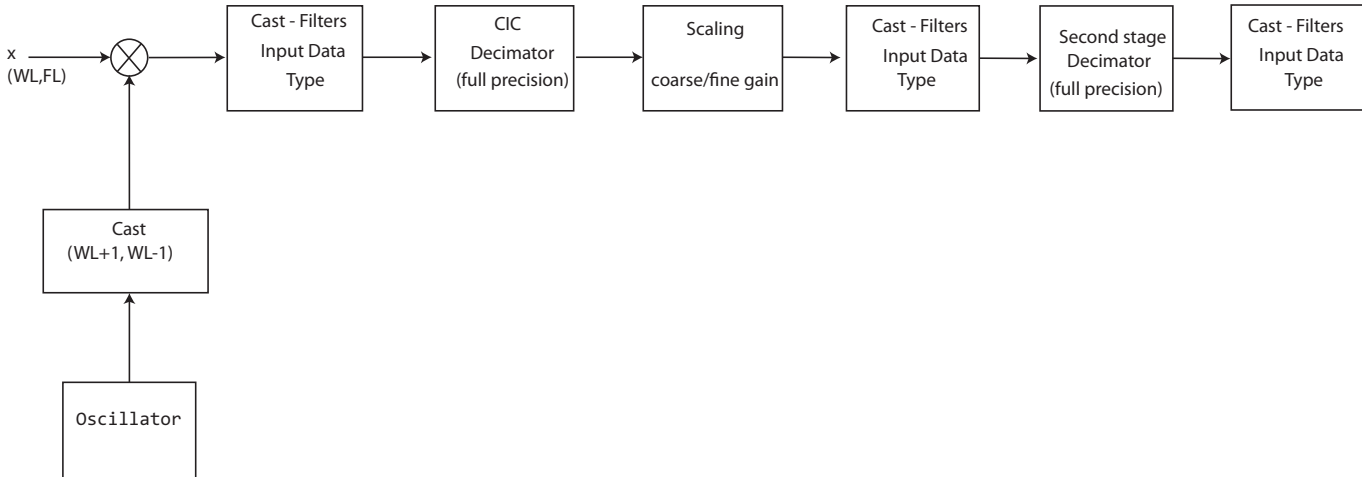

The scaling section normalizes the CIC gain and the oscillator power. It may also contain a correction factor to achieve the desired ripple specification. When you set the **Oscillator** property to `InputPort`, the normalization factor does not include the oscillator power factor. Depending on the setting of the **DecimationFactor** property, you may be able to bypass the third filter stage. When the input data type is double or single, the object implements an N -section CIC decimation filter as an FIR filter with a response that corresponds to a cascade of N boxcar filters. A true CIC filter with actual comb and integrator sections is implemented when the input data is of a fixed-point type. The CIC filter is emulated with an FIR filter so that you can run simulations with floating-point data.

The following block diagram represents the DDC arithmetic with single or double-precision, floating-point inputs.

The following block diagram represents the DDC arithmetic with signed fixed-point inputs.

- WL is the word length of the input, and FL is the fraction length of the input.
- The input of each filter is cast to the data type specified in the **FiltersInputDataType** and **CustomFiltersInputDataType** properties.
- The oscillator output is cast to a word length equal to the input word length plus one. The fraction length is equal to the input word length minus one.
- The scaling at the output of the CIC decimator consists of coarse- and fine-gain adjustments. The coarse gain is achieved using the `reinterpretcast` function on the CIC decimator output. The fine gain is achieved using full-precision multiplication.

The following figure depicts the coarse- and fine-gain operations.

If the normalization gain is G (where $0 < G \leq 1$), then:

- $WLCic$ is the word length of the CIC decimator output and $FLCic$ is the fraction length of the CIC decimator output
- $F1 = \text{abs}(\text{nextpow2}(G))$, indicating the part of G achieved using bit shifts (coarse gain)
- $F2 =$ fraction length specified by the **FiltersInputDataType** and **CustomFiltersInputDataType** properties
- $fg = \text{fi}((2^{F1}) * G, \text{true}, 16)$, indicating that the remaining gain cannot be achieved with a bit shift (fine gain)

`dwnConv = dsp.DigitalDownConverter(Name, Value)` returns a DDC object, `dwnConv`, with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

Properties

SampleRate

Sample rate of input signal

Set this property to a positive scalar value, greater than or equal to twice the value of the `CenterFrequency` property. The default is 30 MHz.

DecimationFactor

Decimation factor

Set this property to a positive integer scalar, or to a 1-by-2 or 1-by-3 vector of positive integers.

When you set this property to a scalar, the object automatically chooses the decimation factors for each of the three filtering stages.

When you set this property to a 1-by-2 vector, the object bypasses the third filter stage and sets the decimation factor of the first and second filtering stages to the values in the first and second vector elements respectively. Both elements of the `DecimationFactor` vector must be greater than one.

When you set this property to a 1-by-3 vector, the i th element of the vector specifies the decimation factor for the i th filtering stage. The first and second elements of the `DecimationFactor` vector must be greater than one, and the third element must be 1 or 2. The default is 100.

MinimumOrderDesign

Minimum order filter design

When you set this property to `true`, the object designs filters with the minimum order that meets the passband ripple, stopband attenuation, passband frequency, and stopband frequency specifications that you set using the `PassbandRipple`, `StopbandAttenuation`, `Bandwidth`, `StopbandFrequencySource`, and `StopbandFrequency` properties.

When you set this property to `false`, the object designs filters with orders that you specify in the `NumCICSections`, `SecondFilterOrder`, and `ThirdFilterOrder` properties. The filter designs meet the passband and stopband frequency specifications that you set using the `Bandwidth`, `StopbandFrequencySource`, and `StopbandFrequency` properties. The default is `true`.

NumCICSections

Number of sections of CIC decimator

Set this property to a positive integer scalar. This property applies when you set the `MinimumOrderDesign` property to `false`. The default is 3.

SecondFilterOrder

Order of CIC compensation filter stage

Set this property to a positive integer scalar. This property applies when you set the `MinimumOrderDesign` property to `false`. The default is 12.

ThirdFilterOrder

Order of third filter stage

Set this property to an even positive integer scalar. When you set the `DecimationFactor` property to a 1-by-2 vector, the object ignores the `ThirdFilterOrder` property because the third filter stage is bypassed. This property applies when you set the `MinimumOrderDesign` property to `false`. The default is 10.

Bandwidth

Two-sided bandwidth of input signal in Hz

Set this property to a positive integer scalar. The object sets the passband frequency of the cascade of filters to one-half of the value that you specify in the `Bandwidth` property. Set the value of this property to less than `SampleRate/DecimationFactor`. The default is 200 kHz.

StopbandFrequencySource

Source of stopband frequency

Specify the source of the stopband frequency as one of `Auto` | `Property`. The default is `Auto`. When you set this property to `Auto`, the object places the cutoff frequency of the cascade filter response at approximately $F_c = \text{SampleRate}/M/2$ Hz, where M is the total decimation factor that you specify in the `DecimationFactor` property. The object computes the stopband frequency as $F_{stop} = F_c + TW/2$. TW is the transition bandwidth of the cascade response computed as $2 \times (F_c - F_p)$, and the passband frequency, F_p , equals `Bandwidth/2`.

StopbandFrequency

Stopband frequency in Hz

Set this property to a double-precision positive scalar. This property applies when you set the `StopbandFrequencySource` property to `Property`. The default is 150 kHz.

PassbandRipple

Passband ripple of cascade response in dB.

Set this property to a double-precision positive scalar. When you set the `MinimumOrderDesign` property to `true`, the object designs the filters so that the cascade response meets the passband ripple that you specify in the `PassbandRipple` property. This property applies when you set the `MinimumOrderDesign` property to `true`. The default is 0.1 dB.

StopbandAttenuation

Stopband attenuation of cascade response in dB

Set this property to a double-precision positive scalar. When you set the `MinimumOrderDesign` property to `true`, the object designs the filters so that the cascade response meets the stopband attenuation that you specify in the `StopbandAttenuation` property. This property applies when you set the `MinimumOrderDesign` property to `true`. The default is 60 dB.

Oscillator

Type of oscillator

Specify the oscillator as one of `Sine wave` | `NCO` | `Input port` | `None`. The default is `Sine wave`. When you set this property to `Sine wave`, the object frequency down converts the input signal using a complex exponential obtained from samples of a sinusoidal trigonometric function. When you set this property to `NCO`, the object performs frequency down conversion with a complex exponential obtained using a numerically controlled oscillator (NCO). When you set this property to `Input port`, the object performs frequency down conversion using the complex signal that you set as an input to the `step` method. When you set this property to `None`, the mixer stage in the object is not present and the object acts as three stage cascaded decimator.

CenterFrequency

Center frequency of input signal in Hz

Specify this property as a double-precision positive scalar that is less than or equal to half the value of the `SampleRate` property. The object down converts the input signal from the passband center frequency you specify in the `CenterFrequency` property, to 0 Hz. This property applies when you set the `Oscillator` property to `Sine wave` or `NCO`. The default is 14 MHz.

NumAccumulatorBits

Number of NCO accumulator bits

Specify this property as an integer scalar in the range [1 128]. This property applies when you set the `Oscillator` property to `NCO`. The default is 16.

NumQuantizedAccumulatorBits

Number of NCO quantized accumulator bits

Specify this property as an integer scalar in the range [1 128]. The value you specify in this property must be less than the value you specify in the `NumAccumulatorBits` property. This property applies when you set the `Oscillator` property to `NCO`. The default is 12.

Dither

Dither control for NCO

When you set this property to `true`, a number of dither bits specified in the `NumDitherBits` property will be used to apply dither to the NCO signal. This property applies when you set the `Oscillator` property to `NCO`. The default is `true`.

NumDitherBits

Number of NCO dither bits

Specify this property as an integer scalar smaller than the number of accumulator bits that you specify in the `NumAccumulatorBits` property. This property applies when you set the `Oscillator` property to `NCO` and the `Dither` property to `true`. The default is 4.

Fixed-Point Properties

FiltersInputDataType

Data type of input of each filter stage

Specify the data type at the input of the first, second, and third (if it has not been bypassed) filter stages as one of `Same as input` | `Custom`. The default is `Same as input`. The object casts the data at the input of each filter stage according to the value you set in this property.

CustomFiltersInputDataType

Fixed-point data type of input of each filter stage

Specify the filters input fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `FiltersInputDataType` property to `Custom`. The default is `numericType([], 16, 15)`.

OutputDataType

Data type of output

Specify the data type of output as `Same as input` | `Custom`. The default is `Same as input`.

CustomOutputDataType

Fixed-point data type of output

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numericType([], 16, 15)`.

Methods

<code>fvtool</code>	Visualize response of filter cascade

<code>release</code>	Allow System object property value changes

Examples

Upconvert and Downconvert a Sine Wave Signal

Create a digital up converter object that up samples a 1 KHz sinusoidal signal by a factor of 20 and up converts it to 50 KHz. Create a digital down converter object that down converts the signal to 0 Hz and down samples it by a factor of 20.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Create a sine wave generator to obtain the 1 KHz sinusoidal signal with a sample rate of 6 KHz.

```

Fs = 6e3; % Sample rate
sine = dsp.SineWave('Frequency',1000,'SampleRate',...

```

```
Fs, 'SamplesPerFrame', 1024);  
x = sine(); % generate signal
```

Create a `DigitalUpConverter` object. Use minimum order filter designs and set passband ripple to 0.2 dB and the stopband attenuation to 55 dB. Set the double sided signal bandwidth to 2 KHz.

```
upConv = dsp.DigitalUpConverter(...  
    'InterpolationFactor', 20,...  
    'SampleRate', Fs,...  
    'Bandwidth', 2e3,...  
    'StopbandAttenuation', 55,...  
    'PassbandRipple', 0.2,...  
    'CenterFrequency', 50e3);
```

Create a `DigitalDownConverter` object. Use minimum order filter designs and set the passband ripple to 0.2 dB and the stopband attenuation to 55 dB.

```
dwnConv = dsp.DigitalDownConverter(...  
    'DecimationFactor', 20,...  
    'SampleRate', Fs*20,...  
    'Bandwidth', 3e3,...  
    'StopbandAttenuation', 55,...  
    'PassbandRipple', 0.2,...  
    'CenterFrequency', 50e3);
```

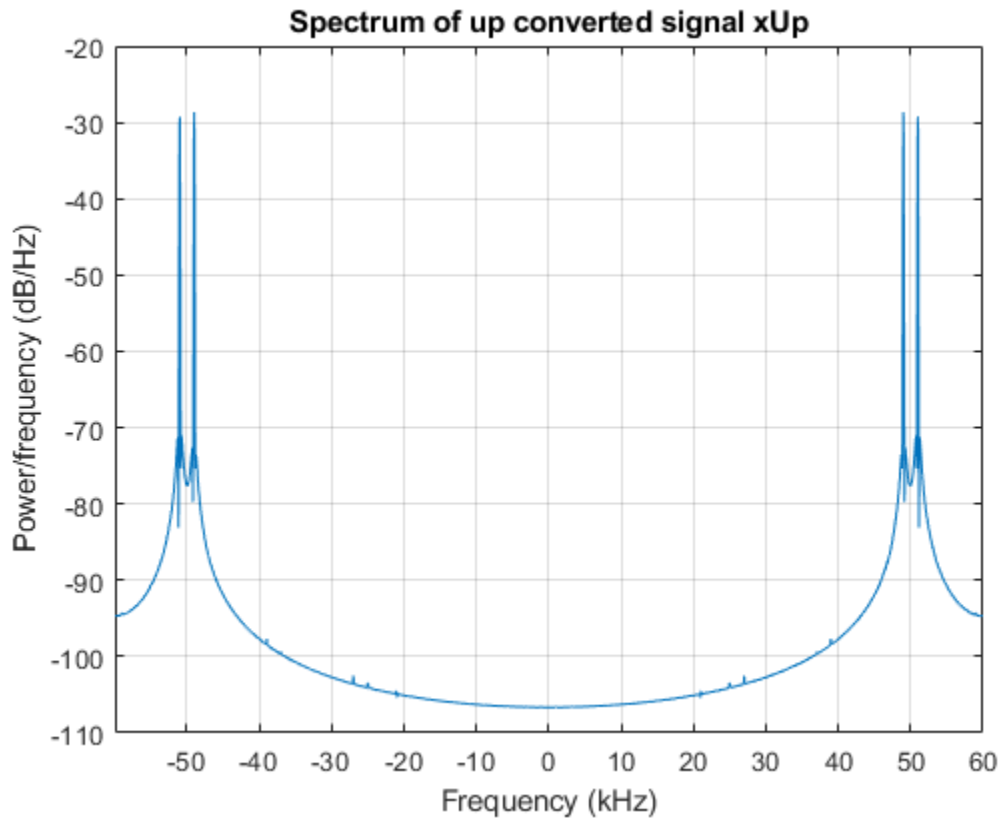

Create a spectrum estimator to visualize the signal spectrum before up converting, after up converting, and after down converting.

```
window = hamming(floor(length(x)/10));  
figure; pwelch(x, window, [], [], Fs, 'centered')  
title('Spectrum of baseband signal x')
```

Up convert the signal and visualize the spectrum

```
xUp = upConv(x); % up convert
window = hamming(floor(length(xUp)/10));
figure; pwelch(xUp,window,[],[],20*Fs,'centered');
title('Spectrum of up converted signal xUp')
```

Down convert the signal and visualize the spectrum

```
xDown = dwnConv(xUp); % down convert
window = hamming(floor(length(xDown)/10));
figure; pwelch(xDown,window,[],[],Fs,'centered')
title('Spectrum of down converted signal xDown')
```

Visualize the response of the decimation filters

```
visualizeFilterStages(dwnConv)
```

fvtool

System object: dsp.DigitalDownConverter

Package: dsp

Visualize response of filter cascade

Syntax

```
fvtool(dwnConv)
fvtool(dwnConv,...,'Arithmetic',ARITH,...)
fvtool(dwnConv,...,PROP1,VALUE1,PROP2,VALUE2,...)
```

Description

`fvtool(dwnConv)` plots the magnitude response of the cascade of filters. By default, the object plots the cascade response up to the second CIC null frequency (or to the first when only one CIC null exists). When you set the `FilterSpecification` property to `Design` parameters the method plots a mask based on the filter specifications.

`fvtool(dwnConv,...,'Arithmetic',ARITH,...)` specifies the arithmetic of the filter cascade. You set input `ARITH` to `double`, `single`, or `fixed-point`. When object `dwnConv` is in an unlocked state you must specify the arithmetic. When object `dwnConv` is in a locked state the arithmetic input is ignored.

`fvtool(dwnConv,...,PROP1,VALUE1,PROP2,VALUE2,...)` launches `FVTool` and sets the specified `FVTool` properties to the specified values.

getDecimationFactors

System object: dsp.DigitalDownConverter

Package: dsp

Get decimation factors of each filter stage

Syntax

```
M = getDecimationFactors(dwnConv)
```

Description

`M = getDecimationFactors(dwnConv)` returns a vector, `M`, with the decimation factors of each filter stage. If the third filter stage is bypassed, then `M` is a 1-by-2 vector containing the decimation factors of the first and second filter stages in the first and second elements respectively. If the third filter stage is not bypassed then `M` is a 1-by-3 vector containing the decimation factors of the first, second and third filter stages.

getFilters

System object: dsp.DigitalDownConverter

Package: dsp

Get handles to decimation filter objects

Syntax

```
S = getFilters(dwnConv)
getFilters(dwnConv, 'Arithmetic', ARITH)
```

Description

`S = getFilters(dwnConv)` returns a structure, `S`, with copies of the filter System objects and the CIC normalization factor that form the decimation filter cascade. The `ThirdFilterStage` structure field is empty if the third filter stage has been bypassed. The CIC normalization factor equals the inverse of the CIC filter gain. In some cases, this gain includes a correction factor to ensure that the cascade response meets the ripple specifications.

`getFilters(dwnConv, 'Arithmetic', ARITH)` specifies the arithmetic of the filter stages. You can set `ARITH` to `double`, `single`, or `fixed-point`. When object `dwnConv` is in an unlocked state, you must specify the arithmetic input. When object `dwnConv` is in a locked state, the arithmetic input is ignored.

When `dwnConv` is in an unlocked state, and you specify the arithmetic as `fixed-point`, the `getFilters` method returns filter System objects. The custom coefficient data type properties of these System objects are set to the values that the `dsp.DigitalDownConverter` System object uses to process data when you call the `step` method. All other fixed-point properties are set to their default values.

When `dwnConv` is in a locked state, and the input to the `step` method is of a fixed-point data type, the `getFilters` method returns filter System objects. All fixed-point

properties of these System objects are set to the exact values that the `dsp.DigitalDownConverter` System object uses to process the data.

getFilterOrders

System object: dsp.DigitalDownConverter

Package: dsp

Get orders of decimation filters

Syntax

```
S = getFilterOrders(dwnConv)
```

Description

`S = getFilterOrders(dwnConv)` returns a structure, `S`, that contains the orders of the interpolation filter stages. The `ThirdFilterOrder` structure field will be empty if the third filter stage has been bypassed.

groupDelay

System object: dsp.DigitalDownConverter

Package: dsp

Group delay of filter cascade

Syntax

```
D = groupDelay(dwnConv,N)  
[D,F] = groupDelay(dwnConv,N)
```

Description

`D = groupDelay(dwnConv,N)` returns a vector of group delays, `D`, evaluated at `N` frequency points equally spaced around the upper half of the unit circle. If you don't specify `N`, it defaults to 8192.

`[D,F] = groupDelay(dwnConv,N)` returns a vector of frequencies, `F`, at which the group delay has been computed.

step

System object: dsp.DigitalDownConverter

Package: dsp

Digitally down convert input signal

Syntax

`Y = step(dwnConv, X)`

`Y = step(dwnConv, X, Z)`

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

`Y = step(dwnConv, X)` takes a real or complex input column vector `X` and outputs a frequency down converted and down sampled signal `Y`. The length of input `X` must be a multiple of the decimation factor. `X` can be of data type double, single, signed integer, or signed fixed point (fi objects). The length of `Y` is equal to the length of `X` divided by the `DecimationFactor`. When the data type of `X` is double or single precision, the data type of `Y` is the same as that of `X`. When the data type of `X` is of a fixed point type, the data type of `Y` is defined by the `OutputDataType` property.

`Y = step(dwnConv, X, Z)` uses the complex input, `Z`, as the oscillator signal used to frequency down convert input `X`, when you set the `Oscillator` property to `Input port`. The length of `Z` must be equal to the length of `X`. `Z` can be of data type double, single, signed integer, or signed fixed point (fi objects).

visualizeFilterStages

System object: dsp.DigitalDownConverter

Package: dsp

Display response of filter stages

Syntax

```
visualizeFilterStages(dwnConv)
visualizeFilterStages(dwnConv, 'Arithmetic', ARITH)
fvt = visualizeFilterStages(dwnConv)
```

Description

`visualizeFilterStages(dwnConv)` plots the magnitude response of the filter stages and of the cascade response. When you set the `FilterSpecification` property to `Design` parameters the method plots a mask based on the filter specifications. By default, the object plots the response of the filters up to the second CIC null frequency (or to the first when only one CIC null exists).

`visualizeFilterStages(dwnConv, 'Arithmetic', ARITH)` specifies the arithmetic of the filter stages. You set input `ARITH` to `double`, `single`, or `fixed-point`. When object `dwnConv` is in an unlocked state you must specify the arithmetic. When object `dwnConv` is in a locked state the arithmetic input is ignored.

`fvt = visualizeFilterStages(dwnConv)` returns the handle to the `FVTool` object.

dsp.DigitalUpConverter System object

Package: dsp

Interpolate digital signal and translate it from baseband to Intermediate Frequency (IF) band

Description

The `DigitalUpConverter` object interpolates digital signal, and translates it from baseband to Intermediate Frequency (IF) band.

To digitally up convert the input signal:

- 1 Define and set up your digital up converter. See “Construction” on page 4-562.
- 2 Call `step` to upconvert the input according to the properties of `dsp.DigitalUpConverter`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

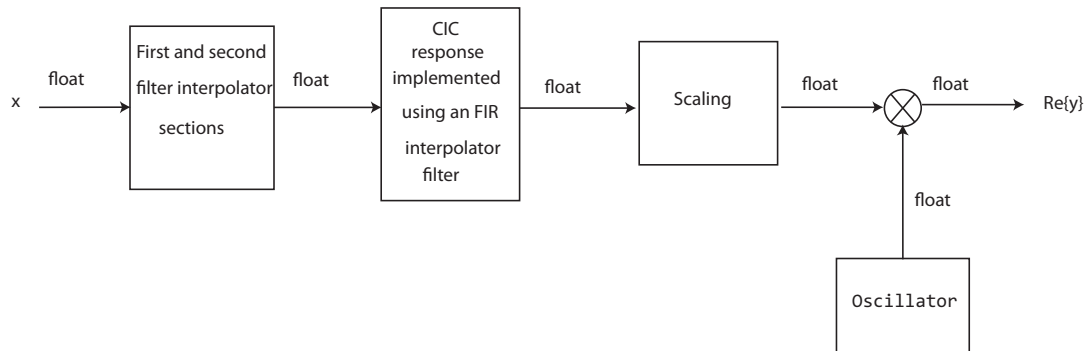

Construction

`upConv = dsp.DigitalUpConverter` returns a digital up-converter (DUC) System object, `upConv`. The object `upConv` samples the input signal using a cascade of three interpolation filters. This object frequency upconverts the up sampled signal by multiplying it with a complex exponential with center frequency equal to the value in the `CenterFrequency` property. In this case, the filter cascade consists of a first FIR interpolation stage, a CIC compensator, and a CIC interpolator. The following block diagram shows the architecture of the digital up converter.

The scaling section normalizes the CIC gain and the oscillator power. It may also contain a correction factor to achieve the desired ripple specification. Depending on the setting of the **InterpolationFactor** property, you may be able to bypass the first filter stage. When the input data type is double or single, the object implements an N -section CIC interpolation filter as an FIR filter with a response that corresponds to a cascade of N boxcar filters. A true CIC filter with actual comb and integrator sections is implemented when the input data is of a fixed-point type. The CIC filter is emulated with an FIR filter so that you can run simulations with floating-point data.

The following diagram represents the DUC arithmetic with single or double-precision, floating-point inputs.

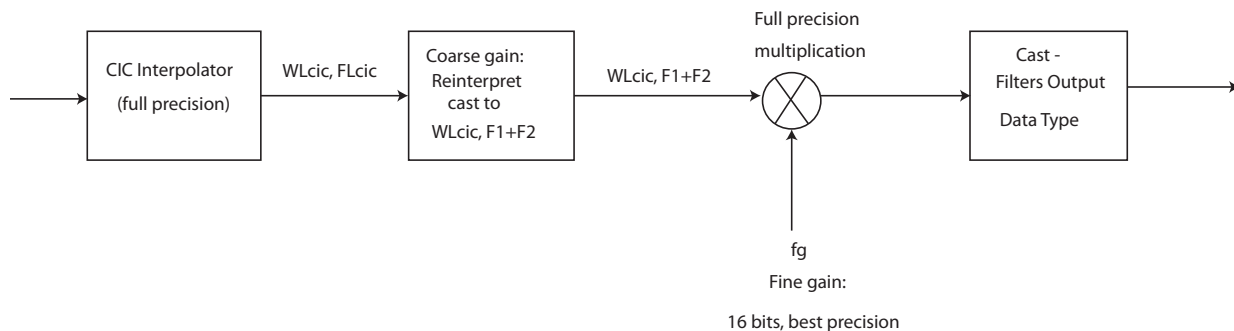

The following block diagram represents the DUC arithmetic with signed fixed-point inputs.

- `WL` is the word length of the input, and `FL` is the fraction length of the input.
- The output of each filter is cast to the data type specified in the **FiltersOutputDataType** and **CustomFiltersOutputDataType** properties. The casting of the CIC output occurs after the scaling factor is applied.
- The oscillator output is cast to a word length equal to the **FiltersOutputDataType** word length plus one. The fraction length is equal to the **FiltersOutputDataType** word length minus one.
- The scaling at the output of the CIC interpolator consists of coarse- and fine-gain adjustments. The coarse gain is achieved using the `reinterpretcast` function on the CIC interpolator output. The fine gain is achieved using full-precision multiplication.

The following figure depicts the coarse- and fine-gain operations.

If the normalization gain is G (where $0 < G \leq 1$), then:

- $WLCic$ is the word length of the CIC interpolator output and $FLCic$ is the fraction length of the CIC interpolator output
- $F1 = \text{abs}(\text{nextpow2}(G))$, indicating the part of G achieved using bit shifts (coarse gain)
- $F2 =$ fraction length specified by the **FiltersOutputDataType** and **CustomFiltersOutputDataType** properties
- $fg = \text{fi}((2^{F1}) * G, \text{true}, 16)$, indicating that the remaining gain cannot be achieved with a bit shift (fine gain)

`upConv = dsp.DigitalUpConverter('PropertyName', 'PropertyValue')`
 returns a DUC object, `upConv`, with each specified property set to the specified value.
 You can specify additional name-value pair arguments in any order as
`(Name1,Value1,...,NameN,ValueN)`.

Properties

SampleRate

Sample rate of input signal

Set this property to a positive scalar. The value of this property multiplied by the total interpolation factor must be greater than or equal to twice the value of the `CenterFrequency` property. The default is 30 MHz.

InterpolationFactor

Interpolation factor

Set this property to a positive, integer scalar, or to a 1-by-2 or 1-by-3 vector of positive integers.

When you set this property to a scalar the object automatically chooses the interpolation factors for each of the three filtering stages.

When you set this property to a 1-by-2 vector, the object bypasses the first filter stage and sets the interpolation factor of the second and third filtering stages to the values in the first and second vector elements respectively. Both elements of the `InterpolationFactor` vector must be greater than one.

When you set this property to a 1-by-3 vector, the *i*th element of the vector specifies the interpolation factor for the *i*th filtering stage. The second and third elements of the `InterpolationFactor` vector must be greater than one and the first element must be 1 or 2. The default is 100.

MinimumOrderDesign

Minimum order filter design.

When you set this property to `true`, the object designs filters with the minimum order that meets the passband ripple, stopband attenuation, passband frequency, and stopband frequency specifications that you set using the `PassbandRipple`, `StopbandAttenuation`, `Bandwidth`, `StopbandFrequencySource`, and `StopbandFrequency` properties. When you set this property to `false`, the object designs filters with orders that you specify in the `FirstFilterOrder`, `SecondFilterOrder`, and `NumCICSections` properties. The filter designs meet the passband and stopband frequency specifications that you set using the `Bandwidth`, `StopbandFrequencySource`, and `StopbandFrequency` properties. The default is `true`.

SecondFilterOrder

Order of CIC compensation filter stage

Set this property to a positive, integer scalar. This property applies when you set the `MinimumOrderDesign` property to `false`. The default is 12.

FirstFilterOrder

Order of first filter stage

Set this property to a positive, integer, even scalar. When you set the `InterpolationFactor` property to a 1-by-2 vector, the object ignores the `FirstFilterOrder` property because the first filter stage is bypassed. This property applies when you set the `MinimumOrderDesign` property to `false`. The default is 10.

NumCICSections

Number of sections of CIC interpolator

Set this property to a positive, integer scalar. This property applies when you set the `MinimumOrderDesign` property to `false`. The default is 3.

Bandwidth

Two-sided bandwidth of input signal in Hz .

Set this property to a positive, integer scalar. The object sets the passband frequency of the cascade of filters to one-half of the value that you specify in the `Bandwidth` property. The default is 200 kHz.

StopbandFrequencySource

Source of stopband frequency.

Specify the source of the stopband frequency as one of `Auto` | `Property`. The default is `Auto`. When you set this property to `Auto`, the object places the cutoff frequency of the cascade filter response at approximately $F_c = \text{SampleRate}/2$ Hz, and computes the stopband frequency as $F_{stop} = F_c + TW/2$. TW is the transition bandwidth of the cascade response, computed as $2 \times (F_c - F_p)$, and the passband frequency, F_p , equals `Bandwidth/2`.

StopbandFrequency

Stopband frequency in Hz.

Set this property to a double precision positive scalar. This property applies when you set the `StopbandFrequencySource` property to `Property`. The default is 150 kHz.

PassbandRipple

Passband ripple of cascade response in dB.

Set this property to a double precision, positive scalar. When you set the `MinimumOrderDesign` property to `true`, the object designs the filters so that the cascade response meets the passband ripple that you specify in the `PassbandRipple` property. This property applies when you set the `MinimumOrderDesign` property to `true`. The default is 0.1 dB.

StopbandAttenuation

Stopband attenuation of cascade response in dB.

Set this property to a double precision, positive scalar. When you set the `MinimumOrderDesign` property to `true`, the object designs the filters so that the cascade response meets the stopband attenuation that you specify in the `StopbandAttenuation` property. This property applies when you set the `MinimumOrderDesign` property to `true`. The default is 60 dB.

Oscillator

Type of oscillator.

Specify the oscillator as one of `Sine wave` | `NCO`. The default is `Sine wave`. When you set this property to `Sine wave`, the object frequency up converts the output of the interpolation filter cascade using a complex exponential signal obtained from samples of a sinusoidal trigonometric function. When you set this property to `NCO` the object performs frequency up conversion with a complex exponential obtained using a numerically controlled oscillator (NCO).

CenterFrequency

Center frequency of output signal in Hz.

Specify this property as a double precision, positive scalar. The value of this property must be less than or equal to half the product of the `SampleRate` property times the total interpolation factor. The object up converts the input signal so that the output spectrum centers at the frequency you specify in the `CenterFrequency` property. The default is 14 MHz.

NumAccumulatorBits

Number of NCO accumulator bits

Specify this property as an integer scalar in the range [1 128]. This property applies when you set the `Oscillator` property to `NCO`. The default is 16.

See also `dsp.NCO`.

NumQuantizedAccumulatorBits

Number of NCO quantized accumulator bits.

Specify this property as an integer scalar in the range [1 128]. The value you specify for this property must be less than the value you specify in the `NumAccumulatorBits` property. This property applies when you set the `Oscillator` property to `NCO`. The default is 12.

See also `dsp.NCO`.

Dither

Dither control for NCO.

When you set this property to `true`, the object uses the number of dither bits specified in the `NumDitherBits` property when applying dither to the NCO signal. This property applies when you set the `Oscillator` property to `NCO`. The default is `true`.

See also `dsp.NCO`.

NumDitherBits

Number of NCO dither bits.

Specify this property as an integer scalar smaller than the number of accumulator bits that you specify in the `NumAccumulatorBits` property. This property applies when you set the `Oscillator` property to `NCO` and the `Dither` property to `true`. The default is 4.

See also `dsp.NCO`.

Fixed-Point Properties

FiltersOutputDataType

Data type of output of each filter stage

Specify the data type at the output of the first (if it has not been bypassed), second, and third filter stages as one of `Same as input` | `Custom`. The default is `Same as input`. The object casts the data at the output of each filter stage according to the value you set in this property. For the CIC stage, the casting is done after the signal has been scaled by the normalization factor.

CustomFiltersOutputDataType

Fixed-point data type of output of each filter stage

Specify the filters output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `FiltersOutputDataType` property to `Custom`. The default is `numericType([], 16, 15)`.

OutputDataType

Data type of output

Specify the data type of output as `Same as input` | `Custom`. The default is `Same as input`.

CustomOutputDataType

Fixed-point data type of output

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numericType([], 16, 15)`.

Methods

<code>fvtool</code>	Visualize response of filter cascade
<code>getFilters</code>	Get handles to interpolation filter objects
<code>getFilterOrders</code>	Get orders of interpolation filters
<code>getInterpolationFactors</code>	Get interpolation factors of each filter stage
<code>groupDelay</code>	Group delay of filter cascade
<code>step</code>	Process inputs using the digital up converter

<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

Upconvert a Sine Wave Signal

Create a digital up converter object that upsamples a 1 KHz sinusoidal signal by a factor of 20, and up converts it to 50 KHz.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Initialization

Create a sine wave generator to obtain the 1 KHz sinusoidal signal with a sample rate of 6 KHz.

```
Fs = 6e3; % Sample rate
sine = dsp.SineWave('Frequency',1000,'SampleRate', Fs,'SamplesPerFrame',1024);
x = sine(); % generate signal
```

Create a DUC object. Use minimum order filter designs and set the passband ripple to 0.2 dB and the stopband attenuation to 55 dB. Set the double sided signal bandwidth to 2 KHz.

```
upConv = dsp.DigitalUpConverter(...
    'InterpolationFactor', 20,...
    'SampleRate', Fs,...
    'Bandwidth', 2e3,...
    'StopbandAttenuation', 55,...
    'PassbandRipple',0.2,...
    'CenterFrequency',50e3);
```

Create a spectrum estimator to visualize the signal spectrum before and after up converting.

```
window = hamming(floor(length(x)/10));
figure; pwelch(x>window, [], [], Fs, 'centered')
title('Spectrum of baseband signal x')
```

Upconvert the Signal and Visualize the Spectrum

```
xUp = upConv(x); % up convert
window = hamming(floor(length(xUp)/10));
figure; pwelch(xUp,window,[],[],20*Fs,'centered')
title('Spectrum of up converted signal xUp')
```

Visualize the response of the interpolation filters

```
visualizeFilterStages(upConv)
```

fvtool

System object: dsp.DigitalUpConverter

Package: dsp

Visualize response of filter cascade

Syntax

```
fvtool(upConv)
fvtool(upConv,...,'Arithmetic',ARITH,...)
fvtool(upConv,...,PROP1,VALUE1,PROP2,VALUE2)
```

Description

`fvtool(upConv)` plots the magnitude response of the cascade of filters. By default, the object plots the cascade response up to the second CIC null frequency (or to the first when only one CIC null exists). When you set the `FilterSpecification` property to `Design` parameters the method plots a mask based on the filter specifications.

`fvtool(upConv,...,'Arithmetic',ARITH,...)` specifies the arithmetic of the filter cascade. You set input `ARITH` to `double`, `single`, or `fixed-point`. When object `upConv` is in an unlocked state you must specify the arithmetic. When object `upConv` is in a locked state the arithmetic input is ignored.

`fvtool(upConv,...,PROP1,VALUE1,PROP2,VALUE2)` launches `FVTool` and sets the specified `FVTool` properties to the specified values.

getFilters

System object: dsp.DigitalUpConverter

Package: dsp

Get handles to interpolation filter objects

Syntax

```
S = getFilters(upConv)
getFilters(upConv, 'Arithmetic', ARITH)
```

Description

`S = getFilters(upConv)` returns a structure, `S`, with copies of the filter System objects and the CIC normalization factor that form the interpolation filter cascade. The `FirstFilterStage` structure field is empty if the first filter stage has been bypassed. The CIC normalization factor equals the inverse of the CIC filter gain. In some cases, this gain includes a correction factor to ensure that the cascade response meets the ripple specifications.

`getFilters(upConv, 'Arithmetic', ARITH)` specifies the arithmetic of the filter stages. You set `ARITH` to `double`, `single`, or `fixed-point`. When object `upConv` is in an unlocked state, you must specify the arithmetic input. When object `upConv` is in a locked state, the arithmetic input is ignored.

When `upConv` is in an unlocked state, and you specify the arithmetic as `fixed-point`, the `getFilters` method returns filter System objects. The custom coefficient data type properties of these System objects are set to the values that the `dsp.DigitalUpConverter` System object uses to process data when you call the `step` method. All other fixed-point properties are set to their default values.

When `upConv` is in a locked state, and the input to the `step` method is of a fixed-point data type, the `getFilters` method returns filter System objects. All fixed-point

properties of these System objects are set to the exact values that the `dsp.DigitalUpConverter` System object uses to process the data.

getFilterOrders

System object: dsp.DigitalUpConverter

Package: dsp

Get orders of interpolation filters

Syntax

```
S = getFilterOrders(upConv)
```

Description

`S = getFilterOrders(upConv)` returns a structure, `S`, that contains the orders of the interpolation filter stages. The `FirstFilterOrder` structure field will be empty if the first filter stage has been bypassed.

getInterpolationFactors

System object: dsp.DigitalUpConverter

Package: dsp

Get interpolation factors of each filter stage

Syntax

`M = getInterpolationFactors(upConv)`

Description

`M = getInterpolationFactors(upConv)` returns a vector, `M`, with the interpolation factors of each filter stage. If the first filter stage is bypassed, then `M` is a 1-by-2 vector containing the interpolation factors of the second and third stages in the first and second elements respectively. If the first filter stage is not bypassed then `M` is a 1-by-3 vector containing the interpolation factors of the first, second and third filter stages.

groupDelay

System object: dsp.DigitalUpConverter

Package: dsp

Group delay of filter cascade

Syntax

`D = groupDelay(upConv,N)`

`[D,F] = groupDelay(upConv,N)`

Description

`D = groupDelay(upConv,N)` returns a vector of group delays, `D`, evaluated at `N` frequency points equally spaced around the upper half of the unit circle. If you don't specify `N`, it defaults to 8192.

`[D,F] = groupDelay(upConv,N)` returns a vector, `F`, of frequencies at which the group delay has been computed.

step

System object: dsp.DigitalUpConverter

Package: dsp

Process inputs using the digital up converter

Syntax

```
Y = step(upConv,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(upConv,X)` takes a real or complex input column vector `X` and outputs an up sampled and frequency up converted signal `Y`. `X` can be of data type double, single, signed integer, or signed fixed point (fi objects). The length of `Y` is equal to the length of `X` multiplied by the `InterpolationFactor`. When the data type of `X` is double or single precision, the data type of `Y` is the same as that of `X`. When the data type of `X` is of a fixed point type, the data type of `Y` is defined by the `OutputDataType` property.

visualizeFilterStages

System object: dsp.DigitalUpConverter

Package: dsp

Display response of filter stages

Syntax

```
visualizeFilterStages(upConv)
visualizeFilterStages(upConv, 'Arithmetic', ARITH)
fvt = visualizeFilterStages(upConv)
```

Description

`visualizeFilterStages(upConv)` plots the magnitude response of the filter stages and of the cascade response. When the `FilterSpecification` property is set to `Design` parameters the method plots a mask based on the filter specifications. By default, the object plots the response of the filters up to the second CIC null frequency (or to the first when only one CIC null exists).

`visualizeFilterStages(upConv, 'Arithmetic', ARITH)` specifies the arithmetic of the filter stages. You set input `ARITH` to 'double', 'single', or 'fixed-point'. When object `upConv` is in an unlocked state you must specify the arithmetic. When object `upConv` is in a locked state the arithmetic input is ignored.

`fvt = visualizeFilterStages(upConv)` returns the handle to the `FVTool` object.

dsp.DyadicAnalysisFilterBank System object

Package: dsp

Dyadic analysis filter bank

Description

The `DyadicAnalysisFilterBank` object uses a series of highpass and lowpass FIR filters to provide approximate octave band frequency decompositions of the input. Each filter output is downsampled by a factor of two. With the appropriate analysis filters and tree structure, the dyadic analysis filter bank is a discrete wavelet transform (DWT) or discrete wavelet packet transform (DWPT).

To obtain approximate octave band frequency decompositions of the input:

- 1 Define and set up your dyadic analysis filter bank. See “Construction” on page 4-585.
- 2 Call `step` to get the octave half band frequency decompositions of the input according to the properties of `dsp.DyadicAnalysisFilterBank`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`dydan = dsp.DyadicAnalysisFilterBank` constructs a dyadic analysis filter bank object, `dydan`, that computes the level-two discrete wavelet transform (DWT) of a column vector input. For a 2-D matrix input, the object transforms the columns using the Daubechies third-order extremal phase wavelet. The length of the input along the first dimension must be a multiple of 4.

dydan =
 dsp.DyadicAnalysisFilterBank('PropertyName',PropertyValue, ...)
 returns a dyadic analysis filter bank object, dydan, with each property set to the specified value.

Properties

Filter

Type of filter used in subband decomposition

Specify the type of filter used to determine the high and lowpass FIR filters in the dyadic analysis filter bank as `Custom`, `Haar`, `Daubechies`, `Symlets`, `Coiflets`, `Biorthogonal`, `Reverse Biorthogonal`, or `Discrete Meyer`. All property values except `Custom` require Wavelet Toolbox software. If the value of this property is `Custom`, the filter coefficients are specified by the values of the `CustomLowpassFilter` and `CustomHighpassFilter` properties. Otherwise, the dyadic analysis filter bank object uses the Wavelet Toolbox function `wfilters` to construct the filters. The following table lists supported wavelet filters and example syntax to construct the filters:

Filter	Example Setting	Syntax for Analysis Filters
Haar	N/A	[Lo_D,Hi_D]=wfilters('haar');
Daubechies extremal phase	WaveletOrder=3;	[Lo_D,Hi_D]=wfilters('db3');
Symlets (Daubechies least-asymmetric)	WaveletOrder=4;	[Lo_D,Hi_D]=wfilters('sym4');
Coiflets	WaveletOrder=1;	[Lo_D,Hi_D]=wfilters('coif1');
Biorthogonal	FilterOrder='[3/1]';	[Lo_D,Hi_D,Lo_R,Hi_R]=... wfilters('bior3.1');
Reverse biorthogonal	FilterOrder='[3/1]';	[Lo_D,Hi_D,Lo_R,Hi_R]=... wfilters('rbior3.1');
Discrete Meyer	N/A	[Lo_D,Hi_D]=wfilters('dmey');

CustomLowpassFilter

Lowpass FIR filter coefficients

Specify a vector of lowpass FIR filter coefficients, in powers of z^{-1} . Use a half-band filter that passes the frequency band stopped by the filter specified in the `CustomHighpassFilter` property. This property applies when you set the `Filter` property to `Custom`. The default specifies a Daubechies third-order extremal phase scaling (lowpass) filter.

CustomHighpassFilter

Highpass FIR filter coefficients

Specify a vector of highpass FIR filter coefficients, in powers of z^{-1} . Use a half-band filter that passes the frequency band stopped by the filter specified in the `CustomLowpassFilter` property. This property applies when you set the `Filter` property to `Custom`. The default specifies a Daubechies 3rd-order extremal phase wavelet (highpass) filter.

WaveletOrder

Order for orthogonal wavelets

Specify the order of the wavelet selected in the `Filter` property. This property applies when you set the `Filter` property to an orthogonal wavelet: `Daubechies` (Daubechies extremal phase), `Symlets` (Daubechies least-asymmetric), or `Coiflets`. The default is 2.

FilterOrder

Analysis and synthesis filter orders for biorthogonal filters

Specify the order of the analysis and synthesis filter orders for biorthogonal filter banks as 1 / 1, 1 / 3, 1 / 5, 2 / 2, 2 / 4, 2 / 6, 2 / 8, 3 / 1, 3 / 3, 3 / 5, 3 / 7, 3 / 9, 4 / 4, or 5 / 5, 6 / 8. Unlike orthogonal wavelets, biorthogonal wavelets require different filters for the analysis (decomposition) and synthesis (reconstruction) of an input. The first number indicates the order of the synthesis (reconstruction) filter. The second number indicates the order of the analysis (decomposition) filter. This property applies when you set the `Filter` property to `Biorthogonal` or `Reverse Biorthogonal`. The default is 1 / 1.

NumLevels

Number of filter bank levels used in analysis (decomposition)

Specify the number of filter bank analysis levels a positive integer. A level- N asymmetric structure produces $N+1$ output subbands. A level- N symmetric structure produces 2^N output subbands. The default is 2. The size of the input along the first dimension must be a multiple of 2^N , where N is the number of levels.

TreeStructure

Structure of filter bank

Specify the structure of the filter bank as `Asymmetric` or `Symmetric`. The asymmetric structure decomposes only the lowpass filter output from each level. The symmetric structure decomposes the highpass and lowpass filter outputs from each level. If the analysis filters are scaling (lowpass) and wavelet (highpass) filters, the asymmetric structure is the discrete wavelet transform, while the symmetric structure is the discrete wavelet packet transform.

When this property is `Symmetric`, the output has 2^N subbands each of size $M/2^N$. In this case, M is the length of the input along the first dimension and N is the value of the `NumLevels` property. When this property is `Asymmetric`, the output has $N+1$ subbands. The following equation gives the length of the output in the k th subband in the asymmetric case:

$$M_k = \begin{cases} \frac{M}{2^k} & 1 \leq k \leq N \\ \frac{M}{2^N} & k = N + 1 \end{cases}$$

The default is `Asymmetric`.

Methods

- reset Reset filter states
- step Decompose input with dyadic filter bank

Common to All System Objects	
clone	Create System object with same property values
getNumInputs	Expected number of inputs to a System object

Common to All System Objects	
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Filter Square Wave Using Dyadic Filter Banks

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Denoise square wave input using dyadic analysis and synthesis filter banks.

```
t = 0:.0001:.0511;
x = square(2*pi*30*t);
xn = x' + 0.08*randn(length(x),1);
dydan1 = dsp.DyadicAnalysisFilterBank;
```

The filter coefficients correspond to a haar wavelet.

```
dydan1.CustomLowpassFilter = [1/sqrt(2) 1/sqrt(2)];
dydan1.CustomHighpassFilter = [-1/sqrt(2) 1/sqrt(2)];
dydsyn = dsp.DyadicSynthesisFilterBank;
dydsyn.CustomLowpassFilter = [1/sqrt(2) 1/sqrt(2)];
dydsyn.CustomHighpassFilter = [1/sqrt(2) -1/sqrt(2)];
C = dydan1(xn);
```

Subband outputs.

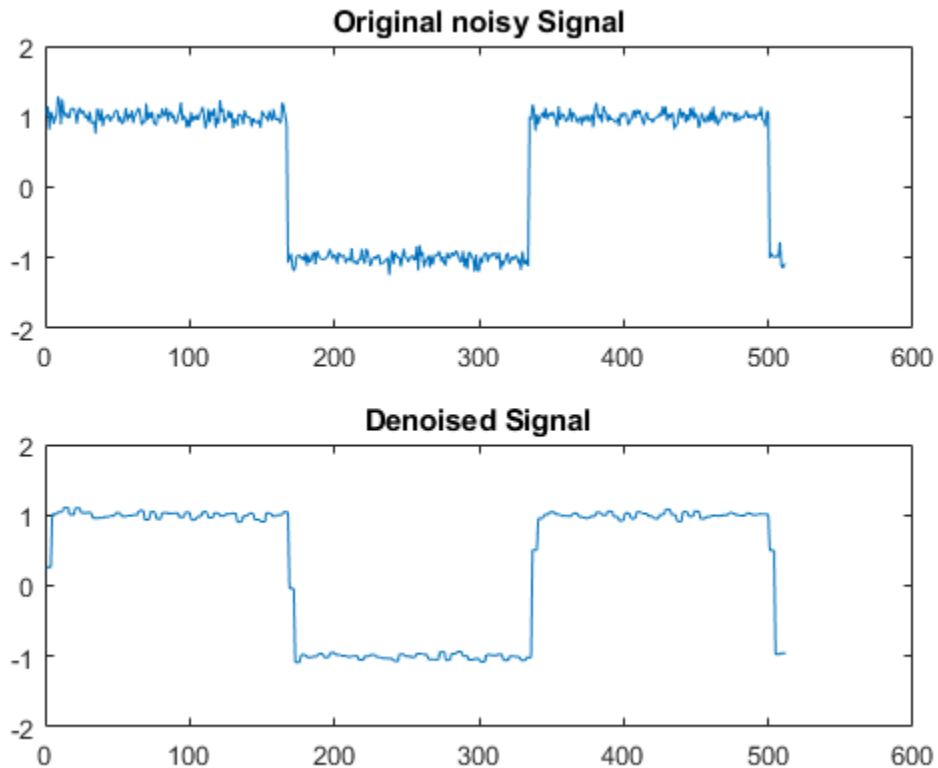

```
C1 = C(1:256); C2 = C(257:384); C3 = C(385:512);
```

Set higher frequency coefficients to zero to remove the noise.

```
x_den = dydsyn([zeros(length(C1),1);...
    zeros(length(C2),1);C3]);
```

Plot the original and denoised signals.

```
subplot(2,1,1), plot(xn); title('Original noisy Signal');  
subplot(2,1,2), plot(x_den); title('Denoised Signal');
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Dyadic Analysis Filter Bank block reference page. The object properties correspond to the block parameters, except:

The dyadic analysis filter bank object always concatenates the subbands into a single column vector for a column vector input, or into the columns of a matrix for a matrix

input. This behavior corresponds to the block's behavior when you set the **Output** parameter to `Single port`.

`dsp.DyadicSynthesisFilterBank` | `dsp.SubbandAnalysisFilter`

Introduced in R2012a

reset

System object: dsp.DyadicAnalysisFilterBank

Package: dsp

Reset filter states

Syntax

```
reset(dydan)
```

Description

`reset(dydan)` resets the filter states of the dyadic analysis filter bank object, `dydan`, to their initial values of zero. After the `step` method applies the dyadic analysis filter bank to nonzero input data, the filter states may change. Invoking the `step` method again without first invoking the `reset` method may produce different outputs for an identical input.

Reset a Dyadic Analysis Filter Bank

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
X = [1 1 7 9 2 8 8 6]';  
dydan = dsp.DyadicAnalysisFilterBank('NumLevels',1);
```

Filter states are zero.

```
y = dydan(X);
```

Invoke `step` method again without resetting states.

```
y1 = dydan(X);  
isequal(y,y1)
```

```
ans =  
  
    logical  
  
     0
```

Reset the filter states.

```
reset(dydan); % Reset filter states to zero  
y2 = dydan(X);  
isequal(y,y2)
```

```
ans =  
  
    logical  
  
     1
```

step

System object: dsp.DyadicAnalysisFilterBank

Package: dsp

Decompose input with dyadic filter bank

Syntax

```
Y = step(dydan,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(dydan,X)` computes the subband decomposition of the input `X` and outputs the dyadic subband decomposition in `Y` as a single concatenated column vector or matrix of coefficients. Each column of `X` is treated as an independent input, and the number of rows of `X` must be a multiple of 2^N , where N is the value of the `NumLevels` property. The elements of `Y` are ordered with the highest frequency subband first followed by subbands in decreasing frequency

Examples

Subband Ordering For Asymmetric Tree Structure Using Dyadic Analysis Filter Bank

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Sampling frequency 1 kHz input length 1024

```
t = 0:.001:1.023;
x = square(2*pi*30*t);
xn = x' + 0.08*randn(length(x),1);
```

Default asymmetric structure with Daubechies order 3 extremal phase wavelet

```
dydan = dsp.DyadicAnalysisFilterBank;
Y = dydan(xn);
```

Level 2 yields 3 subbands (two detail-one approximation) Nyquist frequency is 500 Hz

```
D1 = Y(1:512); % subband approx. [250, 500] Hz
D2 = Y(513:768); % subband approx. [125, 250] Hz
Approx = Y(769:1024); % subband approx. [0,125] Hz
```

Subband Ordering For Symmetric Tree Structure Using Dyadic Analysis Filter Bank

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Sampling frequency 1 kHz input length 1024.

```
t = 0:.001:1.023;
x = square(2*pi*30*t);
xn = x' + 0.08*randn(length(x),1);
```

symmetric structure with Daubechies order 3 extremal phase wavelets.

```
dydan = dsp.DyadicAnalysisFilterBank('TreeStructure',...
'Symmetric');
Y = dydan(xn);

```

dsp.DyadicSynthesisFilterBank System object

Package: dsp

Reconstruct signals from subbands

Description

The `DyadicSynthesisFilterBank` object reconstructs signals from subbands with smaller bandwidths and lower sample rates. The filter bank uses a series of highpass and lowpass FIR filters to repeatedly reconstruct the signal.

To reconstruct signals from subbands with smaller bandwidths and lower sample rates:

- 1 Define and set up your synthesis filter bank. See “Construction” on page 4-596.
- 2 Call `step` to reconstruct the signal according to the properties of `dsp.DyadicSynthesisFilterBank`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`dydsyn = dsp.DyadicSynthesisFilterBank` returns a synthesis filter bank, `dydsyn`, that reconstructs a signal from its subbands with smaller bandwidths and smaller sample rates.

`dydsyn = dsp.DyadicSynthesisFilterBank('PropertyName',PropertyValue,...)` returns a synthesis filter bank, `dydsyn`, with each specified property set to the specified value.

Properties

Filter

Type of filter used in filter bank

Specify the type of filter used to determine the highpass and lowpass FIR filters in the filter bank as one of `Custom`, `Haar`, `Daubechies`, `Symlets`, `Coiflets`, `Biorthogonal`, `Reverse Biorthogonal`, or `Discrete Meyer`. If you set this property to `Custom`, the `CustomLowpassFilter` and `CustomHighpassFilter` properties specify the filter coefficients. Otherwise, the object uses the Wavelet Toolbox `wfilters` function to construct the filters. Depending on the filter, the `WaveletOrder` or “`FilterOrder`” on page 4-0 property might apply. For a list of the supported wavelets, see the following table.

Filter	Sample Setting for Related Filter Specification Properties	Corresponding Wavelet Toolbox Function Syntax
Haar	None	<code>wfilters('haar')</code>
Daubechies	<code>H.WaveletOrder = 4</code>	<code>wfilters('db4')</code>
Symlets	<code>H.WaveletOrder = 3</code>	<code>wfilters('sym3')</code>
Coiflets	<code>H.WaveletOrder = 1</code>	<code>wfilters('coif1')</code>
Biorthogonal	<code>H.FilterOrder = ' [3/1] '</code>	<code>wfilters('bior3.1')</code>
Reverse Biorthogonal	<code>H.FilterOrder = ' [3/1] '</code>	<code>wfilters('rbior3.1')</code>
Discrete Meyer	None	<code>wfilters('dmey')</code>

In order to automatically design wavelet-based filters, install the Wavelet Toolbox product. Otherwise, use the `CustomLowpassFilter` and `CustomHighpassFilter` properties to specify lowpass and highpass FIR filters.

CustomLowpassFilter

Lowpass FIR filter coefficients

Specify a vector of lowpass FIR filter coefficients, in descending powers of z . Use a half-band filter that passes the frequency band stopped by the filter specified in the `CustomHighpassFilter` property. This property applies only when you set the `Filter`

property to `Custom`. To perfectly reconstruct a signal decomposed by the `dsp.DyadicAnalysisFilterBank` object, design the filters in the synthesis filter bank to perfectly reconstruct the outputs of the analysis filter bank. Otherwise, the reconstruction is imperfect. The default values of this property specify a perfect reconstruction filter for the default settings of the analysis filter bank (based on a third-order Daubechies wavelet).

CustomHighpassFilter

Highpass FIR filter coefficients

Specify a vector of highpass FIR filter coefficients, in descending powers of z . Use a half-band filter that passes the frequency band stopped by the filter specified in the `CustomLowpassFilter` property. This property applies only when you set the `Filter` property to `Custom`. To perfectly reconstruct a signal decomposed by the `dsp.DyadicAnalysisFilterBank` object, design the filters in the synthesis filter bank to perfectly reconstruct the outputs of the analysis filter bank. Otherwise, the reconstruction is imperfect. The default values of this property specify a perfect reconstruction filter for the default settings of the analysis filter bank (based on a third-order Daubechies wavelet).

WaveletOrder

Wavelet order

Specify the order of the wavelet selected in the `Filter` property. This property applies only when you set the `Filter` property to `Daubechies`, `Symlets` or `Coiflets`. The default is 2.

FilterOrder

Wavelet order for synthesis filter stage

Specify the order of the wavelet for the synthesis filter stage as:

- First order: `'[1/1]'`, `'[1/3]'`, or `'[1/5]'`.
- Second order: `'[2/2]'`, `'[2/4]'`, `'[2/6]'`, or `'[2/8]'`.
- Third order: `'[3/1]'`, `'[3/3]'`, `'[3/5]'`, `'[3/7]'`, or `'[3/9]'`.
- Fourth order: `'[4/4]'`.

- Fifth order: '[5/5]'.
- Sixth order: '[6/8]'.

This property applies only when you set the `Filter` property to `Biorthogonal` or `Reverse Biorthogonal`. The default is '[1/1]'.

NumLevels

Number of filter bank levels

Specify the number of filter bank levels as a scalar integer. An N -level asymmetric structure has $N + 1$ input subbands, and an N -level symmetric structure has 2^N input subbands. The default is 2.

rg

TreeStructure

Structure of filter bank

Specify the structure of the filter bank as `Asymmetric` or `Symmetric`. In the asymmetric structure, the low-frequency subband input to each level is the output of the previous level, while the high-frequency subband input to each level is an input to the filter bank. In the symmetric structure, both the low- and high-frequency subband inputs to each level are outputs from the previous level. The default is `Asymmetric`.

Methods

`step` Reconstruct signal from high- and low-frequency subbands

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)

Examples

Filter Square Wave Using Dyadic Filter Banks

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Denoise square wave input using dyadic analysis and synthesis filter banks.

```
t = 0:.0001:.0511;
x = square(2*pi*30*t);
xn = x' + 0.08*randn(length(x),1);
dydanl = dsp.DyadicAnalysisFilterBank;
```

The filter coefficients correspond to a haar wavelet.

```
dydanl.CustomLowpassFilter = [1/sqrt(2) 1/sqrt(2)];
dydanl.CustomHighpassFilter = [-1/sqrt(2) 1/sqrt(2)];
dydsyn = dsp.DyadicSynthesisFilterBank;
dydsyn.CustomLowpassFilter = [1/sqrt(2) 1/sqrt(2)];
dydsyn.CustomHighpassFilter = [1/sqrt(2) -1/sqrt(2)];
C = dydanl(xn);
```

Subband outputs.

```
C1 = C(1:256); C2 = C(257:384); C3 = C(385:512);
```

Set higher frequency coefficients to zero to remove the noise.

```
x_den = dydsyn([zeros(length(C1),1);...
               zeros(length(C2),1);C3]);
```

Plot the original and denoised signals.

```
subplot(2,1,1), plot(xn); title('Original noisy Signal');
subplot(2,1,2), plot(x_den); title('Denoised Signal');
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Dyadic Synthesis Filter Bank block reference page. The object properties correspond to the block parameters, except:

The object only receives data as a vector or matrix of concatenated subbands, as specified using the `step` method.

See Also

`dsp.DyadicAnalysisFilterBank` | `dsp.SubbandSynthesisFilter`

Introduced in R2012a

step

System object: dsp.DyadicSynthesisFilterBank

Package: dsp

Reconstruct signal from high- and low-frequency subbands

Syntax

```
X = step(dydsyn,S)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`X = step(dydsyn,S)` reconstructs the concatenated subband input `S` to output `X`. Each column of input `S` contains the subbands for an independent signal. Upper rows contain the high-frequency subbands, and lower rows contain the low-frequency subbands. The number of rows of `S` must be a multiple of 2^N , where N is the value of the `NumLevels` property.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.FarrowRateConverter System object

Package: dsp

Polynomial sample rate converter with arbitrary conversion factor

Description

The `FarrowRateConverter` System object implements an efficient polynomial-fit sample rate conversion filter using a Farrow structure. You can use this object to convert the sample rate of a signal up or down by an arbitrary factor. This object supports fixed-point operations.

To convert the sample rate of a signal:

- 1 Define and set up your sample rate converter. See “Construction” on page 4-604.
- 2 Call `step` to convert the sample rate according to the properties of `dsp.FarrowRateConverter`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`src = dsp.FarrowRateConverter` creates a polynomial filter-based sample rate converter System object, `src`. For each channel of an input signal, `src` converts the input sample rate to the output sampling rate.

`src = dsp.FarrowRateConverter(Name,Value)` uses additional rate and filter properties, specified by one or more `Name,Value` pair arguments.

`src = dsp.FarrowRateConverter(FSIN,FSOUT,TOL,NP)` returns a sample rate converter object, `src`, with `InputSampleRate` property set to `FSIN`,

OutputSampleRate property set to FSOUT, OutputRateTolerance property set to TOL, and PolynomialOrder property set to NP.

Properties

InputSampleRate — Sample rate of input signal

44100 Hz (default) | positive scalar in Hz

Sample rate of the input signal, specified as a positive scalar in Hz. The input sample rate must be greater than the bandwidth of interest. The default is 44.1 kHz.

OutputSampleRate — Sample rate of output signal

48000 Hz (default) | positive scalar in Hz

Sample rate of the output signal, specified as a positive scalar in Hz. The output sample rate can be higher or lower than the input sample rate. The default is 48 kHz.

OutputRateTolerance — Maximum allowed tolerance for output sample rate

0 (default) | positive scalar

Maximum allowed tolerance for the sample rate of the output signal, specified as a positive scalar from 0 through 0.5, inclusive. The default is 0.

The actual output sample rate varies but is within the specified range. For example, if OutputRateTolerance is specified as 0.01, then the actual output sample rate is in the range given by OutputSampleRate \pm 1%. This flexibility allows for a simpler filter design often.

Specification — Polynomial specification

'Polynomial order' (default) | 'Coefficients'

Method used to specify the polynomial interpolator coefficients, specified as one of the following:

- 'Polynomial order' — Specify the order of the Lagrange interpolation filter polynomial through the PolynomialOrder property.
- 'Coefficients' — Specify the polynomial coefficients directly through the Coefficients property.

PolynomialOrder — Order of filter polynomial

3 (default) | positive integer less than or equal to 4

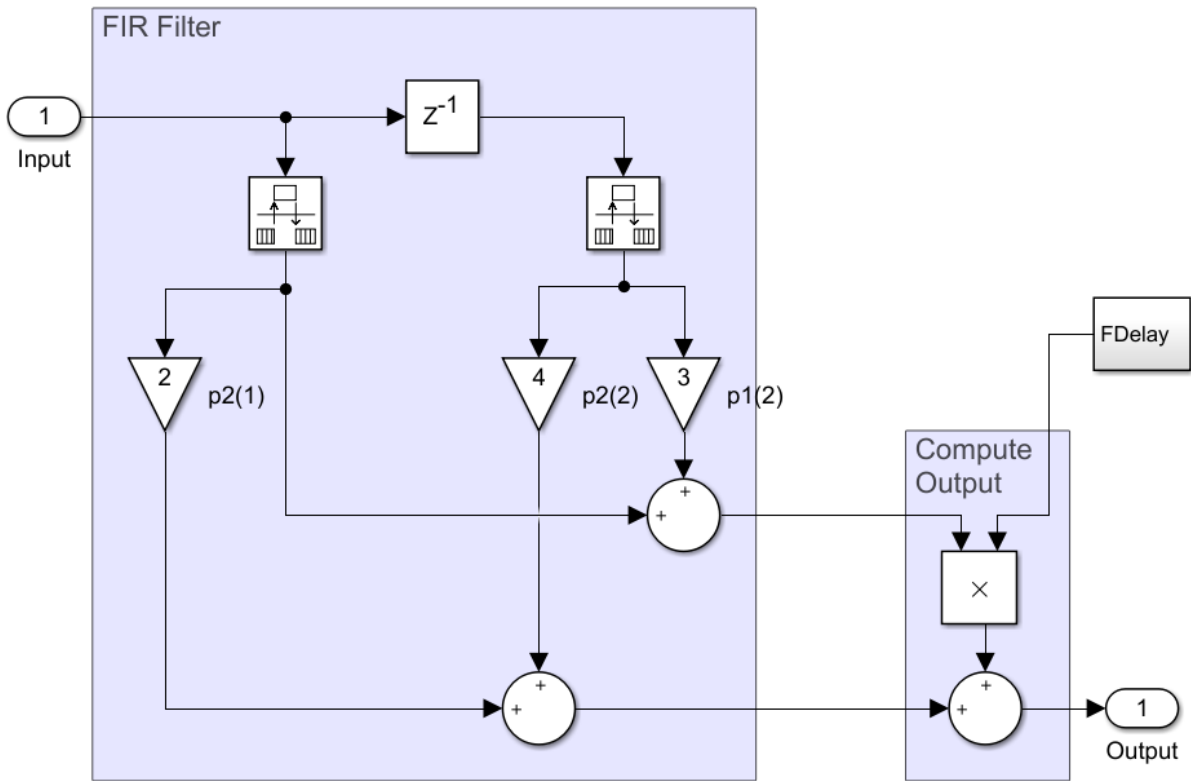

Order of the Lagrange interpolation filter polynomial, specified as a positive integer less than or equal to 4. The default is 3. This property applies only when you set `Specification` to `'Polynomial order'`.

Coefficients — Filter polynomial coefficients

`[-1 1; 1 0]` (default) | real-valued square matrix

Filter polynomial coefficients, specified as a real-valued square matrix. The default is `[-1 1; 1 0]`. This property applies only when you set `Specification` to `'Coefficients'`.

Here is the signal flow graph for farrow rate converter with coefficients set to `[1 2; 3 4]`.

Each branch of the FIR filter corresponds to each row of the coefficients matrix.

Fixed-Point Properties

RoundingMethod — Rounding method for fixed-point operations

'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Zero'

Rounding method, specified as a character vector. For more information on the rounding modes, see “Precision and Range”.

This property is not tunable.

OverflowAction — Overflow action for fixed-point operations

'Wrap' | 'Saturate'

Overflow action, specified as `Wrap` | `Saturate`. For more details on the overflow modes, see the 'Overflow Handling' section of “Precision and Range”.

This property is not tunable.

CoefficientsDataType — Data type of the filter coefficients

`numerictype(1,16)` | `numerictype(1,16,3)`

Data type of the filter coefficients, specified as a signed `numerictype` object. The default, `numerictype(1,16)` corresponds to a signed numeric type object with 16-bit coefficients. To give the best possible precision, the fraction length of this data type is determined based on the coefficient values.

This property is not tunable.

FractionalDelayDataType — Data type of the fractional delay

`numerictype(0,8)` | `numerictype(0,16)`

Data type of the fractional delay, specified as an unsigned `numerictype` object. The default, `numerictype(0,8)` corresponds to an unsigned fixed-point fractional delay data type object with 8-bit word length. To give the best possible precision, the fraction length of this data type is determined based on the fractional delay values.

This property is not tunable.

MultiplicandDataType — Data type of the multiplicand

`numerictype(1,16,13)`

Data type of the multiplicand, specified as a signed `numerictype` object. The default, `numerictype(1,16,13)` corresponds to a signed fixed-point multiplicand data type with 16-bit word length and 13-bit fraction length.

This property is not tunable.

OutputDataType — Data type of the farrow rate converter output

'Same word length as input' | 'Same as accumulator' | `numerictype(1,16)`
| `numerictype(1,16,0)`

Data type of the output data type, specified as one of the following:

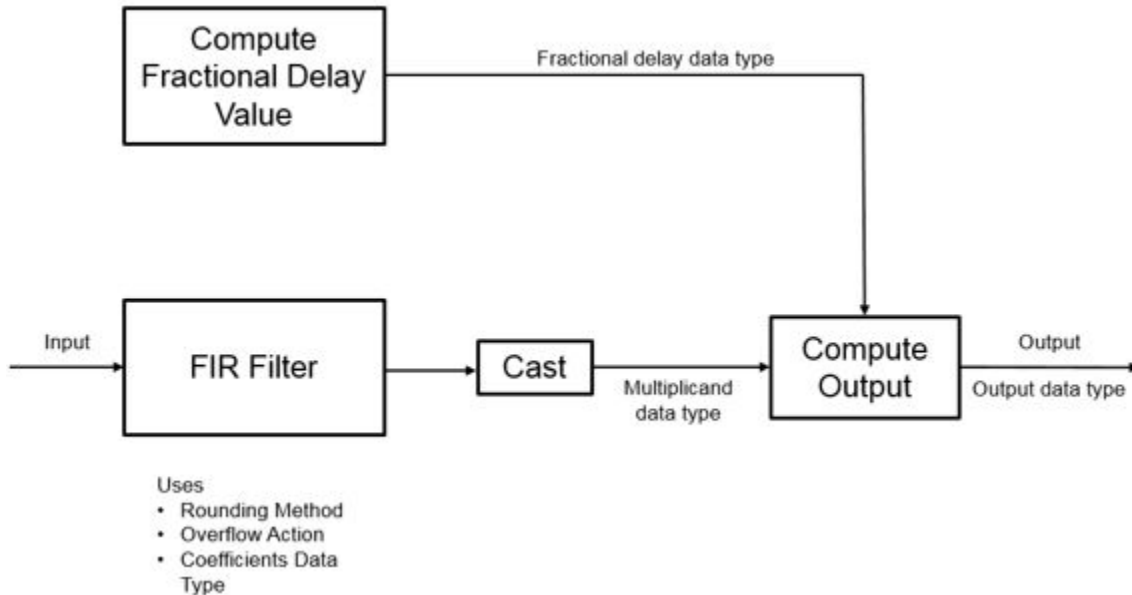

- `Same word length as input` (default) — Output word length and fraction lengths are the same as the input.

- Same as `accumulator` — Output word length and fraction lengths are the same as the accumulator.
- `numerictype(1,16)` — Signed fixed-point output data type with 16-bit word length. To give the best possible precision, the fraction length is computed based on the input range. The dynamic range of the input is preserved.
- `numerictype(1,16,0)` — Signed fixed-point output data type with 16-bit word length and zero fraction length.

This property is not tunable.

Fixed-Point Data Types

The signal flow diagram shows the data types used within the farrow rate converter for fixed-point signals and floating-point signals. You can specify these data types in the Farrow rate converter. If the input is floating point, all the data types within the signal flow diagram have the same data type as the input, which can be single or double.

If the input is fixed point, the FIR filter uses the rounding mode, overflow mode, and the coefficients data type data you provide to the Farrow rate converter. The accumulator data type and the product data type in the signal flow are full precision.

Methods

<code>cost</code>	Implementation cost
<code>freqz</code>	Frequency response
<code>getPolynomialCoefficients</code>	Polynomial filter coefficients
<code>getActualOutputRate</code>	Actual output rate, accounting for tolerance
<code>getRateChangeFactors</code>	Overall interpolation and decimation factors
<code>info</code>	Filter implementation details
<code>reset</code>	Reset internal states of polynomial sample rate converter
<code>step</code>	Convert sample rate of signal

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

Upsample an Audio Signal Using Farrow Sample Rate Converter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Create a Farrow rate converter object to convert an audio signal from 44.1 kHz to 96 kHz. Set the polynomial order for the Farrow filter.

```
fs1 = 44.1e3;
fs2 = 96e3;
```

```

LagrangeOrder = 2; % 1 = linear interpolation
frc = dsp.FarrowRateConverter('InputSampleRate', fs1, ...
                             'OutputSampleRate', fs2, ...
                             'PolynomialOrder', LagrangeOrder);
ar = dsp.AudioFileReader('guitar10min.ogg', 'SamplesPerFrame', 14700);
aw = dsp.AudioFileWriter('guitar10min_96kHz.wav', 'SampleRate', fs2);

```

Check the resulting interpolation (L) and decimation (M) factors.

```
[L,M] = getRateChangeFactors(frc)
```

```
L = 320
```

```
M = 147
```

Display the polynomial the object uses to fit the input samples.

```
coeffs = getPolynomialCoefficients(frc)
```

```
coeffs =
```

```

    0.5000    -0.5000         0
   -1.0000         0     1.0000
    0.5000     0.5000         0

```

Convert 100 frames of the audio signal. Write the result to a file.

```

for n = 1:1:100
    x = ar();
    y = frc(x);
    aw(y);
end

```

Release the AudioFileWriter object to complete creation of the output file.

```

release(aw)
release(ar)

```

Plot the input and output signals of the 100th frame of data. Delay the input to compensate for the latency introduced by the filter.

```

t1 = 0:1/fs1:1/30-1/fs1;
t2 = 0:1/fs2:1/30-1/fs2;

delay = ceil((LagrangeOrder+1)/2)/fs1;

```

```
e11 = 1:length(t1)-delay;
e12 = 1:length(t2);
e12(1:delay) = [];

figure

subplot(2,1,1)
plot(t1(1:length(e11)),x(e11,1))
hold on
plot(t1(1:length(e11)),x(e11,2))
title('Input channels')

subplot(2,1,2)
plot(t2(1:length(e12)),y(e12,1))
hold on
plot(t2(1:length(e12)),y(e12,2))
xlabel('Time (s)')
title('Output channels')
```

Zoom in to see the difference in sample rates.

figure

```
subplot(2,1,1)
plot(t1(1:length(e11)),x(e11,1),'o-')
hold on
plot(t2(1:length(e12)),y(e12,1),'d--')
xlim([0.0104 0.0107])
title('First channel')
legend('Input','Output')
```

```
subplot(2,1,2)
plot(t1(1:length(e11)),x(e11,2),'o-')
```

```
hold on
plot(t2(1:length(e12)),y(e12,2),'d--')
xlim([0.0104 0.0107])
xlabel('Time (s)')
title('Second channel')
legend('Input','Output')
```

Using Output Tolerance To Reduce Input Size Restriction

Create a Farrow rate converter with 0% tolerance. The output rate matches `OutputSampleRate` exactly. However, the input size must be a multiple of the decimation factor, `M`. In this case `M` is 320.

```
frc = dsp.FarrowRateConverter('InputSampleRate', 96e3, 'OutputSampleRate', 44.1e3);
FsOut = getActualOutputRate(frc)
[L,M] = getRateChangeFactors(frc)
```

```
FsOut =
    44100
```

```
L =
    147
```

```
M =
    320
```

Allow a 1% tolerance on the output rate and observe the difference in decimation factor. `M` is now only 13. The lower decimation factor allows more flexibility in input size. The output rate is within the range `OutputSampleRate` $\pm 1\%$.

```
frc.OutputRateTolerance = 0.01;
FsOut = getActualOutputRate(frc)
[Le,Me] = getRateChangeFactors(frc)
```

```
FsOut =
    4.4308e+04
```

```
Le =
    6
```

Me =

Algorithms

Farrow filters implement piecewise polynomial interpolation using Horner’s rule to compute samples from the polynomial. The polynomial coefficients used to fit the input samples correspond to the Lagrange interpolation coefficients.

Once a polynomial is fitted to the input data, the value of the polynomial can be calculated at any point. Therefore, a polynomial filter allows for interpolation at arbitrary locations between input samples.

You can use a polynomial of any order to fit to the existing samples. However, since large order polynomials oscillate a lot, polynomials of order 1, 2, 3, or 4 are used in practice.

The block computes interpolated values at the desired locations by varying only the fractional interval, μ . This interval is the distance between the previous input sample and the current output sample. All filter coefficients remain constant.

- The input samples, x , are filtered using $M + 1$ FIR filters, where M is the polynomial order.
- The outputs of these filters are multiplied by the fractional delay, μ .
- The output, y , is the sum of the multiplication results.

Topics

“Efficient Sample Rate Conversion Between Arbitrary Factors”

Introduced in R2014b

cost

System object: `dsp.FarrowRateConverter`

Package: `dsp`

Implementation cost

Syntax

```
c = cost(src)
```

Description

`c = cost(src)` returns a structure, `c`, whose fields contain information about the computational cost of implementing a polynomial sample rate converter, `src`.

Input Arguments

src — Polynomial sample rate converter

`FarrowRateConverter` System object

Polynomial sample rate converter, specified as a `FarrowRateConverter` System object.

Output Arguments

c — Output structure

structure

Output structure containing information about the computational cost of `src`, including the number of:

- Coefficients
- States

- Multiplications per unit sample
- Additions per unit sample

Examples

Computational Cost of Farrow Rate Converter

Create a polynomial sample rate converter with default values. Determine its computational cost: the number of coefficients, states, multiplications per unit sample, and additions per unit sample.

```
frc = dsp.FarrowRateConverter;
cst = cost(frc)

cst =

    struct with fields:

        NumCoefficients: 16
        NumStates: 3
        MultiplicationsPerInputSample: 13.0612
        AdditionsPerInputSample: 11.9728
```

Repeat the computation, allowing for a 10% tolerance in the output sample rate.

```
frc.OutputRateTolerance = 0.1;
ctl = cost(frc)

ctl =

    struct with fields:

        NumCoefficients: 16
        NumStates: 3
        MultiplicationsPerInputSample: 12
        AdditionsPerInputSample: 11
```

freqz

System object: `dsp.FarrowRateConverter`

Package: `dsp`

Frequency response

Syntax

```
[h, fout] = freqz(src, n, range)
```

```
[h, fout] = freqz(src, fin)
```

Description

`[h, fout] = freqz(src, n, range)` returns the complex frequency response, `h`, of the polynomial sample rate converter, `src`, evaluated at the `n` frequencies returned in `fout`. `range` is the frequency range over which the response is computed. The sample rate is taken to be the largest of `InputSampleRate` and `OutputSampleRate`.

`[h, fout] = freqz(src, fin)` returns the complex frequency response evaluated at the frequency points specified in the vector `fin`. `fin` is assumed to be expressed in hertz.

Input Arguments

src — Polynomial sample rate converter

`FarrowRateConverter` System object

Polynomial sample rate converter, specified as a `FarrowRateConverter` System object.

n — Number of evaluation points

512 (default) | positive integer

Number of frequencies for response evaluation, specified as a positive integer scalar. If not specified, `n` defaults to 512.

range — Range of frequencies`'half' (default) | 'whole'`

Range of frequencies considered when computing the frequency response, specified as either `'half'` (from 0 to π) or `'whole'` (from 0 to 2π). If not specified, `range` defaults to `'half'`.

fin — Frequencies`vector`

Frequencies at which the response is evaluated, specified as a vector.

Output Arguments

h — Complex frequency response`vector`

Complex frequency response, returned as a vector.

fout — Frequencies`vector`

Frequencies at which the response is evaluated, returned as a vector.

Examples

Frequency Response of Farrow Rate Converter

Create a polynomial sample rate converter with default properties. Compute and display the frequency response.

```
frc = dsp.FarrowRateConverter;  
[h,f] = freqz(frc);  
plot(f,20*log10(abs(h)))
```

getPolynomialCoefficients

System object: dsp.FarrowRateConverter

Package: dsp

Polynomial filter coefficients

Syntax

```
[c] = getPolynomialCoefficients(src)
```

Description

[c] = getPolynomialCoefficients(src) returns the polynomial coefficients that the polynomial filter sample rate converter, src, uses to achieve the requested rate conversion.

Input Arguments

src — Polynomial filter sample rate converter

FarrowRateConverter System object

Polynomial sample rate converter, specified as a FarrowRateConverter System object.

Output Arguments

c — Polynomial filter coefficients

matrix

Polynomial filter coefficients, returned as a matrix.

Examples

Polynomial Coefficients of the Default Farrow Rate Converter

Create a default Farrow Rate Converter object to convert a signal from 44.1 kHz to 48 kHz.

```
FRC = dsp.FarrowRateConverter()

FRC =
  dsp.FarrowRateConverter with properties:

    Main
      InputSampleRate: 44100
      OutputSampleRate: 48000
      OutputRateTolerance: 0
      Specification: 'Polynomial order'
      PolynomialOrder: 3

  Show all properties
```

Check the self-designed polynomial.

```
coeffs = getPolynomialCoefficients(FRC)

coeffs =

   -0.1667    0.5000   -0.3333         0
    0.5000   -1.0000   -0.5000    1.0000
   -0.5000    0.5000    1.0000         0
    0.1667         0   -0.1667         0
```

getActualOutputRate

System object: dsp.FarrowRateConverter

Package: dsp

Actual output rate, accounting for tolerance

Syntax

```
fsout = getActualOutputRate(src)
```

Description

`fsout = getActualOutputRate(src)` returns the actual output sample rate yielded by a `FarrowRateConverter` System object, accounting for the `OutputRateTolerance` parameter.

Input Arguments

src — Polynomial filter sample rate converter

`FarrowRateConverter` System object

Polynomial sample rate converter, specified as a `FarrowRateConverter` System object.

Output Arguments

fsout — Actual output sample rate

scalar

Actual output sample rate, returned as a scalar expressed in hertz.

Examples

Output Sample Rate of Farrow Rate Converter with Given Tolerance

Get the actual output sample rate for conversion between 44.1 kHz and 48 kHz, given a tolerance of 1%.

```
frc = dsp.FarrowRateConverter();  
frc.OutputRateTolerance = 0.01;  
FsOut = getActualOutputRate(frc)
```

```
FsOut = 4.8109e+04
```

getRateChangeFactors

System object: dsp.FarrowRateConverter

Package: dsp

Overall interpolation and decimation factors

Syntax

```
[L,M] = getRateChangeFactors(src)
```

Description

`[L,M] = getRateChangeFactors(src)` returns the overall interpolation factor, *L*, and the overall decimation factor, *M*, corresponding to the polynomial filter sample rate converter, *src*. The overall decimation factor affects the allowable frame size of the input signal, which must be an integer multiple of *M*.

Input Arguments

src — Polynomial sample rate converter

FarrowRateConverter System object

Polynomial sample rate converter, specified as a FarrowRateConverter System object.

Output Arguments

L — Overall interpolation factor

scalar

Overall interpolation factor, returned as a scalar.

M — Overall decimation factor

scalar

Overall decimation factor, returned as a scalar.

Examples

Resampling Factors of Farrow Rate Converter

Create a default Farrow rate converter object to convert a signal from 44.1 kHz to 48 kHz. Determine its overall interpolation (L) and decimation (M) factors.

```
frc = dsp.FarrowRateConverter

frc =
  dsp.FarrowRateConverter with properties:

    Main
      InputSampleRate: 44100
      OutputSampleRate: 48000
      OutputRateTolerance: 0
      Specification: 'Polynomial order'
      PolynomialOrder: 3

  Show all properties

[L,M] = getRateChangeFactors(frc)

L = 160
M = 147
```

info

System object: dsp.FarrowRateConverter

Package: dsp

Filter implementation details

Syntax

```
info(src)
```

Description

`info(src)` displays information about the `FarrowRateConverter` System object, `src`.

Input Arguments

src — Polynomial sample rate converter

`FarrowRateConverter` System object

Polynomial sample rate converter, specified as a `FarrowRateConverter` System object.

Examples

Displaying Filter Information for Farrow Rate Converter

Use the `info` method to display the filter implementation details of a Farrow rate converter object.

```
frc = dsp.FarrowRateConverter;  
info(frc)
```

```
ans =
```

10x52 char array

```
'Discrete-Time FIR Multirate Filter (real)      '  
'-----'  
'Filter Structure      : Farrow Sample-Rate Converter'  
'Interpolation Factor : 160                          '  
'Decimation Factor    : 147                          '  
'Filter Length        : 4                            '  
'Stable                : Yes                          '  
'Linear Phase          : No                            '  
'  
'Arithmetic            : double                       '
```

reset

System object: dsp.FarrowRateConverter

Package: dsp

Reset internal states of polynomial sample rate converter

Syntax

```
reset(src)
```

Description

`reset(src)` resets the internal states of a polynomial `FarrowRateConverter` System object, `src`, to their initial values.

Input Arguments

src — Polynomial sample rate converter

`FarrowRateConverter` System object

Polynomial sample rate converter, specified as a `FarrowRateConverter` System object.

step

System object: `dsp.FarrowRateConverter`

Package: `dsp`

Convert sample rate of signal

Syntax

```
y = step(src,x)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`y = step(src,x)` resamples input `x` to create output `y` according to the rate conversion defined by `src`.

Input Arguments

src — Polynomial sample rate converter

`FarrowRateConverter` System object

Polynomial sample rate converter, specified as a `FarrowRateConverter` System object.

x — Input signal

vector | matrix

Input signal, specified as a vector or matrix. The row length of `x` must be a multiple of the overall decimation factor. Each column of `x` is treated as a separate channel.

Output Arguments

y — Resampled signal

vector | matrix

Resampled signal, returned as a vector or matrix.

Examples

Upsample an Audio Signal Using Farrow Sample Rate Converter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Create a Farrow rate converter object to convert an audio signal from 44.1 kHz to 96 kHz. Set the polynomial order for the Farrow filter.

```
fs1 = 44.1e3;
fs2 = 96e3;
LagrangeOrder = 2; % 1 = linear interpolation
frc = dsp.FarrowRateConverter('InputSampleRate',fs1,...
                              'OutputSampleRate',fs2,...
                              'PolynomialOrder',LagrangeOrder);
ar = dsp.AudioFileReader('guitar10min.ogg','SamplesPerFrame',14700);
aw = dsp.AudioFileWriter('guitar10min_96kHz.wav','SampleRate',fs2);
```

Check the resulting interpolation (L) and decimation (M) factors.

```
[L,M] = getRateChangeFactors(frc)
```

```
L = 320
```

```
M = 147
```

Display the polynomial the object uses to fit the input samples.

```
coeffs = getPolynomialCoefficients(frc)
```

```
coeffs =
```

```
    0.5000    -0.5000         0
   -1.0000         0    1.0000
    0.5000    0.5000         0
```

Convert 100 frames of the audio signal. Write the result to a file.

```
for n = 1:1:100
    x = ar();
    y = frc(x);
    aw(y);
end
```

Release the `AudioFileWriter` object to complete creation of the output file.

```
release(aw)
release(ar)
```

Plot the input and output signals of the 100th frame of data. Delay the input to compensate for the latency introduced by the filter.

```
t1 = 0:1/fs1:1/30-1/fs1;
t2 = 0:1/fs2:1/30-1/fs2;

delay = ceil((LagrangeOrder+1)/2)/fs1;
e11 = 1:length(t1)-delay;
e12 = 1:length(t2);
e12(1:delay) = [];

figure

subplot(2,1,1)
plot(t1(1:length(e11)),x(e11,1))
hold on
plot(t1(1:length(e11)),x(e11,2))
title('Input channels')

subplot(2,1,2)
plot(t2(1:length(e12)),y(e12,1))
hold on
plot(t2(1:length(e12)),y(e12,2))
xlabel('Time (s)')
title('Output channels')
```

Zoom in to see the difference in sample rates.

figure

```
subplot(2,1,1)
plot(t1(1:length(e11)),x(e11,1),'o-')
hold on
plot(t2(1:length(e12)),y(e12,1),'d--')
xlim([0.0104 0.0107])
title('First channel')
legend('Input','Output')
```

```
subplot(2,1,2)
plot(t1(1:length(e11)),x(e11,2),'o-')
```

```
hold on
plot(t2(1:length(e12)),y(e12,2),'d--')
xlim([0.0104 0.0107])
xlabel('Time (s)')
title('Second channel')
legend('Input','Output')
```

dsp.FastTransversalFilter System object

Package: dsp

Fast Transversal filter

Description

The `dsp.FastTransversalFilter` computes output, error and coefficients using a fast transversal least-squares FIR adaptive filter.

To implement the adaptive FIR filter object:

- 1 Define and set up your adaptive FIR filter object. See “Construction” on page 4-637.
- 2 Call `step` to implement the filter according to the properties of `dsp.FastTransversalFilter`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`ftf = dsp.FastTransversalFilter` returns a System object, `ftf`, which is a fast transversal, least-squares FIR adaptive filter. This System object is used to compute the filtered output and the filter error for a given input and desired signal.

`ftf = dsp.FastTransversalFilter('PropertyName', PropertyValue,...)` returns a `FastTransversalFilter` System object, `ftf`, with each specified property set to the specified value.

`ftf = dsp.FastTransversalFilter(LEN, 'PropertyName', PropertyValue,...)`

returns a `FastTrasversalFilter` System object, `ftf`. In this case, the `Length` property set to `LEN`, and other specified properties set to the specified values.

Properties

Method

Method to calculate filter coefficients

Specify the method used to calculate filter coefficients as one of 'Fast transversal least-squares' | 'Sliding-window fast transversal least-squares'. The default value is 'Fast transversal least-squares'. For algorithms used to implement these three different methods, refer to [1]. This property is nontunable.

Length

Length of filter coefficients vector

Specify the length of the FIR filter coefficients vector as a positive integer value. This property is nontunable.

The default value is 32.

SlidingWindowBlockLength

Width of sliding window

Specify the width of the sliding window as a positive integer value greater than or equal to the `Length` property value. This property applies only if the `Method` property is set to 'Sliding-window fast transversal least-squares'. The default vale is the value of the `Length` property. This property is nontunable.

ForgettingFactor

Fast transversal filter forgetting factor

Specify the fast transversal filter forgetting factor as a positive numeric value. Setting this value to 1 denotes infinite memory while adaptation. Setting this property value to 1 denotes infinite memory while adapting to find the new filter. For best results, set this property to a value that lies in the range $[1-0.5/L, 1]$, where `L` is the `Length` property

value. This property applies only if the Method property is set to 'Fast transversal least-squares'. The default value is 1. This property is tunable.

InitialPredictionErrorPower

Initial prediction error power

Specify the initial value of the forward and backward prediction error vectors as a positive numeric scalar. This scalar should be sufficiently large to maintain stability and prevent an excessive number of Kalman gain rescues. The default value is 10.

This property is tunable.

InitialConversionFactor

Initial conversion factor (gamma)

Specify the initial value of the conversion factor of the fast transversal filter. If the Method property is set to 'Fast transversal least-squares', this property must be a positive numeric value less than or equal to 1. In this case, the default value is 1. If the Method property is set to 'Sliding-window fast transversal least-squares', this property must be a 2-element numeric vector. The first element of this vector must lie within the range $[0, 1]$, and the second element must be less than or equal to -1 . In this case, the default value is $[1, -1]$.

This property is tunable.

InitialCoefficients

Initial coefficients of the filter

Specify the initial values of the FIR adaptive filter coefficients as a scalar or a vector of length equal to the value of the Length property. The default value is 0.

This property is tunable.

LockCoefficients

Locked status of the coefficient updates

Specify whether to lock the filter coefficient values. By default, the value of this property is `false`, and the object continuously updates the filter coefficients. If this property is set to `true`, the filter coefficients do not update and their values remain the same.

This property is tunable.

Methods

mseSim	Mean-square error for Fast Transversal filter
reset	Reset filter states for Fast Transversal filter
step	Apply Fast Transversal filter to input

Common to All System Objects	
clone	Create System object with same property values

getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

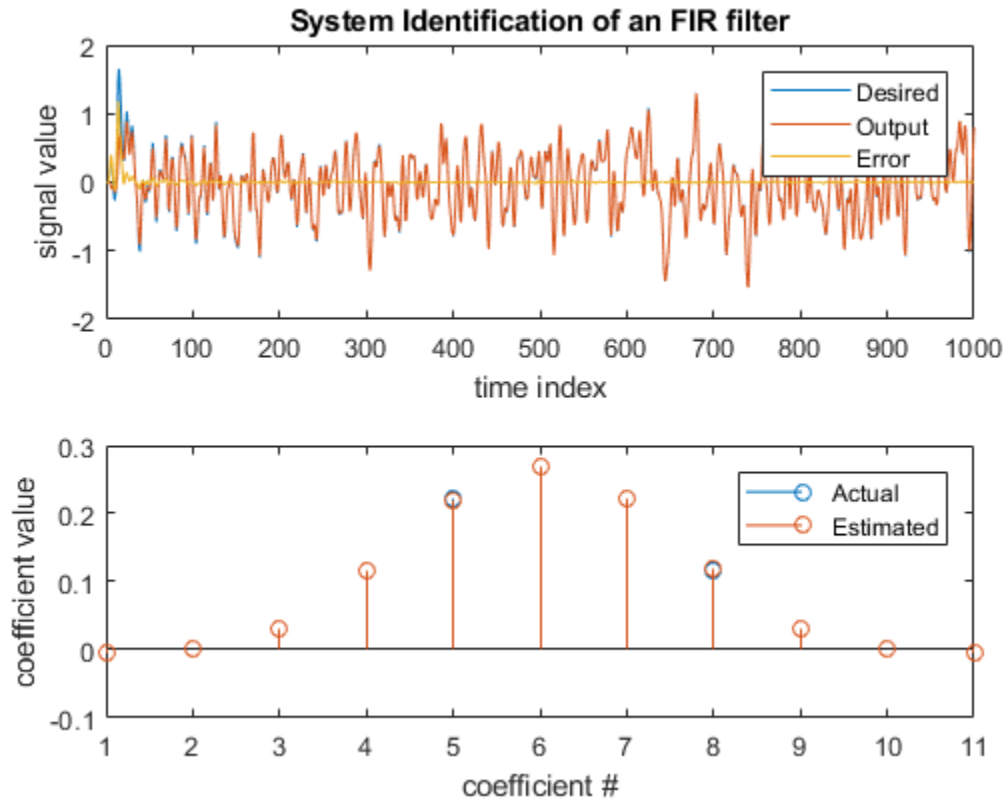

System Identification Using Fast Transversal Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
ftf1 = dsp.FastTransversalFilter(11, 'ForgettingFactor', 0.99);  
filt = dsp.FIRFilter;  
filt.Numerator = fir1(10, .25);  
x = randn(1000, 1);  
d = filt(x) + 0.01*randn(1000, 1);  
[y, e] = ftf1(x, d);  
w = ftf1.Coefficients;  
subplot(2, 1, 1);  
plot(1:1000, [d, y, e]);  
title('System Identification of an FIR filter');
```

```
legend('Desired','Output','Error');  
xlabel('time index');  
ylabel('signal value');  
subplot(2,1,2);  
stem([filt.Numerator; w].');  
legend('Actual','Estimated');  
xlabel('coefficient #');  
ylabel('coefficient value');
```

mstesim

System object: dsp.FastTransversalFilter

Package: dsp

Mean-square error for Fast Transversal filter

Syntax

```
MSE = mstesim(sysObj, X, D)
[MSE, MEANW, W, TRACEK] = mstesim(sysObj, X, D)
[...] = mstesim(sysObj, X, D, M)
```

Description

`MSE = mstesim(sysObj, X, D)` returns a sequence of mean-square errors. This column vector contains estimates of the mean-square error of the adaptive filter at each time instant. The length of `MSE` is equal to `SIZE(X, 1)`. The columns of the matrix `X` contain individual input signal sequences, and the columns of the matrix `D` contain corresponding desired response signal sequences.

`[MSE, MEANW, W, TRACEK] = mstesim(sysObj, X, D)` calculates three parameters corresponding to the simulated behavior of the adaptive filter defined by `sysObj`. `MEANW` is a sequence of coefficient vector means. The columns of this matrix contain estimates of the mean values of the adaptive filter coefficients at each time instant. The dimensions of `MEANW` are `(SIZE(X, 1))` by `(sysObj.length)`. `W` is an estimate of the final values of the adaptive filter coefficients for the algorithm corresponding to `sysObj`. `TRACEK` is a sequence of total coefficient error powers. This column vector contains estimates of the total coefficient error power of the adaptive filter at each time instant. The length of `TRACEK` is equal to `SIZE(X, 1)`.

`[...] = mstesim(sysObj, X, D, M)` specifies an optional decimation factor for computing `MSE`, `MEANW`, and `TRACEK`. If `M > 1`, every M^{th} predicted value of each of these sequences is saved. If omitted, the value of `M` is the default, which is 1.

reset

System object: dsp.FastTransversalFilter

Package: dsp

Reset filter states for Fast Transversal filter

Syntax

```
reset(sysObj)
```

Description

`reset(sysObj)` resets the internal states of the System object, `sysObj`, to their initial values. The reset method is always a no-op for unlocked System objects, as the states may not be allocated when the object is not locked.

step

System object: dsp.FastTransversalFilter

Package: dsp

Apply Fast Transversal filter to input

Syntax

```
[Y, ERR] = step(sysObj, x, D)
Y = step(sysObj, x)
[Y1, ..., YN] = step(sysObj, x)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

`[Y, ERR] = step(sysObj, x, D)` filters the input `x`, using `D` as the desired signal, and returns the filtered output in `Y` and the filter error in `ERR`. The System object estimates the filter weights needed to minimize the error between the output signal and the desired signal.

`Y = step(sysObj, x)` processes the input data, `x`, to produce the output, `Y`, from the System object, `sysObj`. `[Y1, ..., YN] = step(sysObj, x)` produces `N` outputs.

Every System object has a `step` method. The `step` method processes the input data according to the object algorithm. The number of input and output arguments depends on the algorithm, and may depend also on one or more property settings. The `step` method for some objects accepts fixed-point (fi) inputs.

Calling `step` on an object puts that object into a locked state. When locked, you cannot change nontunable properties or any input characteristics (size, data type and complexity) without reinitializing (unlocking and relocking) the object.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.FFT System object

Package: dsp

Discrete Fourier transform

Description

The `FFT` object computes the discrete Fourier transform (DFT) of an input. The object uses one or more of the following fast Fourier transform (FFT) algorithms depending on the complexity of the input and whether the output is in linear or bit-reversed order:

- Double-signal algorithm
- Half-length algorithm
- Radix-2 decimation-in-time (DIT) algorithm
- Radix-2 decimation-in-frequency (DIF) algorithm
- An algorithm chosen by `FFTW` [1], [2]

To compute the DFT of an input:

- 1 Define and set up your `FFT` object. See “Construction” on page 4-647.
- 2 Call `step` to compute the DFT of the input according to the properties of `dsp.FFT`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`fft = dsp.FFT` returns a `FFT` object, `H`, that computes the DFT of an N -D array. For column vectors or multidimensional arrays, the `FFT` object computes the DFT along the

first dimension. If the input is a row vector, the `FFT` object computes a row of single-sample DFTs and issues a warning.

`H = dsp.FFT('PropertyName', PropertyValue, ...)` returns a `FFT` object, `H`, with each property set to the specified value.

Properties

FFTImplementation

FFT implementation

Specify the implementation used for the FFT as one of `Auto` | `Radix-2` | `FFTW`. When you set this property to `Radix-2`, the FFT length must be a power of two.

BitReversedOutput

Order of output elements relative to input elements

Designate order of output channel elements relative to order of input elements. Set this property to `true` to output the frequency indices in bit-reversed order. The default is `false`, which corresponds to a linear ordering of frequency indices.

Normalize

Divide butterfly outputs by two

Set this property to `true` if the output of the FFT should be divided by the FFT length. This option is useful when you want the output of the FFT to stay in the same amplitude range as its input. This is particularly useful when working with fixed-point data types.

The default value of this property is `false` with no scaling.

FFTLengthSource

Source of FFT length

Specify how to determine the FFT length as `Auto` or `Property`. When you set this property to `Auto`, the FFT length equals the number of rows of the input signal. The default is `Auto`.

FFTLength

FFT length

Specify the FFT length. This property applies when you set the `FFTLengthSource` property to `Property`. The default is 64.

This property must be a power of two when the input is a fixed-point data type, or when you set the “`BitReversedOutput`” on page 4-0 property to `true`, or when you set the `FFTImplementation` property to `Radix-2`.

WrapInput

Boolean value of wrapping or truncating input

Wrap input data when FFT length is shorter than input length. If this property is set to `true`, modulo-length data wrapping occurs before the FFT operation, given FFT length is shorter than the input length. If this property is set to `false`, truncation of the input data to the FFT length occurs before the FFT operation. The default is `true`.

Fixed-Point Properties**RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, `Zero`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

SineTableDataType

Sine table word and fraction lengths

Specify the sine table data type as `Same word length as input` or `Custom`. The default is `Same word length as input`.

CustomSineTableDataType

Sine table word and fraction lengths

Specify the sine table fixed-point type as an unscaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `SineTableDataType` property to `Custom`. The default is `numerictype([],16)`.

ProductDataType

Product word and fraction lengths

Specify the product data type as `Full precision`, `Same as input`, or `Custom`. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator data type as `Full precision`, `Same as input`, `Same as product`, or `Custom`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output data type as one of `Full` precision, `Same as input`, `Custom`. The default is `Full` precision.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the “`OutputDataType`” on page 4-0 property to `Custom`. The default is `numerictype([],16,15)`.

Methods

`step` Discrete Fourier transform of input

Common to All System Objects	
<code>clone</code>	Create System object with same property values

Examples

Single-Sided Amplitude Spectrum Of a Signal

Find frequency components of a signal in additive noise.

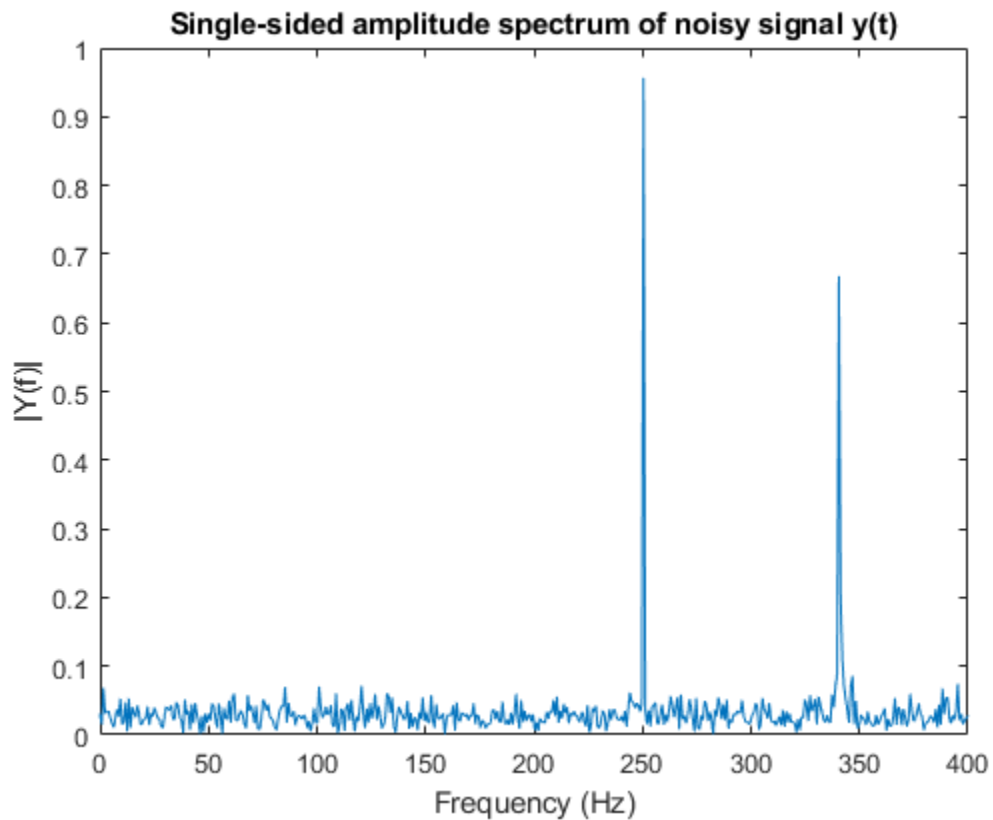

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
Fs = 800; L = 1000;
t = (0:L-1)'/Fs;
```

```
x = sin(2*pi*250*t) + 0.75*cos(2*pi*340*t);  
y = x + .5*randn(size(x)); % noisy signal  
ft = dsp.FFT('FFTLengthSource', 'Property', ...  
    'FFTLength', 1024);  
Y = ft(y);
```

Plot the single-sided amplitude spectrum

```
plot(Fs/2*linspace(0,1,512), 2*abs(Y(1:512))/1024);  
title('Single-sided amplitude spectrum of noisy signal y(t)');  
xlabel('Frequency (Hz)'); ylabel('|Y(f)|');
```

Construct a Sinusoidal Signal Using High Energy FFT Coefficients

Compute the FFT of a noisy sinusoidal input signal. The energy of the signal is stored as the magnitude square of the FFT coefficients. Determine the FFT coefficients which occupy 99.99% of the signal energy and reconstruct the time-domain signal by taking the IFFT of these coefficients. Compare the reconstructed signal with the original signal.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj)(x)`.

Consider a time-domain signal $x[n]$, which is defined over the finite time interval $0 \leq n \leq N - 1$. The energy of the signal $x[n]$ is given by the following equation:

$$E_N = \sum_{n=0}^{N-1} |x[n]|^2$$

FFT Coefficients, $X[k]$ are considered as signal values in the frequency domain. The energy of the signal $x[n]$ in the frequency-domain is hence the sum of the squares of the magnitude of the FFT coefficients:

$$E_N = \frac{1}{N} \sum_{k=0}^{N-1} |X[k]|^2$$

According to Parseval's theorem, the total energy of the signal in time or frequency-domain is the same.

$$E_N = \sum_{n=0}^{N-1} |x[n]|^2 = \frac{1}{N} \sum_{k=0}^{N-1} |X[k]|^2$$

Initialization

Initialize a `dsp.SineWave` System object to generate a sine wave sampled at 44.1 kHz and has a frequency of 1000 Hz. Construct a `dsp.FFT` and `dsp.IFFT` objects to compute the FFT and the IFFT of the input signal.

The 'FFTLenghSource' property of each of these transform objects is set to 'Auto'. The FFT length is hence considered as the input frame size. The input frame size in this

example is 1020, which is not a power of 2. Hence, select the 'FFTImplementation' as 'FFTW'.

```
L = 1020;
Sineobject = dsp.SineWave('SamplesPerFrame',L,'PhaseOffset',10,...
    'SampleRate',44100,'Frequency',1000);
ft = dsp.FFT('FFTImplementation','FFTW');
ift = dsp.IFFT('FFTImplementation','FFTW','ConjugateSymmetricInput',true);
rng(1);
```

Streaming

Stream in the noisy input signal. Compute the FFT of each frame and determine the coefficients which constitute 99.99% energy of the signal. Take IFFT of these coefficients to reconstruct the time-domain signal.

```
numIter = 1000;
for Iter = 1:numIter
    Sinewavel = Sineobject();
    Input = Sinewavel + 0.01*randn(size(Sinewavel));
    FFTCoeff = ft(Input);
    FFTCoeffMagSq = abs(FFTCoeff).^2;

    EnergyFreqDomain = (1/L)*sum(FFTCoeffMagSq);
    [FFTCoeffSorted, ind] = sort(((1/L)*FFTCoeffMagSq),1,'descend');

    CumFFTCoeffs = cumsum(FFTCoeffSorted);
    EnergyPercent = (CumFFTCoeffs/EnergyFreqDomain)*100;
    Vec = find(EnergyPercent > 99.99);
    FFTCoeffsModified = zeros(L,1);
    FFTCoeffsModified(ind(1:Vec(1))) = FFTCoeff(ind(1:Vec(1)));
    ReconstrSignal = ift(FFTCoeffsModified);
end
```

99.99% of the signal energy can be represented by the number of FFT coefficients given by Vec(1):

```
Vec(1)
ans = 296
```

The signal is reconstructed efficiently using these coefficients. If you compare the last frame of the reconstructed signal with the original time-domain signal, you can see that the difference is very small and the plots match closely.

```
max(abs(Input-ReconstrSignal))
```

```
ans = 0.0431
```

```
plot(Input, '*');
```

```
hold on;
```

```
plot(ReconstrSignal, 'o');
```

```
hold off;
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the FFT block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- “System Objects in MATLAB Code Generation” (MATLAB Coder).
- When the following conditions apply, the executable generated from this System object relies on prebuilt dynamic library files (.dll files) included with MATLAB:
 - `FFTImplementation` is set to 'FFTW'.
 - `FFTImplementation` is set to 'Auto', `FFTLengthSource` is set to 'Property', and `FFTLength` is not a power of two.

Use the `packNGo` function to package the code generated from this System object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

- When the FFT length is a power of two, you can generate standalone C and C++ code from this System object.

Introduced in R2012a

step

System object: dsp.FFT

Package: dsp

Discrete Fourier transform of input

Syntax

```
Y = step(ft,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(ft,X)` computes the FFT, `Y`, of the input `X` along the first dimension of `X`. When the `FFTLengthSource` property is `Auto`, the length of `X` along the first dimension must be a positive integer power of two. This length is also the FFT length. When the `FFTLengthSource` property is `Property`, the `FFTLength` property must be a positive integer power of two.

dsp.FilterCascade System object

Package: dsp

Create a cascade of filter System objects

Description

The `dsp.FilterCascade` object creates a multistage System object that enables cascading of filter System objects, delays, and scalar gains. To see the System objects you can assign, at the MATLAB command prompt, enter:

```
dsp.FilterCascade.helpSupportedSystemObjects
```

You can use the cascaded filter for filtering a signal, and for generating the filtering code. You can pass the `dsp.FilterCascade` System object as a stage to another `dsp.FilterCascade` System object. You can also pass `dsp.FilterCascade` System object as an input to the `cascade` function. This object supports variable-size signals if the stages within support variable-size signals.

To filter a signal using the cascaded filter:

- 1 Define and set up your `dsp.FilterCascade` System object. See “Construction” on page 4-660.
- 2 Call `step` to filter each channel of the input signal using the stages in the cascade. The size, data type, and complexity of the input signal must be supported by the stages in the filter cascade.
- 3 Run the `dsp.FilterCascade.generateFilteringCode` method to generate MATLAB code using the design specified through the System objects.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`filtCasc = dsp.FilterCascade` returns a System object, `filtCasc`. This System object has a single stage of the `dsp.FIRFilter` object.

`filtCasc = dsp.FilterCascade(Filter_1, Filter_2, ...)` returns a multistage System object, `filtCasc`, with the first stage set to `Filter_1`, the second stage set to `Filter_2`, and so on. `Filter_1`, `Filter_2`, etc. can be a filter System object, a `dsp.FilterCascade` System object, delay, or a scalar gain.

`filtCasc = cascade(Filter_1, Filter_2, ...)` returns a `dsp.FilterCascade` System object, `filtCasc`, with the first stage set to `Filter_1`, the second stage set to `Filter_2`, and so on. `Filter_1`, `Filter_2`, etc. can be a filter System object, a `dsp.FilterCascade` System object, or a scalar gain. `cascade` function does not support delay as a filter stage.

Properties

Stage i (**Stage1**, **Stage2**, ...)

Specify the i th stage of the `dsp.FilterCascade` System object. You can assign any of the filter System objects, delay, or a scalar gain to this property. To see the System objects you can assign, at the MATLAB command prompt, enter:

```
dsp.FilterCascade.helpSupportedSystemObjects
```

The default value of this property is `dsp.FIRFilter`. For more information, see `dsp.FIRFilter`.

Methods

addStage	Add a new filter stage to the cascade
generateFilteringCode	Generate MATLAB code to filter using cascade
getNumStages	Get the number of stages in the cascade object
releaseStages	Release the locked state of all stages in the cascade
removeStage	Remove a stage from filter cascade
step	Process inputs using the filter cascade

More “Analysis Methods for Filter System Objects” on page 3-2.

Common to All System Objects	
clone	Create System object with same property values
getNumInputs	Expected number of inputs to a System object
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Filter a Signal Using Cascaded Lowpass and Highpass Filters

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Design a bandpass filter by cascading:

- A highpass filter with a stopband frequency of 5000 Hz and a passband frequency of 8000 Hz.
- A lowpass filter with a passband frequency of 12,000 Hz and a stopband frequency of 15,000 Hz.

Visualize the frequency response using `fvtool`.

```
lpFilt = dsp.LowpassFilter('StopbandFrequency',15000,...  
    'PassbandFrequency',12000);  
hpFilt = dsp.HighpassFilter('StopbandFrequency',5000,...  
    'PassbandFrequency',8000);  
  
bpFilt = dsp.FilterCascade(lpFilt, hpFilt);  
  
fvtool(bpFilt);  
legend('Bandpass Filter');
```

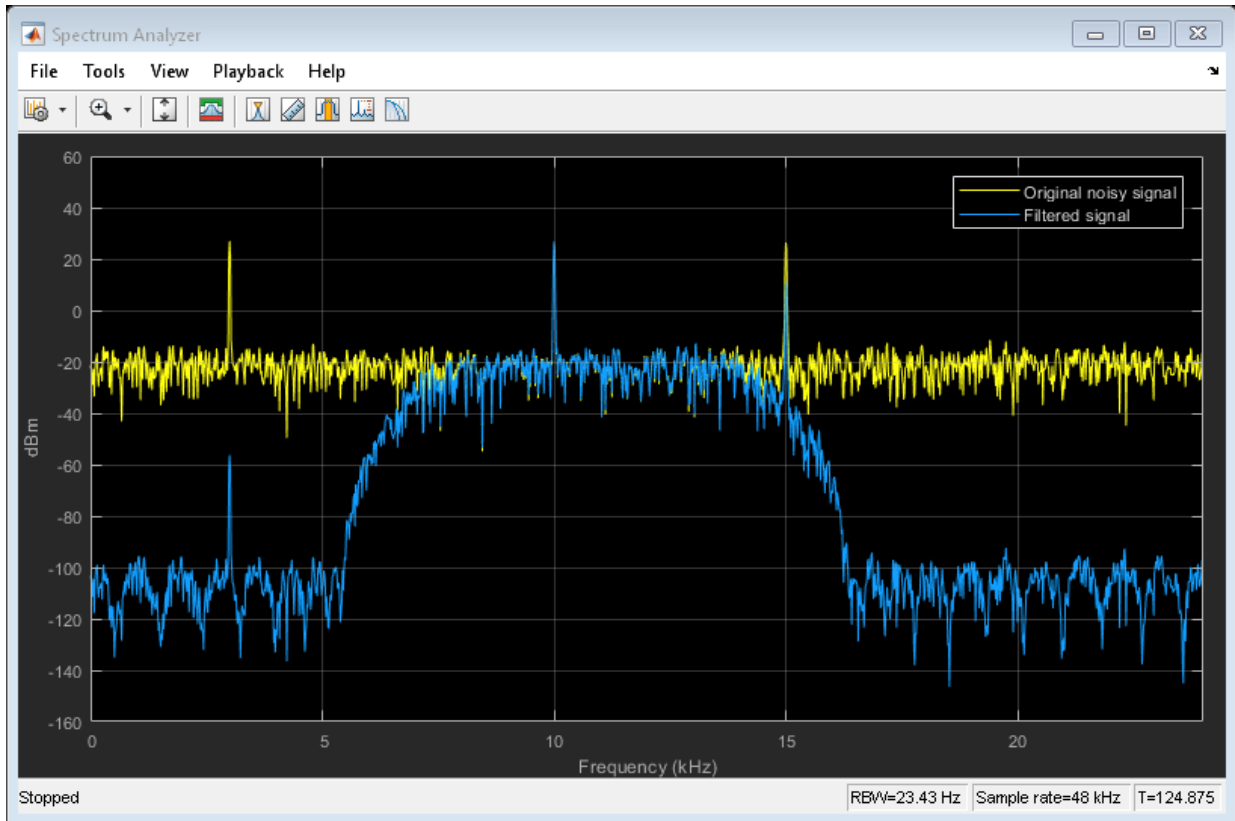

Pass a noisy sine wave as the input to the bandpass filter. The input is a sum of three sine waves with frequencies at 3 kHz, 10 kHz, and 15 kHz. The sampling frequency is 48 kHz. View the input and the filtered output on a spectrum analyzer.

```
Sine1 = dsp.SineWave('Frequency',3e3,'SampleRate',48e3,'SamplesPerFrame',6000);
Sine2 = dsp.SineWave('Frequency',10e3,'SampleRate',48e3,'SamplesPerFrame',6000);
Sine3 = dsp.SineWave('Frequency',15e3,'SampleRate',48e3,'SamplesPerFrame',6000);

SpecAna = dsp.SpectrumAnalyzer('PlotAsTwoSidedSpectrum',false, ...
    'SampleRate',Sine1.SampleRate, ...
    'NumInputPorts',2,...
    'ShowLegend',true, ...
    'YLimits',[-160,60]);

SpecAna.ChannelNames = {'Original noisy signal','Filtered signal'};

for i = 1 : 1000
    x = Sine1()+Sine2()+Sine3()+0.1.*randn(Sine1.SamplesPerFrame,1);
    y = bpFilt(x);
    SpecAna(x,y);
end
release(SpecAna)
```

The tones at 3 kHz and 15 kHz are attenuated, and the tone at 10 kHz is preserved by the bandpass filter.

Design a Compensation Decimator for a CIC Decimator

Create a CIC decimator. Cascade the decimator with a gain.

```
cicdecim = dsp.CICDecimator('DecimationFactor', 6, ...
    'NumSections', 6);
decimcasc = dsp.FilterCascade(cicdecim, 1/gain(cicdecim));
```

Design a compensation decimator and cascade it with the filter cascade, decimcasc.

```
fs = 16e3;      % Sampling frequency of input of compensation decimator
fPass = 4e3;   % Passband frequency
fStop = 4.5e3; % Stopband frequency
ciccomp = dsp.CICCompensationDecimator(cicdecim, ...
    'DecimationFactor', 2, ...
    'PassbandFrequency', fPass, ...
    'StopbandFrequency', fStop, ...
    'SampleRate', fs);
filtchain = dsp.FilterCascade(decimcasc, ciccomp);
```

Visualize the frequency response of the cascade of cascades.

```
f = fvtool(decimcasc, ciccomp, filtchain, 'Fs', [fs*6, fs, fs*6], ...
    'Arithmetic', 'fixed');
legend(f, 'CIC Decimator', 'CIC Compensation Decimator', ...
    'Overall Response');
```

The CIC compensation decimator has an inherent gain, `gain(cicdecim)`. By cascading with a factor of `1/gain(cicdecim)`, the filter cascade compensates for this gain.

Generate Code to Filter Using Cascade

Design a two-stage decimator with a 100 Hz transition width, a 2 kHz sampling frequency, and 60 dB attenuation in the stopband. The decimator needs to downsample by a factor of 4.

```
decimSpec = fdesign.decimator(4, 'Nyquist', 4, 'Tw,Ast', 100,60,2000);
filtCasc = design(decimSpec, 'multistage', 'SystemObject', true);
```

Verify your design using fvtool.

```
info(filtCasc)
fvtool(filtCasc)
```

ans =

```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- You cannot generate code directly from `dsp.FilterCascade`. You can use the `generateFilteringCode` method to generate a MATLAB function. You can generate C/C++ code from this MATLAB function, if the filters in each stage support code generation.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

See Also

System Objects

`dsp.CICCompensationDecimator` | `dsp.CICDecimator` | `dsp.FIRFilter`

Introduced in R2014b

addStage

System object: dsp.FilterCascade

Package: dsp

Add a new filter stage to the cascade

Syntax

```
addStage(FC, FILTERSYSOBJ)
addStage(FC, FILTERSYSOBJ, STAGEID)
```

Description

`addStage(FC, FILTERSYSOBJ)` adds `FILTERSYSOBJ` at the end of the filter cascade stored in the `dsp.FilterCascade` object `FC`. To see the System objects you can assign to `FILTERSYSOBJ`, at the MATLAB command prompt, enter

```
dsp.FilterCascade.helpSupportedSystemObjects
```

`addStage(FC, FILTERSYSOBJ, STAGEID)` adds `FILTERSYSOBJ` at stage position `STAGEID` of the filter cascade stored in the `dsp.FilterCascade` object `FC`. All existing filters from `STAGEID` to end of the cascade are shifted down in the cascade.

`FILTERSYSOBJ` can be any of the filter System objects provided by the DSP System Toolbox.

Examples

Add Stage to Cascade End

Add a stage at the end of the filter cascade:

```
FC = dsp.FilterCascade;
addStage(FC, dsp.IIRFilter);
```

Add Stage inside Cascade

Add a filter at the second stage of a filter cascade consisting of three filters:

```
FC = dsp.FilterCascade(dsp.CICDecimator,dsp.FIRDecimator,dsp.FIRFilter);  
addStage(FC, dsp.IIRFilter, 2);
```

generateFilteringCode

System object: dsp.FilterCascade

Package: dsp

Generate MATLAB code to filter using cascade

Syntax

```
generateFilteringCode(FC)
generateFilteringCode(FC, FNAME)
```

Description

`generateFilteringCode(FC)` creates a MATLAB function in the editor that contains code to create stages of the cascade and calls `step` method on each stage in sequence.

`generateFilteringCode(FC, FNAME)` generates code and saves it to the file specified in the string `FNAME`.

Examples

Create a filter cascade object and generate code from it:

```
FC = dsp.FilterCascade(dsp.FIRFilter('Numerator',ones(1,5)),...
                      dsp.FIRDecimator);
fName = 'filterCascade.m'; % The code will be saved in this
                          % file in the current directory
generateFilteringCode(FC, fName);
```

getNumStages

System object: dsp.FilterCascade

Package: dsp

Get the number of stages in the cascade object

Syntax

```
getNumStages(FC)
```

Description

`getNumStages(FC)` returns the number of stages in the `dsp.FilterCascade` object, `FC`.

Examples

Get the number of stages in a filter cascade object:

```
FC = cascade(dsp.FIRFilter, dsp.IIRFilter);  
N = getNumStages(FC);    % This will return 2
```

releaseStages

System object: dsp.FilterCascade

Package: dsp

Release the locked state of all stages in the cascade

Syntax

```
releaseStages(FC)
```

Description

`releaseStages(FC)` calls the `release` method of individual stages in the `dsp.FilterCascade` object `FC`.

For instance, if a `dsp.FilterCascade` object consists of a `dsp.FIRFilter` object and a `dsp.FIRInterpolator` object, the `releaseStages` method calls the:

- `release` method of the `dsp.FIRFilter` object.
- `release` method of the `dsp.FIRInterpolator` object.

Examples

Release Stages of a Filter Cascade

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Create and release stages of a filter cascade.

```
firfilt = dsp.FIRFilter;  
y = firfilt(randn);  
FC = dsp.FilterCascade(dsp.FIRInterpolator, firfilt);
```

```
isLocked(FC.Stage2) % Returns 1  
releaseStages(FC);  
isLocked(FC.Stage2) % Returns 0
```

```
ans =
```

```
logical
```

```
1
```

```
ans =
```

```
logical
```

```
0
```

removeStage

System object: dsp.FilterCascade

Package: dsp

Remove a stage from filter cascade

Syntax

```
removeStage(FC)
removeStage(FC, STAGEID)
```

Description

`removeStage(FC)` removes a stage from the end of the filter cascade stored in the `dsp.FilterCascade` object `FC`.

`removeStage(FC, STAGEID)` removes the stage from the stage position `STAGEID` of the filter cascade stored in the `dsp.FilterCascade` object `FC`. All existing filters from `STAGEID` to end of the cascade are shifted up in the cascade.

Examples

Remove Stage from Cascade End

Remove a stage from the end of a filter cascade:

```
FC = dsp.FilterCascade(dsp.FIRFilter, dsp.IIRFilter);
removeStage(FC);
```

Remove Stage from Inside Cascade

Remove a filter from the third stage of a cascade consisting of four stages:

```
FC = cascade(dsp.FIRInterpolator, dsp.FIRInterpolator, ...  
            dsp.FIRDecimator, dsp.FIRDecimator);  
removeStage(FC, 3);
```

step

System object: dsp.FilterCascade

Package: dsp

Process inputs using the filter cascade

Syntax

```
y = step(filtCasc,x)
```

Description

Note Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`y = step(filtCasc,x)` runs the input `x` through the filter cascade, `filtCasc`, and returns the filtered output, `y`. The size, data type, and complexity of the input signal must be supported by the stages in the filter cascade.

Introduced in R2017a

dsp.FilteredXLMSFilter System object

Package: dsp

Filtered XLMS filter

Description

The `dsp.FilteredXLMSFilter` computes output, error and coefficients using Filtered-X Least Mean Squares FIR adaptive filter.

To implement the adaptive FIR filter object:

- 1 Define and set up your adaptive FIR filter object. See “Construction” on page 4-680.
- 2 Call `step` to implement the filter according to the properties of `dsp.FilteredXLMSFilter`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`fxlms = dsp.FilteredXLMSFilter` returns a filtered-x Least Mean Square FIR adaptive filter System object, `fxlms`. This System object is used to compute the filtered output and the filter error for a given input and desired signal.

`fxlms = dsp.FilteredXLMSFilter('PropertyName', PropertyValue,...)` returns a `FilteredXLMSFilter` System object, `fxlms`, with each specified property set to the specified value.

`fxlms = dsp.FilteredXLMSFilter(LEN, 'PropertyName', PropertyValue,...)` returns a `FilteredXLMSFilter` System object, `fxlms`, with the Length property set to

LEN, and other specified properties set to the specified values. For the algorithm on how to implement this filter, refer to [1], [2].

Properties

Length

Length of filter coefficients vector

Specify the length of the FIR filter coefficients vector as a positive integer value. This property is nontunable.

The default value is 10.

StepSize

Adaptation step size

Specify the adaptation step size factor as a positive numeric scalar. The default value is 0.1. This property is tunable.

LeakageFactor

Adaptation leakage factor

Specify the leakage factor used in a leaky adaptive filter as a numeric value between 0 and 1, both inclusive. When the value is less than 1, the System object implements a leaky adaptive algorithm. The default value is 1, providing no leakage in the adapting method. This property is tunable.

SecondaryPathCoefficients

Coefficients of the secondary path filter model

Specify the coefficients of the secondary path filter model as a numeric vector. The secondary path connects the output actuator and the error sensor. The default value is a vector that represents the coefficients of a 10th-order FIR lowpass filter. This property is tunable.

SecondaryPathEstimate

An estimate of the secondary path filter model

Specify the estimate of the secondary path filter model as a numeric vector. The secondary path connects the output actuator and the error sensor. The default value equals to the `SecondaryPathCoefficients` property value. This property is not tunable.

InitialCoefficients

Initial coefficients of the filter

Specify the initial values of the FIR adaptive filter coefficients as a scalar or a vector of length equal to the value of the `Length` property. The default value is 0.

This property is tunable.

LockCoefficients

Locked status of the coefficient updates

Specify whether to lock the filter coefficient values. By default, the value of this property is `false`, and the object continuously updates the filter coefficients. If this property is set to `true`, the filter coefficients do not update and their values remain the same.

This property is tunable.

Methods

<code>msexim</code>	Mean-square error for Filtered-X LMS filter
<code>reset</code>	Reset filter states for Filtered-X LMS filter
<code>step</code>	Apply Filtered-X LMS filter to input

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object

Common to All System Objects	
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Active Noise Control of a Random Noise Signal

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Generate noise, create FIR primary path system model, generate observation noise, filter the primary path system model output with added noise, and create FIR secondary path system model.

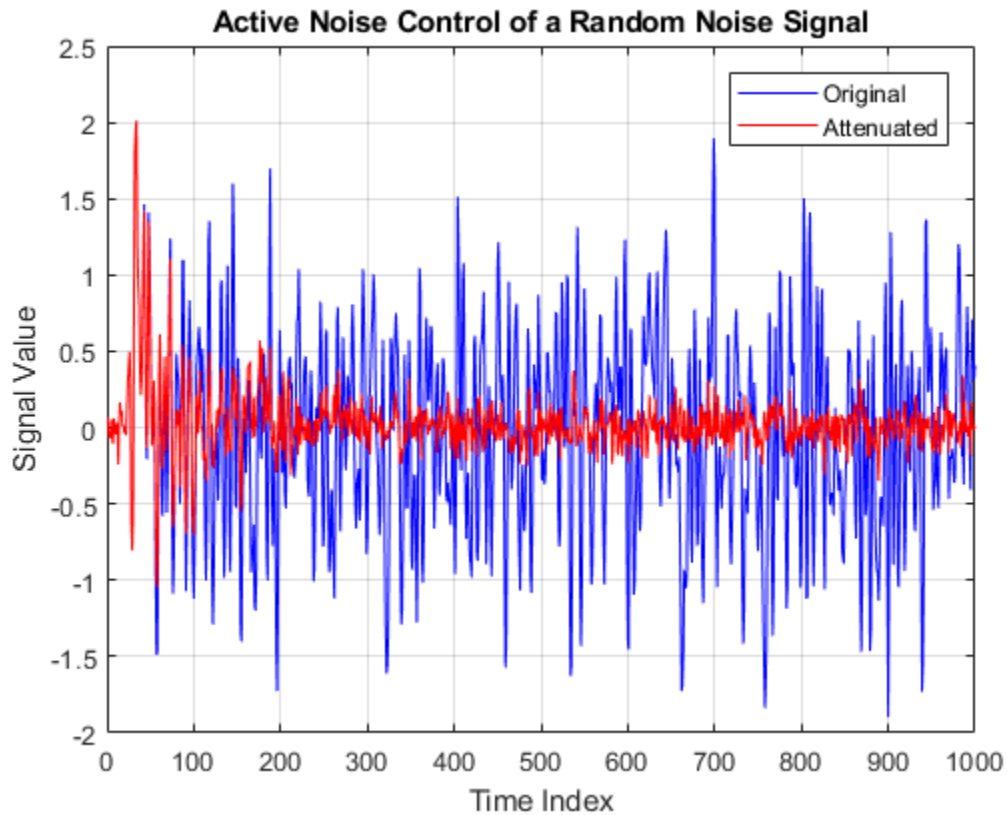

```
x = randn(1000,1);
g = fir1(47,0.4);
n = 0.1*randn(1000,1);
d = filter(g,1,x) + n;
b = fir1(31,0.5);
```

Use the Filtered-X LMS Filter to compute the filtered output and the filter error for the input and the signal to be cancelled.

```
mu = 0.008;
fxlms = dsp.FilteredXLMSFilter(32, 'StepSize', mu, 'LeakageFactor', ...
    1, 'SecondaryPathCoefficients', b);
[y,e] = fxlms(x,d);
```

Plot the results.

```
plot(1:1000,d,'b',1:1000,e,'r');
title('Active Noise Control of a Random Noise Signal');
legend('Original','Attenuated');
xlabel('Time Index'); ylabel('Signal Value'); grid on;
```

msesim

System object: dsp.FilteredXLMSFilter

Package: dsp

Mean-square error for Filtered-X LMS filter

Syntax

```
MSE = msesim(sysObj,X,D)
[MSE,MEANW,W,TRACEK] = msesim(sysObj,X,D)
[...] = msesim(sysObj,X,D,M)
```

Description

`MSE = msesim(sysObj,X,D)` returns a sequence of mean-square errors. This column vector contains estimates of the mean-square error of the adaptive filter at each time instant. The length of `MSE` is equal to `SIZE(X,1)`. The columns of the matrix `X` contain individual input signal sequences, and the columns of the matrix `D` contain corresponding desired response signal sequences.

`[MSE,MEANW,W,TRACEK] = msesim(sysObj,X,D)` calculates three parameters corresponding to the simulated behavior of the adaptive filter defined by `sysObj`. `MEANW` is a sequence of coefficient vector means. The columns of this matrix contain estimates of the mean values of the adaptive filter coefficients at each time instant. The dimensions of `MEANW` are `(SIZE(X,1))` by `(sysObj.length)`. `W` is an estimate of the final values of the adaptive filter coefficients for the algorithm corresponding to `sysObj`. `TRACEK` is a sequence of total coefficient error powers. This column vector contains estimates of the total coefficient error power of the adaptive filter at each time instant. The length of `TRACEK` is equal to `SIZE(X,1)`.

`[...] = msesim(sysObj,X,D,M)` specifies an optional decimation factor for computing `MSE`, `MEANW`, and `TRACEK`. If `M > 1`, every `Mth` predicted value of each of these sequences is saved. If omitted, the value of `M` is the default, which is 1.

System Identification of an FIR Filter Using Filtered XLMS Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent step syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
ha = fir1(31,0.5);
fir = dsp.FIRFilter('Numerator',ha); % FIR system to be identified
iir = dsp.IIRFilter('Numerator',sqrt(0.75),...
    'Denominator',[1 -0.5]);
x = iir(sign(randn(2000,25)));
n = 0.1*randn(size(x));           % Observation noise signal
d = fir(x)+n;                     % Desired signal
l = 32;                           % Filter length
mu = 0.008;                       % Filtered-X LMS filter Step size.
m = 5;                             % Decimation factor for analysis
                                   % and simulation results
fxlms = dsp.FilteredXLMSFilter(l,'StepSize',mu);
[simmse,meanWsim,Wsim,traceKsim] = mstesim(fxlms,x,d,m);
plot(m*(1:length(simmse)),10*log10(simmse));
xlabel('Iteration'); ylabel('MSE (dB)');
title('Learning curve for Filtered-X LMS filter used in system identification')
```

reset

System object: dsp.FilteredXLMSFilter

Package: dsp

Reset filter states for Filtered-X LMS filter

Syntax

```
reset(sysObj)
```

Description

`reset(sysObj)` resets the internal states of the System object, `sysObj`, to their initial values. The reset method is always a no-op for unlocked System objects, as the states may not be allocated when the object is not locked.

step

System object: dsp.FilteredXLMSFilter

Package: dsp

Apply Filtered-X LMS filter to input

Syntax

```
[Y, ERR] = step(sysObj, x, D)
Y = step(sysObj, x)
[Y1, ..., YN] = step(sysObj, x)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

`[Y, ERR] = step(sysObj, x, D)` filters the input `x`, using `D` as the desired signal, and returns the filtered output in `Y` and the filter error in `ERR`. The System object estimates the filter weights needed to minimize the error between the output signal and the desired signal.

`Y = step(sysObj, x)` processes the input data, `x`, to produce the output, `Y`, from the System object, `sysObj`. `[Y1, ..., YN] = step(sysObj, x)` produces `N` outputs.

Every System object has a `step` method. The `step` method processes the input data according to the object algorithm. The number of input and output arguments depends on the algorithm, and may depend also on one or more property settings. The `step` method for some objects accepts fixed-point (fi) inputs.

Calling `step` on an object puts that object into a locked state. When locked, you cannot change nontunable properties or any input characteristics (size, data type and complexity) without reinitializing (unlocking and relocking) the object.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.FIRDecimator System object

Package: dsp

Polyphase FIR decimator

Description

The `FIRDecimator` object resamples vector or matrix inputs along the first dimension. The object resamples at a rate M times slower than the input sampling rate, where M is the integer-valued downsampling factor. The decimation combines an FIR anti-aliasing filter with downsampling. The FIR decimator object uses a polyphase implementation of the FIR filter.

To resample vector or matrix inputs along the first dimension:

- 1 Define and set up your FIR decimator. See “Construction” on page 4-692.
- 2 Call `step` to resample the vector or matrix inputs according to the properties of `dsp.FIRDecimator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`firdecim = dsp.FIRDecimator` returns an FIR decimator, `firdecim`, which applies an FIR filter with a cutoff frequency of 0.4π radians/sample to the input and downsamples the filter output by factor of 2. This System object supports variable-size input.

`firdecim = dsp.FIRDecimator ('PropertyName', PropertyValue, ...)` returns an FIR decimator, `firdecim`, with each property set to the specified value.

`firdecim = dsp.FIRDecimator(DECIM, NUM, 'PropertyName', PropertyValue, ...)` returns an FIR decimator, `firdecim`, with the integer-valued `DecimationFactor` property set to `DECIM`, the `Numerator` property set to `NUM`, and other specified properties set to the specified values.

Properties

DecimationFactor

Decimation factor

Specify the downsampling factor as a positive integer. The FIR decimator reduces the sampling rate of the input by this factor. The size of the input along the first dimension must be a multiple of the decimation factor. The default is 2.

NumeratorSource

FIR filter coefficient source

Specify the source of the numerator coefficients as one of `'Property'` (default) or `'Input port'`. When you specify `'Input port'`, the filter object requires the numerator coefficients to be specified as the third argument to every step.

Numerator

FIR filter coefficients

Specify the numerator coefficients of the FIR filter in powers of z^{-l} . The following equation defines the system function for a filter of length L :

$$H(z) = \sum_{l=0}^{L-1} b_l z^{-l}$$

To prevent aliasing as a result of downsampling, the filter transfer function should have a normalized cutoff frequency no greater than $1/\text{DecimationFactor}$. You can specify the filter coefficients as a vector in the supported data types. The default is `fir1(35, 0.4)`.

Structure

Filter structure

Specify the implementation of the FIR filter as either `Direct form` or `Direct form transposed`. The default is `Direct form`.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |. The default is `Floor`. This property applies only if the object is not in full precision mode.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. This property applies only if the object is not in full precision mode.

CoefficientsDataType

Coefficients word and fraction lengths

Specify the coefficients fixed-point data type as `Same word length as input` or `Custom`. The default is `Same word length as input`.

CustomCoefficientsDataType

Coefficients word and fraction lengths

Specify the coefficients fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `CoefficientsDataType` property to `Custom`. The default is `numerictype([],16,15)`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of `| Full precision | Same as input | Custom |`. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `| Full precision | Same as product | Same as input | Custom |`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of | Same as accumulator | Same as product | Same as input | Custom |. The default is Same as accumulator.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the “OutputDataType” on page 4-0 property to `Custom`. The default is `numericType([1,16,15])`.

Methods

- `freqz` Frequency response
- `fvtool` Open filter visualization tool
- `impz` Impulse response
- `phasez` Unwrapped phase response
- `reset` Reset filter states of FIR decimator
- `step` Decimate input by integer factor

More “Analysis Methods for Filter System Objects” on page 3-2.

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

Decimate a Sum of Sine Waves

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

This example shows how to decimate a sum of sine waves with angular frequencies of $\pi/4$ and $2\pi/3$ radians/sample by a factor of two. To prevent aliasing, the FIR decimator filters out the $2\pi/3$ radians/sample component before downsampling.

```
x = cos(pi/4*[0:95]') + sin(2*pi/3*[0:95]');  
firdecim = dsp.FIRDecimator;  
y = firdecim(x);
```

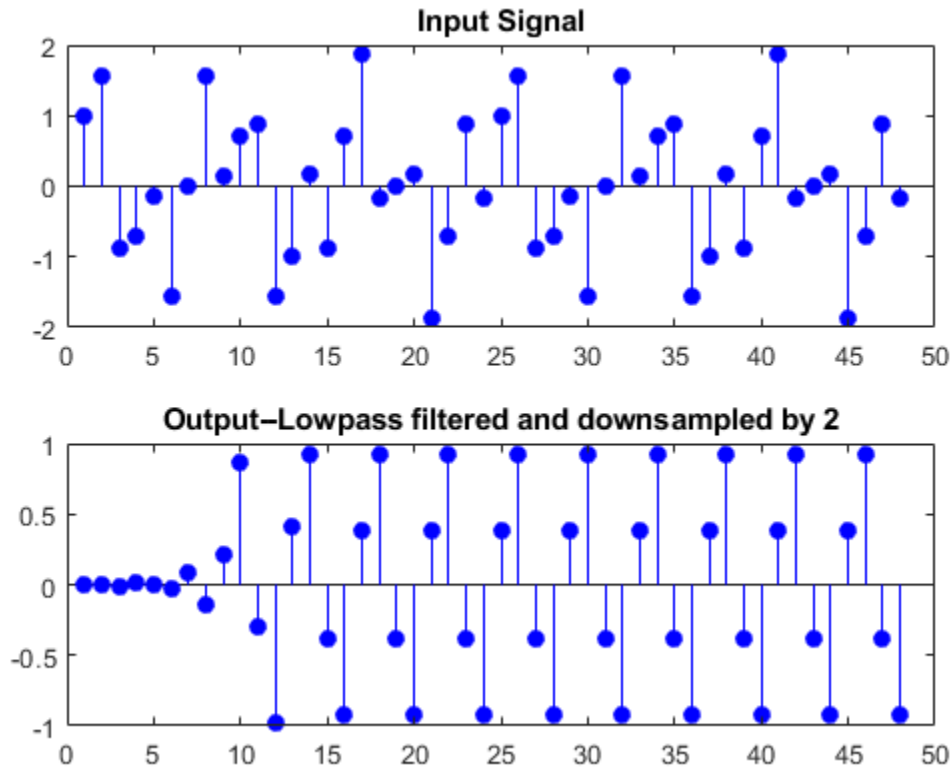

View group delay of default FIR filter

```
fvttool(fir1(35,0.4),1,'analysis','grpdelay');
```

Group delay of the default linear-phase FIR filter is 17.5 samples. Downsampling by a factor of two expect an approx. 8.75 sample delay in the output y with the initial filter states of zero

```
subplot(211);  
stem(x(1:length(x)/2),'b','markerfacecolor',[0 0 1]);  
title('Input Signal');  
subplot(212);  
stem(y,'b','markerfacecolor',[0 0 1]);  
title('Output--Lowpass filtered and downsampled by 2');
```

Reduce the Sample Rate of an Audio Signal

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

This example shows how to reduce the sampling rate of an audio signal by 1/2 and plays it.

```
afr = dsp.AudioFileReader('OutputDataType',...  
    'single');
```

```
adw = audioDeviceWriter(22050/2);
firdecim = dsp.FIRDecimator;

while ~isDone(afr)
    frame = afr();
    y = firdecim(frame);
    adw(y);
end

release(afr);
pause(0.5);
release(adw);
```

Definitions

Polyphase Subfilters

A polyphase implementation of an FIR decimator *splits* the lowpass FIR filter impulse response into M different subfilters, where M is the downsampling, or decimation factor. Let $h(n)$ denote the FIR filter impulse response of length L and $u(n)$ the input signal. Decimating the filter output by a factor of M is equivalent to the downsampled convolution:

$$y(n) = \sum_{l=0}^{L-1} h(l)u(nM - l)$$

The key to the efficiency of polyphase filtering is that specific input values are only multiplied by select values of the impulse response in the downsampled convolution. For example, letting $M=2$, the input values $u(0), u(2), u(4), \dots$ are only combined with the filter coefficients $h(0), h(2), h(4), \dots$, and the input values $u(1), u(3), u(5), \dots$ are only combined with the filter coefficients $h(1), h(3), h(5), \dots$. By splitting the filter coefficients into two polyphase subfilters, no unnecessary computations are performed in the convolution. The outputs of the convolutions with the polyphase subfilters are interleaved and summed to yield the filter output. The following MATLAB code demonstrates how to construct the two polyphase subfilters for the default order 35 filter in the “Numerator” on page 4-0 property and the default “DecimationFactor” on page 4-0 property value of two:

```
M = 2;
Num = fir1(35, 0.4);
```

```

FiltLength = length(Num);
Num = flipud(Num(:));

if (rem(FiltLength, M) ~= 0)
    nzeros = M - rem(FiltLength, M);
    Num = [zeros(nzeros,1); Num]; % Appending zeros
end

len = length(Num);
nrows = len / M;
PolyphaseFilt = flipud(reshape(Num, M, nrows).');

```

The columns of `PolyphaseFilt` are subfilters containing the two *phases* of the filter in `Num`. For a general downsampling factor of M , there are M phases and therefore M subfilters.

Algorithms

This object implements the algorithm, inputs, and outputs described on the FIR Decimation block reference page. The object properties correspond to the block parameters, except:

- **Framing** – The FIR decimator object only supports `Maintain` input frame rate
- **Output buffer initial conditions** – The FIR decimator object does not support this parameter.
- **Rate options** – The FIR decimator object does not support this parameter.
- **Input processing** The FIR decimator object does not support this parameter.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

`dsp.FIRInterpolator` | `dsp.FIRRateConverter`

Introduced in R2012a

freqz

System object: dsp.FIRDecimator

Package: dsp

Frequency response

Syntax

```
[h,w] = freqz(firdecim)
[h,w] = freqz(firdecim,n)
[h,w] = freqz(firdecim,Name,Value)
freqz(firdecim)
```

Description

`[h,w] = freqz(firdecim)` returns the complex, 8192–element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample.

`[h,w] = freqz(firdecim,n)` returns the complex, `n`–element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[h,w] = freqz(firdecim,Name,Value)` returns the frequency response and the corresponding frequencies, with additional options specified by one or more `Name, Value` pair arguments.

`freqz(firdecim)` uses `FVTool` to plot the magnitude and unwrapped phase of the frequency response of the filter System object `firdecim`.

fvtool

System object: dsp.FIRDecimator

Package: dsp

Open filter visualization tool

Syntax

```
fvtool(firdecim)
fvtool(firdecim, 'Arithmetic', ARITH, ...)
```

Description

`fvtool(firdecim)` performs an analysis and computes the magnitude response of the filter System object `firdecim`.

`fvtool(firdecim, 'Arithmetic', ARITH, ...)` analyzes the filter System object `firdecim`, based on the arithmetic specified in the `ARITH` input. `ARITH` can be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The 'Arithmetic' input is only relevant for the analysis of filter System objects.

impz

System object: dsp.FIRDecimator

Package: dsp

Impulse response

Syntax

```
[h,t] = impz(firdecim)
[h,t] = impz(firdecim,Name,Value)
impz(firdecim)
```

Description

`[h,t] = impz(firdecim)` returns the impulse response `h`, and the corresponding time points `t` at which the impulse response of `firdecim` is computed.

`[h,t] = impz(firdecim,Name,Value)` returns the impulse response `h`, and the corresponding time points `t`, with additional options specified by one or more `Name, Value` pair arguments.

`impz(firdecim)` uses FVTool to plot the impulse response of the filter System object `firdecim`.

Note You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

phasez

System object: dsp.FIRDecimator

Package: dsp

Unwrapped phase response

Syntax

```
[phi,w] = phasez(firdecim)
[phi,w] = phasez(firdecim,n)
[phi,w] = phasez(firdecim,Name,Value)
phasez(firdecim)
```

Description

`[phi,w] = phasez(firdecim)` returns the 8192–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample.

`[phi,w] = phasez(firdecim,n)` returns the `n`–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[phi,w] = phasez(firdecim,Name,Value)` returns the phase response and the corresponding frequencies, with additional options specified by one or more `Name, Value` pair arguments.

`phasez(firdecim)` uses FVTool to plot the phase response of the filter System object `firdecim`.

reset

System object: dsp.FIRDecimator

Package: dsp

Reset filter states of FIR decimator

Syntax

```
reset(firdecim)
```

Description

`reset(firdecim)` resets the filter states of the FIR decimator object, `firdecim`, to the initial values of zero. After the `step` method applies the FIR decimator to nonzero input data, the filter states may change. Invoking the `step` method again without first invoking the `reset` method may produce different outputs for an identical input.

Reset an FIR Decimator

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
firdecim = dsp.FIRDecimator;  
x = cos(pi/8*(0:1023'))+sin(pi/4*(0:1023'));  
y = firdecim(x);
```

Call the FIR decimator again without reset.

```
y1 = firdecim(x);  
isequal(y,y1)
```

```
ans =
```

```
logical
```

0

Reset filter states.

```
reset(firdecim);
```

Call the FIR decimator again.

```
y2 = firdecim(x);  
isequal(y,y2)
```

```
ans =
```

```
logical
```

```
1
```

step

System object: dsp.FIRDecimator

Package: dsp

Decimate input by integer factor

Syntax

```
Y = step(firdecim,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(firdecim,X)` outputs the filtered and downsampled values, Y , of the input signal, X . A K_i -by- N input matrix is treated as N independent channels. The length of each column must be a multiple of the `DecimationFactor` property value. The FIR decimator operates on each channel separately and generates a K_o -by- N output matrix where $K_o = K_i/M$ with M the decimation factor. The object supports real and complex floating-point and fixed-point inputs, except for complex unsigned fixed-point inputs.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.FIRFilter System object

Package: dsp

Static or time-varying FIR filter

Description

The `FIRFilter` object filters each channel of the input using static or time-varying FIR filter implementations.

To filter each channel of the input:

- 1 Define and set up your FIR filter. See “Construction” on page 4-710.
- 2 Call `step` to filter each channel of the input according to the properties of `dsp.FIRFilter`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`fir = dsp.FIRFilter` returns a finite impulse response (FIR) filter object, `fir`, which independently filters each channel of the input over time using a specified FIR filter implementation. This System object supports variable-size input.

`fir = dsp.FIRFilter('PropertyName', PropertyValue, ...)` returns an FIR filter System object, `fir`, with each property set to the specified value.

`fir = dsp.FIRFilter(num, 'PropertyName', PropertyValue, ...)` returns an FIR filter System object, `fir`, with the `Numerator` property set to `num` and other specified properties set to the specified values.

Properties

Structure

Filter structure

Specify the filter structure.

You can specify the filter structure as one of | `Direct form` | `Direct form symmetric` | `Direct form antisymmetric` | `Direct form transposed` | `Lattice MA` |. The default is `Direct form`.

NumeratorSource

Source of filter coefficients

Specify the source of the filter coefficients as one of | `Property` | `Input port` |. The default is `Property`. When you specify `Input port`, the filter object updates the time-varying filter once every frame.

This applies when you set the `Structure` to `Direct form` | `Direct form symmetric` | `Direct form antisymmetric` | `Direct form transposed`.

ReflectionCoefficientsSource

Source of filter coefficients

Specify the source of the Lattice filter coefficients as one of | `Property` | `Input port` |. The default is `Property`. When you specify `Input port`, the filter object updates the time-varying filter once every frame.

This applies when you set the `Structure` to `Lattice MA`.

Numerator

Numerator coefficients

Specify the filter coefficients as a real or complex numeric row vector. This property applies when you set the `NumeratorSource` property to `Property`, and the “`Structure`” on page 4-0 property is set to `Direct form`, `Direct form symmetric`, `Direct form antisymmetric`, or `Direct form transposed`. The default is `[0.5 0.5]`. This property is tunable.

ReflectionCoefficients

Reflection coefficients of lattice filter structure

Specify the reflection coefficients of a lattice filter as a real or complex numeric row vector. This property applies when you set the “Structure” on page 4-0 property to `Lattice MA`, and the `ReflectionCoefficientsSource` property to `Property`. The default is `[0.5 0.5]`. This property is tunable.

InitialConditions

Initial conditions for the FIR filter

Specify the initial conditions of the filter states. The number of states or delay elements equals the number of reflection coefficients for the lattice structure, or the number of filter coefficients–1 for the other direct form structures.

You can specify the initial conditions as a scalar, vector, or matrix. If you specify a scalar value, the FIR filter object initializes all delay elements in the filter to that value. If you specify a vector whose length equals the number of delay elements in the filter, each vector element specifies a unique initial condition for the corresponding delay element. The object applies the same vector of initial conditions to each channel of the input signal.

If you specify a vector whose length equals the product of the number of input channels and the number of delay elements in the filter, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel.

If you specify a matrix with the same number of rows as the number of delay elements in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel. The default is 0.

This property is tunable.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types

using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `| Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |`. The default is `Floor`. This property applies only if the object is not in full precision mode.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `| Wrap | Saturate |`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

CoefficientsDataType

Coefficients word and fraction lengths

Specify the coefficients fixed-point data type as one of `| Same word length as input | Custom |`. This property applies when you set the `NumeratorSource` property to `Property`. The default is `Same word length as input`.

CustomCoefficientsDataType

Custom coefficients word and fraction lengths

Specify the coefficients fixed-point type as a signed or unsigned `numericType` object. This property applies when you set the `CoefficientsDataType` property to `Custom`. The default is `numericType(true,16,15)`.

ReflectionCoefficientsDataType

Reflection coefficients word and fraction lengths

Specify the reflection coefficients fixed-point data type as one of | Same word length as input | Custom |. This property applies when you set the `ReflectionCoefficientsSource` property to `Property`. The default is Same word length as input.

CustomReflectionCoefficientsDataType

Custom reflection coefficients word and fraction lengths

Specify the reflection coefficients fixed-point type as a signed or unsigned numeric type object. This property applies when you set the `ReflectionCoefficientsDataType` property to `Custom`. The default is numeric type (true, 16, 15).

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of | Full precision | Same as input | Custom |. The default is Full precision.

CustomProductDataType

Custom product word and fraction lengths

Specify the product fixed-point type as a signed or unsigned scaled numeric type object. This property applies when you set the `ProductDataType` property to `Custom`. The default is numeric type (true, 32, 30).

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type to one of | Full precision | Same as input | Same as product | Custom |. The default is Full precision.

CustomAccumulatorDataType

Custom accumulator word and fraction lengths

Specify the accumulator fixed-point type as a signed or unsigned scaled numeric type object. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is numeric type (true, 32, 30).

StateDataType

State word and fraction lengths

Specify the state fixed-point data type as one of | Same as input | Same as accumulator | Custom |. This property does not apply to any of the direct form or direct form I filter structures. The default is Same as accumulator.

CustomStateDataType

Custom state word and fraction lengths

Specify the state fixed-point type as a signed or unsigned scaled `numericType` object. This property applies when you set the `StateDataType` property to `Custom`. The default is `numericType(true,16,15)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of | Same as input | Same as accumulator | Custom |. The default is Same as accumulator.

CustomOutputDataType

Custom output word and fraction lengths

Specify the output fixed-point type as a signed or unsigned scaled `numericType` object. This property applies when you set the “OutputDataType” on page 4-0 property to `Custom`. The default is `numericType(true,16,15)`.

Methods

freqz	Frequency response
fvtool	Open filter visualization tool
impz	Impulse response
phasez	Unwrapped phase response
reset	Reset internal states of FIR filter
step	Filter input with FIR filter object

More “Analysis Methods for Filter System Objects” on page 3-2.

Common to All System Objects	
clone	Create System object with same property values
getNumInputs	Expected number of inputs to a System object
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Lowpass Filter a Sinusoid Signal Using FIRFilter object

Use an FIR filter to apply a low pass filter to a waveform with two sinusoidal components.

```
t = (0:1000)'/8e3;  
xin = sin(2*pi*0.3e3*t)+sin(2*pi*3e3*t);  
  
sr = dsp.SignalSource;  
sr.Signal = xin;  
sink = dsp.SignalSink;  
  
fir = dsp.FIRFilter(fir1(10,0.5));
```

```
sa = dsp.SpectrumAnalyzer('SampleRate',8e3,...  
    'PlotAsTwoSidedSpectrum',false,...  
    'OverlapPercent', 80, 'PowerUnits','dBW',...  
    'YLimits', [-150 -10]);  
  
while ~isDone(sr)  
    input = sr();  
    filteredOutput = fir(input);  
    sink(filteredOutput);  
    sa(filteredOutput)  
end  
  
filteredResult = sink.Buffer;  
fvtool(fir,'Fs',8000)
```

Design an FIR filter as a System object.

```
N = 10;  
Fc = 0.4;  
B = fir1(N,Fc);  
fir1 = dsp.FIRFilter(B);  
fvtool(fir1)
```

This can also be achieved by using `fdesign` as a constructor and `design` to design the filter.

```
N = 10;  
Fc = 0.4;  
specLowpass = fdesign.lowpass('N,Fc',N,Fc);  
fir2 = design(specLowpass,'systemobject',true)  
fvtool(fir2);
```

```
fir2 =
```

```
    dsp.FIRFilter with properties:
```

```
Structure: 'Direct form'  
NumeratorSource: 'Property'  
Numerator: [1x11 double]  
InitialConditions: 0
```

Use `get` to show all properties

Algorithms

This object implements the algorithm, inputs, and outputs described on the Discrete FIR Filter block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Only the `Numerator` property is tunable for code generation.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation if you have the HDL Coder installed. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

“FIR Nyquist (L-th band) Filter Design” | Discrete FIR Filter | `dsp.BiquadFilter`

Introduced in R2012a

freqz

System object: dsp.FIRFilter

Package: dsp

Frequency response

Syntax

```
[h,w] = freqz(fir)
[h,w] = freqz(fir,n)
[h,w] = freqz(fir,Name,Value)
freqz(fir)
```

Description

`[h,w] = freqz(fir)` returns the complex, 8192–element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample.

`[h,w] = freqz(fir,n)` returns the complex, `n`-element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[h,w] = freqz(fir,Name,Value)` returns the frequency response and the corresponding frequencies, with additional options specified by one or more `Name, Value` pair arguments.

`freqz(fir)` uses FVTool to plot the magnitude and unwrapped phase of the frequency response of the filter System object `fir`.

fvtool

System object: dsp.FIRFilter

Package: dsp

Open filter visualization tool

Syntax

```
fvtool(fir)
fvtool(fir, 'Arithmetic', ARITH, ...)
```

Description

`fvtool(fir)` performs an analysis and computes the magnitude response of the filter System object `fir`.

`fvtool(fir, 'Arithmetic', ARITH, ...)` analyzes the filter System object `fir`, based on the arithmetic specified in the `ARITH` input. `ARITH` can be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The 'Arithmetic' input is only relevant for the analysis of filter System objects.

impz

System object: dsp.FIRFilter

Package: dsp

Impulse response

Syntax

```
[h,t] = impz(fir)
[h,t] = impz(fir,Name,Value)
impz(fir)
```

Description

`[h,t] = impz(fir)` returns the impulse response `h`, and the corresponding time points `t` at which the impulse response of `fir` is computed.

`[h,t] = impz(fir,Name,Value)` returns the impulse response `h`, and the corresponding time points `t`, with additional options specified by one or more `Name, Value` pair arguments.

`impz(fir)` uses `FVTool` to plot the impulse response of the filter System object `fir`.

Note You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

phasez

System object: dsp.FIRFilter

Package: dsp

Unwrapped phase response

Syntax

```
[phi,w] = phasez(fir)
[phi,w] = phasez(fir,n)
[phi,w] = phasez(fir,Name,Value)
phasez(fir)
```

Description

`[phi,w] = phasez(fir)` returns the 8192–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample.

`[phi,w] = phasez(fir,n)` returns the `n`-element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[phi,w] = phasez(fir,Name,Value)` returns the phase response and the corresponding frequencies, with additional options specified by one or more `Name, Value` pair arguments.

`phasez(fir)` uses `FVTool` to plot the phase response of the filter System object `fir`.

reset

System object: dsp.FIRFilter

Package: dsp

Reset internal states of FIR filter

Syntax

```
reset(fir)
```

Description

`reset(fir)` resets the filter states of the FIR filter object, `fir`, to their initial values of 0. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the `step` method applies the FIR filter object to nonzero input data, the states may be nonzero. Invoking the `step` method again without first invoking the `reset` method may produce different outputs for an identical input.

Reset an FIR Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
fir = dsp.FIRFilter;  
fir.Numerator = fir1(20,0.25);  
n = 0:100;  
x = cos(0.2*pi*n)+sin(0.8*pi*n);  
y = fir(x);
```

Filter states are nonzero. Invoke `step` method again without resetting states

```
y1 = fir(x);  
isequal(y,y1)
```

```
ans =
```

```
logical
```

```
0
```

Now reset filter states to 0

```
reset(fir)
```

Invoke step method

```
y2 = fir(x);  
isequal(y,y2)
```

```
ans =
```

```
logical
```

```
1
```

step

System object: `dsp.FIRFilter`

Package: `dsp`

Filter input with FIR filter object

Syntax

```
Y = step(fir,X)
```

```
Y = step(fir,X,COEFF)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(fir,X)` filters the real or complex input signal `X` using the FIR filter, `fir`, to produce the output `Y`. When the input data is of a fixed-point type, it must be signed when the structure is set to `DirectFormSymmetric` or `DirectFormAntisymmetric`. The FIR filter object operates on each channel of the input signal independently over successive calls to `step` method.

`Y = step(fir,X,COEFF)` uses the time-varying coefficients, `COEFF`, to filter the input signal `X` and produce the output `Y`. You can use this option when you set the `NumeratorSource` or `ReflectionCoefficientsSource` property to `InputPort`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable

property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.HDLFIRFilter System object

Package: dsp

Finite impulse response filter—optimized for HDL code generation

Description

The `dsp.HDLFIRFilter` System object models FIR filter architectures optimized for HDL code generation. The object is sample based, accepting one scalar at a time. It provides a hardware-friendly interface with optional input and output flow control signals.

The object implements a direct-form systolic FIR filter architecture based on multiply-accumulate operations with pipeline registers. The choice of architecture makes the object well-suited for high-throughput HDL code generation targeted for FPGAs with dedicated DSP blocks. The generated HDL code runs at a high clock rate and can filter new input data on every cycle.

The object provides flexible and efficient resource sharing options. This property results in tradeoffs between throughput and resource utilization. A sharing factor of N indicates that the object reduces overall DSP resource utilization by a factor of N . In this case, the object can process an input sample only every N calls to the object. To determine when the object is ready for new input data, use the optional `readyPort` property.

To provide a cycle-accurate simulation of the generated HDL code, the object models pipeline registers and resource sharing. These operations cause a delay between valid input data and the corresponding valid output data. The actual latency depends on the number of coefficients and the sharing factor.

To filter input data with an HDL-optimized FIR filter:

- 1 Create the `dsp.HDLFIRFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

Creation

Syntax

```
firFilt = dsp.HDLFIRFilter
firFilt = dsp.HDLFIRFilter(num)
firFilt = dsp.HDLFIRFilter( ____, Name, Value)
```

Description

`firFilt = dsp.HDLFIRFilter` creates an HDL-optimized discrete FIR filter System object, `firFilt`, with default filter properties.

`firFilt = dsp.HDLFIRFilter(num)` creates the filter with the `Numerator` property set to `num`.

`firFilt = dsp.HDLFIRFilter(____, Name, Value)` creates the filter with properties set using one or more name-value pairs. Enclose each property name in single quotes.

For example:

```
Numerator = firpm(10, [0, 0.1, 0.5, 1], [1, 1, 0, 0]);
fir = dsp.HDLFIRFilter(Numerator, 'ValidInPort', false);
...
[dataOut, validOut] = fir(dataIn); ;
```

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects \(MATLAB\)](#).

Main

Numerator — Discrete FIR filter coefficients

[0.5 0.5] (default) | vector of numeric values

Discrete FIR filter coefficients, specified as a vector of numeric values. You can also specify the vector as a workspace variable, or as a call to a filter design function. Complex coefficients are not supported. When the input data type is floating point, the object casts the coefficients to the same data type as the input. When the input data type is integer or fixed point, you can modify coefficient type casting details using the `CoefficientsDataType` property.

Example: `'Numerator', firpm(30, [0 0.1 0.2 0.5]*2, [1 1 0 0])` defines the coefficients using a linear-phase filter design function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Sharing — Resource sharing option

`false` (default) | `true`

Resource sharing option, specified `false` or `true`. To reduce the overall DSP resource utilization on the FPGA, set this property to `true`. Then set the `SharingFactor` property to the value by which you want to reduce the number of DSPs.

SharingFactor — Factor by which number of DSPs is reduced

2 (default) | positive integer

Factor by which the number of DSPs is reduced, specified as a positive integer. A sharing factor of N indicates that the object reduces DSP resource utilization by a factor of N . In this case, the object can process an input sample only every N calls to the object.

Dependencies

To enable this property, set the `Sharing` property to `true`.

Data Types

Rounding — Rounding method for type casting

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Zero'

Rounding method for type casting, specified as 'Floor', 'Ceiling', 'Convergent', 'Nearest', 'Round', or 'Zero'. The rounding method is used when casting the output

to the data type specified by the `OutputDataType` property. When the input data type is floating point, the `RoundingMethod` property has no effect. See “Rounding Modes” for more details.

OverflowAction — Overflow handling for type casting

`'Wrap'` (default) | `'Saturate'`

Overflow handling for type casting, specified as `'Wrap'` or `'Saturate'`. Overflow handling is used when casting the output to the data type specified by the `OutputDataType` property. When the input data type is floating point, the `OverflowAction` property has no effect. See “Overflow Handling” for more details.

CoefficientsDataType — Data type of discrete FIR filter coefficients

`'Same word length as input'` (default) | `numericType` object

Data type of discrete FIR filter coefficients, specified as `'Same word length as input'`, or as a `numericType` object. To specify the object, call `numericType(s, w, f)`, where

- `s` is 1 for signed and 0 for unsigned.
- `w` is the word length in bits.
- `f` is the number of fractional bits.

The object casts the filter coefficients of the discrete FIR filter to the specified data type. The quantization uses nearest rounding and saturate overflow modes. When the input data type is floating point, the `CoefficientsDataType` property has no effect.

OutputDataType — Data type of discrete FIR filter output

`'Same word length as input'` (default) | `'Full precision'` | `numericType` object

Data type of discrete FIR filter output, specified as `'Same word length as input'`, `'Full precision'`, or as a `numericType` object. To specify the object, call `numericType(s, w, f)`, where

- `s` is 1 for signed and 0 for unsigned.
- `w` is the word length in bits.
- `f` is the number of fractional bits.

The object casts the output of the discrete FIR filter to the specified data type. The quantization uses the settings of `RoundingMethod` and `OverflowAction`. When the input data type is floating point, the `OutputDataType` property has no effect.

Control Ports

ValidInPort — Enable optional valid input control signal

`true` (default) | `false`

Enable optional valid input control signal, specified as `true` or `false`. When `ValidInPort` is `true`, you must call the object with an extra argument, `validIn`. The first argument of the object, `dataIn`, is treated as valid only when `validIn` is `true`. The extra argument is mandatory when DSP resources are shared. In this case, the object ignores the value of `ValidInPort`.

ReadyPort — Enable optional ready output control signal

`false` (default) | `true`

Enable optional ready output control signal, specified as `true` or `false`. When `ReadyPort` is `true`, the object returns an extra value, `ready`. The object sets `ready` to `true` to indicate that it is ready to accept new input data on the next call.

Usage

Syntax

```
[dataOut,validOut] = firFilt(dataIn)
[dataOut,validOut] = firFilt(dataIn,validIn)
[dataOut,validOut,ready] = firFilt(dataIn,validIn)
```

Description

`[dataOut,validOut] = firFilt(dataIn)` filters the input data, `dataIn`, using the specified `firFilt` filter object. The returned output data, `dataOut`, is valid only when `validOut` is `true`.

`[dataOut,validOut] = firFilt(dataIn,validIn)` filters the input data only when `validIn` is true.

Use this syntax when the `ValidInPort` or the `Sharing` property is true. When you set `Sharing` to true, the object forces `ValidInPort` to true. For example:

```

firFilt = dsp.FIRHDLFilter(Numerator,'Sharing',true,'SharingFactor',10);
...
for k=1:length(dataIn)
    [dataOut,validOut] = firFilt(dataIn(k),validIn(k));

```

`[dataOut,validOut,ready] = firFilt(dataIn,validIn)` returns `ready` set to true when the object is ready to accept new input data on the next call.

To return `ready`, set the `ReadyPort` property to true. For example:

```

firFilt = dsp.FIRHDLFilter(Numerator,'Sharing',true, ...
    'SharingFactor',10,'ReadyPort',true)
...
for k=1:length(dataIn)
    [dataOut,validOut,ready] = firFilt(dataIn(k),validIn(k));

```

Input Arguments

dataIn — Input data

real or complex scalar

Input data, specified as a real or complex scalar. When the input data type is integer or fixed point, the object uses fixed-point arithmetic for internal calculations. `double` and `single` are accepted for simulation but not for HDL code generation.

Data Types: `fi` | `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Complex Number Support: Yes

validIn — Validity of input data

logical scalar

Validity of the input data, specified as a logical scalar. The first argument, `dataIn`, is treated as valid only when `validIn` is 1 (true). `validIn` is required when `Sharing` is set to true. Otherwise, it is required only when `ValidInPort` property is set to true.

Data Types: `logical`

Output Arguments

dataOut — Filtered output data

real or complex scalar

Filtered output data, returned as a real or complex scalar. When the input data is floating point, the output data inherits the data type of the input data. When the input data is integer or fixed point, the `OutputDataType` property determines the output data type.

Data Types: `fi` | `single` | `double`

validOut — Validity of output data

logical scalar

Validity of the output data, returned as a logical scalar. The object sets `validOut` to 1 (true) with each valid output data on `dataOut`.

Data Types: `logical`

ready — Indicates that the object is ready for new input data

logical scalar

Indicator of whether the object is ready for new input data, returned as a logical scalar. The object sets `ready` to `true` to indicate that it is ready to accept new input data on the next call. The object returns this value only when the `ReadyPort` property is set to `true`.

Data Types: `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>clone</code>	Create duplicate System object
<code>getNumInputs</code>	Number of inputs required to call the System object

getNumOutputs	Number of outputs from calling the System object
isLocked	Determine if System object is locked
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

HDL FIR Filter System Object with Default Settings

Create an HDL FIR filter System object with default settings.

```
firFilt = dsp.HDLFIRFilter;
```

Create an input signal of some random noise, and allocate memory for outputs.

```
L = 100;
dataIn = randn(L,1);
dataOut = zeros(L,1);
validOut = false(L,1);
```

Call the object on the input signal, asserting that the input data is always valid. The object processes one data sample at a time.

```
for k=1:L
    [dataOut(k),validOut(k)] = firFilt(dataIn(k),true);
end
```

HDL FIR Filter System Object with Resource Sharing

Operate a 31-tap lowpass filter with resource sharing.

Design the filter coefficients. Then create an HDL FIR filter System object. Enable resource sharing and the ready output port.

```
numerator = firpm(30,[0 0.1 0.2 0.5]*2,[1 1 0 0]);
sharingFactor = 10;
firFilt = dsp.HDLFIRFilter('Numerator',numerator, ...
    'Sharing',true,'SharingFactor',sharingFactor,'ReadyPort',true);
```

The specified `sharingFactor` indicates that the filter requires 10 time steps to calculate each output. Create input signals `dataIn` and `validIn` such that new data is applied only every `sharingFactor` time steps.

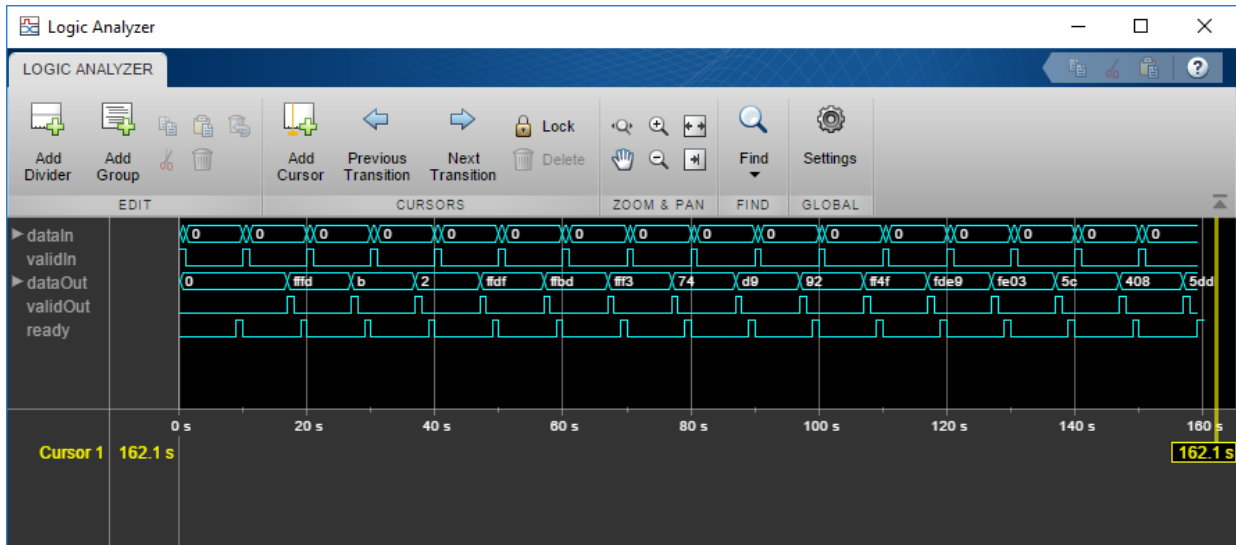

```
L = 16;
x = fi(randn(L,1),1,16);
dataIn = zeros(L*sharingFactor,1,'like',x);
dataIn(1:sharingFactor:end) = x;
validIn = false(L*sharingFactor,1);
validIn(1:sharingFactor:end) = true;
```

Create a `LogicAnalyzer` object to view the inputs and outputs

```
la = dsp.LogicAnalyzer('NumInputPorts',5, ...
    'SampleTime',1,'TimeSpan',length(dataIn));
tags = getDisplayChannelTags(la);
modifyDisplayChannel(la,tags{1},'Name','dataIn');
modifyDisplayChannel(la,tags{2},'Name','validIn');
modifyDisplayChannel(la,tags{3},'Name','dataOut');
modifyDisplayChannel(la,tags{4},'Name','validOut');
modifyDisplayChannel(la,tags{5},'Name','ready');
```

Call the filter `System` object on the input signals, and view the results in the Logic Analyzer.

```
for k=1:length(dataIn)
    [dataOut,validOut,ready] = firFilt(dataIn(k),validIn(k));
    la(dataIn(k),validIn(k),dataOut,validOut,ready)
end
```

The object models HDL pipeline registers and resource sharing. Therefore, there is an initial delay before the object returns valid output samples.

Create HDL FIR Filter System Object for HDL Code Generation

To generate HDL code from a System object™, create a function that contains and calls the object.

Create Function

Write a function that creates and calls an 11-tap HDL FIR filter System object. You can generate HDL from this function.

```
function [dataOut,validOut] = HDLFIR11Tap(dataIn)
%HDLFIR11Tap
% Process one sample of data using the dsp.HDLFIRFilter System
% object.
% dataIn is a fixed-point scalar value.
% You can generate HDL code from this function.
    persistent fir
    if isempty(fir)
```

```
        Numerator = firpm(10,[0 0.1 0.5 1],[1 1 0 0]);
        fir = dsp.HDLFIRFilter(Numerator,'ValidInPort',false);
    end
    [dataOut,validOut] = fir(dataIn);
end
```

Create Test Bench for Function

Clear the workspace, create an input signal of some random noise, and allocate memory for outputs.

```
clear variables
clear HDLFIR11Tap
L = 200;
dataIn = fi(randn(L,1),1,16);
dataOut = zeros(L,1);
validOut = false(L,1);
```

Call the function on the input signal.

```
for k = 1:L
    [dataOut(k),validOut(k)] = HDLFIR11Tap(dataIn(k));
end
```

Plot the signals with the Logic Analyzer.

```
la = dsp.LogicAnalyzer('NumInputPorts',3,'SampleTime',1,'TimeSpan',L);
tags = getDisplayChannelTags(la);
modifyDisplayChannel(la,tags{1},'Name','dataIn','Format','Analog','Height',50);
modifyDisplayChannel(la,tags{2},'Name','dataOut','Format','Analog','Height',50);
modifyDisplayChannel(la,tags{3},'Name','validOut');
la(dataIn,dataOut,validOut)
```

Algorithms

This object implements the algorithms described on the Discrete FIR Filter HDL Optimized block reference page.

`dsp.FIRFilter`

Introduced in R2017a

dsp.FIRHalfbandDecimator System object

Package: dsp

Halfband decimator

Description

`dsp.FIRHalfbandDecimator` performs an efficient polyphase decimation of the input signal by a factor of two. You can use `dsp.FIRHalfbandDecimator` to implement the analysis portion of a two-band filter bank to filter a signal into lowpass and highpass subbands. `dsp.FIRHalfbandDecimator` uses an FIR equiripple design to construct the halfband filters and a polyphase implementation to filter the input. This object supports fixed-point operations and ARM Cortex code generation.

To filter and downsample your data:

- 1 Define and set up your halfband decimator. See “Construction” on page 4-742.
- 2 Call `step` to filter the input signal according to the properties of `dsp.FIRHalfbandDecimator`. The input signal can be a real- or complex-valued column vector or matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel. The number of rows in the input signal must be a multiple of 2.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`firhalfbanddecim = dsp.FIRHalfbandDecimator` returns a halfband decimator, `firhalfbanddecim`, with the default settings. Calling `step` with the default property settings filters and downsamples the input data with a halfband frequency of 11025 Hz, a transition width of 4.1 kHz, and a stopband attenuation of 80 dB.

`firhalfbanddecim = dsp.FIRHalfbandDecimator(Name, Value)` returns a halfband decimator, with additional properties specified by one or more `Name, Value` pair arguments. `Name` is the property name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Properties

Specification — Filter design parameters

'Transition width and stopband attenuation' (default) | 'Filter order and stopband attenuation' | 'Filter order and transition width'

Filter design parameters, specified as a character vector. Valid options are 'Transition width and stopband attenuation' (default), 'Filter order and stopband attenuation', or 'Filter order and transition width'. The filter design has only two degrees of freedom so you can only specify two of the following: filter order, transition width, or stopband attenuation. Setting a filter design specification without additionally specifying values for the design parameters results in default values for the specifications.

FilterOrder — Filter order

52 (default) | even positive integer

Filter order, specified as the comma-separated pair of 'FilterOrder' and an even positive integer. Specifying a filter order is only valid when the value of 'Specification' is 'Filter order and stopband attenuation' or 'Filter order and transition width'.

StopbandAttenuation — Stopband attenuation

80 (default) | positive real scalar

Stopband attenuation in dB, specified as the comma-separated pair of 'StopbandAttenuation' and a positive real scalar. Specifying the stopband attenuation is only valid when the value of 'Specification' is 'Filter order and stopband attenuation' or 'Transition width and stopband attenuation'.

TransitionWidth — Transition width

4100 (default) | positive real scalar

Transition width in Hz, specified as the comma-separated pair of 'TransitionWidth' and a positive real scalar. The value of the transition width in Hz must be less than 1/2 the input sample rate. Specifying the transition width is valid only when the value of 'Specification' is 'Transition width and stopband attenuation' or 'Filter order and transition width'.

SampleRate — Input sample rate

44100 (default) | positive real scalar

Input sample rate in Hz, specified as a comma-separated pair of 'SampleRate' and a positive real scalar. The input sample rate defaults to 44100 Hz. If you specify a transition width as one of your filter design parameters, the transition width cannot exceed 1/2 the input sample rate.

Fixed-Point Properties

CoefficientsDataType — Word and fraction lengths of coefficients

numericType(1,16) (default) | numericType object

Word and fraction lengths of coefficients, specified as a signed or unsigned numericType object. The default, numericType(1,16) corresponds to a signed numeric type object with 16-bit coefficients and a fraction length determined based on the coefficient values, to give the best possible precision.

This property is not tunable.

Word length of the output is same as the word length of the input. Fraction length of the output is computed such that the entire dynamic range of the output can be represented without overflow. For details on how the fraction length of the output is computed, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

RoundingMethod — Rounding method for output fixed-point operations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see “Precision and Range”.

Methods

reset Reset internal states of FIR halfband decimator
 step Filter input with FIR halfband decimator

For additional methods, see “Analysis Methods for Filter System Objects” on page 3-2.

For a complete list of analysis methods supported for the `dsp.FIRHalfbandDecimator` object, enter `dsp.FIRHalfbandDecimator.helpFilterAnalysis` at the MATLAB command prompt.

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object

Examples

Impulse and Frequency Response of Halfband Decimation Filter

Create a lowpass halfband decimation filter for data sampled at 44.1 kHz. The output data rate is 1/2 the input sampling rate, or 22.05 kHz. Specify the filter order to be 52 with a transition width of 4.1 kHz.

```
Fs = 44.1e3;
filterspec = 'Filter order and transition width';
Order = 52;
TW = 4.1e3;
firhalfbanddecim = dsp.FIRHalfbandDecimator('Specification',filterspec, ...
                                             'FilterOrder',Order, ...
                                             'TransitionWidth',TW, ...
                                             'SampleRate',Fs);
```

Plot the impulse response. The zeroth-order coefficient is delayed 26 samples, which is equal to the group delay of the filter. This yields a causal halfband filter.

```
fvtool(firhalfbanddecim,'Analysis','impulse')
```

Plot the magnitude and phase response.

```
fvtool(firhalfbanddecim,'Analysis','freq')
```

Extract Low Frequency Subband From Speech

Use a halfband analysis filter bank and interpolation filter to extract the low frequency subband from a speech signal.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Set up the audio file reader, the analysis filter bank, audio device writer, and interpolation filter. The sampling rate of the audio data is 22050 Hz. The order of the halfband filter is 52, with a transition width of 2 kHz.

```
afr = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);

filterspec = 'Filter order and transition width';
Order = 52;
TW = 2000;

firhalfbanddecim = dsp.FIRHalfbandDecimator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',afr.SampleRate);

firhalfbandinterp = dsp.FIRHalfbandInterpolator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',afr.SampleRate/2);

adw = audioDeviceWriter('SampleRate',afr.SampleRate);
```

View the magnitude response of the halfband filter.

```
fvtool(firhalfbanddecim)
```

Read the speech signal from the audio file in frames of 1024 samples. Filter the speech signal into lowpass and highpass subbands with a halfband frequency of 5512.5 Hz. Reconstruct a lowpass approximation of the speech signal by interpolating the lowpass subband. Play the filtered output.

```
while ~isDone(afr)
    audioframe = afr();
    xlo = firhalfbanddecim(audioframe);
    ylow = firhalfbandinterp(xlo);
    adw(ylow);
end
```

Wait until the audio file is played to the end, then close the input file and release the audio output resource.

```
release(afr);
release(adw);
```

Two-Channel Filter Bank

Use a halfband decimator and interpolator to implement a two-channel filter bank. This example uses an audio file input and shows that the power spectrum of the filter bank output does not differ significantly from the input.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Set up the audio file reader and device writer. Construct the FIR halfband decimator and interpolator. Finally, set up the spectrum analyzer to display the power spectra of the filter-bank input and output.

```
AF = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);
AP = audioDeviceWriter('SampleRate',AF.SampleRate);

filterspec = 'Filter order and transition width';
Order = 52;
TW = 2000;

firhalfbanddecim = dsp.FIRHalfbandDecimator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',AF.SampleRate);

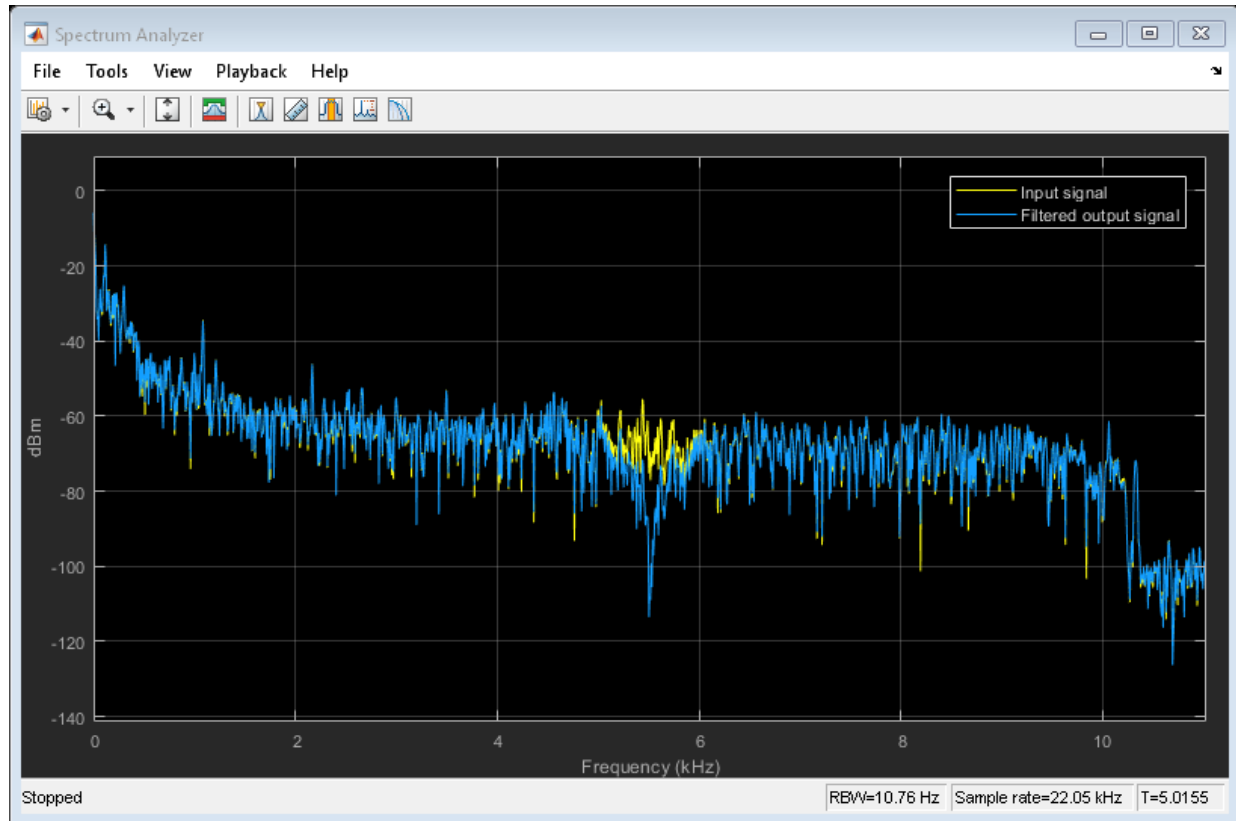

firhalfbandinterp = dsp.FIRHalfbandInterpolator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',AF.SampleRate/2,...
    'FilterBankInputPort',true);

SpecAna = dsp.SpectrumAnalyzer('SampleRate',AF.SampleRate,...
    'PlotAsTwoSidedSpectrum',false,'ReducePlotRate',false,...
    'ShowLegend',true,...
    'ChannelNames',{'Input signal','Filtered output signal'});
```

Read the audio 1024 samples at a time. Filter the input to obtain the lowpass and highpass subband signals decimated by a factor of two. This is the analysis filter bank. Use the halfband interpolator as the synthesis filter bank. Display the running power spectrum of the audio input and the output of the synthesis filter bank. Play the output.

```
while ~isDone(AF)
    audioInput = AF();
    [xlo,xhigh] = firhalfbanddecim(audioInput);
    audioOutput = firhalfbandinterp(xlo,xhigh);
    spectrumInput = [audioInput audioOutput];
    SpecAna(spectrumInput);
    AP(audioOutput);
end

release(AF);
release(AP);
release(SpecAna);
```

Definitions

Halfband Filters

The ideal lowpass halfband filter is given by

$$h(n) = \frac{1}{2\pi} \int_{-\pi/2}^{\pi/2} e^{j\omega n} d\omega = \frac{\sin(\frac{\pi}{2}n)}{\pi n}.$$

The ideal filter is not realizable because the impulse response is noncausal and not absolutely summable. However, the impulse response of the ideal lowpass filter possesses

some important properties that are required of a realizable approximation. Specifically, the ideal lowpass halfband filter's impulse response is:

- equal to 0 for all even-indexed samples
- equal to 1/2 at $n=0$. You can see this by using L'Hopital's rule on the continuous-valued equivalent of the discrete-time impulse response.

The ideal highpass halfband filter is given by

$$g(n) = \frac{1}{2\pi} \int_{-\pi}^{-\pi/2} e^{j\omega n} d\omega + \frac{1}{2\pi} \int_{\pi/2}^{\pi} e^{j\omega n} d\omega.$$

Evaluating the preceding integral gives the following impulse response

$$g(n) = \frac{\sin(\pi n)}{\pi n} - \frac{\sin(\frac{\pi}{2} n)}{\pi n}.$$

The ideal highpass halfband filter's impulse is:

- equal to 0 for all even-indexed samples
- equal to 1/2 at $n=0$.

`dsp.FIRHalfbandDecimator` uses a causal FIR approximation to the ideal halfband response, which is based on minimizing the ℓ^∞ norm of the error (minimax). See "Algorithms" on page 4-753 for more details.

Algorithms

Halfband Equiripple Design

`dsp.FIRHalfbandDecimator` uses a minimax FIR design to design a fullband linear phase filter with the desired specifications. The fullband filter is upsampled so that the even-indexed samples of the filter are replaced with zeros. The upsampling of the filter produces a halfband filter. Finally, the filter tap corresponding to the group delay of the filter in samples is set equal to 1/2. This yields a causal linear-phase FIR filter approximation to the ideal halfband filter defined in "Halfband Filters" on page 4-752. See [1] for a description of this filter design method using the Remez exchange algorithm.

Polyphase Implementation with Halfband Filters

`dsp.FIRHalfbandDecimator` uses an efficient polyphase implementation for halfband filters when you call `step` to filter your signal. The chief advantage of the polyphase implementation is that you can downsample the signal prior to filtering. This allows you to filter at the lower sampling rate.

Splitting a filter's impulse response, $h(n)$, into two polyphase components results in an even polyphase component with z -transform

$$H_0(z) = \sum_n h(2n)z^{-n}.$$

and an odd polyphase component with z -transform

$$H_1(z) = \sum_n h(2n+1)z^{-n}.$$

The z -transform of the filter can be written in terms of the even and odd polyphase components as

$$H(z) = H_0(z^2) + z^{-1}H_1(z^2).$$

Graphically, you can represent filtering and input followed by downsampling by two with the following figure

Using the multirate noble identity for downsampling, you can move the downsampling operation before filtering. This allows you to filter at the lower rate.

For a halfband filter, the only nonzero coefficient in the even polyphase component is the coefficient corresponding to z^0 . Implementing the halfband filter as a causal FIR filter shifts the nonzero coefficient to approximately $z^{-N/4}$ where N is the number of filter taps. This process is illustrated in the following figure.

The top plot shows a halfband filter of order 52. The bottom plot shows the even polyphase component. Both of these filters are noncausal. Delaying the even polyphase component by 13 samples creates a causal FIR filter.

To efficiently implement the halfband decimator, `dsp.FIRHalfbandDecimator` replaces the delay block and downsampling operator with a commutator switch. This is illustrated in the following figure where one polyphase component is replaced by a gain and delay.

The commutator switch takes input samples from a single branch and supplies every other sample to one of the two polyphase components for filtering. This halves the sampling rate of the input signal. Which polyphase component reduces to a simple delay depends on whether the half order of the filter is even or odd. This is because the delay required to make the even polyphase component causal can be odd or even depending on the filter half order. You can see this by inspecting the polyphase components of the following filters.

```
filterspec = 'Filter order and stopband attenuation' ;
halfOrderEven = dsp.FIRHalfbandDecimator('Specification',filterspec,...
    'FilterOrder',64,'StopbandAttenuation',80);
halfOrderOdd = dsp.FIRHalfbandDecimator('Specification',filterspec,...
    'FilterOrder',54,'StopbandAttenuation',80);
polyphase(halfOrderEven)
polyphase(halfOrderOdd)
```

To summarize, `dsp.FIRHalfbandDecimator`

- decimates the input prior to filtering and filters the even and odd polyphase components of the input separately with the even and odd polyphase components of the filter.
- exploits the fact that one filter polyphase component is a simple delay for a halfband filter.

reset

System object: dsp.FIRHalfbandDecimator

Package: dsp

Reset internal states of FIR halfband decimator

Syntax

```
reset(firhalfbanddecim)
```

Description

`reset(firhalfbanddecim)` resets the filter states of the FIR halfband decimator, `firhalfbanddecim`, to their initial values of 0. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the `step` method applies the half-band decimator to nonzero input data, the states may be nonzero. Invoking the `step` method again without first invoking the `reset` method may produce different outputs for an identical input.

step

System object: dsp.FIRHalfbandDecimator

Package: dsp

Filter input with FIR halfband decimator

Syntax

```
Y = step(firhalfbanddecim,X)
[Ylow,Yhigh] = step(firhalfbanddecim,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(firhalfbanddecim,X)` filters the real or complex input signal `X` using the FIR halfband filter, `firhalfbanddecim`, and downsamples the output by a factor of 2. `Y` is a lowpass halfband filtered and downsampled version of the input `X`. The input `X` must be a column vector or matrix with an even number of rows. If `X` is a matrix, each column is treated as an independent channel. The input `X` supports single, double, and fixed-point data types.

`[Ylow,Yhigh] = step(firhalfbanddecim,X)` outputs the lowpass, `Ylow`, and highpass, `Yhigh`, subbands.

Examples

Filter Input into Lowpass and Highpass Subbands

Create a halfband decimator for data sampled at 44.1 kHz. Use a minimum-order design with a transition width of 2 kHz and a stopband attenuation of 60 dB.

```
hfirhalfbanddecim = dsp.FIRHalfbandDecimator(...  
    'Specification','Transition width and stopband attenuation',...  
    'TransitionWidth',2000,'StopbandAttenuation',60,'SampleRate',44.1e3);
```

Filter a two-channel input into low and highpass subbands

```
x = randn(1024,2);  
[ylow,yhigh] = step(hfirhalfbanddecim,x);
```

dsp.FIRHalfbandInterpolator System object

Package: dsp

Halfband interpolator

Description

`dsp.FIRHalfbandInterpolator` performs efficient polyphase interpolation of the input signal using an upsampling factor of two. You can use `dsp.FIRHalfbandInterpolator` to implement the synthesis portion of a two-band filter bank to synthesize a signal from lowpass and highpass subbands. `dsp.FIRHalfbandInterpolator` uses an FIR equiripple design to construct the halfband filters and a polyphase implementation to filter the input. This object supports fixed-point operations and ARM Cortex code generation.

To upsample and interpolate your data:

- 1 Define and set up your halfband interpolator. See “Construction” on page 4-762.
- 2 Call `step` to filter the input signal according to the properties of `dsp.FIRHalfbandInterpolator`. The input signal can be a real- or complex-valued column vector or matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`firhalfbandinterp = dsp.FIRHalfbandInterpolator` returns a FIR halfband interpolation filter, `firhalfbandinterp`, with the default settings. Calling `step` with the default property settings upsamples and interpolates the input data using a halfband

frequency of 11025 Hz, a transition width of 4.1 kHz, and a stopband attenuation of 80 dB.

`firhalfbandinterp = dsp.FIRHalfbandInterpolator(Name, Value)` returns a halfband interpolator, with additional properties specified by one or more `Name, Value` pair arguments. `Name` is the property name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Properties

Specification — Filter design parameters

'Transition width and stopband attenuation' (default) | 'Filter order and stopband attenuation' | 'Filter order and transition width'

Filter design parameters, specified as a character vector. Valid options are 'Transition width and stopband attenuation' (default), 'Filter order and stopband attenuation', or 'Filter order and transition width'. The filter design has only two degrees of freedom, so you can specify only two of the following: filter order, transition width, or stopband attenuation. Setting a filter design specification without additionally specifying values for the design parameters results in default values for the specifications.

FilterOrder — Filter order

52 (default) | even positive integer

Filter order, specified as the comma-separated pair of 'FilterOrder' and an even positive integer. Specifying a filter order is valid only when the value of 'Specification' is 'Filter order and stopband attenuation' or 'Filter order and transition width'.

StopbandAttenuation — Stopband attenuation

80 (default) | positive real scalar

Stopband attenuation in dB, specified as the comma-separated pair of 'StopbandAttenuation' and a positive real scalar. Specifying the stopband attenuation is valid only when the value of 'Specification' is 'Filter order and stopband attenuation' or 'Transition width and stopband attenuation'.

TransitionWidth — Transition width

4100 (default) | positive real scalar

Transition width in Hz, specified as the comma-separated pair of 'TransitionWidth' and a positive real scalar. The value of the transition width in Hz must be less than 1/2 the output sample rate. Specifying the transition width is valid only when the value of 'Specification' is 'Transition width and stopband attenuation' or 'Filter order and transition width'.

SampleRate — Input sample rate

44100 (default) | positive real scalar

Input sample rate in Hz, specified as a comma-separated pair of 'SampleRate' and a positive real scalar. The input sample rate defaults to 44100 Hz. If you specify a transition width as one of your filter design parameters, the transition width cannot exceed 1/2 the input sample rate.

FilterBankInputPort — Synthesis filter bank

false (default) | true

Synthesis filter bank, specified as a comma-separated pair consisting of 'FilterBankInputPort' and a logical value. If this property is false, `dsp.FIRHalfbandInterpolator` is an interpolation filter for a single vector- or matrix-valued input when you use `step`. If this property is true, `dsp.FIRHalfbandInterpolator` is a synthesis filter bank and `step` accepts two inputs, the lowpass and highpass subbands to synthesize.

Fixed-Point Properties

CoefficientsDataType — Word and fraction lengths of coefficients

`numericType(1,16)` (default) | `numericType` object

Word and fraction lengths of coefficients, specified as a signed or unsigned `numericType` object. The default, `numericType(1,16)` corresponds to a signed numeric type object with 16-bit coefficients and a fraction length determined based on the coefficient values, to give the best possible precision.

This property is not tunable.

Word length of the output is same as the word length of the input. Fraction length of the output is computed such that the entire dynamic range of the output can be represented

without overflow. For details on how the fraction length of the output is computed, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

RoundingMethod — Rounding method for output fixed-point operations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see “Precision and Range”.

Methods

`reset` Reset internal states of FIR halfband interpolator
`step` Filter input with FIR halfband interpolator

For additional methods, see “Analysis Methods for Filter System Objects” on page 3-2.

For a complete list of analysis methods supported for the `dsp.FIRHalfbandInterpolator` object, enter `dsp.FIRHalfbandInterpolator.helpFilterAnalysis` at the MATLAB command prompt.

Examples

Impulse and Frequency Response of Halfband Interpolation Filter

Create a lowpass halfband interpolation filter for upsampling data to 44.1 kHz. Specify a filter order of 52 and a transition width of 4.1 kHz.

```
Fs = 44.1e3;  
InputSampleRate = Fs/2;  
Order = 52;  
TW = 4.1e3;  
filterspec = 'Filter order and transition width';  
  
firhalfbandinterp = dsp.FIRHalfbandInterpolator(...  
    'Specification',filterspec,'FilterOrder',Order,...  
    'TransitionWidth',TW,'SampleRate',InputSampleRate);
```

Plot the impulse response. The 0th order coefficient is delayed 26 samples, which is equal to the group delay of the filter. This yields a causal halfband filter.

```
fvtool(firhalfbandinterp,'Analysis','Impulse');
```

Plot the magnitude and phase response.

```
fvtool(firhalfbandinterp, 'Analysis', 'freq');
```

Extract Low Frequency Subband From Speech

Use a halfband analysis filter bank and interpolation filter to extract the low frequency subband from a speech signal.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Set up the audio file reader, the analysis filter bank, audio device writer, and interpolation filter. The sampling rate of the audio data is 22050 Hz. The order of the halfband filter is 52, with a transition width of 2 kHz.

```
afr = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);

filterspec = 'Filter order and transition width';
Order = 52;
TW = 2000;

firhalfbanddecim = dsp.FIRHalfbandDecimator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',afr.SampleRate);

firhalfbandinterp = dsp.FIRHalfbandInterpolator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',afr.SampleRate/2);

adw = audioDeviceWriter('SampleRate',afr.SampleRate);
```

View the magnitude response of the halfband filter.

```
fvtool(firhalfbanddecim)
```

Read the speech signal from the audio file in frames of 1024 samples. Filter the speech signal into lowpass and highpass subbands with a halfband frequency of 5512.5 Hz. Reconstruct a lowpass approximation of the speech signal by interpolating the lowpass subband. Play the filtered output.

```
while ~isDone(afr)
    audioframe = afr();
    xlo = firhalfbanddecim(audioframe);
    ylow = firhalfbandinterp(xlo);
    adw(ylow);
end
```

Wait until the audio file is played to the end, then close the input file and release the audio output resource.

```
release(afr);
release(adw);
```

Two-Channel Filter Bank

Use a halfband decimator and interpolator to implement a two-channel filter bank. This example uses an audio file input and shows that the power spectrum of the filter bank output does not differ significantly from the input.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Set up the audio file reader and device writer. Construct the FIR halfband decimator and interpolator. Finally, set up the spectrum analyzer to display the power spectra of the filter-bank input and output.

```
AF = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);
AP = audioDeviceWriter('SampleRate',AF.SampleRate);

filterspec = 'Filter order and transition width';
Order = 52;
TW = 2000;

firhalfbanddecim = dsp.FIRHalfbandDecimator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',AF.SampleRate);

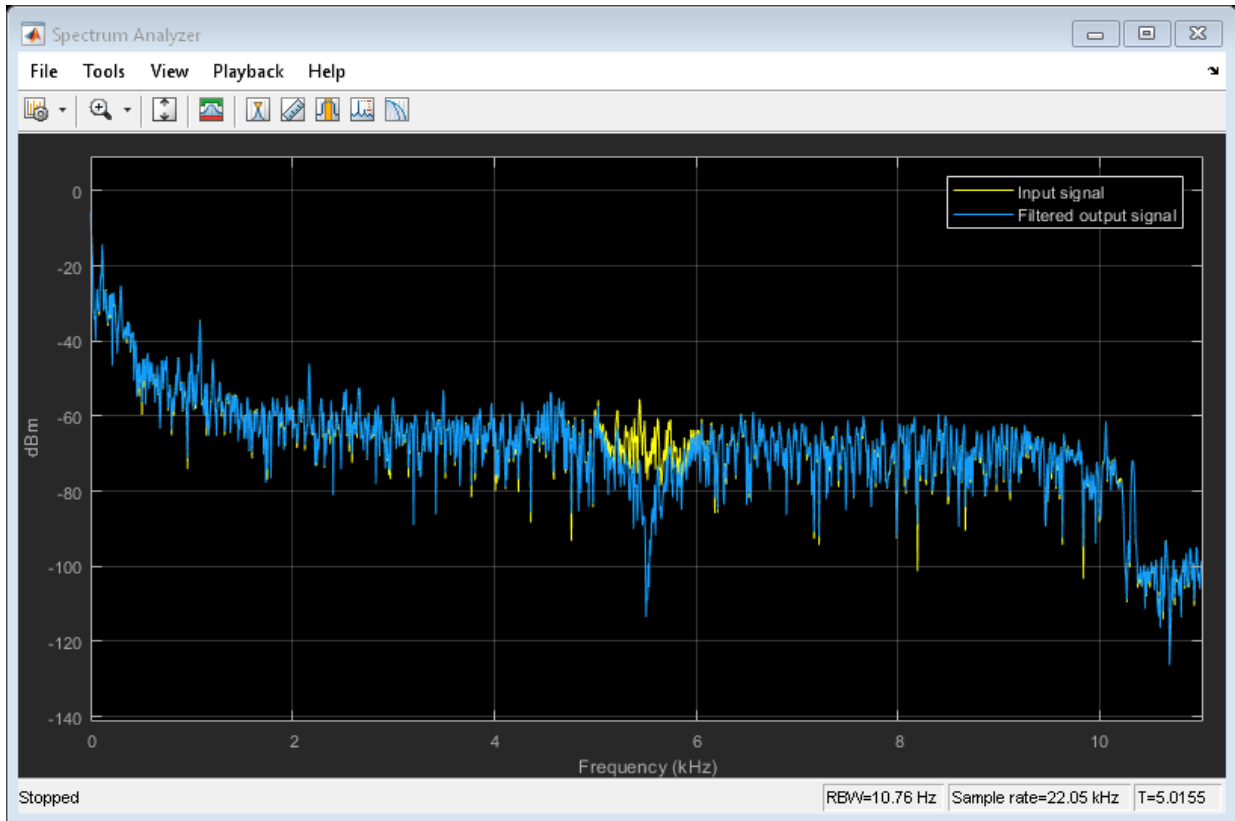

firhalfbandinterp = dsp.FIRHalfbandInterpolator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',AF.SampleRate/2,...
    'FilterBankInputPort',true);

SpecAna = dsp.SpectrumAnalyzer('SampleRate',AF.SampleRate,...
    'PlotAsTwoSidedSpectrum',false,'ReducePlotRate',false,...
    'ShowLegend',true,...
    'ChannelNames',{'Input signal','Filtered output signal'});
```

Read the audio 1024 samples at a time. Filter the input to obtain the lowpass and highpass subband signals decimated by a factor of two. This is the analysis filter bank. Use the halfband interpolator as the synthesis filter bank. Display the running power spectrum of the audio input and the output of the synthesis filter bank. Play the output.

```
while ~isDone(AF)
    audioInput = AF();
    [xlo,xhigh] = firhalfbanddecim(audioInput);
    audioOutput = firhalfbandinterp(xlo,xhigh);
    spectrumInput = [audioInput audioOutput];
    SpecAna(spectrumInput);
    AP(audioOutput);
end

release(AF);
release(AP);
release(SpecAna);
```

Definitions

Halfband Filters

The ideal lowpass halfband filter is given by

$$h(n) = \frac{1}{2\pi} \int_{-\pi/2}^{\pi/2} e^{j\omega n} d\omega = \frac{\sin(\frac{\pi}{2}n)}{\pi n}.$$

The ideal filter is not realizable because the impulse response is noncausal and not absolutely summable. However, the impulse response of the ideal lowpass filter possesses

some important properties that are required of a realizable approximation. Specifically, the ideal lowpass halfband filter's impulse response is:

- equal to 0 for all even-indexed samples
- equal to 1/2 at $n=0$. You can see this by using L'Hopital's rule on the continuous-valued equivalent of the discrete-time impulse response.

The ideal highpass halfband filter is given by

$$g(n) = \frac{1}{2\pi} \int_{-\pi}^{-\pi/2} e^{j\omega n} d\omega + \frac{1}{2\pi} \int_{\pi/2}^{\pi} e^{j\omega n} d\omega.$$

Evaluating the preceding integral gives the following impulse response

$$g(n) = \frac{\sin(\pi n)}{\pi n} - \frac{\sin(\frac{\pi}{2} n)}{\pi n}.$$

The ideal highpass halfband filter's impulse is:

- Equal to 0 for all even-indexed samples
- Equal to 1/2 at $n=0$.

`dsp.FIRHalfbandInterpolator` uses a causal FIR approximation to the ideal

halfband response, which is based on minimizing the ℓ^∞ norm of the error (minimax). See "Algorithms" on page 4-774 for more details.

Algorithms

Halfband Equiripple Design

`dsp.FIRHalfbandInterpolator` uses a minimax FIR design to design a fullband linear phase filter with the desired specifications. The fullband filter is upsampled so that the even-indexed samples of the filter are replaced with zeros. The upsampling of the filter produces a halfband filter. Finally, the filter tap corresponding to the group delay of the filter in samples is set equal to 1/2. This yields a causal linear-phase FIR filter approximation to the ideal halfband filter defined in "Halfband Filters" on page 4-773. See [1] for a description of this filter design method using the Remez exchange algorithm.

The coefficients of the halfband interpolation filter are scaled by the interpolation factor, two, to preserve the output power of the signal.

Polyphase Implementation with Halfband Filters

`dsp.FIRHalfbandInterpolator` uses an efficient polyphase implementation for halfband filters when you call `step` to filter your signal. You can use a polyphase implementation to move the upsampling operation after filtering. This allows you to filter at the lower sampling rate.

Splitting a filter's impulse response, $h(n)$, into two polyphase components results in an even polyphase component with z -transform

$$H_0(z) = \sum_n h(2n)z^{-n}.$$

and an odd polyphase component with z -transform

$$H_1(z) = \sum_n h(2n+1)z^{-n}.$$

The z -transform of the filter can be written in terms of the even and odd polyphase components as

$$H(z) = H_0(z^2) + z^{-1}H_1(z^2).$$

Graphically, you can represent upsampling by two followed by filtering with the following figure

Using the multirate noble identity for upsampling, you can move the upsampling operation after filtering. This enables you to filter at the lower rate.

For a halfband filter, the only nonzero coefficient in the even polyphase component is the coefficient corresponding to z^0 . Implementing the halfband filter as a causal FIR filter shifts the nonzero coefficient to approximately $z^{-N/4}$, where N is the number of filter taps. This process is shown in the following figure.

The top plot shows a halfband filter of order 52. The bottom plot shows the even polyphase component. Both of these filters are noncausal. Delaying the even polyphase component by 13 samples creates a causal FIR filter.

To efficiently implement the halfband interpolator, `dsp.FIRHalfbandInterpolator` replaces the upsampling operator, delay block, and adder with a commutator switch. This is shown in the following figure, where one polyphase component is replaced by a delay.

The commutator switch takes input samples from the two branches alternately, one sample at a time. This doubles the sampling rate of the input signal. The polyphase component that reduces to a simple delay depends on whether the half order of the filter is even or odd. This is because the delay required to make the even polyphase component causal can be odd or even, depending on the filter half order. For an example of this behavior, inspect the polyphase components of the following filters.

```
filterspec = 'Filter order and stopband attenuation';
halfOrderEven = dsp.FIRHalfbandInterpolator('Specification',filterspec,...
    'FilterOrder',64,'StopbandAttenuation',80);
halfOrderOdd = dsp.FIRHalfbandInterpolator('Specification',filterspec,...
    'FilterOrder',54,'StopbandAttenuation',80);
polyphase(halfOrderEven)
polyphase(halfOrderOdd)
```

One of the polyphase components has a single nonzero coefficient indicating that it is a simple delay. To preserve the output power of the signal, the coefficients are scaled by the interpolation factor, two. To see this scaling, compare the polyphase components of a halfband interpolator with the coefficients of a halfband decimator.

```
hfirinterp = dsp.FIRHalfbandInterpolator;
hfirdecim = dsp.FIRHalfbandDecimator;
polyphase(hfirdecim)
polyphase(hfirinterp)
```

To summarize, `dsp.FIRHalfbandInterpolator`

- Filters the input before upsampling with the even and odd polyphase components of the filter.
- Exploits the fact that one filter polyphase component is a simple delay for a halfband filter.

reset

System object: dsp.FIRHalfbandInterpolator

Package: dsp

Reset internal states of FIR halfband interpolator

Syntax

```
reset(firhalfbandinterp)
```

Description

`reset(firhalfbandinterp)` resets the filter states of the FIR halfband interpolator, `firhalfbandinterp`, to their initial values of 0. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the `step` method applies the halfband interpolator to nonzero input data, the states may be nonzero. Invoking the `step` method again without first invoking the `reset` method may produce different outputs for an identical input.

step

System object: dsp.FIRHalfbandInterpolator

Package: dsp

Filter input with FIR halfband interpolator

Syntax

```
Y = step(firhalfbandinterp,X)
Y = step(firhalfbandinterp,X1,X2)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(firhalfbandinterp,X)` upsamples by two and interpolates the real or complex input signal `X` using the FIR halfband interpolator, `firhalfbandinterp`. The input `X` must be a column vector or matrix. If `X` is a matrix, each column is treated as an independent channel. The input `X` supports single, double, and fixed-point data types.

`Y = step(firhalfbandinterp,X1,X2)` implements a halfband synthesis filter bank for the inputs `X1` and `X2`. `X1` is the lowpass output of a halfband analysis filter bank and `X2` is the highpass output of a halfband analysis filter bank.

`dsp.FIRHalfbandInterpolator` implements a synthesis filter bank only when the `'FilterBankInputPort'` property is true.

Examples

Upsample and Interpolate Multichannel Input

Create a half-band interpolation filter for data sampled at 44.1 kHz. The filter order is 52 with a transition width of 4.1 kHz. Use the filter to upsample and interpolate a multichannel input.

```
Fs = 44.1e3;
filterspec = 'Filter order and transition width';
Order = 52;
TW = 4.1e3;
firhalfbandinterp = dsp.FIRHalfbandInterpolator(...
    'Specification', filterspec, ...
    'FilterOrder', Order, ...
    'TransitionWidth', TW, ...
    'SampleRate', Fs);

x = randn(1024, 4);
y = step(firhalfbandinterp, x);
```

dsp.FIRInterpolator System object

Package: dsp

Polyphase FIR interpolator

Description

The `FIRInterpolator` object upsamples an input by the integer upsampling factor, L , followed by an FIR anti-imaging filter. The filter coefficients are scaled by the interpolation factor. A polyphase interpolation structure implements the filter. The resulting discrete-time signal has a sampling rate L times the original sampling rate.

To upsample an input:

- 1 Define and set up your FIR interpolator. See “Construction” on page 4-783.
- 2 Call `step` to upsample the input according to the properties of `dsp.FIRInterpolator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`firinterp = dsp.FIRInterpolator` returns an FIR interpolator, `firinterp`, which upsamples an input signal by a factor of 3 and applies an FIR filter to interpolate the output.

`firinterp = dsp.FIRInterpolator('PropertyName',PropertyValue, ...)` returns an FIR interpolator, `firinterp`, with each property set to the specified value.

`firinterp = dsp.FIRInterpolator(INTERP, NUM, 'PropertyName', PropertyValue, ...)` returns an FIR interpolation object,

`firinterp`, with the `InterpolationFactor` property set to `INTERP`, the `Numerator` property set to `NUM`, and other properties set to the specified values.

Properties

InterpolationFactor

Interpolation factor

Specify the integer factor, L , by which to increase the sampling rate of the input signal. The polyphase implementation uses L polyphase subfilters to compute convolutions at the lower sample rate. The FIR interpolator delays and interleaves these lower-rate convolutions to obtain the higher-rate output. The property value defaults to 3.

NumeratorSource

FIR filter coefficient source

Specify the source of the numerator coefficients as one of `'Property'` (default) or `'Input port'`. When you specify `'Input port'`, the filter object requires the numerator coefficients to be specified as the third argument to every step.

Numerator

FIR filter coefficients

Specify the numerator coefficients of the FIR anti-imaging filter as the coefficients of a polynomial in z^{-1} . Indexing from zero, the filter coefficients are:

$$H(z) = \sum_{n=0}^{N-1} b(n)z^{-n}$$

To act as an effective anti-imaging filter, the coefficients must correspond to a lowpass filter with a normalized cutoff frequency no greater than the reciprocal of the “`InterpolationFactor`” on page 4-0 . The filter coefficients are scaled by the value of the `InterpolationFactor` property before filtering the signal. To form the L polyphase subfilters, `Numerator` is appended with zeros if necessary. The default is the output of `fir1(15,0.25)`. This property is valid only when the `NumeratorSource` property is `'Property'`.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `| Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |`. The default is `Floor`. This property applies only if the object is not in full precision mode.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `| Wrap | Saturate |`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

CoefficientsDataType

Coefficient word and fraction lengths

Specify the coefficients fixed-point data type as one of `| Same word length as input | Custom |`. The default is `Same word length as input`.

CustomCoefficientsDataType

Coefficient word and fraction lengths

Specify the coefficients fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property applies only when the `CoefficientsDataType` property is `Custom`. The default is `numericType([], 16, 15)`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of `| Full precision | Same as input | Custom |`. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when the `ProductDataType` property is `Custom`. The default is `numericType([], 32, 30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `| Full precision | Same as product | Same as input | Custom |`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when the `AccumulatorDataType` property is `Custom`. The default is `numericType([], 32, 30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of `| Same as accumulator | Same as product | Same as input | Custom |`. The default is `Same as accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when the “`OutputDataType`” on page 4-0 property is `Custom`. The default is `numericType([],16,15)`.

Examples

Double the Sample Rate Using FIR Intepolator

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

This example shows how to double the sampling rate of an audio signal from 22.05 kHz to 44.1 kHz, and play the audio.

```
afr = dsp.AudioFileReader('OutputDataType',...
    'single');
adw = audioDeviceWriter(44100);
firinterp = dsp.FIRInterpolator(2, ...
    firpm(30, [0 0.45 0.55 1], [1 1 0 0]));

while ~isDone(afr)
    frame = afr();
    y = firinterp(frame);
    adw(y);
end

pause(1);
release(afr);
release(adw);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the FIR Interpolation block reference page. The object properties correspond to the block parameters, except:

- The `FIRInterpolator` object does not have a property that corresponds to the **Input processing** parameter of the FIR Interpolation block.
- The **Rate options** block parameter is not supported by the `FIRInterpolator` object.

`dsp.FIRDecimator` | `dsp.FIRRateConverter`

Introduced in R2012a

freqz

System object: dsp.FIRInterpolator

Package: dsp

Frequency response

Syntax

```
[h,w] = freqz(firinterp)
[h,w] = freqz(firinterp,n)
[h,w] = freqz(firinterp,Name,Value)
freqz(firinterp)
```

Description

`[h,w] = freqz(firinterp)` returns the complex, 8192–element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample.

`[h,w] = freqz(firinterp,n)` returns the complex, `n`-element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[h,w] = freqz(firinterp,Name,Value)` returns the frequency response and the corresponding frequencies, with additional options specified by one or more `Name, Value` pair arguments.

`freqz(firinterp)` uses FVTool to plot the magnitude and unwrapped phase of the frequency response of the filter System object `firinterp`.

fvtool

System object: dsp.FIRInterpolator

Package: dsp

Open filter visualization tool

Syntax

```
fvtool(firinterp)
fvtool(firinterp, 'Arithmetic', ARITH, ...)
```

Description

`fvtool(firinterp)` performs an analysis and computes the magnitude response of the filter System object `firinterp`.

`fvtool(firinterp, 'Arithmetic', ARITH, ...)` analyzes the filter System object `firinterp`, based on the arithmetic specified in the `ARITH` input. `ARITH` can be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The 'Arithmetic' input is only relevant for the analysis of filter System objects.

impz

System object: dsp.FIRInterpolator

Package: dsp

Impulse response

Syntax

```
[h,t] = impz(firinterp)
[h,t] = impz(firinterp,Name,Value)
impz(firinterp)
```

Description

`[h,t] = impz(firinterp)` returns the impulse response `h`, and the corresponding time points `t` at which the impulse response of `firinterp` is computed.

`[h,t] = impz(firinterp,Name,Value)` returns the impulse response `h`, and the corresponding time points `t`, with additional options specified by one or more `Name, Value` pair arguments.

`impz(firinterp)` uses `FVTool` to plot the impulse response of the filter System object `firinterp`.

Note You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

phasez

System object: dsp.FIRInterpolator

Package: dsp

Unwrapped phase response

Syntax

```
[phi,w] = phasez(firinterp)
[phi,w] = phasez(firinterp,n)
[phi,w] = phasez(firinterp,Name,Value)
phasez(firinterp)
```

Description

`[phi,w] = phasez(firinterp)` returns the 8192–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample.

`[phi,w] = phasez(firinterp,n)` returns the `n`-element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[phi,w] = phasez(firinterp,Name,Value)` returns the phase response and the corresponding frequencies, with additional options specified by one or more `Name, Value` pair arguments.

`phasez(firinterp)` uses `FVTool` to plot the phase response of the filter System object `firinterp`.

reset

System object: dsp.FIRInterpolator

Package: dsp

Reset FIR interpolator filter states

Syntax

```
reset(firinterp)
```

Description

`reset(firinterp)` resets the filter states of the FIR filter in the interpolator object, `firinterp`, to their initial values of 0. The initial filter state values correspond to the initial conditions for the constant coefficient linear difference equation defining the FIR filter. After the `step` method applies the interpolator to nonzero input data, the states may be nonzero. Invoking the `step` method again without first invoking the `reset` method may produce different outputs for an identical input.

Reset an FIR Interpolator

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Reset filter states to 0 to produce consistent output.

```
firinterp = dsp.FIRInterpolator(2);  
x = [1 -1]'; x = repmat(x,8,1);  
y = firinterp(x); % Filter states are nonzero
```

Use `reset` method to set states to zero.

```
reset(firinterp);
```

Apply FIR interpolator to input `x`

```
y1 = firinterp(x);  
isequal(y,y1)
```

```
ans =
```

```
logical
```

```
1
```

step

System object: dsp.FIRInterpolator

Package: dsp

Upsample and interpolate input

Syntax

```
Y = step(firinterp,X)
```

```
Y = step(firinterp,X,Num)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(firinterp,X)` outputs the upsampled and interpolated values, Y , of the input signal X . A K -by- N input matrix is treated as N independent channels. The FIR interpolator object interpolates each channel over the first dimension and generates a M -by- N output matrix, where M is the product of K and the upsampling factor, L .

`Y = step(firinterp,X,Num)` uses the FIR filter, `Num`, to interpolate the input signal. This configuration is valid only when the `'NumeratorSource'` property is `'Input port'`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.FIRRateConverter System object

Package: dsp

Sample rate converter

Description

The `FIRRateConverter` performs sampling rate conversion by a rational factor on a vector or matrix input. The FIR rate converter cascades an interpolator with a decimator. The interpolator upsamples the input by the upsampling factor, L , followed by a lowpass FIR filter. The FIR filter acts both as an anti-imaging filter and an anti-aliasing filter prior to decimation. The decimator downsamples the output of upsampling and FIR filtering by the downsampling factor M . You must use upsampling and downsampling factors that are relatively prime, or coprime. The resulting discrete-time signal has a sampling rate L/M times the original sampling rate.

To perform sampling rate conversion:

- 1 Define and set up your FIR sample rate converter. See “Construction” on page 4-798.
- 2 Call `step` to perform sampling rate conversion according to the properties of `dsp.FIRRateConverter`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`firrc = dsp.FIRRateConverter` returns a FIR sample rate converter, `firrc`, that resamples an input signal at a rate $3/2$ times the original sampling rate.

`firrc = dsp.FIRRateConverter('PropertyName', PropertyValue, ...)`
returns an FIR sample rate converter, `firrc`, with each property set to the specified value.

`firrc = dsp.FIRRateConverter(L,M,NUM, 'PropertyName',
PropertyValue, ...)` returns an FIR sample rate converter, `firrc`, with the `InterpolationFactor` property set to `L`, the `DecimationFactor` property set to `M`, the `Numerator` property set to `NUM`, and other specified properties set to the specified values.

Properties

InterpolationFactor

Interpolation factor

Specify the integer upsampling factor. The default is 3.

DecimationFactor

Decimation factor

Specify the integer downsampling factor. The default is 2.

Numerator

FIR filter coefficients

Specify the FIR filter coefficients in powers of z^{-1} . The length of filter coefficients must exceed the interpolation factor. Use a lowpass with normalized cutoff frequency no greater than $\min(1/\text{InterpolationFactor}, 1/\text{DecimationFactor})$. All initial filter states are zero. The default is `firpm(70, [0 0.28 0.32 1], [1 1 0 0])`.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It

also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `| Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |`. The default is `Floor`. This property applies only if the object is not in full precision mode.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `| Wrap | Saturate |`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

CoefficientsDataType

Word and fraction lengths of filter coefficients

Specify the filter coefficient fixed-point data type as one of `| Same word length as input | Custom |`. The default is `Same word length as input`.

CustomCoefficientsDataType

Word and fraction lengths of filter coefficients

Specify the filter coefficient fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property applies only when the `CoefficientsDataType` property is `Custom`. The default is `numericType([], 16, 15)`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of `| Full precision | Same as input | Custom |`. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when the `ProductDataType` property is `Custom`. The default is `numericType([], 32, 30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `Full precision` | `Same as product` | `Same as input` | `Custom` |. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when the `AccumulatorDataType` property is `Custom`. The default is `numericType([], 32, 30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of `Same as accumulator` | `Same as product` | `Same as input` | `Custom` |. The default is `Same as accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when the “`OutputDataType`” on page 4-0 property is `Custom`. The default is `numericType([], 16, 15)`.

Methods

- reset Reset states of FIR sample rate converter
 step Resample input with FIR rate converter

Common to All System Objects	
clone	Create System object with same property values
getNumInputs	Expected number of inputs to a System object
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Resample a Signal using FIR Rate Converter

This example shows how to resample a 100 Hz sine wave signal by a factor of 3:2.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
sine = dsp.SineWave(1, 100, 'SampleRate', 5000, 'SamplesPerFrame', 50);
```

Create a FIR rate converter filter. The default interpolation factor is 3 and decimation factor is 2.

```
firrc = dsp.FIRRateConverter;  
input = sine();  
output = firrc(input);
```

Plot the original and resampled signals.

```
ndelay = round(length(firrc.Numerator)/2/firrc.DecimationFactor);  
indx = ndelay+1:length(output);
```

```
x = (0:length(indx)-1)/sine.SampleRate*firrc.DecimationFactor/firrc.InterpolationFactor;  
stem((0:38)/sine.SampleRate, input(1:39)); hold on;  
stem(x, firrc.InterpolationFactor*output(indx), 'r');  
legend('Original', 'Resampled');
```

Resample and Play an Audio Signal

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

This example shows how to resample and play an audio signal from 48 kHz to 32 kHz on a Windows® platform.

```
afr = dsp.AudioFileReader('audio48kHz.wav', ...  
    'OutputDataType', 'single', ...  
    'SamplesPerFrame', 300);  
adw = audioDeviceWriter(32000);
```

Create an FIRRateConverter System object with interpolation factor = 2, decimation factor = 3. Default FIR filter coefficients define a lowpass filter with normalized cutoff frequency of 1/3.

```
firrc = dsp.FIRRateConverter(2,3);  
  
while ~isDone(afr)  
    audio1 = afr();  
    audio2 = firrc(audio1);  
    adw(audio2);  
end  
  
release(afr);  
release(adw);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the FIR Rate Conversion block reference page. The object properties correspond to the block parameters.

step

System object: dsp.FIRRateConverter

Package: dsp

Resample input with FIR rate converter

Syntax

```
Y = step(firrc,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(firrc,X)` resamples the input `X` and returns the resampled signal `Y`. An M -by- N matrix input is treated as N independent channels.

dsp.FrequencyDomainAdaptiveFilter System object

Package: dsp

Frequency Domain Adaptive filter

Description

The `dsp.FrequencyDomainAdaptiveFilter` computes output, error, and coefficients using a frequency domain FIR adaptive filter.

To implement the adaptive FIR filter object:

- 1 Define and set up your adaptive FIR filter object. See “Construction” on page 4-809.
- 2 Call `step` to implement the filter according to the properties of `dsp.FrequencyDomainAdaptiveFilter`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`fdaf = dsp.FrequencyDomainAdaptiveFilter` returns a frequency domain FIR adaptive filter System object, `fdaf`. This System object is used to compute the filtered output and the filter error for a given input and desired signal.

`fdaf = dsp.FrequencyDomainAdaptiveFilter('PropertyName', PropertyValue, ...)` returns an `FrequencyDomainAdaptiveFilter` System object, `fdaf`, with each specified property set to the specified value.

`fdaf = dsp.FrequencyDomainAdaptiveFilter(LEN, 'PropertyName', PropertyValue, .`

...) returns an `FrequencyDomainAdaptiveFilter System` object, `fdaf`, with the `Length` property set to `LEN` and other specified properties set to the specified values.

Properties

Method

Method to calculate filter coefficients

Specify the method used to calculate filter coefficients as one of `'Constrained FDAF'` or `'Unconstrained FDAF'`. The default is `'Constrained FDAF'`. For algorithms on how to implement this filter and its three methods, refer to [1]. This property is nontunable.

Length

Length of filter coefficients vector

Specify the length of the FIR filter coefficients vector as a positive integer value. This property is nontunable.

The default value is 32.

BlockLength

Block length for coefficient updates

Specify the block length of the coefficients updates as a positive integer value. The length of the input vectors must be divisible by the `BlockLength` property value. For faster execution, the sum of the length property value and the `BlockLength` property value should be a power of two. The default value is the value of `Length`. This property is nontunable.

StepSize

Adaptation step size

Specify the adaptation step size factor as a positive numeric scalar less than or equal to 1. Setting the `StepSize` property equal to 1 provides the fastest convergence during adaptation. The default is 1. This property is tunable.

LeakageFactor

Adaptation leakage factor

Specify the leakage factor used in leaky adaptive filter as a scalar numeric value between 0 and 1, both inclusive. When the value is less than 1, the System object implements a leaky adaptive algorithm. The default is 1, providing no leakage in the adapting method. This property is tunable.

AveragingFactor

Averaging factor of energy estimator

Specify the averaging factor used to compute the exponentially windowed FFT input signal powers for the coefficient updates as a scalar positive numeric value less than or equal to 1. The default value is 0.9. This property is tunable.

Offset

Offset for normalization terms

Specify the offset for the normalization terms in the coefficient updates as a scalar nonnegative numeric value. Use this property to avoid divide by zero or divide by very small numbers. This situation occurs if any of the FFT input signal powers becomes very small. The default value is 0. This property is tunable.

InitialPower

Initial FFT input signal power

Specify the initial common value of all of the FFT input signal powers as a scalar positive numeric value. The default is 1. This property is tunable.

InitialCoefficients

Time-domain initial coefficients of the filter

Specify the initial time-domain coefficients of the adaptive filter as a scalar or a vector of length equal to the `Length` property value. The adaptive filter object uses these coefficients to compute the initial frequency-domain filter coefficients. The default is 0. This property is tunable.

LockCoefficients

Locked status of coefficient updates

Specify whether to lock the filter coefficient values. By default, the value of this property is `false`, and the object continuously updates the filter coefficients. If this property is set to `true`, the filter coefficients do not update and their values remain the same.

This property is tunable.

FFTCoefficients

Current FFT coefficients of the filter

This property stores the current discrete Fourier transform of the filter coefficients as a row vector. The length of this vector is equal to the sum of the `Length` value and the `BlockLength` value. This property is initialized to the FFT values of the `InitialCoefficients` property. To get the discrete Fourier transform of the filter coefficients, call the object, and access the `FFTCoefficients` property of the object.

Methods

`reset` Reset filter states for Frequency Domain Adaptive filter

`step` Apply Frequency Domain Adaptive filter to input

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

QPSK Adaptive Equalization With FIR Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Generate QPSK and noise signals, filter to obtain the received signal, and delay the QPSK signal to obtain the desired signal.

```
D = 16;
b = exp(1i*pi/4)*[-0.7 1];
a = [1 -0.7];
ntr= 1024;
s = sign(randn(1,ntr+D))+1i*sign(randn(1,ntr+D));
n = 0.1*(randn(1,ntr+D) + 1i*randn(1,ntr+D));
r = filter(b,a,s) + n;
x = r(1+D:ntr+D);
d = s(1:ntr);
```

Use the Frequency Domain Adaptive Filter to compute the filtered output and the filter error for the input and desired signal. To get the discrete Fourier transform of the filter coefficients, call the `fdaf` object, and access the `FFTCoefficients` property of this object.

```
mu = 0.1;
fdaf = dsp.FrequencyDomainAdaptiveFilter('Length',32,'StepSize',mu);
[y,e] = fdaf(x,d);
fftCoeffs = fdaf.FFTCoefficients

fftCoeffs =

System Objects

`dsp.AdaptiveLatticeFilter` | `dsp.AffineProjectionFilter` | `dsp.FIRFilter`
| `dsp.FilteredXLMSFilter` | `dsp.LMSFilter` | `dsp.RLSFilter`

Introduced in R2013b

reset

System object: dsp.FrequencyDomainAdaptiveFilter

Package: dsp

Reset filter states for Frequency Domain Adaptive filter

Syntax

```
reset(sysObj)
```

Description

`reset(sysObj)` resets the internal states of the System object, `sysObj`, to their initial values. The reset method is always a no-op for unlocked System objects, as the states may not be allocated when the object is not locked.

step

System object: dsp.FrequencyDomainAdaptiveFilter

Package: dsp

Apply Frequency Domain Adaptive filter to input

Syntax

```
[y,err] = step(fdaf,x,d)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[y,err] = step(fdaf,x,d)` filters the input `x`, using `d` as the desired signal, and returns the filtered output in `y` and the filter error in `err`. The System object estimates the filter weights needed to minimize the error between the output signal and the desired signal. You can obtain the FFT of these filter weights by accessing the `FFTCoefficients` property after calling the `step` method by `fdaf.FFTCoefficients`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.FrequencyDomainFIRFilter System object

Package: dsp

Filter input signal in frequency domain

Description

The `dsp.FrequencyDomainFIRFilter` System object implements frequency-domain, fast Fourier transform (FFT)-based filtering to filter a streaming input signal. In the time domain, the filtering operation involves a convolution between the input and the impulse response of the finite impulse response (FIR) filter. In the frequency domain, the filtering operation involves the multiplication of the Fourier transform of the input and the Fourier transform of the impulse response. The frequency-domain filtering is efficient when the impulse response is very long. This object uses the overlap-save and overlap-add methods to perform the frequency-domain filtering. For filters with a long impulse response length, the latency inherent to these two methods can be significant. To mitigate this latency, the `dsp.FrequencyDomainFIRFilter` object partitions the impulse response into shorter blocks and implements the overlap-save and overlap-add methods on these shorter blocks. To partition the impulse response, set the “PartitionForReducedLatency” on page 4-0 property to `true`. For more details on these two methods and on reducing latency through impulse response partitioning, see “Algorithms” on page 4-831.

To filter the input signal in the frequency domain:

- 1 Create the `dsp.FrequencyDomainFIRFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#) (MATLAB).

Creation

Syntax

```
fdf = dsp.FrequencyDomainFIRFilter
fdf = dsp.FrequencyDomainFIRFilter(num)
fdf = dsp.FrequencyDomainFIRFilter(Name,Value)
```

Description

`fdf = dsp.FrequencyDomainFIRFilter` creates a frequency domain FIR filter System object that filters each channel of the input signal independently over time in the frequency domain using the overlap-save or overlap-add method.

`fdf = dsp.FrequencyDomainFIRFilter(num)` creates a frequency domain FIR filter object with the “Numerator” on page 4-0 property set to `num`.

Example: `dsp.FrequencyDomainFIRFilter(fir1(400,2 * 2000 / 8000));`

`fdf = dsp.FrequencyDomainFIRFilter(Name,Value)` creates a frequency domain FIR filter System object with each specified property set to the specified value. Enclose each property name in single quotes. You can use this syntax with any previous input argument combinations.

Example: `dsp.FrequencyDomainFIRFilter('Method','Overlap-add');`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects \(MATLAB\)](#).

Method — Frequency-domain filter method`'Overlap-save' (default) | 'Overlap-add'`

Frequency-domain filter method, specified as either `'Overlap-save'` or `'Overlap-add'`. For more details on these two methods, see “Algorithms” on page 4-831.

Numerator — FIR filter coefficients`fir1(100,0.3) (default) | row vector`

FIR filter coefficients, specified as a row vector.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Complex Number Support: Yes

PartitionForReducedLatency — Flag to partition numerator to reduce latency`false (default) | true`

Flag to partition numerator to reduce latency, specified as one of the following:

- `false` — The filter uses the traditional overlap-save or overlap-add method. The latency in this case is “FFTLength” on page 4-0 – length(“Numerator” on page 4-0) + 1.
- `true` — In this mode, the object partitions the numerator into segments of length specified by the “PartitionLength” on page 4-0 property. The filter performs overlap-save or overlap-add on each partition, and combines the partial results to form the overall output. The latency is now reduced to the partition length.

FFTLength — FFT length`[] (default) | positive integer`

FFT length, specified as a positive integer. The default value of this property, `[]`, indicates that the FFT length is equal to twice the numerator length. The FFT length must be greater than or equal to the numerator length.

Example: 64

Dependencies

This property applies when you set the “PartitionForReducedLatency” on page 4-0 property to `false`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

PartitionLength — Numerator partition length

32 (default) | positive integer

Numerator partition length, specified as a positive integer less than or equal to the length of the numerator.

Example: 40

Example: 60

Dependencies

This property applies when you set the “PartitionForReducedLatency” on page 4-0 property to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Latency — Filter latency

102 (default) | positive integer

This property is read-only.

Filter latency in samples, returned as an integer greater than 0. When “PartitionForReducedLatency” on page 4-0 is `false`, the latency is equal to “FFTLenght” on page 4-0 – length(“Numerator” on page 4-0) + 1. When PartitionForReducedLatency is `true`, the latency is equal to the partition length.

Data Types: `uint32`

Usage

Syntax

```
fdfOut = fdf(input)
```

Description

`fdfOut = fdf(input)` filters the input signal and outputs the filtered signal. The object filters each channel of the input signal independently over time in the frequency domain.

Input Arguments

input — Data input

vector | matrix

Data input, specified as a vector or matrix. This object supports variable-size input signals. That is, you can change the input frame size (number of rows) even after calling the algorithm. However, the number of channels (number of columns) must remain constant.

Example: `randn(164,4)`

Data Types: `single` | `double`

Output Arguments

fdfOut — Filtered output

vector | matrix

Filtered output, returned as a vector or matrix. The size, data type, and complexity of the output match those of the input.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.FrequencyDomainFIRFilter

Common to All System Objects

step	Run System object algorithm
clone	Create duplicate System object
getNumInputs	Number of inputs required to call the System object
getNumOutputs	Number of outputs from calling the System object
isLocked	Determine if System object is locked
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Frequency Domain Filtering Using Overlap-Add and Overlap-Save

Filter input signal using overlap-add and overlap-save methods, and compare the outputs to the output of a FIR filter.

Initialization

Design the FIR lowpass filter coefficients using the `fir1` function. The sampling frequency is 8 kHz, and the cutoff frequency of the filter is 2 kHz. The impulse response has a length of 400.

```
impL    = 400;  
Fs      = 8000;  
Fcutoff = 2000;  
imp     = fir1(impL, 2*Fcutoff/Fs);
```

Create two `dsp.FrequencyDomainFIRFilter` objects and a `dsp.FIRFilter` object. Set the numerator of all the three filters to `imp`. Delay the FIR output by the latency of the frequency-domain filter.

```
fdfOA = dsp.FrequencyDomainFIRFilter(imp, 'Method', 'overlap-add');  
fdfOS = dsp.FrequencyDomainFIRFilter(imp, 'Method', 'overlap-save');  
fir    = dsp.FIRFilter('Numerator', imp);  
dly    = dsp.Delay('Length', fdfOA.Latency);
```

Create two `dsp.SineWave` objects. The sine waves generated have a sample rate of 8000 Hz, frame size of 256, and frequencies of 100 Hz and 3 kHz, respectively. Create a `dsp.TimeScope` object to view the filtered outputs.

```

frameLen = 256;

sin_100Hz = dsp.SineWave('Frequency',100,'SampleRate',Fs,...
    'SamplesPerFrame',frameLen);
sin_3KHz = dsp.SineWave('Frequency',3e3,'SampleRate',Fs,...
    'SamplesPerFrame',frameLen);
ts = dsp.TimeScope('TimeSpanOverrunAction','Scroll',...
    'ShowGrid',true,'TimeSpan',5 * frameLen/Fs,...
    'YLimits',[-1.1 1.1],...
    'ShowLegend',true,...
    'SampleRate',Fs,...
    'ChannelNames',{'Overlap-add','Overlap-save','Direct-form FIR'});

```

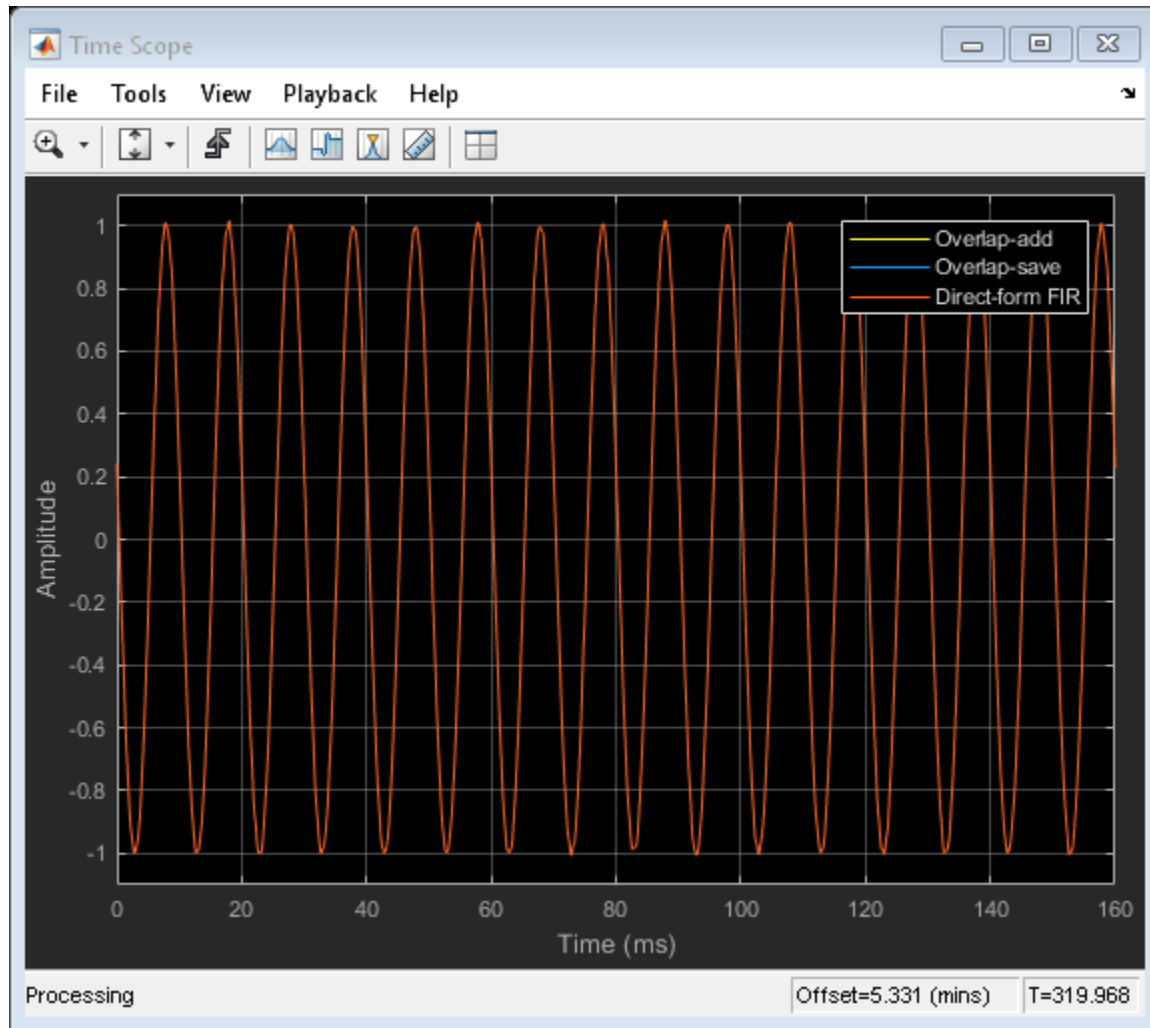

Streaming

Stream 1e4 frames of noisy input data. Pass this data through the frequency domain filters and the FIR filter. View the filtered outputs in the time scope.

```

numFrames = 1e4;
for idx = 1:numFrames
    x = sin_100Hz() + sin_3KHz() + 0.01*randn(frameLen,1);
    yOA = fdfOA(x);
    yOS = fdfOS(x);
    yFIR = fir(dly(x));
    ts([yOA,yOS,yFIR]);
end

```

The outputs of all the three filters match exactly.

Reduce Latency Through Partitioned Numerator

Partition the impulse response length of a frequency domain FIR filter. Compare the outputs of the partitioned filter and the original filter.

Design the FIR lowpass filter coefficients using the `fir1` function. The sampling frequency is 8 kHz and the cutoff frequency of the filter is 2 kHz. The impulse response is of length 4000.

```
impL    = 4000;
Fs      = 8000;
Fcutoff = 2000;
imp     = fir1(impL,2 * Fcutoff / Fs);
```

Create a `dsp.FrequencyDomainFIRFilter` with coefficients set to the `imp` vector. The latency of this filter is given by $FFTLength - Length(Numerator) + 1$, which is equal to 4002. By default, FFT length is equal to twice the numerator length. This makes the latency proportional to the impulse response length.

```
fdfOS = dsp.FrequencyDomainFIRFilter(imp,'Method','overlap-save');
fprintf('Frequency domain filter latency is %d samples\n',fdfOS.Latency);
```

```
Frequency domain filter latency is 4002 samples
```

Partition the impulse response to blocks of length 256. The latency after partitioning is proportional to the block length.

```
fdfRL = dsp.FrequencyDomainFIRFilter(imp,'Method','overlap-save',...
    'PartitionForReducedLatency',true,...
    'PartitionLength',256);
fprintf('Frequency domain filter latency is %d samples\n',fdfRL.Latency);
```

```
Frequency domain filter latency is 256 samples
```

Compare the outputs of the two frequency domain filters. The latency of `fdfOS` is 4002, and the latency of `fdfRL` is 256. To compare the two outputs, delay the input to `fdfRL` by $4002 - 256$ samples.

```
dly = dsp.Delay('Length',(fdfOS.Latency-fdfRL.Latency));
```

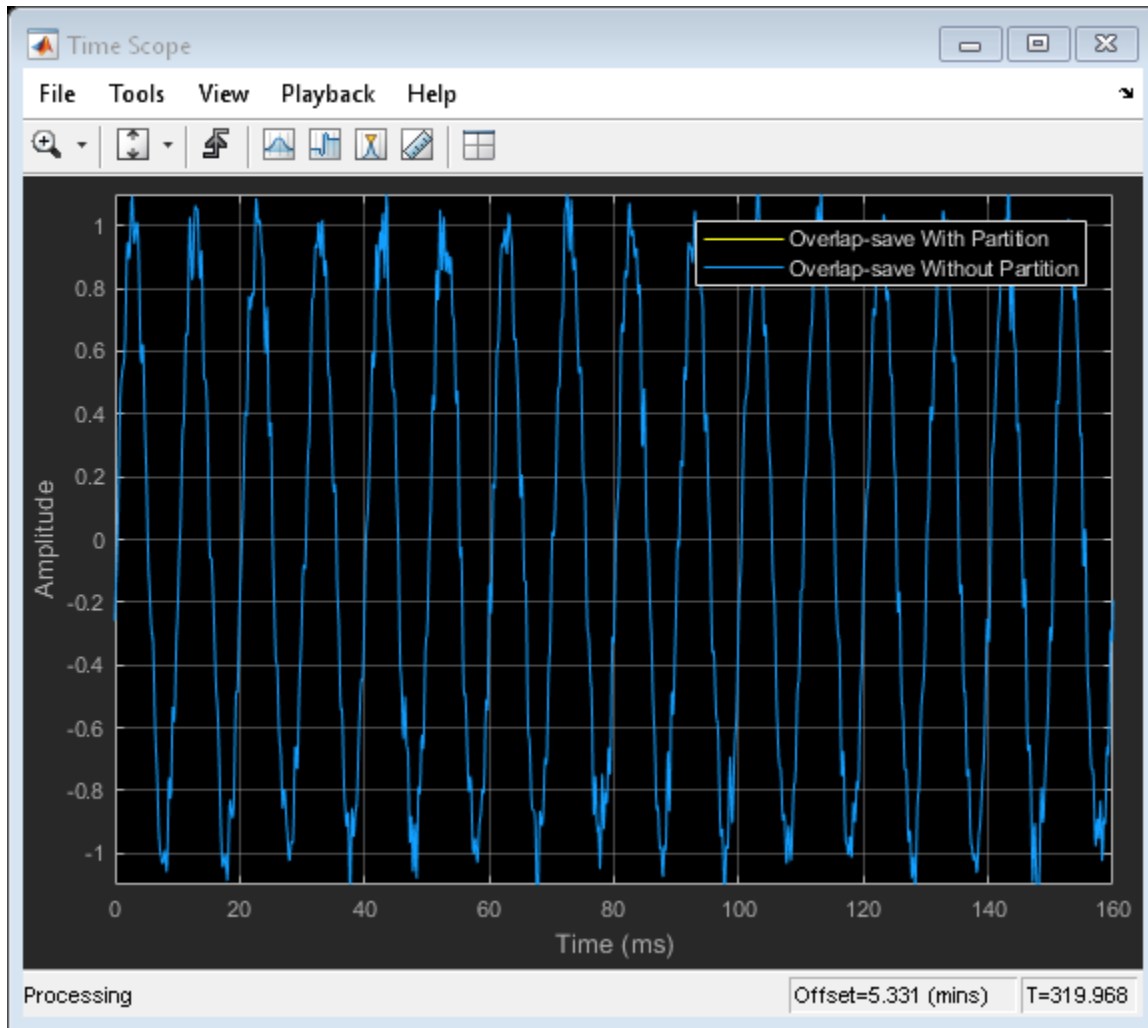

Create two `dsp.SineWave` objects. The sine waves have a sample rate of 8000 Hz, frame size of 256, and frequencies of 100 Hz and 3 kHz, respectively. Create a `dsp.TimeScope` object to view the filtered outputs.

```
frameLen = 256;
sin_100Hz = dsp.SineWave('Frequency',100,'SampleRate',Fs,...
    'SamplesPerFrame',frameLen);
sin_3KHz = dsp.SineWave('Frequency',3e3,'SampleRate',Fs,...
    'SamplesPerFrame',frameLen);
```

```
ts = dsp.TimeScope('TimeSpanOverrunAction','Scroll',...
    'ShowGrid',true,'TimeSpan',5 * frameLen/Fs,...
    'YLimits',[-1.1 1.1],...
    'ShowLegend',true,...
    'SampleRate',Fs,...
    'ChannelNames',{'Overlap-save With Partition','Overlap-save Without Partition'});
```

Stream 1e4 frames of noisy input data. Pass this data through the two frequency domain filters. View the filtered outputs in the time scope.

```
numFrames = 1e4;
for idx = 1:numFrames
    x = sin_100Hz() + sin_3KHz() + .1 * randn(frameLen,1);
    yRL = fdfRL(dly(x));
    yOS = fdfOS(x);
    ts([yRL,yOS]);
end
```

The outputs match exactly.

Algorithms

Overlap-save and overlap-add are the two frequency-domain FFT-based filtering methods this algorithm uses.

Overlap-Save

The overlap-save method is implemented using the following approach:

The input stream is partitioned into overlapping blocks of size $FFTLen$, with an overlap factor of $NumLen - 1$ samples. $FFTLen$ is the FFT length and $NumLen$ is the length of the FIR filter numerator. The FFT of each block of input samples is computed and multiplied with the length- $FFTLen$ FFT of the FIR numerator. The inverse fast Fourier transform (IFFT) of the result is performed, and the last $FFTLen - NumLen + 1$ samples are saved. The remaining samples are dropped.

The latency of overlap-save is $FFTLen - NumLen + 1$. The first $FFTLen - NumLen + 1$ samples are equal to zero. The filtered value of the first input sample appears as the $FFTLen - NumLen + 2$ output sample.

Note that the FFT length must be larger than the numerator length, and is typically set to a value much greater than $NumLen$.

Overlap-Add

The overlap-add method is implemented using the following approach:

The input stream is partitioned into blocks of length $FFLen - NumLen + 1$, with no overlap between consecutive blocks. Similar to overlap-save, the FFT of the block is computed, and multiplied by the FFT of the FIR numerator. The IFFT of the result is then computed. The first $NumLen + 1$ samples are modified by adding the values of the last $NumLen + 1$ samples from the previous computed IFFT.

The latency of overlap-add is $FFLen - NumLen + 1$. The first $FFLen - NumLen + 1$ samples are equal to zero. The filtered value of the first input sample appears as the $FFLen - NumLen + 2$ output sample.

Reduce Latency Through Impulse Response Partitioning

With an FFT length that is twice the length of the FIR numerator, the latency roughly equals the length of the FIR numerator. If the impulse response is very long, the latency becomes significantly large. However, frequency domain FIR filtering is still faster than the time-domain filtering. To mitigate the latency and make the frequency domain filtering even more efficient, the algorithm partitions the impulse response into multiple short blocks and performs overlap-save or overlap-add on each block. The results of the different blocks are then combined to obtain the final output. The latency of this approach is of the order of the block length, rather than the entire impulse response length. This reduced latency comes at the cost of additional computation. For more details, see [1].

Frequency-Domain FIR Filter

Introduced in R2017b

dsp.HampelFilter System object

Package: dsp

Filter outliers using Hampel identifier

Description

The `dsp.HampelFilter` System object detects and removes the outliers of the input signal by using the Hampel identifier. The Hampel identifier is a variation of the three-sigma rule of statistics that is robust against outliers. For each sample of the input signal, the object computes the median of a window composed of the current sample and

$\frac{Len - 1}{2}$

adjacent samples on each side of current sample. *Len* is the window length you specify through the `WindowLength` property. The object also estimates the standard deviation of each sample about its window median by using the median absolute deviation. If a sample differs from the median by more than the threshold multiplied by the standard deviation, the filter replaces the sample with the median. For more information, see “Algorithms” on page 4-844.

The object accepts multichannel inputs, that is, *m*-by-*n* size inputs, where $m \geq 1$, and $n > 1$. *m* is the number of samples in each frame (channel), and *n* is the number of channels. The object also accepts variable-size inputs. After the object is locked, you can change the size of each input channel. However, the number of channels cannot change.

To filter the input signal using a Hampel identifier:

- 1 Create a `dsp.HampelFilter` object and set the properties of the object.
- 2 Call `step` to filter the signal using the Hampel identifier.

Note Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Construction

`hampFilt = dsp.HampelFilter` returns a Hampel filter object, `hampFilt`, using the default properties.

`hampFilt = dsp.HampelFilter(Len)` sets the `WindowLength` property to `Len`.

`hampFilt = dsp.HampelFilter(Len, Lim)` sets the `WindowLength` property to `Len` and the `Threshold` property to `Lim`.

`hampFilt = dsp.HampelFilter(Name, Value)` specifies properties using `Name, Value` pairs. Unspecified properties have default values.

Example:

```
hampFilt = dsp.HampelFilter(11,2);
```

Properties

If a property is listed as tunable, then you can change its value even when the object is locked.

WindowLength — Length of the sliding window

11 (default) | positive odd scalar integer

Length of the sliding window, specified as a positive odd scalar integer. The window of finite length slides over the data, and the object computes the median and median absolute deviation of the data in the window.

Threshold — Threshold for outlier detection

3 (default) | positive real scalar

Threshold for outlier detection, specified as a positive real scalar. For information on how this property is used to detect the outlier, see “Algorithms” on page 4-844.

Tunable: Yes

Methods

reset Reset internal states of System object
 step Remove outliers from input

Common to All System Objects	
clone	Create System object with same property values
getNumInputs	Expected number of inputs to a System object
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Remove High-Frequency Noise Using Hampel Filter

Filter high-frequency noise from a noisy sine wave signal using a Hampel filter. Compare the performance of the Hampel filter with a median filter.

Initialization

Set up a `dsp.HampelFilter` and a `dsp.MedianFilter` object. These objects use the sliding window method with a window length of 7. Create a time scope for viewing the output.

```
Fs = 1000;
hampFilt = dsp.HampelFilter(7);
medFilt = dsp.MedianFilter(7);
scope = dsp.TimeScope('SampleRate',Fs, ...
    'TimeSpanOverrunAction','Scroll', ...
    'TimeSpan',1,'ShowGrid',true, ...
    'YLimits',[-3 3], ...
    'LayoutDimensions',[3 1], ...
    'NumInputPorts',3);
```

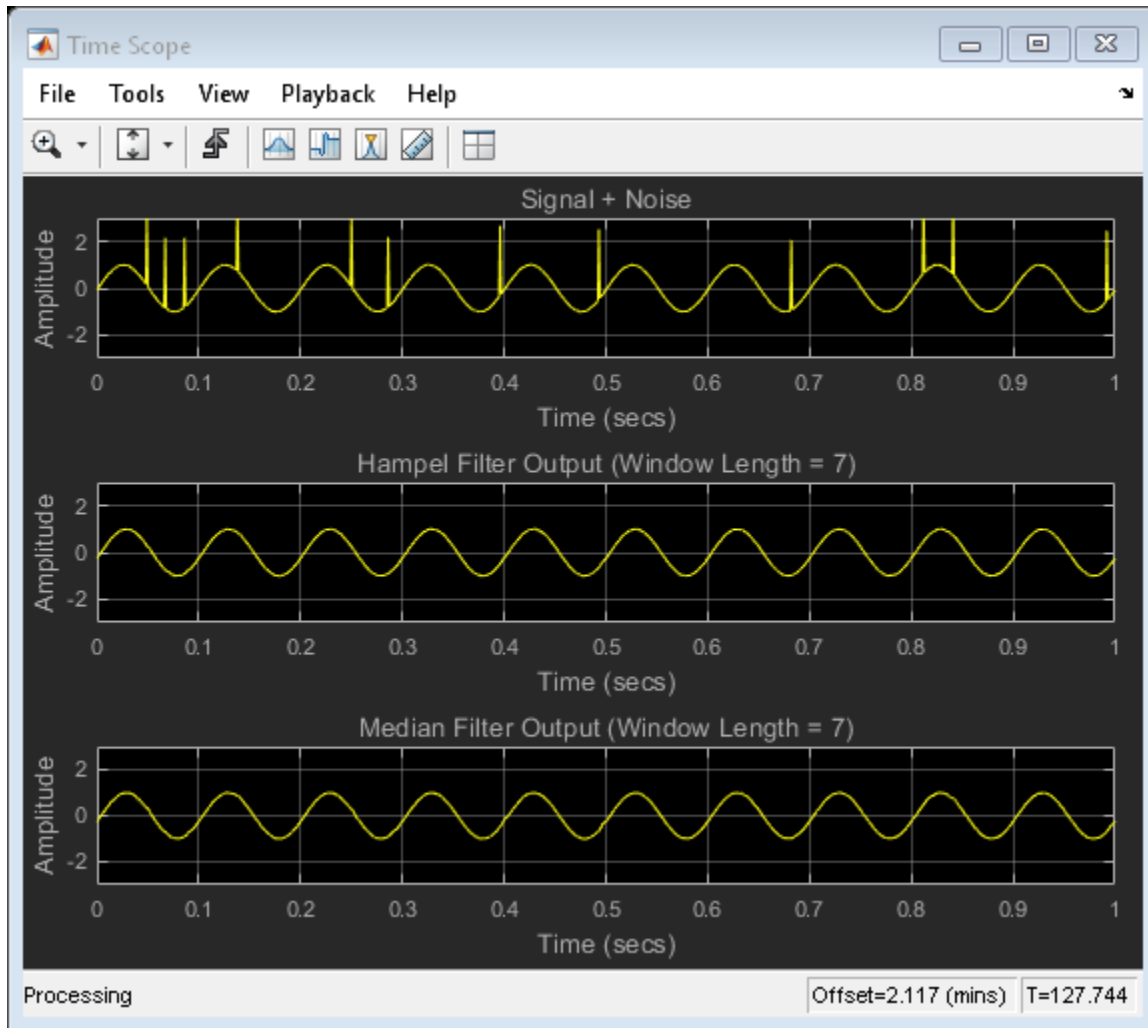

```
scope.ActiveDisplay = 1;
scope.Title = 'Signal + Noise';
scope.ActiveDisplay = 2;
scope.Title = 'Hampel Filter Output (Window Length = 7)';
scope.ActiveDisplay = 3;
scope.Title = 'Median Filter Output (Window Length = 7)';
```

Filter the Noisy Sine Wave Using a Window of Length 7

Generate a noisy sine wave signal with a frequency of 10 Hz. Apply the Hampel filter and the median filter object to the signal. View the output on the time scope.

```
FrameLength = 256;
sine = dsp.SineWave('SampleRate',Fs,'Frequency',10,...
    'SamplesPerFrame',FrameLength);

for i = 1:500
    hfn = 3 * (rand(FrameLength,1) < 0.02);
    x = sine() + 1e-2 * randn(FrameLength,1) + hfn;
    y1 = hampFilt(x);
    y2 = medFilt(x);
    scope(x,y1,y2);
end
```

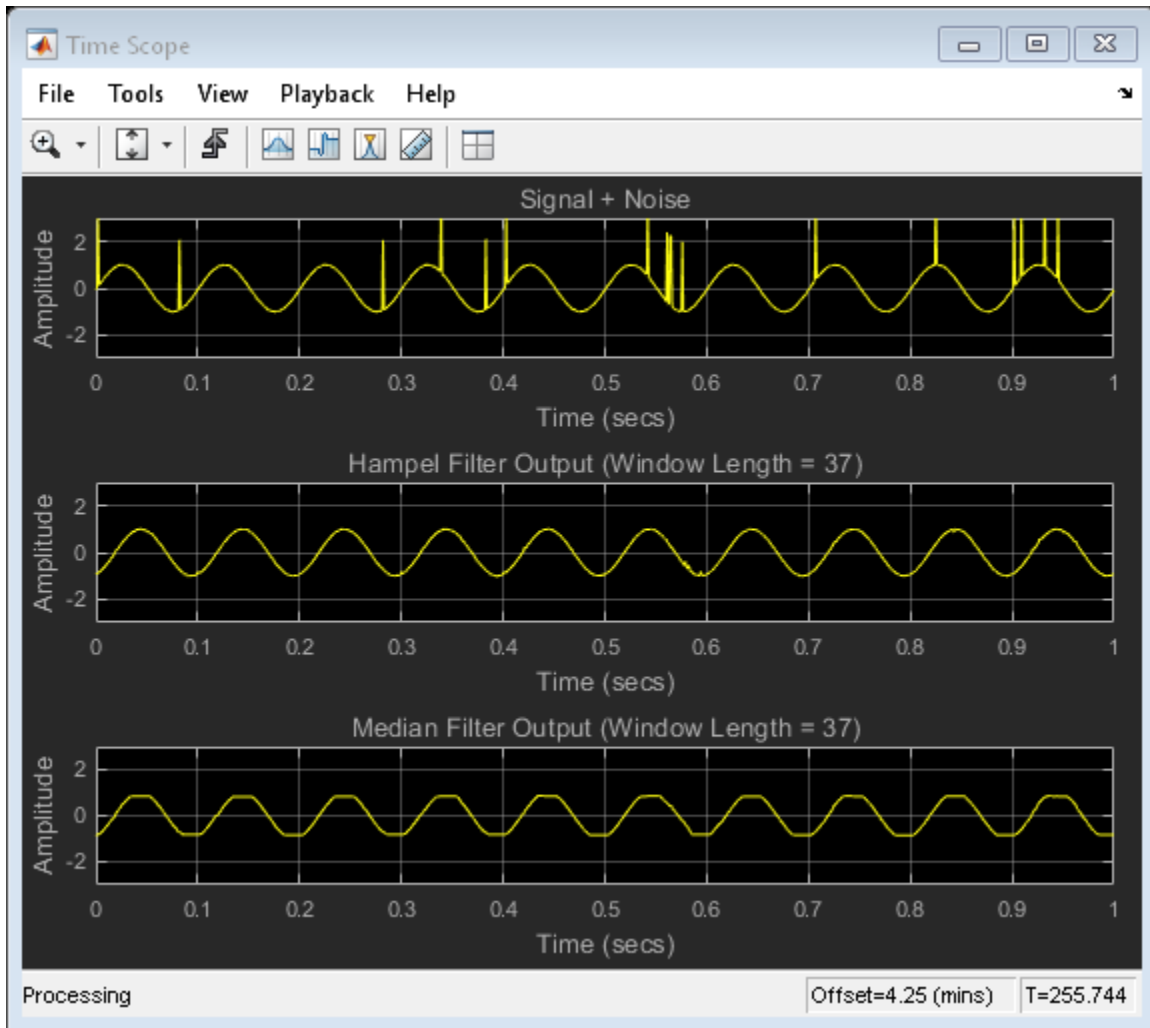

Both filters remove the high-frequency noise. However, when you increase the window length, the Hampel filter is preferred. Unlike the median filter, the Hampel filter preserves the shape of the sine wave even with large window lengths.

Filter the Noisy Sine Wave Using a Window of Length 37

Increase the window length of both the filters to 37. Filter the noisy sine wave and view the filtered output on the time scope. To change the window length of the filters, you must release the filter objects at the start of the processing loop.

```
release(hampFilt);
release(medFilt);
hampFilt.WindowLength = 37;
medFilt.WindowLength = 37;
scope.ActiveDisplay = 1;
scope.Title = 'Signal + Noise';
scope.ActiveDisplay = 2;
scope.Title = 'Hampel Filter Output (Window Length = 37)';
scope.ActiveDisplay = 3;
scope.Title = 'Median Filter Output (Window Length = 37)';
for i = 1:500
    hfn = 3 * (rand(FrameLength,1) < 0.02);
    x = sine() + 1e-2 * randn(FrameLength,1) + hfn;
    y1 = hampFilt(x);
    y2 = medFilt(x);
    scope(x,y1,y2);
end
```

The median filter flattens the crests and troughs of the sine wave due to the median operation over a large window of data. The Hampel filter preserves the shape of the signal, in addition to removing the outliers.

Remove High-Frequency Noise from Gyroscope Data Using Hampel Filter

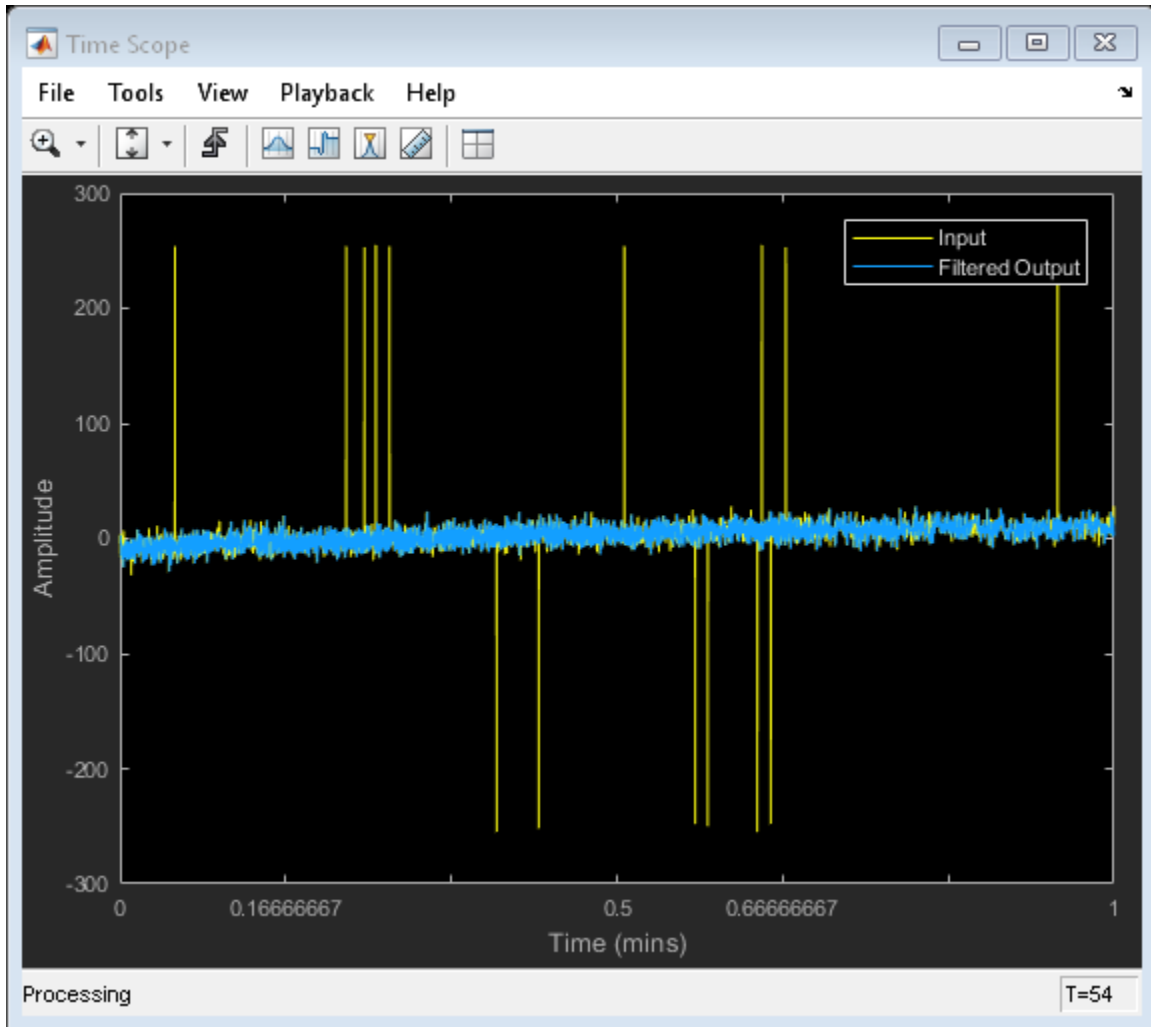

Remove the high-frequency outliers from a streaming signal using the `dsp.HampelFilter` System object™.

Use the `dsp.MatFileReader` System object to read the gyroscope MAT file. The file contains three columns of data, with each column containing 7140 samples. The three columns represent the *x*-axis, *y*-axis, and *z*-axis data from the gyroscope motion sensor. Choose a frame size of 714 samples so that each column of the data contains 10 frames. The `dsp.HampelFilter` System object uses a window length of 11. Create a `dsp.TimeScope` object to view the filtered output.

```
reader = dsp.MatFileReader('SamplesPerFrame',714,'Filename','LSM9DSHampelgyroData73.mat', ...  
    'VariableName','data');  
hampFilt = dsp.HampelFilter(11);  
scope = dsp.TimeScope('NumInputPorts',1,'SampleRate',119,'YLimits',[-300 300], ...  
    'ChannelNames',{'Input','Filtered Output'},'TimeSpan',60,'ShowLegend',true);
```

Filter the gyroscope data using the `dsp.HampelFilter` System object. View the filtered *z*-axis data in the Time Scope.

```
for i = 1:10  
    gyroData = reader();  
    filteredData = hampFilt(gyroData);  
    scope([gyroData(:,3),filteredData(:,3)]);  
end
```

The Hampel filter removes all the outliers and preserves the shape of the signal.

Definitions

Hampel Identifier

The Hampel identifier is a variation of the three-sigma rule of statistics that is robust against outliers.

Given a sequence $x_1, x_2, x_3, \dots, x_n$ and a sliding window of length k , define point-to-point median and standard-deviation estimates using:

- Local median — $m_i = \text{median}(x_{i-k}, x_{i-k+1}, x_{i-k+2}, \dots, x_i, \dots, x_{i+k-2}, x_{i+k-1}, x_{i+k})$
- Standard deviation — $\sigma_i = \kappa \text{median}(|x_{i-k} - m_i|, \dots, |x_{i+k} - m_i|)$, where

$$\kappa = \frac{1}{\sqrt{2} \operatorname{erfc}^{-1} 1/2} \approx 1.4826$$

The quantity σ_i / κ is known as the median absolute deviation (MAD).

If a sample x_i is such that

$$|x_i - m_i| > n_o \sigma_i$$

for a given threshold n_o , then the Hampel identifier declares x_i an outlier and replaces it with m_i . If n_o is 0, then the Hampel filter behaves as a regular median filter.

Algorithms

For a given sample of data, x_s , the algorithm:

- Centers the window of odd length at the current sample.
- Computes the local median, m_i , and standard deviation, σ_i , over the current window of data.
- Compares the current sample with $n_o \times \sigma_i$, where n_o is the threshold value. If $|x_s - m_i| > n_o \times \sigma_i$, the filter identifies the current sample, x_s , as an outlier and replaces it with the median value, m_i .

Consider a frame of data that is passed into the Hampel filter.

1	2	4	9	23	8	12	4	2
---	---	---	---	----	---	----	---	---

In this example, the Hampel filter slides a window of length 5 (Len) over the data. The filter has a threshold value of 2 (n_o). To have a complete window at the beginning of the frame, the filter algorithm prepends the frame with $Len - 1$ zeros. To compute the first

sample of the output, the window centers on the $\left[\frac{Len-1}{2} + 1\right]^{th}$ sample in the appended frame, the third zero in this case. The filter computes the median, median absolute deviation, and the standard deviation over the data in the local window.

- Current sample: $x_s = 0$.
- Window of data: $win = [0\ 0\ 0\ 0\ 1]$.
- Local median: $m_i = \text{median}([0\ 0\ 0\ 0\ 1]) = 0$.
- Median absolute deviation: $mad_i = \text{median}(|x_{i-k} - m_i|, \dots, |x_{i+k} - m_i|)$. For this window of data, $mad = \text{median}(|0 - 0|, \dots, |1 - 0|) = 0$.

•

Standard deviation: $\sigma_i = \kappa \times mad_i = 0$, where $\kappa = \frac{1}{\sqrt{2} \operatorname{erfc}^{-1}(1/2)} \approx 1.4826$.

- The current sample, $x_s = 0$, does not obey the relation for outlier detection.

$$[|x_s - m_i| = 0] > [(n_\sigma \times \sigma_i) = 0]$$

Therefore, the Hampel filter outputs the current input sample, $x_s = 0$.

Repeat this procedure for every succeeding sample until the algorithm centers the

window on the $\left[\operatorname{End} - \frac{\operatorname{Len} - 1}{2} \right]^{th}$ sample, marked as End. Because the window centered

on the last $\frac{\operatorname{Len} - 1}{2}$ samples cannot be full, these samples are processed with the next frame of input data.

Here is the first output frame the Hampel filter generates:

The seventh sample of the appended input frame, 23, is an outlier. The Hampel filter replaces this sample with the median over the local window [4 9 23 8 12].

Functions

`hampel`

System Objects

`dsp.MedianFilter` | `dsp.MovingAverage`

Blocks

Hampel Filter | Median Filter | Moving Average

Introduced in R2017a

reset

System object: dsp.HampelFilter

Package: dsp

Reset internal states of System object

Syntax

```
reset(hampFilt)
```

Description

`reset(hampFilt)` resets the states of the input object to their initial values. The initial state values correspond to the initial conditions for the difference equation defining the object. After you call the object using nonzero input data, the filter might have nonzero states. If you continue to pass nonzero input data to the object without first calling `reset`, the object might produce different outputs for an identical input.

Introduced in R2017a

step

System object: dsp.HampelFilter

Package: dsp

Remove outliers from input

Syntax

```
y = step(hampFilt,x)
[y,isOutlier] = step(hampFilt,x)
```

Description

Note Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`y = step(hampFilt,x)` detects and removes the outliers of each channel of the input signal, `x`, independently over time using the input `dsp.HampelFilter` System object, `hampFilt`. The input `x` must be real, and it supports single and double data types.

`[y,isOutlier] = step(hampFilt,x)` returns a logical array, `IsOutlier`, where each element is `true` when the corresponding element in the input is an outlier. `isOutlier` is the same size as the input and output vectors.

Introduced in R2017a

dsp.HDLChannelizer System object

Package: dsp

Polyphase filter bank and fast Fourier transform—optimized for HDL code generation

Description

The `dsp.HDLChannelizer` System object separates a broadband input signal into multiple narrowband output signals. It provides hardware speed and area optimization for streaming data applications. The object accepts scalar or vector input of real or complex data, provides hardware-friendly control signals, and has optional output frame control signals. You can achieve giga-sample-per-second (GSPS) throughput by using vector input. The object implements a polyphase filter, with one subfilter per input vector element. The hardware implementation interleaves the subfilters, which results in sharing each filter multiplier (*FFT Length / Input Size*) times. The object implements the same pipelined Radix 2^2 FFT algorithm as the `dsp.HDLFFT` System object.

To channelize input data:

- 1 Create the `dsp.HDLChannelizer` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

Creation

Syntax

```
channelizer = dsp.HDLChannelizer  
channelizer = dsp.HDLChannelizer(Name, Value)
```

Description

`channelizer = dsp.HDLChannelizer` returns a System object, `channelizer`, that implements a raised-cosine filter and an 8-point FFT.

`channelizer = dsp.HDLChannelizer(Name, Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

NumFrequencyBands — FFT length

8 (default) | integer power of two

FFT length, specified as an integer power of two. For HDL code generation, the FFT length must be between 2^3 and 2^{16} , inclusive.

FilterCoefficients — Polyphase filter coefficients

`[-0.032 0.121 0.318 0.482 0.546 0.482 0.318 0.121 -0.032]` (default) | vector of numeric values

Polyphase filter coefficients, specified as a vector of numeric values. If the number of coefficients is not a multiple of `NumFrequencyBands`, the object pads this vector with zeros. The default filter specification is a raised-cosine FIR filter, `rcosdesign(0.25, 2, 4, 'sqrt')`. You can specify a vector of coefficients or a call to a filter design function that returns the coefficient values. Complex coefficients are not supported. By default, the object casts the coefficients to the same data type as the input.

ComplexMultiplication — HDL implementation of complex multipliers

'Use 4 multipliers and 2 adders' (default) | 'Use 3 multipliers and 5 adders'

HDL implementation of complex multipliers, specified as either 'Use 4 multipliers and 2 adders' or 'Use 3 multipliers and 5 adders'. Depending on your synthesis tool and target device, one option may be faster or smaller.

Dependencies

This option applies only if you use the Radix 2^2 architecture.

OutputSize — Size and order of output data

'Same as number of frequency bands' (default) | 'Same as input size'

Size and order of output data, specified as:

- 'Same as number of frequency bands' — Output data is a 1-by- M vector, where M is the FFT length. The output order is bit natural.
- 'Same as input size' — Output data is an M -by-1 vector, where M is the input vector size. The output order is bit reversed.

Normalize — FFT scaling

true (default) | false

FFT output scaling, specified as either:

- true — The FFT implements an overall $1/N$ scale factor by scaling the result of each pipeline stage by 2. This adjustment keeps the output of the FFT in the same amplitude range as its input.
- false — The FFT avoids overflow by increasing the word length by one bit at each stage.

RoundingMethod — Rounding mode used for internal fixed-point calculations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Zero'

Rounding mode used for fixed-point operations. The object uses fixed-point arithmetic for internal calculations when the input is any integer or fixed-point data type. This option does not apply when the input is single or double. Each FFT stage rounds after the twiddle factor multiplication but before the butterflies. Rounding can also occur when casting the coefficients and the output of the polyphase filter to the data types you specify.

OverflowAction — Overflow handling for internal fixed-point calculations

'Wrap' (default) | 'Saturate'

“Overflow Handling” used for fixed-point operations. The object uses fixed-point arithmetic for internal calculations when the input is any integer or fixed-point data type. This option does not apply when the input is `single` or `double`. This option applies to casting the coefficients and the output of the polyphase filter to the data types you specify.

The FFT algorithm avoids overflow by either scaling the output of each stage (`Normalize` enabled), or by increasing the word length by 1 bit at each stage (`Normalize` disabled).

CoefficientsDataType — Data type of filter coefficients

'Same word length as input' (default) | `numericType` object

The object casts the polyphase filter coefficients to this data type, using the rounding and overflow settings you specify. When you select `Inherit: Same word length as input` (default), the object selects the binary point using `fi()` best-precision rules.

FilterOutputDataType — Data type of output of polyphase filter

'Same word length as input' (default) | `numericType` object

Data type of the output of the polyphase filter, specified as 'Same word length as input' or a `numericType` object. The object casts the output of the polyphase filter (the input to the FFT) to this data type, using the rounding and overflow settings you specify. When you specify 'Same word length as input', the object selects a best-precision binary point by considering the values of your filter coefficients and the range of your input data type.

By default, the FFT logic does not change the data type. When you disable `Normalize`, the FFT algorithm avoids overflow by increasing the word length by 1 bit at each stage.

ResetInputPort — Enable reset argument

`false` (default) | `true`

Enable `reset` input argument to the object. When `reset` is 1 (`true`), the object stops calculation and clears all internal state.

StartOutputPort — Enable start output argument

`false` (default) | `true`

Enable `startOut` output argument of the object. When enabled, the object returns an additional output signal that is 1 (`true`) on the first cycle of each valid output frame.

EndOutputPort — Enable end output argument

false (default) | true

Enable endOut output argument of the object. When enabled, the object returns an additional output signal that is 1 (true) on the first cycle of each valid output frame.

Usage

Syntax

```
[dataOut,validOut] = channelizer(dataIn,validIn)
[dataOut,validOut] = channelizer(dataIn,validIn,reset)
[dataOut,startOut,endOut,validOut] = channelizer(____)
```

Description

[dataOut,validOut] = channelizer(dataIn,validIn) filters and computes a fast Fourier transform, and returns the frequency channels, dataOut, detected in the input signal, dataIn, when validIn is 1 (true). The validIn and validOut arguments are logical scalars that indicate the validity of the input and output signals, respectively.

[dataOut,validOut] = channelizer(dataIn,validIn,reset) returns the frequency channels, dataOut, detected in the input signal, dataIn, when validIn is 1 (true) and reset is 0 (false). When reset is 1 (true), the object stops the current calculation and clears all internal state.

To use this syntax, set the ResetInputPort property to true. For example:

```
channelizer = dsp.HDLChannelizer(...,'ResetInputPort',true);
...
[dataOut,validOut] = channelizer(dataIn,validIn,reset)
```

[dataOut,startOut,endOut,validOut] = channelizer(____) returns the frequency channels, dataOut, computed from the input arguments of any of the previous syntaxes. startOut is 1 (true) for the first sample of a frame of output data. endOut is 1 (true) for the last sample of a frame of output data.

To use this syntax, set the `StartOutputPort` and `EndOutputPort` properties to `true`. For example:

```
channelizer = dsp.HDLChannelizer(...,'StartOutputPort',true,'EndOutputPort',true);
...
[dataOut,startOut,endOut,validOut] = channelizer(dataIn,validIn)
```

Input Arguments

dataIn — Input data

scalar or column vector of real or complex values

Input data, specified as a scalar or column vector of real or complex values. The vector size must be a power of 2 between 1 and 64 that is not greater than the number of channels (FFT length). `double` and `single` are allowed for simulation but not for HDL code generation.

The object does not accept `uint64` data.

Data Types: `fi` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `single` | `double`

validIn — Validity of input data

logical scalar

Validity of input data, specified as a logical scalar. When `validIn` is 1 (`true`), the object captures the value on `dataIn`.

Data Types: `logical`

reset — Reset internal state

logical scalar

Reset internal state, specified as a logical scalar. When `reset` is 1 (`true`), the object stops the current calculation and clears internal state.

Dependencies

To enable this argument, set `ResetInputPort` to `true`.

Data Types: `logical`

Output Arguments

dataOut — Frequency channel output data

row vector

Frequency channel output data, returned as a row vector.

- If you set `OutputSize` to 'Same as number of frequency bands' (default), the output data is a 1-by- M vector, where M is the FFT length. The output order is bit natural.
- If you set `OutputSize` to 'Same as input size', the output data is an M -by-1 vector, where M is the input vector size. The output order is bit reversed.

The data type is a result of the `FilterOutputDataType` and the FFT bit growth necessary to avoid overflow.

validOut — Validity of output data

logical scalar

Validity of output data, returned as a logical scalar. The object sets `validOut` to 1 (true) with each valid sample on `dataOut`.

Data Types: `logical`

startOut — First valid cycle of output data

logical scalar

First sample of output frame, returned as a logical scalar. The object sets `startOut` to 1 (true) during the first valid sample on `dataOut`.

Dependencies

To enable this argument, set `StartOutputPort` to `true`.

Data Types: `logical`

endOut — Last valid cycle of output data

logical scalar

Last sample of output frame, returned as a logical scalar. The object sets `endOut` to 1 (true) during the last valid sample on `dataOut`.

Dependencies

To enable this argument, set `EndOutputPort` to `true`.

Data Types: `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.HDLChannelizer

`getLatency` Latency of FFT or channelizer calculation

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>clone</code>	Create duplicate System object
<code>getNumInputs</code>	Number of inputs required to call the System object
<code>getNumOutputs</code>	Number of outputs from calling the System object
<code>isLocked</code>	Determine if System object is locked
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Create Channelizer for HDL Generation

Create a function that contains a channelizer object and supports HDL code generation.

Create the specifications and input signal. The signal has 8 frequency channels.

```
N = 8;
loopCount = 1024;
offsets = [-40 -30 -20 10 15 25 35 -15];
```

```
sinewave = dsp.SineWave('ComplexOutput',true,'Frequency', ...
    offsets+(-375:125:500),'SamplesPerFrame',loopCount);
spectrumAnalyzer = dsp.SpectrumAnalyzer('ShowLegend',true, ...
    'SampleRate',sinewave.SampleRate/N);
```

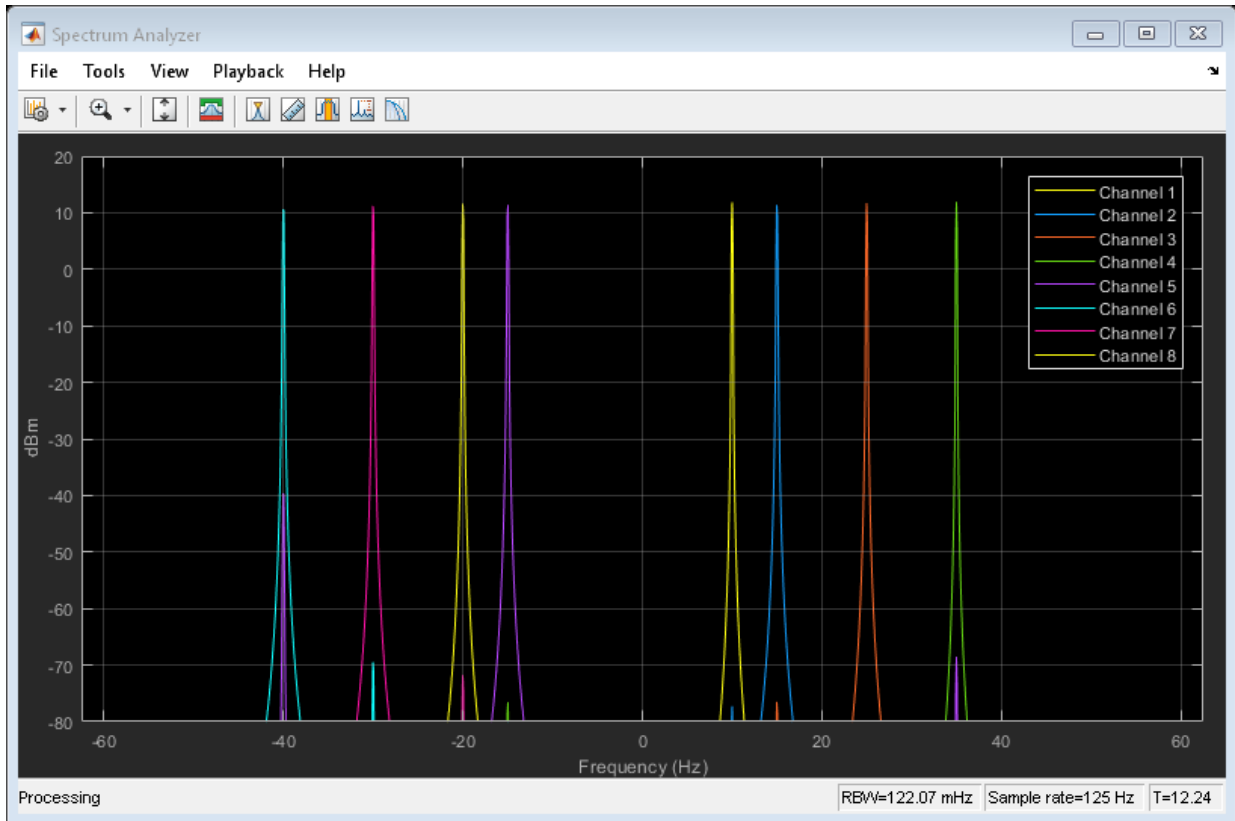

Write a function that creates and calls the channelizer System object™. You can generate HDL from this function.

```
function [yOut,validOut] = HDLChannelizer8(yIn,validIn)
%HDLChannelizer8
% Process one sample of data using the dsp.HDLChannelizer System object
% yIn is a fixed-point scalar or column vector.
% validIn is a logical scalar value.
% You can generate HDL code from this function.

persistent channelize8;
if isempty(channelize8)
    % Use filter coeffs from non-HDL channelizer, or supply your own.
    channelizer = dsp.Channelizer('NumFrequencyBands',8);
    channelize8 = dsp.HDLChannelizer('NumFrequencyBands',8,'FilterCoefficients',tf(chan
end
[yOut,validOut] = channelize8(yIn,validIn);
end
```

Channelize the input data by calling the object for each data sample.

```
y = zeros(loopCount/N,N);
validOut = false(loopCount/N,1);
yValid = zeros(loopCount/(N*N),N);
for reps=1:20
    x = sum(sinewave(),2);
    for loop=1:length(x)
        [y(loop,:),validOut(loop)] = HDLChannelizer8(complex(x(loop)),true);
    end
    yValid = y(validOut == 1,:);
    spectrumAnalyzer(yValid);
end
```

Explore Latency of the HDL Channelizer Object

The latency of the `dsp.HDLChannelizer` object varies with the FFT length and the vector size. Use the `getLatency` function to find the latency of a particular configuration. The latency is measured as the number of cycles between the first valid input and the first valid output, assuming that the input is contiguous. The number of filter coefficients does not affect the latency. Setting the output size equal to the input size reduces the latency because the samples are not saved and reordered.

Create a `dsp.HDLChannelizer` object and request the latency.

```
channelize = dsp.HDLChannelizer('NumFrequencyBands',512);  
L512 = getLatency(channelize)
```

```
L512 = 1118
```

Request hypothetical latency information about a similar object with a different number of frequency bands (FFT length). The properties of the original object do not change.

```
L256 = getLatency(channelize,256)
```

```
L256 = 592
```

```
N = channelize.NumFrequencyBands
```

```
N = 512
```

Request hypothetical latency information of a similar object that accepts eight-sample vector input.

```
L256v8 = getLatency(channelize,256,8)
```

```
L256v8 = 132
```

Enable scaling at each stage of the FFT. The latency does not change.

```
channelize.Normalize = true;  
L512n = getLatency(channelize)
```

```
L512n = 1118
```

Request the same output size and order as the input data. The latency decreases because the object does not need to store and reorder the data before output. The default input size is scalar.

```
channelize.OutputSize = 'Same as input size';  
L512r = getLatency(channelize)
```

```
L512r = 605
```

Check the latency of a vector input implementation where the input and output are the same size. Specify the current value of the FFT length and a vector size of 8 samples. The latency decreases because the object computes results in parallel when the input is a vector.

```
L256rv8 = getLatency(channelize,channelize.NumFrequencyBands,8)
```

L256rv8 = 145

Algorithms

This object implements the algorithm described on the Channelizer HDL Optimized block reference page.

Latency

The latency varies with the FFT length and the vector size. Use the `getLatency` function to find the latency of a particular configuration. The latency is the number of cycles between the first valid input and the first valid output, assuming that the input is contiguous. The filter coefficients do not affect the latency. Setting the output size equal to the input size reduces the latency, because the samples are not saved and reordered.

Control Signals

This diagram shows `validIn` and `validOut` signals for contiguous input data with a vector size of 16 and an FFT length of 512.

The diagram also shows the optional `startOut` and `endOut` signals that indicate frame boundaries. When enabled, `startOut` pulses for one cycle with the first `validOut` of the frame, and `endOut` pulses for one cycle with the last `validOut` of the frame.

If you apply continuous input frames (no gap in `validIn` between frames), the output will also be continuous, after the initial latency.

The `validIn` signal can be noncontiguous. Data accompanied by a `validIn` signal is stored until a frame is filled. Then the data is output in a contiguous frame of N (FFT

length) cycles. This diagram shows noncontiguous input and contiguous output for an FFT length of 512 and a vector size of 16 samples.

Performance

These resource and performance data are the place-and-route results from the generated HDL targeted to a Xilinx Virtex 6 (XC6VLX240-1ff784) FPGA. The three examples in the tables use this configuration:

- FFT length (default) — 8
- Filter length — 96 coefficients
- 16-bit complex input data
- Coefficient and filter output data types (default) — same word length as input data
- Complex multiplication (default) — 4 multipliers, 2 adders
- Output scaling — Enabled
- Minimize clock enables (HDL Coder parameter)

Performance of the synthesized HDL code varies with your target and synthesis options.

For scalar input, the design achieves a clock frequency of 346 MHz. The latency is 53 cycles. The subfilters share each multiplier eight (N) times. The design uses these resources.

Resource	Number Used
LUT	1591
FFS	2681
Xilinx LogiCORE DSP48	16

For four-sample vector input, the design achieves a clock frequency of 333 MHz. The latency is 31 cycles. The subfilters share each multiplier twice (N/M). The design uses these resources.

Resource	Number Used
LUT	1912
FFS	3986
Xilinx LogiCORE DSP48	56

For eight-sample vector input, the design achieves a clock frequency of 292 MHz. The latency is 20 cycles. When the input size is the same as the FFT length, the subfilters do not share any multipliers. The design uses these resources.

Resource	Number Used
LUT	1388
FFS	2302
Xilinx LogiCORE DSP48	110

`dsp.Channelizer` | `dsp.HDLFFT`

Introduced in R2017a

dsp.HDLComplexToMagnitudeAngle System object

Package: dsp

Magnitude and phase angle of complex signal—optimized for HDL code generation

Description

The `dsp.HDLComplexToMagnitudeAngle` System object computes the magnitude and phase angle of a complex signal. It provides hardware-friendly control signals. The object uses a pipelined coordinate rotation digital computer (CORDIC) algorithm to achieve an efficient HDL implementation.

To compute the magnitude and phase angle of a complex signal:

- 1 Create the `dsp.HDLComplexToMagnitudeAngle` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

Creation

Syntax

```
HCMA = dsp.HDLComplexToMagnitudeAngle  
HCMA = dsp.HDLComplexToMagnitudeAngle (Name, Value)
```

Description

`HCMA = dsp.HDLComplexToMagnitudeAngle` returns a System object, `HCMA`, that computes the magnitude and phase angle of a complex input.

HCMA = dsp.HDLComplexToMagnitudeAngle(Name, Value) returns a System object, HCMA, sets properties using one or more name-value pairs. Enclose each property name in single quotes. For example,

```
cma = dsp.HDLComplexToMagnitudeAngle('AngleFormat', 'Radians')
```

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects \(MATLAB\)](#).

OutputValue — Values to return

'Magnitude and angle' (default) | 'Magnitude' | 'Angle'

Output values the object returns. The object returns the magnitude, or angle, or both.

AngleFormat — Format of angle

'Normalized' (default) | 'Radians'

Format of the angle output of the object, specified as either:

- 'Normalized' — Fixed-point format that normalizes the angles in the range $[-1, 1]$.
- 'Radians' — Fixed-point values between π and $-\pi$.

ScaleOutput — Scale output by the inverse of the CORDIC gain factor

true (default) | false

Scale output by the inverse of the CORDIC gain factor, specified as true or false.

Note If you turn off output scaling and apply the CORDIC gain elsewhere in your design, you must exclude the $\pi/4$ term. The quadrant mapping algorithm replaces the first CORDIC iteration by mapping inputs onto the angle range, $[0, \pi/4]$. Therefore, the initial rotation does not contribute a gain term.

NumIterationsSource — Source of NumIterations

'Auto' (default) | 'Property'

Source of the NumIterations property for the CORDIC algorithm, specified as:

- 'Property' — Uses the NumIterations property.
- 'Auto' — Sets the number of iterations to *input word length* – 1. If the input is double or single, the number of iterations is 16.

NumIterations — Number of CORDIC iterations

integer less than or equal to *input word length* – 1

Number of CORDIC iterations that the object executes, specified as an interger. The number of iterations must be less than or equal to the *input word length* – 1.

Dependencies

To enable this property, set NumIterationsSource to 'Property'.

Usage

Note For versions earlier than R2016b, use the `step` function to run the System object™ algorithm. The arguments to `step` are the object you created, followed by the arguments shown in this section.

For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Syntax

```
[mag,angle,validOut] = HCMA(X,validIn)
[mag,validOut] = HCMA(X,validIn)
[angle,validOut] = HCMA(X,validIn)
```

Description

`[mag,angle,validOut] = HCMA(X,validIn)` converts complex scalar `X` into its component magnitude and angle. `validIn` and `validOut` are logical scalars that

indicate the validity of the input and output signals respectively. If `validOut` is 1 (true), the output is valid.

`[mag,validOut] = HCMA(X,validIn)` converts complex scalar `X` into its component magnitude.

To use this syntax, set `OutputValue` to `'Magnitude'`. For example:

```
HCMA = dsp.HDLComplexToMagnitudeAngle('OutputValue','Magnitude');
...
[mag,validOut] = HCMA(X,validIn)
```

`[angle,validOut] = HCMA(X,validIn)` converts complex scalar `X` into its component angle.

To use this syntax, set `OutputValue` to `'Angle'`. For example

```
HCMA = dsp.HDLComplexToMagnitudeAngle('OutputValue','Angle');
...
[angle,validOut] = HCMA(X,validIn)
```

Input Arguments

x — Input data

complex scalar

Input data, specified as a complex scalar value. `double` and `single` are allowed for simulation but not for HDL code generation.

Data Types: `fi` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `single` | `double`

validIn — Validity of input data

logical scalar

Validity of the `X` value, specified as a logical scalar.

Data Types: `logical`

Output Arguments

mag — Magnitude

scalar

Magnitude calculated from complex input, returned as a scalar value with the same data type as the input data.

angle — Angle

scalar

Angle calculated from complex input, returned as a scalar value with the same data type as the input data. The format of this value depends on the `AngleFormat` property.

validOut — Validity of output data

logical scalar

Validity of the output data, returned as a logical scalar.

Data Types: `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>clone</code>	Create duplicate System object
<code>getNumInputs</code>	Number of inputs required to call the System object
<code>getNumOutputs</code>	Number of outputs from calling the System object
<code>isLocked</code>	Determine if System object is locked
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Convert Complex Data to Magnitude-Angle Data

Use the `dsp.HDLComplexToMagnitudeAngle` object to compute the magnitude and angle of a complex signal. The object uses a CORDIC algorithm for an efficient hardware implementation.

Choose word lengths and create random complex input data. Then, convert the input to fixed-point.

```
a = -4;
b = 4;
inputWL = 16;
inputFL = 12;
numSamples = 10;
reData = ((b-a).*rand(numSamples,1)+a);
imData = ((b-a).*rand(numSamples,1)+a);
dataIn = (fi(reData+imData*1i,1,inputWL,inputFL));
figure
plot(dataIn)
title('Random Complex Input Data')
xlabel('Real')
ylabel('Imaginary')
```

Write a function that creates and calls the System object™. You can generate HDL from this function.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
function [mag,angle,validOut] = Complex2MagAngle(yIn,validIn)
%Complex2MagAngle
% Converts one sample of complex data to magnitude and angle data.
% yIn is a fixed-point complex number.
% validIn is a logical scalar value.
% You can generate HDL code from this function.
```

```

persistent cma;
if isempty(cma)
    cma = dsp.HDLComplexToMagnitudeAngle('AngleFormat','Radians');
end
[mag,angle,validOut] = cma(yIn,validIn);
end

```

The object takes some latency to computer the answer for each input sample, depending on the number of CORDIC iterations. When you set NumIterationsSource to 'Auto', the number of iterations is $\text{inputWL}-1$. The latency is $\text{NumIterations}+2$, or $\text{inputWL}+1$.

```

latency = inputWL+1;
mag = zeros(1,numSamples+latency);
ang = zeros(1,numSamples+latency);
validOut = false(1,numSamples+latency);

```

Call the function to convert each sample. After you apply all input samples, continue calling the function with invalid input to flush remaining output samples.

```

for ii = 1:1:numSamples
    [mag(ii),ang(ii),validOut] = Complex2MagAngle(dataIn(ii),true);
end
for ii = (numSamples+1):1:(numSamples+latency)
    [mag(ii),ang(ii),validOut(ii)] = Complex2MagAngle(fi(0+0*1i,1,inputWL,inputFL),false);
end
% Remove non-valid output values
mag = mag(validOut == 1);
ang = ang(validOut == 1);
figure
polar(ang,mag,'--r') % Red is output from HDL-optimized object
title('Output from dsp.HDLComplexToMagnitudeAngle')
magD = abs(dataIn);
angD = angle(dataIn);
figure
polar(angD,magD,'--g') % Green is output from abs and angle functions
title('Output from abs and angle Functions')

```

Output from dsp.HDLComplexToMagnitudeAngle

Algorithms

This object implements the algorithm described on the Complex to Magnitude-Angle HDL Optimized block reference page.

Delay

The latency is `NumIterations + 2` cycles from input to output. Each call to the object models one clock cycle.

When you set `NumIterationsSource` to 'Auto', the number of iterations is *input word length* - 1, and the latency is *input word length* + 1. If the input is double or single type, the number of iterations is 16, and the latency is 18.

Performance

Performance was measured for the default configuration, with output scaling disabled and `fixdt(1,16,12)` input. When the generated HDL code is synthesized into a Xilinx Virtex-6 (XC6VLX240T-1FFG1156) FPGA, the design achieves 260 MHz clock frequency. It uses the following resources.

Resource	Number Used
LUT	882
FFS	792
Xilinx LogiCORE DSP48	0
Block RAM (16K)	0

Performance of the synthesized HDL code varies depending on your target and synthesis options.

Introduced in R2014b

dsp.HDLFIRRateConverter System object

Package: dsp

Upsample, filter, and downsample—optimized for HDL code generation

Description

The `dsp.HDLFIRRateConverter` System object upsamples, filters, and downsamples input signals. It is optimized for HDL code generation and operates on one sample of each channel at a time. The object implements an efficient polyphase architecture to avoid unnecessary arithmetic operations and high intermediate sample rates.

The object upsamples by an integer factor of L , applies an FIR filter, and downsamples by an integer factor of M . The object accepts and returns control signal arguments for pacing the flow of samples. For detail of the flow control interface, see “Flow Control” on page 4-891.

To resample and filter input data:

- 1 Create the `dsp.HDLFIRRateConverter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#) (MATLAB).

Creation

Syntax

```
HDLFIRRC = dsp.HDLFIRRateConverter
HDLFIRRC = dsp.HDLFIRRateConverter(L,M,num)
HDLFIRRC = dsp.HDLFIRRateConverter( ____, Name, Value)
```

Description

`HDLFIRRC = dsp.HDLFIRRateConverter` returns a System object, `HDLFIRRC`, that resamples each channel of the input. The object upsamples by an integer factor of L , applies an FIR filter, and downsamples by an integer factor of M . The default L/M is $3/2$.

`HDLFIRRC = dsp.HDLFIRRateConverter(L,M,num)` sets the `InterpolationFactor` property to L , the `DecimationFactor` property to M , and the `Numerator` property to `num`.

`HDLFIRRC = dsp.HDLFIRRateConverter(____, Name, Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes. For example:

```
HDLFIRRC = dsp.HDLFIRRateConverter(L,M,Num,'ReadyPort',true,'RequestPort',true);
```

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects \(MATLAB\)](#).

InterpolationFactor — Upsampling factor

3 (default) | positive integer scalar

Upsampling factor, L , specified as a positive integer.

DecimationFactor — Downsampling factor

2 (default) | positive integer scalar

Downsampling factor, M , specified as a positive integer scalar.

Numerator — FIR filter coefficients

`firpm(70,[0 .28 .32 1],[1 1 0 0])` (default) | vector in descending powers of z^{-1}

FIR filter coefficients, specified as a vector in descending powers of z^{-1} .

You can generate filter coefficients by using the Signal Processing Toolbox filter design functions, such as `fir1`. Design a lowpass filter with normalized cutoff frequency no greater than $\min(1/L, 1/M)$. The object initializes internal filter states to zero.

ReadyPort — Enable ready argument

`false` (default) | `true`

Enable `ready` output argument of the object. When enabled, the object returns a logical scalar value, `ready`, when you call the object. When `ready` is 1 (true), the object is ready for a new input sample the next time you call it.

RequestPort — Enable request argument

`false` (default) | `true`

Enable `request` input argument of the object. When `request` is 1 (true), the object returns a new output sample on the current call to the object.

RoundingMethod — Rounding mode used for fixed-point operations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Zero'

Rounding mode used for fixed-point operations. This property does not apply when the input is `single` or `double` type. 'Simplest' mode is not supported.

OverflowAction — Overflow mode used for fixed-point operations

'Wrap' (default) | 'Saturate'

Overflow mode used for fixed-point operations. This property does not apply when the input is `single` or `double` type.

CoefficientsDataType — Data type of the FIR filter coefficients

`numericType(1,16,16)` (default) | `numericType(s,wl,fl)`

Data type of the FIR filter coefficients, specified as a `numericType(s,wl,fl)` object with signedness, word length, and fractional length properties.

OutputDataType — Data type of the output data samples

'Same word length as input' (default) | `numericType(s,wl,fl)` | 'Full precision'

Data type of the output data samples, specified as 'Same word length as input', 'Full precision', or as a `numericType(s,wl,fl)` object with signedness, word length, and fractional length properties.

Usage

Note For versions earlier than R2016b, use the `step` function to run the System object™ algorithm. The arguments to `step` are the object you created, followed by the arguments shown in this section.

For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Syntax

```
[dataOut,validOut] = HDLFIRRC(dataIn,validIn)
[dataOut,ready,validOut] = HDLFIRRC(dataIn,validIn)
[dataOut,ready,validOut] = HDLFIRRC(dataIn,validIn,request)
```

Description

`[dataOut,validOut] = HDLFIRRC(dataIn,validIn)` resamples `dataIn` according to the *InterpolationFactor* (L) and *DecimationFactor* (M) properties. To avoid dropped samples when using this syntax, apply new valid input samples, with `validIn` set to true, only every `ceil(L/M)` calls to the object. The object sets `validOut` to true when `dataOut` is a new valid sample.

`[dataOut, ready, validOut] = HDLFIRRC(dataIn, validIn)` resamples the input data and returns `ready` to indicate whether the object can accept a new sample on the next call.

This syntax applies when you set the `ReadyPort` property to `true`. For example:

```
HDLFIRRC = dsp.HDLFIRRateConverter(..., 'ReadyPort', true);
...
[dataOut, validOut, ready] = rateConverter(dataIn, validIn);
```

`[dataOut, ready, validOut] = HDLFIRRC(dataIn, validIn, request)` resamples the input data, indicates whether the object can accept a new sample, and, if `request` is `true`, returns the next available sample.

This syntax applies when you set the `RequestPort` property to `true`. For example:

```
HDLFIRRC = dsp.HDLFIRRateConverter(..., 'RequestPort', true);
...
[dataOut, validOut] = rateConverter(dataIn, validIn, request);
```

You can connect the `ready` output of a downstream object to the `request` input of an upstream object.

Input Arguments

dataIn — Data input

scalar or row vector

Data input, specified as a scalar, or as a row vector where each element represents an independent channel.

The data can be real or complex. `double` and `single` are allowed for simulation but not for HDL code generation.

Data Types: `fi` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `single` | `double`

validIn — Validity of input data

logical scalar

Validity of the input data, specified as a logical scalar.

When `validIn` is 1 (true), the object captures the value on `dataIn`. You can apply a valid data sample every `ceil(L/M)` calls to the object. You can use the optional `ready` output signal to indicate when the object can accept a new sample.

Data Types: `logical`

request — Request for a new output sample

logical scalar

Request for a new output sample, specified as a logical scalar.

When `request` is 1 (true), and a new output data sample is available, the object returns the sample with `validOut` set to 1 (true). If no sample is available, the object returns `validOut` set to 0 (false). The object accepts this argument when you set the `RequestPort` property to `true`.

Data Types: `logical`

Output Arguments

dataOut — Resampled and filtered data sample

scalar or row vector

Resampled and filtered data sample, returned as a scalar, or as a vector in which each element represents an independent channel. `double` and `single` are allowed for simulation but not for HDL code generation.

Data Types: `fi` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `single` | `double`

validOut — Validity of output data

logical scalar

Validity of the output data, returned as a logical scalar.

When `validOut` is 1 (true), the data output is valid. When `validOut` is 0 (false), the data output is not valid.

Data Types: `logical`

ready — Ready for a new input sample

logical scalar

Indicator that the object is ready for a new input sample, returned as a logical scalar.

The object returns `ready = 1` (true) to indicate that the object can accept a new input data sample on the next call. The object returns this additional output when you set the `ReadyPort` property to `true`.

Data Types: `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>clone</code>	Create duplicate System object
<code>getNumInputs</code>	Number of inputs required to call the System object
<code>getNumOutputs</code>	Number of outputs from calling the System object
<code>isLocked</code>	Determine if System object is locked
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Downsample Signal

Convert a signal from 48 kHz to 32 kHz by using the `dsp.HDLFIRRateConverter` System object™.

Define the sample rate and length of the input signal, and a 2 kHz cosine waveform. Set `validIn = true` for every sample.

```
Fs = 48e3;
Ns = 100;
```

```
t = (0:Ns-1) ./ Fs;
dataIn = cos(2*pi*2e3*t);
validIn = true(Ns,1);
```

Preallocate `dataOut` and `validOut` signals for faster simulation.

```
dataOut = zeros(Ns,1);
validOut = false(Ns,1);
```

Create the System object. Configure it to perform rate conversion by a factor of 2/3, using an equiripple filter.

```
Numerator = firpm(70,[0 0.25 0.32 1],[1 1 0 0]);
firrc = dsp.HDLFIRRateConverter(2,3,Numerator);
```

Call the System object to perform the rate conversion and obtain each output sample.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

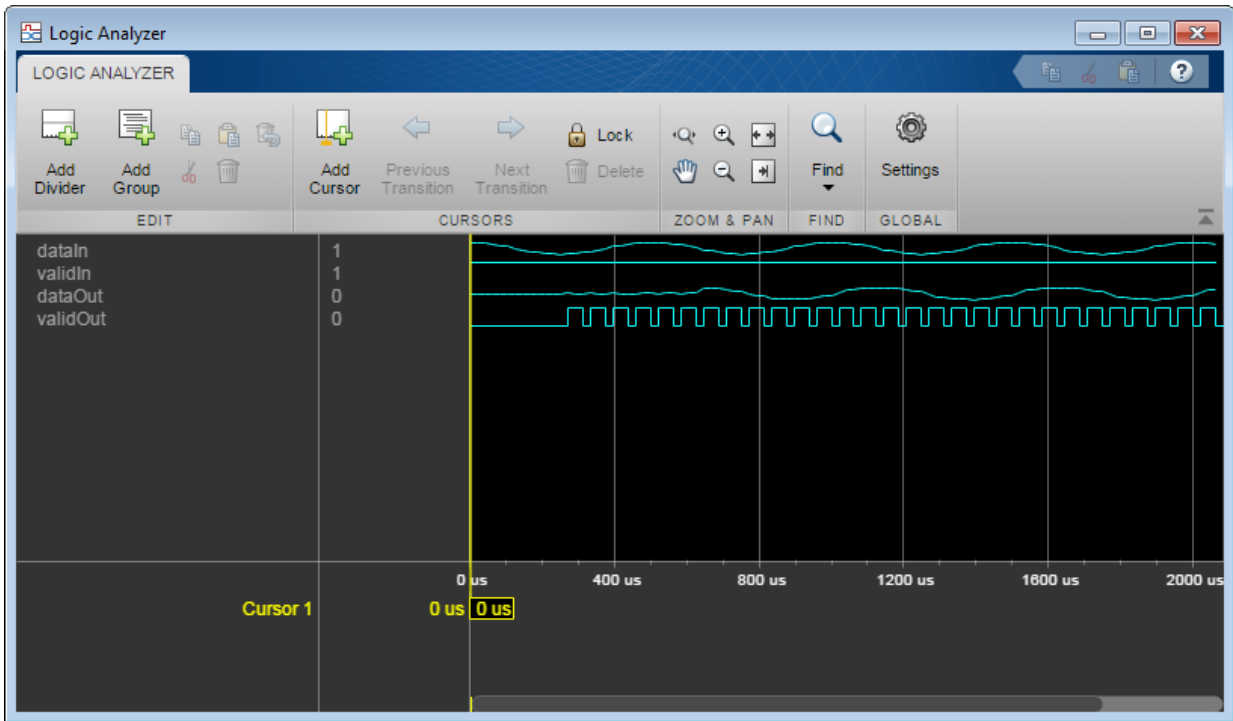

```
for k = 1:Ns
    [dataOut(k),validOut(k)] = firrc(dataIn(k),validIn(k));
end
```

Because the input sample rate is higher than the output sample rate, not every member of `dataOut` is valid. Use `validOut` to extract the valid samples from `dataOut`.

```
y = dataOut(validOut);
```

View the input and output signals with the Logic Analyzer.

```
la = dsp.LogicAnalyzer('NumInputPorts',4,'SampleTime',1/Fs,'TimeSpan',Ns/Fs);
modifyDisplayChannel(la,1,'Name','dataIn','Format','Analog','Height',8)
modifyDisplayChannel(la,2,'Name','validIn')
modifyDisplayChannel(la,3,'Name','dataOut','Format','Analog','Height',8)
modifyDisplayChannel(la,4,'Name','validOut')
la(dataIn,validIn,dataOut,validOut)
```

Upsample Signal

Convert a signal from 40 MHz to 100 MHz by using the `dsp.HDLFIRRateConverter` System object™. To avoid overrunning the object as the signal is upsampled, control the input rate manually.

Define the sample rate and length of the input signal, and a fixed-point cosine waveform.

```

Fs = 40e6;
Ns = 50;
t = (0:Ns-1) ./ Fs;
x = fi(cos(2*pi*1.2e6*t), 1, 16, 14);

```

Define the rate conversion parameters. Use an interpolation factor of 5 and a decimation factor of 2. Calculate how often the object can accept a new input sample.

```
L = 5;
M = 2;
stepsPerInput = ceil(L/M);
numSteps = stepsPerInput*Ns;
```

Generate `dataIn` and `validIn` based on how often the object can accept a new sample.

```
dataIn = zeros(numSteps,1,'like',x);
dataIn(1:stepsPerInput:end) = x;
validIn = false(numSteps,1);
validIn(1:stepsPerInput:end) = true;
```

Create the System object. Configure it to perform rate conversion using the specified factors and an equiripple FIR filter.

```
Numerator = firpm(70,[0 0.15 0.25 1],[1 1 0 0]);
rateConverter = dsp.HDLFIRRateConverter(L,M,Numerator);
```

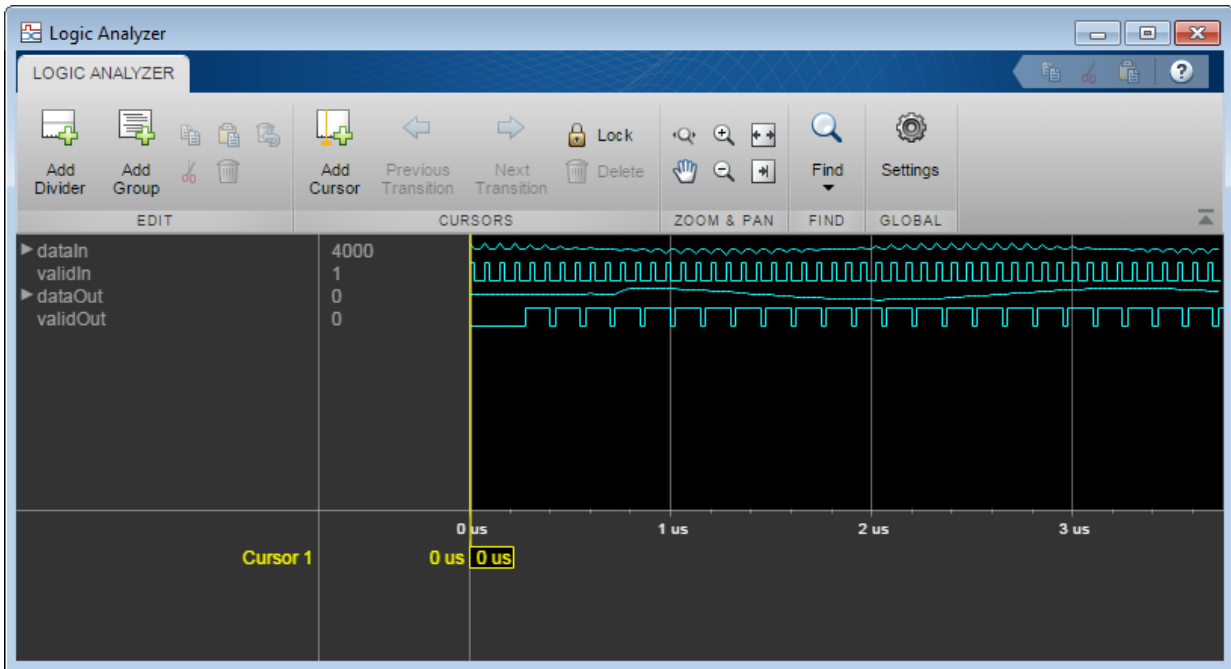

Create a Logic Analyzer to capture and view the input and output signals.

```
la = dsp.LogicAnalyzer('NumInputPorts',4,'SampleTime',1/Fs,'TimeSpan',numSteps/Fs);
modifyDisplayChannel(la,1,'Name','dataIn','Format','Analog','Height',8)
modifyDisplayChannel(la,2,'Name','validIn')
modifyDisplayChannel(la,3,'Name','dataOut','Format','Analog','Height',8)
modifyDisplayChannel(la,4,'Name','validOut')
```

Call the System object to perform the rate conversion and obtain each output sample.
Call the Logic Analyzer to add each sample to the waveform display.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent step syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
for k = 1:numSteps
    [dataOut,validOut] = rateConverter(dataIn(k),validIn(k));
    la(dataIn(k),validIn(k),dataOut,validOut)
end
```

Control Input Rate When Upsampling

Convert a signal from 40 MHz to 100 MHz by using the `dsp.HDLFIRRateConverter` System object™. Use the optional `ready` output signal to avoid overrunning the object as the data is upsampled. The `ready` signal indicates the object can accept a new data sample on the next call to the object.

Define the sample rate and length of the input signal, and a fixed-point cosine waveform. Create a `SignalSource` object to provide data samples on demand.

```
Fs = 40e6;
Ns = 50;
t = (0:Ns-1) ./ Fs;
x = fi(cos(2*pi*1.2e6*t), 1, 16, 14);
inputSource = dsp.SignalSource(x);
```

Define the rate conversion parameters. Use an interpolation factor of 5 and a decimation factor of 2. Determine the number of calls to the object needed to convert N_s samples.

```
L = 5;
M = 2;
numSteps = floor(Ns*L/M);
```

Create the HDL FIR rate converter System object. Configure it to perform rate conversion using the specified factors and an equiripple FIR filter. Enable the optional ready output port.

```
Numerator = firpm(70,[0 0.15 0.25 1],[1 1 0 0]);
rateConverter = dsp.HDLFIRRateConverter(L,M,Numerator,'ReadyPort',true);
```

Create a Logic Analyzer to capture and view the input and output signals.

```
la = dsp.LogicAnalyzer('NumInputPorts',5,'SampleTime',1/Fs,'TimeSpan',numSteps/Fs);
modifyDisplayChannel(la,1,'Name','dataIn','Format','Analog','Height',8)
modifyDisplayChannel(la,2,'Name','validIn')
modifyDisplayChannel(la,3,'Name','dataOut','Format','Analog','Height',8)
modifyDisplayChannel(la,4,'Name','validOut')
modifyDisplayChannel(la,5,'Name','ready')
```

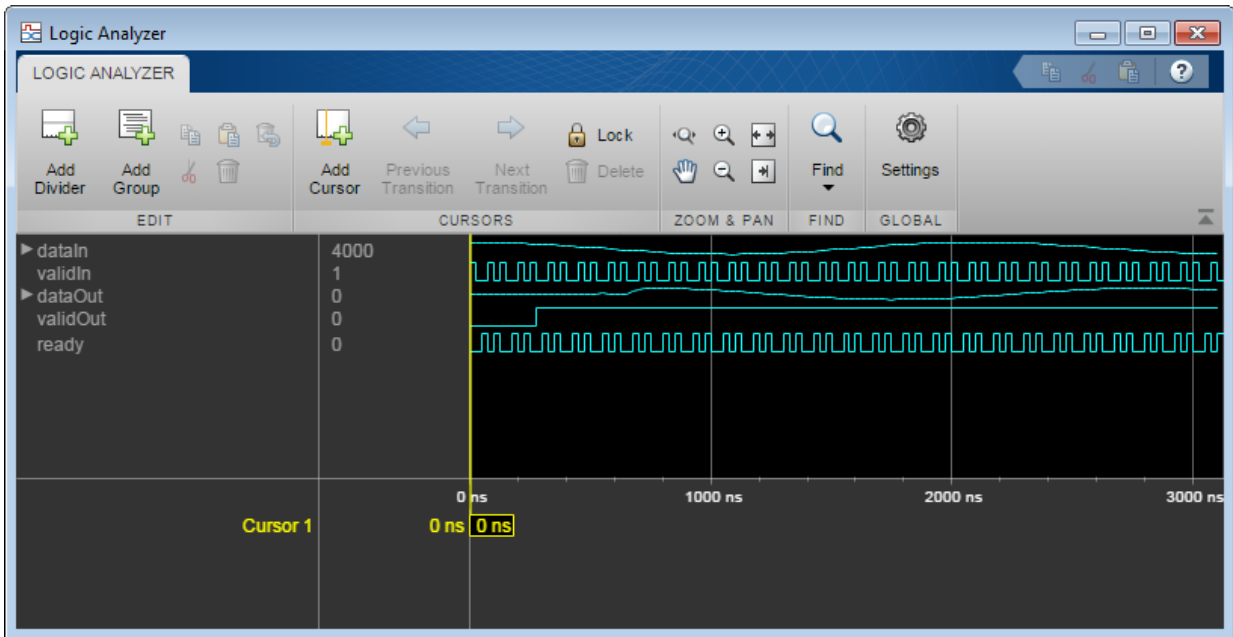

Initialize the ready signal. The object is always ready for input data on the first call.

```
ready = true;
```

Call the System object to perform the rate conversion and obtain each output sample. Apply a new input sample when the object indicates it is ready. Otherwise, set `validIn` to false.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
for k = 1:numSteps
    if ready
        dataIn = inputSource();
    end
    validIn = ready;
    [dataOut,validOut,ready] = rateConverter(dataIn,validIn);
    la(dataIn,validIn,dataOut,validOut,ready)
end
```

Control Output Rate When Upsampling

Convert a signal from 40 MHz to 100 MHz by using the `dsp.HDLFIRRateConverter` System object™. Use the optional `request` input signal to control the output data rate. When the object receives the `request` signal, it returns a new output data sample. This example models a clock rate of 200 MHz by requesting an output sample every second call to the object.

Define the sample rate and length of the input signal, and a fixed-point cosine waveform. Create a `SignalSource` object to provide data samples on demand.

```

Fs = 40e6;
Ns = 50;
t = (0:Ns-1) ./ Fs;
x = fi(cos(2*pi*1.2e6*t), 1, 16, 14);
inputSource = dsp.SignalSource(x);

```

Define the rate conversion parameters. Use an interpolation factor of 5 and a decimation factor of 2. Determine the number of calls to the object needed to convert `Ns` samples.

```
L = 5;
M = 2;
numSteps = floor(2*Ns*L/M);
```

Create the HDL FIR rate converter System object. Configure it to perform rate conversion using the specified factors and an equiripple FIR filter. Enable the optional ready and request ports.

```
Numerator = firpm(70,[0 0.15 0.25 1],[1 1 0 0]);
rateConverter = dsp.HDLFIRRateConverter(L,M,Numerator,...
    'ReadyPort',true,...
    'RequestPort',true);
```

Create a **Logic Analyzer** to capture and view the input and output signals.

```
la = dsp.LogicAnalyzer('NumInputPorts',6,'SampleTime',1/Fs,'TimeSpan',numSteps/Fs);
modifyDisplayChannel(la,1,'Name','dataIn','Format','Analog','Height',8)
modifyDisplayChannel(la,2,'Name','validIn')
modifyDisplayChannel(la,3,'Name','request')
modifyDisplayChannel(la,4,'Name','dataOut','Format','Analog','Height',8)
modifyDisplayChannel(la,5,'Name','validOut')
modifyDisplayChannel(la,6,'Name','ready')
```

Generate a signal that requests a new output sample every second call to the object.

```
request = false(numSteps,1);
request(1:2:end) = true;
```

Initialize the ready signal. The object is always ready for input data on the first call.

```
ready = true;
```

Call the System object to perform the rate conversion and obtain each output sample. Apply a new input sample when the object indicates it is ready. Otherwise, set `validIn` to false. The object returns valid output samples when `request` is set to true.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

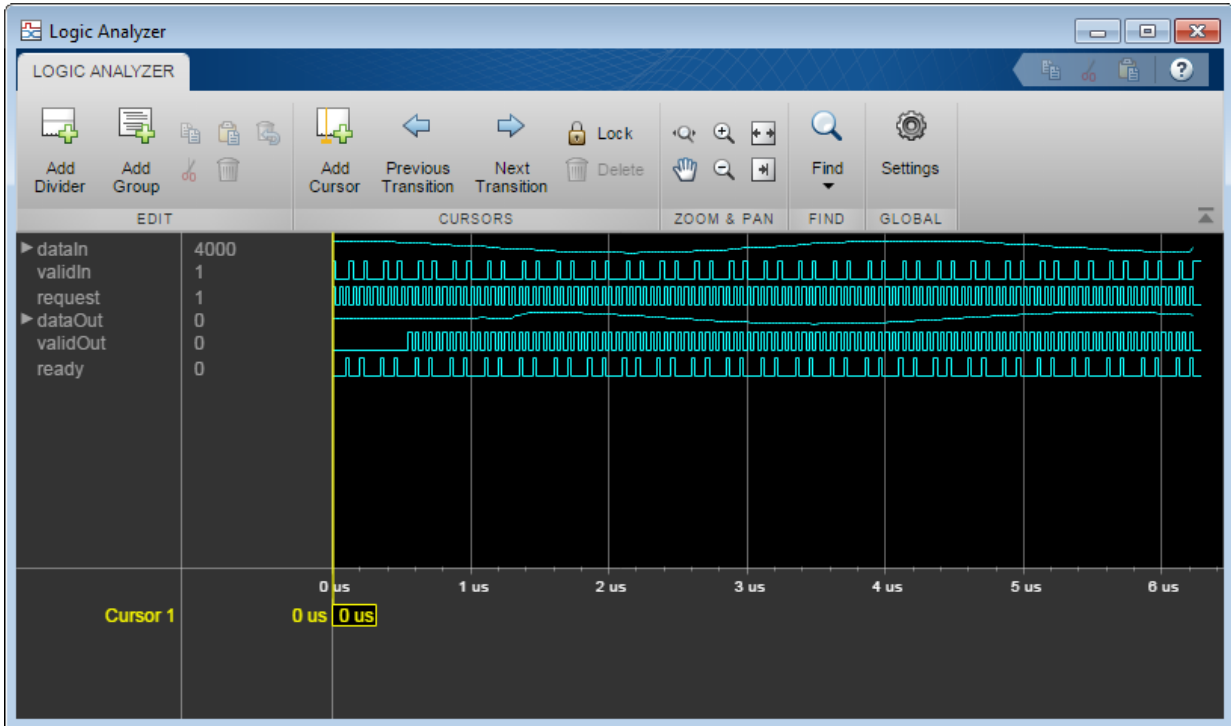

```
for k = 1:numSteps
    if ready
        dataIn = inputSource();
    end
```

```

validIn = ready;
[dataOut,validOut,ready] = rateConverter(dataIn,validIn,request(k));
la(dataIn,validIn,request(k),dataOut,validOut,ready)
end

```

Design for HDL Code Generation from HDL FIR Rate Converter

Create a rate conversion function targeted for HDL code generation, and a test bench to exercise it. The function converts a signal from 40 MHz to 100 MHz. To avoid overrunning the object, the test bench manually controls the input rate.

Define the sample rate and length of the input signal, and a fixed-point cosine waveform.

```

Fs = 40e6;
Ns = 50;
t = (0:Ns-1) ./ Fs;
x = fi(cos(2*pi*1.2e6*t), 1, 16, 14);

```

Define the rate conversion parameters. Use an interpolation factor of 5 and a decimation factor of 2. Calculate how often the object can accept a new data sample.

```
L = 5;
M = 2;
stepsPerInput = ceil(L/M);
numSteps = stepsPerInput*Ns;
```

Generate `dataIn` and `validIn` based on how often the object can accept a new sample.

```
dataIn = zeros(numSteps,1,'like',x);
dataIn(1:stepsPerInput:end) = x;
validIn = false(numSteps,1);
validIn(1:stepsPerInput:end) = true;
```

Create a Logic Analyzer to capture and view the input and output signals.

```
la = dsp.LogicAnalyzer('NumInputPorts',4,'SampleTime',1/Fs,'TimeSpan',numSteps/Fs);
modifyDisplayChannel(la,1,'Name','dataIn','Format','Analog','Height',8)
modifyDisplayChannel(la,2,'Name','validIn')
modifyDisplayChannel(la,3,'Name','dataOut','Format','Analog','Height',8)
modifyDisplayChannel(la,4,'Name','validOut')
```

Write a function that creates and calls the System object.

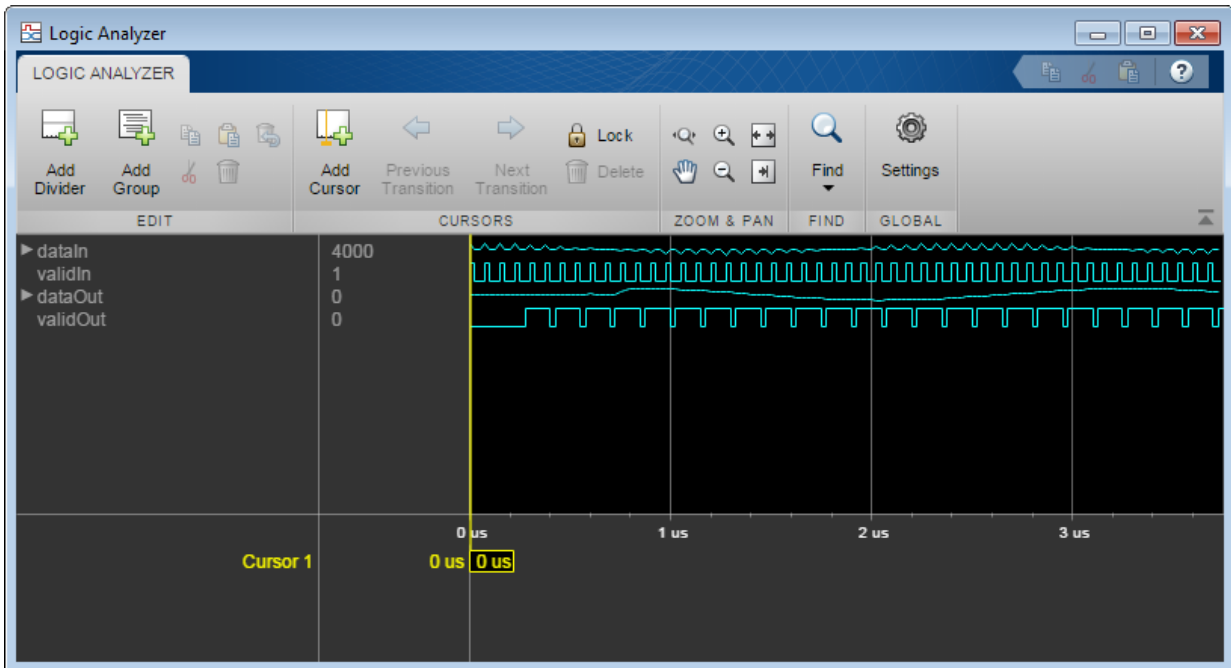

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
function [dataOut,validOut] = HDLFIRRC5_2(dataIn,validIn)
%HDLFIRRC5_2
% Processes one sample of data using the dsp.HDLFIRRateConverter System
% object. dataIn is a fixed-point scalar value. validIn is a logical scalar value.
% You can generate HDL code from this function.

persistent firrc5_2;
if isempty(firrc5_2)
    Numerator = firpm(70,[0,.15,.25,1],[1,1,0,0]);
    firrc5_2 = dsp.HDLFIRRateConverter(5,2,Numerator);
end
[dataOut,validOut] = firrc5_2(dataIn,validIn);
end
```

Resample the signal by calling the function for each data sample.

```
for k = 1:numSteps
    [dataOut,validOut] = HDLFIRRC5_2(dataIn(k),validIn(k));
    la(dataIn(k),validIn(k),dataOut,validOut)
end
```

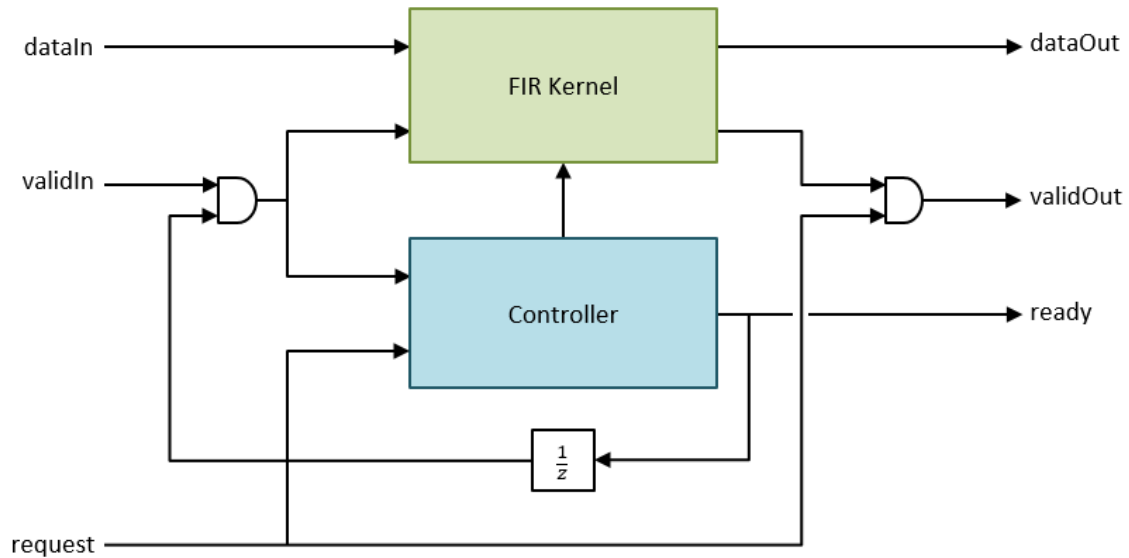

Algorithms

This object implements the algorithms described on the FIR Rate Conversion HDL Optimized block reference page.

Flow Control

The object accepts and returns control signal arguments for pacing the flow of samples. By default, the object uses `validIn` and `validOut` control signals. You can also enable a ready output signal and a request input signal.

The `ready` output indicates that the object can accept a new input data sample on the next call to the object. When $L \geq M$, you can use the `ready` argument to achieve continuous output data samples. If you apply a new input sample after each time object returns `ready = true`, each call to the object returns a data output sample with `validOut = true`.

When you do not enable the `ready` argument, you can apply a valid data sample only every $\text{ceil}(L/M)$ calls to the object. For example:

- $L/M = 4/5$ — You can apply a new input sample on every call.
- $L/M = 3/2$ — You can apply a new input sample on every other call.

When you enable the `request` input, the object returns the next output sample when `request` is `true` and a valid output sample is available. When you do not use `request`, the object returns output samples when they are available. Calls to the object that do not return a new sample return `validOut = false`.

You can connect `request` to the `ready` output of a downstream object.

FIR Rate Conversion HDL Optimized

System Objects

`dsp.FIRRateConverter`

Introduced in R2015b

dsp.HDLFFT System object

Package: dsp

Fast Fourier transform — optimized for HDL code generation

Description

The HDL FFT System object provides two architectures to optimize either throughput or area. Use the streaming Radix 2² architecture for high-throughput applications. This architecture supports scalar or vector input data. You can achieve giga-sample-per-second (GSPS) throughput using vector input. Use the burst Radix 2 architecture for a minimum resource implementation, especially with large FFT sizes. Your system must be able to tolerate bursty data and higher latency. This architecture supports only scalar input data. The object accepts real or complex data, provides hardware-friendly control signals, and has optional output frame control signals.

To calculate the fast Fourier transform:

- 1 Create the dsp.HDLFFT object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#) (MATLAB).

Creation

Syntax

```
FFT_N = dsp.HDLFFT  
FFT_N = dsp.HDLFFT(Name,Value)
```

Description

`FFT_N = dsp.HDLFFT` returns an HDL FFT System object, `FFT_N`, that performs a fast Fourier transform.

`FFT_N = dsp.HDLFFT(Name, Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

Example: `fft128 = dsp.HDLFFT('FFTLength',128)`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects \(MATLAB\)](#).

Architecture — Hardware implementation

'Streaming Radix 2^2' (default) | 'Burst Radix 2'

Hardware implementation, specified as either:

- 'Streaming Radix 2^2' — Low-latency architecture. Supports giga-sample-per-second (GSPS) throughput when you use vector input.
- 'Burst Radix 2' — Minimum resource architecture. Vector input is not supported when you select this architecture.

ComplexMultiplication — HDL implementation of complex multipliers

'Use 4 multipliers and 2 adders' (default) | 'Use 3 multipliers and 5 adders'

HDL implementation of complex multipliers, specified as either 'Use 4 multipliers and 2 adders' or 'Use 3 multipliers and 5 adders'. Depending on your synthesis tool and target device, one option may be faster or smaller.

BitReversedOutput — Order of the output data

`true` (default) | `false`

Order of the output data, specified as either:

- `true` — The output channel elements are bit reversed relative to the input order.
- `false` — The output channel elements are in linear order.

The FFT algorithm calculates output in the reverse order to the input. When you request output in the same order as the input, the algorithm performs an extra reversal operation. For vector data, input and output data must be in opposite orders, so choose only one of `BitReversedOutput` or `BitReversedInput`. For more information on ordering of the output, see “Linear and Bit-Reversed Output Order”.

BitReversedInput — Expected order of the input data

`false` (default) | `true`

Expected order of the input data, specified as either:

- `true` — The input channel elements are in bit-reversed order.
- `false` — The input channel elements are in linear order.

The FFT algorithm calculates output in the reverse order to the input. When you request output in the same order as the input, the algorithm performs an extra reversal operation. For vector data, input and output data must be in opposite orders, so choose only one of `BitReversedOutput` or `BitReversedInput`. For more information on ordering of the output, see “Linear and Bit-Reversed Output Order”.

Normalize — Output scaling

`false` (default) | `true`

Output scaling, specified as either:

- `true` — The object implements an overall $1/N$ scale factor by scaling the output of each butterfly multiplication by 2. This adjustment keeps the output of the FFT in the same amplitude range as its input.
- `false` — The object avoids overflow by increasing the word length by one bit after each butterfly multiplication. The bit growth is the same for both architectures.

FFTLength — Number of data points used for one FFT calculation

1024 (default) | integer power of 2 between 2^3 and 2^{16}

Number of data points used for one FFT calculation, specified as an integer power of 2 between 2^3 and 2^{16} . The object accepts FFT lengths outside this range, but they are not supported for HDL code generation.

ResetInputPort — Enable reset argument

`false` (default) | `true`

Enable reset input argument to the object. When `reset` is `true`, the object stops calculation and clears all internal state.

StartOutputPort — Enable start output argument

`false` (default) | `true`

Enable `startOut` output argument of the object. When enabled, the object returns an additional output signal that is `true` on the first cycle of each valid output frame.

EndOutputPort — Enable end output argument

`false` (default) | `true`

Enable `endOut` output argument of the object. When enabled, the object returns an additional output signal that is `true` on the first cycle of each valid output frame.

RoundingMethod — Rounding mode used for fixed-point operations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Zero'

Rounding mode used for fixed-point operations. When the input is any integer or fixed-point data type, the FFT algorithm uses fixed-point arithmetic for internal calculations. This option does not apply when the input is single or double type. Rounding applies to twiddle factor multiplication and scaling operations.

Usage

Note For versions earlier than R2016b, use the `step` function to run the System object™ algorithm. The arguments to `step` are the object you created, followed by the arguments shown in this section.

For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Syntax

```
[Y,validOut] = FFT_N(X,validIn)
[Y,validOut,ready] = FFT_N(X,validIn)
[Y,startOut,endOut,validOut] = FFT_N(X,validIn)
[Y,validOut] = FFT_N(X,validIn,resetIn)
[Y,startOut,endOut,validOut] = FFT_N(X,validIn,resetIn)
```

Description

`[Y,validOut] = FFT_N(X,validIn)` returns the FFT, `Y`, of the input, `X`, when `validIn` is true. `validIn` and `validOut` are logical scalars that indicate the validity of the input and output signals, respectively.

`[Y,validOut,ready] = FFT_N(X,validIn)` returns the fast Fourier transform (FFT) when using the burst Radix 2 architecture. The `ready` signal indicates when the object can accept input samples.

To use this syntax, set the “Architecture” on page 4-0 property to 'Burst Radix 2'. For example:

```
FFT_N = dsp.HDLFFT(___, 'Architecture', 'Burst Radix 2');
...
[y,validOut,ready] = FFT_N(x,validIn)
```

`[Y,startOut,endOut,validOut] = FFT_N(X,validIn)` also returns frame control signals `startOut` and `endOut`. `startOut` is true on the first sample of a frame of output data. `endOut` is true for the last sample of a frame of output data.

To use this syntax, set the `StartOutputPort` and `EndOutputPort` properties to true. For example:

```
FFT_N = dsp.HDLFFT(___, 'StartOutputPort', true, 'EndOutputPort', true);
...
[y,startOut,endOut,validOut] = FFT_N(x,validIn)
```

`[Y,validOut] = FFT_N(X,validIn,resetIn)` returns the FFT when `validIn` is true and `resetIn` is false. When `resetIn` is true, the object stops the current calculation and clears all internal state.

To use this syntax set the `ResetInputPort` property to true. For example:

```
FFT_N = dsp.HDLFFT(___, 'ResetInputPort', true);
...
[y, validOut] = FFT_N(x, validIn, resetIn)
```

[Y, startOut, endOut, validOut] = FFT_N(X, validIn, resetIn) returns the FFT, Y, using all optional control signals. You can use any combination of the optional port syntaxes.

Input Arguments

x — Input data

scalar or column vector of real or complex values

Input data, specified as a scalar or column vector of real or complex values, in fixed-point or integer format. Vector input is supported with 'Streaming Radix 2²' architecture only. The vector size must be a power of 2 between 1 and 64, and not greater than the FFT length. `double` and `single` are supported for simulation but not for HDL code generation.

Data Types: `fi` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `single` | `double`

validIn — Validity of input data

logical scalar

Validity of input data, specified as a logical scalar.

Data Types: `logical`

resetIn — Reset internal state

logical scalar

Reset internal state, specified as a logical scalar. To enable this argument, set the `ResetInputPort` property to `true`.

Data Types: `logical`

Output Arguments

y — Output data

scalar or column vector of real or complex values

Output data, returned as a scalar or column vector of real or complex values. The output format matches the format of the input data.

ready — Memory available for input data

logical scalar

Indication that the object has memory available for input data, returned as a logical scalar. This output is returned when you select 'Burst Radix 2' architecture.

Data Types: `logical`

startOut — First sample of output frame

logical scalar

First sample of output frame, returned as a logical scalar. To enable this argument, set the `StartOutputPort` property to `true`.

Data Types: `logical`

endOut — Last sample of output frame

logical scalar

Last sample of output frame, returned as a logical scalar. To enable this argument, set the `EndOutputPort` property to `true`.

Data Types: `logical`

validOut — Validity of output data

logical scalar

Validity of output data, returned as a logical scalar.

Data Types: `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.HDLFFT

getLatency Latency of FFT or channelizer calculation

Common to All System Objects

step	Run System object algorithm
clone	Create duplicate System object
getNumInputs	Number of inputs required to call the System object
getNumOutputs	Number of outputs from calling the System object
isLocked	Determine if System object is locked
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Create FFT for HDL Generation

Create the specifications and input signal.

```
N = 128;
Fs = 40;
t = (0:N-1)'/Fs;
x = sin(2*pi*15*t) + 0.75*cos(2*pi*10*t);
y = x + .25*randn(size(x));
y_fixed = sfi(y,32,24);
```

Write a function that creates and calls the System object™. You can generate HDL from this function.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
function [yOut,validOut] = HDLFFT128(yIn,validIn)
%HDLFFT128
% Processes one sample of FFT data using the dsp.HDLFFT System object(TM)
% yIn is a fixed-point scalar or column vector.
% validIn is a logical scalar value.
```

```
% You can generate HDL code from this function.
```

```
persistent fft128;  
if isempty(fft128)  
    fft128 = dsp.HDLFFT('FFTLength',128);  
end  
[yOut,validOut] = fft128(yIn,validIn);  
end
```

Compute the FFT by calling the function for each data sample.

```
Yf = zeros(1,3*N);  
validOut = false(1,3*N);  
for loop = 1:1:3*N  
    if (mod(loop, N) == 0)  
        i = N;  
    else  
        i = mod(loop, N);  
    end  
    [Yf(loop),validOut(loop)] = HDLFFT128(complex(y_fixed(i)),(loop <= N));  
end
```

Discard invalid data samples. Then plot the frequency channel results from the FFT.

```
Yf = Yf(validOut == 1);  
Yr = bitrevorder(Yf);  
plot(Fs/2*linspace(0,1,N/2), 2*abs(Yr(1:N/2)/N))  
title('Single-Sided Amplitude Spectrum of Noisy Signal y(t)')  
xlabel('Frequency (Hz)')  
ylabel('Output of FFT (f)')
```

Create Vector-Input FFT for HDL Generation

Create specifications and input signal. This example uses a 128-point FFT and computes the transform over 16 samples at a time.

```
N = 128;  
V = 16;  
Fs = 40;  
t = (0:N-1)'/Fs;  
x = sin(2*pi*15*t) + 0.75*cos(2*pi*10*t);  
y = x + .25*randn(size(x));
```

```
y_fixed = sfi(y,32,24);  
y_vect = reshape(y_fixed,V,N/V);
```

Write a function that creates and calls the System object™. The function does not need to know the vector size. The object saves the size of the input signal the first time you call it.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
function [yOut,validOut] = HDLFFT128V16(yIn,validIn)  
%HDLFFT128V16  
% Processes 16-sample vectors of FFT data  
% yIn is a fixed-point column vector.  
% validIn is a logical scalar value.  
% You can generate HDL code from this function.  
  
persistent fft128v16;  
if isempty(fft128v16)  
    fft128v16 = dsp.HDLFFT('FFTLenght',128);  
end  
[yOut,validOut] = fft128v16(yIn,validIn);  
end
```

Compute the FFT by passing 16-element vectors to the object. Use the `getLatency` function to find out when the first output data sample will be ready. Then, add the frame length to determine how many times to call the object. Because the object variable is inside the function, use a second object to call `getLatency`. Use the loop counter to flip `validIn` to false after N input samples.

```
tempfft = dsp.HDLFFT;  
loopCount = getLatency(tempfft,N,V)+N/V;  
Yf = zeros(V,loopCount);  
validOut = false(V,loopCount);  
for loop = 1:1:loopCount  
    if ( mod(loop,N/V) == 0 )  
        i = N/V;  
    else  
        i = mod(loop,N/V);  
    end  
end
```

```
[Yf(:,loop),validOut(loop)] = HDLFFT128V16(complex(y_vect(:,i)),(loop<=N/V));  
end
```

Discard invalid output samples.

```
C = Yf(:,validOut==1);  
Yf_flat = C(:);
```

Plot the frequency channel data from the FFT. The FFT output is in bit-reversed order.
Reorder it before plotting.

```
Yr = bitrevorder(Yf_flat);  
plot(Fs/2*linspace(0,1,N/2),2*abs(Yr(1:N/2)/N))  
title('Single-Sided Amplitude Spectrum of Noisy Signal y(t)')  
xlabel('Frequency (Hz)')  
ylabel('Output of FFT (f)')
```

Explore Latency of HDL FFT Object

The latency of the object varies with the FFT length and the vector size. Use the `getLatency` function to find the latency of a particular configuration. The latency is the number of cycles between the first valid input and the first valid output, assuming that the input is contiguous.

Create a new `dsp.HDLFFT` object and request the latency.

```
hdlfft = dsp.HDLFFT('FFTLength',512);  
L512 = getLatency(hdlfft)
```

```
L512 = 599
```

Request hypothetical latency information about a similar object with a different FFT length. The properties of the original object do not change.

```
L256 = getLatency(hdlfft,256)
```

```
L256 = 329
```

```
N = hdlfft.FFTLength
```

```
N = 512
```

Request hypothetical latency information of a similar object that accepts eight-sample vector input.

```
L256v8 = getLatency(hdlfft,256,8)
```

```
L256v8 = 93
```

Enable scaling at each stage of the FFT. The latency does not change.

```
hdlfft.Normalize = true;
```

```
L512n = getLatency(hdlfft)
```

```
L512n = 599
```

Request the same output order as the input order. The latency increases because the object must collect the output before reordering.

```
hdlfft.BitReversedOutput = false;
```

```
L512r = getLatency(hdlfft)
```

```
L512r = 1078
```

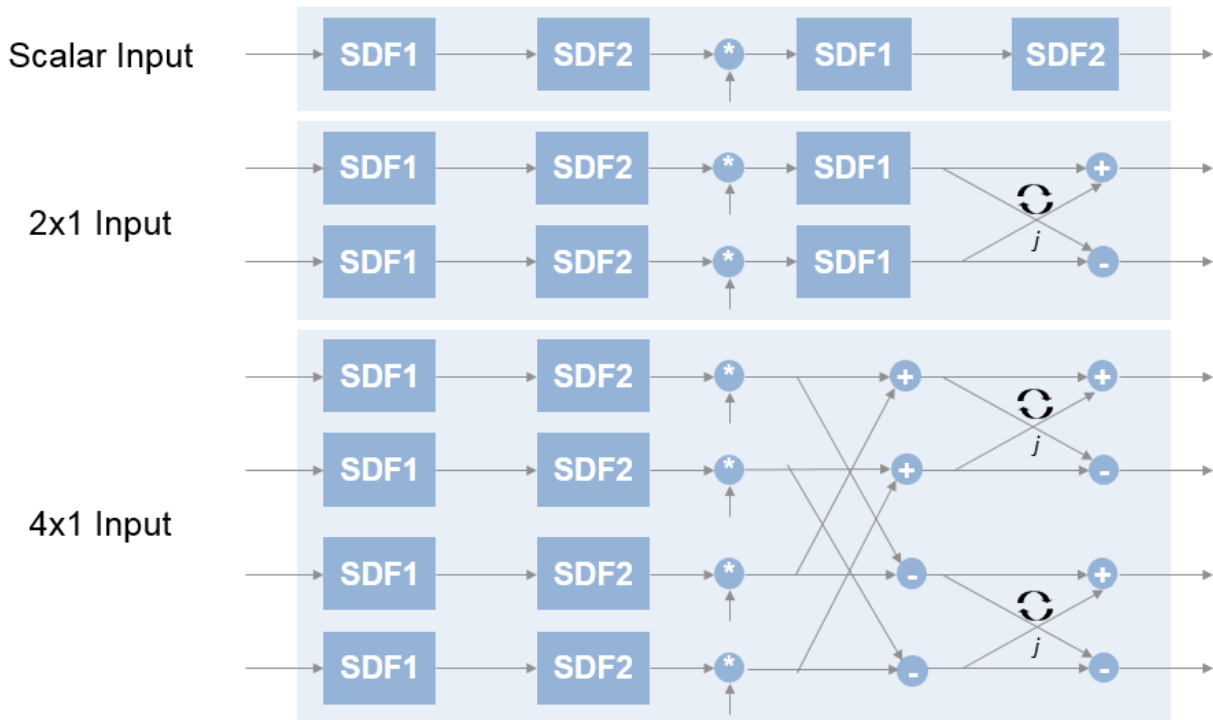

Algorithms

Streaming Radix 2²

The streaming Radix 2² architecture implements a low-latency architecture. It saves resources compared to a streaming Radix 2 implementation by factoring and grouping the FFT equation. The architecture has $\log_4(N)$ stages. Each stage contains two single-

path delay feedback (SDF) butterflies with memory controllers. When you use vector input, each stage operates on fewer input samples, so some stages reduce to a simple butterfly, without SDF.

16-Point FFT

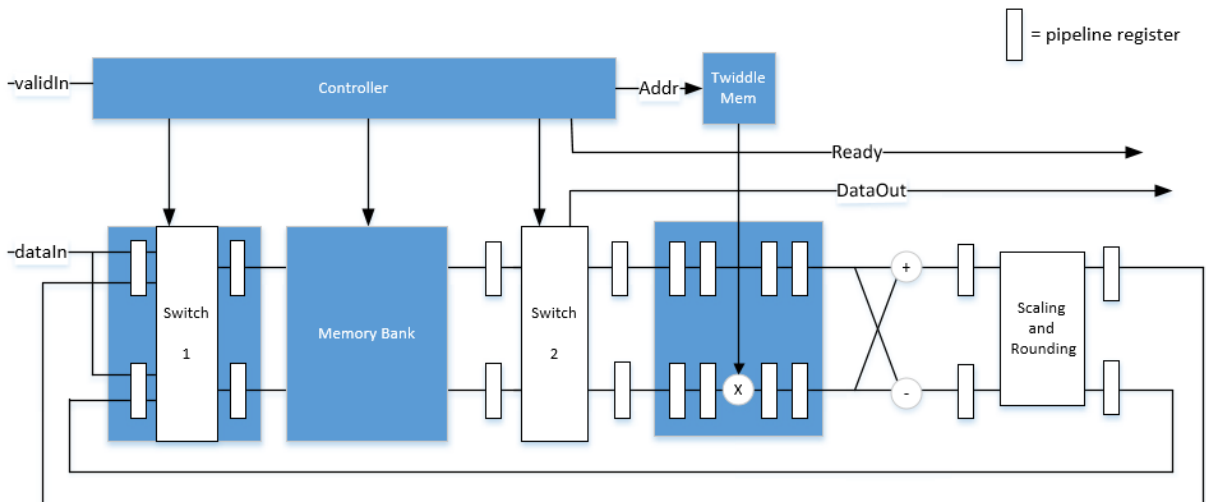

The first SDF stage is a regular butterfly. The second stage multiplies by $-j$ by swapping the real and imaginary parts of the input, and swapping the imaginary parts of the output. Each stage rounds the result of the twiddle factor multiplication to the input word length. The twiddle factors have the same bit width as the input data. They use two integer bits, and the remainder are fractional bits.

If you enable scaling, the algorithm divides the result of each butterfly stage by 2. Scaling at each stage avoids overflow, keeps the word length the same as the input, and results in an overall scale factor of $1/N$. If scaling is disabled, the algorithm avoids overflow by increasing the word length by 1 bit at each stage. The diagram shows the butterflies and internal word lengths of each stage, not including the memory.

Burst Radix 2

The burst Radix 2 architecture implements the FFT by using a single complex butterfly multiplier. The algorithm cannot start until it has stored the entire input frame, and it cannot accept the next frame until computations are complete. The `ready` output signal indicates when the algorithm is ready for new data. The diagram shows the burst architecture, with pipeline registers.

Control Signals

The algorithm processes input data only when `validIn` is high. Output data is valid only when `validOut` is high.

When the optional `reset` input signal is high, the algorithm stops the current calculation and clears all internal state. The algorithm begins fresh calculations when `reset` is low and `validIn` starts a new frame.

This diagram shows `validIn` and `validOut` signals for contiguous scalar input data, streaming Radix 2^2 architecture, an FFT length of 1024, and a vector size of 16.

The diagram also shows the optional `startOut` and `endOut` signals that indicate frame boundaries. If you enable `startOut`, it pulses for one cycle with the first `validOut` of the frame. If you enable `endOut`, it pulses for one cycle with the last `validOut` of the frame.

If you apply continuous input frames, the output will also be continuous, after the initial latency.

The `validIn` signal can be noncontiguous. Data accompanied by a `validIn` signal is processed as it arrives, and the output is stored until a frame is filled. Then the algorithm returns contiguous output samples in a frame of N (FFT length) cycles. This diagram shows noncontiguous input and contiguous output for an FFT length of 512 and a vector size of 16.

When you use the burst architecture, you cannot provide the next frame of input data until memory space is available. The `ready` signal indicates when the algorithm can accept new input data.

Latency

The latency varies with the FFT length and the vector size. Use the `getLatency` function to find the latency of a particular configuration. The latency is the number of cycles between the first valid input and the first valid output, assuming that the input is contiguous.

When using the burst architecture with contiguous input, if your design waits for `ready=0` before deasserting `validIn`, then one extra cycle of data arrives at the input. This data sample is the first sample of the next frame. The algorithm can save one sample while processing the current frame. Due to this one sample advance, the observed latency of the later frames (`validIn` to `validOut`) is one cycle shorter than the reported latency. The number of cycles between `ready` low and `validOut` high is always *latency* – *FFTLengh*.

Performance

These resource and performance data are the synthesis results from the generated HDL targeted to a Xilinx Virtex-6 (XC6VLX75T-1FF484) FPGA. The examples in the tables have this configuration:

- 1024 FFT length (default)
- Complex multiplication using 4 multipliers, 2 adders
- Output scaling enabled
- 16-bit complex input data
- Clock enables minimized (HDL Coder parameter)

Performance of the synthesized HDL code varies with your target and synthesis options. For instance, natural-order output uses more RAM than bit-reversed output, and real input uses less RAM than complex input.

For a scalar input Radix 2² configuration, the design achieves 326 MHz clock frequency. The latency is 1116 cycles. The design uses these resources.

Resource	Number Used
LUT	4597
FFS	5353
Xilinx LogiCORE DSP48	12
Block RAM (16K)	6

When you vectorize the same Radix 2² implementation to process two 16-bit input samples in parallel, the design achieves 316 MHz clock frequency. The latency is 600 cycles. The design uses these resources.

Resource	Number Used
LUT	7653
FFS	9322
Xilinx LogiCORE DSP48	24
Block RAM (16K)	8

The burst Radix 2 implementation is supported with scalar input data only. The burst design achieves 309 MHz clock frequency. The latency is 5811 cycles. The design uses these resources.

Resource	Number Used
LUT	971
FFS	1254
Xilinx LogiCORE DSP48	3

Resource	Number Used
Block RAM (16K)	6

FFT HDL Optimized

Introduced in R2014b

dsp.HDLIFFT System object

Package: dsp

Inverse fast Fourier transform — optimized for HDL code generation

Description

The HDL IFFT System object provides two architectures to optimize either throughput or area. Use the streaming Radix 2² architecture for high-throughput applications. This architecture supports scalar or vector input data. You can achieve giga-sample-per-second (GSPS) throughput using vector input. Use the burst Radix 2 architecture for a minimum resource implementation, especially with large FFT sizes. Your system must be able to tolerate bursty data and higher latency. This architecture supports only scalar input data. The object accepts real or complex data, provides hardware-friendly control signals, and has optional output frame control signals.

To calculate the inverse fast Fourier transform:

- 1 Create the dsp.HDLIFFT object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#) (MATLAB).

Creation

Syntax

```
IFFT_N = dsp.HDLIFFT  
IFFT_N = dsp.HDLIFFT(Name,Value)
```

Description

`IFFT_N = dsp.HDLIFFT` returns an HDL IFFT System object, `IFFT_N`, that performs a fast Fourier transform.

`IFFT_N = dsp.HDLIFFT(Name, Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

Example: `ifft128 = dsp.HDLIFFT('FFTLength',128)`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects \(MATLAB\)](#).

Architecture — Hardware implementation

'Streaming Radix 2^2' (default) | 'Burst Radix 2'

Hardware implementation, specified as either:

- 'Streaming Radix 2^2' — Low-latency architecture. Supports giga-sample-per-second (GSPS) throughput when you use vector input.
- 'Burst Radix 2' — Minimum resource architecture. Vector input is not supported when you select this architecture.

ComplexMultiplication — HDL implementation of complex multipliers

'Use 4 multipliers and 2 adders' (default) | 'Use 3 multipliers and 5 adders'

HDL implementation of complex multipliers, specified as either 'Use 4 multipliers and 2 adders' or 'Use 3 multipliers and 5 adders'. Depending on your synthesis tool and target device, one option may be faster or smaller.

BitReversedOutput — Order of the output data

`true` (default) | `false`

Order of the output data, specified as either:

- `true` — The output channel elements are bit reversed relative to the input order.
- `false` — The output channel elements are in linear order.

The IFFT algorithm calculates output in the reverse order to the input. When you request output in the same order as the input, the algorithm performs an extra reversal operation. For vector data, input and output data must be in opposite orders, so choose only one of `BitReversedOutput` or `BitReversedInput`. For more information on ordering of the output, see “Linear and Bit-Reversed Output Order”.

BitReversedInput — Expected order of the input data

`false` (default) | `true`

Expected order of the input data, specified as either:

- `true` — The input channel elements are in bit-reversed order.
- `false` — The input channel elements are in linear order.

The IFFT algorithm calculates output in the reverse order to the input. When you request output in the same order as the input, the algorithm performs an extra reversal operation. For vector data, input and output data must be in opposite orders, so choose only one of `BitReversedOutput` or `BitReversedInput`. For more information on ordering of the output, see “Linear and Bit-Reversed Output Order”.

Normalize — Output scaling

`false` (default) | `true`

Output scaling, specified as either:

- `true` — The object implements an overall $1/N$ scale factor by scaling the output of each butterfly multiplication by 2. This adjustment keeps the output of the IFFT in the same amplitude range as its input.
- `false` — The object avoids overflow by increasing the word length by one bit after each butterfly multiplication. The bit growth is the same for both architectures.

FFTLength — Number of data points used for one FFT calculation

1024 (default) | integer power of 2 between 2^3 and 2^{16}

Number of data points used for one FFT calculation, specified as an integer power of 2 between 2^3 and 2^{16} . The object accepts FFT lengths outside this range, but they are not supported for HDL code generation.

ResetInputPort — Enable reset argument

false (default) | true

Enable reset input argument to the object. When reset is true, the object stops calculation and clears all internal state.

StartOutputPort — Enable start output argument

false (default) | true

Enable startOut output argument of the object. When enabled, the object returns an additional output signal that is true on the first cycle of each valid output frame.

EndOutputPort — Enable end output argument

false (default) | true

Enable endOut output argument of the object. When enabled, the object returns an additional output signal that is true on the first cycle of each valid output frame.

RoundingMethod — Rounding mode used for fixed-point operations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Zero'

Rounding mode used for fixed-point operations. When the input is any integer or fixed-point data type, the IFFT algorithm uses fixed-point arithmetic for internal calculations. This option does not apply when the input is single or double type. Rounding applies to twiddle factor multiplication and scaling operations.

Usage

Note For versions earlier than R2016b, use the `step` function to run the System object™ algorithm. The arguments to `step` are the object you created, followed by the arguments shown in this section.

For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Syntax

```
[Y,validOut] = IFFT_N(X,validIn)
[Y,validOut,ready] = IFFT_N(X,validIn)
[Y,startOut,endOut,validOut] = IFFT_N(X,validIn)
[Y,validOut] = IFFT_N(X,validIn,resetIn)
[Y,startOut,endOut,validOut] = IFFT_N(X,validIn,resetIn)
```

Description

`[Y,validOut] = IFFT_N(X,validIn)` returns the inverse fast Fourier transform (IFFT), `Y`, of the input, `X`, when `validIn` is true. `validIn` and `validOut` are logical scalars that indicate the validity of the input and output signals, respectively.

`[Y,validOut,ready] = IFFT_N(X,validIn)` returns the inverse fast Fourier transform (IFFT) when using the burst Radix 2 architecture. The `ready` signal indicates when the object can accept input samples.

To use this syntax, set the “Architecture” on page 4-0 property to 'Burst Radix 2'. For example:

```
IFFT_N = dsp.HDLIFFT(___, 'Architecture', 'Burst Radix 2');
...
[y,validOut,ready] = IFFT_N(x,validIn)
```

`[Y,startOut,endOut,validOut] = IFFT_N(X,validIn)` also returns frame control signals `startOut` and `endOut`. `startOut` is true on the first sample of a frame of output data. `endOut` is true for the last sample of a frame of output data.

To use this syntax, set the `StartOutputPort` and `EndOutputPort` properties to true. For example:

```
IFFT_N = dsp.HDLIFFT(___, 'StartOutputPort', true, 'EndOutputPort', true);
...
[y,startOut,endOut,validOut] = IFFT_N(x,validIn)
```

`[Y,validOut] = IFFT_N(X,validIn,resetIn)` returns the IFFT, `Y`, when `validIn` is true and `resetIn` is false. When `resetIn` is true, the object stops the current calculation and clears all internal state.

To use this syntax, set the `ResetInputPort` property to true. For example:

```
IFFT_N = dsp.HDLIFFT(___, 'ResetInputPort', true);
...
[y, validOut] = IFFT_N(x, validIn, resetIn)
```

[Y, startOut, endOut, validOut] = IFFT_N(X, validIn, resetIn) returns the IFFT, Y, using all optional control signals. You can use any combination of the optional port syntaxes.

Input Arguments

x — Input data

scalar or column vector of real or complex values

Input data, specified as a scalar or column vector of real or complex values, in fixed-point or integer format. Vector input is supported with 'Streaming Radix 2²' architecture only. The vector size must be a power of 2 between 1 and 64 that is not greater than the FFT length. `double` and `single` are supported for simulation but not for HDL code generation.

Data Types: `fi` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `single` | `double`

validIn — Validity of input data

logical scalar

Validity of input data, specified as a logical scalar.

Data Types: `logical`

resetIn — Reset internal state

logical scalar

Reset internal state, specified as a logical scalar. To enable this argument, set the `ResetInputPort` property to `true`.

Data Types: `logical`

Output Arguments

y — Output data

scalar or column vector of real or complex values

Output data, returned as a scalar or column vector of real or complex values. The output format matches the format of the input data.

ready — Memory available for input data

logical scalar

Indication that the object has memory available for input data, returned as a logical scalar. This output is returned when you select 'Burst Radix 2' architecture.

Data Types: `logical`

startOut — First sample of output frame

logical scalar

First sample of output frame, returned as a logical scalar. To enable this argument, set the `StartOutputPort` property to `true`.

Data Types: `logical`

endOut — Last sample of output frame

logical scalar

Last sample of output frame, returned as a logical scalar. To enable this argument, set the `EndOutputPort` property to `true`.

Data Types: `logical`

validOut — Validity of output data

logical scalar

Validity of output data, returned as a logical scalar.

Data Types: `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.HDLIFFT

getLatency Latency of FFT or channelizer calculation

Common to All System Objects

step	Run System object algorithm
clone	Create duplicate System object
getNumInputs	Number of inputs required to call the System object
getNumOutputs	Number of outputs from calling the System object
isLocked	Determine if System object is locked
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Create IFFT for HDL Code Generation

Create the specifications and input signal. This example uses a 128-point FFT.

```
N = 128;
Fs = 40;
t = (0:N-1)'/Fs;
x = sin(2*pi*15*t) + 0.75*cos(2*pi*10*t);
y = x + .25*randn(size(x));
y_fixed = sfi(y,32,16);
noOp = zeros(1,'like',y_fixed);
```

Compute the FFT of the signal to use as the input to the IFFT object.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
hdlfft = dsp.HDLIFFT('FFTLength',N,'BitReversedOutput',false);
Yf = zeros(1,4*N);
validOut = false(1,4*N);
for loop = 1:1:N
    [Yf(loop),validOut(loop)] = hdlfft(complex(y_fixed(loop)),true);
end
```

```

for loop = N+1:1:4*N
    [Yf(loop),validOut(loop)] = hdlfft(complex(noOp),false);
end
Yf = Yf(validOut == 1);

```

Plot the single-sided amplitude spectrum.

```

plot(Fs/2*linspace(0,1,N/2),2*abs(Yf(1:N/2)/N))
title('Single-Sided Amplitude Spectrum of Noisy Signal y(t)')
xlabel('Frequency (Hz)')
ylabel('Output of FFT (f)')

```

Select frequencies that hold the majority of the energy in the signal. The `cumsum` function does not accept fixed-point arguments, so convert the data back to `double`.

```

[Ysort,i] = sort(abs(double(transpose(Yf(1:N))))),1,'descend');
Ysort_d = double(Ysort);
CumEnergy = sqrt(cumsum(Ysort_d.^2))/norm(Ysort_d);
j = find(CumEnergy > 0.9, 1);
    disp(['Number of FFT coefficients that represent 90% of the ', ...
        'total energy in the sequence: ', num2str(j)])
Yin = zeros(N,1);
Yin(i(1:j)) = Yf(i(1:j));

```

Number of FFT coefficients that represent 90% of the total energy in the sequence: 4

Write a function that creates and calls the IFFT System object™. You can generate HDL from this function.

```

function [yOut,validOut] = HDLIFFT128(yIn,validIn)
% HDLIFFT128
% Processes one sample of data using the dsp.HDLIFFT System object (TM)
% yIn is a fixed-point scalar or column vector.
% validIn is a logical scalar.
% You can generate HDL code from this function.

    persistent ifft128;
    if isempty(iff128)
        ifft128 = dsp.HDLIFFT('FFTLength',128);
    end
    [yOut,validOut] = ifft128(yIn,validIn);
end

```

Compute the IFFT by calling the function for each data sample.

```

Xt = zeros(1,3*N);
validOut = false(1,3*N);
for loop = 1:1:N
    [Xt(loop),validOut(loop)] = HDLIFFT128(complex(Yin(loop)),true);
end
for loop = N+1:1:3*N
    [Xt(loop),validOut(loop)] = HDLIFFT128(complex(0),false);
end

```

Discard invalid output samples. Then inspect the output and compare it with the input signal. The original input is in green.

```
Xt = Xt(validOut==1);
Xt = bitrevorder(Xt);
norm(x-transpose(Xt(1:N)))
figure
stem(real(Xt))
figure
stem(real(x), '--g')
```

Create a Vector-Input IFFT for HDL Code Generation

Create the specifications and input signal. This example uses a 128-point FFT and computes the transform over 16 samples at a time.

```
N = 128;  
V = 16;  
Fs = 40;  
t = (0:N-1)'/Fs;  
x = sin(2*pi*15*t) + 0.75*cos(2*pi*10*t);  
y = x + .25*randn(size(x));
```

```
y_fixed = sfi(y,32,24);  
y_vect = reshape(y_fixed,V,N/V);
```

Compute the FFT of the signal, to use as the input to the IFFT object.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
hdlfft = dsp.HDLFFT('FFTLength',N);  
loopCount = getLatency(hdlfft,N,V)+N/V;  
Yf = zeros(V,loopCount);  
validOut = false(V,loopCount);  
for loop = 1:1:loopCount  
    if ( mod(loop,N/V) == 0 )  
        i = N/V;  
    else  
        i = mod(loop,N/V);  
    end  
    [Yf(:,loop),validOut(loop)] = hdlfft(complex(y_vect(:,i)),(loop<=N/V));  
end
```

Plot the single-sided amplitude spectrum.

```
C = Yf(:,validOut==1);  
Yf_flat = C(:);  
Yr = bitrevorder(Yf_flat);  
plot(Fs/2* linspace(0,1,N/2),2*abs(Yr(1:N/2)/N))  
title('Single-Sided Amplitude Spectrum of Noisy Signal y(t)')  
xlabel('Frequency (Hz)')  
ylabel('Output of FFT(f)')
```

Select frequencies that hold the majority of the energy in the signal. The `cumsum` function doesn't accept fixed-point arguments, so convert the data back to double.

```
[Ysort,i] = sort(abs(double(Yr(1:N))),1,'descend');
CumEnergy = sqrt(cumsum(Ysort.^2))/norm(Ysort);
j = find(CumEnergy > 0.9, 1);
    disp(['Number of FFT coefficients that represent 90% of the ', ...
        'total energy in the sequence: ', num2str(j)])
Yin = zeros(N,1);
Yin(i(1:j)) = Yr(i(1:j));
YinVect = reshape(Yin,V,N/V);
```

Number of FFT coefficients that represent 90% of the total energy in the sequence: 4

Write a function that creates and calls the IFFT System object™. You can generate HDL from this function.

```
function [yOut,validOut] = HDLIFFT128V16(yIn,validIn)
%HDLIFFT128V16
% Processes 16-sample vectors of FFT data
% yIn is a fixed-point column vector.
% validIn is a logical scalar value.
% You can generate HDL code from this function.

persistent ifft128v16;
if isempty(ifft128v16)
    ifft128v16 = dsp.HDLIFFT('FFTLength',128)
end
[yOut,validOut] = ifft128v16(yIn,validIn);
end
```

Compute the IFFT by calling the function for each data sample.

```
Xt = zeros(V,loopCount);
validOut = false(V,loopCount);
for loop = 1:1:loopCount
    if ( mod(loop,N/V) == 0 )
        i = N/V;
    else
        i = mod(loop,N/V);
    end
    [Xt(:,loop),validOut(loop)] = HDLIFFT128V16(complex(YinVect(:,i)),(loop<=N/V));
end
```

```
ifft128v16 =
```

```
    dsp.HDLIFFT with properties:
```

```
        FFTLength: 128
        Architecture: 'Streaming Radix 2^2'
        ComplexMultiplication: 'Use 4 multipliers and 2 adders'
        BitReversedOutput: true
        BitReversedInput: false
        Normalize: true
```

Use `get` to show all properties

Discard invalid output samples. Then inspect the output and compare it with the input signal. The original input is in green.

```
C = Xt(:, validOut==1);  
Xt = C(:);  
Xt = bitrevorder(Xt);  
norm(x-Xt(1:N))  
figure  
stem(real(Xt))  
figure  
stem(real(x), '--g')
```

```
ans =
```

```
0.7863
```

Explore Latency of HDL IFFT Object

The latency of the object varies with the FFT length and the vector size. Use the `getLatency` function to find the latency of a particular configuration. The latency is the number of cycles between the first valid input and the first valid output, assuming that the input is contiguous.

Create a new `dsp.HDLIFFT` object and request the latency.

```
hdlifft = dsp.HDLIFFT('FFTLength',512);  
L512 = getLatency(hdlifft)
```

```
L512 = 599
```

Request hypothetical latency information about a similar object with a different FFT length. The properties of the original object do not change. When you do not specify a vector length, the function assumes scalar input data.

```
L256 = getLatency(hdlifft,256)
```

```
L256 = 329
```

```
N = hdlifft.FFTLength
```

```
N = 512
```

Request hypothetical latency information of a similar object that accepts eight-sample vector input.

```
L256v8 = getLatency(hdlifft,256,8)
```

```
L256v8 = 93
```

Enable scaling at each stage of the IFFT. The latency does not change.

```
hdlifft.Normalize = true;
```

```
L512n = getLatency(hdlifft)
```

```
L512n = 599
```

Request the same output order as the input order. This setting increases the latency because the object must collect the output before reordering.

```
hdlifft.BitReversedOutput = false;
```

```
L512r = getLatency(hdlifft)
```

```
L512r = 1078
```

Algorithms

Streaming Radix 2²

The streaming Radix 2² architecture implements a low-latency architecture. It saves resources compared to a streaming Radix 2 implementation by factoring and grouping

the FFT equation. The architecture has $\log_4(N)$ stages. Each stage contains two single-path delay feedback (SDF) butterflies with memory controllers. When you use vector input, each stage operates on fewer input samples, so some stages reduce to a simple butterfly, without SDF.

16-Point FFT

The first SDF stage is a regular butterfly. The second stage multiplies by $-j$ by swapping the real and imaginary parts of the input, and swapping the imaginary parts of the output. Each stage rounds the result of the twiddle factor multiplication to the input word length. The twiddle factors have the same bit width as the input data. They use two integer bits, and the remainder are fractional bits.

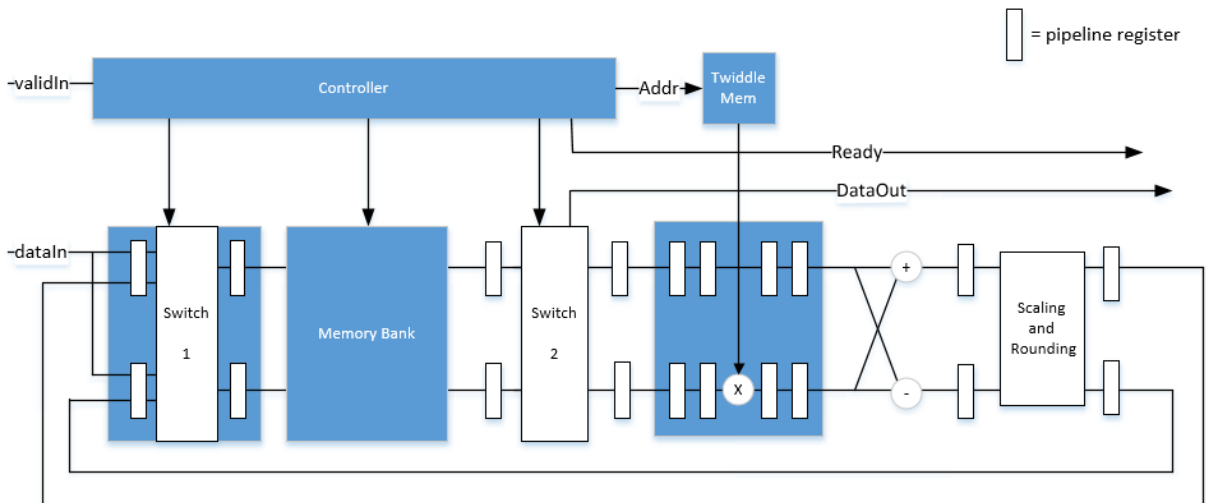

If you enable scaling, the algorithm divides the result of each butterfly stage by 2. Scaling at each stage avoids overflow, keeps the word length the same as the input, and results in an overall scale factor of $1/N$. If scaling is disabled, the algorithm avoids

overflow by increasing the word length by 1 bit at each stage. The diagram shows the butterflies and internal word lengths of each stage, not including the memory.

Burst Radix 2

The burst Radix 2 architecture implements the FFT by using a single complex butterfly multiplier. The algorithm cannot start until it has stored the entire input frame, and it cannot accept the next frame until computations are complete. The `ready` output signal indicates when the algorithm is ready for new data. The diagram shows the burst architecture, with pipeline registers.

Control Signals

The algorithm processes input data only when `validIn` is high. Output data is valid only when `validOut` is high.

When the optional `reset` input signal is high, the algorithm stops the current calculation and clears all internal state. The algorithm begins fresh calculations when `reset` is low and `validIn` starts a new frame.

This diagram shows `validIn` and `validOut` signals for contiguous scalar input data, streaming Radix 2^2 architecture, an FFT length of 1024, and a vector size of 16.

The diagram also shows the optional `startOut` and `endOut` signals that indicate frame boundaries. If you enable `startOut`, it pulses for one cycle with the first `validOut` of the frame. If you enable `endOut`, it pulses for one cycle with the last `validOut` of the frame.

If you apply continuous input frames, the output will also be continuous, after the initial latency.

The `validIn` signal can be noncontiguous. Data accompanied by a `validIn` signal is processed as it arrives, and the output is stored until a frame is filled. Then the algorithm returns contiguous output samples in a frame of N (FFT length) cycles. This diagram shows noncontiguous input and contiguous output for an FFT length of 512 and a vector size of 16.

When you use the burst architecture, you cannot provide the next frame of input data until memory space is available. The `ready` signal indicates when the algorithm can accept new input data.

Latency

The latency varies with the FFT length and the vector size. Use the `getLatency` function to find the latency of a particular configuration. The latency is the number of cycles between the first valid input and the first valid output, assuming that the input is contiguous.

When using the burst architecture with contiguous input, if your design waits for `ready=0` before deasserting `validIn`, then one extra cycle of data arrives at the input. This data sample is the first sample of the next frame. The algorithm can save one sample while processing the current frame. Due to this one sample advance, the observed latency of the later frames (`validIn` to `validOut`) is one cycle shorter than the reported latency. The number of cycles between `ready` low and `validOut` high is always *latency* – *FFTLenght*.

Performance

These resource and performance data are the synthesis results from the generated HDL targeted to a Xilinx Virtex-6 (XC6VLX75T-1FF484) FPGA. The examples in the tables have this configuration:

- 1024 FFT length (default)
- Complex multiplication using 4 multipliers, 2 adders
- Output scaling enabled
- 16-bit complex input data
- Clock enables minimized (HDL Coder parameter)

Performance of the synthesized HDL code varies with your target and synthesis options. For instance, natural-order output uses more RAM than bit-reversed output, and real input uses less RAM than complex input.

For a scalar input Radix 2² configuration, the design achieves 326 MHz clock frequency. The latency is 1116 cycles. The design uses these resources.

Resource	Number Used
LUT	4597
FFS	5353
Xilinx LogiCORE DSP48	12
Block RAM (16K)	6

When you vectorize the same Radix 2² implementation to process two 16-bit input samples in parallel, the design achieves 316 MHz clock frequency. The latency is 600 cycles. The design uses these resources.

Resource	Number Used
LUT	7653
FFS	9322
Xilinx LogiCORE DSP48	24
Block RAM (16K)	8

The burst Radix 2 implementation is supported with scalar input data only. The burst design achieves 309 MHz clock frequency. The latency is 5811 cycles. The design uses these resources.

Resource	Number Used
LUT	971
FFS	1254
Xilinx LogiCORE DSP48	3

Resource	Number Used
Block RAM (16K)	6

System Objects

`dsp.HDLFFT` | `dsp.IFFT`

Blocks

IFFT HDL Optimized

Introduced in R2014b

dsp.HDLNCO System object

Package: dsp

Generate real or complex sinusoidal signals—optimized for HDL code generation

Description

The HDL NCO System object generates real or complex sinusoidal signals. In addition, the HDL NCO System object provides hardware-friendly control signals, optional reset signal, optional valid input signal, optional phase output signal, and an optional external dither input signal. It uses the same phase accumulation and lookup table technology as implemented in the NCO System object. You can use the lookup table compression option to significantly reduce the lookup table size with less than one LSB loss in precision. The System object does not support the property that allows the block to synthesize the LUT to a ROM on an FPGA.

Given a desired output frequency F_0 , calculate the *phase_increment* input value using

$$\text{phase increment} = \left(\frac{F_0 \cdot 2^N}{F_s} \right)$$

where N is the accumulator word length and

$$F_s = \frac{1}{T_s} = \frac{1}{\text{sample time}}$$

You can specify the phase increment using a property or an input argument.

The frequency resolution of an NCO is defined by

$$\Delta f = \frac{1}{T_s \cdot 2^N} \text{ Hz}$$

Given a desired phase offset (in radians), calculate the *phase_offset* input value using

$$\text{phase offset} = \frac{2^N \cdot \text{desired phase offset}}{2\pi}$$

You can specify the phase offset using a property or an input argument.

To generate real or complex sinusoidal signals:

- 1 Create the `dsp.HDLNCO` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

Creation

Syntax

```
HDLNCO = dsp.HDLNCO
HDLNCO = dsp.HDLNCO(Name,Value)
HDLNCO = dsp.HDLNCO(Inc,'PhaseIncrementSource','Property')
```

Description

`HDLNCO = dsp.HDLNCO` returns a numerically controlled oscillator (NCO) System object, `HDLNCO`, that generates a real or complex sinusoidal signal. The amplitude of the generated signal is always 1.

`HDLNCO = dsp.HDLNCO(Name,Value)` returns an HDL NCO System object, `HDLNCO`, with properties set using one or more name-value pairs. Enclose each property name in single quotes.

`HDLNCO = dsp.HDLNCO(Inc,'PhaseIncrementSource','Property')` returns an HDL NCO System object, `HDLNCO`, with the `PhaseIncrement` property set to `Inc`. `Inc` is an integer scalar. To use the `PhaseIncrement` property, set the `PhaseIncrementSource` property to `Property`. You can add other `Name,Value` pairs before or after `PhaseIncrementSource`.

Properties

Note This object supports floating point types for simulation but not for HDL code generation. When a data input is fixed point, or when no data input ports are enabled, the object computes the output waveform based on the fixed-point property settings.

When a data input is floating-point, the object ignores NumDitherBits, PhaseQuantization, NumQuantizerAccumulatorBits, LUTCompress, and the fixed-point data type properties, and computes a double-precision output waveform.

When you switch to using a floating-point phase increment, you must adjust the value of the increment to account for the lack of phase quantization.

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

Waveform Generation

PhaseIncrementSource — Source of phase increment

'Input port' (default) | 'Property'

Source of phase increment, specified as 'Input port', or 'Property'. You can set the phase increment from an input argument or from a property.

PhaseIncrement — Phase increment

100 (default) | scalar integer

Phase increment for generating the waveform, specified as a scalar integer. `double` and `single` are allowed for simulation but not for HDL code generation.

Dependencies

This property applies when you set the `PhaseIncrementSource` property to 'Property'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixdt([],N,0)`

PhaseOffsetSource — Source of phase offset

'Input port' (default) | 'Property'

Source of phase offset, specified as 'Input port', or 'Property'. You can set the phase offset from an input argument or from a property.

PhaseOffset — Phase offset

0 (default) | scalar integer

Phase offset, specified as a scalar integer. `double` and `single` are allowed for simulation but not for HDL code generation.

Dependencies

This property applies when you set the `PhaseOffsetSource` property to 'Property'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixdt([],N,0)`

DitherSource — Source of number of dither bits

'Input port' (default) | 'Property' | 'None'

Source of number of dither bits, specified as 'Input port', 'Property', or 'None'. You can set the dither from an input port or from a parameter, or you can disable dither. When you select 'Property', configure the dither in `NumDitherBits` property.

NumDitherBits — Bits used to express dither

4 (default) | scalar integer

Number of dither bits, specified as a positive integer.

Dependencies

This property applies when you set the `DitherSource` property to 'Property'.

PhaseQuantization — Quantize accumulated phase

`true` (default) | `false`

Whether to quantize accumulated phase, specified as `true` or `false`. When this option is enabled, the NCO output is calculated by quantizing the result of the phase accumulator to a fixed bit- width. This quantized value is used to select a waveform value from the lookup table. Select the resolution of the lookup table using the `NumQuantizerAccumulatorBits` property.

The frequency resolution of an NCO is defined by

$$\Delta f = \frac{1}{T_s \cdot 2^N} \text{ Hz}$$

When you disable this option,

NumQuantizerAccumulatorBits — Bits used to express the phase

12 (default) | scalar integer

Number of quantizer accumulator bits, specified as an integer scalar greater than 1 and less than the accumulator word length. The lookup table of sine values has $2^{\text{NumQuantizerAccumulatorBits}}$ entries.

Dependencies

This property applies when you set `PhaseQuantization` to `true`.

LUTCompress — Enable lookup table compression

`true` (default) | `false`

Whether to enable lookup table compression, specified as `true` or `false`. By default, the object implements a compressed lookup table. The Sunderland compression method reduces the size of the lookup table with less than one LSB loss in precision. The spurious free dynamic range (SFDR) is empirically 1-3dB lower than the non-compressed case. With a compressed lookup table, you can increase the word length of the accumulator, and the number of quantize bits, to improve the performance. For detail of the compression method, see “Algorithms” on page 4-952.

When this option is disabled, the output matches the output of the `dsp.NCO` System object.

waveform — Type of output waveform

'Sine' (default) | 'Cosine' | 'Complex exponential' | 'Sine and cosine'

Type of output waveform. If you select 'Complex exponential', the output is of the form $\text{sine} + j \cdot \text{cosine}$. If you select 'Sine and cosine', the object returns an additional output.

PhasePort — Return current phase

`false` (default) | `true`

Whether to return current phase, specified as `true` or `false`. Set this property to `true` to return the current phase along with the output waveform.

Control Signals

ResetAction — Enable reset argument

`false` (default) | `true`

Whether to enable reset argument, specified as `true` or `false`. Set this property to `true` to enable a reset argument to the object.

ValidInputPort — Enable valid input signal

`true` (default) | `false`

Whether to enable valid input signal, specified as `true` or `false`. Set this property to `false` to disable the `ValidIn` input argument to the object.

Data Types

OverflowAction — Overflow mode for fixed-point operations

`'Wrap'` (default)

Overflow mode for fixed-point operations. `OverflowAction` is a read-only property with value `'Wrap'`.

RoundingMethod — Rounding mode for fixed-point operations

`'Floor'` (default)

Rounding mode for fixed-point operations. `RoundingMethod` is a read-only property with value `'Floor'`.

AccumulatorDataType — Accumulator data type

`'Binary point scaling'` (default)

Accumulator data type. This property is read-only, with value `'Binary point scaling'`. The accumulator sign, word length, and fraction length are taken from the following three properties.

AccumulatorSigned — Signed or unsigned accumulator data format

`'Signed'` (default)

Signed or unsigned accumulator data format. This property is read-only. All output is signed format.

AccumulatorWL — Accumulator word length

16 bits (default) | scalar integer

Accumulator word length, in bits, specified as a scalar integer.

AccumulatorFL — Accumulator fraction length

0 bits (default) | scalar integer

Accumulator fraction length, in bits, specified as a scalar integer.

OutputDataType — Output data type

'Binary point scaling' (default) | 'double' | 'single'

Output data type. If this property is set to 'Binary point scaling', the output sign, word length, and fraction length are taken from the following three properties.

OutputSigned — Signed or unsigned output data format

'Signed' (default)

Signed or unsigned output data format. This property is read-only. All output is signed format.

OutputWL — Output word length

16 bits (default) | scalar integer

Output word length, in bits, specified as a scalar integer.

OutputFL — Output fraction length

14 bits (default) | scalar integer

Output fraction length, in bits, specified as a scalar integer.

Usage

Note For versions earlier than R2016b, use the `step` function to run the System object™ algorithm. The arguments to `step` are the object you created, followed by the arguments shown in this section.

For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

Syntax

```
[Y,ValidOut] = HDLNCO(Inc,ValidIn)
[Y,ValidOut] = HDLNCO
[Y,ValidOut] = HDLNCO(Inc,Offset,Dither,ValidIn)
[Y,Phase,ValidOut] = HDLNCO(____)
```

Description

The object returns the waveform value, Y , as a sine value, a cosine value, a complex exponential value, or a [Sine, Cosine] pair of values, depending on the Waveform property.

`[Y,ValidOut] = HDLNCO(Inc,ValidIn)` returns a sinusoidal signal, Y , generated by the HDLNCO System object, with the specified phase increment, `Inc`. When `ValidIn` is true, `Inc` is added to the accumulator.

`[Y,ValidOut] = HDLNCO` returns a waveform, Y , using waveform parameters from properties rather than input arguments.

To use this syntax, set the `PhaseIncrementSource`, `PhaseOffsetSource`, and `DitherSource` properties to 'Property', and `ValidInputPort` to false. These properties are independent of each other. You can mix and match the activation of these arguments. For example:

```
hdlnco = dsp.HDLNCO('PhaseIncrementSource','Property', ...
    'PhaseIncrement',phIncr,...
    'PhaseOffset',phOffset,...
    'ValidInputPort',false,...
    'NumDitherBits',4)
```

`[Y,ValidOut] = HDLNCO(Inc,Offset,Dither,ValidIn)` returns a waveform, Y , with phase increment, `Inc`, phase offset, `Offset`, and dither, `Dither`.

This syntax applies when you set the `PhaseIncrementSource`, `PhaseOffsetSource`, and `DitherSource` properties to 'Input port'. These properties are independent of each other. You can mix and match the activation of these arguments. `PhaseIncrementSource` is 'Input port' by default. For example:

```
hdlnco = dsp.HDLNCO('PhaseOffsetSource','Input port',...
    'DitherSource','Input port')
for k = 1:1/Ts
    y(k) = hdlnco(phIncr,phOffset,ditherBits,true);
end
```

[Y,Phase,ValidOut] = HDLNCO(____) returns a waveform, Y, and output Phase.

To use this syntax, set the PhasePort property to `true`. This syntax can include any of the arguments from other syntaxes. For example:

```
hdlnco = dsp.HDLNCO('PhaseOffsetSource','Input port',...
    'DitherSource','Input port',...
    'PhasePort',true)
for k = 1:1/Ts
    [phase(k),y(k)] = hdlnco(phIncr,phOffset,ditherBits,true);
end
```

Input Arguments

Inc — Phase increment

integer

Phase increment, specified as a scalar integer. `double` and `single` are allowed for simulation but not for HDL code generation.

Dependencies

The object accepts this argument when you set the `PhaseIncrementSource` property to `'Input port'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixdt([],N,0)`

ValidIn — Validity of input arguments

`true` | `false`

Enable signal, specified as a logical scalar. The object increments the phase when `ValidIn` input is high. When `ValidIn` is low, the phase is held.

Dependencies

The object accepts this argument when you set the `ValidInputPort` property to `true`.

Data Types: `logical`

Offset — Phase offset

scalar integer

Phase offset, specified as a scalar integer. `double` and `single` are allowed for simulation but not for HDL code generation.

Dependencies

The object accepts this argument when you set the `PhaseOffsetSource` property to `'Input port'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixdt([],N,0)`

Dither — Dither

scalar integer

Dither, specified as a scalar integer. `double` and `single` are allowed for simulation but not for HDL code generation.

Dependencies

The object accepts this argument when you set the `DitherSource` property to `'Input port'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixdt([],N,0)`

Reset — Reset input signal

`true` | `false`

Request reset of the accumulator, specified as a `logical` scalar value. The object resets the accumulator to zero when `Reset` is high.

Dependencies

The object accepts this argument when you set the `ResetAction` property to `true`.

Data Types: `logical`

Output Arguments

y — Output waveform

scalar fixed-point or floating-point value | [*Sine*,*Cosine*] pair

Waveform, returned as a scalar fixed-point or floating-point value, or as a [*Sine*,*Cosine*] pair of values.

Dependencies

The type of the output waveform depends on the *Waveform* property.

- 'Sine' (default) — returns a generated sine wave
- 'Cosine' — returns a generated cosine wave
- 'Complex exponential' — returns a wave in the form $\text{sine} + j \cdot \text{cosine}$
- 'Sine and cosine' — returns a pair of values representing corresponding sine and cosine waves

validOut — Validity of output value

true | false

Validity of the *Y* output, returned as a logical scalar. When *validOut* is high, the data output is valid. When *validOut* is low, the data output is not valid.

Data Types: logical

Phase — Current phase of the NCO

scalar fixed-point or floating-point value

Current phase of the NCO, returned as a scalar of type `fixdt(1, M, -Z)`, where *M* is the number of quantized accumulator bits, and *Z* is the accumulator word length. The object returns *Phase* as floating point if the input to the object is floating point. Floating point is allowed for simulation but not for HDL code generation.

Dependencies

The object returns this additional output when you set the *PhasePort* property to true.

Data Types: single | double | `fixdt(1, NumQuantizerAccumulatorBits, - AccumulatorWL)`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>clone</code>	Create duplicate System object
<code>getNumInputs</code>	Number of inputs required to call the System object
<code>getNumOutputs</code>	Number of outputs from calling the System object
<code>isLocked</code>	Determine if System object is locked
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Design a HDL-Compatible NCO Source

This example shows how to design an HDL-compatible NCO source.

```
F0 = 510;      % Output frequency = 510 Hz
df = 0.05;    % Frequency resolution = 0.05 Hz
minSFDR = 96; % Spurious free dynamic range >= 96 dB
Ts = 1/4000;  % Sample period = 1/4000 seconds
dphi = pi/2;  % Desired phase offset = pi/2;
```

Calculate the number of accumulator bits required for the frequency resolution, and the number of quantized accumulator bits to satisfy the SFDR requirement.

```
Nacc = ceil(log2(1/(df*Ts)));
actdf = 1/(Ts*2^Nacc); % Actual frequency resolution achieved
Nqacc = ceil((minSFDR-12)/6);
```

Calculate the phase increment and offset.

```
phIncr = round(F0*Ts*2^Nacc);
phOffset = 2^Nacc*dphi/(2*pi);
```

Construct a NCO HDL System object™. Set the properties to the values calculated. Call the object to generate data points in a sine wave. The input to the object is a valid signal.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
hdlnco = dsp.HDLNCO('PhaseIncrementSource','Property', ...
    'PhaseIncrement',phIncr,...
    'PhaseOffset',phOffset,...
    'NumDitherBits',4, ...
    'NumQuantizerAccumulatorBits',Nqacc,...
    'AccumulatorWL',Nacc)
for k = 1:1/Ts
    y(k) = hdlnco(true);
end
```

hdlnco =

dsp.HDLNCO with properties:

```
    PhaseIncrementSource: 'Property'
        PhaseIncrement: 16712
    PhaseOffsetSource: 'Property'
        PhaseOffset: 32768
        DitherSource: 'Property'
        NumDitherBits: 4
    PhaseQuantization: true
NumQuantizerAccumulatorBits: 14
    LUTCompress: false
    ResetAction: false
    ValidInputPort: true
        Waveform: 'Sine'
        PhasePort: false
```

Use `get` to show all properties

Plot the mean-square spectrum of the 510 Hz sine wave generated by the NCO.

```
sa = dsp.SpectrumAnalyzer('SampleRate',1/Ts);
sa.SpectrumType = 'Power density';
sa.PlotAsTwoSidedSpectrum = false;
sa(y');
```

Algorithms

Lookup Table Algorithm

When you enable lookup table (LUT) compression, the HDL NCO System object applies the Sunderland compression method. Sunderland techniques use trigonometric identities to divide each phase of the quarter sine wave into three components and express it as:

$$\sin(A + B + C) = \sin(A + B)\cos C + \cos A \cos B \cos C - \sin A \sin B \sin C$$

If the phase has 12 bits, the components are defined as:

- A, the four most significant bits

$$(0 \leq A \leq \frac{\pi}{2})$$

- B, the following four bits

$$(0 \leq B \leq \frac{\pi}{2} \times 2^{-4})$$

- C, the four least significant bits

$$(0 \leq C \leq \frac{\pi}{2} \times 2^{-8})$$

Because C is small enough that $\sin(C) \cong 1$ and $\cos(C) \cong 0$, the equation is approximated by:
 $\sin(A + B + C) \approx \sin(A + B) + \cos A \sin C$

The HDL NCO System object implements this equation with one LUT for $\sin(A+B)$ and one LUT for $\cos(A)\sin(C)$. The second term is a fine correction factor and can be truncated to fewer bits without losing precision. With the default accumulator size of 16 bits, and the example phase width of 12 bits, the LUTs use only $2^8 \times 16$ plus $2^8 \times 4$ bits (5kb). A quarter sine lookup table would use $2^{12} \times 16$ bits (65kb). This approximation is accurate within 1 LSB which gives an SNR of at least 60 dB on the output. See L. Cordesses, "Direct Digital Synthesis: A Tool for Periodic Wave Generation (Part 1)", IEEE Signal Processing Magazine, DSP Tips & Tricks column, pp. 50–54, Vol. 21, No. 4 July 2004.

dsp.HighpassFilter System object

Package: dsp

FIR or IIR highpass filter

Description

`dsp.HighpassFilter` independently filters each channel of the input over time using the given design specifications. You can set the `FilterType` property of `dsp.HighpassFilter` to 'FIR' or 'IIR' to implement the object as a FIR or IIR highpass filter. This object supports fixed-point operations, HDL code generation, and ARM Cortex code generation.

To filter each channel of your input:

- 1 Define and set up your highpass filter. See “Construction” on page 4-954.
- 2 Call `step` to filter each channel of the input signal according to the properties of `dsp.HighpassFilter`. The input signal can be a real- or complex-valued column vector or matrix, with floating point or fixed-point precision. If the input signal is a matrix, each column of the matrix is treated as an independent channel. The number of rows in the input signal denote the channel length.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`HPF = dsp.HighpassFilter` returns a minimum order FIR highpass filter, `HPF`, with the default filter settings. Calling `step` with the default property settings filters the input data with a stopband frequency of 8 kHz, a passband frequency of 12 kHz, a stopband attenuation of 80 dB, and a passband ripple of 0.1 dB.

HPF = dsp.HighpassFilter(Name,Value) returns a highpass filter, with additional properties specified by one or more Name, Value pair arguments. Name is the property name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Properties

SampleRate — Input sample rate

44100 (default) | positive real scalar

Input sample rate in Hz, specified as the comma-separated pair consisting of 'SampleRate' and a positive real scalar.

FilterType — Filter type

'FIR' (default) | 'IIR'

Filter type, specified as one of the following options:

- 'FIR' — The object designs an FIR highpass filter.
- 'IIR' — The object designs an IIR highpass (biquad) filter.

DesignForMinimumOrder — Minimum order filter design

true (default) | false

Minimum order filter design, specified as the comma-separated pair consisting of 'DesignForMinimumOrder' and a logical value. If this property is true, then dsp.HighpassFilter designs filters with the minimum order that meets the passband frequency, stopband frequency, passband ripple, and stopband attenuation specifications. Set these specifications using the corresponding properties. If this property is false, then the object designs filters with the order that you specify in the FilterOrder property. This filter design meets the passband frequency, passband ripple, and stopband attenuation specifications that you set using the respective properties.

FilterOrder — Order of the FIR or IIR filter

50 (default) | positive integer scalar

Order of the FIR or IIR filter, specified as the comma-separated pair consisting of 'FilterOrder' and a positive integer scalar. Specifying a filter order is only valid when the value of 'DesignForMinimumOrder' is false.

StopbandFrequency — Filter stopband edge frequency

8000 (default) | real positive scalar

Filter stopband edge frequency in Hz, specified as the comma-separated pair consisting of 'StopbandFrequency' and a real positive scalar. The value of the stopband edge frequency in Hz must be less than the passband frequency. You can specify the stopband edge frequency only when 'DesignForMinimumOrder' is true.

PassbandFrequency — Filter passband edge frequency

12000 (default) | real positive scalar

Filter passband edge frequency in Hz, specified as the comma-separated pair consisting of 'PassbandFrequency' and a real positive scalar. The value of the passband edge frequency in Hz must be less than half the SampleRate and greater than StopbandFrequency.

StopbandAttenuation — Minimum attenuation in the stopband

80 (default) | real positive scalar

Minimum attenuation in the stopband in dB, specified as the comma-separated pair consisting of 'StopbandAttenuation' and a real positive scalar. Minimum attenuation in the stopband defaults to 80 dB.

PassbandRipple — Maximum ripple of filter response in the passband

0.1 (default) | real positive scalar

Maximum ripple of filter response in the passband, in dB, specified as the comma-separated pair consisting of 'PassbandRipple' and a real positive scalar. Maximum ripple of filter response defaults to 0.1 dB.

Fixed-Point Properties

RoundingMethod — Rounding method for output fixed-point operations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see “Precision and Range”.

CoefficientsDataType — Word and fraction lengths of coefficients

`numericType([],16)` (default) | `numericType` object

Word and fraction lengths of coefficients, specified as a `numericType` object. The default, `numericType(1,16)` corresponds to a signed numeric type object with 16-bit coefficients and a fraction length determined based on the coefficient values, to give the best possible precision.

This property is not tunable.

Word length of the output is same as the word length of the input. Fraction length of the output is computed such that the entire dynamic range of the output can be represented without overflow. For details on how the fraction length of the output is computed, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

Methods

- `measure` Measure frequency response characteristics of `dsp.HighpassFilter` System object.
- `reset` Reset internal states of highpass filter
- `step` Filter input using FIR or IIR highpass filter

For additional methods, see “Analysis Methods for Filter System Objects” on page 3-2.

For a complete list of analysis methods supported for the `dsp.HighpassFilter` object, enter `dsp.HighpassFilter.helpFilterAnalysis` at the MATLAB command prompt.

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

Impulse and Frequency Response of FIR and IIR Highpass Filters

Create a minimum order FIR highpass filter for data sampled at 44.1 kHz. Specify a passband frequency of 12 kHz, a stopband frequency of 8 kHz, a passband ripple of 0.1 dB, and a stopband attenuation of 80 dB.

```
Fs = 44.1e3;
filtertype = 'FIR';
Fpass = 12e3;
Fstop = 8e3;
Rp = 0.1;
Astop = 80;
FIRHPF = dsp.HighpassFilter('SampleRate',Fs,...
                            'FilterType',filtertype,...
                            'PassbandFrequency',Fpass,...
                            'StopbandFrequency',Fstop,...
                            'PassbandRipple',Rp,...
                            'StopbandAttenuation',Astop);
```

Design a minimum order IIR highpass filter with the same properties as the FIR highpass filter. Use `clone` to create a system object with the same properties as the FIR Highpass filter. Change the `FilterType` property of the cloned filter to `IIR`.

```
IIRHPF = clone(FIRHPF);
IIRHPF.FilterType = 'IIR';
```

Plot the impulse response of the FIR highpass filter. The zeroth order coefficient is delayed by 19 samples, which is equal to the group delay of the filter. The FIR highpass filter is a causal FIR filter

```
fvtool(FIRHPF,'Analysis','impulse')
```

Plot the impulse response of the IIR highpass filter.

```
fvtool(IIRHPF,'Analysis','impulse')
```

Plot the magnitude and phase response of the FIR highpass filter.

```
fvtool(FIRHPF, 'Analysis', 'freq')
```

Plot the magnitude and phase response of the IIR highpass filter.

```
fvtool(IIRHPF, 'Analysis', 'freq')
```

Calculate the cost of implementing the FIR highpass filter.

```
cost (FIRHPF)
```

```
ans =
```

```
struct with fields:
```

```

    NumCoefficients: 39
    NumStates: 38
    MultiplicationsPerInputSample: 39
    AdditionsPerInputSample: 38

```

Calculate the cost of implementing the IIR highpass filter. The IIR filter is more efficient to implement than its FIR counterpart.

```
cost(IIRHPF)
```

```
ans =
```

```
struct with fields:
```

```
    NumCoefficients: 18  
    NumStates: 14  
    MultiplicationsPerInputSample: 18  
    AdditionsPerInputSample: 14
```

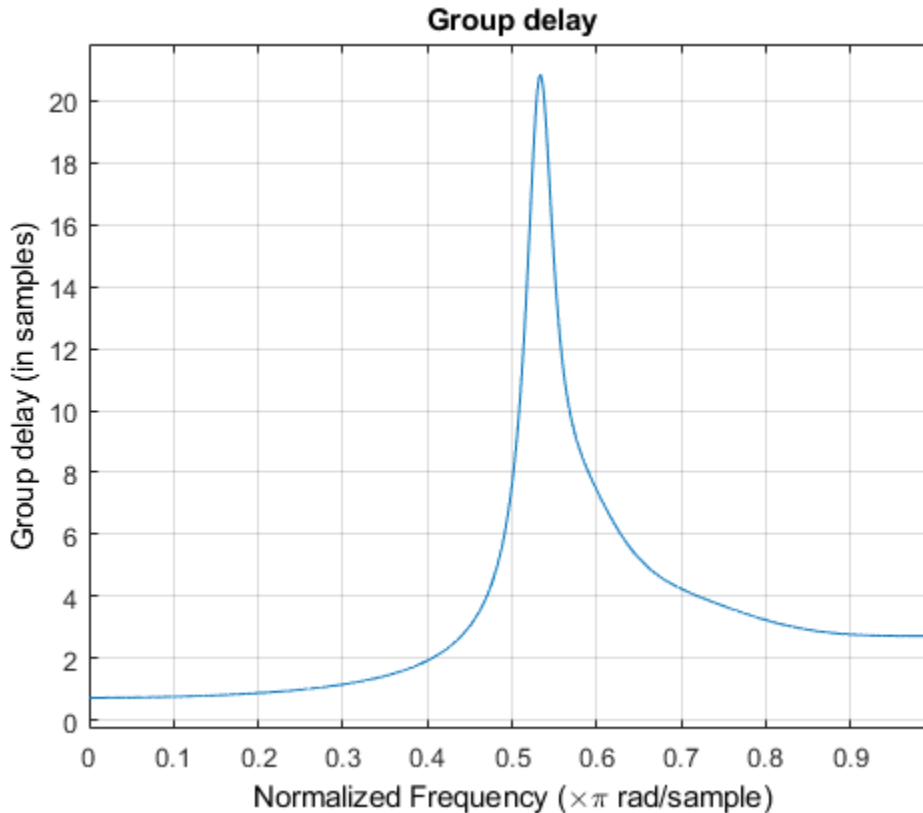

Calculate the group delay of the FIR highpass filter.

```
grpdelay(FIRHPF)
```

Calculate the group delay of the IIR highpass filter. The FIR filter has a constant group delay (linear phase) while its IIR counterpart does not.

```
grpdelay(IIRHPF)
```

Filter White Gaussian Noise with an IIR Highpass filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Set up the IIR highpass filter. The sampling rate of the white Gaussian noise is 44,100 Hz. The passband frequency of the filter is 12 kHz, the stopband frequency is 8 kHz, the passband ripple is 0.1 dB, and the stopband attenuation is 80 dB.

```
Fs = 44.1e3;  
filtertype = 'IIR';
```

```
Fpass = 12e3;  
Fstop = 8e3;  
Rp = 0.1;  
Astop = 80;  
hpf = dsp.HighpassFilter('SampleRate',Fs,...  
    'FilterType',filtertype,...  
    'PassbandFrequency',Fpass,...  
    'StopbandFrequency',Fstop,...  
    'PassbandRipple',Rp,...  
    'StopbandAttenuation',Astop);
```

View the magnitude response of the highpass filter.

```
fvtool(hpf)
```

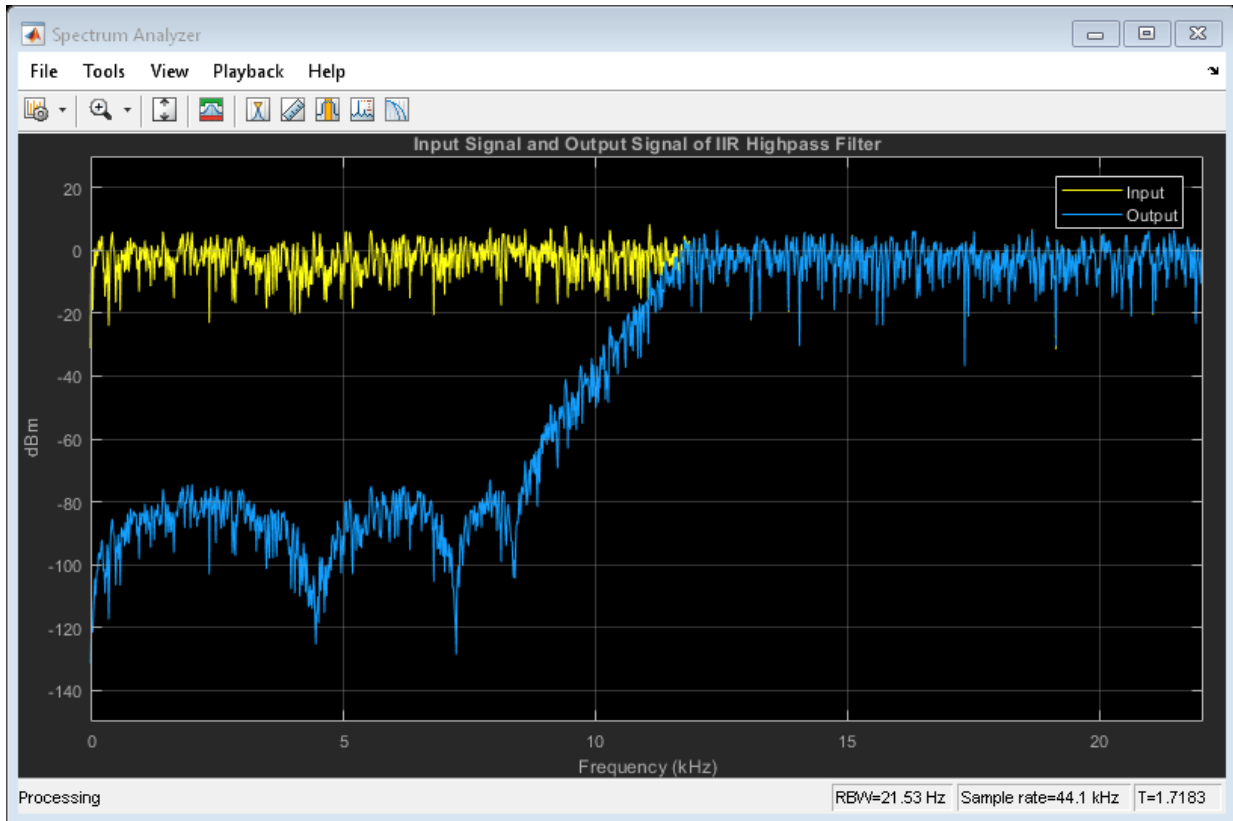

Create a spectrum analyzer object.

```
sa = dsp.SpectrumAnalyzer('SampleRate',44.1e3,...  
    'PlotAsTwoSidedSpectrum',false,'ShowLegend',true,'YLimits',...  
    [-150 30],...  
    'Title',...  
    'Input Signal and Output Signal of IIR Highpass Filter');  
sa.ChannelNames = {'Input','Output'};
```

Filter the white Gaussian noisy input signal. View the input and output signals using the spectrum analyzer.

```
for k = 1:100  
    Input = randn(1024,1);  
    Output = hpf(Input);  
    sa([Input,Output]);  
end
```

Supported Data Types

Argument	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point

Algorithms

FIR Highpass Filter

When the `FilterType` property is set to 'FIR', the `dsp.HighpassFilter` object acts as a FIR highpass filter. In this configuration, `dsp.HighpassFilter` is an alternative to using `firceqrip` and `firgr` with `dsp.FIRFilter`. This object condenses the two-step process into one. For the minimum order design, the object uses generalized Remez FIR filter design algorithm. For the specified order design, the object uses constrained equiripple FIR filter design algorithm. The designed filter is then implemented as a linear phase Type-1 filter with a `Direct form` structure. You can use `dsp.HighpassFilter.measure` to verify that the design meets the prescribed specifications.

IIR Highpass Filter

When the `FilterType` property is set to 'IIR', the `dsp.HighpassFilter` object acts as an IIR highpass filter. In this configuration, this object uses the elliptic design method to compute the SOS and scale values required to meet the filter design specifications. The object uses the SOS and scale values to set up a `Direct form I biquadratic` IIR filter, which forms the basis of the IIR version of the `dsp.HighpassFilter` System object. You can use `dsp.HighpassFilter.measure` to verify that the design meets the prescribed specifications.

measure

System object: `dsp.HighpassFilter`

Package: `dsp`

Measure frequency response characteristics of `dsp.HighpassFilter` System object.

Syntax

```
HPFMeas = measure(HPF)
```

Description

`HPFMeas = measure(HPF)` measures the frequency response characteristics of the `dsp.HighpassFilter` System object, `HPF`.

Input Arguments

HPF — FIR or IIR highpass filter

`HighpassFilter` System object

FIR or IIR highpass filter, specified as a `HighpassFilter` System object.

Output Arguments

HPFMeas — Measurements of frequency response characteristics of the highpass filter

`HighpassFilter` System object

Measurements of frequency response characteristics of the highpass filter, returned as an `fdesign.highpassmeas` object.

Examples

Measure Frequency Response Characteristics of Highpass Filter

Measure the frequency response characteristics of a highpass filter. Create a `dsp.HighpassFilter` System object with default properties. Measure the frequency response characteristics of the filter.

```
HPF = dsp.HighpassFilter

HPF =
    dsp.HighpassFilter with properties:

        FilterType: 'FIR'
    DesignForMinimumOrder: true
        StopbandFrequency: 8000
        PassbandFrequency: 12000
    StopbandAttenuation: 80
        PassbandRipple: 0.1000
        SampleRate: 44100

    Show all properties
```

```
HPFMeas = measure(HPF)
```

```
HPFMeas =
    Sample Rate      : 44.1 kHz
    Stopband Edge    : 8 kHz
    6-dB Point       : 10.418 kHz
    3-dB Point       : 10.8594 kHz
    Passband Edge    : 12 kHz
    Stopband Atten.  : 81.8558 dB
    Passband Ripple  : 0.08066 dB
    Transition Width : 4 kHz
```

Introduced in R2015a

reset

System object: dsp.HighpassFilter

Package: dsp

Reset internal states of highpass filter

Syntax

```
reset (HPF)
```

Description

`reset (HPF)` resets the filter states of the highpass filter, `HPF`, to their initial values. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the `step` method applies the highpass filter to nonzero input data, the filter might have nonzero states. If you invoke the `step` method again without first invoking the `reset` method, the object might produce different outputs for an identical input.

Input Arguments

HPF — FIR or IIR highpass filter

`HighpassFilter` System object

FIR or IIR highpass filter, specified as a `HighpassFilter` System object.

Examples

Reset a Highpass Filter

Create a highpass filter with default properties.

```
HPF = dsp.HighpassFilter;
```

Create a two-channel random signal. Apply the `step` method twice on the signal.

```
x = randn(10,2);
```

```
y1 = step(HPF,x);
```

```
y2 = step(HPF,x);
```

```
no = all(y2==y1)
```

```
no =
```

```
1x2 logical array
```

```
0 0
```

The output is different because the internal states of `HPF` have changed. Reset the highpass filter and apply `step` again. Verify that the output is unchanged.

```
reset(HPF)
```

```
y3 = step(HPF,x);
```

```
yes = all(y3==y1)
```

```
yes =
```

```
1x2 logical array
```

```
1 1
```

step

System object: dsp.HighpassFilter

Package: dsp

Filter input using FIR or IIR highpass filter

Syntax

```
Y = step(HPF,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(HPF,X)` filters the real or complex input signal, `X`, using the highpass filter, `HPF`. `Y` is a highpass-filtered version of `X`. The input `X` must be a column vector or matrix. If `X` is a matrix, each column is treated as an independent channel. `X` can be a floating point or a fixed-point input.

Input Arguments

HPF — FIR or IIR highpass filter

HighpassFilter System object

FIR or IIR highpass filter, specified as a HighpassFilter System object.

x — Input signal

vector | matrix

Input signal, specified as a vector or matrix with floating point or fixed-point precision. The row length of X is the frame size, that is, channel length. Each column of X is treated as a separate channel. The column length of X is the number of channels.

Output Arguments

y — Highpass-filtered signal

vector | matrix

Highpass-filtered signal, returned as a vector or matrix of the same size, data type, and complexity as the input signal, X .

Examples

Filter White Gaussian Noise Signal With a Highpass Filter

Create a highpass filter with default properties.

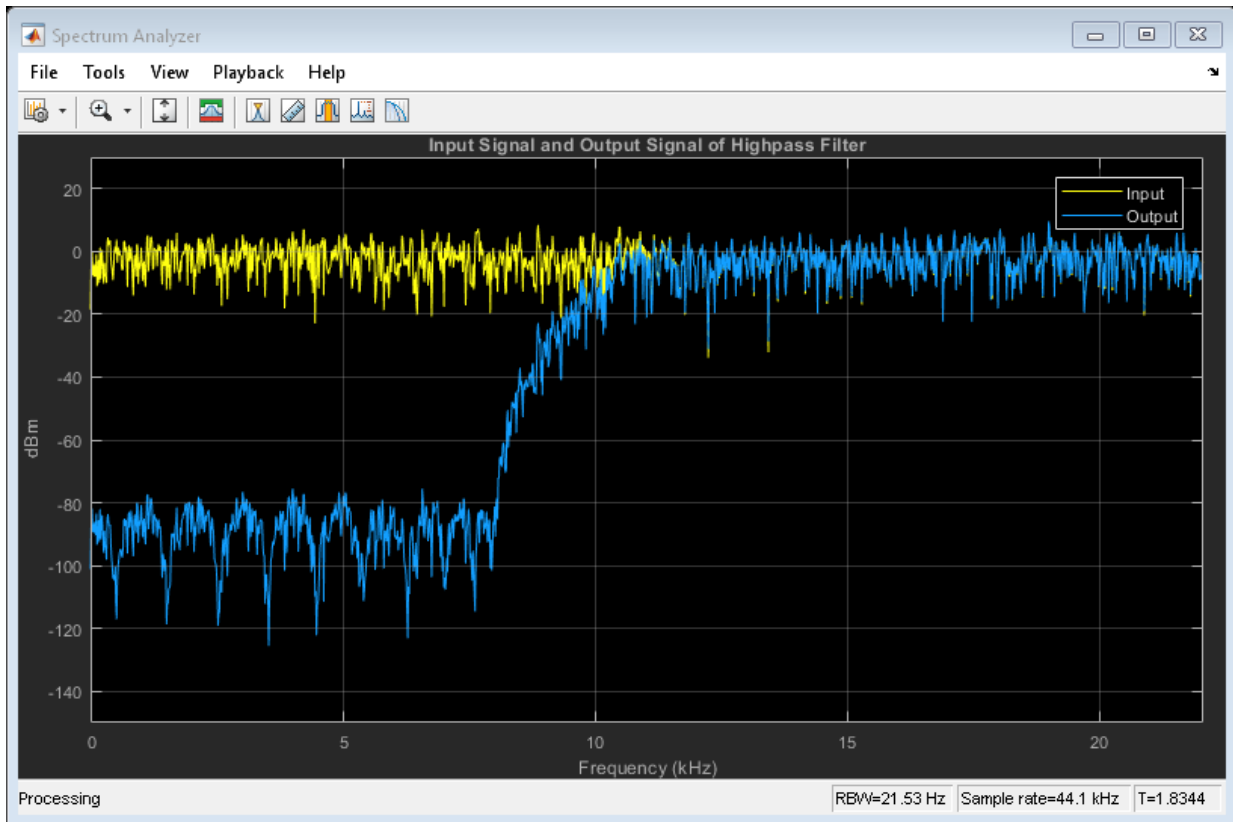

```
HPF = dsp.HighpassFilter;
```

Create a spectrum analyzer object.

```
hSA = dsp.SpectrumAnalyzer('SampleRate',44.1e3,...  
    'PlotAsTwoSidedSpectrum',false,'ShowLegend',true,'YLimits',...  
    [-150 30],...  
    'Title',...  
    'Input Signal and Output Signal of Highpass Filter');  
hSA.ChannelNames = {'Input','Output'};
```

Implement `step` on `HPF` to filter the white Gaussian noisy input signal. View the input and output signals using the spectrum analyzer.

```
for k = 1:100  
    Input = randn(1024,1);  
  
    Output = step(HPF,Input);  
  
    step(hSA, [Input,Output]);  
end
```

Introduced in R2015a

dsp.Histogram System object

Package: dsp

Histogram of input or sequence of inputs

Description

The `Histogram` object generates a histogram for an input or a sequence of inputs.

To generate a histogram for an input or a sequence of inputs:

- 1 Define and set up your histogram object. See “Construction” on page 4-978.
- 2 Call `step` to generate the histogram for an input according to the properties of `dsp.Histogram`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`hist = dsp.Histogram` returns a histogram object, `hist`, that computes the frequency distribution of the elements in each input matrix.

`hist = dsp.Histogram('PropertyName', PropertyValue, ...)` returns a histogram object, `hist`, with each specified property set to the specified value.

`hist = dsp.Histogram(MIN, MAX, NUMBINS, 'PropertyName', PropertyValue, ...)` returns a histogram object, `hist`, with the `LowerLimit` property set to `MIN`, `UpperLimit` property set to `MAX`, `NumBins` property set to `NUMBINS` and other specified properties set to the specified values.

Properties

LowerLimit

Lower boundary

Specify the lower boundary of the lowest-valued bin as a real-valued scalar. NaN and Inf are not valid values for this property. The default is 0. This property is tunable.

UpperLimit

Upper boundary

Specify the upper boundary of the highest-valued bin as a real-valued scalar. NaN and Inf are not valid values for this property. The default is 10. This property is tunable.

NumBins

Number of bins in histogram

Specify the number of bins in the histogram. The default is 11.

Dimension

Specify how the histogram calculation is performed over the data as one of | All | Column |. The default is Column.

Normalize

Enable output vector normalization

Specify whether the histogram object normalizes the output vector, v , so that $sum(v) = 1$. When you set this property to true, the output vector is normalized. When you set it to false, the object supports fixed-point operations and does not use this property for normalization. The default is false.

RunningHistogram

Enable calculation over successive step method calls

Set this property to `true` to enable running histogram calculations for the input elements over successive calls to the `step` method. Set this property to `false` to compute a histogram for the current input. The default is `false`.

ResetInputPort

Enable resetting in running histogram mode

Set this property to `true` to enable resetting the running histogram. When you set the property to `true`, specify a reset input to the `step` method that resets the running histogram. This property applies when you set the `RunningHistogram` property to `true`. When this property is `false`, the histogram object does not reset. The default is `false`.

ResetCondition

Reset condition for running histogram mode

Specify the event that resets the running histogram as one of `| Rising edge | Falling edge | Either edge | Non-zero |`. This property applies when you set the `ResetInputPort` property to `true`. The default is `Non-zero`

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `| Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `| Wrap | Saturate |`. The default is `Wrap`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of `| Same as input | Custom |`. The default is `Same as input`.

CustomProductDataType

Custom product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `| Same as product | Same as input | Custom |`. The default is `Same as input`.

CustomAccumulatorDataType

Custom accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

Methods

`reset` Reset histogram bin values to zero
`step` Histogram for input data

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object

Common to All System Objects	
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Compute Histogram of a Sequence

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Compute a histogram with four bins, for possible input values 1 through 4.

```
hist = dsp.Histogram(1,4,4);  
y = hist([1 2 2 3 3 3 4 4 4 4]');
```

y is equal to [1; 2; 3; 4] - one ones, two twos, etc.

Algorithms

This object implements the algorithm, inputs, and outputs described on the Histogram block reference page. The object properties correspond to the block parameters, except:

- The **Reset port** block parameter corresponds to both the `ResetCondition` and the `ResetInputPort` object properties.
- The **Find histogram over** block parameter corresponds to the “Dimension” on page 4-0 property of the object.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- This object has no tunable properties for code generation.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(hist,X)` returns a histogram `Y` for the input data `X`. When the `RunningHistogram` property is `true`, `Y` corresponds to the histogram of the input elements over successive calls to the `step` method.

`Y = step(hist,X,R)` resets the histogram state based on the value of `R` and the object's `ResetCondition` property. You can reset the histogram state only when the `RunningHistogram` and the `ResetInputPort` properties are `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.IDCT System object

Package: dsp

Inverse discrete cosine transform (IDCT)

Description

The `IDCT` object computes the inverse discrete cosine transform (IDCT) of an input.

To compute the IDCT of an input:

- 1 Define and set up your IDCT object. See “Construction” on page 4-987.
- 2 Call `step` to compute the IDCT of an input according to the properties of `dsp.IDCT`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`idct = dsp.IDCT` returns a inverse discrete cosine transform (IDCT) object, `idct`. This object computes the IDCT of a real or complex input signal using the `Table` lookup method.

`idct = dsp.IDCT('PropertyName', PropertyValue, ...)` returns an inverse discrete cosine transform (IDCT) object, `idct`, with each property set to the specified value.

Properties

SineComputation

Method to compute sines and cosines

Specify how the IDCT object computes the trigonometric function values as `Trigonometric function` or `Table lookup`. You must set this property to `Table lookup` for fixed-point inputs. The default is `Table lookup`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. This property applies when you set the `SineComputation` property to `Table lookup`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. This property applies when you set the `SineComputation` property to `Table lookup`.

SineTableDataType

Sine table word-length designation

Specify the sine table fixed-point data type as one of `Same word length as input` or `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`.

CustomSineTableDataType

Sine table word length

Specify the sine table fixed-point type as a signed, unscaled `numericType` object. This property applies when you set the `SineComputation` property to `Table lookup` and the `SineTableDataType` property to `Custom`. The default is `numericType(true, 16)`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of `Full` precision, `Same as input`, `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a signed, scaled `numericType` object. This property applies when you set the `SineComputation` property to `Table lookup` and the `ProductDataType` property to `Custom`. The default is `numericType(true, 32, 30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `Full` precision, `Same as input`, `Same as product`, or `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a signed, scaled `numericType` object. This property applies when you set the `SineComputation` property to `Table lookup` and the `AccumulatorDataType` property to `Custom`. The default is `numericType(true, 32, 30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of `Full` precision, `Same as input`, `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`. The default is `Full` precision.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a signed, scaled `numerictype` object. This property applies when you set the `SineComputation` property to `Table` lookup and the “`OutputDataType`” on page 4-0 property to `Custom`. The default is `numerictype(true,16,15)`.

Methods

`step` Inverse discrete cosine transform (IDCT) of input

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

Analyze the Energy Content in a Sequence

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Use DCT to analyze the energy content in a sequence:

```
x = (1:128).' + 50*cos((1:128).'*2*pi/40);
dct = dsp.DCT;
X = dct(x);
```

Set the DCT coefficients which represent less than 0.1% of the total energy to 0 and reconstruct the sequence using IDCT.

```
[XX, ind] = sort(abs(X),1,'descend');  
ii = 1;  
while (norm([XX(1:ii);zeros(128-ii,1)]) <= 0.999*norm(XX))  
    ii = ii+1;  
end  
disp(['Number of DCT coefficients that represent 99.9%',...  
     'of the total energy in the sequence: ',num2str(ii)]);
```

Number of DCT coefficients that represent 99.9%of the total energy in the sequence: 10

```
XXt = zeros(128,1);  
XXt(ind(1:ii)) = X(ind(1:ii));  
idct = dsp.IDCT;  
xt = idct(XXt);  
plot(1:128,[x xt]);  
legend('Original signal','Reconstructed signal',...  
      'location','best');
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the IDCT block reference page. The object properties correspond to the block parameters.

step

System object: dsp.IDCT

Package: dsp

Inverse discrete cosine transform (IDCT) of input

Syntax

```
Y = step(idct,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(idct,X)` computes the inverse discrete cosine transform, `Y`, of input `X`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.IFFT System object

Package: dsp

Inverse discrete Fourier transform (IDFFT)

Description

The `IFFT` object computes the inverse discrete Fourier transform (IDFFT) of the input. The object uses one or more of the following fast Fourier transform (FFT) algorithms depending on the complexity of the input and whether the output is in linear or bit-reversed order:

- Double-signal algorithm
- Half-length algorithm
- Radix-2 decimation-in-time (DIT) algorithm
- Radix-2 decimation-in-frequency (DIF) algorithm
- An algorithm chosen by FFTW [1], [2]

To compute the IFFT of the input:

- 1 Define and set up your IFFT object. See “Construction” on page 4-995.
- 2 Call `step` to compute the IFFT of the input according to the properties of `dsp.IFFT`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`ift = dsp.IFFT` returns an IFFT object, `ift`, that computes the IDFT of a column vector or N -D array. For column vectors or N -D arrays, the IFFT object computes the

IDFT along the first dimension of the array. If the input is a row vector, the `IFFT` object computes a row of single-sample IDFTs and issues a warning.

`ift = dsp.IFFT('PropertyName', PropertyValue, ...)` returns an `IFFT` object, `ift`, with each property set to the specified value.

Properties

FFTImplementation

FFT implementation

Specify the implementation used for the FFT as one of `Auto` | `Radix-2` | `FFTW`. When you set this property to `Radix-2`, the FFT length must be a power of two.

BitReversedInput

Enable bit-reversed order interpretation of input elements

Set this property to `true` if the order of Fourier transformed input elements to the `IFFT` object are in bit-reversed order. This property applies only when the `FFTLengthSource` property is `Auto`. The default is `false`, which denotes linear ordering.

ConjugateSymmetricInput

Enable conjugate symmetric interpretation of input

Set this property to `true` if the input is conjugate symmetric to yield real-valued outputs. The discrete Fourier transform of a real valued sequence is conjugate symmetric, and setting this property to `true` optimizes the IDFT computation method. Setting this property to `false` for conjugate symmetric inputs may result in complex output values with nonzero imaginary parts. This occurs due to rounding errors. Setting this property to `true` for nonconjugate symmetric inputs results in invalid outputs. This property applies only when the `FFTLengthSource` property is `Auto`. The default is `false`.

Normalize

Enable dividing output by FFT length

Specify whether to divide the `IFFT` output by the FFT length. The default is `true` and each element of the output is divided by the FFT length.

FFTLengthSource

Source of FFT length

Specify how to determine the FFT length as `Auto` or `Property`. When you set this property to `Auto`, the FFT length equals the number of rows of the input signal. This property applies only when both the `BitReversedInput` and `ConjugateSymmetricInput` properties are `false`. The default is `Auto`.

FFTLength

FFT length

Specify the FFT length as a numeric scalar. This property applies when you set the `BitReversedInput` and `ConjugateSymmetricInput` properties to `false`, and the `FFTLengthSource` property to `Property`. The default is 64.

This property must be a power of two when the input is a fixed-point data type, or when you set the `FFTImplementation` property to `Radix-2`.

When you set the `FFTImplementation` property to `Radix-2`, or when you set the `BitReversedOutput` property to `true`, this value must be a power of two.

WrapInput

Boolean value of wrapping or truncating input

Wrap input data when `FFTLength` is shorter than input length. If this property is set to `true`, modulo-length data wrapping occurs before the FFT operation, given `FFTLength` is shorter than the input length. If this property is set to `false`, truncation of the input data to the `FFTLength` occurs before the FFT operation. The default is `true`.

Fixed-Point Properties**RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

SineTableDataType

Sine table word and fraction lengths

Specify the sine table data type as `Same word length as input` or `Custom`. The default is `Same word length as input`.

CustomSineTableDataType

Sine table word and fraction lengths

Specify the sine table fixed-point type as an `unscaled numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `SineTableDataType` property to `Custom`. The default is `numerictype([],16)`.

ProductDataType

Product word and fraction lengths

Specify the product data type as `Full precision`, `Same as input`, or `Custom`. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a `scaled numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator data type as `Full precision`, `Same as input`, `Same as product`, or `Custom`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

OutputDataType

Output word and fraction lengths

Specify the output data type as `Full` precision, `Same as input`, or `Custom`. The default is `Full` precision.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numericType([], 16, 15)`.

Methods

`step` Inverse discrete Fourier transform of input

Common to All System Objects	
<code>clone</code>	Create System object with same property values

<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

Construct a Sinusoidal Signal Using High Energy FFT Coefficients

Compute the FFT of a noisy sinusoidal input signal. The energy of the signal is stored as the magnitude square of the FFT coefficients. Determine the FFT coefficients which occupy 99.99% of the signal energy and reconstruct the time-domain signal by taking the IFFT of these coefficients. Compare the reconstructed signal with the original signal.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj(x))`.

Consider a time-domain signal $x[n]$, which is defined over the finite time interval $0 \leq n \leq N - 1$. The energy of the signal $x[n]$ is given by the following equation:

$$E_N = \sum_{n=0}^{N-1} |x[n]|^2$$

FFT Coefficients, $X[k]$ are considered as signal values in the frequency domain. The energy of the signal $x[n]$ in the frequency-domain is hence the sum of the squares of the magnitude of the FFT coefficients:

$$E_N = \frac{1}{N} \sum_{k=0}^{N-1} |X[k]|^2$$

According to Parseval's theorem, the total energy of the signal in time or frequency-domain is the same.

$$E_N = \sum_{n=0}^{N-1} |x[n]|^2 = \frac{1}{N} \sum_{k=0}^{N-1} |X[k]|^2$$

Initialization

Initialize a `dsp.SineWave` System object to generate a sine wave sampled at 44.1 kHz and has a frequency of 1000 Hz. Construct a `dsp.FFT` and `dsp.IFFT` objects to compute the FFT and the IFFT of the input signal.

The `'FFTLengthSource'` property of each of these transform objects is set to `'Auto'`. The FFT length is hence considered as the input frame size. The input frame size in this example is 1020, which is not a power of 2. Hence, select the `'FFTImplementation'` as `'FFTW'`.

```
L = 1020;
Sineobject = dsp.SineWave('SamplesPerFrame',L,'PhaseOffset',10,...
    'SampleRate',44100,'Frequency',1000);
ft = dsp.FFT('FFTImplementation','FFTW');
ift = dsp.IFFT('FFTImplementation','FFTW','ConjugateSymmetricInput',true);
rng(1);
```

Streaming

Stream in the noisy input signal. Compute the FFT of each frame and determine the coefficients which constitute 99.99% energy of the signal. Take IFFT of these coefficients to reconstruct the time-domain signal.

```
numIter = 1000;
for Iter = 1:numIter
    Sinewave1 = Sineobject();
    Input = Sinewave1 + 0.01*randn(size(Sinewave1));
    FFTCoeff = ft(Input);
    FFTCoeffMagSq = abs(FFTCoeff).^2;

    EnergyFreqDomain = (1/L)*sum(FFTCoeffMagSq);
    [FFTCoeffSorted, ind] = sort((1/L)*FFTCoeffMagSq,1,'descend');

    CumFFTCoeffs = cumsum(FFTCoeffSorted);
    EnergyPercent = (CumFFTCoeffs/EnergyFreqDomain)*100;
    Vec = find(EnergyPercent > 99.99);
    FFTCoeffsModified = zeros(L,1);
    FFTCoeffsModified(ind(1:Vec(1))) = FFTCoeff(ind(1:Vec(1)));
    ReconstrSignal = ift(FFTCoeffsModified);
end
```

99.99% of the signal energy can be represented by the number of FFT coefficients given by `Vec(1)`:

```
Vec(1)
```

```
ans = 296
```

The signal is reconstructed efficiently using these coefficients. If you compare the last frame of the reconstructed signal with the original time-domain signal, you can see that the difference is very small and the plots match closely.

```
max(abs(Input-ReconstrSignal))
```

```
ans = 0.0431
```

```
plot(Input, '*');  
hold on;  
plot(ReconstrSignal, 'o');  
hold off;
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the IFFT block reference page. The object properties correspond to the block parameters, except: **Output sampling mode** parameter is not supported by `dsp.IFFT`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- See “System Objects in MATLAB Code Generation” (MATLAB Coder).
- When the following conditions apply, the executable generated from this System object relies on prebuilt dynamic library files (.dll files) included with MATLAB:
 - `FFTImplementation` is set to 'FFTW'.
 - `FFTImplementation` is set to 'Auto', `FFTLengthSource` is set to 'Property', and `FFTLength` is not a power of two.

Use the `packNGo` function to package the code generated from this System object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

- When the FFT length is a power of two, you can generate standalone C and C++ code from this System object.

System Objects

`dsp.DCT` | `dsp.FFT` | `dsp.IDCT`

Introduced in R2012a

step

System object: dsp.IFFT

Package: dsp

Inverse discrete Fourier transform of input

Syntax

```
Y = step(ift,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(ift,X)` computes the inverse discrete Fourier transform (IDFT), Y , of the input X along the first dimension of X . When the `FFTLengthSource` property is `Auto`, the length of X along the first dimension must be a positive integer power of two. When the `FFTLengthSource` property is `'Property'`, the length of X along the first dimension can be any positive integer and the `FFTLength` property must be a positive integer power of two.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.IIRFilter System object

Package: dsp

Infinite impulse response (IIR) filter

Description

The `dsp.IIRFilter` System object filters each channel of the input using the specified filter. You can specify the filter to have a 'Direct form I', 'Direct form I transposed', 'Direct form II', or 'Direct form II transposed' structure.

Use the “Numerator” on page 4-0 and “Denominator” on page 4-0 properties to specify the coefficients of the filter numerator and denominator coefficients. In addition to these coefficients, you can also specify nonzero initial filter states through the “InitialConditions” on page 4-0 property.

To filter a signal using an IIR filter:

- 1 Create the `dsp.IIRFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#)

Creation

Syntax

```
iir = dsp.IIRFilter
iir = dsp.IIRFilter(Name,Value)
```

Description

`iir = dsp.IIRFilter` creates an infinite impulse response (IIR) filter System object that independently filters each channel of the input over time using a specified IIR filter implementation.

`iir = dsp.IIRFilter(Name,Value)` creates an IIR filter object with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `iir = dsp.IIRFilter('Structure','Direct form I');`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects \(MATLAB\)](#).

Structure — IIR filter structure

'Direct form II transposed' (default) | 'Direct form I' | 'Direct form I transposed' | 'Direct form II'

IIR filter structure, specified as 'Direct form I', 'Direct form I transposed', 'Direct form II', or 'Direct form II transposed'.

Numerator — Numerator coefficients

[1 1] (default) | row vector

Numerator coefficients, specified as a row vector.

Example: [0.0296 0.1775 0.4438 0.5918 0.4438 0.1775 0.0296]

Tunable: Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Complex Number Support: Yes

Denominator — Denominator coefficients

[1 0.1] (default) | row vector

Denominator coefficients, specified as a row vector.

Example: [1.0000 -0.0000 0.7777 -0.0000 0.1142 -0.0000 0.0018]

Tunable: Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Complex Number Support: Yes

InitialConditions — Initial conditions

0 (default) | scalar | vector | matrix

Initial conditions of the filter states, specified as one of the following:

- scalar — The object initializes all delay elements in the filter to the scalar value.
- vector — The length of the vector equals the number of delay elements in the filter. Each vector element specifies a unique initial condition for the corresponding delay element. The object applies the same vector to each channel of the input signal.
- matrix — The number of rows in the matrix must equal the number of delay elements in the filter. The number of columns in the matrix must equal the number of channels in the input. Each element specifies a unique initial condition for the corresponding delay element in the corresponding channel.

The number of filter states equals $\max(N,M) - 1$, where N is the number of poles, and M is the number of zeros.

Tunable: Yes

Dependencies

This property applies only when you set the “Structure” on page 4-0 property to 'Direct form II' or 'Direct form II transposed'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Complex Number Support: Yes

NumeratorInitialConditions — Initial conditions on zeros side

0 (default) | scalar | vector | matrix

Initial conditions of the filter states on the side of the filter structure with the zeros, specified as one of the following:

- **scalar** — The object initializes all delay elements on the zeros side in the filter to the scalar value.
- **vector** — The length of the vector equals the number of delay elements on the zeros side in the filter. Each vector element specifies a unique initial condition for the corresponding delay element on the zeros side. The object applies the same vector of initial conditions to each channel of the input signal.
- **matrix** — The number of rows in the matrix must equal the number of delay elements on the zeros side in the filter. The number of columns in the matrix must equal the number of channels in the input signal. Each element specifies a unique initial condition for the corresponding delay element on the zeros side in the corresponding channel.

The number of filter states equals $\max(N,M) - 1$, where N is the number of poles, and M is the number of zeros, respectively.

Tunable: Yes

Dependencies

This property applies only when you set the “Structure” on page 4-0 property to 'Direct form I' or 'Direct form I transposed'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Complex Number Support: Yes

DenominatorInitialConditions — Initial conditions on poles side

0 (default) | `scalar` | `vector` | `matrix`

Initial conditions of the filter states on the side of the filter structure with the poles, specified as one of the following:

- **scalar** — The object initializes all delay elements on the poles side in the filter to the scalar value.
- **vector** — The length of the vector equals the number of delay elements on the poles side in the filter. Each vector element specifies a unique initial condition for the corresponding delay element on the poles side. The object applies the same vector of initial conditions to each channel of the input signal.

- **matrix** — The number of rows in the matrix must equal the number of delay elements on the poles side in the filter. The number of columns in the matrix must equal the number of channels in the input signal. Each element specifies a unique initial condition for the corresponding delay element on the poles side in the corresponding channel.

The number of filter states equals $\max(N,M) - 1$, where N is the number of poles, and M is the number of zeros, respectively.

Tunable: Yes

Dependencies

This property applies only when you set the “Structure” on page 4-0 property to 'Direct form I' or 'Direct form I transposed'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Complex Number Support: Yes

Fixed-Point Properties

RoundingMethod — Rounding method

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Select the rounding mode for fixed-point operations.

OverflowAction — Overflow action

'Wrap' (default) | 'Saturate'

Overflow action for fixed-point operations, specified as one of the following:

- 'Wrap' — The object wraps the result of its fixed-point operations.
- 'Saturate' — The object saturates the result of its fixed-point operations.

For more details on overflow actions, see overflow mode for fixed-point operations.

StateDataType — State data type

'Same as input' (default) | 'Custom'

State data type, specified as one of the following:

- 'Same as input' — The state data type is same as the input data type.
- 'Custom' — The state output data type is an autosigned numeric type through the “CustomStateDataType” on page 4-0 property.

CustomStateDataType — State word and fraction lengths

`numericType([],16,15)` (default)

State word and fraction lengths, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Dependencies

This property applies only when you set “StateDataType” on page 4-0 to 'Custom'.

NumeratorCoefficientsDataType — Data type of numerator coefficients

'Same word length as input' (default) | 'Custom'

Data type of numerator coefficients, specified as one of the following:

- 'Same word length as input' — The word length of the numerator coefficients is the same as the input word length. The fraction length is chosen to give the best possible precision.
- 'Custom' — The data type of the numerator coefficients is the autosigned numeric type specified by the “CustomNumeratorCoefficientsDataType” on page 4-0 property.

CustomNumeratorCoefficientsDataType — Word and fraction lengths of the numerator coefficients

`numericType([],16,15)` (default)

Word and fraction lengths of the numerator coefficients, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Dependencies

This property applies only when you set “NumeratorCoefficientsDataType” on page 4-0 to 'Custom'.

DenominatorCoefficientsDataType — Data type of the denominator coefficients

'Same word length as input' (default) | 'Custom'

Data type of the denominator coefficients, specified as one of the following:

- 'Same word length as input' — The word length of the denominator coefficients is the same as that of the input word length. The fraction length is chosen to give the best possible precision.
- 'Custom' — The data type of the denominator coefficients is the autosigned numeric type specified by the “CustomDenominatorCoefficientsDataType” on page 4-0 property.

CustomDenominatorCoefficientsDataType — Word and fraction lengths of denominator coefficients

`numericType([],16,15)` (default)

Word and fraction lengths of denominator coefficients, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Dependencies

This property applies only when you set “DenominatorCoefficientsDataType” on page 4-0 to 'Custom'.

NumeratorProductDataType — Numerator product data type

'Full precision' (default) | 'Same as input' | 'Custom'

Data type of the output of a product operation in the numerator polynomial of the IIR filter, specified as one of the following:

- 'Full precision' — The object computes the numerator product output data type using the full-precision rules. These rules provide the most accurate fixed-point numerics. No quantization occurs. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- 'Same as input' — The product output data type is the same as the input data type.
- 'Custom' — The product output data type is the custom numeric type specified by the “CustomNumeratorProductDataType” on page 4-0 property. The rounding method and the overflow action are specified by the “RoundingMethod” on page 4-0 and “OverflowAction” on page 4-0 properties.

CustomNumeratorProductDataType — Numerator product word and fraction lengths

`numericType([],32,30)` (default)

Numerator product word and fraction lengths, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set “NumeratorProductDataType” on page 4-0 to 'Custom'.

DenominatorProductDataType — Denominator product data type

'Full precision' (default) | 'Same as input' | 'Custom'

Data type of the output of a product operation in the denominator polynomial of the IIR filter, specified as one of the following:

- 'Full precision' — The object computes the denominator product output data type using the full-precision rules. These rules provide the most accurate fixed-point numerics. No quantization occurs. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- 'Same as input' — The product output data type is the same as the input data type.
- 'Custom' — The product output data type is custom numeric type specified by the “CustomDenominatorProductDataType” on page 4-0 property. The rounding method and the overflow action are specified by the “RoundingMethod” on page 4-0 and “OverflowAction” on page 4-0 properties.

CustomDenominatorProductDataType — Denominator product word and fraction lengths

numericType([], 32, 30) (default)

Denominator product word and fraction lengths, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set “DenominatorProductDataType” on page 4-0 to 'Custom'.

NumeratorAccumulatorDataType — Numerator accumulator data type

'Full precision' (default) | 'Same as input' | 'Same as product' | 'Custom'

Data type of the output of an accumulation operation in the numerator polynomial of the IIR filter, specified as one of the following:

- 'Full precision' — The object computes the numerator accumulator data type using the full-precision rules. These rules provide the most accurate fixed-point

numerics. No quantization occurs. Bits are added, as needed, to ensure that no roundoff or overflow occurs.

- 'Same as input' — The accumulator data type is the same as the input data type.
- 'Same as product' — The accumulator data type is the same as the product output data type.
- 'Custom' — The accumulator data type is the custom numeric type specified by the “CustomNumeratorAccumulatorDataType” on page 4-0 property. The rounding method and the overflow action are specified by the “RoundingMethod” on page 4-0 and “OverflowAction” on page 4-0 properties.

CustomNumeratorAccumulatorDataType — Numerator accumulator word and fraction lengths

`numericType([],32,30)` (default)

Numerator accumulator word and fraction lengths, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set “NumeratorAccumulatorDataType” on page 4-0 to 'Custom'.

DenominatorAccumulatorDataType — Denominator accumulator data type

'Full precision' (default) | 'Same as input' | 'Same as product' | 'Custom'

Data type of the output of an accumulation operation in the denominator polynomial of the IIR filter, specified as one of the following:

- 'Full precision' — The object computes the denominator accumulator data type using the full-precision rules. These rules provide the most accurate fixed-point numerics. No quantization occurs. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- 'Same as input' — The accumulator data type is the same as the input data type.
- 'Same as product' — The accumulator data type is the same as the product output data type.
- 'Custom' — The accumulator data type is the custom numeric type specified by the “CustomDenominatorAccumulatorDataType” on page 4-0 property. The rounding method and the overflow action are specified by the “RoundingMethod” on page 4-0 and “OverflowAction” on page 4-0 properties.

CustomDenominatorAccumulatorDataType — Denominator accumulator word and fraction lengths

`numericType([],32,30)` (default)

Denominator accumulator word and fraction lengths, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set “DenominatorAccumulatorDataType” on page 4-0 to 'Custom'.

OutputDataType — Output data type

'Same as input' (default) | 'Full precision' | 'Custom'

Data type of the output of the `dsp.IIRFilter` object, specified as one of the following:

- 'Same as input' — The output data type is the same as the input data type.
- 'Full precision' — The object computes the output data type using the full-precision rules. These rules provide the most accurate fixed-point numerics. No quantization occurs. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- 'Custom' — The output data type is the custom numeric type specified by the “CustomOutputDataType” on page 4-0 property. The rounding method and the overflow action are specified by the “RoundingMethod” on page 4-0 and “OverflowAction” on page 4-0 properties.

CustomOutputDataType — Output word and fraction lengths

`numericType([],16,15)` (default)

Output word and fraction lengths, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Dependencies

This property applies only when you set “OutputDataType” on page 4-0 to 'Custom'.

MultiplicandDataType — Multiplicand data type

'Same as input' (default) | 'Custom'

Multiplicand data type, specified as one of the following:

- 'Same as input' — The multiplicand data type is the same as the input data type.
- 'Custom' — The multiplicand data type is the autosigned numeric type specifies by the “CustomMultiplicandDataType” on page 4-0 property.

CustomMultiplicandDataType — Multiplicand output word and fraction lengths

`numericType([],16,15)` (default)

Multiplicand output word and fraction lengths, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Dependencies

This property applies only when you set “MultiplicandDataType” on page 4-0 to 'Custom'.

Usage

Syntax

```
iirOut = iir(input)
```

Description

`iirOut = iir(input)` filters the input signal using the specified filter to produce the filtered output. The System object filters each column of the input signal independently over time.

Input Arguments

input — Data input

vector | matrix

Data input that is filtered, specified as a vector or matrix.

Example: `randn(34,24)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Output Arguments

iirOut — Filtered output

vector | matrix

Filtered output, returned as a vector or a matrix. The size, data type, and complexity of the output match that of the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Note For versions earlier than R2016b, use the `step` function to run the System object™ algorithm. The arguments to `step` are the object you created, followed by the arguments shown in this section.

For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.IIRFilter

<code>freqz</code>	Frequency response of filter
<code>fvtool</code>	Visualize frequency response of DSP filters
<code>impz</code>	Impulse response of discrete-time filter System object
<code>phasez</code>	Unwrapped phase response for filter

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>clone</code>	Create duplicate System object
<code>getNumInputs</code>	Number of inputs required to call the System object
<code>getNumOutputs</code>	Number of outputs from calling the System object
<code>isLocked</code>	Determine if System object is locked
<code>release</code>	Release resources and allow changes to System object property values and input characteristics

reset Reset internal states of System object

Examples

Filter Noisy Signal Using IIR Filter

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

View the magnitude response of the IIR filter. Use the `Spectrum Analyzer` to display the power spectrum of the output signal.

Initialization

```
x = randn(2048,1);
x = x-mean(x);
src = dsp.SignalSource;
src.Signal = x;
sink = dsp.SignalSink;

N = 10;
Fc = 0.4;
[b,a] = butter(N,Fc);
iir = dsp.IIRFilter('Numerator',b,'Denominator',a);

sa = dsp.SpectrumAnalyzer('SampleRate',8e3,...
    'PlotAsTwoSidedSpectrum',false,...
    'OverlapPercent',80,'PowerUnits','dBW',...
    'YLimits',[-220 -10]);
```

Filter the Signal

```
while ~isDone(src)
    input = src();
    output = iir(input);
    sa(output)
    sink(output);
end

Result = sink.Buffer;
fvtool(iir,'Fs',8000)
```

Design an IIR Filter

This example shows the two ways of designing an IIR filter.

Design the filter using `fdesign` and `design`.

```
D = fdesign.comb('notch', 'N,BW', 8, 0.02);  
iir = design(D, 'systemobject', true)  
fvtool(iir);
```

```
iir =
```

```
dsp.IIRFilter with properties:
```

```
    Structure: 'Direct form II'  
    Numerator: [0.8878 0 0 0 0 0 0 0 -0.8878]  
    Denominator: [1 0 0 0 0 0 0 0 -0.7757]  
    InitialConditions: 0
```

```
Use get to show all properties
```

Design the filter using filter coefficients.

```
b = [0.9 zeros(9,1)' -0.9];  
a = [1 zeros(9,1)' -0.8];  
iir = dsp.IIRFilter('Numerator',b,'Denominator',a)  
fvtool(iir);
```

```
iir =
```

```
    dsp.IIRFilter with properties:
```

```
        Structure: 'Direct form II transposed'  
        Numerator: [0.9000 0 0 0 0 0 0 0 0 0 -0.9000]  
        Denominator: [1 0 0 0 0 0 0 0 0 0 -0.8000]  
        InitialConditions: 0
```

```
Use get to show all properties
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Only the `Numerator` and `Denominator` properties are tunable for code generation.

- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Fixed-Point Conversion

Design and simulate fixed-point algorithms using Fixed-Point Designer™.

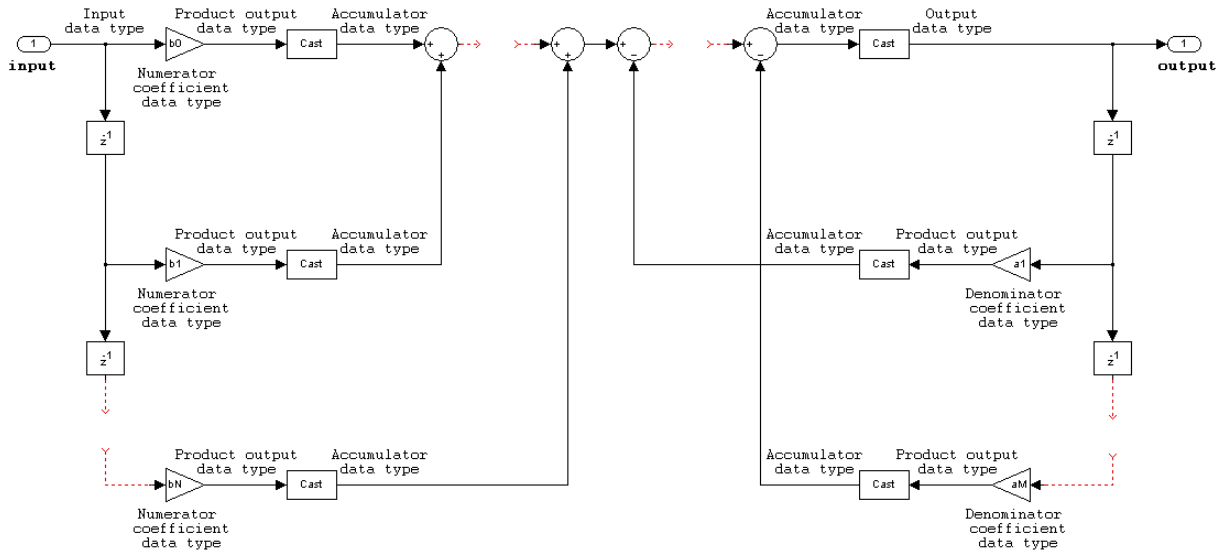

The `dsp.IIRFilter` System object supports the following filter structures. The diagrams in each section show the data types used in the filter structures for fixed-point signals. You can set the data types using the fixed-point properties of the object.

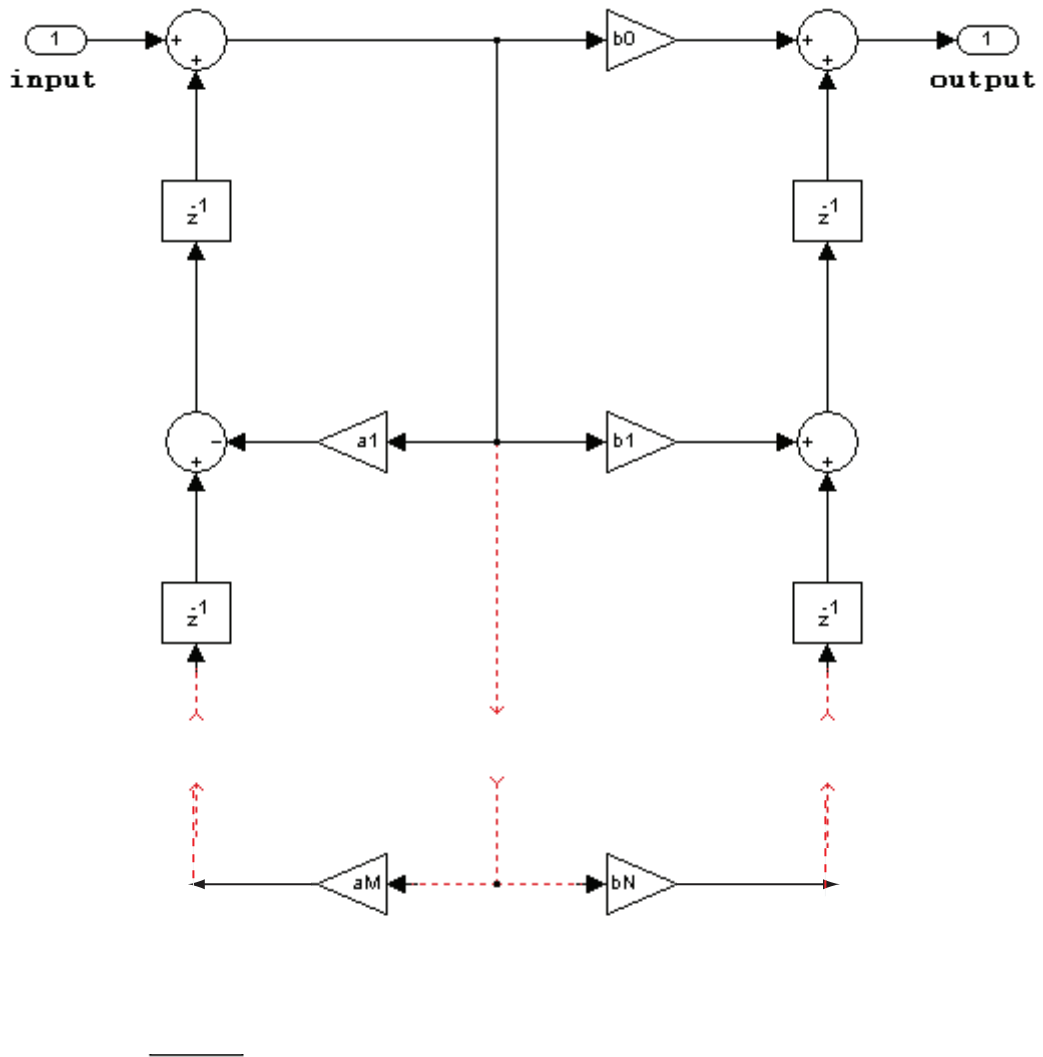

The following constraints apply when the Structure property is set to 'Direct form I':

- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.

- Numerator and denominator coefficients must have the same complexity characteristics. When the numerator and denominator coefficients have different complexities from each other, the object processes the filter as if two sets of complex coefficients are provided. The real-valued coefficient set is treated as if it is a complex vector with zero-valued imaginary parts.
- The State data type cannot be specified for this structure. Doing so is not possible because the input and output states have the same data types as the input and output buffers.

The following constraints apply when the Structure property is set to 'Direct form I transposed':

- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.

- Numerator and denominator coefficients must have the same complexity characteristics. When the numerator and denominator coefficients have different complexities from each other, the object processes the filter as if two sets of complex coefficients are provided. The real-valued coefficient set is treated as if it is a complex vector with zero-valued imaginary parts.
- States are complex when either the input or the coefficients are complex.

4 System Objects — Alphabetical List

Introduced in R2012b

dsp.IIRHalfbandDecimator System object

Package: dsp

Decimate by factor of two using polyphase IIR

Description

`dsp.IIRHalfbandDecimator` performs efficient polyphase decimation of the input signal by a factor of two. To design the halfband filter, you can specify the object to use an elliptic design or a quasi-linear phase design. The object uses these design methods to compute the filter coefficients. To filter the inputs, the object uses a polyphase structure. The allpass filters in the polyphase structure are in a minimum multiplier form.

Elliptic design introduces nonlinear phase and creates the filter using fewer coefficients than quasi linear design. Quasi-linear phase design overcomes phase nonlinearity at the cost of additional coefficients.

Alternatively, instead of designing the halfband filter using a design method, you can specify the filter coefficients directly. When you choose this option, the allpass filters in the two branches of the polyphase implementation can be in a minimum multiplier form or in a wave digital form.

You can also use the `dsp.IIRHalfbandDecimator` object to implement the analysis portion of a two-band filter bank to filter a signal into lowpass and highpass subbands. This object supports ARM Cortex code generation.

To filter and downsample your data:

- 1 Define and set up your halfband decimator. See “Construction” on page 4-1036.
- 2 Call `step` to filter the input signal according to the properties of `dsp.IIRHalfbandDecimator`. The input signal can be a real- or complex-valued column vector or matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel. The number of rows in the input signal must be a multiple of 2.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a

function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`IIRHalfbandDecim = dsp.IIRHalfbandDecimator` returns a halfband decimator, `IIRHalfbandDecim`, with the default settings. Calling `step` with the default property settings filters and downsamples the input data with a halfband frequency of 11025 Hz, a transition width of 4100 Hz, and a stopband attenuation of 80 dB.

`IIRHalfbandDecim = dsp.IIRHalfbandDecimator(Name,Value)` sets each property `Name` to the specified `Value`. Unspecified properties have default values.

Properties

Specification — Filter design parameters

```
'Transition width and stopband attenuation' (default) | 'Filter order and  
stopband attenuation' | 'Filter order and transition width' |  
'Coefficients'
```

Filter design parameters, specified as a character vector. When you set `Specification` to one of the filter design options, you can specify the filter design parameters using the corresponding `FilterOrder`, `StopbandAttenuation`, and `TransitionWidth` properties. Also, you can specify the design method using `DesignMethod`. When you set `Specification` to `'Coefficients'`, you can specify the coefficients directly.

FilterOrder — Order of the IIR halfband filter

```
9 (default) | positive scalar integer
```

Order of the IIR halfband filter, specified as a positive scalar integer. If you set `DesignMethod` to `'Elliptic'`, then `FilterOrder` must be an odd integer greater than one. If you set `DesignMethod` to `'Quasi-linear phase'`, then `FilterOrder` must be a multiple of four. This property applies when you set `Specification` to `'Filter order and stopband attenuation'` or `'Filter order and transition width'`.

StopbandAttenuation — Minimum attenuation needed in stopband

```
80 (default) | positive real scalar
```

Minimum attenuation needed in the stopband of the IIR halfband filter, specified as a positive real scalar. Units are in dB. This property applies only when you set `Specification` to 'Filter order and stopband attenuation' or 'Transition width and stopband attenuation'.

TransitionWidth — Transition width

4100 (default) | positive real scalar

Transition width of the IIR halfband filter, specified as a positive real scalar. Units are in Hz. The value of the transition width must be less than half the input sample rate. This property applies only when you set `Specification` to 'Transition width and stopband attenuation' or 'Filter order and transition width'.

DesignMethod — Design method

'Elliptic' (default) | 'Quasi-linear phase'

Design method for the IIR halfband filter, specified as 'Elliptic' or 'Quasi-linear phase'. When the property is set to 'Quasi-linear phase', the first branch of the polyphase structure is a pure delay, which results in an approximately linear phase response. This property applies only when you set `Specification` to any accepted value except 'Coefficients'.

SampleRate — Input sample rate

44100 (default) | positive real scalar

Input sample rate, specified as a positive real scalar. Units are in Hz. This property applies only when you set `Specification` to any accepted value except 'Coefficients'.

Structure — Internal allpass filter implementation structure

'Minimum multiplier' (default) | 'Wave Digital Filter'

Internal allpass filter implementation structure, specified as 'Minimum multiplier' or 'Wave Digital Filter'. This property applies only when you set 'Specification' to 'Coefficients'. Each structure uses a different coefficients set, independently stored in the corresponding object property.

This property is not tunable.

AllpassCoefficients1 — Allpass polynomial filter coefficients of first branch

[0.1284563; 0.7906755] (default) | [0.1284563 0.1534; 0.7906755 0.6745]

Allpass polynomial filter coefficients of the first branch, specified as an N -by-1 or N -by-2 matrix. N is the number of first-order or second-order allpass sections. This property applies only when you set `Specification` to 'Coefficients' and `Structure` to 'Minimum multiplier'.

This property is tunable.

AllpassCoefficients2 — Allpass polynomial filter coefficients of second branch

[0.4295667] (default) | [0.7906755 0.1534]

Allpass polynomial filter coefficients of the second branch, specified as an N -by-1 or N -by-2 matrix. N is the number of first-order or second-order allpass sections. This property applies only when you set `Specification` to 'Coefficients' and `Structure` to 'Minimum multiplier'.

This property is tunable.

WDFCoefficients1 — Allpass filter coefficients of first branch in Wave Digital Filter form

[0.1284563; 0.7906755] (default) | [0.1284563 0.1534; 0.7906755 0.6745]

Allpass filter coefficients of the first branch in Wave Digital Filter form, specified as an N -by-1 or N -by-2 matrix. N is the number of first-order or second-order allpass sections. This property applies only when you set `Specification` to 'Coefficients' and `Structure` to 'Wave Digital Filter'. Each element must have an absolute value less than or equal to 1.

This property is not tunable.

WDFCoefficients2 — Allpass filter coefficients of second branch in Wave Digital Filter form

[0.4295667] (default) | [0.7906755 0.1534]

Allpass filter coefficients of the second branch in Wave Digital Filter form, specified as the comma-separated pair consisting of 'WDFCoefficients2' and a N -by-1 or N -by-2 matrix. N is the number of first-order or second-order allpass sections. This property applies only when you set 'Specification' to 'Coefficients' and 'Structure' to 'Wave Digital Filter'. Each element must have an absolute value less than or equal to 1.

This property is not tunable.

HasPureDelayBranch — Make first branch a pure delay`false (default) | true`

Flag to make the first allpass branch a delay, specified as a logical scalar. This property applies only when you set `Specification` to `'Coefficients'`. When this property is true, the first branch is treated as a pure delay and the properties `AllpassCoefficients1` and `WDFCoefficients1` do not apply.

This property is not tunable.

Delay — Length of delay`1 (default) | finite positive scalar`

Length of the first branch delay, specified as a finite positive scalar. This property applies only when you set `Specification` to `'Coefficients'` and `HasPureDelayBranch` to 1. The value of this property specifies the number of samples by which you can delay the input to the first branch.

This property is not tunable.

HasTrailingFirstOrderSection — Treat the last section of the second branch as first order`false (default) | true`

Option to treat the last section of the second branch as first order, specified as a logical scalar. This property applies only when you set `Specification` to `'Coefficients'`. When this property is 1 and the coefficients of the second branch are in an N -by-2 matrix, the object ignores the second element of the last row of the matrix. The last section of the second branch then becomes a first-order section. When this property is set to 0, the last section of the second branch is a second-order section. When the coefficients of the second branch are in an N -by-1 matrix, this property is ignored.

This property is not tunable.

Methods

<code>reset</code>	Reset internal states of IIR halfband decimator
<code>step</code>	Filter input with IIR halfband decimator

For additional methods, see “Analysis Methods for Filter System Objects” on page 3-2.

For a complete list of analysis methods supported for the `dsp.IIRHalfbandDecimator` object, enter `dsp.IIRHalfbandDecimator.helpFilterAnalysis` at the MATLAB command prompt.

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

Frequency Response of Quasi-Linear Phase IIR Halfband Decimator

Create a minimum-order lowpass IIR halfband decimation filter for data sampled at 44.1 kHz. The filter has a transition width of 4.1 kHz, and a stopband attenuation of 80 dB.

```
IIRHalfbandDecim = dsp.IIRHalfbandDecimator(...
    'DesignMethod', 'Quasi-linear phase');
```

Obtain the filter coefficients.

```
c = coeffs(IIRHalfbandDecim);
```

Plot the magnitude and phase response.

```
fvtool(IIRHalfbandDecim, 'Analysis', 'freq')
```

Extract Low Frequency Subband from Speech

Use a halfband analysis filter bank and interpolation filter to extract the low frequency subband from a speech signal.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Set up the audio file reader, the analysis filter bank, the audio device writer, and the interpolation filter. The sampling rate of the audio data is 22050 Hz. The halfband filter has an order of 21 and a transition width of 2 kHz.

```
afr = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);

filterspec = 'Filter order and transition width';
Order = 21;
TW = 2000;

IIRHalfbandDecim = dsp.IIRHalfbandDecimator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',afr.SampleRate);

IIRHalfbandInterp = dsp.IIRHalfbandInterpolator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',afr.SampleRate/2);

ap = audioDeviceWriter('SampleRate',afr.SampleRate);
```

View the magnitude response of the halfband filter.

```
fvtool(IIRHalfbandDecim)
```

Read the speech signal from the audio file in frames of 1024 samples. Filter the speech signal into lowpass and highpass subbands with a halfband frequency of 5512.5 Hz. Reconstruct a lowpass approximation of the speech signal by interpolating the lowpass subband. Play the filtered output.

```
while ~isDone(afr)
    audioframe = afr();
    xlo = IIRHalfbandDecim(audioframe);
    ylow = IIRHalfbandInterp(xlo);
    ap(ylow);
end
```

Wait until the audio file ends, and then close the input file and release the audio output resource.

```
release(afr);  
release(ap);
```

Two-Channel Filter Bank

Use a halfband decimator and interpolator to implement a two-channel filter bank. This example uses an audio file input and shows that the power spectrum of the filter bank output does not differ significantly from the input.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

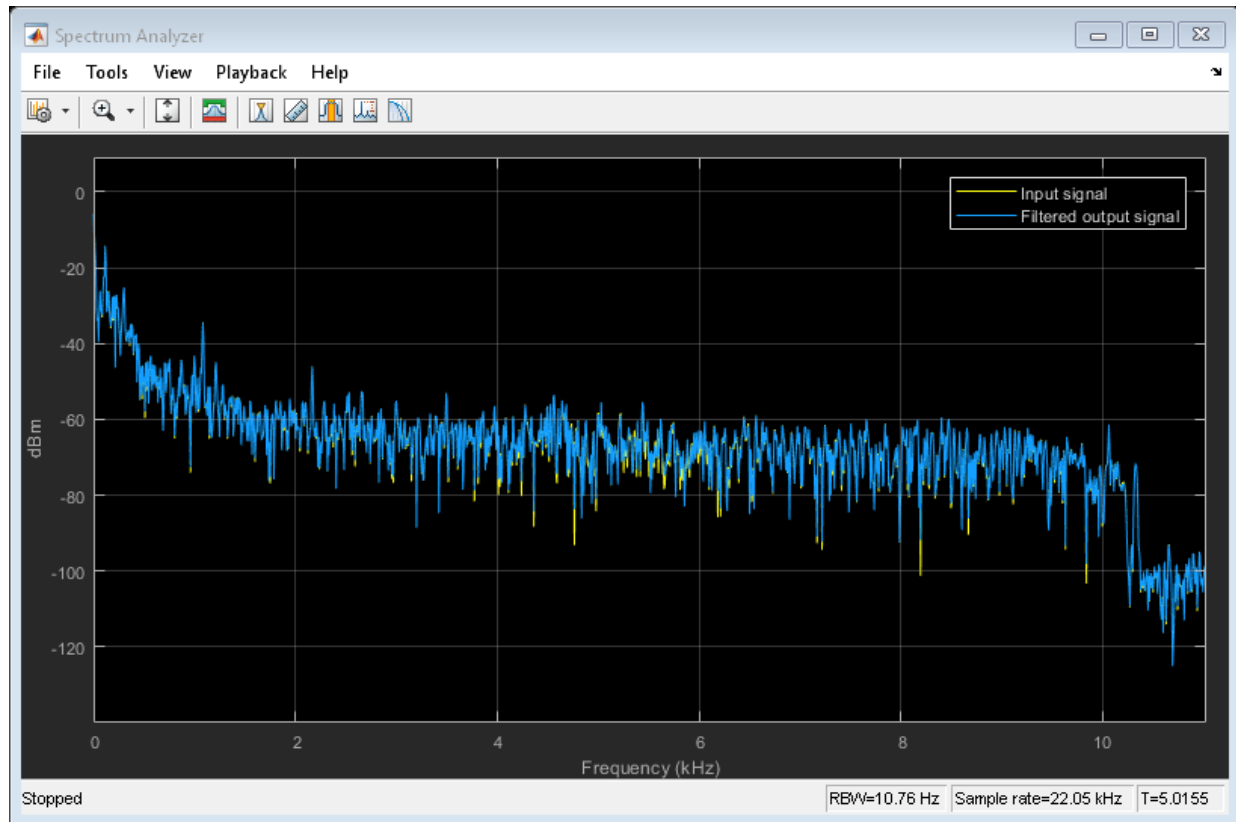

Set up the audio file reader and audio device writer. Construct the IIR halfband decimator and interpolator. Finally, set up the spectrum analyzer to display the power spectra of the filter-bank input and output.

```
AF = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);  
AP = audioDeviceWriter('SampleRate',AF.SampleRate);  
  
filterspec = 'Filter order and transition width';  
Order = 51;  
TW = 2000;  
  
IIRHalfbandDecim = dsp.IIRHalfbandDecimator(...  
    'Specification',filterspec,'FilterOrder',Order,...  
    'TransitionWidth',TW,'SampleRate',AF.SampleRate);  
  
IIRHalfbandInterp = dsp.IIRHalfbandInterpolator(...  
    'Specification',filterspec,'FilterOrder',Order,...  
    'TransitionWidth',TW,'SampleRate',AF.SampleRate/2,...  
    'FilterBankInputPort',true);  
  
SpecAna = dsp.SpectrumAnalyzer('SampleRate',AF.SampleRate,...  
    'PlotAsTwoSidedSpectrum',false,'ReducePlotRate',false,...  
    'ShowLegend',true,...  
    'ChannelNames',{'Input signal','Filtered output signal'});
```

Read the audio 1024 samples at a time. Filter the input to obtain the lowpass and highpass subband signals decimated by a factor of two. This is the analysis filter bank. Use the halfband interpolator as the synthesis filter bank. Display the running power spectrum of the audio input and the output of the synthesis filter bank. Play the output.

```
while ~isDone(AF)
    audioInput = AF();
    [xlo,xhigh] = IIRHalfbandDecim(audioInput);
    audioOutput = IIRHalfbandInterp(xlo,xhigh);
    spectrumInput = [audioInput audioOutput];
    SpecAna(spectrumInput);
    AP(audioOutput);
end

release(AF);
release(AP);
release(SpecAna);
```

Algorithms

Polyphase Implementation with Halfband Filters

When you call `step` to filter your signal, `dsp.IIRHalfbandDecimator` uses an efficient polyphase implementation for halfband filters. You can use the polyphase implementation to move the downsample operation before filtering. This change enables you to filter at the lower sampling rate.

IIR halfband filters are generally modeled using two parallel allpass filter branches.

$$H(z) = 0.5 * [A_1(z^2) + z^{-1}A_2(z^2)]$$

Elliptic Design

The allpass filters for elliptic IIR halfband filter are given as

$$A_1(z) = \prod_{k=1}^{K_1} \frac{a_k^{(1)} + z^{-1}}{1 + a_k^{(1)} z^{-1}}$$

$$A_2(z) = \prod_{k=1}^{K_2} \frac{a_k^{(2)} + z^{-1}}{1 + a_k^{(2)} z^{-1}}$$

Quasi-Linear Phase Design

To achieve a near-linear phase response for IIR halfband filters, make one of the branches a pure delay. In this design, the cost of the filter increases.

The allpass filters for the quasi-linear phase IIR halfband filter are

$$A_1(z) = z^{-k}$$

where k is the length of the delay.

$$A_2(z) = \prod_{k=1}^{K_2^{(1)}} \frac{a_k + z^{-1}}{1 + a_k z^{-1}} \prod_{k=1}^{K_2^{(2)}} \frac{c_k + b_k z^{-1} + z^{-2}}{1 + b_k z^{-1} + c_k z^{-2}}$$

where N is the order of the IIR halfband filter.

This figure represents filtering and downsampling the input by two.

Using the multirate noble identity for downsampling, you can move the downsampling operation before filtering. This change enables you to filter at the lower rate.

To implement the halfband decimator efficiently, `dsp.IIRHalfbandDecimator` replaces the delay block and downsampling operator with a commutator switch.

Analysis Filter Bank

The transfer function of the complementary highpass filter branch of the analysis filter bank is given by

$$G(z) = 0.5 * [A_1(z^2) - z^{-1} A_2(z^2)]$$

Graphically, you can represent the analysis filter bank as follows.

`dsp.IIRHalfbandDecimator` generates two power-complementary output signals by adding and subtracting the two polyphase branch outputs respectively.

To summarize, `dsp.IIRHalfbandDecimator`

- Decimates the input prior to filtering.
- Acts as an analysis filter bank.
- Has non-linear phase response and uses few coefficients with elliptic design method.
- Has near-linear phase response at the cost of additional coefficients with quasi-linear phase design method. One of the branches in this design is a pure delay.

System object: dsp.IIRHalfbandDecimator

Package: dsp

Reset internal states of IIR halfband decimator

Syntax

```
reset(IIRHalfbandDecim)
```

Description

`reset(IIRHalfbandDecim)` resets the filter states of the IIR halfband decimator to their initial values of 0. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the `step` method applies the halfband decimator to nonzero input data, the filter might have nonzero states. If you invoke the `step` method again without first invoking the `reset` method, the object might produce different outputs for an identical input.

Input Arguments

IIRHalfbandDecim — IIR halfband decimator

`IIRHalfbandDecimator` System object

IIR halfband decimator, specified as an `IIRHalfbandDecimator` System object.

Examples

Reset an IIR Halfband Decimator

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Create an IIR halfband decimator with default properties.

```
IIRHalfbandDecim = dsp.IIRHalfbandDecimator;
```

Create a two-channel random signal. Apply the `step` method twice on the signal.

```
x = randn(10,2);
```

```
y1 = IIRHalfbandDecim(x);
```

```
y2 = IIRHalfbandDecim(x);
```

```
no = all(y2==y1)
```

```
no =
```

```
1x2 logical array
```

```
0 0
```

The output is different because the internal states of `IIRHalfbandDecim` have changed. Use `reset` to reset the IIR halfband decimator and apply `step` again. Verify that the output is unchanged.

```
reset(IIRHalfbandDecim)
```

```
y3 = IIRHalfbandDecim(x);
```

```
yes = all(y3==y1)
```

```
y3 =

step

System object: dsp.IIRHalfbandDecimator

Package: dsp

Filter input with IIR halfband decimator

Syntax

```
Y = step(IIRHalfbanddecim,X)
[Ylow,Yhigh] = step(IIRHalfbanddecim,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(IIRHalfbanddecim,X)` filters the real or complex input signal, `X`, using the IIR halfband filter, `hiirhalfbanddecim`, and downsamples the output by a factor of 2. `Y` is a lowpass filtered and downsampled version of the input `X`. The input `X` must be a column vector or matrix with an even number of rows. If `X` is a matrix, each column is treated as an independent channel. The input `X` supports single and double data types.

`[Ylow,Yhigh] = step(IIRHalfbanddecim,X)` computes the `Ylow` and `Yhigh`, of the analysis filter bank, `IIRHalfbanddecim` for input `X`. A K_i -by- N input matrix is treated as N independent channels. The System object generates two power-complementary output signals by adding and subtracting the two polyphase branch outputs respectively. `Ylow` and `Yhigh` are of the same size (K_o -by- N) and data type. $K_o = K_i/2$, where 2 is the decimation factor.

Examples

Filter Input into Lowpass and Highpass Subbands

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Create a halfband decimator for data sampled at 44.1 kHz. Use a minimum-order design with a transition width of 2 kHz and a stopband attenuation of 60 dB.

```
IIRHalfbanddecim = dsp.IIRHalfbandDecimator(...  
    'Specification','Transition width and stopband attenuation',...  
    'TransitionWidth',2000,'StopbandAttenuation',60,'SampleRate',44.1e3);
```

Filter a two-channel input into lowpass and highpass subbands.

```
x = randn(1024,2);  
[y_low,y_high] = IIRHalfbanddecim(x);
```

Introduced in R2015b

dsp.IIRHalfbandInterpolator System object

Package: dsp

Interpolate by a factor of two using polyphase IIR

Description

`dsp.IIRHalfbandInterpolator` performs efficient polyphase interpolation of the input signal by a factor of two. To design the halfband filter, you can specify the object to use an elliptic design or a quasi-linear phase design. The object uses these design methods to compute the filter coefficients. To filter the inputs, the object uses a polyphase structure. The allpass filters in the polyphase structure are in a minimum multiplier form.

Elliptic design introduces nonlinear phase and creates the filter using fewer coefficients than quasi linear design. Quasi-linear phase design overcomes phase nonlinearity at the cost of additional coefficients.

Alternatively, instead of designing the halfband filter using a design method, you can specify the filter coefficients directly. When you choose this option, the allpass filters in the two branches of the polyphase implementation can be in a minimum multiplier form or in a wave digital form.

You can also use `dsp.IIRHalfbandInterpolator` object to implement the synthesis portion of a two-band filter bank to synthesize a signal from lowpass and highpass subbands. This object supports ARM Cortex code generation.

To upsample and interpolate your data:

- 1 Define and set up your halfband interpolator. See “Construction” on page 4-1057.
- 2 Call `step` to filter the input signal according to the properties of `dsp.IIRHalfbandInterpolator`. The input signal can be a real- or complex-valued column vector or matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a

function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`IIRHalfbandInterp = dsp.IIRHalfbandInterpolator` returns an IIR halfband interpolation filter, `IIRHalfbandInterp`, with the default settings. Calling `step` with the default property settings upsamples and interpolates the input data using a halfband frequency of 11025 Hz, a transition width of 4100 Hz, and a stopband attenuation of 80 dB.

`IIRHalfbandInterp = dsp.IIRHalfbandInterpolator(Name,Value)` sets each property `Name` to the specified `Value`. Unspecified properties have default values.

Properties

Specification — Filter design parameters

'Transition width and stopband attenuation' (default) | 'Filter order and stopband attenuation' | 'Filter order and transition width' | 'Coefficients'

Filter design parameters, specified as a character vector. When you set `Specification` to one of the filter design options, you can specify the filter design parameters using the corresponding `FilterOrder`, `StopbandAttenuation`, and `TransitionWidth` properties. Also, you can specify the design method using `DesignMethod`. When you set `Specification` to 'Coefficients', you can specify the coefficients directly.

FilterOrder — Order of the IIR halfband filter

9 (default) | positive scalar integer

Order of the IIR halfband filter, specified as a positive scalar integer. If you set `DesignMethod` to 'Elliptic', then `FilterOrder` must be an odd integer greater than one. If you set `DesignMethod` to 'Quasi-linear phase', then `FilterOrder` must be a multiple of four. This property applies when you set `Specification` to 'Filter order and stopband attenuation' or 'Filter order and transition width'.

StopbandAttenuation — Minimum attenuation needed in stopband

80 (default) | positive real scalar

Minimum attenuation needed in the stopband of the IIR halfband filter, specified as a positive real scalar. Units are in dB. This property applies only when you set `Specification` to 'Filter order and stopband attenuation' or 'Transition width and stopband attenuation'.

TransitionWidth — Transition width

4100 (default) | positive real scalar

Transition width of the IIR halfband filter, specified as a positive real scalar. Units are in Hz. The value of the transition width must be less than half the input sample rate. This property applies only when you set `Specification` to 'Transition width and stopband attenuation' or 'Filter order and transition width'.

DesignMethod — Design method

'Elliptic' (default) | 'Quasi-linear phase'

Design method for the IIR halfband filter, specified as 'Elliptic' or 'Quasi-linear phase'. When the property is set to 'Quasi-linear phase', the first branch of the polyphase structure is a pure delay, which results in an approximately linear phase response. This property applies only when you set `Specification` to any accepted value except 'Coefficients'.

SampleRate — Input sample rate

44100 (default) | positive real scalar

Input sample rate, specified as a positive real scalar. Units are in Hz. This property applies only when you set `Specification` to any accepted value except 'Coefficients'.

FilterBankInputPort — Option to use object as synthesis filter bank

false (default) | true

Option to use object as synthesis filter bank, specified as a logical value. If this property is false, `dsp.IIRHalfbandInterpolator` acts as an interpolator. If this property is true, then `dsp.IIRHalfbandInterpolator` acts as a synthesis filter bank and `step` accepts two inputs: the lowpass and highpass subbands. This property applies only when you set `Specification` to any accepted value except 'Coefficients'.

Structure — Filter structure used in coefficient mode

'Minimum multiplier' (default) | 'Wave Digital Filter'

Internal allpass filter implementation structure, specified as 'Minimum multiplier' or 'Wave Digital Filter'. This property applies only when you set 'Specification' to 'Coefficients'. Each structure uses a different coefficients set, independently stored in the corresponding object property.

This property is not tunable.

AllpassCoefficients1 — Allpass polynomial filter coefficients of first branch

[0.1284563; 0.7906755] (default) | [0.1284563 0.1534; 0.7906755 0.6745]

Allpass polynomial filter coefficients of the first branch, specified as an N -by-1 or N -by-2 matrix. N is the number of first-order or second-order allpass sections. This property applies only when you set Specification to 'Coefficients' and Structure to 'Minimum multiplier'.

This property is tunable.

AllpassCoefficients2 — Allpass polynomial filter coefficients of second branch

[0.4295667] (default) | [0.7906755 0.1534]

Allpass polynomial filter coefficients of the second branch, specified as an N -by-1 or N -by-2 matrix. N is the number of first-order or second-order allpass sections. This property applies only when you set Specification to 'Coefficients' and Structure to 'Minimum multiplier'.

This property is tunable.

WDFCoefficients1 — Allpass filter coefficients of first branch in Wave Digital Filter form

[0.1284563; 0.7906755] (default) | [0.1284563 0.1534; 0.7906755 0.6745]

Allpass filter coefficients of the first branch in Wave Digital Filter form, specified as an N -by-1 or N -by-2 matrix. N is the number of first-order or second-order allpass sections. This property applies only when you set Specification to 'Coefficients' and Structure to 'Wave Digital Filter'. All elements must have an absolute value less than or equal to 1.

This property is not tunable.

WDFCoefficients2 — Allpass filter coefficients of second branch in Wave Digital Filter form

[0.4295667] (default) | [0.7906755 0.1534]

Allpass filter coefficients of the second branch in Wave Digital Filter form, specified as an N -by-1 or N -by-2 matrix. N is the number of first-order or second-order allpass sections. This property applies only when you set `Specification` to 'Coefficients' and `Structure` to 'Wave Digital Filter'. All elements must have an absolute value less than or equal to 1.

This property is not tunable.

HasPureDelayBranch — Make the first branch a pure delay

false (default) | true

Flag to make the first allpass branch a delay, specified as a logical scalar. This property applies only when you set `Specification` to 'Coefficients'. When this property is true, the first branch is treated as a pure delay and the properties `AllpassCoefficients1` and `WDFCoefficients1` do not apply.

This property is not tunable.

Delay — Length of the delay

1 (default) | finite positive scalar

Length of the first branch delay, specified as a finite positive scalar. This property is applicable only when you set 'Specification' to 'Coefficients' and `HasPureDelayBranch` to 1. The value of this property specifies the number of samples by which you can delay the input to the first branch.

This property is not tunable.

HasTrailingFirstOrderSection — Make the last section of the second branch as first order

false (default) | true

Option to treat the last section of the second branch as first order, specified as a logical scalar. This property applies only when you set `Specification` to 'Coefficients'. When this property is 1 and the coefficients of the second branch are in an N -by-2 matrix, the object ignores the second element of the last row of the matrix. The last section of the second branch then becomes a first-order section. When this property is set to 0, the last section of the second branch is a second-order section. When the coefficients of the second branch are in an N -by-1 matrix, this property is ignored.

This property is not tunable.

Examples

Frequency response of Quasi-linear Phase IIR Halfband Interpolator

Create a minimum order lowpass IIR half-band interpolation filter for data sampled at 44.1 kHz. The filter has a transition width of 4.1 kHz, and a stopband attenuation of 80 dB.

```
IIRHalfbandInterp = dsp.IIRHalfbandInterpolator(...
    'DesignMethod', 'Quasi-linear phase');
```

Obtain filter coefficients

```
c = coeffs(IIRHalfbandInterp);
```

Plot the Magnitude and Phase response

```
fvtool(IIRHalfbandInterp, 'Analysis', 'freq')
```

Extract Low Frequency Subband from Speech

Use a halfband analysis filter bank and interpolation filter to extract the low frequency subband from a speech signal.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Set up the audio file reader, the analysis filter bank, the audio device writer, and the interpolation filter. The sampling rate of the audio data is 22050 Hz. The halfband filter has an order of 21 and a transition width of 2 kHz.

```
afr = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);

filterspec = 'Filter order and transition width';
Order = 21;
TW = 2000;

IIRHalfbandDecim = dsp.IIRHalfbandDecimator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',afr.SampleRate);

IIRHalfbandInterp = dsp.IIRHalfbandInterpolator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',afr.SampleRate/2);

ap = audioDeviceWriter('SampleRate',afr.SampleRate);
```

View the magnitude response of the halfband filter.

```
fvtool(IIRHalfbandDecim)
```

Read the speech signal from the audio file in frames of 1024 samples. Filter the speech signal into lowpass and highpass subbands with a halfband frequency of 5512.5 Hz. Reconstruct a lowpass approximation of the speech signal by interpolating the lowpass subband. Play the filtered output.

```
while ~isDone(afr)
    audioframe = afr();
    xlo = IIRHalfbandDecim(audioframe);
    ylow = IIRHalfbandInterp(xlo);
    ap(ylow);
end
```

Wait until the audio file ends, and then close the input file and release the audio output resource.

```
release(afr);
release(ap);
```

Two-Channel Filter Bank

Use a halfband decimator and interpolator to implement a two-channel filter bank. This example uses an audio file input and shows that the power spectrum of the filter bank output does not differ significantly from the input.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Set up the audio file reader and audio device writer. Construct the IIR halfband decimator and interpolator. Finally, set up the spectrum analyzer to display the power spectra of the filter-bank input and output.

```
AF = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);
AP = audioDeviceWriter('SampleRate',AF.SampleRate);

filterspec = 'Filter order and transition width';
Order = 51;
TW = 2000;

IIRHalfbandDecim = dsp.IIRHalfbandDecimator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',AF.SampleRate);

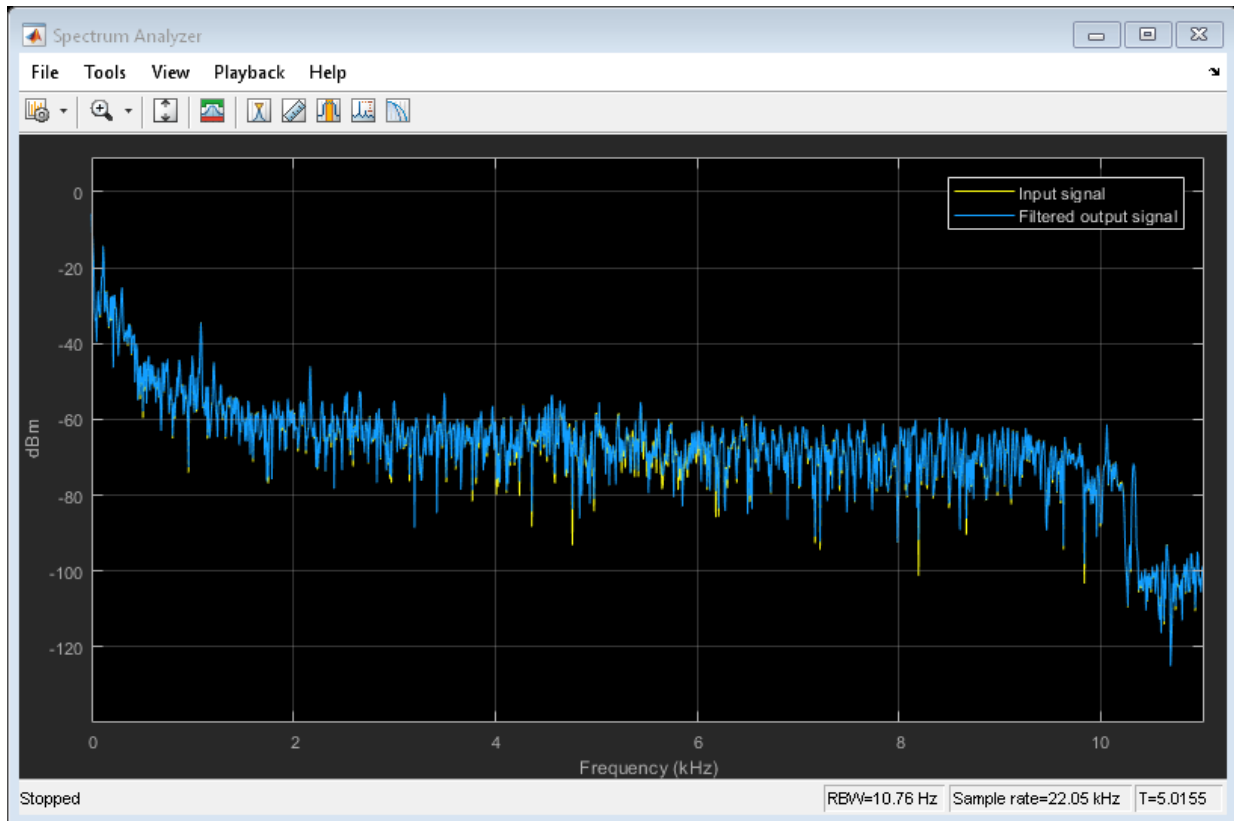

IIRHalfbandInterp = dsp.IIRHalfbandInterpolator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',AF.SampleRate/2,...
    'FilterBankInputPort',true);

SpecAna = dsp.SpectrumAnalyzer('SampleRate',AF.SampleRate,...
    'PlotAsTwoSidedSpectrum',false,'ReducePlotRate',false,...
    'ShowLegend',true,...
    'ChannelNames',{'Input signal','Filtered output signal'});
```

Read the audio 1024 samples at a time. Filter the input to obtain the lowpass and highpass subband signals decimated by a factor of two. This is the analysis filter bank. Use the halfband interpolator as the synthesis filter bank. Display the running power spectrum of the audio input and the output of the synthesis filter bank. Play the output.

```
while ~isDone(AF)
    audioInput = AF();
    [xlo,xhigh] = IIRHalfbandDecim(audioInput);
    audioOutput = IIRHalfbandInterp(xlo,xhigh);
    spectrumInput = [audioInput audioOutput];
    SpecAna(spectrumInput);
    AP(audioOutput);
end

release(AF);
release(AP);
release(SpecAna);
```

Algorithms

Polyphase Implementation with Halfband Filters

When you call `step` to filter your signal, `dsp.IIRHalfbandInterpolator` uses an efficient polyphase implementation for halfband filters. You can use a polyphase implementation to move the upsampling operation after filtering. This change enables you to filter at the lower sampling rate.

IIR halfband filters are generally modeled using two parallel allpass filter branches.

$$H(z) = 0.5 * [A_1(z^2) + z^{-1}A_2(z^2)]$$

Elliptic Design

The allpass filters for elliptic IIR halfband filter are given as

$$A_1(z) = \prod_{k=1}^{K_1} \frac{a_k^{(1)} + z^{-1}}{1 + a_k^{(1)} z^{-1}}$$

$$A_2(z) = \prod_{k=1}^{K_2} \frac{a_k^{(2)} + z^{-1}}{1 + a_k^{(2)} z^{-1}}$$

Quasi-Linear Phase Design

A near-linear phase response for IIR halfband filters is achieved by making one of the branches a pure delay. In this design, the cost of the filter increases.

The allpass filters for quasi-linear phase IIR halfband filter are

$$A_1(z) = z^{-k}$$

where, k is the length of the delay.

$$A_2(z) = \prod_{K=1}^{K_2^{(1)}} \frac{a_k + z^{-1}}{1 + a_k z^{-1}} \prod_{K=1}^{K_2^{(2)}} \frac{c_k + b_k z^{-1} + z^{-2}}{1 + b_k z^{-1} + c_k z^{-2}}$$

where N is the order of the IIR halfband filter.

Graphically, you can represent upsampling by two followed by filtering with the following figure

Using the multirate noble identity for upsampling, you can move the upsampling operation after filtering. This enables you to filter at the lower rate.

To efficiently implement the halfband interpolator, `dsp.IIRHalfbandInterpolator` replaces the upsampling operator, delay block, and adder with a commutator switch. The commutator switch operates at twice the input sample rate. This is shown in the following figure:

The commutator switch takes input samples from the two branches alternately, one sample at a time. This doubles the sampling rate of the input signal.

Synthesis Filter Bank

Transfer function of the complementary high-pass filter branch of the synthesis filter bank is given by

$$G(z) = 0.5 * [A_1(z^2) - z^{-1}A_2(z^2)]$$

Graphically, you can represent the synthesis filter bank as

`dsp.IIRHalfbandInterpolator` to implement the synthesis portion of a two-band filter bank to synthesize a signal from lowpass and highpass subbands.

To summarize, `dsp.IIRHalfbandInterpolator`

- Filters the input before upsampling
- acts as a synthesis filter bank
- has non-linear phase response and uses few coefficients with elliptic design method
- has near-linear phase response at the cost of additional coefficients with quasi-linear phase design method. One of the branches in this design is a pure delay.

reset

System object: `dsp.IIRHalfbandInterpolator`

Package: `dsp`

Reset internal states of IIR halfband interpolator

Syntax

```
reset(IIRHalfbandInterp)
```

Description

`reset(IIRHalfbandInterp)` resets the filter states of the IIR halfband interpolator, `IIRHalfbandInterp`, to their initial values of 0. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the `step` method applies the halfband interpolator to nonzero input data, the states may be nonzero. If you invoke the `step` method again without first invoking the `reset` method, the object might produce different outputs for an identical input.

Input Arguments

`IIRHalfbandInterp` — IIR halfband interpolator

`dsp.IIRHalfbandInterpolator` System object

IIR halfband interpolator, specified as a `dsp.IIRHalfbandInterpolator` System object.

Examples

Reset an IIR Halfband Interpolator

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Create an IIR halfband interpolator with default properties.

```
IIRHalfbandInterp = dsp.IIRHalfbandInterpolator;
```

Create a two-channel random signal. Apply the `step` method twice on the signal.

```
x = randn(10,2);
```

```
y1 = IIRHalfbandInterp(x);
```

```
y2 = IIRHalfbandInterp(x);
```

```
no = all(y2==y1)
```

```
no =
```

```
1x2 logical array
```

```
0 0
```

The output is different because the internal states of `IIRHalfbandInterp` have changed. Use `reset` to reset the IIR halfband interpolator and apply `step` again. Verify that the output is unchanged.

```
reset(IIRHalfbandInterp)
```

```
y3 = IIRHalfbandInterp(x);
```

```
yes = all(y3==y1)
```

```
yes =
```

```
1x2 logical array
```

1 1

step

System object: dsp.IIRHalfbandInterpolator

Package: dsp

Filter input with IIR halfband interpolator

Syntax

```
Y = step(IIRHalfbandInterp,X)
Y = step(hiirhalfbandinterp,X1,X2)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(IIRHalfbandInterp,X)` upsamples by two and interpolates the real or complex input signal `X` using the IIR halfband interpolator, `hfirhalfbandinterp`. The input `X` must be a column vector or matrix. If `X` is a matrix, each column is treated as an independent channel. The input `X` supports single, and double data types.

`Y = step(hiirhalfbandinterp,X1,X2)` implements a halfband synthesis filter bank for the inputs `X1` and `X2`. `X1` is the lowpass output of a halfband analysis filter bank and `X2` is the highpass output of a halfband analysis filter bank.

`dsp.IIRHalfbandInterpolator` implements a synthesis filter bank only when the `FilterBankInputPort` property is `true`.

Examples

Upsample and Interpolate Multichannel Input with IIR Halfband Interpolator

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Create a half-band interpolation filter for data sampled at 44.1 kHz. The filter order is 51 with a transition width of 4.1 kHz. Use the filter to upsample and interpolate a multichannel input.

```
Fs = 44.1e3;
filterspec = 'Filter order and transition width';
Order = 51;
TW = 4.1e3;
iirhalfbandinterp = dsp.IIRHalfbandInterpolator(...
    'Specification', filterspec, ...
    'FilterOrder', Order, ...
    'TransitionWidth', TW, ...
    'SampleRate', Fs);

x = randn(1024, 4);
y = iirhalfbandinterp(x);
```

dsp.Interpolator System object

Package: dsp

Linear or polyphase FIR interpolation

Description

The `dsp.Interpolator` System object interpolates values between real-valued input samples using linear or polyphase FIR interpolation. Specify which values to interpolate by providing a vector of interpolation points. An interpolation point of 1 refers to the first sample in the input. To interpolate the value halfway between the second and third sample in the input, specify an interpolation point of 2.5. Interpolation points that are not within the valid range are replaced with the closest value in the valid range.

To interpolate a real-valued input signal:

- 1 Create the `dsp.Interpolator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#) (MATLAB).

Creation

Syntax

```
interp = dsp.Interpolator  
interp = dsp.Interpolator(Name,Value)
```

Description

`interp = dsp.Interpolator` creates an interpolation System object, `interp`, to interpolate values between real-valued input samples using linear interpolation.

`interp = dsp.Interpolator(Name, Value)` creates an interpolation System object, `interp`, with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `interp = dsp.Interpolator('InterpolationPointsSource', 'Input port')`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects \(MATLAB\)](#).

InterpolationPointsSource — Source of interpolation points

'Property' (default) | 'Input port'

Method to specify the interpolation points, specified as one of the following:

- 'Property' — Specify the interpolation points through the “InterpolationPoints” on page 4-0 property.
- 'Input port' — Pass the interpolation points as an input to the System object algorithm.

InterpolationPoints — Interpolation points

[1.1;4.8;2.67;1.6;3.2] (default) | vector | matrix | *N*-D array

Interpolation points, specified as a vector, matrix, or an *N*-D array. The valid range of the values in the interpolation vector is from 1 to the number of samples in each channel of the input. If you specify interpolation points outside the valid range, the object *clips* the point to the nearest point in the valid range. For example, if the input is [2; 3.1; -2.1], the valid range of interpolation points is from 1 to 3. If you specify a [-1; 1.5; 2; 2.5; 3; 3.5] vector of interpolation points, the interpolator object clips -1 to 1 and 3.5 to 3. This clipping results in the interpolation points [1 1.5 2 2.5 3 3].

For details on the dimension of the interpolation points array and how that influences the dimension of the output, see the tables in the “`ipts`” on page 4-0 input of the System object.

Tunable: Yes

Dependencies

This property applies only when you set the “`InterpolationPointsSource`” on page 4-0 property to 'Property'.

Method — Interpolation method

'Linear' (default) | 'FIR'

Interpolation method, specified as one of the following:

- 'Linear' — The object interpolates data values by assuming that the data varies linearly between samples taken at adjacent sample times.
- 'FIR' — The object uses polyphase interpolation to replace filtering (convolution) at the upsampled rate with a series of convolutions at the lower rate. If the input has insufficient low-rate samples to perform FIR interpolation, the interpolator object performs linear interpolation. For more details, see the “`FilterHalfLength`” on page 4-0 property.

FilterHalfLength — Half-length of interpolation filter

3 (default) | integer scalar greater than 0

For a filter half-length of P , the polyphase FIR subfilters have length $2P$. FIR interpolation always requires $2P$ low-rate samples for every interpolation point.

- If the interpolation point does not correspond to a low-rate sample, FIR interpolation requires P low-rate samples below and P low-rate samples above the interpolation point.
- If the interpolation point corresponds to a low-rate sample, the $2P$ -sample requirement includes the low-rate sample.
- If the input has less than $2P$ neighboring low-rate samples, the interpolator object uses linear interpolation.

For example, for an input `[1 4 1 4 1 4 1 4]`, upsampling by a factor of 4 results in equally spaced interpolation points, `InterP = [1:0.25:8]`. The points `InterP(9:12)` are `[3.0 3.25 3.5 3.75]`. If you set `FilterHalfLength` to 2, interpolating at these

points uses the 4 low-rate samples from the input with indices (2, 3, 4, 5). If you set `FilterHalfLength` to 4, the interpolator object uses linear interpolation, because the input does not have enough low-rate samples to perform FIR interpolation.

The longer the `FilterHalfLength` property, the better the quality of the interpolation. However, increasing the filter half-length increases computation time and requires more low-rate samples below and above the interpolation point. In general, setting the `FilterHalfLength` property between 4 and 6 provides a reasonably accurate interpolation.

Dependencies

This property applies only when you set the “Method” on page 4-0 property to 'FIR'.

InterpolationPointsPerSample — Upsampling factor

3 (default) | integer scalar greater than 0

Upsampling factor, specified as an integer scalar greater than 0. An upsampling factor of L inserts $L - 1$ zeros between low-rate samples. Interpolation results from filtering the upsampled sequence with a lowpass anti-imaging filter. The interpolator object uses a polyphase FIR implementation with `InterpolationPointsPerSample` subfilters of length $2P$, where P is the value you specify in the “FilterHalfLength” on page 4-0 property. For nL low-rate samples in the upsampled input, where $n=1,2,\dots$, the interpolator object uses exactly one of the `InterpolationPointsPerSample` subfilters to interpolate at the points $nL+i/L$, where $i = 0, 1, 2, \dots, L - 1$.

If you specify interpolation points that do not correspond to a polyphase subfilter, the object rounds the point down to the nearest interpolation point associated with a polyphase subfilter. Suppose you set the `InterpolationPointsPerSample` property to 4 and interpolate at the points [3 3.2 3.4 3.6 3.8]. The interpolator object uses the first polyphase subfilter for the points [3.0 3.2], the second subfilter for the point 3.4, the third subfilter for the point 3.6, and the fourth subfilter for the point 3.8.

Dependencies

This property applies only when you set the “Method” on page 4-0 property to 'FIR'.

Bandwidth — Normalized input bandwidth

0.5 (default) | real scalar greater than 0 and less than or equal to 1

Bandwidth to which the interpolated output samples must be constrained, specified as a real scalar greater than 0 and less than or equal to 1. A value of 1 equals the Nyquist

frequency, or half the sampling frequency, F_s . Use this property to take advantage of the bandlimited frequency content of the input. For example, if the input signal does not have frequency content above $F_s/4$, you can specify a value of 0.5 for the Bandwidth property.

Dependencies

This property applies only when you set the “Method” on page 4-0 property to 'FIR'.

Usage

Syntax

```
interpOut = interp(input)
interpOut = interp(input, ipts)
```

Description

`interpOut = interp(input)` outputs the interpolated sequence, `interpOut`, of the input vector or matrix *input*, as specified in the “InterpolationPoints” on page 4-0 property. Each column of `input` is treated as an independent channel of the input.

`interpOut = interp(input, ipts)` outputs the interpolated sequence as specified by `ipts`.

To specify the interpolation points, set the “InterpolationPointsSource” on page 4-0 property to 'Input port'.

```
t = 0:.0001:.0511;
x = sin(2*pi*20*t);
x1 = x(1:50:end);
ipts = 1:0.1:length(x1);
interp = dsp.Interpolator('InterpolationPointsSource', 'Input port');
interpOut = interp(x1, ipts);
```

Input Arguments

input — Data input

vector | matrix | *N*-D array

Input that is interpolated by the object, specified as a vector, matrix, or *N*-D array.

Example: `t = 0:0.0001:0.0511; input = sin(2*pi*20*t);`

Data Types: `single` | `double`

ipts — Interpolation points

vector | matrix | *N*-D array

Interpolation array I_{pts} , specified as a vector, matrix, or *N*-D array. The interpolation array represents the points in time at which to interpolate values of the input signal. An entry of 1 in I_{pts} refers to the first sample of the input, an entry of 2.5 refers to the sample halfway between the second and third input sample, and so on. In most cases, when I_{pts} is a vector, it can be of any length.

Valid values in the interpolation array I_{pts} range from 1 to the number of samples in each channel of the input. For instance, given a length-5 input vector D , all entries of I_{pts} must range from 1 to 5. I_{pts} cannot contain entries such as 7 or -9 , because D does not have a seventh or ninth entry.

The algorithm replaces any out-of-range values in I_{pts} with the closest value in the valid range (from 1 to the number of input samples). Then it performs the interpolation using the clipped version of I_{pts} .

Consider the following input data and interpolation points vector:

- `D = [11 22 33 44]'`
- `Ipts = [10 2.6 -3]'`

Because D has four samples, valid interpolation points range from 1 to 4. The algorithm clips interpolation point 10 down to 4 and the point -3 up to 1. The result is the clipped interpolation vector `IptsClipped = [4 2.6 1]'`.

Depending on the dimension of the input and the dimension of I_{pts} , the algorithm applies I_{pts} to the input in one of the following ways:

- If I_{pts} is an array, the object applies I_{pts} across the first dimension of an *N*-D array, resulting in an *N*-D array output.

- If I_{pts} is a vector, the object applies I_{pts} to each input vector (as if the input vector were a single channel), resulting in a vector output with the same orientation as the input (row or column).

The following tables summarize how the object applies the interpolation array I_{pts} to all the possible types of inputs. The table also shows the resulting output dimensions.

This table describes the behavior when InterpolationPointsSource is set to 'Property'.

Input Dimensions	Valid Dimensions of Interpolation Array I_{pts}	How Object Applies I_{pts} to Input	Output Dimensions
M -by- N -by- K matrix	P -by-1 column	Applies I_{pts} to the first dimension of the input	P -by- N -by- K array
	P -by- N -by- K matrix	Applies each column element of I_{pts} to the corresponding column of the input matrix	P -by- N -by- K array
M -by- N matrix	1-by- N row	Applies each column element of I_{pts} to the corresponding column of the input matrix	1-by- N row
	P -by-1 column	Applies I_{pts} to each input column	P -by- N matrix
	P -by- N matrix	Applies the columns of I_{pts} to the corresponding columns of the input matrix	
M -by-1 column	1-by- P row	Applies I_{pts} to the input column	P -by-1 column
	(the algorithm treats I_{pts} as a column) P -by-1 column		

Input Dimensions	Valid Dimensions of Interpolation Array I_{pts}	How Object Applies I_{pts} to Input	Output Dimensions
1-by- N row (not recommended)	1-by- N row	Not applicable. Object copies input vector.	1-by- N row, a copy of the input vector
	P -by-1 column		P -by- N matrix, where each row is a copy of the input vector
	P -by- N matrix		

This table describes the behavior when `InterpolationPointsSource` is set to 'Input port'.

Input Dimensions	Valid Dimensions of Interpolation Array I_{pts}	How Object Applies I_{pts} to Input	Output Dimensions
M -by- N -by- K matrix	Column vector of length P	Applies I_{pts} to the first dimension of the input	P -by- N -by- K array
	P -by- N -by- K matrix	Applies each column element of I_{pts} to the corresponding column of the input matrix	P -by- N -by- K array
M -by- N matrix	1-by- N row	Applies each column element of I_{pts} to the corresponding column of the input matrix	1-by- N row
	P -by-1 column	Applies I_{pts} to each input column	P -by- N matrix
	P -by- N matrix	Applies the columns of I_{pts} to the corresponding columns of the input matrix	
M -by-1 column	1-by- P row	Applies I_{pts} to the input column	P -by-1 column
	P -by-1 column		

Input Dimensions	Valid Dimensions of Interpolation Array $/pts$	How Object Applies $/pts$ to Input	Output Dimensions
1-by- N row (not recommended)	1-by- N row	Not applicable. Object copies input vector.	1-by- N row, a copy of the input vector
	P -by-1 column		P -by- N matrix, where each row is a copy of the input vector
	P -by- N matrix		

Example: `ipts = [1:10];`

Data Types: `single` | `double`

Output Arguments

`interpOut` — Interpolated sequence

vector | matrix | N -D array

Interpolated sequence, returned as a vector, matrix, or N -D array. The dimension of the output depends on the dimensions of the input and the interpolation points array. For more details on the dimensions, see the tables in “`ipts`” on page 4-0 .

Data Types: `single` | `double`

Note For versions earlier than R2016b, use the `step` function to run the System object™ algorithm. The arguments to `step` are the object you created, followed by the arguments shown in this section.

For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
clone	Create duplicate System object
getNumInputs	Number of inputs required to call the System object
getNumOutputs	Number of outputs from calling the System object
isLocked	Determine if System object is locked
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Compare Linear Interpolation with FIR Interpolation

Note: If you are using R2016a or earlier, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

```
x = [1 4];
x = repmat(x,1,4);
x1 = 1:0.25:8;
firInterp = dsp.Interpolator('Method','FIR','FilterHalfLength',2,...
    'InterpolationPoints',x1,'InterpolationPointsPerSample',4);
linInterp = dsp.Interpolator('InterpolationPoints',x1);
OutFIR = firInterp(x');
OutLin = linInterp(x');
stem(OutFIR,'b-.','linewidth',2);
hold on;
stem(OutLin,'r','markerfacecolor',[1 0 0]);
axis([0 30 0 5]);
legend('FIR','Linear','Location','Northeast');
```

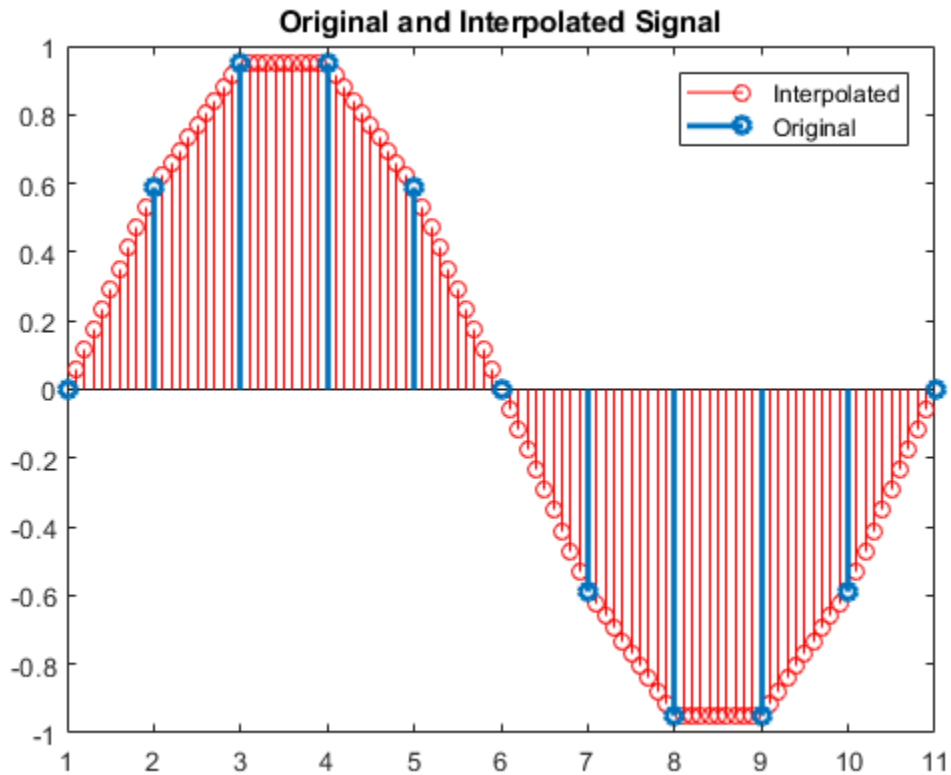

The interpolation points at indices 1 to 5 and 25 to 29 do not have enough low-rate samples surrounding them to use FIR interpolation with the specified filter length. Therefore, the interpolator object uses linear interpolation instead.

Interpolate a Sinusoid with Linear Interpolation

Note: If you are using R2016a or earlier, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

```
t = 0:.0001:.0511;
x = sin(2*pi*20*t);
```

```
x1 = x(1:50:end);  
I = 1:0.1:length(x1);  
interp = dsp.Interpolator('InterpolationPointsSource',...  
    'Input port');  
y = interp(x1,I);  
stem(I',y, 'r');  
title('Original and Interpolated Signal');  
hold on;  
stem(x1, 'Linewidth', 2);  
legend('Interpolated','Original');
```

Interpolate a Sum of Sinusoids

Note: If you are using R2016a or earlier, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Interpolate a sum of sinusoids with FIR interpolation, and with 'Input port' as the source of interpolation points.

```
Fs = 1000;
t = 0:(1/Fs):0.1-(1/Fs);
x = cos(2*pi*50*t)+0.5*sin(2*pi*100*t);
x1 = x(1:4:end);
I = 1:(1/4):length(x1);
interp = dsp.Interpolator('Method','FIR',...
    'FilterHalfLength',3,'InterpolationPointsSource','Input Port');
y = interp(x1,I);
stem(I,y,'r');
hold on;
axis([0 25 -2 2]);
stem(x1,'b','linewidth',2);
legend('Interpolated Signal','Original',...
    'Location','Northeast');
```

Determine the Polyphase Subfilters of an FIR Interpolator

Note: If you are using R2016a or earlier, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

The `dsp.Interpolator` object with the `Method` property set to 'FIR' models a polyphase FIR Interpolator. The polyphase implementation splits the lowpass FIR filter impulse response into several subfilters. Each subfilter occupies a specific narrow frequency band. This example shows how to determine the polyphase subfilters.

The default upsampling factor and the default polyphase half-length is 3. Using these values, design the linear phase FIR filter by using the `intfilt` function. The filter returned is of length $2 * P * L - 1$, where P is the upsampling factor and L is the filter half length.

```
interp = dsp.Interpolator('Method','FIR');
L = interp.InterpolationPointsPerSample;
P = interp.FilterHalfLength;
FiltCoeffs = intfilt(L,P,interp.Bandwidth);
FiltLen=length(FiltCoeffs);
FiltCols = ceil(FiltLen/2/L);
```

The filter needs $2*P*L$ coefficients. Prepending a zero does not affect the filter magnitude.

```
FiltCoeffs = [zeros(FiltCols*2*L-FiltLen,1); FiltCoeffs(:)];
```

Each column of `PolyPhaseCoeffs` is a polyphase subfilter.

```
PolyPhaseCoeffs = reshape(FiltCoeffs,FiltCols,2*L)';
```

Algorithms

Linear Interpolation Mode

In the linear interpolation mode, the algorithm interpolates data values by assuming that the data varies linearly between samples taken at adjacent sample times.

Suppose the input signal is $D = [1 \ 2 \ 1.5 \ 3 \ 0.25]'$. The left plot shows the samples in D and the right plot shows the linearly interpolated values between the samples in D .

When the interpolation points are out of range, the algorithm clips the invalid interpolation points. Consider an input signal, $D = [1 \ 2 \ 1.5 \ 3 \ 0.25]'$, and an interpolation vector, $I_{pts} = [-4 \ 2.7 \ 4.3 \ 10]'$. The interpolated output is given by $[1 \ 1.65 \ 2.175 \ 0.25]'$.

Interpolated Values of D at Clipped Interpolation Points

$$D = [1 \ 2 \ 1.5 \ 3 \ 0.25]'$$

$$I_{pts} = [-4 \ 2.7 \ 4.3 \ 10]'$$

Valid interpolation points range from 1 to 5, so -4 is clipped to 1 and 10 is clipped to 5.

$$\text{Clipped } I_{pts} = [1 \ 2.7 \ 4.3 \ 5]'$$

$$\text{Output} = [1 \ 1.65 \ 2.175 \ 0.25]'$$

FIR Interpolation Mode

In the FIR interpolation mode, the algorithm interpolates data values using an FIR interpolation filter. The FIR filter is implemented using a polyphase structure. A polyphase implementation *splits* the lowpass FIR filter impulse response into a number of different subfilters.

Let L represent the number of interpolation points per sample, or the upsampling factor. Let P represent the half length of the polyphase subfilters. Indexing from zero, if $h(n)$ is the impulse response of the FIR filter, the k th subfilter is:

$$h_k(n) = h(k + nL) \quad k = 0, 1, \dots, L-1 \quad n = 0, 1, \dots, 2P-1$$

The table describes the decomposition of an 18-coefficient FIR filter into 3 polyphase subfilters of length 6, the defaults for the FIR interpolator object.

Coefficients	Polyphase Subfilter
$h(0), h(3), h(6), \dots, h(15)$	$h_0(n)$
$h(1), h(4), h(7), \dots, h(16)$	$h_1(n)$
$h(2), h(5), h(8), \dots, h(17)$	$h_2(n)$

An upsampling factor of L inserts $L - 1$ zeros between low-rate samples. Interpolation results from filtering the upsampled sequence with a lowpass anti-imaging filter.

dsp.KalmanFilter System object

Package: dsp

Estimate system measurements and states using Kalman filter

Description

The `KalmanFilter` is an estimator used to recursively obtain a solution for linear optimal filtering. This estimation is made without precise knowledge of the underlying dynamic system. The Kalman filter implements the following linear discrete-time process with state, x , at the k^{th} time-step: $x(k) = Ax(k-1) + Bu(k-1) + w(k-1)$ (state equation).

This measurement, z , is given as: $z(k) = Hx(k) + v(k)$ (measurement equation).

The Kalman filter algorithm computes the following two steps recursively:

- **Prediction:** Process parameters x (state) and P (state error covariance) are estimated using the previous state,
- **Correction:** The state and error covariance are corrected using the current measurement,

To filter each channel of the input:

- 1 Define and set up your Kalman filter. See “Construction” on page 4-1096.
- 2 Call `step` to filter each channel of the input according to the properties of `dsp.KalmanFilter`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

Construction

`kalman = dsp.KalmanFilter` returns the Kalman filter System object, `kalman`, with default values for the parameters.

`kalman = dsp.KalmanFilter('PropertyName', PropertyValue, ...)` returns an Kalman filter System object, `kalman`, with each property set to the specified value.

`kalman = dsp.KalmanFilter(STMatrix, MMatrix, PNCovariance, MNCovariance, CIMatrix, 'PropertyName', PropertyValue, ...)` returns a Kalman filter System object, `kalman`. The `StateTransitionMatrix` property is set to `STMatrix`, and `MeasurementMatrix` property is set to `MMatrix`. In addition, the `ProcessNoiseCovariance` property set to `PNCovariance`, `MeasurementNoiseCovariance` property set to `MNCovariance`, `ControlInputMatrix` property set to `CIMatrix`. Other specified properties are set to the specified values.

Properties

StateTransitionMatrix

Model of state transition

Specify `A` in the state equation that relates the state at the previous time step to the state at current time step. `A` is a square matrix with each dimension equal to the number of states. The default value is 1.

ControlInputMatrix

Model of relation between control input and states

Specify `B` in the state equation that relates the control input to the state. `B` is a matrix with a number of rows equal to the number of states. This property is activated only when the `ControlInputPort` property value is `true`. The default value is 1.

MeasurementMatrix

Model of relation between states and measurement output

Specify H in the measurement equation that relates the states to the measurements. H is a matrix with the number of columns equal to the number of measurements. The default value is 1.

ProcessNoiseCovariance

Covariance of process noise

Specify Q as a square matrix with each dimension equal to the number of states. This matrix, Q , is the covariance of the white Gaussian process noise, w , in the state equation. The default value is 0.1.

MeasurementNoiseCovariance

Covariance of measurement noise

Specify R as a square matrix with each dimension equal to the number of states. This matrix, R , is the covariance of the white Gaussian process noise, v , in the measurement equation. The default value is 0.1.

InitialStateEstimate

Initial value for states

Specify an initial estimate of the states of the model as a column vector with length equal to the number of states. The default value is 0.

InitialErrorCovarianceEstimate

Initial value for state error covariance

Specify an initial estimate for covariance of the state error, as a square matrix with each dimension equal to the number of states. The default value is 0.1.

DisableCorrection

Disable port for filters

Specify as a scalar logical value, disabling System object filters from performing the correction step after the prediction step in the Kalman filter algorithm. The default value is false.

ControlInputPort

Presence of a control input

Specify if the control input is present, using a scalar logical value. The default value is true.

Methods

reset Reset internal states of Kalman filter
 step Filter input with Kalman filter object

Common to All System Objects	
clone	Create System object with same property values
getNumInputs	Expected number of inputs to a System object
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Estimate a Changing Scalar

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

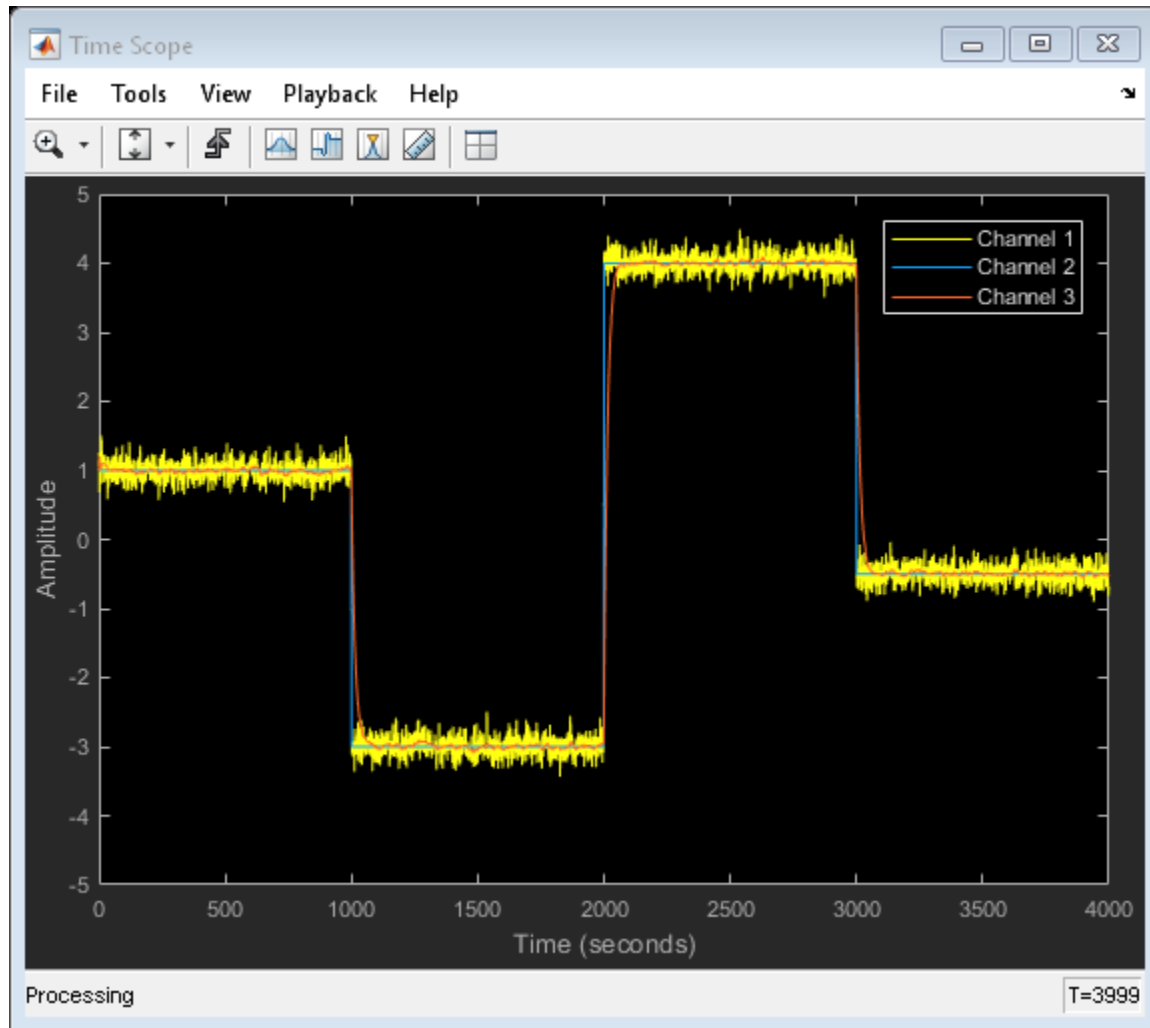

Create the System objects for the changing scalar input, the Kalman filter, and the scope (for plotting).

```
numSamples = 4000;
R = 0.02;
src = dsp.SignalSource;
```

```
src.Signal = [ones(numSamples/4,1); -3*ones(numSamples/4,1);...
 4*ones(numSamples/4,1); -0.5*ones(numSamples/4,1)];
tScope = dsp.TimeScope('NumInputPorts', 3, 'TimeSpan', numSamples, ...
  'TimeUnits', 'Seconds', 'YLimits', [-5 5], ...
  'ShowLegend', true); % Create the Time Scope
kalman = dsp.KalmanFilter('ProcessNoiseCovariance', 0.0001,...
  'MeasurementNoiseCovariance', R,...
  'InitialStateEstimate', 5,...
  'InitialErrorCovarianceEstimate', 1,...
  'ControlInputPort', false); %Create Kalman filter
```

Add noise to the scalar, and pass the result to the Kalman filter. Stream the data, and plot the filtered signal.

```
while(~isDone(src))
    trueVal = src();
    noisyVal = trueVal + sqrt(R)*randn;
    estVal = kalman(noisyVal);
    tScope(noisyVal,trueVal,estVal);
end
```

Disable the Correction Step in the Kalman Filter Algorithm

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Create the signal, Kalman Filter, and Time Scope System objects.

```

numSamples = 4000;
R = 0.02;
src = dsp.SignalSource;
src.Signal = [ ones(numSamples/4,1); -3*ones(numSamples/4,1);...
              4*ones(numSamples/4,1); -0.5*ones(numSamples/4,1)];
tScope = dsp.TimeScope('NumInputPorts', 3, 'TimeSpan', numSamples, ...
                       'TimeUnits', 'Seconds', 'YLimits', [-5 5], ...
                       'Title', ['True(channel 1), noisy(channel 2) and ',...
                                  'estimated(channel 3) values'], ...
                       'ShowLegend', true);
kalman = dsp.KalmanFilter('ProcessNoiseCovariance', 0.0001,...
                          'MeasurementNoiseCovariance', R,...
                          'InitialStateEstimate', 5,...
                          'InitialErrorCovarianceEstimate', 1,...
                          'ControlInputPort', false);
ctr = 0;

```

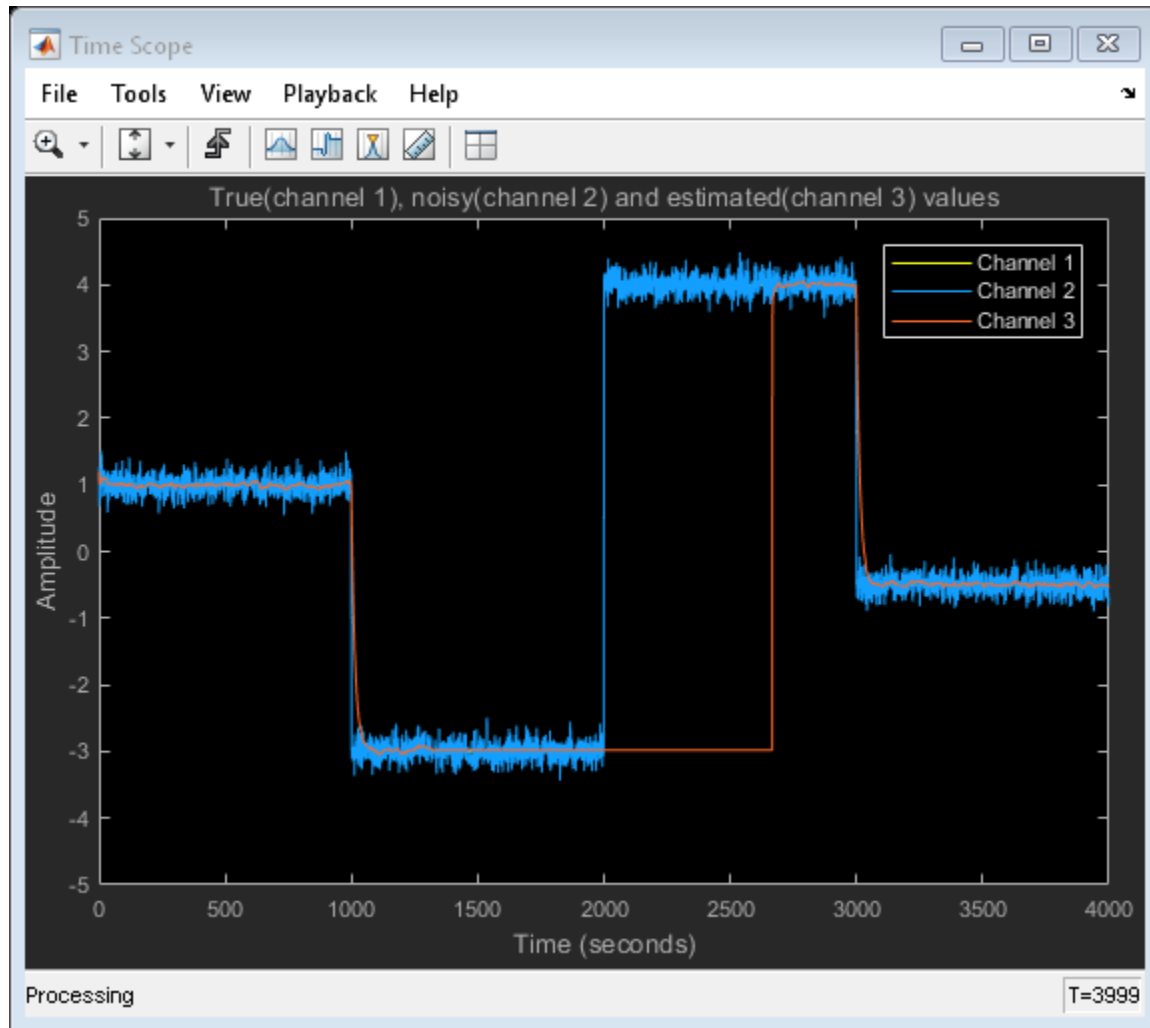

Add noise to the signal. Stream the data, and plot the filtered signal.

```

while(~isDone(src))
    trueVal = src();
    noisyVal = trueVal + sqrt(R)*randn;
    estVal = kalman(noisyVal);
    tScope(trueVal,noisyVal,estVal);

    % Disabling the correction step of second filter for the middle
    % one-third of the simulation
    if ctr == floor(numSamples/3)
        kalman.DisableCorrection = true;
    end
    if ctr == floor(2*numSamples/3)
        kalman.DisableCorrection = false;
    end
    ctr = ctr + 1;
end

```

Use a Single System object to Track Multiple Scalar Values

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Create the signal where the columns are the two scalar values to be tracked. Also create the Kalman Filter, and the Time Scopes.

```

numSamples = 4000;
R = 0.02;
src = dsp.SignalSource;
sig1 = [ ones(numSamples/4,1); -3*ones(numSamples/4,1);...
        4*ones(numSamples/4,1); -0.5*ones(numSamples/4,1)];
sig2 = [-2*ones(numSamples/4,1); 4*ones(numSamples/4,1);...
        -3*ones(numSamples/4,1); 1.5*ones(numSamples/4,1)];

src.Signal = [sig1, sig2];

tScope1 = dsp.TimeScope('NumInputPorts', 3, 'TimeSpan', numSamples, ...
    'TimeUnits', 'Seconds', 'YLimits', [-5 5], ...
    'Title', ['True(channel 1), noisy(channel 2) and ',...
    'estimated(channel 3) values'], ...
    'ShowLegend', true);
tScope2 = clone(tScope1);
kalman = dsp.KalmanFilter('ProcessNoiseCovariance', 0.0001,...
    'MeasurementNoiseCovariance', R,...
    'InitialStateEstimate', -3,...
    'InitialErrorCovarianceEstimate', 1,...
    'ControlInputPort', false);

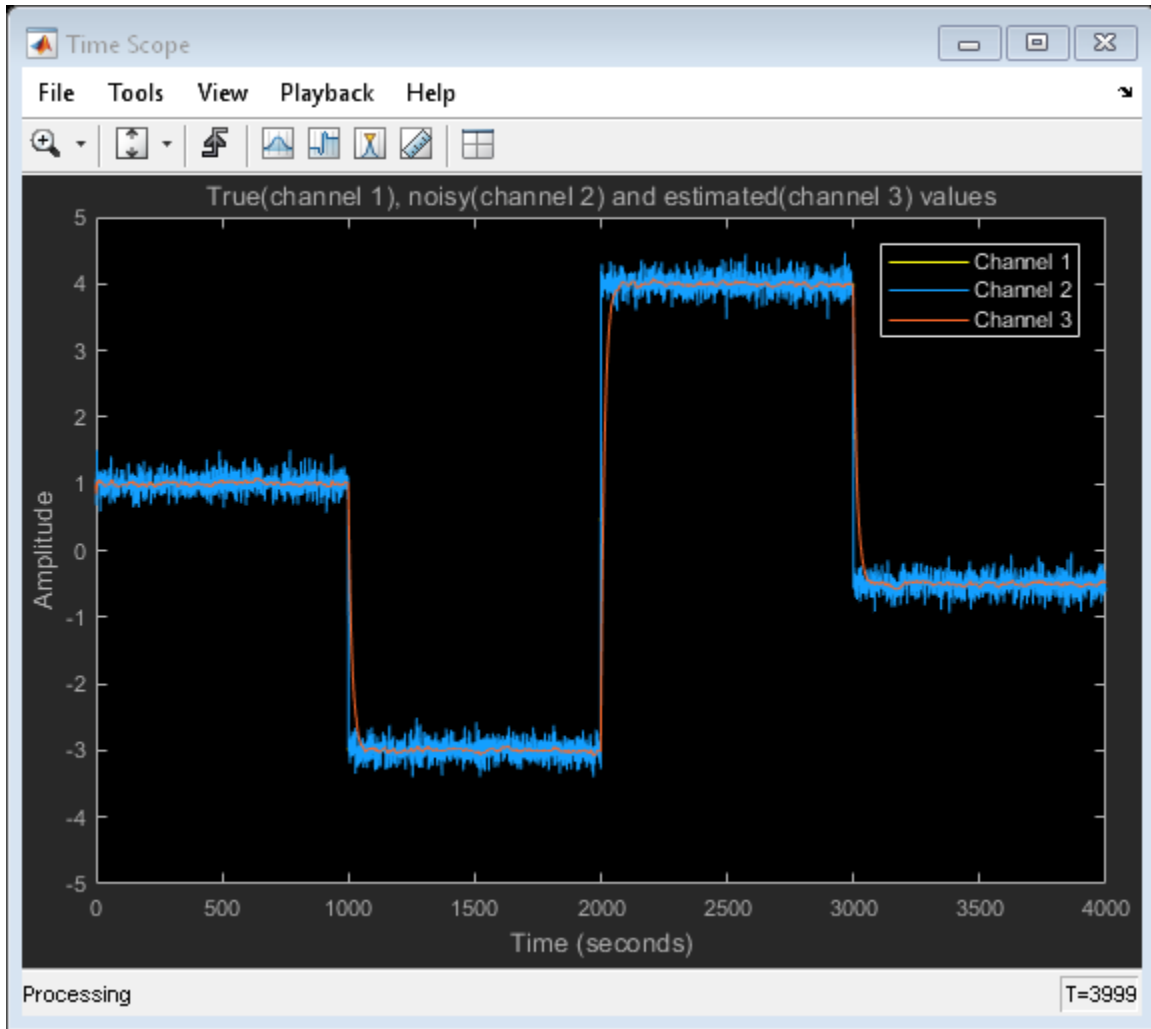

```

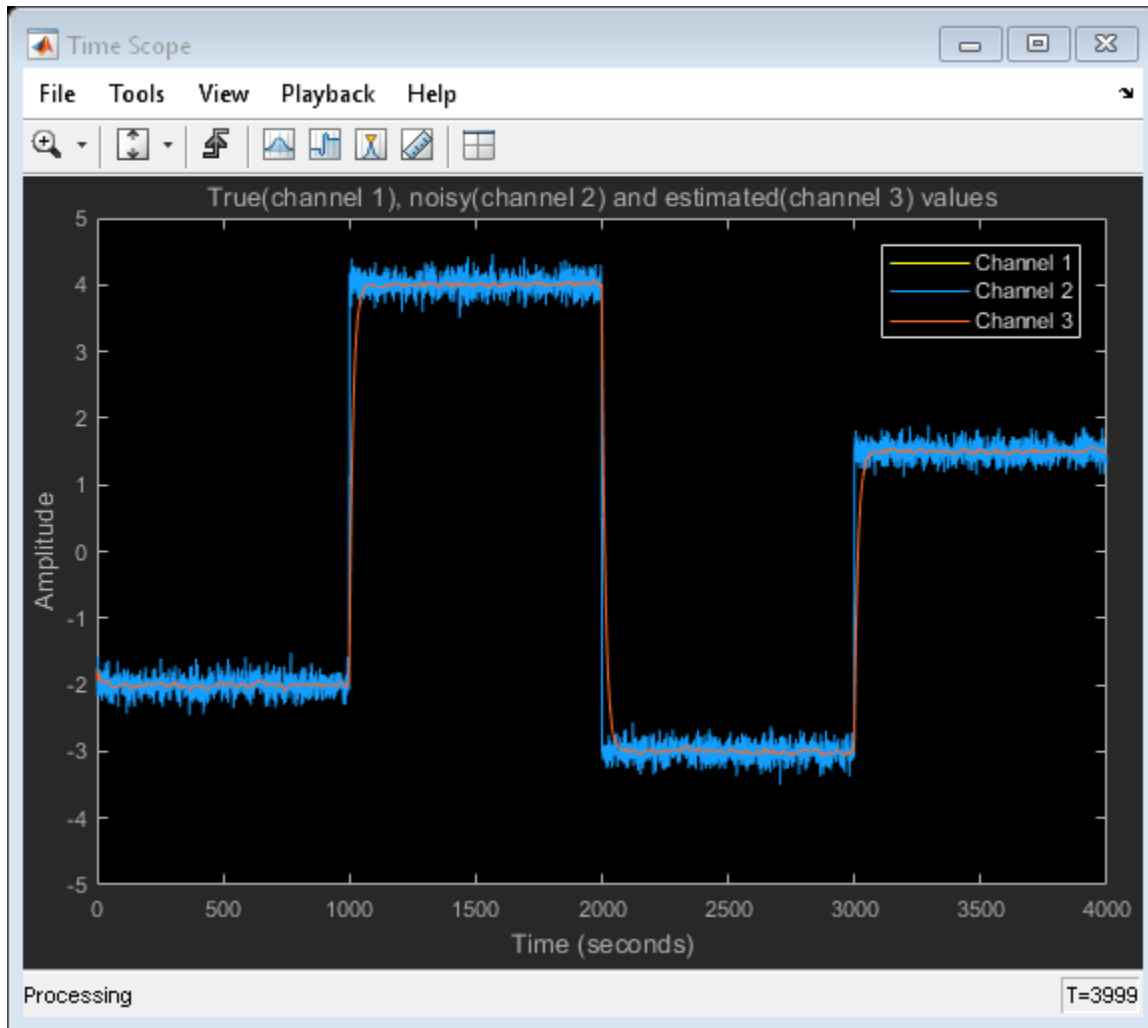

Add noise to the signal. Stream the data, and plot the filtered signal.

```

while(~isDone(src))
    trueVal = src();
    noisyVal = trueVal + sqrt(R)*randn(1,2);
    estVal = kalman(noisyVal);
    % Plot results of first channel on Time Scope
    tScope1(trueVal(:,1),noisyVal(:,1),estVal(:,1));
    % Plot results of second channel on Time Scope
    tScope2(trueVal(:,2),noisyVal(:,2),estVal(:,2));
end

```

Use a Unit Step To Track a Ramp Signal

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

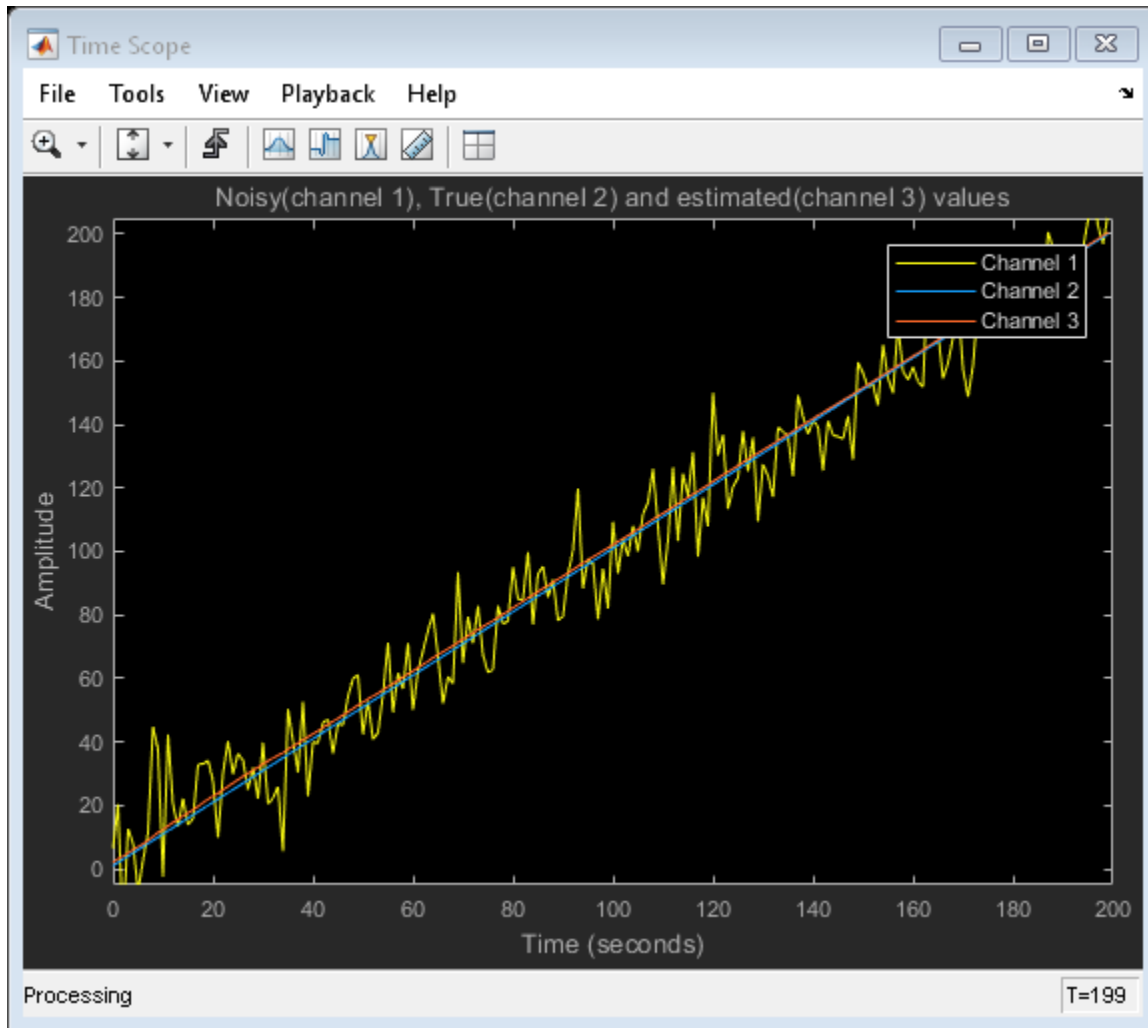

Use a unit step as the control input to track a ramp signal. Create the ramp signal to be tracked, the control input, the Time Scope, and the Kalman Filter.

```
numSamples = 200;
R = 100;
src = dsp.SignalSource;
src.Signal = (1:numSamples)';
control = dsp.SignalSource;
control.Signal = ones(numSamples,1);

tScope = dsp.TimeScope('NumInputPorts', 3, 'TimeSpan', numSamples, ...
    'TimeUnits', 'Seconds', 'YLimits', [-5 205], ...
    'Title', ['Noisy(channel 1), True(channel 2) and ', ...
    'estimated(channel 3) values'], ...
    'ShowLegend', true);
kalman = dsp.KalmanFilter('ProcessNoiseCovariance', 0.0001, ...
    'MeasurementNoiseCovariance', R, ...
    'InitialStateEstimate', 1, ...
    'InitialErrorCovarianceEstimate', 1);
```

Add noise to the signal. Filter the signal using kalman filter. View the output using time scope.

```
while(~isDone(src))
    trueVal = src();
    ctrl = control();
    noisyVal = trueVal + sqrt(R)*randn;
    estVal = kalman(noisyVal,ctrl);
    tScope(noisyVal,trueVal,estVal);
end
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Kalman Filter block reference page. The object properties correspond to the block parameters.

Kalman Filter

Introduced in R2013b

reset

System object: dsp.KalmanFilter

Package: dsp

Reset internal states of Kalman filter

Syntax

```
reset(kalman)
```

Description

`reset(kalman)` resets the internal states of the Kalman filter object, `kalman`, to their initial values. The reset method is always a no-op for unlocked System objects, as the states may not be allocated when the object is not locked.

step

System object: dsp.KalmanFilter

Package: dsp

Filter input with Kalman filter object

Syntax

```
Y = step(kalman,X)
```

```
[Y1,...,YN] = step(kalman,X)
```

```
[zEst, xEst, MSE_Est, zPred, xPred, MSE_Pred] = step(kalman, z, u)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(kalman,X)` processes the input data, `X` to produce the output, `Y`, for System object, `kalman`.

`[Y1,...,YN] = step(kalman,X)` produces `N` outputs.

```
[zEst, xEst, MSE_Est, zPred, xPred, MSE_Pred] = step(kalman, z, u)
```

Carries out the iterative Kalman filter algorithm over measurements `z` and control inputs `u`. The columns in `z` and `u` are treated as inputs to separate parallel filters, whose correction (or update) step can be disabled by the `DisableCorrection` property. The values returned are estimated measurements `z_est`, estimated states `x_est`, MSE of estimated states `MSE_Est`, predicted measurements `zPred`, predicted states `xPred` and MSE of predicted states `MSE_Pred`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.LDLFactor System object

Package: dsp

Factor square Hermitian positive definite matrices into components

Description

The `LDLFactor` object factors square Hermitian positive definite matrices into lower, upper, and diagonal components. The object uses only the lower triangle of S .

To factor these matrices into lower, upper, and diagonal components:

- 1 Define and set up your LDL factor object. See “Construction” on page 4-1112.
- 2 Call `step` to factor the matrices according to the properties of `dsp.LDLFactor`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`ldl = dsp.LDLFactor` returns an LDL factor System object, `ldl`, that computes unit lower triangular L and diagonal D such that $S = LDL$ for square, symmetric/Hermitian, positive definite input matrix S .

`ldl = dsp.LDLFactor('PropertyName', PropertyValue, ...)` returns an LDL factor System object, `ldl`, with each specified property set to the specified value.

Properties

Fixed-Point Properties

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as Full precision, Same as input, Same as product or Custom. The default is Full precision

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

CustomIntermediateProductDataType

Intermediate product word and fraction lengths

Specify the intermediate product fixed-point type as a signed, scaled `numericType` object. This property applies when you set the `IntermediateProductDataType` property to `Custom`. The default is `numericType(true, 16, 15)`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numericType([], 16, 15)`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

IntermediateProductDataType

Intermediate product word and fraction lengths

Specify the intermediate product fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. The default is `Wrap`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as `Full precision`, `Same as input` or `Custom`. The default is `Full precision`.

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as: `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest` or `Zero`. The default is `Floor`.

Methods

`step` Decompose matrix into components

Common to All System Objects	
clone	Create System object with same property values
getNumInputs	Expected number of inputs to a System object
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Decompose a Matrix

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Decompose a square Hermitian positive definite matrix using LDL factor.

```
A = gallery('randcorr',5);
ldl = dsp.LDLFactor;
y = ldl(A);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the LDL Factorization block reference page. The object properties correspond to the block parameters, except:

No object property that corresponds to the **Non-positive definite input** block parameter. The object does not issue any alerts for nonpositive definite inputs. The output is not a valid factorization. A partial factorization is in the upper left corner of the output.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

`dsp.LUFactor`

Introduced in R2012a

step

System object: dsp.LDLFactor

Package: dsp

Decompose matrix into components

Syntax

```
Y = step(ldl,S)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(ldl,S)` decomposes the matrix `S` into lower, upper, and diagonal components. The output `Y` is a composite matrix with the `L` as its lower triangular part and `D` as the diagonal and `L'` as its upper triangular part. If `S` is not positive definite the output `Y` is not a valid factorization.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.LevinsonSolver System object

Package: dsp

Solve linear system of equations using Levinson-Durbin recursion

Description

The `LevinsonSolver` object solves linear systems of equations using Levinson-Durbin recursion.

To solve linear systems of equations using Levinson-Durbin recursion:

- 1 Define and set up your System object. See “Construction” on page 4-1118.
- 2 Call `step` to solve the system of equations according to the properties of `dsp.LevinsonSolver`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`levinson = dsp.LevinsonSolver` returns a System object, `levinson`, that solves a Hermitian Toeplitz system of equations using the Levinson-Durbin recursion.

`levinson = dsp.LevinsonSolver('PropertyName', PropertyValue, ...)` returns a Levinson-Durbin object, `levinson`, with each specified property set to the specified value.

Properties

AOutputPort

Enable polynomial coefficients output

Set this property to `true` to output the polynomial coefficients A . Both `AOutputPort` and `KOutputPort` properties cannot be `false` at the same time. For scalar inputs, set the `AOutputPort` property to `true`. The default is `false`.

KOutputPort

Enable reflection coefficients output

Set this property to `true` to output the reflection coefficients K . You cannot set both the `AOutputPort` and `KOutputPort` properties to `false` at the same time. For scalar inputs, you must set the `KOutputPort` property to `false`. The default is `true`.

PredictionErrorOutputPort

Enable prediction error output

Set this property to `true` to output the prediction error. The default is `false`.

ZerorthLagZeroAction

Action when value of lag zero is zero

Specify the output for an input with the first coefficient as zero. Select `Ignore` or `Use zeros`. The default is `Use zeros`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap`, `Saturate`. The default is `Wrap`.

ACoefficientDataType

A coefficient word and fraction lengths

This constant property has a value of `Custom`.

CustomACoefficientDataType

A coefficient word and fraction lengths

Specify the *A* coefficient fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. The default is `numericType([],16,15)`.

KCoefficientDataType

K coefficient word and fraction lengths

This constant property has a value of `Custom`.

CustomKCoefficientDataType

K coefficient word and fraction lengths

Specify the *K* coefficient fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. The default is `numericType([],16,15)`.

PredictionErrorDataType

Prediction error power word and fraction lengths

Specify the prediction error power fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

CustomPredictionErrorDataType

Prediction error power word and fraction lengths

Specify the prediction error power fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `PredictionErrorDataType` property is `Custom`. The default is `numerictype([], 16, 15)`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as `Same as input` or `Custom`. The default is `Custom`

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `ProductDataType` property is `Custom`. The default is `numerictype([], 32, 30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the Accumulator fixed-point data type as `Same as input`, `Same as product`, or `Custom`. The default is `Custom`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `AccumulatorDataType` property is `Custom`. The default is `numerictype([], 32, 30)`.

Methods

`step` Reflection coefficients corresponding to columns of input

Common to All System Objects	
clone	Create System object with same property values
getNumInputs	Expected number of inputs to a System object
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Compute Polynomial Coefficients

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Use the Levinson solver to compute polynomial coefficients from autocorrelation coefficients.

```
levinson = dsp.LevinsonSolver;
levinson.AOutputPort = true;
levinson.KOutputPort = false;
x = (1:100)';
ac = dsp.Autocorrelator(...
    'MaximumLagSource', 'Property', ...
    'MaximumLag', 10);
a = ac(x);
c = levinson(a); % Compute polynomial coefficients
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Levinson-Durbin block reference page. The object properties correspond to the block parameters, except:

Output(s) block parameter corresponds to the `AOutputPort` and the `KOutputPort` object properties.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

See Also

`dsp.Autocorrelator`

Introduced in R2012a

step

System object: dsp.LevinsonSolver

Package: dsp

Reflection coefficients corresponding to columns of input

Syntax

```
K = step(levinson,X)
A = step(levinson,X)
[A, K] = step(levinson,X)
[... , P] = step(levinson,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`K = step(levinson,X)` returns reflection coefficients `K` corresponding to the columns of input `X`. `X` is typically a column or matrix of autocorrelation coefficients with lag 0 as the first element.

`A = step(levinson,X)` returns polynomial coefficients `A` when the `AOutputPort` property is true and the `KOutputPort` property is false.

`[A, K] = step(levinson,X)` returns polynomial coefficients `A` and reflection coefficients `K` when both the `AOutputPort` and `KOutputPort` properties are true.

`[... , P] = step(levinson,X)` also returns the error power `P` when the `PredictionErrorOutputPort` property is true.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.LMSFilter System object

Package: dsp

LMS adaptive filter

Description

The `LMSFilter` implements an adaptive FIR filter object that returns the filtered output, the error vector, and filter weights. The LMS filter uses one of five different LMS algorithms.

To implement the adaptive FIR filter object:

- 1 Define and set up your adaptive FIR filter object. See “Construction” on page 4-1126.
- 2 Call `step` to implement the filter according to the properties of `dsp.LMSFilter`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`lms = dsp.LMSFilter` returns an adaptive FIR filter object, `lms`, that computes the filtered output, filter error and the filter weights for a given input and desired signal using the Least Mean Squares (LMS) algorithm.

`lms = dsp.LMSFilter('PropertyName', PropertyValue,...)` returns an LMS filter object, `lms`, with each property set to the specified value.

`lms = dsp.LMSFilter(LEN,'PropertyName',PropertyValue,...)` returns an LMS filter object, `lms`, with the `Length` property set to `LEN`, and other specified properties set to the specified values.

Properties

Method

Method to calculate filter weights

Specify the method used to calculate filter weights as `LMS`, `Normalized LMS`, `Sign-Error LMS`, `Sign-Data LMS`, or `Sign-Sign LMS`. The default is `LMS`.

Length

Length of FIR filter weights vector

Specify the length of the FIR filter weights vector as a positive integer. The default is 32.

StepSizeSource

How to specify adaptation step size

Choose how to specify the adaptation step size factor as `Property` or `Input port`. The default is `Property`.

StepSize

Adaptation step size

Specify the adaptation step size factor as a nonnegative real number. For convergence of the normalized LMS method, set the step size greater than 0 and less than 2. This property only applies when the `StepSizeSource` property is `Property`. The default is 0.1. This property is tunable.

LeakageFactor

Leakage factor used in LMS filter

Specify the leakage factor as a real number between 0 and 1 inclusive. A leakage factor of 1 corresponds to no leakage in the adapting method. The default is 1. This property is tunable.

InitialConditions

Initial conditions of filter weights

Specify the initial values of the FIR filter weights as a scalar or vector of length equal to the `Length` property value. The default is 0.

AdaptInputPort

Enable weight adaptation

Specify when the LMS filter should adapt the filter weights. By default, the value of this property is `false`, and the object continuously updates the filter weights. When this property is set to `true`, an adaptation control input is provided to the `step` method. If the value of this input is nonzero, the object continuously updates the filter weights. If the input is zero, the filter weights remain at their current value.

WeightsResetInputPort

Enable weight reset

Specify when the LMS filter should reset the filter weights. By default, the value of this property is `false`, and the object does not reset the weights. When this property is set to `true`, a reset control input is provided to the `step` method, and the `WeightsResetCondition` property applies. The object resets the filter weights based on the values of the `WeightsResetCondition` property and the reset input to the `step` method.

WeightsResetCondition

Reset trigger setting for filter weights

Specify the event to reset the filter weights as `Rising edge`, `Falling edge`, `Either edge`, or `Non-zero`. The LMS filter resets the filter weights based on the values of this property and the reset input to the `step` method. This property only applies when the `WeightsResetInputPort` property is `true`. The default is `Non-zero`.

WeightsOutput

Enable returning filter weights

Specify how to output the adapted filter weights as one of the following:

- `'Last'` (default) — The object returns a column vector of weights corresponding to the last sample of the data frame. The length of the weights vector is the value given by the `Length` property.

- 'All' — The object returns a *FrameLength*-by-*Length* matrix of weights. The matrix corresponds to the full sample-by-sample history of weights values for all *FrameLength* samples of the input values. Each row in the matrix corresponds to a set of LMS filter weights calculated for the corresponding input sample.
- 'None' — This setting disables the weights output.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as Ceiling, Convergent, Floor, Nearest, Round, Simplest, or Zero. The default is Floor.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as Wrap or Saturate. The default is Wrap.

StepSizeDataType

Step size word and fraction lengths

Specify the step size fixed-point data type as Same word length as first input or Custom. Setting this property also sets the LeakageFactorDataType property to the same value. This property only applies when the StepSizeSource property is Property. The default is Same word length as first input.

CustomStepSizeDataType

Step size word and fraction lengths

Specify the step size fixed-point type as a numeric type object with a Signedness of Auto. This property only applies when the StepSizeSource property is Property and the StepSizeDataType property is Custom. The default is numeric type ([], 16, 15).

LeakageFactorDataType

Leakage factor word and fraction lengths

Specify the leakage factor fixed-point data type as `Same word length as first input` or `Custom`. Setting this property also sets the `StepSizeDataType` property to the same value. This property only applies when the `StepSizeSource` property is `Property`. The default is `Same word length as first input`.

CustomLeakageFactorDataType

Leakage factor word and fraction lengths

Specify the leakage factor fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property only applies when the `StepSizeSource` property is `Property` and the `LeakageFactorDataType` property is `Custom`. The default is `numericType([],16,15)`.

WeightsDataType

Weights word and fraction lengths

Specify the filter weights fixed-point data type as `Same as first input` or `Custom`. The default is `Same as first input`.

CustomWeightsDataType

Weights word and fraction lengths

Specify the filter weights fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property only applies when the `WeightsDataType` property is `Custom`. The default is `numericType([],16,15)`.

EnergyProductDataType

Energy product word and fraction lengths

Specify the energy product fixed-point data type as `Same as first input` or `Custom`. This property only applies when the `Method` property is `Normalized LMS`. Setting this property also sets the `ConvolutionProductDataType`, `StepSizeErrorProductDataType`, `WeightsUpdateProductDataType`, and `QuotientDataType` properties to the same value. The default is `Same as first input`.

CustomEnergyProductDataType

Energy product word and fraction lengths

Specify the energy product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property only applies when the `Method` property is `Normalized LMS` and the `EnergyProductDataType` property is `Custom`. The default is `numericType([], 32, 20)`.

EnergyAccumulatorDataType

Energy accumulator word and fraction lengths

Specify the energy accumulator fixed-point data type as `Same as first input` or `Custom`. This property only applies when the `Method` property is `Normalized LMS`. Setting this property also sets the `ConvolutionAccumulatorDataType` property to the same value. The default is `Same as first input`.

CustomEnergyAccumulatorDataType

Energy accumulator word and fraction lengths

Specify the energy accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property only applies when the `Method` property is `Normalized LMS` and the `EnergyAccumulatorDataType` property is `Custom`. The default is `numericType([], 32, 20)`.

ConvolutionProductDataType

Convolution product word and fraction lengths

Specify the convolution product fixed-point data type as `Same as first input` or `Custom`. Setting this property also sets the `EnergyProductDataType`, `StepSizeErrorProductDataType`, `WeightsUpdateProductDataType` and `QuotientDataType` properties to the same value. The default is `Same as first input`.

CustomConvolutionProductDataType

Convolution product word and fraction lengths

Specify the convolution product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property only applies when the `ConvolutionProductDataType` property is `Custom`. The default is `numerictype([], 32, 20)`.

ConvolutionAccumulatorDataType

Convolution accumulator word and fraction lengths

Specify the convolution accumulator fixed-point data type as `Same as first input` or `Custom`. Setting this property also sets the `EnergyAccumulatorDataType` property to the same value. The default is `Same as first input`.

CustomConvolutionAccumulatorDataType

Convolution accumulator word and fraction lengths

Specify the convolution accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property only applies when the `ConvolutionAccumulatorDataType` property is `Custom`. The default is `numerictype([], 32, 20)`.

StepSizeErrorProductDataType

Step size error product word and fraction lengths

Specify the step size error product fixed-point data type as `Same as first input` or `Custom`. Setting this property also sets the `ConvolutionProductDataType`, `EnergyProductDataType`, `WeightsUpdateProductDataType`, and `QuotientDataType` properties to the same value. The default is `Same as first input`.

CustomStepSizeErrorProductDataType

Step size error product word and fraction lengths

Specify the step size error product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property only applies when the `StepSizeErrorProductDataType` property is `Custom`. The default is `numerictype([], 32, 20)`.

WeightsUpdateProductDataType

Weight update product word and fraction lengths

Specify the weight update product fixed-point data type as Same as first input or Custom. Setting this property also sets the ConvolutionProductDataType, EnergyProductDataType, StepSizeErrorProductDataType, and QuotientDataType properties to the same value. The default is Same as first input.

CustomWeightsUpdateProductDataType

Weight update product word and fraction lengths

Specify the weight update product fixed-point type as a scaled numeric type object with a Signedness of Auto. This property only applies when the WeightsUpdateProductDataType property is Custom. The default is numeric type ([], 32, 20).

QuotientDataType

Quotient word and fraction lengths

Specify the quotient fixed-point data type as one of Same as first input or Custom. This property only applies when the Method property is Normalized LMS. Setting this property also sets the ConvolutionProductDataType, EnergyProductDataType, StepSizeErrorProductDataType, and WeightsUpdateProductDataType properties to the same value. The default is Same as first input.

CustomQuotientDataType

Quotient word and fraction lengths

Specify the quotient fixed-point type as a scaled numeric type object with a Signedness of Auto. This property only applies when the Method property is Normalized LMS and the QuotientDataType property is Custom. The default is numeric type ([], 32, 20).

Methods

maxstep	Maximum step size for LMS adaptive filter convergence
msepred	Predicted mean-square error for LMS filter
msesim	Mean-squared error for LMS filter
reset	Reset filter states for LMS filter
step	Apply LMS adaptive filter to input

Common to All System Objects	
clone	Create System object with same property values
getNumInputs	Expected number of inputs to a System object
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

System Identification Using LMS Filter

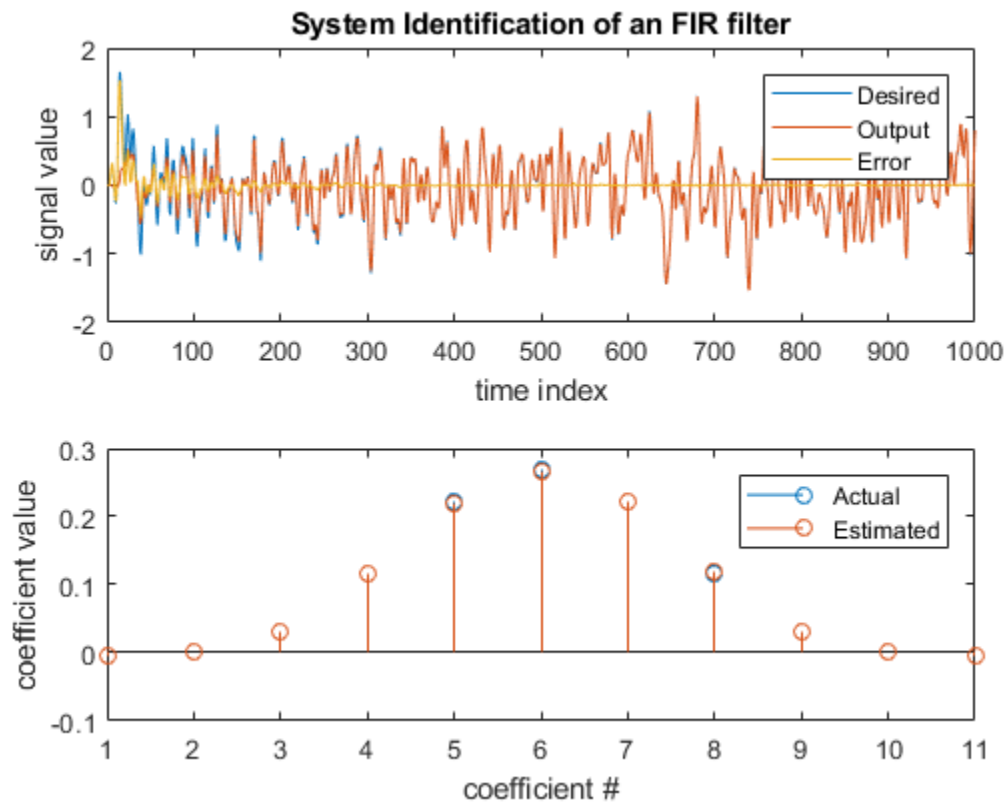

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
lms1 = dsp.LMSFilter(11,'StepSize',0.01);
filt = dsp.FIRFilter; % System to be identified
filt.Numerator = fir1(10,.25);
x = randn(1000,1); % input signal

d = filt(x) + 0.01*randn(1000,1); % desired signal
[y,e,w] = lms1(x,d);

subplot(2,1,1);
plot(1:1000, [d,y,e]);
```

```
title('System Identification of an FIR filter');  
legend('Desired', 'Output', 'Error');  
xlabel('time index');  
ylabel('signal value');  
subplot(2,1,2);  
stem([filt.Numerator.',w]);  
legend('Actual', 'Estimated');  
xlabel('coefficient #');  
ylabel('coefficient value');
```

Cancel Noise Using LMS Filter

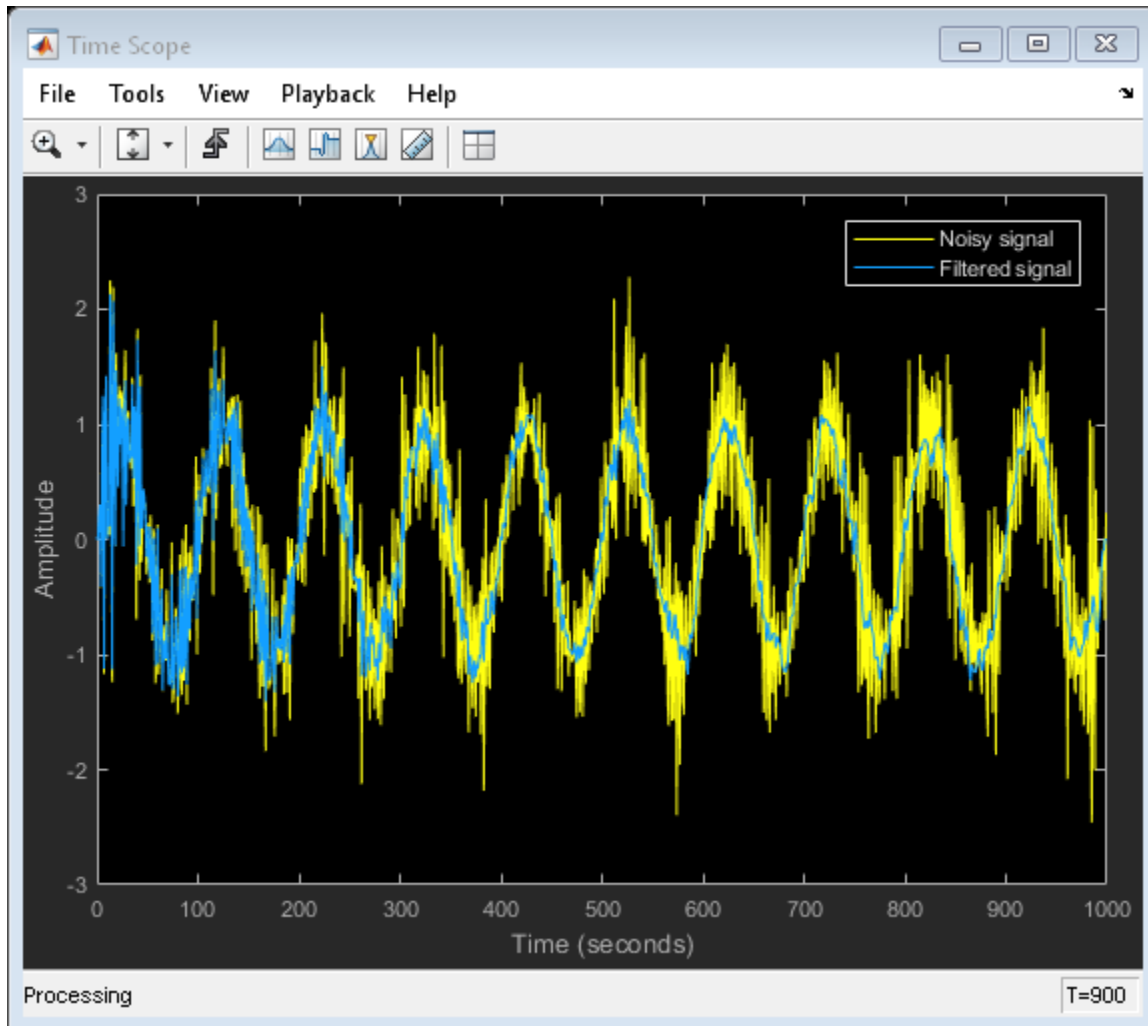

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Initialize the LMS filter with a length of 11 and step size of 0.05.

```
FrameSize = 100; NIter = 10;
lmsfilt2 = dsp.LMSFilter('Length',11,'Method','Normalized LMS', ...
    'StepSize',0.05);
firfilt2 = dsp.FIRFilter('Numerator', fir1(10,[.5, .75]));
sinewave = dsp.SineWave('Frequency',0.01, ...
    'SampleRate',1,'SamplesPerFrame',FrameSize);
TS = dsp.TimeScope('TimeSpan',FrameSize*NIter,'TimeUnits','Seconds',...
    'YLimits',[-3 3],'BufferLength',2*FrameSize*NIter, ...
    'ShowLegend',true,'ChannelNames', ...
    {'Noisy signal', 'Filtered signal'});
```

Pass the noisy input signal into the LMS filter and view the filtered output in the time scope.

```
for k = 1:NIter
    x = randn(FrameSize,1);           % Input signal
    d = firfilt2(x) + sinewave();    % Noise + Signal
    [y,e,w] = lmsfilt2(x,d);
    TS([d,e]);                       % Noisy = channel 1; Filtered = channel 2
end
```

Access the Full History of LMS Filter Weights

Note: This example runs only in R2017a or later. If you are using a release earlier than R2017a, the object does not output a full sample-by-sample history of filter weights. If

you are using a release earlier than R2016b, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Initialize the `dsp.LMSFilter` System object™ and set the `WeightsOutput` property to `'All'`. This setting enables the LMS filter to output a matrix of weights with dimensions `[FrameLength Length]`, corresponding to the full sample-by-sample history of weights for all `FrameLength` samples of input values.

```
FrameSize = 15000;
lmsfilt3 = dsp.LMSFilter('Length',63,'Method','LMS', ...
    'StepSize',0.001,'LeakageFactor',0.99999, ...
    'WeightsOutput','All'); % full Weights history

w_actual = fir1(64,[0.5 0.75]);
firfilt3 = dsp.FIRFilter('Numerator',w_actual);
sinewave = dsp.SineWave('Frequency',0.01, ...
    'SampleRate',1,'SamplesPerFrame',FrameSize);

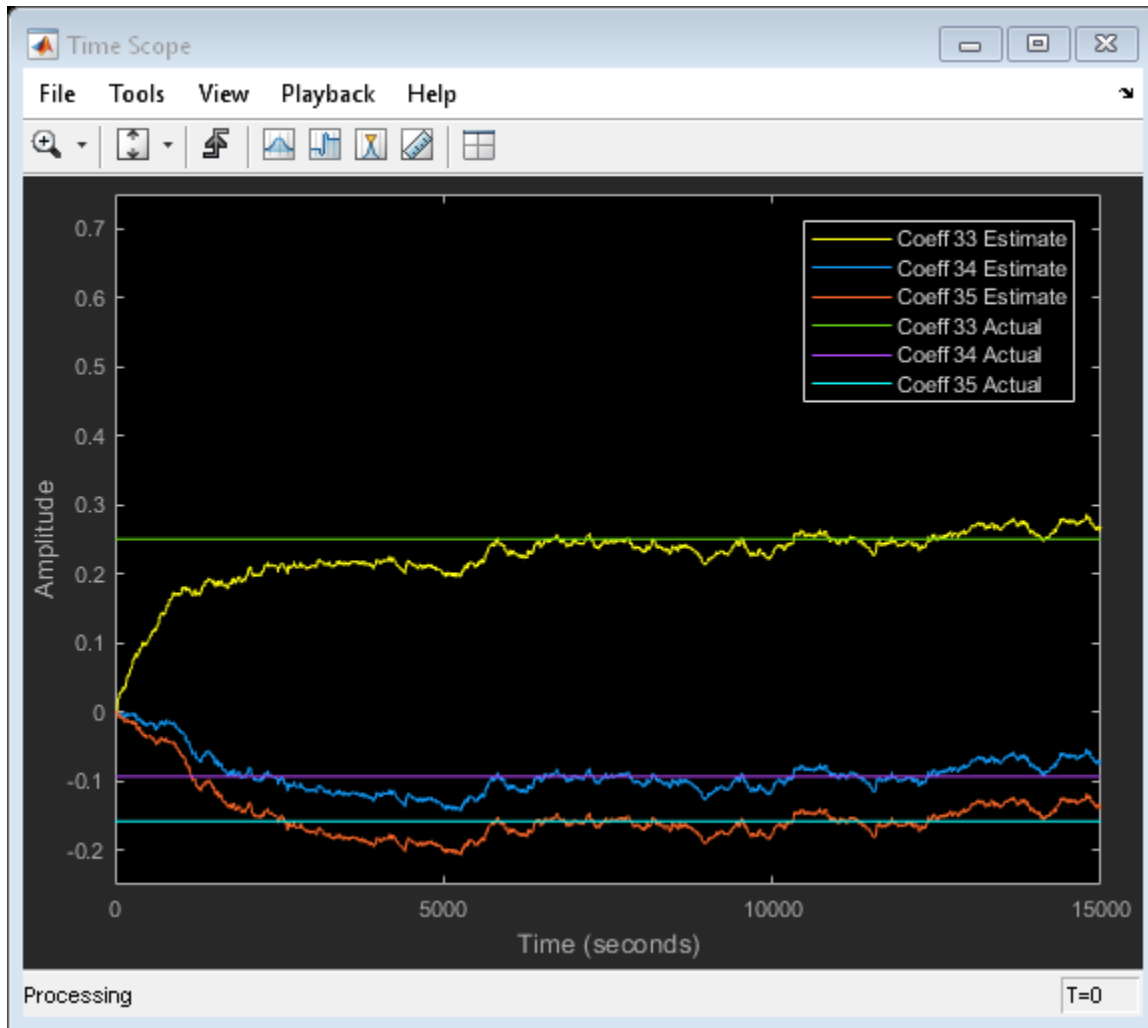

TS = dsp.TimeScope('TimeSpan',FrameSize,'TimeUnits','Seconds', ...
    'YLimits',[-0.25 0.75],'BufferLength',2*FrameSize, ...
    'ShowLegend',true,'ChannelNames', ...
    {'Coeff 33 Estimate','Coeff 34 Estimate','Coeff 35 Estimate', ...
    'Coeff 33 Actual','Coeff 34 Actual','Coeff 35 Actual'});
```

Run one frame and output the full adaptive weights history, `w`.

```
x = randn(FrameSize,1); % Input signal
d = firfilt3(x) + sinewave(); % Noise + Signal
[~,~,w] = lmsfilt3(x,d);
```

Each row in `w` is a set of weights estimated for the respective input sample. Each column in `w` gives the complete history of a specific weight. Plot the actual weight and the entire history of the 33rd, 34th, and the 35th weight. In the plot, you can see that the estimated weight output eventually converges with the actual weight as the adaptive filter receives input samples and continues to adapt.

```
idxBeg = 33;
idxEnd = 35;
TS([w(:,idxBeg:idxEnd), repmat(w_actual(idxBeg:idxEnd),FrameSize,1)]);
```

Algorithms

This filter's algorithm is defined by the following equations.

$$y(n) = \mathbf{w}^T(n-1)\mathbf{u}(n)$$

$$e(n) = d(n) - y(n)$$

$$\mathbf{w}(n) = \alpha\mathbf{w}(n-1) + f(\mathbf{u}(n), e(n), \mu)$$

The various LMS adaptive filter algorithms available in this System object are defined as:

- LMS:

$$f(\mathbf{u}(n), e(n), \mu) = \mu e(n) \mathbf{u}^*(n)$$

- Normalized LMS:

$$f(\mathbf{u}(n), e(n), \mu) = \mu e(n) \frac{\mathbf{u}^*(n)}{\varepsilon + \mathbf{u}^H(n)\mathbf{u}(n)}$$

- Sign-Error LMS:

$$f(\mathbf{u}(n), e(n), \mu) = \mu \text{sign}(e(n)) \mathbf{u}^*(n)$$

- Sign-Data LMS:

$$f(\mathbf{u}(n), e(n), \mu) = \mu e(n) \text{sign}(\mathbf{u}(n))$$

where $\mathbf{u}(n)$ is real.

- Sign-Sign LMS:

$$f(\mathbf{u}(n), e(n), \mu) = \mu \text{sign}(e(n)) \text{sign}(\mathbf{u}(n))$$

where $\mathbf{u}(n)$ is real.

The variables are as follows:

Variable	Description
n	The current time index
$\mathbf{u}(n)$	The vector of buffered input samples at step n
$\mathbf{u}^*(n)$	The complex conjugate of the vector of buffered input samples at step n
$\mathbf{w}(n)$	The vector of filter weight estimates at step n
$y(n)$	The filtered output at step n
$e(n)$	The estimation error at step n

Variable	Description
$d(n)$	The desired response at step n
μ	The adaptation step size
α	The leakage factor ($0 < \alpha \leq 1$)

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

Blocks

LMS Filter

Introduced in R2012a

maxstep

System object: dsp.LMSFilter

Package: dsp

Maximum step size for LMS adaptive filter convergence

Syntax

```
MUMAX = maxstep(lms,X)
[MUMAX,MUMAXMSE] = maxstep(lms,X)
```

Description

`MUMAX = maxstep(lms,X)` predicts a bound on the step size to provide convergence of the mean values of the adaptive filter coefficients. The columns of the matrix `X` contain individual input signal sequences. The signal set is assumed to have zero mean or nearly so.

`[MUMAX,MUMAXMSE] = maxstep(lms,X)` predicts a bound on the adaptive filter step size to provide convergence of the adaptive filter coefficients in mean square.

Examples

Compute the Maximum Step of the LMS Adaptive Filter

Analyze and simulate a 32-coefficient (31st-order) LMS adaptive filter object. To demonstrate the adaptation process, run 2000 iterations and 50 trials.

Specify `[numiterations,numexamples] = size(x)`;

```
x = zeros(2000,50);
d = x;
lp = fdesign.lowpass('n,fc',31,0.5);
```

```
FIRFilter = design(lp, 'window', 'SystemObject', true);  
coef = FIRFilter.Numerator;
```

Create input and desired response signal matrices.

```
for k=1:size(x,2)  
% Set the kth input to the filter.  
x(:,k) = filter(sqrt(0.75), [1 -0.5], sign(randn(size(x,1),1)));  
n = 0.1*randn(size(x,1),1); % (k)th observation noise signal.  
d(:,k) = filter(coef,1,x(:,k))+n; % (k)th desired signal end  
end  
mu = 0.1; % LMS step size.  
LMSFilter = dsp.LMSFilter('Length',32, 'StepSize',mu);
```

Compute the maximum step of the filter.

```
[mumax,mumaxmse] = maxstep(LMSFilter,x)  
  
mumax = 0.0628  
  
mumaxmse = 0.0536
```

msepred

System object: dsp.LMSFilter

Package: dsp

Predicted mean-square error for LMS filter

Syntax

```
[MMSE, EMSE] = msepred(sysObj, X, D)
[MMSE, EMSE, MEANW, MSE, TRACEK] = msepred(sysObj, X, D)
[MMSE, EMSE, MEANW, MSE, TRACEK] = msepred(sysObj, X, D, M)
```

Description

`[MMSE, EMSE] = msepred(sysObj, X, D)` predicts the steady-state values at convergence of the minimum mean-squared error (MMSE) and the excess mean-squared error (EMSE) given the input and desired response signal sequences in `X` and `D` and the quantities in the adaptive filter `sysObj`.

`[MMSE, EMSE, MEANW, MSE, TRACEK] = msepred(sysObj, X, D)` calculates three sequences corresponding to the analytical behavior of the adaptive filter defined by `sysObj`. `MEANW` is the sequence of coefficient vector means. The columns of this matrix contain predictions of the mean values of the adaptive filter coefficients at each time instant. The dimensions of `MEANW` are $(\text{SIZE}(X, 1))$ by $(H.\text{length})$. `MSE` is the sequence of mean-square errors. This column vector contains predictions of the mean-square error of the adaptive filter at each time instant. The length of `MSE` is equal to $\text{SIZE}(X, 1)$. `TRACEK` is a sequence of total coefficient error powers. This column vector contains predictions of the total coefficient error power of the adaptive filter at each time instant. The length of `TRACEK` is equal to $\text{SIZE}(X, 1)$.

`[MMSE, EMSE, MEANW, MSE, TRACEK] = msepred(sysObj, X, D, M)` specifies an optional decimation factor for computing `MEANW`, `MSE`, and `TRACEK`. If $M > 1$, every M^{th} predicted value of each of these sequences is saved. If omitted, the value of `M` is the default, which is one.

Examples

Predict Mean Square Error for LMS Filter

```

x = zeros(2000,25); d = x;
firCoeff = fir1(31,0.5);
x = filter(sqrt(0.75),[1 -0.5],sign(randn(size(x)))));
n = 0.1*randn(size(x));
d = filter(firCoeff,1,x)+n;
l = 32;
mu = 0.008;
m = 5;

lms = dsp.LMSFilter('Length',l,'StepSize',mu);
[mmse,emse,meanW,mse,traceK] = msepred(lms,x,d,m);
[simmse,meanWsim,Wsim,traceKsim] = msesim(lms,x,d,m);
nn = m:m:size(x,1);
subplot(2,1,1);
plot(nn,meanWsim(:,12),'b',nn,meanW(:,12),'r',nn,...
meanWsim(:,13:15),'b',nn,meanW(:,13:15),'r');
PlotTitle ={'Average Coefficient Trajectories for';...
            'W(12), W(13), W(14), and W(15)'};
title(PlotTitle);
legend('Simulation','Theory');
xlabel('Time Index'); ylabel('Coefficient Value');
subplot(2,2,3);
semilogy(nn,simmse,[0 size(x,1)],[(emse+mmse)...
(emse+mmse)],nn,mse,[0 size(x,1)],[mmse mmse]);
title('Mean-Square Error Performance');
axis([0 size(x,1) 0.001 10]);
legend('MSE (Sim.)','Final MSE','MSE','Min. MSE');
xlabel('Time Index'); ylabel('Squared Error Value');
subplot(2,2,4);
semilogy(nn,traceKsim,nn,traceK,'r');
title('Sum-of-Squared Coefficient Errors'); axis([0 size(x,1)...
0.0001 1]);
legend('Simulation','Theory');
xlabel('Time Index'); ylabel('Squared Error Value');

```

mstesim

System object: dsp.LMSFilter

Package: dsp

Mean-squared error for LMS filter

Syntax

```
MSE = mstesim(sysObj,X,D)
[MSE,MEANW,W,TRACEK] = mstesim(sysObj,X,D)
[...] = mstesim(sysObj,X,D,M)
```

Description

`MSE = mstesim(sysObj,X,D)` returns a sequence of mean-square errors. This column vector contains estimates of the mean-square error of the adaptive filter at each time instant. The length of `MSE` is equal to `SIZE(X,1)`. The columns of the matrix `X` contain individual input signal sequences, and the columns of the matrix `D` contain corresponding desired response signal sequences.

`[MSE,MEANW,W,TRACEK] = mstesim(sysObj,X,D)` calculates three parameters corresponding to the simulated behavior of the adaptive filter defined by `sysObj`. `MEANW` is a sequence of coefficient vector means. The columns of this matrix contain estimates of the mean values of the adaptive filter coefficients at each time instant. The dimensions of `MEANW` are `(SIZE(X,1))` by `(sysObj.length)`. `W` is an estimate of the final values of the adaptive filter coefficients for the algorithm corresponding to `sysObj`. `TRACEK` is a sequence of total coefficient error powers. This column vector contains estimates of the total coefficient error power of the adaptive filter at each time instant. The length of `TRACEK` is equal to `SIZE(X,1)`.

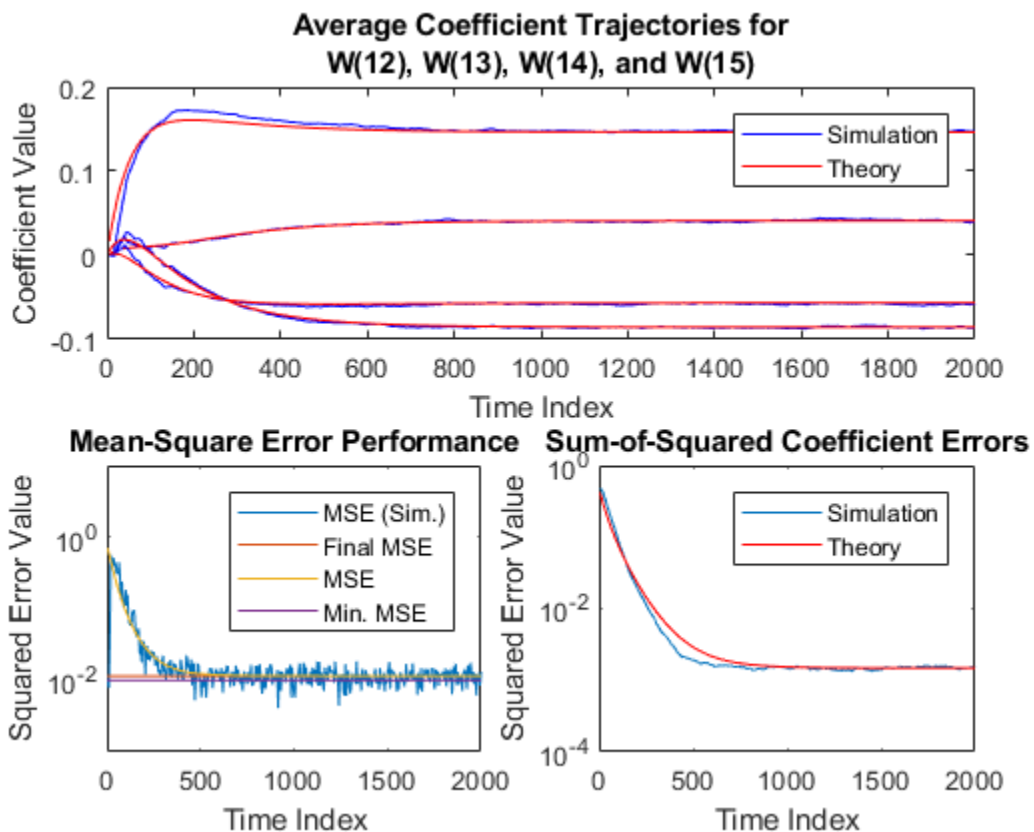

`[...] = mstesim(sysObj,X,D,M)` specifies an optional decimation factor for computing `MSE`, `MEANW`, and `TRACEK`. If `M > 1`, every `Mth` predicted value of each of these sequences is saved. If omitted, the value of `M` is the default, which is 1.

Examples

Predict Mean Square Error for LMS Filter

```
x = zeros(2000,25); d = x;
firCoeff = fir1(31,0.5);
x = filter(sqrt(0.75),[1 -0.5],sign(randn(size(x)))));
n = 0.1*randn(size(x));
d = filter(firCoeff,1,x)+n;
l = 32;
mu = 0.008;
m = 5;

lms = dsp.LMSFilter('Length',l,'StepSize',mu);
[mmse,emse,meanW,mse,traceK] = msepred(lms,x,d,m);
[simmse,meanWsim,Wsim,traceKsim] = msesim(lms,x,d,m);
nn = m:m:size(x,1);
subplot(2,1,1);
plot(nn,meanWsim(:,12),'b',nn,meanW(:,12),'r',nn,...
meanWsim(:,13:15),'b',nn,meanW(:,13:15),'r');
PlotTitle ={'Average Coefficient Trajectories for';...
           'W(12), W(13), W(14), and W(15)'};
title(PlotTitle);
legend('Simulation','Theory');
xlabel('Time Index'); ylabel('Coefficient Value');
subplot(2,2,3);
semilogy(nn,simmse,[0 size(x,1)],[(emse+mmse)...
(emse+mmse)],nn,mse,[0 size(x,1)],[mmse mmse]);
title('Mean-Square Error Performance');
axis([0 size(x,1) 0.001 10]);
legend('MSE (Sim.)','Final MSE','MSE','Min. MSE');
xlabel('Time Index'); ylabel('Squared Error Value');
subplot(2,2,4);
semilogy(nn,traceKsim,nn,traceK,'r');
title('Sum-of-Squared Coefficient Errors'); axis([0 size(x,1)...
0.0001 1]);
legend('Simulation','Theory');
xlabel('Time Index'); ylabel('Squared Error Value');
```

reset

System object: dsp.LMSFilter

Package: dsp

Reset filter states for LMS filter

Syntax

```
reset(lms)
```

Description

`reset(lms)` resets the filter states of the LMS FIR filter, `lms`, to their initial values specified in the `InitialConditions` property. The initial filter state values correspond to the initial conditions for difference equation defining the adaptive filter. After the `step` method applies the LMS filter to nonzero input data, the states may be different. Invoking the `step` method again without first invoking the `reset` method may produce different outputs for an identical input.

Reset an LMS Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
lms1 = dsp.LMSFilter(11, 'StepSize', 0.01);  
filt = dsp.FIRFilter; % System to be identified  
filt.Numerator = fir1(10, .25);  
x = randn(1000,1); % input signal  
d = filt(x) + 0.01*randn(1000,1); % desired signal  
[y,e,w] = lms1(x, d);
```

Call LMS algorithm again without resetting filter states.

```
[y1,e1,w1] = lms1(x,d);  
isequal(y,y1)
```

```
ans =  
  
    logical  
  
    0
```

Now reset the filter states to zero.

```
reset(lms1)
```

Call the LMS algorithm.

```
[y2,e2,w2] = lms1(x,d);  
isequal(y,y2)
```

```
ans =  
  
    logical  
  
    1
```

step

System object: dsp.LMSFilter

Package: dsp

Apply LMS adaptive filter to input

Syntax

```
[Y,ERR,WTS] = step(lms,X,D)
[Y, ERR] = step(lms,X,D)
[...] = step(lms,X,D,MU)
[...] = step(lms,X,D,A)
[...] = step(lms,X,D,R)
[Y,ERR,WTS] = step(lms,X,D,MU,A,R)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[Y,ERR,WTS] = step(lms,X,D)` applies the LMS filter object, `lms` to the input `X`, using `D` as the desired signal. This approach returns the filtered output in `Y`, the filter error in `ERR`, and the estimated filter weights in `WTS`. The LMS filter estimates the filter weights needed to minimize the mean square error between the output and the desired signal.

`[Y, ERR] = step(lms,X,D)` filters the input `X`, using `D` as the desired signal. This approach returns the filtered output in `Y` and the filter error in `ERR` when the `WeightsOutputPort` property is `false`.

`[...] = step(lms,X,D,MU)` uses `MU` as the step size, when the `StepSizeSource` property is `'Input port'`.

[...] = `step(lms, X, D, A)` uses `A` as the adaptation control, when the `AdaptInputPort` property is `true`. When `A` is nonzero, the LMS filter continuously updates the filter weights. When `A` is zero, the filter weights remain constant.

[...] = `step(lms, X, D, R)` uses `R` as a reset signal when the `WeightsResetInputPort` property is `true`. The `WeightsResetCondition` property can be used to set the reset trigger condition. If a reset event occurs, the LMS filter resets the filter weights to their initial values.

[`Y`, `ERR`, `WTS`] = `step(lms, X, D, MU, A, R)` filters the input `X` using `D` as the desired signal, `MU` as the step size, `A` as the adaptation control, and `R` as the reset signal. This approach returns the filtered output in `Y`, the filter error in `ERR`, and the adapted filter weights in `WTS`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.LogicAnalyzer System object

Package: dsp

Visualize, measure, and analyze transitions and states over time

Description

The Logic Analyzer System object displays the transitions in time-domain signals.

- Debug and analyze models
- Trace and correlate many signals simultaneously
- Detect and analyze timing violations
- Trace system execution
- Detect signal changes using triggers

To display the transitions of signals in the Logic Analyzer:

- 1 Create the dsp.LogicAnalyzer object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#) (MATLAB).

For more information about how to configure and customize the Logic Analyzer, see [Logic Analyzer](#).

Creation

Syntax

```
scope = dsp.LogicAnalyzer
scope = dsp.LogicAnalyzer (Name, Value)
```

Description

`scope = dsp.LogicAnalyzer` creates a Logic Analyzer System object, `scope`.

`scope = dsp.LogicAnalyzer(Name, Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects \(MATLAB\)](#).

BackgroundColor — Background color for display

'Black' (default) | 'White'

Background color of the display, specified as 'Black' or 'White'.

Tunable: Yes

Data Types: char

DisplayChannelColor — Color for channels in the display

[0.0588 1 1] (default) | RGB triplet

Color for channels in the display, specified as an RGB triplet.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1]; for example, [0.4 0.6 0.7].

Tunable: Yes

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

DisplayChannelFontSize — Font size for channels in the display (points)

10 (default) | nonnegative scalar integer

Font size for channels in the display, in points, specified as a nonnegative scalar integer.

Tunable: Yes

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

DisplayChannelFormat — Format for channels in the display

'Automatic' (default) | 'Analog' | 'Digital'

Format for channels in the display, specified as one of the following:

- 'Automatic' — Displays floating-point signals in Analog format and integer and fixed-point signals in Digital format. Boolean signals are displayed as zero or one.
- 'Analog' — Shows values as an analog plot.
- 'Digital' — Shows values as digital transitions.

Tunable: Yes

Data Types: char

DisplayChannelHeight — Channel height in the display (pixels)

12 (default)

Channel height in the display, in pixels, specified as a positive real scalar in the range 8 to 200.

Tunable: Yes

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

DisplayChannelRadix — Base of the enumeration used to display values

'Hexadecimal' (default) | 'Binary' | 'Octal' | 'Signed decimal' | 'Unsigned decimal'

Base of the enumeration used to display values, specified as one of the following:

- 'Hexadecimal' — Displays values as symbols from zero to nine and A to F

- 'Binary' — Displays values as zeros and ones
- 'Octal' — Displays values as numbers from zero to seven
- 'Signed decimal' — Displays the signed, stored integer value
- 'Unsigned decimal' — Displays the stored integer value

This property applies only to fixed-point (`fi`) values.

Tunable: Yes

Data Types: `char`

DisplayChannelSpacing — Spacing between channels in display (pixels)

4 (default) | positive scalar integer

Spacing between channels in the display, in pixels, specified as a positive scalar integer.

Tunable: Yes

Data Types: `double` | `single` | `uint8` | `uint16` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64`

Name — Caption to display on scope window

'Logic Analyzer' (default) | character vector

Caption to display on the scope window, specified as a character vector.

Tunable: Yes

Data Types: `char`

NumInputPorts — Number of input ports

1 (default) | integer between [1, 96]

Number of input ports, specified as a positive integer. Each signal coming through an input port becomes a separate channel in the scope. You must invoke the scope with the same number of inputs as the value of this property.

Position — Scope window position (pixels)

[left bottom width height] vector

Position of the scope window on your screen, in pixels, specified as a [left bottom width height] vector. The default position depends on your screen resolution. By

default, the scope window appears in the center of your screen, with a width of 800 pixels and height of 600 pixels.

Tunable: Yes

Data Types: `double` | `single` | `uint8` | `uint16` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64`

SampleTime — Input sample time

1 (default) | scalar

Sample time of inputs in seconds, specified as a finite numeric scalar. The same sample time is used for all inputs.

Data Types: `double` | `single` | `uint8` | `uint16` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64`

TimeDisplayOffset — Time display offset (seconds)

0 (default) | nonnegative scalar

Time display offset in seconds, specified as a nonnegative scalar.

Tunable: Yes

Data Types: `double` | `single` | `uint8` | `uint16` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64`

TimeSpan — Time span (seconds)

10 | positive scalar

Time span in seconds, specified as a positive scalar. The x -axis limits are calculated as follows:

- Minimum x -axis limit = $\min(\text{TimeDisplayOffset})$
- Maximum x -axis limit = $\max(\text{TimeDisplayOffset}) + \text{TimeSpan}$

`TimeDisplayOffset` and `TimeSpan` are the values of their respective properties.

Tunable: Yes

Data Types: `double` | `single` | `uint8` | `uint16` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64`

Usage

Note For versions earlier than R2016b, use the `step` function to run the System object™ algorithm. The arguments to `step` are the object you created, followed by the arguments shown in this section.

For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Syntax

```
scope(signal)  
scope(signal1, signal2, ... signalN)
```

Description

`scope(signal)` displays the signal `signal` in the Logic Analyzer scope.

`scope(signal1, signal2, ... signalN)` displays multiple signals in the Logic Analyzer when you set the `NumInputPorts` property to `N`. Each signal can have different data types and dimensions.

Input Arguments

signal — Input signal or signals to visualize

scalar | vector | matrix

Specify one or more input signals to visualize in the `dsp.LogicAnalyzer`. Signals can have different data types and dimensions.

Example: `scope(signal1, signal2)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `string` | `struct` | `table` | `cell` | `categorical` | `datetime` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.LogicAnalyzer

<code>addCursor</code>	Add cursor to display
<code>addDivider</code>	Add divider to Logic Analyzer
<code>addWave</code>	Add wave corresponding to specified input
<code>deleteCursor</code>	Delete Logic Analyzer cursor
<code>deleteDisplayChannel</code>	Delete Logic Analyzer channel
<code>getCursorInfo</code>	Return settings for Logic Analyzer cursor
<code>getCursorTags</code>	Return all cursor tags
<code>getDisplayChannelInfo</code>	Return settings for display channel
<code>getDisplayChannelTags</code>	Return all display channel tags
<code>modifyCursor</code>	Modify properties of Logic Analyzer cursor
<code>modifyDisplayChannel</code>	Modify properties of Logic Analyzer display channel
<code>moveDisplayChannel</code>	Move position of Logic Analyzer display channel

Specific to Scopes

<code>show</code>	Display scope window
<code>hide</code>	Hide scope window

Common to All System Objects

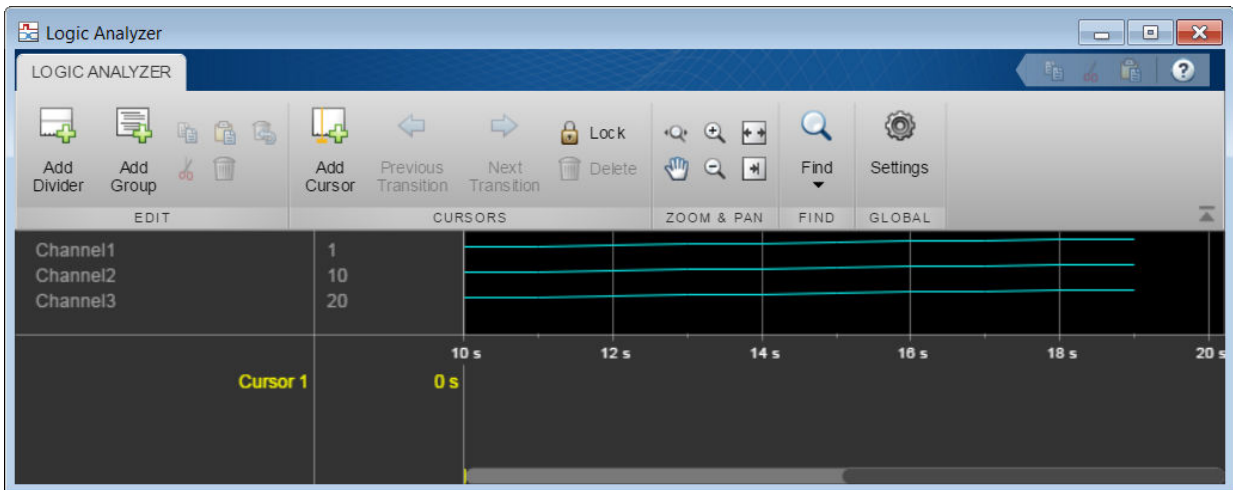

<code>step</code>	Run System object algorithm
<code>clone</code>	Create duplicate System object
<code>getNumInputs</code>	Number of inputs required to call the System object
<code>getNumOutputs</code>	Number of outputs from calling the System object
<code>isLocked</code>	Determine if System object is locked
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Display Simple Ramp Signals

Create a `dsp.LogicAnalyzer` object. Call the scope in a loop to display the signals.

```
scope = dsp.LogicAnalyzer('NumInputPorts',3);
for ii = 1:20
    scope(ii,10*ii,20*ii);
end
```

Display Fixed-Point Signals

Create a `dsp.LogicAnalyzer` object with four channels. Call `modifyDisplayChannel` to set the radix of each of the channels. Run the scope in a loop to display the waves.

```
scope = dsp.LogicAnalyzer('NumInputPorts',4,'DisplayChannelFormat','Digital');
scope.TimeSpan = 12;

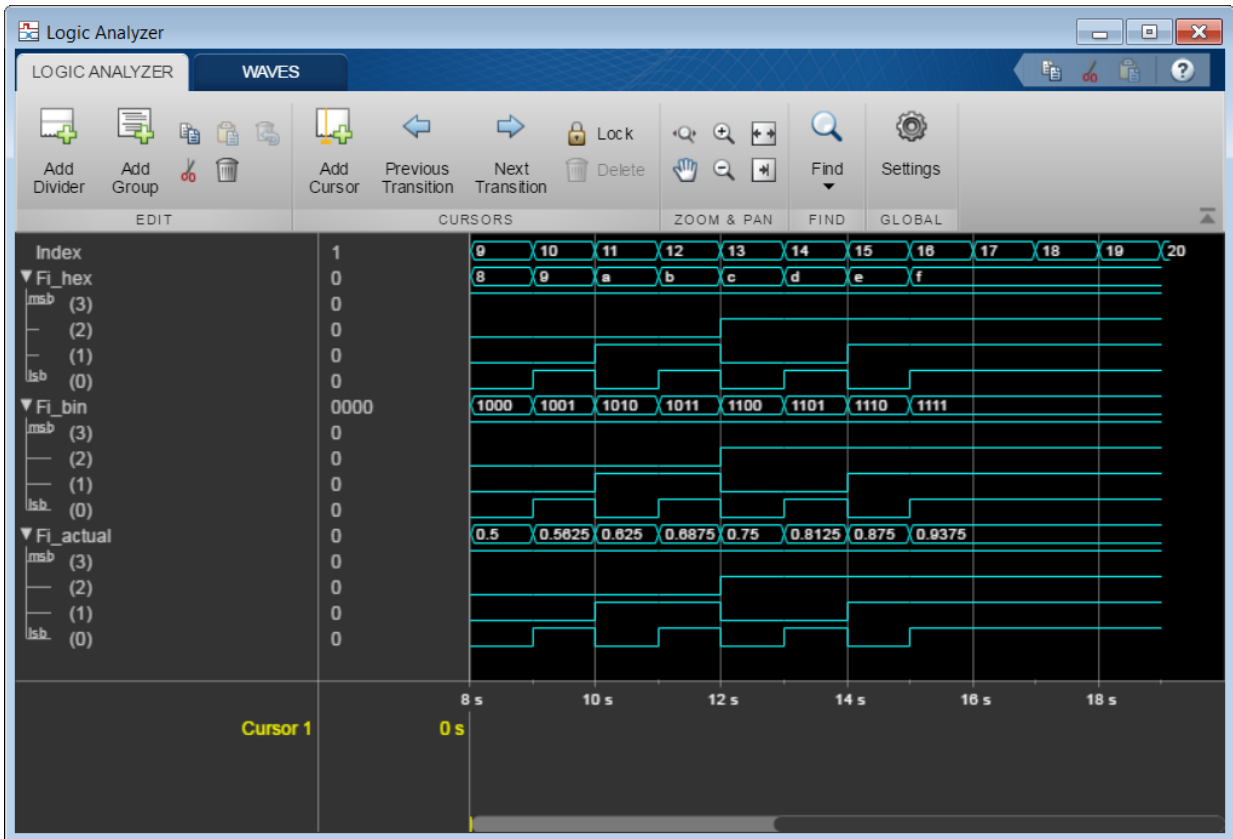

modifyDisplayChannel(scope,1,'Name','Index','Radix','Unsigned decimal');
modifyDisplayChannel(scope,2,'Name','Fi_hex','Radix','Hexadecimal');
modifyDisplayChannel(scope,3,'Name','Fi_bin','Radix','Binary');
modifyDisplayChannel(scope,4,'Name','Fi_actual','Radix','Signed decimal');

for ii = 1:20
    fival = fi((ii-1)/16,0,4,4);
```

```

scope(ii, fival, fival, fival);
end

```

Display Vector, Complex, and Enumerated Signals

Define a `WeekDaysInt` class to hold an enumerated list of weekday values. Create and save the following class definition file.

```

classdef WeekDaysInt < int32
    enumeration
        Monday(1), Tuesday(2), Wednesday(3), Thursday(4), Friday(5)
    end
end

```

Create a `dsp.LogicAnalyzer` object and configure the vector, complex, and enumerated data signals.

```
scope = dsp.LogicAnalyzer('NumInputPorts',6);
waves = getDisplayChannelTags(scope);

modifyDisplayChannel(scope,waves{1},'InputChannel',1,'Name','Vector Digital');
modifyDisplayChannel(scope,waves{2},'InputChannel',2,'Name','Vector Analog',...
    'Format','Analog','Height',80);
modifyDisplayChannel(scope,waves{3},'InputChannel',3,'Name','Complex Digital');
modifyDisplayChannel(scope,waves{4},'InputChannel',4,'Name','Complex Analog',...
    'Format','Analog','Height',80,'Color','Green');
modifyDisplayChannel(scope,waves{5},'InputChannel',5,'Name','Enum Digital');
modifyDisplayChannel(scope,waves{6},'InputChannel',6,'Name','Enum Analog',...
    'Format','Analog','Height',80);
```

Call the scope object in a loop to display the signals.

```
stop = 30;
for count = 1:stop
    sinValVec      = sin(count/stop*2*pi);
    cosValVec      = cos(count/stop*2*pi);
    cosValVecOffset = cos((count+10)/stop*2*pi);
    sinValReal     = sin((count+2)/stop*2*pi);
    cosValImag     = cos((count+2)/stop*2*pi);

    % Create a weekday enumerated value by wrapping the index
    day = WeekDaysInt(1+mod(count-1,5));

    scope(...
        [count (count-(stop/2))],...           % digital vector
        [sinValVec cosValVec cosValVecOffset],... % analog vector
        complex((count-(stop/2)),count),...    % digital complex
        complex(sinValReal, cosValImag),...    % analog complex
        day,...                                 % digital enum
        day...                                  % analog enum
    )
end
```

- “Inspect and Measure Transitions Using the Logic Analyzer”

Tips

- To close the logic analyzer window and clear its associated data, use the MATLAB `clear` function.

dsp.LowerTriangularSolver System object

Package: dsp

Solve lower-triangular matrix equation

Description

The `LowerTriangularSolver` object solves $LX = B$ for X when L is a square, lower-triangular matrix with the same number of rows as B .

To solve $LX = B$ for X :

- 1 Define and set up your linear system solver. See “Construction” on page 4-1167.
- 2 Call `step` to solve the equation according to the properties of `dsp.LowerTriangularSolver`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`lowtriang = dsp.LowerTriangularSolver` returns a linear system solver, `lowtriang`, used to solve the linear system $LX = B$, where L is a lower (or unit-lower) triangular matrix.

`lowtriang = dsp.LowerTriangularSolver('PropertyName', PropertyValue, ...)` returns a linear system solver, `lowtriang`, with each specified property set to the specified value.

Properties

OverwriteDiagonal

Replace diagonal elements of input with ones

When you set this property to `true`, the linear system solver replaces the elements on the diagonal of the input, L , with ones. Set this property to either `true` or `false`. The default is `false`.

RealDiagonalElements

Indicate that diagonal of complex input is real

When you set this property to `true`, the linear system solver optimizes computation speed if the diagonal elements of complex input, L , are real. This property applies only when you set the `OverwriteDiagonal` property to `false`. Set this property to either `true` or `false`. The default is `false`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

ProductDataType

Data type of product

Specify the product data type as `Full precision`, `Same as input`, or `Custom`. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `ProductDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

AccumulatorDataType

Data type of accumulator

Specify the accumulator data type as `Full` precision, `Same` as first input, `Same` as product, or `Custom`. The default is `Full` precision.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

OutputDataType

Data type of output

Specify the output data type as `Same` as first input or `Custom`. The default is `Same` as first input.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `OutputDataType` property to `Custom`. The default is `numericType([], 16, 15)`.

Methods

step Solve matrix equation for specified inputs

Common to All System Objects	
clone	Create System object with same property values
getNumInputs	Expected number of inputs to a System object
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Solve a Lower Triangular Matrix

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
lowtriang = dsp.LowerTriangularSolver;  
u = tril(rand(4, 4));  
b = rand(4, 1);
```

Check that result is the solution to the linear equations.

```
x1 = inv(u)*b
```

```
x1 =
```

```
    0.5177  
    4.5810  
   -3.4853  
    9.6147
```

```
x = lowtriang(u, b)
```

```
x =  
  
    0.5177  
    4.5810  
   -3.4853  
    9.6147
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Forward Substitution block reference page. The object properties correspond to the block parameters.

`dsp.UpperTriangularSolver`

Introduced in R2012a

step

System object: dsp.LowerTriangularSolver

Package: dsp

Solve matrix equation for specified inputs

Syntax

```
X = step(lowtriang,L,B)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`X = step(lowtriang,L,B)` computes the solution, X , of the matrix equation $LX = B$, where L is a square, lower-triangular matrix with the same number of rows as the matrix B .

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.LowpassFilter System object

Package: dsp

FIR or IIR lowpass filter

Description

`dsp.LowpassFilter` independently filters each channel of the input over time using the given design specifications. You can set the `FilterType` property of `dsp.LowpassFilter` to 'FIR' or 'IIR' to implement the object as a FIR or IIR lowpass filter. This object supports fixed-point operations, HDL code generation, and ARM Cortex code generation.

To filter each channel of your input:

- 1 Define and set up your lowpass filter. See “Construction” on page 4-1173.
- 2 Call `step` to filter each channel of the input signal according to the properties of `dsp.LowpassFilter`. The input signal can be a real- or complex-valued column vector or matrix, with floating point or fixed-point precision. If the input signal is a matrix, each column of the matrix is treated as an independent channel. The number of rows in the input signal denote the channel length.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`LPF = dsp.LowpassFilter` returns a minimum order FIR lowpass filter, `LPF`, with the default filter settings. Calling `step` with the default property settings filters the input data with a passband frequency of 8 kHz, a stopband frequency of 12 kHz, a passband ripple of 0.1 dB, and a stopband attenuation of 80 dB.

`LPF = dsp.LowpassFilter(Name,Value)` returns a lowpass filter, with additional properties specified by one, or more `Name,Value` pair arguments. `Name` is the property name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Properties

SampleRate — Input sample rate

44100 (default) | real positive scalar

Input sample rate in Hz, specified as the comma-separated pair consisting of 'SampleRate' and a real positive scalar.

FilterType — Filter type

'FIR' (default) | 'IIR'

Filter type, specified as one of the following options:

- 'FIR' — The object designs an FIR lowpass filter.
- 'IIR' — The object designs an IIR lowpass (biquad) filter.

DesignForMinimumOrder — Minimum order filter design

true (default) | false

Minimum order filter design, specified as the comma-separated pair consisting of 'DesignForMinimumOrder' and a logical value. If this property is true, then `dsp.LowpassFilter` designs filters with the minimum order that meets the passband frequency, stopband frequency, passband ripple, and stopband attenuation specifications. Set these specifications using the corresponding properties. If this property is false, then the object designs filters with the order that you specify in the `FilterOrder` property. This filter design meets the passband frequency, passband ripple, and stopband attenuation specifications that you set using the respective properties.

FilterOrder — Order of the FIR or IIR filter

50 (default) | positive integer scalar

Order of the FIR or IIR filter, specified as the comma-separated pair consisting of 'FilterOrder' and a positive integer scalar. Specifying a filter order is only valid when the value of 'DesignForMinimumOrder' is false.

PassbandFrequency — Filter passband edge frequency

8000 (default) | real positive scalar

Filter passband edge frequency in Hz, specified as the comma-separated pair of 'PassbandFrequency' and a real positive scalar. The value of the passband edge frequency in Hz must be less than half the SampleRate.

StopbandFrequency — Filter stopband edge frequency

12000 (default) | real positive scalar

Filter stopband edge frequency in Hz, specified as the comma-separated pair consisting of 'StopbandFrequency' and a real positive scalar. The value of the stopband edge frequency in Hz must be less than half the SampleRate. You can specify the stopband edge frequency only when 'DesignForMinimumOrder' is true.

PassbandRipple — Maximum ripple of filter response in the passband

0.1 (default) | real positive scalar

Maximum ripple of filter response in the passband, in dB, specified as the comma-separated pair consisting of 'PassbandRipple' and a real positive scalar. Maximum ripple of filter response defaults to 0.1 dB.

StopbandAttenuation — Minimum attenuation in the stopband

80 (default) | real positive scalar

Minimum attenuation in the stopband in dB, specified as the comma-separated pair consisting of 'StopbandAttenuation' and a real positive scalar. Minimum attenuation in the stopband defaults to 80 dB.

Fixed-Point Properties

RoundingMethod — Rounding method for output fixed-point operations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see “Precision and Range”.

CoefficientsDataType — Word and fraction lengths of coefficients

`numericType(1,16)` (default) | `numericType` object

Word and fraction lengths of coefficients, specified as a `numericType` object. The default, `numericType(1,16)` corresponds to a signed numeric type object with 16-bit coefficients and a fraction length determined based on the coefficient values, to give the best possible precision.

This property is not tunable.

Word length of the output is same as the word length of the input. Fraction length of the output is computed such that the entire dynamic range of the output can be represented without overflow. For details on how the fraction length of the output is computed, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

Methods

- `measure` Measure frequency response characteristics of `dsp.LowpassFilter` System object.
- `reset` Reset internal states of lowpass filter
- `step` Filter input using FIR or IIR lowpass filter

For additional methods, see “Analysis Methods for Filter System Objects” on page 3-2.

For a complete list of analysis methods supported for the `dsp.LowpassFilter` object, enter `dsp.LowpassFilter.helpFilterAnalysis` at the MATLAB command prompt.

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

Impulse and Frequency Response of FIR and IIR Lowpass Filters

Create a minimum-order FIR lowpass filter for data sampled at 44.1 kHz. Specify a passband frequency of 8 kHz, a stopband frequency of 12 kHz, a passband ripple of 0.1 dB, and a stopband attenuation of 80 dB.

```
Fs = 44.1e3;
filtertype = 'FIR';
Fpass = 8e3;
Fstop = 12e3;
Rp = 0.1;
Astop = 80;
FIRLPF = dsp.LowpassFilter('SampleRate',Fs, ...
                           'FilterType',filtertype, ...
                           'PassbandFrequency',Fpass, ...
                           'StopbandFrequency',Fstop, ...
                           'PassbandRipple',Rp, ...
                           'StopbandAttenuation',Astop);
```

Design a minimum-order IIR lowpass filter with the same properties as the FIR lowpass filter. Change the `FilterType` property of the cloned filter to `IIR`.

```
IIRLPF = clone(FIRLPF);
IIRLPF.FilterType = 'IIR';
```

Plot the impulse response of the FIR lowpass filter. The zeroth-order coefficient is delayed by 19 samples, which is equal to the group delay of the filter. The FIR lowpass filter is a causal FIR filter.

```
fvtool(FIRLPF, 'Analysis', 'impulse')
```

Plot the impulse response of the IIR lowpass filter.

```
fvtool(IIRLPF,'Analysis','impulse')
```

Plot the magnitude and phase response of the FIR lowpass filter.

```
fvtool(FIRLPF,'Analysis','freq')
```

Plot the magnitude and phase response of the IIR lowpass filter.

```
fvtool(IIRLPF, 'Analysis', 'freq')
```

Calculate the cost of implementing the FIR lowpass filter.

```
cost(FIRLPF)
```

```
ans =
```

```
struct with fields:
```

```

    NumCoefficients: 39
    NumStates: 38
    MultiplicationsPerInputSample: 39
    AdditionsPerInputSample: 38

```

Calculate the cost of implementing the IIR lowpass filter. The IIR filter is more efficient to implement than the FIR filter.

```
cost(IIRLPF)
```

```
ans =
```

```
struct with fields:
```

```
    NumCoefficients: 18  
    NumStates: 14  
    MultiplicationsPerInputSample: 18  
    AdditionsPerInputSample: 14
```

Calculate the group delay of the FIR lowpass filter.

```
grpdelay(FIRLPF)
```

Calculate the group delay of the IIR lowpass filter. The FIR filter has a constant group delay (linear phase), while its IIR counterpart does not.

```
grpdelay(IIRLPF)
```

Filter White Gaussian Noise

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Set up the IIR lowpass filter. The sampling rate of the white Gaussian noise is 44,100 Hz. The passband frequency of the filter is 8 kHz, the stopband frequency is 12 kHz, the passband ripple is 0.1 dB, and the stopband attenuation is 80 dB.

```
Fs = 44.1e3;  
filtertype = 'IIR';
```

```
Fpass = 8e3;  
Fstop = 12e3;  
Rp = 0.1;  
Astop = 80;  
LPF = dsp.LowpassFilter('SampleRate',Fs,...  
    'FilterType',filtertype,...  
    'PassbandFrequency',Fpass,...  
    'StopbandFrequency',Fstop,...  
    'PassbandRipple',Rp,...  
    'StopbandAttenuation',Astop);
```

View the magnitude response of the lowpass filter.

```
fvtool(LPf)
```

Create a spectrum analyzer object.

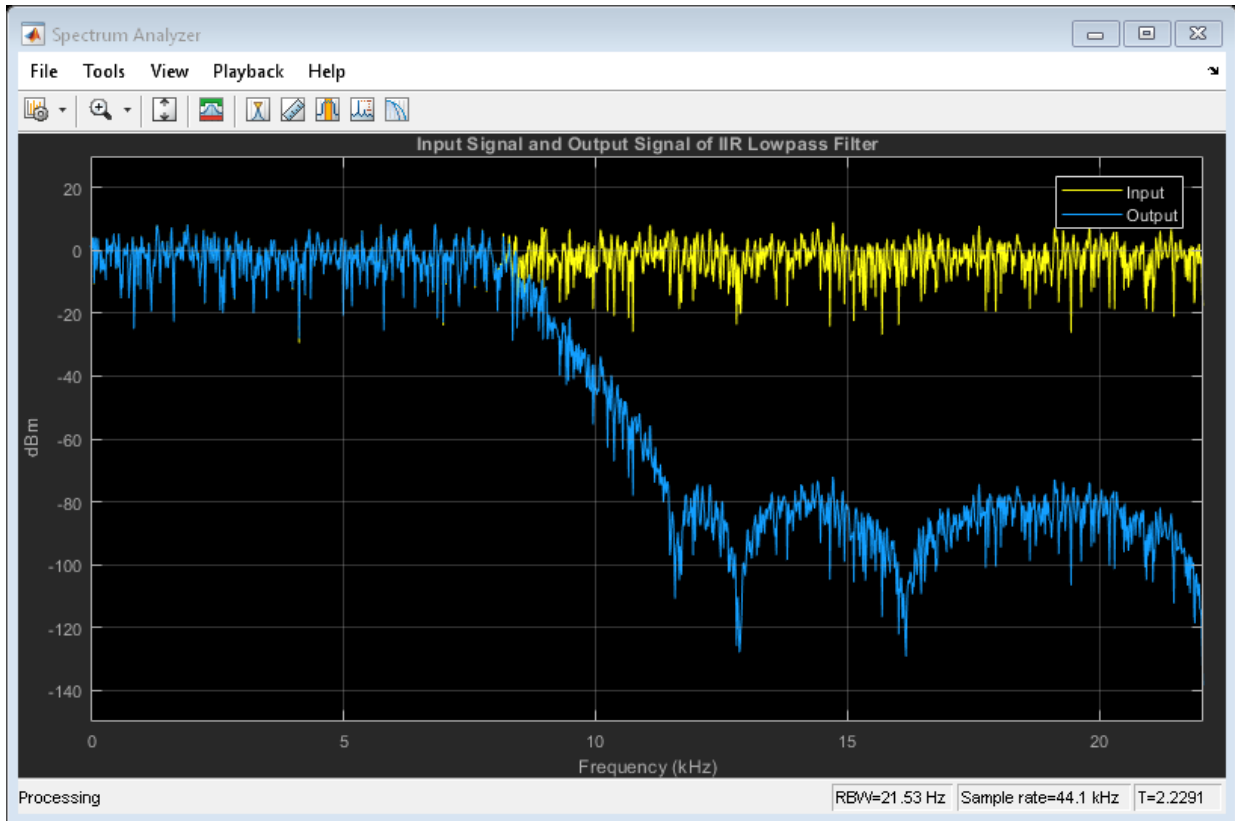

```
hSA = dsp.SpectrumAnalyzer('SampleRate',44.1e3,...
    'PlotAsTwoSidedSpectrum',false,'ShowLegend',true,'YLimits',...
    [-150 30],...
    'Title',...
    'Input Signal and Output Signal of IIR Lowpass Filter');
hSA.ChannelNames = {'Input','Output'};
```

Filter the white Gaussian noisy input signal. View the input and output signals using the spectrum analyzer.

```
for k = 1:100
    Input = randn(1024,1);

    Output = LPF(Input);

    hSA([Input,Output]);
end
```

Supported Data Types

Argument	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point

Algorithms

FIR Lowpass Filter

When the `FilterType` property is set to 'FIR', the `dsp.LowpassFilter` object acts as a FIR lowpass filter.

In this configuration, `dsp.LowpassFilter` is an alternative to using `firceqrip` and `firgr` with `dsp.FIRFilter`. This object condenses the two-step process into one. For the minimum order design, the object uses generalized Remez FIR filter design algorithm. For the specified order design, the object uses the constrained equiripple FIR filter design algorithm. The designed filter is then implemented as a linear phase Type-1 filter with a `Direct form` structure. You can use `dsp.LowpassFilter.measure` to verify that the design meets the prescribed specifications.

IIR Lowpass Filter

When the `FilterType` property is set to 'IIR', the `dsp.LowpassFilter` object acts as an IIR lowpass filter. In this configuration, the object uses the elliptic design method to compute the SOS and scale values required to meet the filter design specifications. The object uses the SOS and scale values to setup a `Direct form I` biquadratic IIR filter, which forms the basis of the IIR version of the `dsp.LowpassFilter System` object. You can use `dsp.LowpassFilter.measure` to verify that the design meets the prescribed specifications.

“Lowpass Filter Design in MATLAB” | `dsp.HighpassFilter`

Introduced in R2015a

measure

System object: `dsp.LowpassFilter`

Package: `dsp`

Measure frequency response characteristics of `dsp.LowpassFilter` System object.

Syntax

```
LPFMeas = measure(LPF)
```

Description

`LPFMeas = measure(LPF)` measures the frequency response characteristics of the `dsp.LowpassFilter` System object, `LPF`.

Input Arguments

LPF — FIR or IIR lowpass filter

`LowpassFilter` System object

FIR or IIR lowpass filter, specified as a `LowpassFilter` System object.

Output Arguments

LPFMeas — Measurements of frequency response characteristics of the lowpass filter

`LowpassFilter` System object

Measurements of frequency response characteristics of the lowpass filter, returned as an `fdesign.lowpassmeas` object.

Examples

Measure Frequency Response Characteristics of Lowpass Filter

Measure the frequency response characteristics of a lowpass filter. Create a `dsp.LowpassFilter` System object with default properties. Measure the frequency response characteristics of the filter.

```
LPF = dsp.LowpassFilter

LPF =
    dsp.LowpassFilter with properties:

        FilterType: 'FIR'
    DesignForMinimumOrder: true
        PassbandFrequency: 8000
        StopbandFrequency: 12000
        PassbandRipple: 0.1000
        StopbandAttenuation: 80
        SampleRate: 44100

    Show all properties
```

```
LPFMeas = measure(LPF)

LPFMeas =
    Sample Rate      : 44.1 kHz
    Passband Edge    : 8 kHz
    3-dB Point       : 9.1311 kHz
    6-dB Point       : 9.5723 kHz
    Stopband Edge    : 12 kHz
    Passband Ripple  : 0.08289 dB
    Stopband Atten.  : 81.6141 dB
    Transition Width : 4 kHz
```

Introduced in R2015a

reset

System object: dsp.LowpassFilter

Package: dsp

Reset internal states of lowpass filter

Syntax

```
reset(LPF)
```

Description

`reset(LPF)` resets the filter states of the lowpass filter, `LPF`, to their initial values. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the `step` method applies the lowpass filter to nonzero input data, the filter might have nonzero states. If you Invoke the `step` method again without first invoking the `reset` method, the object might produce different outputs for an identical input.

Input Arguments

LPF — FIR or IIR lowpass filter

`LowpassFilter` System object

FIR or IIR lowpass filter, specified as a `LowpassFilter` System object.

Examples

Reset a Lowpass Filter

Create a lowpass filter with default properties.

```
LPF = dsp.LowpassFilter;
```

Create a two-channel random signal. Apply the `step` method twice on the signal.

```
x = randn(10,2);
```

```
y1 = step(LPF,x);  
y2 = step(LPF,x);
```

```
no = all(y2==y1)
```

```
no =
```

```
1x2 logical array
```

```
0 0
```

The output is different because the internal states of `LPF` have changed. Use `reset` to reset the lowpass filter and apply `step` again. Verify that the output is unchanged.

```
reset(LPF)
```

```
y3 = step(LPF,x);
```

```
yes = all(y3==y1)
```

```
yes =
```

```
1x2 logical array
```

```
1 1
```

Introduced in R2015a

step

System object: dsp.LowpassFilter

Package: dsp

Filter input using FIR or IIR lowpass filter

Syntax

`Y = step(LPF,X)`

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(LPF,X)` filters the real or complex input signal, `X`, using the lowpass filter, `LPF`. `Y` is a lowpass-filtered version of `X`. The input `X` must be a column vector or matrix. If `X` is a matrix, each column is treated as an independent channel. `X` can be a floating point or a fixed-point input.

Input Arguments

LPF — FIR or IIR lowpass filter

LowpassFilter System object

FIR or IIR lowpass filter, specified as a LowpassFilter System object.

x — Input signal

vector | matrix

Input signal, specified as a vector or matrix with floating point or fixed-point precision. The row length of X is the frame size, that is, channel length. Each column of X is treated as a separate channel. The column length of X is the number of channels.

Output Arguments

y — Lowpass-filtered signal

vector | matrix

Lowpass-filtered signal, returned as a vector or matrix of the same size, data type, and complexity as the input signal, X .

Examples

Filter White Gaussian Noise Signal With Lowpass Filter

Create a lowpass filter with default properties.

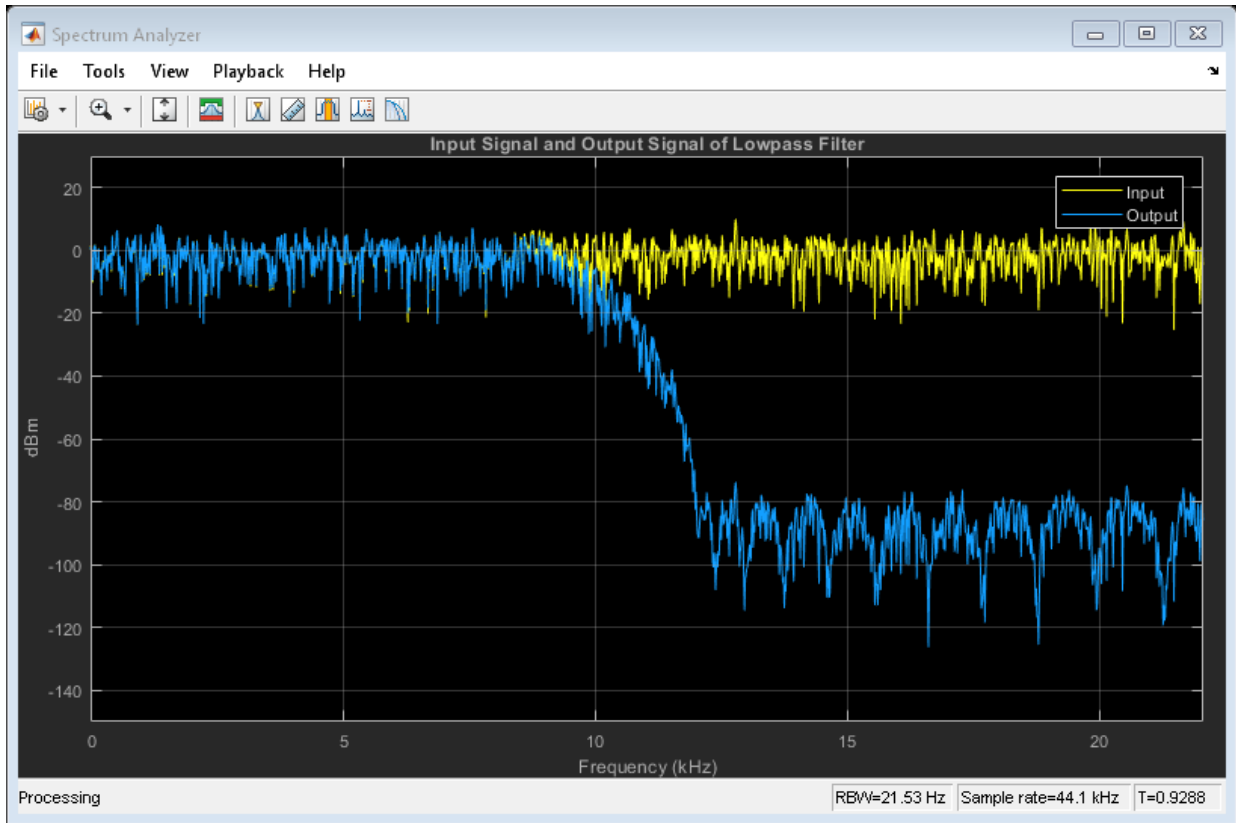

```
LPF = dsp.LowpassFilter;
```

Create a spectrum analyzer object.

```
hSA = dsp.SpectrumAnalyzer('SampleRate',44.1e3,...  
    'PlotAsTwoSidedSpectrum',false,'ShowLegend',true,'YLimits',...  
    [-150 30],...  
    'Title',...  
    'Input Signal and Output Signal of Lowpass Filter');  
hSA.ChannelNames = {'Input','Output'};
```

Implement `step` on `LPF` to filter the white Gaussian noisy input signal. View the input and output signals using the spectrum analyzer.

```
for k = 1:100  
    Input = randn(1024,1);  
  
    Output = step(LPf,Input);  
  
    step(hSA, [Input,Output]);  
end
```

Introduced in R2015a

dsp.LPCToAutocorrelation System object

Package: dsp

Convert linear prediction coefficients to autocorrelation coefficients

Description

The `LPCToAutocorrelation` System object converts linear prediction coefficients to autocorrelation coefficients.

To convert LPC to autocorrelation coefficients:

- 1 Define and set up your LPC to autocorrelation object. See “Construction” on page 4-1197.
- 2 Call `step` to convert LPC according to the properties of `dsp.LPCToAutocorrelation`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`lpc2ac = dsp.LPCToAutocorrelation` returns an LPC to autocorrelation System object, `lpc2ac`, that converts linear prediction coefficients (LPC) to autocorrelation coefficients.

`lpc2ac = dsp.LPCToAutocorrelation('PropertyName',PropertyValue,...)` returns an LPC to autocorrelation conversion object, `lpc2ac`, with each specified property set to the specified value.

Properties

PredictionErrorInputPort

Enable prediction error power input

Choose how to select the prediction error power. When you set this property to `true`, you must specify the prediction error power as a second input to the `step` method. When you set this property to `false`, the object assumes that the prediction error power is 1. The default is `false`.

NonUnityFirstCoefficientAction

Action to take when first LPC coefficient is not 1

Specify the action that the object takes when the first coefficient of each channel of the LPC input is not 1. Select `Replace with 1` or `Normalize`. The default is `Replace with 1`.

Methods

`step` Autocorrelation coefficients from LPC coefficients

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

Convert LPC To Autocorrelation Coefficients

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Convert the linear prediction coefficients to autocorrelation coefficients.

```
a = [1.0 -1.4978 1.4282 -1.3930 0.9076 -0.3855 0.0711].';  
lpc2ac = dsp.LPCToAutocorrelation;  
ac = lpc2ac(a);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the [LPC/RC to Autocorrelation](#) block reference page. The object properties correspond to the block parameters, except:

The object does not have a property that corresponds to the **Type of Conversion** block parameter. The object's behavior corresponds to the block's behavior when you set the **Type of Conversion** parameter to `LPC to autocorrelation`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

See Also

[dsp.LPCToCepstral](#) | [dsp.LPCToLSF](#) | [dsp.LPCToRC](#) | [dsp.RCToAutocorrelation](#)

Introduced in R2012a

step

System object: dsp.LPCToAutocorrelation

Package: dsp

Autocorrelation coefficients from LPC coefficients

Syntax

```
AC = step(lpc2ac,A)
AC = step(lpc2ac,A,P)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`AC = step(lpc2ac,A)` converts the columns of the linear prediction coefficients, `A`, to autocorrelation coefficients, `AC`. The object assumes a prediction error power of 1.

`AC = step(lpc2ac,A,P)` when you set the `PredictionErrorInputPort` property to `true`, converts the columns of the linear prediction coefficients, `A`, to autocorrelation coefficients, `AC`. This conversion uses `P` as the prediction error power. `P` must be a row vector with same number of columns as `A`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.LPCToCepstral System object

Package: dsp

Convert linear prediction coefficients to cepstral coefficients

Description

The `LPCToCepstral` object converts linear prediction coefficients to cepstral coefficients.

To convert LPC to cepstral coefficients:

- 1 Define and set up your LPC to cepstral converter. See “Construction” on page 4-1203.
- 2 Call `step` to convert LPC according to the properties of `dsp.LPCToCepstral`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`lpc2cc = dsp.LPCToCepstral` returns an LPC to cepstral converter object, `lpc2cc`, that converts linear prediction coefficients (LPCs) to cepstral coefficients (CCs).

`lpc2cc = dsp.LPCToCepstral('PropertyName', PropertyValue, ...)` returns an LPC to cepstral converter object, `lpc2cc`, with each specified property set to the specified value.

Properties

PredictionErrorInputPort

Enable prediction error power input

Choose how to set the prediction error power. When you set this property to `true`, you must specify the prediction error as a second input to the `step` method. When you set this property to `false`, the object assumes the prediction error power is 1. The default is `false`.

CepstrumLengthSource

Source of cepstrum length

Select how to specify the length of cepstral coefficients: `Auto` or `Property`. The default is `Auto`. When this property is set to `Auto`, the length of each channel of the cepstral coefficients output is the same as the length of each channel of the input LPC coefficients. The default is `Property`.

CepstrumLength

Number of output cepstral coefficients

Set the length of the output cepstral coefficients vector as a scalar numeric integer. This property applies when you set the `CepstrumLengthSource` property to `Property`. The default is 10.

NonUnityFirstCoefficientAction

LPC coefficient nonunity action

Specify the action that the object takes when the first coefficient of each channel of the LPC input is not 1. Select `Replace with 1` or `Normalize`. The default is `Replace with 1`.

Methods

`step` Cepstral coefficients from columns of input LPC coefficients

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object

Common to All System Objects	
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Convert LPC To Cepstral Coefficients

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
levinson = dsp.LevinsonSolver;
levinson.AOutputPort = true; % Output polynomial coefficients
ac = dsp.Autocorrelator;
ac.MaximumLagSource = 'Property';
ac.MaximumLag = 9; % Compute autocorrelation lags between [0:9]
lpc2cc = dsp.LPCToCepstral;
x = (1:100)';
a = ac(x);
```

Compute LPC coefficients.

```
A = levinson(a);
```

Convert LPC to CC.

```
CC = lpc2cc(A);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the LPC to/from Cepstral Coefficients block reference page. The object properties correspond to the block parameters, except:

The object does not have a property that corresponds to the **Type of Conversion** block parameter. The object's behavior corresponds to the block's behavior when you set the **Type of Conversion** parameter to LPCs to cepstral coefficients.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

Introduced in R2012a

step

System object: dsp.LPCToCepstral

Package: dsp

Cepstral coefficients from columns of input LPC coefficients

Syntax

```
CC = step(lpc2cc,A)
```

```
CC = step(lpc2cc,A,P)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`CC = step(lpc2cc,A)` computes the cepstral coefficients, `CC`, from the columns of input linear prediction coefficients, `A`. The object assumes the prediction error power is 1.

`CC = step(lpc2cc,A,P)` when you set the `PredictionErrorInputPort` property to `true`, computes the cepstral coefficients, `CC`, from the columns of input linear prediction coefficients, `A`. This conversion uses `P` as the prediction error power.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.LPCToLSF System object

Package: dsp

Convert linear prediction coefficients to line spectral frequencies

Description

The `LPCToLSF` object converts linear prediction coefficients to line spectral frequencies.

To convert LPC to LSF:

- 1 Define and set up your LPC to LSF converter. See “Construction” on page 4-1209.
- 2 Call `step` to convert LPC according to the properties of `dsp.LPCToLSF`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`lpc2lsf = dsp.LPCToLSF` returns a System object, `lpc2lsf`, that converts linear prediction coefficients (LPCs) to line spectral frequencies (LSFs).

`lpc2lsf = dsp.LPCToLSF('PropertyName',PropertyValue,...)` returns an LPC to LSF System object, `lpc2lsf`, with each specified property set to the specified value.

Properties

NumCoarseGridPoints

Number of coarse subintervals used for finding roots (LSP values)

Specify the number of coarse subintervals, n , used for finding line spectral pairs (LSP) values as a positive scalar integer. LSPs, which are the roots of two particular polynomials related to the input LPC polynomial, always lie in the range $(-1, 1)$. The System object finds these roots using the Chebyshev polynomial root finding method. To compute LSF outputs, the object computes the arc cosine of the LSPs, outputting values ranging from 0 to pi radians. The object divides the interval $(-1, 1)$ into n subintervals and looks for roots in each subinterval. If you set n too small in relation to the LPC polynomial order, the object can fail to find some of the roots. The default is 64. This property is tunable.

NumBisects

Value of bisection refinement used for finding roots

Specify the root bisection refinement value, k , used in the Chebyshev polynomial root finding method, where each line spectral pair (LSP) output is within

$$\frac{1}{(n \cdot 2^k)}$$

of the actual LSP value. Here n is the value of the `NumCoarseGridPoints` property, and the object searches a maximum of $k \cdot (n - 1)$ points for finding the roots. You must set the `NumBisects` property value k , to a positive scalar integer. The default is 4. This property is tunable.

ExceptionOutputPort

Produces output with validity status of LSF output

Set this property to `true` to return a second output that indicates whether the computed LSF values are valid. The output is a vector with a length equal to the number of channels. A logical value of 1 indicates valid output. A logical value of 0 indicates invalid output. The LSF outputs are invalid when the object fails to find all the LSF values or when the input LPCs are unstable. The default is `false`.

OverwriteInvalidOutput

Enable overwriting invalid output with previous output

Specify the action that the System object should take for invalid LSF outputs. When you set this property to `true`, the object overwrites the invalid output with the previous

output. When you set this property to `false`, the object does not take any action on invalid outputs and ignores the outputs.

FirstOutputValuesSource

Source of values for first output when output is invalid

Specify the source of values for the first output when the output is invalid as `Auto` or `Property`. This property applies when you set the `OverwriteInvalidOutput` property to `true`. The default is `Auto`. When you set this property to `Auto`, the object uses a default value for the first output. The default value corresponds to the LSF representation of an allpass filter.

FirstOutputValues

Value of the first output

Specify a numeric vector of LSF values for overwriting an invalid first output. The length of this vector must be one less than the length of the input LPC vector. For multichannel inputs, you can set this property to a matrix with the same number of channels as the input, or one vector that is applied to every channel. The default is an empty vector. This property applies when you set the `OverwriteInvalidOutput` property to `true` and the `FirstOutputValuesSource` property to `Property`.

NonUnityFirstCoefficientAction

Action to take when first LPC coefficient is not 1

Specify the action the object takes when the first coefficient of each channel of the LPC input is not 1 as `Replace with 1` or `Normalize`. The default is `Replace with 1`.

Methods

- `reset` Reset values for overwriting invalid outputs to their initial values
- `step` Convert LPC coefficients to line spectral frequencies

Common to All System Objects

<code>clone</code>	Create System object with same property values
--------------------	--

Common to All System Objects	
getNumInputs	Expected number of inputs to a System object
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Convert LPC Coefficients To LSF Coefficients

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Convert LPC to LSF coefficients

```
a = [1.0000 0.6149 0.9899 0.0000 0.0031 -0.0082]';  
lpc2lsf = dsp.LPCToLSF;  
y = lpc2lsf(a);  
display(y);
```

y =

```
0.7842  
1.5605  
1.8776  
1.8984  
2.3593
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the LPC to LSF/LSP Conversion block reference page. The object properties correspond to the block parameters, except:

There is no object property that corresponds to the **Output** block parameter. The object only supports LSF outputs in the range $(0, \Pi)$

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

`dsp.LPCToLSP` | `dsp.LSFToLPC`

Introduced in R2012a

reset

Reset values for overwriting invalid outputs to their initial values

Syntax

```
reset(lpc2l5f)
```

Description

`reset(lpc2l5f)` resets the values for overwriting the invalid outputs to their initial values.

step

System object: dsp.LPCToLSF

Package: dsp

Convert LPC coefficients to line spectral frequencies

Syntax

```
LSF = step(lpc2lsf,A)
[... , STATUS] = step(lpc2lsf,A)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

`LSF = step(lpc2lsf,A)` converts the LPC coefficients, A , to line spectral frequencies, LSF, in the range (0π) . The System object operates along the columns of the input A .

`[... , STATUS] = step(lpc2lsf,A)` also returns the status flag, `STATUS`, indicating if the current output is valid when the `ExceptionOutputPort` property is `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.LPCToLSP System object

Package: dsp

Convert linear prediction coefficients to line spectral pairs

Description

The `LPCToLSP` object converts linear prediction coefficients to line spectral pairs.

To convert LPC to LSP:

- 1 Define and set up your LPC to LSP converter. See “Construction” on page 4-1216.
- 2 Call `step` to convert LPC according to the properties of `dsp.LPCToLSP`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`lpc2lsp = dsp.LPCToLSP` returns a System object, `lpc2lsp`, that converts linear prediction coefficients (LPCs) to line spectral pairs (LSPs).

`lpc2lsp = dsp.LPCToLSP('PropertyName',PropertyValue,...)` returns an LPC to LSP System object, `lpc2lsp`, with each specified property set to the specified value.

Properties

NumCoarseGridPoints

Number of coarse subintervals used for finding roots (LSP values)

Specify the number of coarse subintervals, n , used for finding line spectral pairs (LSP) values, as a positive scalar integer. LSPs, which are the roots of two particular polynomials related to the input LPC polynomial, always lie in the range $(-1, 1)$. The System object finds these roots using the Chebyshev polynomial root finding method. The object divides the interval $(-1, 1)$ into n subintervals and looks for roots in each subinterval. If n is set to too small a number in relation to the LPC polynomial order, the object can fail to find some of the roots. The default is 64. This property is tunable.

NumBisects

Value of bisection refinement used for finding roots

Specify the root bisection refinement value, k , that the Chebyshev polynomial uses in the root finding method. For each line spectral pair (LSP) the output is within

$$\frac{1}{n \cdot 2^k}$$

of the actual LSP value. Here n is the value of the `NumCoarseGridPoints` property and the object searches a maximum of

$$k \cdot (n-1)$$

points for finding the roots. The `NumBisects` property value k , must be a positive scalar integer. The default is 4. This property is tunable.

ExceptionOutputPort

Produces output with validity status of LSP output

Set this property to `true` to return a second output that indicates whether the computed LSP values are valid. The object outputs a vector length equal to the number of channels. A logical value of 1 indicates the output is valid. A logical value of 0 indicates the output is invalid. The LSP outputs are invalid when the object fails to find all the LSP values or when the input LPCs are unstable. The default is `false`.

OverwriteInvalidOutput

Enable overwriting invalid output with previous output

Specify the action that the object takes for invalid LSP outputs. When you set this property to `true`, the object overwrites the invalid output with the previous output. When you set this property to `false`, the object takes no action on invalid outputs and ignores the outputs.

FirstOutputValuesSource

Source of values for first output when output is invalid

Specify the source of values for the first output when the output is invalid as `Auto` or `Property`. This property applies only when you set the `OverwriteInvalidOutput` property to `true`. The default is `Auto`. When this property is `Auto`, the object uses a default value for the first output. The default value corresponds to the LSP representation of an allpass filter.

FirstOutputValues

Value of first output

Specify a numeric vector of LSP values for overwriting an invalid first output. The length of this vector must be one less than the length of the input LPC vector. For multichannel inputs, set this property can to a matrix with the same number of channels as the input or one vector that you apply to every channel. The default is an empty vector. This property applies only when you set the `OverwriteInvalidOutput` property to `true` and the `FirstOutputValuesSource` property to `Property`.

NonUnityFirstCoefficientAction

First coefficient nonunity action

Specify the action that the object takes when the first coefficient of each channel of the LPC input is not equal to 1. Specify as one of `Replace with 1` or `Normalize`. The default is `Replace with 1`.

Methods

- `reset` Reset values for overwriting invalid outputs to their initial values
- `step` Convert linear prediction coefficients to line spectral pairs

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object

Common to All System Objects

Description

`reset (H)` resets the values for overwriting the invalid outputs to their initial values.

step

System object: dsp.LPCToLSP

Package: dsp

Convert linear prediction coefficients to line spectral pairs

Syntax

```
LSF = step(lpc2lsp,A)
[... , STATUS] = step(lpc2lsp,A)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

`LSF = step(lpc2lsp,A)` converts the LPC coefficients, A , to line spectral pairs normalized in the range $(-1\ 1)$, LSP. The object operates along the columns of the input A .

`[... , STATUS] = step(lpc2lsp,A)` also returns the status flag, `STATUS`, indicating if the current output is valid when the `ExceptionOutputPort` property is `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.LPCToRC System object

Package: dsp

Convert linear prediction coefficients to reflection coefficients

Description

The `LPCToRC` object converts linear prediction coefficients to reflection coefficients.

To convert LPC to reflection coefficients:

- 1 Define and set up your LPC to RC converter. See “Construction” on page 4-1223.
- 2 Call `step` to convert LPC according to the properties of `dsp.LPCToRC`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`lpc2rc = dsp.LPCToRC` returns an LPC to RC System object, `lpc2rc`, that converts linear prediction coefficients (LPC) to reflection coefficients (RC).

`lpc2rc = dsp.LPCToRC('PropertyName',PropertyValue,...)` returns an LPC to RC conversion object, `lpc2rc`, with each specified property set to the specified value.

Properties

PredictionErrorOutputPort

Enable normalized prediction error power output

Set this property to `true` to return the normalized error power as a vector with one element per input channel. Each element varies between zero and one. The default is `true`.

ExceptionOutputPort

Produces output with stability status of filter represented by LPC coefficients

Set this property to `true` to return the stability status of the filter. A logical value of 1 indicate a stable filter. A logical value of 0 indicate an unstable filter. The default is `false`.

NonUnityFirstCoefficientAction

Action to take when first LPC coefficient is not 1

Specify the action that the object takes when the first coefficient of each channel of the LPC input is not 1. Select `Replace with 1` or `Normalize`. The default is `Replace with 1`.

Methods

`step` Convert columns of linear prediction coefficients to reflection coefficients

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

Convert LPC Coefficients To RC Coefficients

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Convert the linear prediction coefficients to reflection coefficients:

```
load mtlb

levinson = dsp.LevinsonSolver;
levinson.AOutputPort = true;
levinson.KOutputPort = false;

ac = dsp.Autocorrelator;
lpc2rc = dsp.LPCToRC;
ac.MaximumLagSource = 'Property';
```

Compute autocorrelation for lags between [0:10]

```
ac.MaximumLag = 10;
a = ac(mtlb);
A = levinson(a); % Compute LPC coefficients
[K, P] = lpc2rc(A); % Convert to RC
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the LPC to/from RC block reference page. The object properties correspond to the block parameters, except:

- There is no object property that corresponds to the **Type of conversion** block parameter. The object always converts LPC to RC.
- The `NonUnityFirstCoefficientAction` object property corresponds to the **If first input value is not 1** block parameter. There is neither a `Normalize` and `warn` nor an `Error` option for the object.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

See Also

`dsp.LPCToAutocorrelation` | `dsp.RCToLPC`

Introduced in R2012a

step

System object: dsp.LPCToRC

Package: dsp

Convert columns of linear prediction coefficients to reflection coefficients

Syntax

```
[K,P] = step(lpc2rc,A)
K = step(lpc2rc,A)
[... , S] = step(lpc2rc,A)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

`[K,P] = step(lpc2rc,A)` converts the columns of linear prediction coefficients, `A`, to reflection coefficients `K` and outputs the normalized prediction error power, `P`.

`K = step(lpc2rc,A)` when you set the `PredictionErrorOutputPort` property to `false`, converts the columns of linear prediction coefficients, `A`, to reflection coefficients `K`.

`[... , S] = step(lpc2rc,A)` also outputs the LPC filter stability, `S`, when you set the `ExceptionOutputPort` property to `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as

dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.LSFToLPC System object

Package: dsp

Convert line spectral frequencies to linear prediction coefficients

Description

The `LSFToLPC` object converts line spectral frequencies to linear prediction coefficients.

To convert LSF to LPC:

- 1 Define and set up your LSF to LPC converter. See “Construction” on page 4-1229.
- 2 Call `step` to convert LSF according to the properties of `dsp.LSFToLPC`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`lsf2lpc = dsp.LSFToLPC` returns an LSF to LPC System object, `lsf2lpc`, which converts line spectral frequencies (LSFs) to linear prediction coefficients (LPCs).

Methods

`step` Convert input line spectral frequencies to linear prediction coefficients

Common to All System Objects	
<code>clone</code>	Create System object with same property values

Common to All System Objects	
getNumInputs	Expected number of inputs to a System object
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Convert LSF Coefficients to LPC Coefficients

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
a = [1.0000 0.6149 0.9899 0.0000 0.0031 -0.0082]';  
a =  
  
    1.0000  
    0.6149  
    0.9899  
         0  
    0.0031  
   -0.0082  
  
lpc2lsf = dsp.LPCToLSF;  
ylsf = lpc2lsf(a);  
lsf2lpc = dsp.LSFToLPC;  
ylpc = lsf2lpc(ylsf);
```

Check if values in `ylpc` are the same as in `a`.

```
display(ylpc);  
  
ylpc =
```

```
1.0000
0.6149
0.9899
0.0000
0.0031
-0.0082
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the LSF/LSP to LPC Conversion block reference page. The object properties correspond to the block parameters, except:

The object does not have a property that corresponds to the **Input** block parameter. The object's behavior corresponds to the block's behavior when you set the **Input** parameter to LSF in range (0 pi) .

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

step

System object: dsp.LSFToLPC

Package: dsp

Convert input line spectral frequencies to linear prediction coefficients

Syntax

```
A = step(lsf2lpc, LSF)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

`A = step(lsf2lpc, LSF)` converts the input line spectral frequencies, (LSF), in the range $(0, \pi)$, LSF, to linear prediction coefficients, A. The input can be a vector or a matrix, where each column of the matrix is treated as a separate channel.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.LSPToLPC System object

Package: dsp

Convert line spectral pairs to linear prediction coefficients

Description

The `LSPToLPC` object converts line spectral pairs to linear prediction coefficients.

To convert LSP to LPC:

- 1 Define and set up your LSP to LPC converter. See “Construction” on page 4-1233.
- 2 Call `step` to convert LSP according to the properties of `dsp.LSPToLPC`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = dsp.LSPToLPC` returns an LSP to LPC System object, `H`, which converts line spectral pairs (LSPs) to linear prediction coefficients (LPCs).

Methods

`step` Convert input line spectral pairs to linear prediction coefficients

Common to All System Objects	
<code>clone</code>	Create System object with same property values

Common to All System Objects	
getNumInputs	Expected number of inputs to a System object
getNumOutputs	Expected number of outputs of a System object

`dsp.LPCToLSP` | `dsp.LSFToLPC`

Introduced in R2012a

step

System object: dsp.LSPToLPC

Package: dsp

Convert input line spectral pairs to linear prediction coefficients

Syntax

```
A = step(lsp2lpc,LSP)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`A = step(lsp2lpc,LSP)` converts the input line spectral pairs in the range $(-1,1)$, `LSP`, to linear prediction coefficients, `A`. The input can be a vector or a matrix, where each column of the matrix is treated as a separate channel.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.LUFactor System object

Package: dsp

Factor square matrix into lower and upper triangular matrices

Description

The `LUFactor` object factors a square matrix into lower and upper triangular matrices.

To factor a square matrix into lower and upper triangular matrices:

- 1 Define and set up your System object. See “Construction” on page 4-1237.
- 2 Call `step` to factor the square matrix according to the properties of `dsp.LUFactor`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`lu = dsp.LUFactor` returns an `LUFactor` System object, `lu`, which factors a row

permutation of a square input matrix A as $A_p = L \cdot U$, where L is the unit-lower triangular matrix, and U is the upper triangular matrix. The row-pivoted matrix A_p contains the rows of A permuted as indicated by the permutation index vector P . The equivalent MATLAB code is $A_p = A(P, :)$.

`lu = dsp.LUFactor('PropertyName', PropertyValue, ...)` returns an `LUFactor` object, `lu`, with each specified property set to the specified value.

Properties

ExceptionOutputPort

Set to `true` to output singularity of input

Set this property to `true` to output the singularity of the input as logical data type values of `true` or `false`. An output of `true` indicates that the current input is singular, and an output of `false` indicates the current input is nonsingular.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `|Ceiling|Convergent|Floor|Nearest|Round|Simplest|Zero|`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as `Full precision`, `Same as input` or `Custom`. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as `Full` precision, `Same as input`, `Same as product` or `Custom`. The default is `Full` precision.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the “`OutputDataType`” on page 4-0 property to `Custom`. The default is `numericType([], 16, 15)`.

Methods

`step` Decompose matrix into lower and upper triangular matrices

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object

Common to All System Objects	
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Decompose a Square Matrix

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Decompose a square matrix into the lower and upper components.

```
lu = dsp.LUFactor;
x = rand(4)

x =

    0.8147    0.6324    0.9575    0.9572
    0.9058    0.0975    0.9649    0.4854
    0.1270    0.2785    0.1576    0.8003
    0.9134    0.5469    0.9706    0.1419

[LU, P] = lu(x);
L = tril(LU,-1)+diag(ones(size(LU,1),1));
U = triu(LU);
y = L*U

y =

    0.9134    0.5469    0.9706    0.1419
    0.9058    0.0975    0.9649    0.4854
    0.8147    0.6324    0.9575    0.9572
    0.1270    0.2785    0.1576    0.8003
```

Check back whether y equals the permuted x

```
xp = x(P, :)
```

```
xp =
```

```
    0.9134    0.5469    0.9706    0.1419  
    0.9058    0.0975    0.9649    0.4854  
    0.8147    0.6324    0.9575    0.9572  
    0.1270    0.2785    0.1576    0.8003
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the LU Factorization block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

`dsp.LDLFactor`

Introduced in R2012a

step

System object: dsp.LUFactor

Package: dsp

Decompose matrix into lower and upper triangular matrices

Syntax

```
[LU,P] = step(lu,A)
[LU,P,S] = step(lu,A)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[LU,P] = step(lu,A)` decomposes the matrix `A` into lower and upper triangular matrices. The output `LU` is a composite matrix with lower triangle elements from `L` and upper triangle elements from `U`. The permutation vector `P` is the second output.

`[LU,P,S] = step(lu,A)` returns an additional output `S` indicating if the input is singular when the `ExceptionOutputPort` property is set to `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.MatFileReader System object

Package: dsp

Read MAT file

Description

The `MatFileReader` object reads V7.3 MAT files.

To read V7.3 MAT files:

- 1 Define and set up your System object. See “Construction” on page 4-1244.
- 2 Call `step` to read the MAT file according to the properties of `dsp.MatFileReader`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

Construction

`mfr = dsp.MatFileReader` returns a System object, `mfr`, to read scalar stream data from a V7.3 MAT file.

`mfr = dsp.MatFileReader(FILENAME, VARIABLENAME, FRAMESIZE)` reads frames of MAT file data, using the specified file name, variable name, and frame size.

`mfr = dsp.MatFileReader('PropertyName', PropertyValue, ...)` reads MAT file data with each specified property set to the specified value.

`mfr = dsp.MatFileReader(FILENAME, VARIABLENAME, FRAMESIZE, 'PropertyName', PropertyValue, ...)` reads frames of MAT file data, using the specified file name, variable name, and frame size, and other specified properties set to the specified values.

Properties

Filename

Name of MAT file from which to read

Specify the name of a MAT file as a character vector. Specify the full path for the file only if the file is not on the MATLAB path.

Default: Untitled.mat

VariableName

Name of the variable to read

Name of the variable stored in and read from the MAT file.

Default: x

SamplesPerFrame

Number of samples per output frame

Specify the number of elements (samples per frame) to read from the MAT file each time the `step` method is called.

Default: 1

Methods

`isDone` End-of-file status

`reset` Reset internal states of multimedia file reader to read from beginning of file

`step` Read data from a variable in the MAT file

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object

Common to All System Objects	
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Read a MAT File

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Read a MAT file using the `MatFileReader` object.

```
filename = [tempname '.mat']; % Create variable name
originalData = rand(40,2);
save(filename, 'originalData', '-v7.3'); % Write to MAT file

mfr = dsp.MatFileReader(filename, 'VariableName', ...
    'originalData', 'SamplesPerFrame', 4);
while ~isDone(mfr) % Stream data into MATLAB
    finalData = mfr();
end
```

See Also

`dsp.MatFileWriter`

isDone

System object: dsp.MatFileReader

Package: dsp

End-of-file status

Syntax

```
STATUS = isDone(mfr)
```

Description

`STATUS = isDone(mfr)` returns a logical value, `STATUS`. When the `MatFileReader` object, `mfr`, reaches the end of the MAT file, `STATUS` is `true`.

reset

System object: dsp.MatFileReader

Package: dsp

Reset internal states of multimedia file reader to read from beginning of file

Syntax

```
reset(mfr)
```

Description

`reset(mfr)` resets the `MatFileReader` object to read from the beginning of the file.

step

System object: dsp.MatFileReader

Package: dsp

Read data from a variable in the MAT file

Syntax

```
X = step(mfr)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

`X = step(mfr)` reads data, `X`, from a variable stored in a MAT-file. The variable is assumed to be N -dimensional and a MATLAB built-in datatype. The data is read into MATLAB by reading along the first dimension.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.MatFileWriter System object

Package: dsp

Write MAT file

Description

The `MatFileWriter` object writes data to a V7.3 MAT file.

To write data to a V7.3 MAT file:

- 1 Define and set up your System object. See “Construction” on page 4-1250.
- 2 Call `step` to write data according to the properties of `dsp.MatFileWriter`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`mfw = dsp.MatFileWriter` returns a MAT file writer System object, `mfw`, that writes data to a V7.3 MAT file.

`mfw = dsp.MatFileWriter('PropertyName',PropertyValue,...)` returns a MAT file writer System object, `mfw`, with each specified property set to the specified value.

`mfw = dsp.MatFileWriter(FILENAME,'PropertyName',PropertyValue,...)` returns a MAT file writer System object, `mfw`, with `Filename` property set to `FILENAME` and other specified properties set to the specified values.

Properties

Filename

Name of MAT file to write

Specify the name of a MAT file as a character vector. Specify the full path for the file only if the file is not on the MATLAB path. The default file name is `Untitled.mat`.

VariableName

Name of the variable to write

Name of the variable to which to write. This variable is stored in the MAT file. The default variable name is `x`. You cannot overwrite a variable that is already in an existing MAT file.

Methods

`step` Write one frame of MAT file data

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

Write Data Into a MAT File

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

First, create a variable name.

```
filename = [tempname '.mat'];
```

Next, write that variable to a MAT-file.

```
mfw = dsp.MatFileWriter(filename, 'VariableName', 'originalData');  
for i = 1:10  
    originalData = rand(4,2);  
    mfw(originalData);  
end  
release(mfw); % This will close the MAT file
```

Finally, load the variable back into MATLAB.

```
data = load(filename, 'originalData');
```

Plot the data.

```
plot(data.originalData);
```

See Also

`dsp.MatFileReader`

Introduced in R2012b

step

System object: dsp.MatFileWriter

Package: dsp

Write one frame of MAT file data

Syntax

`step(mfw, X)`

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

`step(mfw, X)` writes one frame of data, `X`, to the variable stored in the MAT file. The variable is assumed to be N-dimensional and a MATLAB built-in data type. The data is written to the file by concatenating along the first dimension.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.Maximum System object

Package: dsp

Find maximum value of input or sequence of inputs

Description

The `dsp.Maximum` object finds the maximum values of an input or sequence of inputs.

To compute the maximum value of an input or sequence of inputs:

- 1 Define and set up your System object. See “Construction” on page 4-1255.
- 2 Call `step` to find the maximum according to the properties of `dsp.Maximum`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Note The `Running` mode in the `dsp.Maximum` System object will be removed in a future release. To compute the running maximum in MATLAB, use the `dsp.MovingMaximum` System object instead.

Construction

`max = dsp.Maximum` returns an object, `max`, that computes the value and index of the maximum elements in an input or a sequence of inputs along the specified “Dimension” on page 4-0 .

`max = dsp.Maximum('PropertyName', PropertyValue, ...)` returns a maximum-finding object, `max`, with each specified property set to the specified value.

Properties

ValueOutputPort

Output maximum value

Set this property to `true` in order to output the maximum of the input. This property applies only when you set the `RunningMaximum` property to `false`. The default is `true`.

RunningMaximum

Calculate over single input or multiple inputs

When you set this property to `true`, the object computes the maximum value over successive calls to the `step` method. When you set this property to `false`, the object computes the maximum value over the current input. The default is `false`.

IndexOutputPort

Output index of maximum value

Set this property to `true` to output the index of the maximum value of the input. This property applies only when you set the `RunningMaximum` property to `false`. The default is `true`.

ResetInputPort

Additional input to enable resetting of running maximum

Set this property to `true` to enable resetting the running maximum. When you set this property to `true`, you must specify a reset input to the `step` method to reset the running maximum. This property applies only when you set the `RunningMaximum` property to `true`. The default is `false`.

ResetCondition

Condition that triggers resetting of running maximum

Specify the event that resets the running maximum as one of `| Rising edge | Falling edge | Either edge | Non-zero |`. This property applies only when you set the “ResetInputPort” on page 4-0 property to `true`. The default is `Non-zero`.

IndexBase

Numbering base for index of maximum value

Specify whether to start the index numbering from `One` or `Zero` when computing the index of the maximum value. This property applies only when you set the `IndexOutputPort` property to `true`. The default is `One`.

Dimension

Dimension to operate along

Specify how the maximum calculation is performed over the data as one of `All` | `Row` | `Column` | `Custom` |. This property applies when you set the `RunningMaximum` property to `false`. The default is `Column`.

CustomDimension

Numerical dimension to calculate over

Specify the integer dimension of the input signal over which the object finds the maximum. The cannot exceed the number of dimensions in the input signal. This property only applies when you set the “Dimension” on page 4-0 property to `Custom`. The default is `1`.

Fixed-Point Properties**RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as one of `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |. The default is `Floor`.

OverflowAction

Action to take when integer input is out-of-range

Specify the overflow action as one of `Wrap` | `Saturate` |. The default is `Wrap`.

ProductDataType

Data type of product

Specify the product fixed-point data type as one of | Same as input | Custom |. The default is Same as input.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

AccumulatorDataType

Data type of accumulator

Specify the accumulator fixed-point data type as one of | Same as product | Same as input | Custom |. The default is Same as product.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

Methods

- reset Reset computation of running maximum
- step Maximum value

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object

Common to All System Objects	
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Compute the Maximum and Running Maximum of a Signal

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Find a maximum value and its index.

```
max1 = dsp.Maximum;  
x = randn(100,1);  
[y, I] = max1(x)
```

```
y = 3.5784
```

```
I = 9
```

Compute a running maximum.

```
max2 = dsp.Maximum;  
max2.RunningMaximum = true;  
x = randn(100,1);  
z = max2(x);  
plot(z);
```

$y(i)$ is the minimum of all values in the vector $x(1:i)$.

Algorithms

This object implements the algorithm, inputs, and outputs described on the Maximum block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation if you have the HDL Coder installed. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

Introduced in R2012a

reset

System object: dsp.Maximum

Package: dsp

Reset computation of running maximum

Syntax

`reset(max)`

Description

`reset(max)` resets the computation of the running maximum for the Maximum object `max`.

step

System object: dsp.Maximum

Package: dsp

Maximum value

Syntax

[VAL, IND] = step(max, X)

VAL = step(max, X)

IND = step(max, X)

VAL = step(max, X, R)

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

[VAL, IND] = step(max, X) returns the maximum value, VAL, and the index or position of the maximum value, IND, along the specified Dimension of X.

VAL = step(max, X) returns the maximum value, VAL, of the input X. When the `RunningMaximum` property is true, VAL corresponds to the maximum value over successive calls to the `step` method.

IND = step(max, X) returns the zero- or one-based index IND of the maximum value. To enable this type of processing, set the `IndexOutputPort` property to true and the `ValueOutputPort` and `RunningMaximum` properties to false.

VAL = step(max, X, R) resets the state of max based on the value of reset signal, R, and the `ResetCondition` property. To enable this type of processing, set the `RunningMaximum` property to true and the `ResetInputPort` property to true.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.Mean System object

Package: dsp

Find mean value of input or sequence of inputs

Description

The `dsp.Mean` object finds the mean of an input or sequence of inputs.

To compute the mean of an input or sequence of inputs:

- 1 Define and set up your System object. See “Construction” on page 4-1265.
- 2 Call `step` to compute the mean according to the properties of `dsp.Mean`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Note The Running mode in the `dsp.Mean` System object will be removed in a future release. To compute the running mean in MATLAB, use the `dsp.MovingAverage` System object instead.

Construction

`mn = dsp.Mean` returns an object, `mn`, that computes the mean of an input or a sequence of inputs.

`mn = dsp.Mean('PropertyName', PropertyValue, ...)` returns a mean-finding object, `mn`, with each specified property set to the specified value.

Properties

RunningMean

Calculate over single input or multiple inputs

When you set this property to `true`, the object calculates the mean over successive calls to the `step` method. When you set this property to `false`, the object computes the mean over the current input. The default is `false`.

ResetInputPort

Additional input to enable resetting of running mean

Set this property to `true` to enable resetting of the running mean. When you set this property to `true`, you must specify a reset input to the `step` method to reset the running mean. This property applies only when you set the `RunningMean` property to `true`. The default is `false`.

ResetCondition

Condition that triggers resetting of running mean

Specify the event that resets the running maximum as one of `| Rising edge | Falling edge | Either edge | Non-zero |`. This property applies only when you set the “ResetInputPort” on page 4-0 property to `true`. The default is `Non-zero`.

Dimension

Dimension to operate along

Specify how the mean calculation is performed over the data as one of `| All | Row | Column | Custom |`. This property applies when you set the `RunningMean` property to `false`. The default is `Column`.

CustomDimension

Numerical dimension to calculate over

Specify the integer dimension, indexed from one, of the input signal over which the object calculates the mean. The value cannot exceed the number of dimensions in the input

signal. This property only applies when you set the “Dimension” on page 4-0 property to Custom. The default is 1.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |. The default is Floor.

OverflowAction

Action to take when integer input is out-of-range

Specify the overflow action as one of | Wrap | Saturate |. The default is Wrap.

AccumulatorDataType

Data type of accumulator

Specify the accumulator fixed-point data type as one of | Same as input | Custom |. The default is Same as input.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a Signedness of Auto. This property applies only when you set the `AccumulatorDataType` property to Custom. The default is `numericType([], 32, 30)`.

OutputDataType

Data type of output

Specify the output fixed-point data type as one of | Same as accumulator | Same as input | Custom |. The default is Same as accumulator.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the “`OutputDataType`” on page 4-0 property to `Custom`. The default is `numericType([], 32, 30)`.

step

System object: dsp.Mean

Package: dsp

Mean value

Syntax

$Y = \text{step}(\text{mn}, X)$

$Y = \text{step}(\text{mn}, X, R)$

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

$Y = \text{step}(\text{mn}, X)$ computes the mean of X . When you set the `RunningMean` property to `true`, Y corresponds to the mean successive calls to the `step` method.

$Y = \text{step}(\text{mn}, X, R)$ resets the computation of the running mean based on the value of the reset signal, R , and the `ResetCondition` property. To enable this type of processing, set the `RunningMean` property to `true` and the `ResetInputPort` property to `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.Median System object

Package: dsp

Median value of input

Description

The `Median` object computes the median value of the input. The object can compute the median along each dimension (row or column) of the input or of the entire input.

To compute the median of the input:

- 1 Define and set up your median System object. See “Construction” on page 4-1273.
- 2 Call `step` to compute the median according to the properties of `dsp.Median`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`med = dsp.Median` returns a median System object, `med`, that computes the median along the columns of the input using the `Quick sort` sorting method.

`med = dsp.Median('PropertyName', PropertyValue, ...)` returns a median System object, `med`, with each property set to the value you specify.

Properties

SortMethod

Sort method

Specify the method the object should use to sort the data before computing the median. You can specify `Quick sort` or `Insertion sort`. The quick sort algorithm uses a recursive sort method and is faster at sorting more than 32 elements. The insertion sort algorithm uses a nonrecursive method and is faster at sorting less than 32 elements. If you are using the `Median` object to generate code, you should use the insertion sort algorithm to prevent recursive function calls in your generated code. The default is `Quick sort`.

Dimension

Dimension to operate along

Specify the dimension along which the object computes the median values. You can specify one of `| All | Row | Column | Custom |`. The default is `Column`.

CustomDimension

Numerical dimension to operate along

Specify the dimension of the input signal (as a one-based value), over which the object computes the median. The cannot exceed the number of dimensions in the input signal. This property applies only when you set the “Dimension” on page 4-0 property to `Custom`. The default is `1`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `| Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of | `Wrap` | `Saturate` |. The default is `Wrap`.

ProductDataType

Product word and fraction lengths

Specify the product data type as one of | `Same as input` | `Custom` |. The default is `Same as input`.

CustomProductDataType

Product word and fraction lengths

Specify the product data type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `ProductDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator data type as one of | `Same as product` | `Same as input` | `Custom` |. The default is `Same as product`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the fixed-point accumulator data type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

OutputDataType

Output word and fraction lengths

Specify the output data type as one of | `Same as accumulator` | `Same as product` | `Same as input` | `Custom` |. The default is `Same as accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the data type of the output as a scaled `numeric` object with a `Signedness` of `Auto`. This property applies only when you set the “`OutputDataType`” on page 4-0 property to `Custom`. The default is `numeric([],16,15)`.

Methods

`step` Median value

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

Compute The Median

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Compute the median value of the input column using the `dsp.Median` object.

```
med = dsp.Median;
x = [7 -9 0 -1 2 0 3 5 -9]';
y = med(x)

y = 0
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Median block reference page. The object properties correspond to the block properties, except: **Treat sample-based row input as a column** block parameter is not supported by the `dsp.Median System` object.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

`dsp.Maximum` | `dsp.Mean` | `dsp.Minimum` | `dsp.Variance`

Introduced in R2012a

step

System object: dsp.Median

Package: dsp

Median value

Syntax

`Y = step (med, X)`

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step (obj, x)` and `y = obj (x)` perform equivalent operations.

`Y = step (med, X)` computes the median value of the input `X` and returns the result in `Y`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.MedianFilter System object

Package: dsp

Median filter

Description

The `dsp.MedianFilter` System object computes the moving median of the input signal along each channel, independently over time. The object uses the sliding window method to compute the moving median. In this method, a window of specified length is moved over each channel, sample by sample, and the object computes the median of the data in the window. For more details, see “Algorithms” on page 4-1286.

The object accepts multichannel inputs, that is, m -by- n size inputs, where $m \geq 1$, and $n > 1$. m is the number of samples in each frame (or channel), and n is the number of channels. The object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel. However, the number of channels cannot change. This object supports C and C++ code generation.

To compute the moving median of the input:

- 1 Create a `dsp.MedianFilter` object and set the properties of the object.
- 2 Call `step` to compute the moving median.

Note Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Construction

`medFilt = dsp.MedianFilter` returns a median filter object, `medFilt`, using the default properties.

`medFilt = dsp.MedianFilter(Len)` sets the `WindowLength` property to `Len`.

`medFilt = dsp.MedianFilter(Name,Value)` specifies properties using `Name,Value` pairs. Unspecified properties have default values.

Example:

```
movMin = dsp.MedianFilter('WindowLength',5);
```

Properties

WindowLength — Length of the sliding window

5 (default) | positive scalar integer

Length of the sliding window, specified as a positive scalar integer.

Methods

- `reset` Reset internal states of System object
- `step` Moving median of input signal

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

Remove High-Frequency Noise Using Median Filter

Filter high-frequency noise from a noisy sine wave signal using a median filter. Compare the performance of the median filter with an averaging filter.

Initialization

Set up a `dsp.MedianFilter` object, `medFilt`, and a `dsp.MovingAverage` object, `movavgWin`. These objects use the sliding window method with a window length of 7. Create a time scope for viewing the output.

```

Fs = 1000;
medFilt = dsp.MedianFilter(7);
movavgWin = dsp.MovingAverage(7);
scope = dsp.TimeScope('SampleRate',Fs,...
    'TimeSpanOverrunAction','Scroll',...
    'TimeSpan',1,'ShowGrid',true,...
    'YLimits',[-3 3],...
    'LayoutDimensions',[3 1],...
    'NumInputPorts',3);
scope.ActiveDisplay = 1;
scope.Title = 'Signal + Noise';
scope.ActiveDisplay = 2;
scope.Title = 'Moving Average Output (Window Length = 7)';
scope.ActiveDisplay = 3;
scope.Title = 'Median Filter Output (Window Length = 7)';

FrameLength = 256;
count = 1;
sine = dsp.SineWave('SampleRate',Fs,'Frequency',10,...
    'SamplesPerFrame',FrameLength);

```

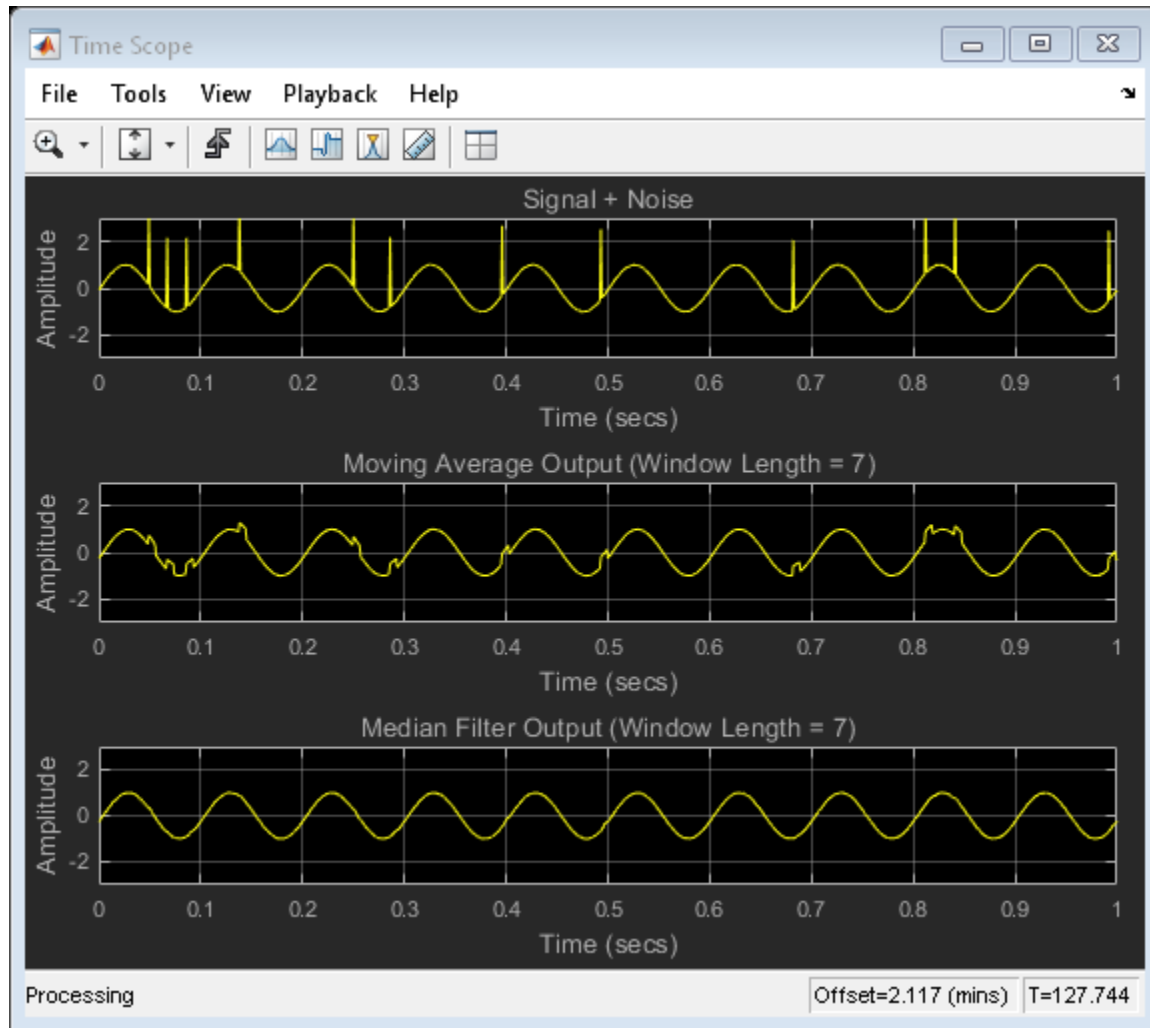

Filter the Noisy Sine Wave

Generate a noisy sine wave signal with a frequency of 10 Hz. Apply the median filter and the moving average object to the signal. View the output on the time scope.

```

for i = 1:500
    hfn = 3 * (rand(FrameLength,1) < 0.02);
    x = sine() + 1e-2 * randn(FrameLength,1) + hfn;
    y1 = movavgWin(x);
    y2 = medFilt(x);
    scope(x,y1,y2);
end

```

The median filter removes the high-frequency noise more effectively than the moving average object does.

Remove High-Frequency Noise from Gyroscope Data

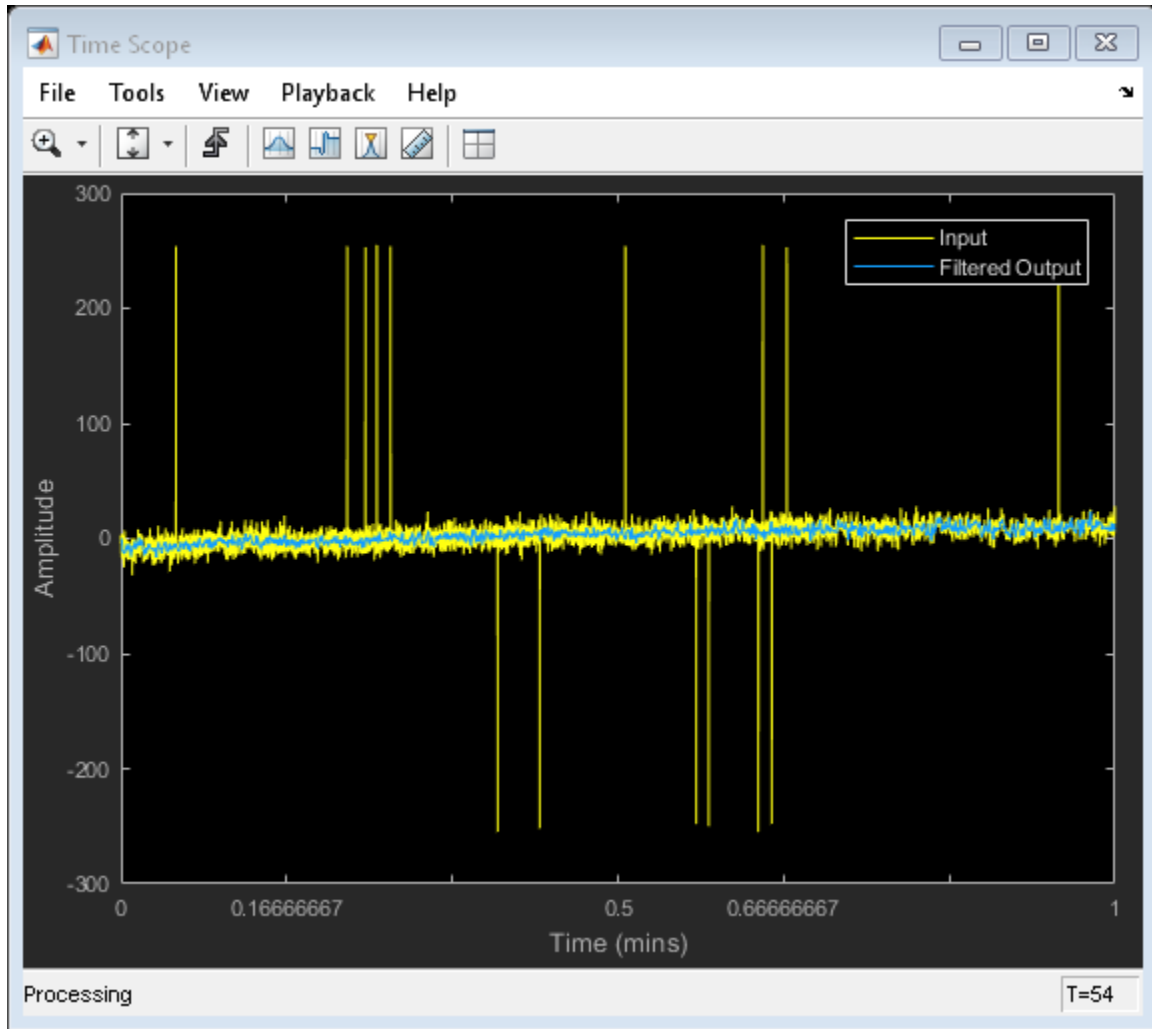

This example shows how to remove the high-frequency outliers from a streaming signal using the `dsp.MedianFilter` System object™.

Use the `dsp.MatFileReader` System object to read the gyroscope MAT file. The gyroscope MAT file contains 3 columns of data, with each column containing 7140 samples. The three columns represent the X-axis, Y-axis, and Z-axis data from the gyroscope motion sensor. Choose a frame size of 714 samples so that each column of the data contains 10 frames. The `dsp.MedianFilter` System object uses a window length of 10. Create a `dsp.TimeScope` object to view the filtered output.

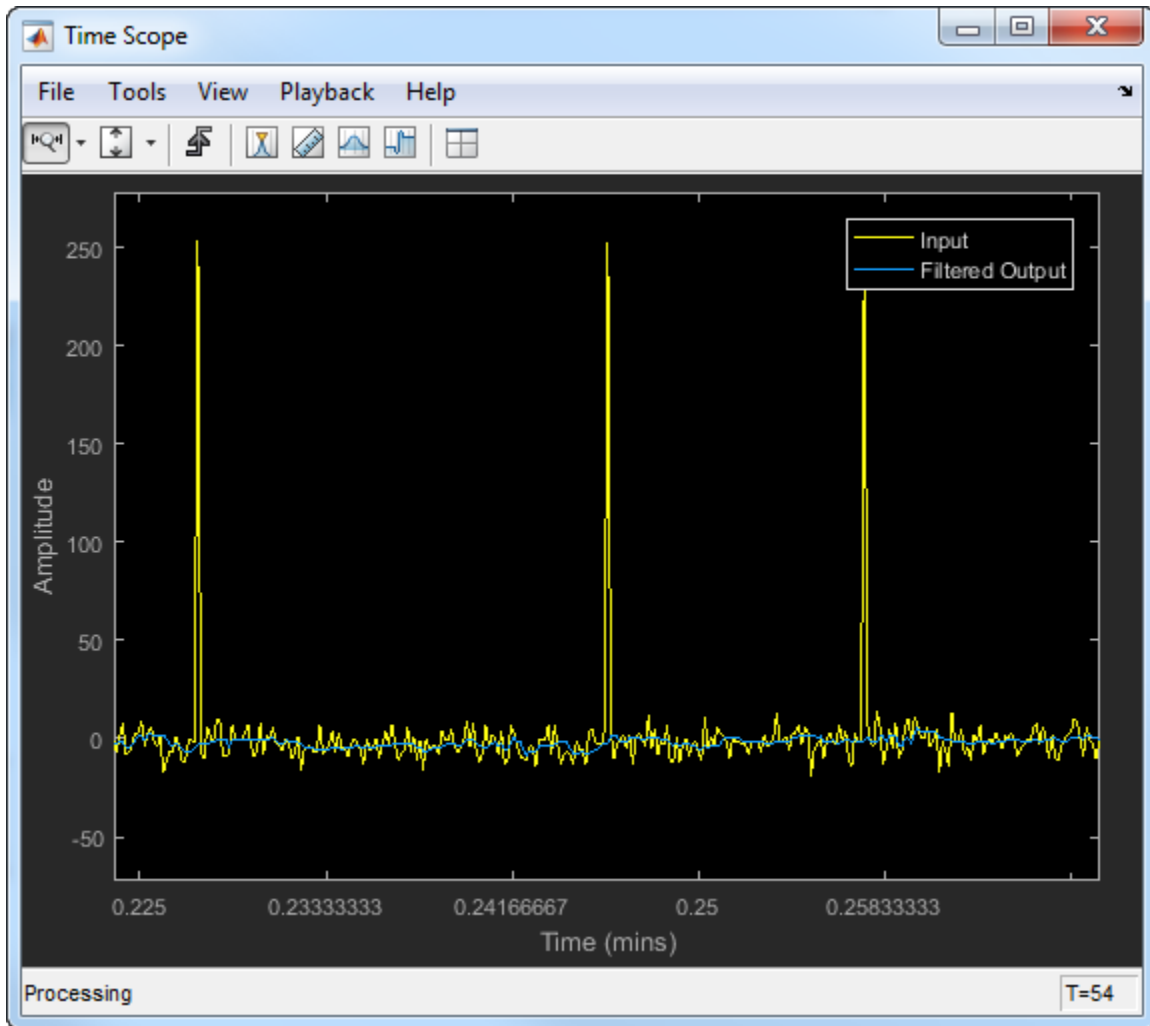

```
reader = dsp.MatFileReader('SamplesPerFrame',714,'Filename','LSM9DS1gyroData73.mat',...  
    'VariableName','data');  
medFilt = dsp.MedianFilter(10);  
scope = dsp.TimeScope('NumInputPorts',1,'SampleRate',119,'YLimits',[-300 300],...  
    'ChannelNames',{'Input','Filtered Output'},'TimeSpan',60,'ShowLegend',true);
```

Filter the gyroscope data using the `dsp.MedianFilter` System object. View the filtered Z-axis data in the time scope.

```
for i = 1:10  
    gyroData = reader();  
    filteredData = medFilt(gyroData);  
    scope([gyroData(:,3),filteredData(:,3)]);  
end
```

The original data contains several outliers. Zoom in on the data to confirm that the median filter removes all the outliers.

Algorithms

Sliding Window Method

In the sliding window method, the output for each input sample is the median of the current sample and the $Len - 1$ previous samples. Len is the length of the window. To compute the first $Len - 1$ outputs, when the window does not have enough data yet, the algorithm fills the window with zeros. As an example, to compute the median value when the second input sample comes in, the algorithm fills the window with $Len - 2$ zeros. The data vector, x , is then the two data samples followed by $Len - 2$ zeros. This object performs median filtering on the input data over time.

Consider an example of computing the moving median of a streaming input data using the sliding window method. The algorithm uses a window length of 4. With each input sample that comes in, the window of length 4 moves along the data.

Introduced in R2016b

reset

System object: dsp.MedianFilter

Package: dsp

Reset internal states of System object

Syntax

```
reset (medFilt)
```

Description

`reset (medFilt)` resets the states of the input object to their initial values. The initial state values correspond to the initial conditions for the difference equation defining the object. After you call the object using nonzero input data, the filter might have nonzero states. If you continue to pass nonzero input data to the object without first calling `reset`, the object might produce different outputs for an identical input.

Introduced in R2016b

step

System object: `dsp.MedianFilter`

Package: `dsp`

Moving median of input signal

Syntax

```
y = step(medFilt,x)
```

Description

Note Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`y = step(medFilt,x)` computes the moving median of the input signal, `x`, using the sliding window method of the input `dsp.MedianFilter` System object, `medFilt`. The input `x` can be a row vector, a column vector, or a matrix. If `x` is a matrix, each column is treated as an independent channel. The moving median is computed along each channel. The input `x` can be complex and supports single and double data types.

Introduced in R2016b

dsp.Minimum System object

Package: dsp

Find minimum values of input or sequence of inputs

Description

The `dsp.Minimum` object finds the minimum value of an input or sequence of inputs.

To compute the minimum value of an input or sequence of inputs:

- 1 Define and set up your System object. See “Construction” on page 4-1291.
- 2 Call `step` to compute the minimum according to the properties of `dsp.Minimum`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Note The Running mode in the `dsp.Minimum` System object will be removed in a future release. To compute the running minimum in MATLAB, use the `dsp.MovingMinimum` System object instead.

Construction

`min = dsp.Minimum` returns an object, `min`, that computes the value and/or index of the minimum elements in an input or a sequence of inputs over the specified `Dimension`.

`min = dsp.Minimum('PropertyName', PropertyValue, ...)` returns a minimum-finding object, `min`, with each specified property set to the specified value.

Properties

ValueOutputPort

Output minimum value

Set this property to `true` in order to output the minimum value of the input. This property applies only when you set the `RunningMinimum` property to `false`. The default is `true`.

RunningMinimum

Calculate over single input or multiple inputs

When you set this property to `true`, the object computes the minimum value over successive calls to the `step` method. When you set this property to `false`, the object computes the minimum value over the current input. The default is `false`.

IndexOutputPort

Output index of minimum value

Set this property to `true` to output the index of the minimum value of the input. This property applies only when you set the `RunningMinimum` property to `false`. The default is `true`.

ResetInputPort

Additional input to enable resetting of running minimum

Set this property to `true` to enable resetting of the running minimum. When you set this property to `true`, you must specify a reset input to the `step` method to reset the running minimum. This property applies only when you set the `RunningMinimum` property to `true`. The default is `false`.

ResetCondition

Condition that triggers resetting of running minimum

Specify the event that resets the running minimum as one of `Rising edge` | `Falling edge` | `Either edge` | `Non-zero` |. This property applies only when you set the “`ResetInputPort`” on page 4-0 property to `true`. The default is `Non-zero`.

IndexBase

Numbering base for index of minimum value

Specify the numbering used when computing the index of the minimum value as starting from either `One` or `Zero`. This property applies only when you set the `IndexOutputPort` property to `true`. The default is `One`.

Dimension

Dimension to operate along

Specify how the minimum calculation is performed over the data as one of `All` | `Row` | `Column` | `Custom` |. This property applies when you set the `RunningMinimum` property to `false`. The default is `Column`.

CustomDimension

Numerical dimension to calculate over

Specify the integer dimension of the input signal over which the object finds the minimum. The cannot exceed the number of dimensions in the input signal. This property only applies when you set the “Dimension” on page 4-0 property to `Custom`. The default is `1`.

Fixed-Point Properties**RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as one of `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |. The default is `Floor`.

OverflowAction

Action to take when integer input is out-of-range

Specify the overflow action as one of `Wrap` | `Saturate` |. The default is `Wrap`.

ProductDataType

Data type of product

Specify the product fixed-point data type as one of | Same as input | Custom |. The default is Same as input.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

AccumulatorDataType

Data type of accumulator

Specify the accumulator fixed-point data type as one of | Same as product | Same as input | Custom |. The default is Same as product.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

Methods

- `reset` Reset internal states of minimum-finding object
- `step` Operate on inputs to calculate outputs

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object

Common to All System Objects	
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Compute the Minimum and Running Minimum of a Signal

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Find a minimum value and its index.

```
min1 = dsp.Minimum;  
x = randn(100,1);  
[y, I] = min1(x)
```

```
y = -2.9443
```

```
I = 35
```

Compute a running minimum.

```
min2 = dsp.Minimum;  
min2.RunningMinimum = true;  
x = randn(100,1);  
y = min2(x);  
plot(y);
```

$y(i)$ is the minimum of all values in the vector $x(1:i)$;

Algorithms

This object implements the algorithm, inputs, and outputs described on the Minimum block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation if you have the HDL Coder installed. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

Blocks

Minimum | Moving Minimum

Introduced in R2012a

reset

System object: dsp.Minimum

Package: dsp

Reset internal states of minimum-finding object

Syntax

```
reset(min)
```

Description

`reset(min)` sets the internal states of the Minimum object `min` to their initial values.

step

System object: dsp.Minimum

Package: dsp

Operate on inputs to calculate outputs

Syntax

```
[VAL, IND] = step(min, X)
VAL = step(min, X)
IND = step(min, X)
VAL = step(min, X, R)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

`[VAL, IND] = step(min, X)` returns the minimum value, `VAL`, and the index or position of the minimum value, `IND`, along the specified Dimension of `X`.

`VAL = step(min, X)` returns the minimum value, `VAL`, of the input `X`. When the `RunningMinimum` property is `true`, `VAL` corresponds to the minimum value over successive calls to the `step` method.

`IND = step(min, X)` returns the zero- or one-based index `IND` of the minimum value when the `IndexOutputPort` property is `true` and the `ValueOutputPort` property is `false`. You must set the `RunningMinimum` property to `false` to use this syntax.

`VAL = step(min, X, R)` resets the state of `min` based on the value of reset signal, `R`, and the `ResetCondition` property. To enable this type of processing, set the `RunningMinimum` property to `true` and the `ResetInputPort` property to `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.MovingAverage System object

Package: dsp

Moving average

Description

The `dsp.MovingAverage` System object computes the moving average of the input signal along each channel, independently over time. The object uses either the sliding window method or the exponential weighting method to compute the moving average. In the sliding window method, a window of specified length is moved over the data, sample by sample, and the average is computed over the data in the window. In the exponential weighting method, the object multiplies the data samples with a set of weighting factors. The average is computed by summing the weighted data. For more details on these methods, see “Algorithms” on page 4-1306.

The object accepts multichannel inputs, that is, m -by- n size inputs, where $m \geq 1$, and $n > 1$. The object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel. However, the number of channels cannot change. This object supports C and C++ code generation.

To compute the moving average of the input:

- 1 Create a `dsp.MovingAverage` object and set the properties of the object.
- 2 Call `step` to compute the moving average.

Note Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

Construction

`movAvg = dsp.MovingAverage` returns a moving average object, `movAvg`, using the default properties.

`movAvg = dsp.MovingAverage(Len)` sets the `WindowLength` property to `Len`.

`movAvg = dsp.MovingAverage(Name, Value)` specifies additional properties using `Name, Value` pairs. Unspecified properties have default values.

Example:

```
movAvg = dsp.MovingAverage('Method', 'Exponential weighting', 'ForgettingFactor', 0.9);
```

Properties

Method — Averaging method

'Sliding window' (default) | 'Exponential weighting'

Averaging method, specified as 'Sliding window' or 'Exponential weighting'.

- 'Sliding window' — A window of length specified by `SpecifyWindowLength` is moved over the input data along each channel. For every sample the window moves by, the object computes the average over the data in the window.
- 'Exponential weighting' — The object multiplies the samples with a set of weighting factors. The magnitude of the weighting factors decreases exponentially as the age of the data increases, never reaching zero. To compute the average, the algorithm sums the weighted data.

For more details on these methods, see “Algorithms” on page 4-1306.

SpecifyWindowLength — Specify window length

true (default) | false

Flag to specify a window length, specified as a scalar boolean.

- true — The length of the sliding window is equal to the value you specify in the `WindowLength` property.
- false — The length of the sliding window is infinite. In this mode, the average is computed using the current sample and all the past samples.

This property applies when you set `Method` to 'Sliding window'.

WindowLength — Length of the sliding window

4 (default) | positive scalar integer

Length of the sliding window, specified as a positive scalar integer. This property applies when you set `Method` to `'Sliding window'` and `SpecifyWindowLength` to `true`.

ForgettingFactor — Exponential weighting factor

0.9 (default) | positive real scalar in the range (0,1]

Exponential weighting factor, specified as a positive real scalar in the range (0,1]. This property applies when you set `Method` to `'Exponential weighting'`. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All the past samples are given an equal weight. This property is tunable. You can change its value even when the object is locked.

Methods

`reset` Reset internal states of System object
`step` Moving average of input signal

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

Moving Average of Noisy Ramp Signal

Compute the moving average of a noisy ramp signal using the `dsp.MovingAverage` object.

Initialization

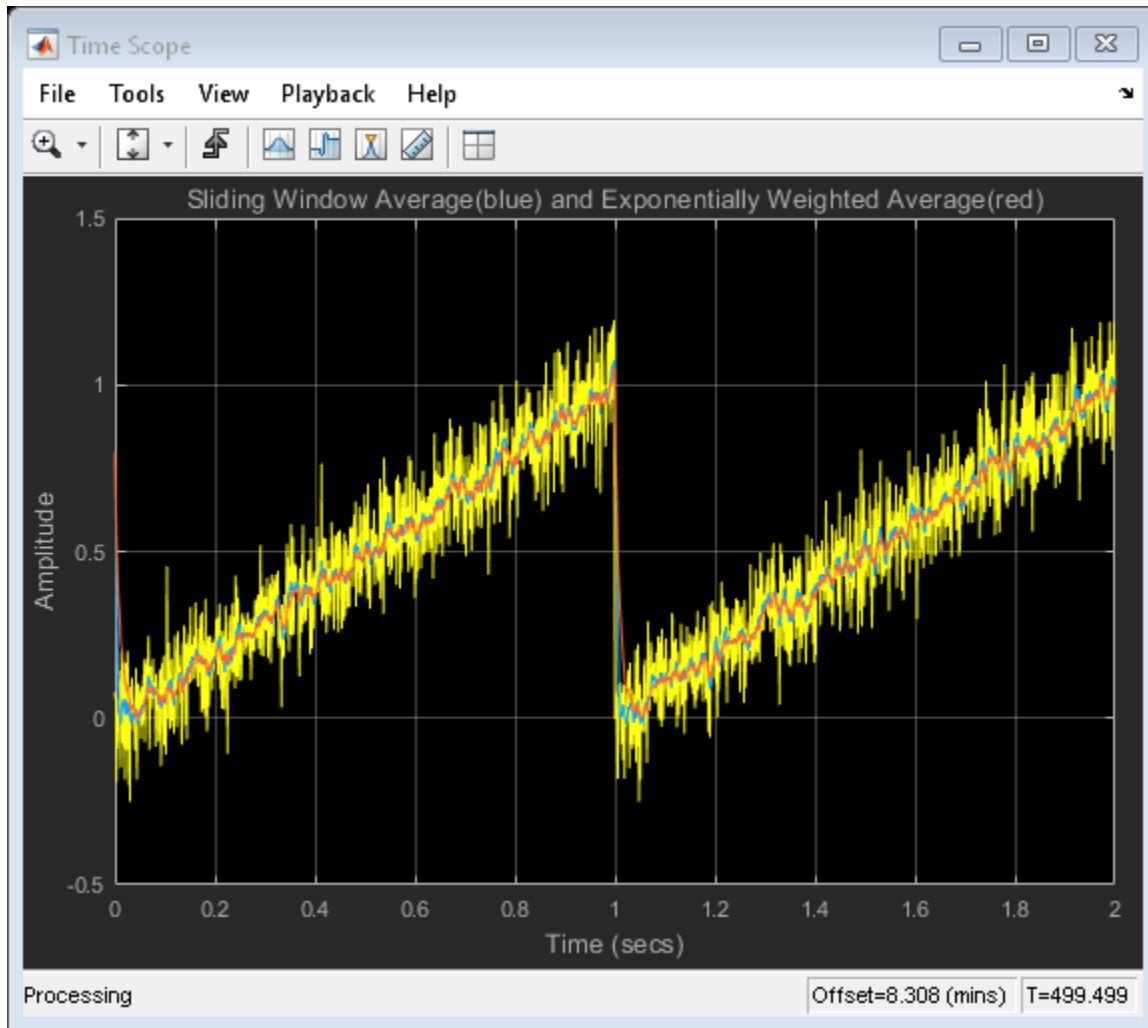

Set up `movavgWindow` and `movavgExp` objects. `movavgWindow` uses the sliding window method with a window length of 10. `movavgExp` uses the exponentially weighting method with a forgetting factor of 0.9. Create a time scope for viewing the output.

```
FrameLength = 1001;
Fs = 1000;
movavgWindow = dsp.MovingAverage(10);
movavgExp = dsp.MovingAverage('Method','Exponential weighting',...
    'ForgettingFactor',0.9);
scope = dsp.TimeScope('SampleRate',Fs,...
    'TimeSpanOverrunAction','Scroll',...
    'TimeSpan',2,...
    'ShowGrid',true,...
    'YLimits',[-0.5 1.5]);
title = 'Sliding Window Average(blue) and Exponentially Weighted Average(red)';
scope.Title = title;
```

Compute the Average

Generate a ramp signal with an amplitude of 1.0 and a time span of 2 seconds. Apply the sliding window average and exponentially weighted average to the ramp. View the output on the time scope.

```
for i = 1:500
    t = (0:0.001:1)';
    unitstep = t>=0;
    ramp = t.*unitstep;
    x = ramp + 0.1 * randn(FrameLength,1);
    y1 = movavgWindow(x);
    y2 = movavgExp(x);
    scope([x,y1,y2]);
end
```

Algorithms

Sliding Window Method

In the sliding window method, the output for each input sample is the average of the current sample and the $Len - 1$ previous samples. Len is the length of the window. To compute the first $Len - 1$ outputs, when the window does not have enough data yet, the algorithm fills the window with zeros. As an example, to compute the average when the second input sample comes in, the algorithm fills the window with $Len - 2$ zeros. The data vector, x , is then the two data samples followed by $Len - 2$ zeros.

When you do not specify the window length, the algorithm chooses an infinite window length. In this mode, the output is the moving average of the current sample and all the previous samples in the channel.

For an example, see “Sliding Window Method and Exponential Weighting Method”.

Exponential Weighting Method

In the exponential weighting method, the moving average is computed recursively using these formulas:

$$w_{N,\lambda} = \lambda w_{N-1,\lambda} + 1,$$

$$\bar{x}_{N,\lambda} = \left(1 - \frac{1}{w_{N,\lambda}}\right) \bar{x}_{N-1,\lambda} + \left(\frac{1}{w_{N,\lambda}}\right) x_N$$

- $\bar{x}_{N,\lambda}$ — Moving average at the current sample
- x_N — Current data input sample
- $\bar{x}_{N-1,\lambda}$ — Moving average at the previous sample
- λ — Forgetting factor
- $w_{N,\lambda}$ — Weighting factor applied to the current data sample
- $\left(1 - \frac{1}{w_{N,\lambda}}\right) \bar{x}_{N-1,\lambda}$ — Effect of the previous data on the average

For the first sample, where $N = 1$, the algorithm chooses $w_{N,\lambda} = 1$. For the next sample, the weighting factor is updated and used to compute the average, as per the recursive equation. As the age of the data increases, the magnitude of the weighting factor decreases exponentially and never reaches zero. In other words, the recent data has more influence on the current average than the older data.

The value of the forgetting factor determines the rate of change of the weighting factors. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All the previous samples are given an equal weight.

For an example, see “Sliding Window Method and Exponential Weighting Method”.

Introduced in R2016b

reset

System object: dsp.MovingAverage

Package: dsp

Reset internal states of System object

Syntax

```
reset (movAvg)
```

Description

`reset (movAvg)` resets the states of the input object to their initial values. The initial state values correspond to the initial conditions for the difference equation defining the object. After you call the object using nonzero input data, the filter might have nonzero states. If you continue to pass nonzero input data to the object without first calling `reset`, the object might produce different outputs for an identical input.

Introduced in R2016b

step

System object: `dsp.MovingAverage`

Package: `dsp`

Moving average of input signal

Syntax

```
y = step(movAvg, x)
```

Description

Note Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

`y = step(movAvg, x)` computes the moving average of the input signal, `x`, using either the sliding window method or exponential weighting method of the input `dsp.MovingAverage` System object, `movAvg`. The input `x` can be a row vector, a column vector, or a matrix. If `x` is a matrix, each column is treated as an independent channel. The moving average is computed along each channel. The input `x` can be complex and supports single and double data types.

Introduced in R2016b

dsp.MovingMaximum System object

Package: dsp

Moving maximum

Description

The `dsp.MovingMaximum` System object determines the moving maximum of the input signal along each channel, independently over time. The object uses the sliding window method to determine the moving maximum. In this method, a window of specified length is moved over each channel, sample by sample, and the object determines the maximum of the data in the window. For more details, see “Algorithms” on page 4-1315.

The object accepts multichannel inputs, that is, m -by- n size inputs, where $m \geq 1$, and $n > 1$. The object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel. However, the number of channels cannot change. This object supports C and C++ code generation.

To determine the moving maximum of the input:

- 1 Create a `dsp.MovingMaximum` object and set the properties of the object.
- 2 Call `step` to compute the moving maximum.

Note Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Construction

`movMax = dsp.MovingMaximum` returns a moving maximum object, `movMax`, using the default properties.

`movMax = dsp.MovingMaximum(Len)` sets the `WindowLength` property to `Len`.

`movMax = dsp.MovingMaximum(Name, Value)` specifies additional properties using `Name, Value` pairs. Unspecified properties have default values.

Example:

```
movMax = dsp.MovingMaximum('SpecifyWindowLength', 1, 'WindowLength', 10);
```

Properties

SpecifyWindowLength — Specify window length

true (default) | false

Flag to specify a window length, specified as a scalar boolean.

- true — The length of the sliding window is equal to the value you specify in the `WindowLength` property.
- false — The length of the sliding window is infinite. In this mode, the object determines the maximum of the current sample and all the past samples.

WindowLength — Length of the sliding window

4 (default) | positive scalar integer

Length of the sliding window, specified as a positive scalar integer. This property applies when you set `SpecifyWindowLength` to true.

Methods

`reset` Reset internal states of System object

`step` Moving maximum of input signal

Common to All System Objects	
<code>clone</code>	Create System object with same property values

Examples

Moving Maximum of Sine Wave Signal

Compute the moving maximum of a sum of three sine waves with varying amplitude. Use a sliding window of length 30.

Initialization

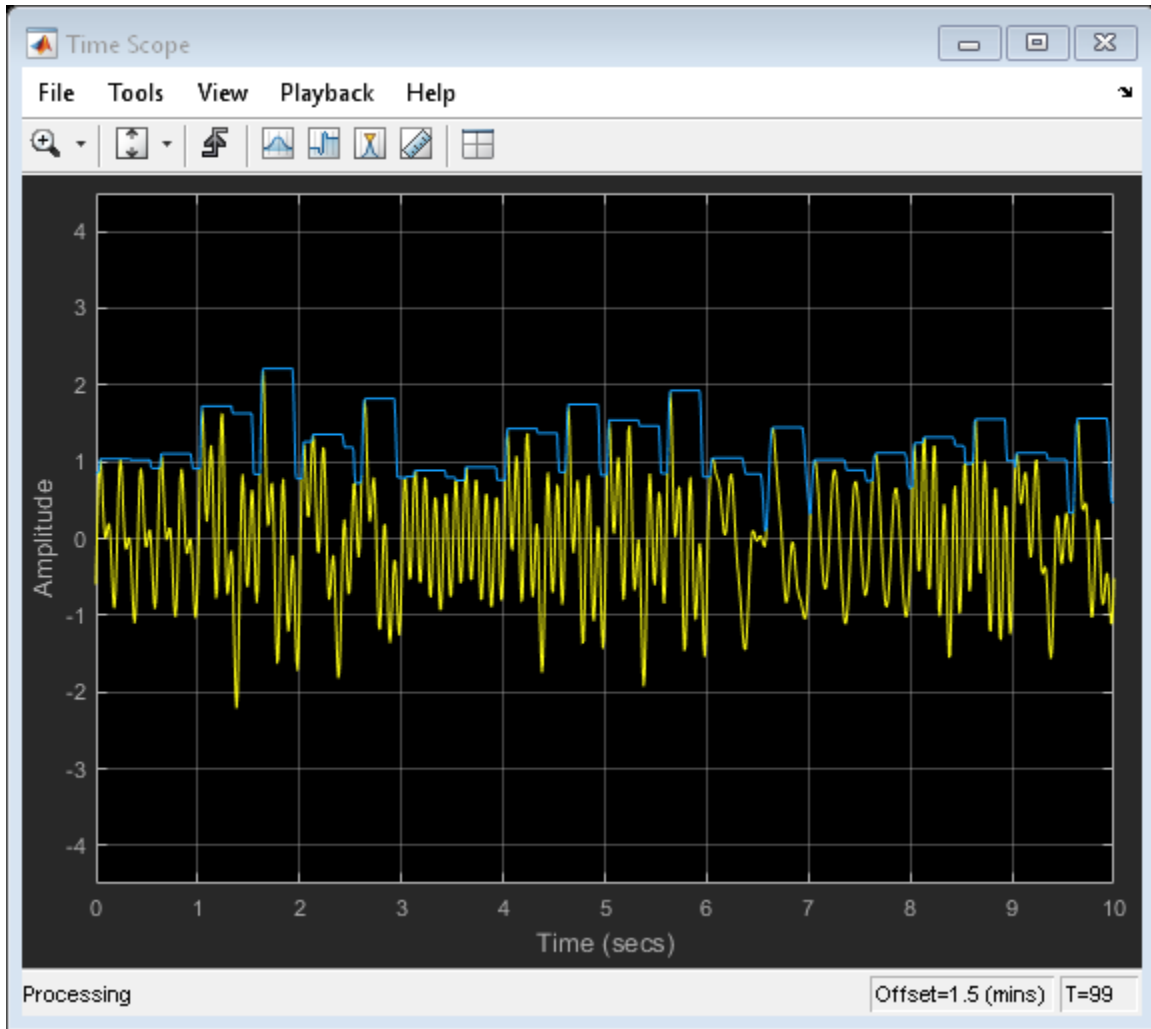

Set up an input signal that is a sum of three sine waves with frequencies at 2 Hz, 5 Hz, and 10 Hz. The sampling frequency is 100 Hz. Create a `dsp.MovingMaximum` object with a window length of 30. Create a time scope for viewing the output.

```
sin = dsp.SineWave('SampleRate',100,...
    'Frequency',[2 5 10],...
    'SamplesPerFrame',100);
movMax = dsp.MovingMaximum(30);
scope = dsp.TimeScope('SampleRate',100,...
    'TimeSpanOverrunAction','Scroll',...
    'TimeSpan',10,'ShowGrid',true,...
    'YLimits',[-4.5 4.5]);
```

Compute the Moving Maximum

Each sine wave component of the input signal has a different amplitude that varies with the iteration. Use the `movMax` object to determine the maximum value of the current sample and the past 29 samples of the input signal.

```
for index = 1:100
    sin.Amplitude = rand(1,3);
    x = sum(sin(),2);
    xmax = movMax(x);
    scope([x,xmax])
end
```

- “What Are Moving Statistics?”

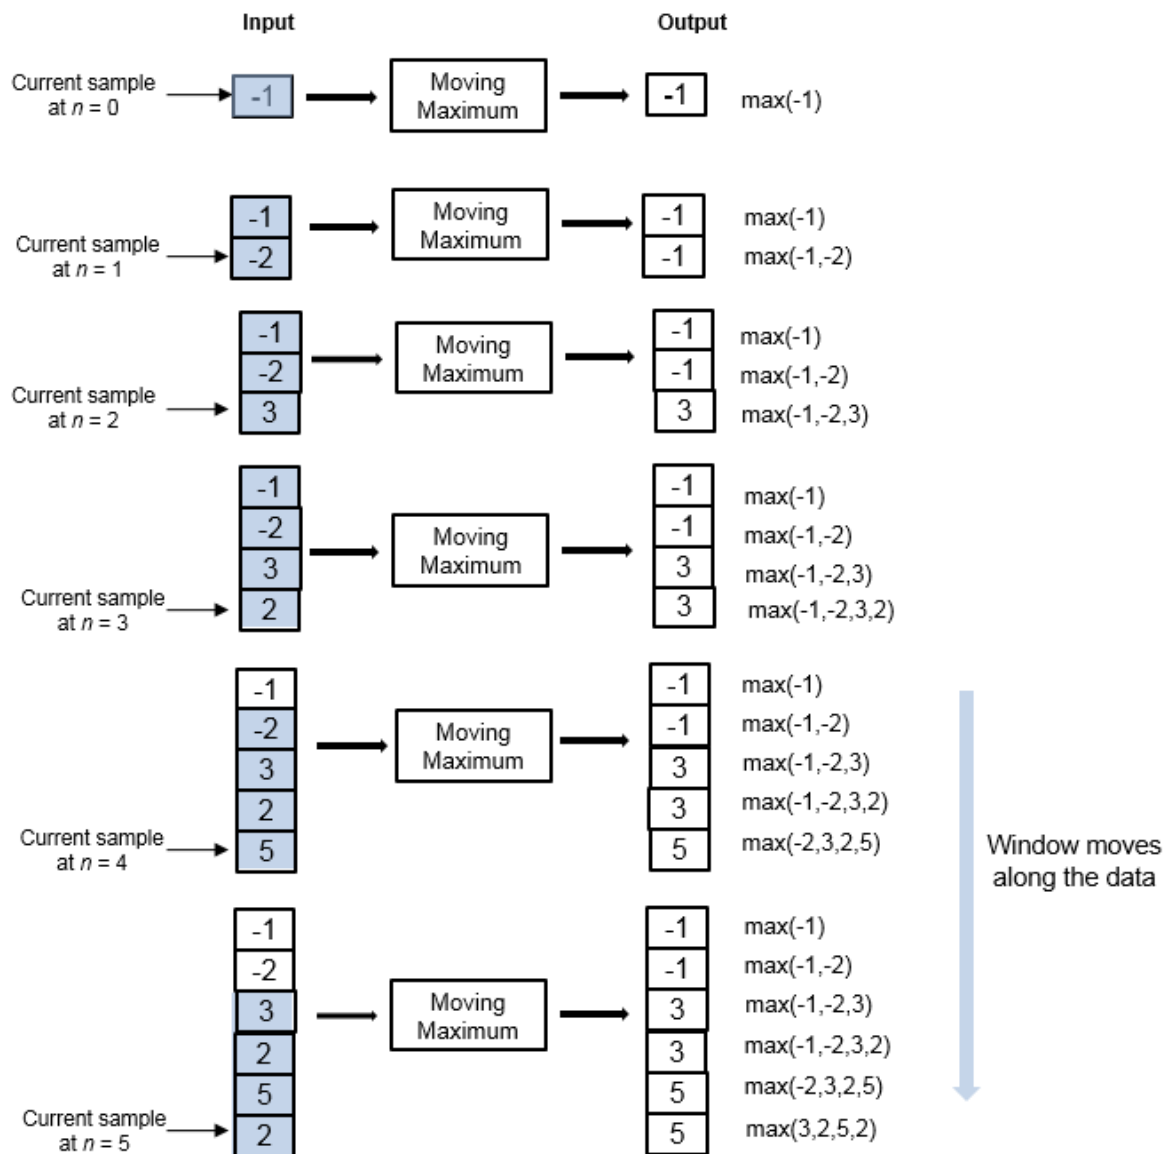

Algorithms

Sliding Window Method

In the sliding window method, the output for each input sample is the maximum of the current sample and the $Len - 1$ previous samples. Len is the length of the window. When the algorithm computes the first $Len - 1$ outputs, the length of the window is the length of the data that is available.

When you do not specify the window length, the algorithm chooses an infinite window length. In this mode, the output is the maximum of the current sample and all the previous samples in the channel.

Consider an example of computing the moving maximum of a streaming input data using the sliding window method. The algorithm uses a window length of 4. With each input sample that comes in, the window of length 4 moves along the data.

y = step(movMax, x)
```

Description

Note Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

`y = step(movMax, x)` determines the moving maximum of the input signal, `x`, using the sliding window method of the input `dsp.MovingMaximum` System object, `movMax`. The input `x` can be a row vector, a column vector, or a matrix. If `x` is a matrix, each column is treated as an independent channel. The moving maximum is determined along each channel. The input `x` can be complex and supports single and double data types.

Introduced in R2016b

dsp.MovingMinimum System object

Package: dsp

Moving minimum

Description

The `dsp.MovingMinimum` System object determines the moving minimum of the input signal along each channel, independently over time. The object uses the sliding window method to determine the moving minimum. In this method, a window of specified length is moved over each channel, sample by sample, and the object determines the minimum of the data in the window. For more details, see “Algorithms” on page 4-1324.

The object accepts multichannel inputs, that is, m -by- n size inputs, where $m \geq 1$, and $n > 1$. The object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel. However, the number of channels cannot change. This object supports C and C++ code generation.

To determine the moving minimum of the input:

- 1 Create a `dsp.MovingMinimum` object and set the properties of the object.
- 2 Call `step` to compute the moving minimum.

Note Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Construction

`movMin = dsp.MovingMinimum` returns a moving minimum object, `movMin`, using the default properties.

`movMin = dsp.MovingMinimum(Len)` sets the `WindowLength` property to `Len`.

`movMin = dsp.MovingMinimum(Name, Value)` specifies additional properties using `Name, Value` pairs. Unspecified properties have default values.

Example:

```
movMin = dsp.MovingMinimum('SpecifyWindowLength', 1, 'WindowLength', 10);
```

Properties

SpecifyWindowLength — Specify window length

true (default) | false

Flag to specify a window length, specified as a scalar boolean.

- `true` — The length of the sliding window is equal to the value you specify in the `WindowLength` property.
- `false` — The length of the sliding window is infinite. In this mode, the object determines the minimum of the current sample and all the past samples.

WindowLength — Length of the sliding window

4 (default) | positive scalar integer

Length of the sliding window, specified as a positive scalar integer. This property applies when you set `SpecifyWindowLength` to `true`.

Methods

`reset` Reset internal states of System object

`step` Moving minimum of input signal

Common to All System Objects	
<code>clone</code>	Create System object with same property values

Examples

Moving Minimum of Sine Wave Signal

Compute the moving minimum of a sum of three sine waves with varying amplitude. Use a sliding window of length 30.

Initialization

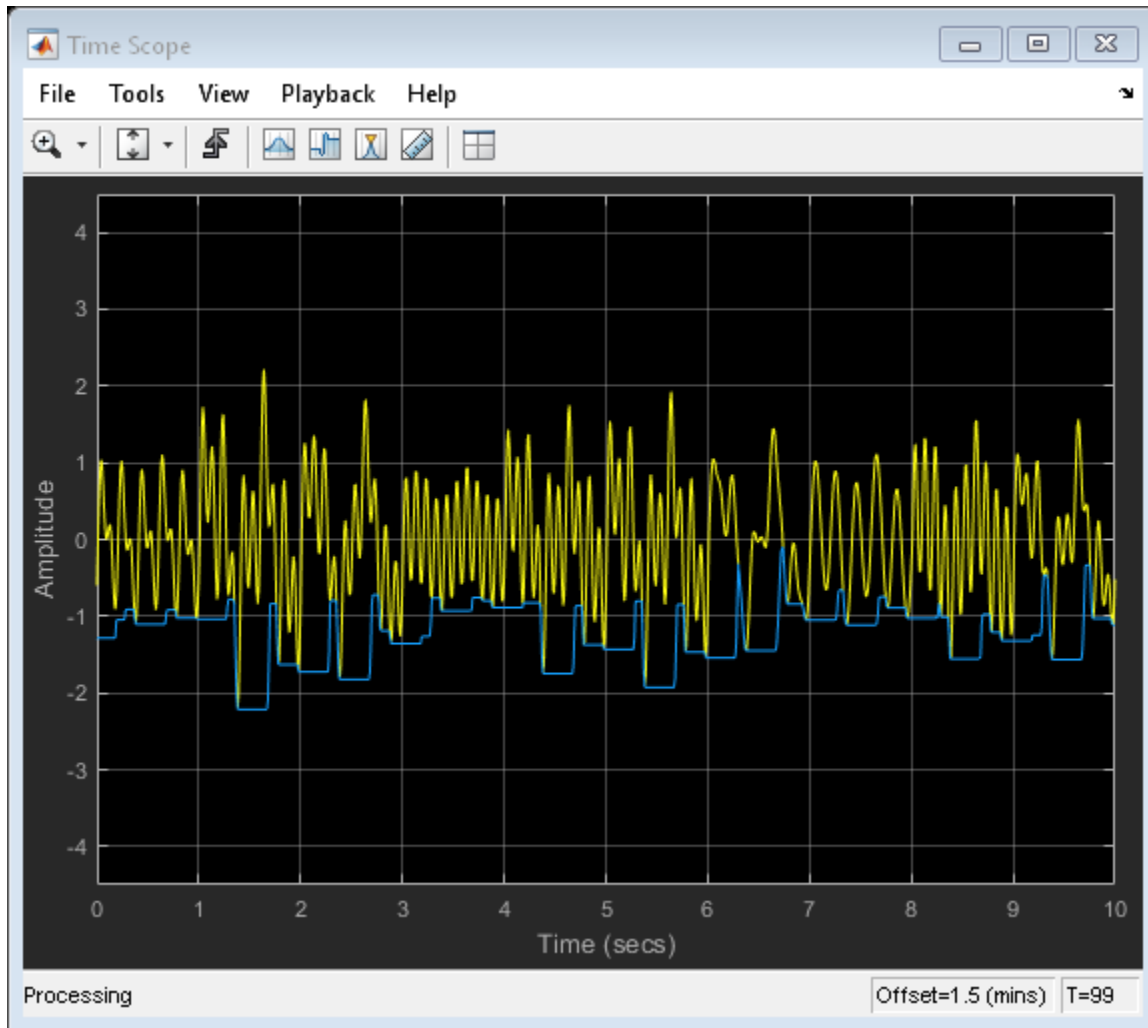

Set up an input signal that is a sum of three sine waves with frequencies at 2 Hz, 5 Hz, and 10 Hz. The sampling frequency is 100 Hz. Create a `dsp.MovingMinimum` object with a window length of 30. Create a time scope for viewing the output.

```
sin = dsp.SineWave('SampleRate',100,...  
    'Frequency',[2 5 10],...  
    'SamplesPerFrame',100);  
movMin = dsp.MovingMinimum(30);  
scope = dsp.TimeScope('SampleRate',100,...  
    'TimeSpanOverrunAction','Scroll',...  
    'TimeSpan',10,'ShowGrid',true,...  
    'YLimits',[-4.5 4.5]);
```

Compute the Moving Minimum

Each sine wave component of the input signal has a different amplitude that varies with the iteration. Use the `movMin` object to determine the minimum value of the current sample and the past 29 samples of the input signal.

```
for index = 1:100  
    sin.Amplitude = rand(1,3);  
    x = sum(sin(),2);  
    xmin = movMin(x);  
    scope([x,xmin])  
end
```

dsp.MovingRMS System object

Package: dsp

Moving Root Mean Square

Description

The `dsp.MovingRMS` System object computes the moving Root Mean Square (RMS) of the input signal along each channel, independently over time. The object uses either the sliding window method or the exponential weighting method to compute the moving RMS. In the sliding window method, a window of specified length is moved over the data, sample by sample, and the RMS is computed over the data in the window. In the exponential weighting method, the object squares the data samples, multiplies them with a set of weighting factors, and sums the weighed data. The object then computes the RMS by taking the square root of the sum. For more details on these methods, see “Algorithms” on page 4-1334.

The object accepts multichannel inputs, that is, m -by- n size inputs, where $m \geq 1$, and $n > 1$. The object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel. However, the number of channels cannot change. This object supports C and C++ code generation.

To compute the moving RMS of the input:

- 1 Create a `dsp.MovingRMS` object and set the properties of the object.
- 2 Call `step` to compute the moving RMS.

Note Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Construction

`movRMS = dsp.MovingRMS` returns a moving RMS object, `movRMS`, using the default properties.

`movRMS = dsp.MovingRMS(Len)` sets the `WindowLength` property to `Len`.

`movRMS = dsp.MovingRMS(Name, Value)` specifies additional properties using `Name, Value` pairs. Unspecified properties have default values.

Example:

```
movRMS = dsp.MovingRMS('Method', 'Exponential weighting', 'ForgettingFactor', 0.9);
```

Properties

Method — Moving RMS method

'Sliding window' (default) | 'Exponential weighting'

Moving RMS method, specified as 'Sliding window' or 'Exponential weighting'.

- 'Sliding window' — A window of length specified by `SpecifyWindowLength` is moved over the input data along each channel. For every sample the window moves by, the object computes the RMS over the data in the window.
- 'Exponential weighting' — The object multiplies the squares of the samples with a set of weighting factors. The magnitude of the weighting factors decreases exponentially as the age of the data increases, never reaching zero. To compute the RMS, the algorithm sums the weighted data, and takes a square root of the sum.

For more details on these methods, see “Algorithms” on page 4-1334.

SpecifyWindowLength — Specify window length

true (default) | false

Flag to specify a window length, specified as a scalar Boolean.

- true — The length of the sliding window is equal to the value you specify in the `WindowLength` property.
- false — The length of the sliding window is infinite. In this mode, the RMS is computed using the current sample and all past samples.

This property applies when you set `Method` to 'Sliding window'.

WindowLength — Length of the sliding window

4 (default) | positive scalar integer

Length of the sliding window, specified as a positive scalar integer. This property applies when you set `Method` to 'Sliding window' and `SpecifyWindowLength` to `true`.

ForgettingFactor — Exponential weighting factor

0.9 (default) | positive real scalar in the range (0,1]

Exponential weighting factor, specified as a positive real scalar in the range (0,1]. This property applies when you set `Method` to 'Exponential weighting'.

A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All the past samples are given an equal weight.

This property is tunable. You can change its value even when the object is locked.

Methods

`reset` Reset internal states of System object
`step` Moving RMS of input signal

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

Moving RMS of Noisy Square Wave Signal

Compute the moving RMS of a noisy square wave signal with varying amplitude using the `dsp.MovingRMS` object.

Initialization

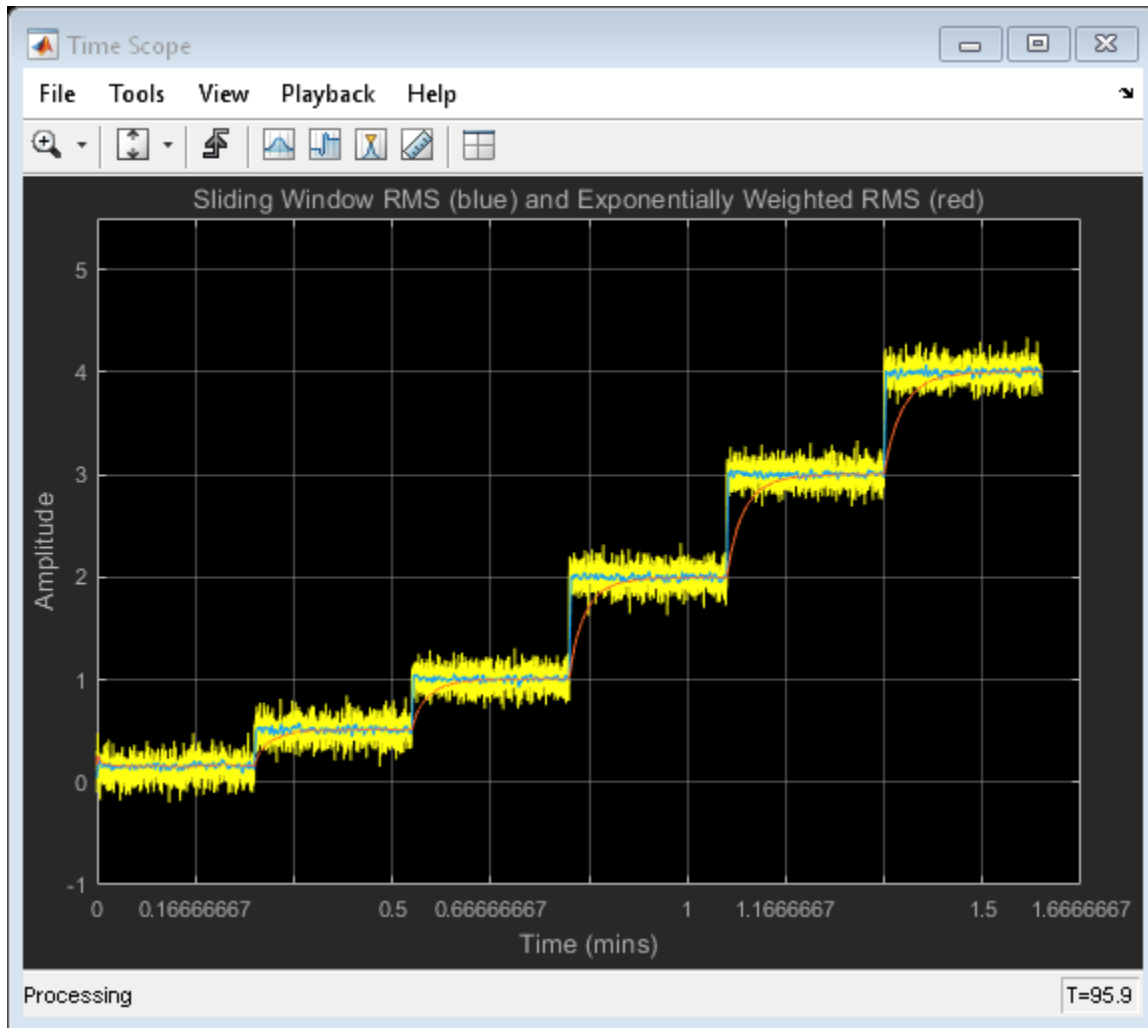

Set up `movrmsWin` and `movrmsExp` objects. `movrmsWin` uses the sliding window method with a window length of 20. `movrmsExp` uses the exponential weighting method with a forgetting factor of 0.995. Create a time scope for viewing the output.

```
FrameLength = 10;
Fs = 100;
movrmsWin = dsp.MovingRMS(20);
movrmsExp = dsp.MovingRMS('Method','Exponential weighting',...
    'ForgettingFactor',0.995);
scope = dsp.TimeScope('SampleRate',Fs,...
    'TimeSpanOverrunAction','Scroll',...
    'TimeSpan',100,...
    'ShowGrid',true,...
    'YLimits',[-1.0 5.5]);
title = 'Sliding Window RMS (blue) and Exponentially Weighted RMS (red)';
scope.Title = title;
```

Compute the RMS

Generate a noisy square wave signal. Vary the amplitude of the square wave after a given number of frames. Apply the sliding window method and the exponential weighting method on this signal. View the output on the time scope.

```
count = 1;
Vect = [1/8 1/2 1 2 3 4];
index = 1;
for index = 1:length(Vect)
    V = Vect(index);
    for i = 1:160
        x = V + 0.1 * randn(FrameLength,1);
        y1 = movrmsWin(x);
        y2 = movrmsExp(x);
        scope([x,y1,y2]);
    end
end
```

Algorithms

Sliding Window Method

In the sliding window method, the output for each input sample is the RMS of the current sample and the $Len - 1$ previous samples. Len is the length of the window. To compute the first $Len - 1$ outputs, when the window does not have enough data yet, the algorithm fills the window with zeros. As an example, to compute the RMS when the second input sample comes in, the algorithm fills the window with $Len - 2$ zeros. The data vector, x , is then the two data samples followed by $Len - 2$ zeros.

When you do not specify the window length, the algorithm chooses an infinite window length. In this mode, the output is the moving RMS of the current sample and all the previous samples in the channel.

Consider an example of computing the moving RMS of a streaming input data using the sliding window method. The algorithm uses a window length of 4. With each input sample that comes in, the window of length 4 moves along the data.

Exponential Weighting Method

In the exponential weighting method, the moving RMS is computed recursively using these formulas:

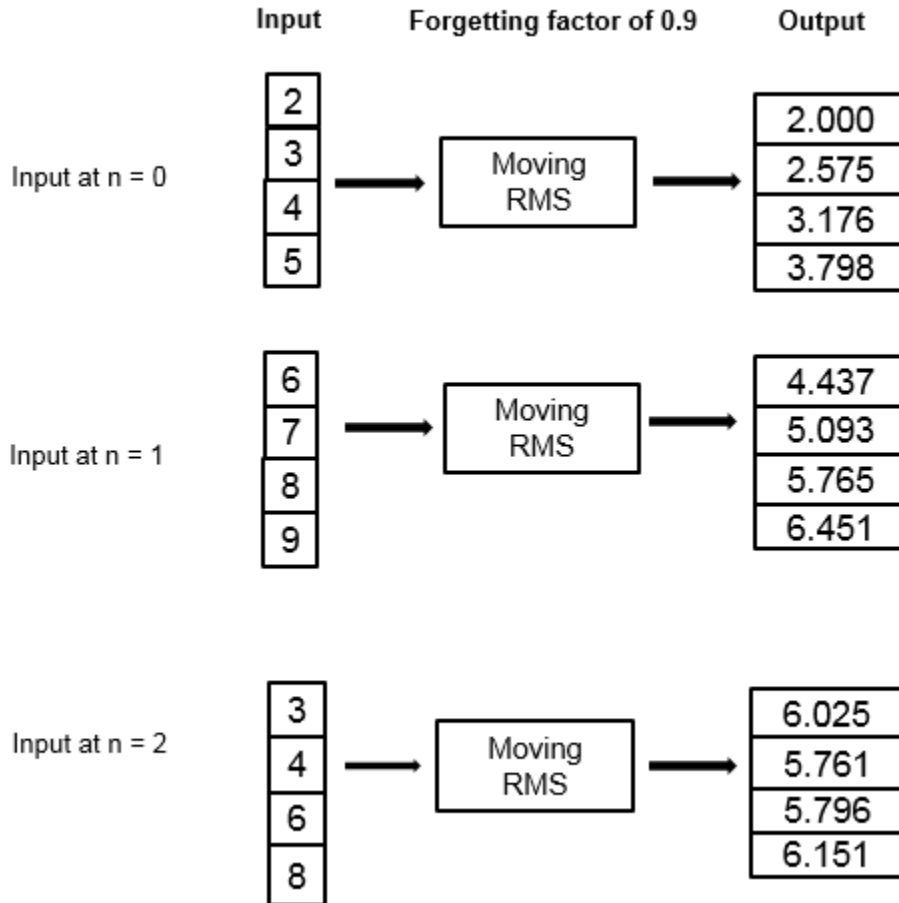

$$w_{N,\lambda} = \lambda w_{N-1,\lambda} + 1,$$
$$x_rms_{N,\lambda} = \sqrt{\left(1 - \frac{1}{w_{N,\lambda}}\right) x_rms_{N-1,\lambda}^2 + \left(\frac{1}{w_{N,\lambda}}\right) x_N^2}$$

- $x_rms_{N,\lambda}$ — Moving RMS at the current sample
- x_N^2 — Square of the current input data sample
- $x_rms_{N-1,\lambda}$ — Moving RMS at the previous sample
- λ — Forgetting factor
- $w_{N,\lambda}$ — Weighting factor applied to the current data sample
- $\left(1 - \frac{1}{w_{N,\lambda}}\right) x_rms_{N-1,\lambda}^2$ — Effect of the previous data on the RMS

For the first sample, where $N = 1$, the algorithm chooses $w_{N,\lambda} = 1$. For the next sample, the weighting factor is updated and used to compute the RMS, as per the recursive equation. As the age of the data increases, the magnitude of the weighting factor decreases exponentially and never reaches zero. In other words, the recent data has more influence on the current RMS than the older data.

The value of the forgetting factor determines the rate of change of the weighting factors. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All the previous samples are given an equal weight.

Here is an example of computing the moving RMS using the exponential weighting method. The forgetting factor is 0.9.

reset

System object: dsp.MovingRMS

Package: dsp

Reset internal states of System object

Syntax

`reset (movRMS)`

Description

`reset (movRMS)` resets the states of the input object to their initial values. The initial state values correspond to the initial conditions for the difference equation defining the object. After you call the object using nonzero input data, the filter might have nonzero states. If you continue to pass nonzero input data to the object without first calling `reset`, the object might produce different outputs for an identical input.

Introduced in R2016b

step

System object: dsp.MovingRMS

Package: dsp

Moving RMS of input signal

Syntax

```
y = step(movRMS, x)
```

Description

Note Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

`y = step(movRMS, x)` computes the moving RMS of the input signal, `x`, using either the sliding window method or exponential weighting method of the input `dsp.MovingRMS` System object, `movRMS`. The input `x` can be a row vector, a column vector, or a matrix. If `x` is a matrix, each column is treated as an independent channel. The moving RMS is computed along each channel. The input `x` can be complex and supports single and double data types.

Introduced in R2016b

dsp.MovingStandardDeviation System object

Package: dsp

Moving standard deviation

Description

The `dsp.MovingStandardDeviation` System object computes the moving standard deviation of the input signal along each channel, independently over time. The object uses either the sliding window method or the exponential weighting method to compute the moving standard deviation. In the sliding window method, a window of specified length is moved over the data, sample by sample, and the object computes the standard deviation over the data in the window. In the exponential weighting method, the object computes the exponentially weighted moving variance, and takes the square root. For more details on these methods, see “Algorithms” on page 4-1346.

The object accepts multichannel inputs, that is, m -by- n size inputs, where $m \geq 1$, and $n > 1$. The object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel. However, the number of channels cannot change. This object supports C and C++ code generation.

To compute the moving standard deviation of the input:

- 1 Create a `dsp.MovingStandardDeviation` object and set the properties of the object.
- 2 Call `step` to compute the moving standard deviation.

Note Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Construction

`MovStd = dsp.MovingStandardDeviation` returns a moving standard deviation object, `MovStd`, using the default properties.

`MovStd = dsp.MovingStandardDeviation(Len)` sets the `WindowLength` property to `Len`.

`MovStd = dsp.MovingStandardDeviation(Name, Value)` specifies additional properties using `Name, Value` pairs. Unspecified properties have default values.

Example:

```
MovStd = dsp.MovingStandardDeviation('Method', 'Exponential weighting', 'ForgettingFactor', 0.999);
```

Properties

Method — Moving standard deviation method

'Sliding window' (default) | 'Exponential weighting'

- 'Sliding window' — A window of length specified by `SpecifyWindowLength` is moved over the input data along each channel. For every sample the window moves by, the object computes the standard deviation over the data in the window.
- 'Exponential weighting' — The object computes the exponentially weighted moving variance, and takes the square root.

For more details on these methods, see “Algorithms” on page 4-1346.

SpecifyWindowLength — Specify window length

true (default) | false

Flag to specify a window length, specified as a scalar boolean.

- true — The length of the sliding window is equal to the value you specify in the `WindowLength` property.
- false — The length of the sliding window is infinite. In this mode, the standard deviation is computed using the current sample and all the past samples.

This property applies when you set `Method` to 'Sliding window'.

WindowLength — Length of the sliding window

4 (default) | positive scalar integer

Length of the sliding window, specified as a positive scalar integer. This property applies when you set `Method` to 'Sliding window' and `SpecifyWindowLength` to true.

ForgettingFactor — Exponential weighting factor

0.9 (default) | positive real scalar in the range (0,1]

Exponential weighting factor, specified as a positive real scalar in the range (0,1].

This property applies when you set `Method` to 'Exponential weighting'.

This property is tunable. You can change its value even when the object is locked.

Methods

`reset` Reset internal states of System object
`step` Moving standard deviation of input signal

Examples

Moving Standard Deviation of Noisy Square Wave Signal

Compute the moving standard deviation of a noisy square wave signal with varying amplitude using the `dsp.MovingStandardDeviation` object.

Initialization

Set up `movstdWindow` and `movstdExp` objects. `movstdWindow` uses the sliding window method with a window length of 800. `movstdExp` uses the exponential weighting method with a forgetting factor of 0.999. Create a time scope for viewing the output.

```
FrameLength = 100;
Fs = 100;
movstdWindow = dsp.MovingStandardDeviation(800);
movstdExp = dsp.MovingStandardDeviation('Method','Exponential weighting',...
    'ForgettingFactor',0.999);
scope = dsp.TimeScope('SampleRate',Fs,...
    'TimeSpanOverrunAction','Scroll',...
    'TimeSpan',1000,...
    'ShowGrid',true,...
    'BufferLength',1e7,...
    'YLimits',[0 3e-2]);
title = 'Actual (yellow) Sliding Window (blue) Exponentially Weighted (red) standard deviation';
scope.Title = title;
```

Compute the Standard Deviation

Generate a noisy square wave signal. Vary the amplitude of the square wave after a given number of frames. Apply the sliding window method and the exponential weighting method on this signal. The actual standard deviation is $\sqrt{\text{np}}$. This value is used while adding noise to the data. Compare the actual standard deviation with the computed standard deviation on the time scope.

```
count = 1;
noisepower = 1e-4 * [1 2 3 4];
index = 1;
for index = 1:length(noisepower)
    np = noisepower(index);
    yexp = sqrt(np)*ones(FrameLength,1);
    for i = 1:250
        x = sqrt(np) * randn(FrameLength,1);
        y1 = movstdWindow(x);
        y2 = movstdExp(x);
        scope([yexp,y1,y2]);
    end
end
```

Algorithms

Sliding Window Method

In the sliding window method, the output at the current sample is the standard deviation of the current sample with respect to the data in the window. To compute the first $Len - 1$ outputs, when the window does not have enough data yet, the algorithm fills the window with zeros. As an example, to compute the standard deviation when the second input sample comes in, the algorithm fills the window with $Len - 2$ zeros. Len is the length of the window. The data vector, x , is then the two data samples followed by $Len - 2$ zeros.

When you do not specify the window length, the algorithm chooses an infinite window length. In this mode, the output is the moving standard deviation of the current sample with respect to all the previous samples in the channel.

Consider an example of computing the moving standard deviation of a streaming input data using the sliding window method. The algorithm uses a window length of 4. With each input sample that comes in, the window of length 4 moves along the data.

Exponential Weighting Method

In the exponential weighting method, the moving standard deviation is computed recursively using these formulas:

$$s_{N,\lambda} = \sqrt{\frac{1}{v_{N,\lambda}} \sum_{k=1}^N \lambda^{N-k} [x_k - \bar{x}_{N,\lambda}]^2},$$
$$v_{N,\lambda} = \frac{2\lambda(1-\lambda^{N-1})}{(1-\lambda)(1+\lambda)}$$

- $s_{N,\lambda}$ — Moving standard deviation of the current data sample with respect to the rest of the data.
- $[x_k - \bar{x}_{N,\lambda}]^2$ — Difference between each data sample and the average of the data, squared.
- $\sum_{k=1}^N \lambda^{N-k} [x_k - \bar{x}_{N,\lambda}]^2$ — Difference between each data sample and the average of the data, squared and multiplied with the forgetting factor. All the squared terms are added.
- $\frac{1}{v_{N,\lambda}}$ — Weighting factor applied to the sum.
- λ — Forgetting factor.

As the age of the data increases, the magnitude of the weighting factor decreases exponentially and never reaches zero. In other words, the recent data has more influence on the current standard deviation than the older data.

The value of the forgetting factor determines the rate of change of the weighting factors. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All previous samples are given an equal weight.

Consider an example of computing the moving standard deviation using the exponential weighting method. The forgetting factor is 0.9.

Introduced in R2016b

dsp.MovingVariance System object

Package: dsp

Moving variance

Description

The `dsp.MovingVariance` System object computes the moving variance of the input signal along each channel, independently over time. The object uses either the sliding window method or the exponential weighting method to compute the moving variance. In the sliding window method, a window of specified length is moved over the data, sample by sample, and the variance is computed over the data in the window. In the exponential weighting method, the object subtracts each sample of the data from the average, squares the difference, and multiplies the squared result with a weighting factor. The object then computes the variance by adding all the weighted data. For more details on these methods, see “Algorithms” on page 4-1358.

The object accepts multichannel inputs, that is, m -by- n size inputs, where $m \geq 1$, and $n > 1$. The object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel. However, the number of channels cannot change. This object supports C and C++ code generation.

To compute the moving variance of the input:

- 1 Create a `dsp.MovingVariance` object and set the properties of the object.
- 2 Call `step` to compute the moving variance.

Note Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Construction

`MovVar = dsp.MovingVariance` returns a moving variance object, `MovVar`, using the default properties.

`MovVar = dsp.MovingVariance(Len)` sets the `WindowLength` property to `Len`.

`MovVar = dsp.MovingVariance(Name, Value)` specifies additional properties using `Name, Value` pairs. Unspecified properties have default values.

Example:

```
MovVar = dsp.MovingVariance('Method', 'Exponential weighting', 'ForgettingFactor', 0.9);
```

Properties

Method — Method to compute the variance

'Sliding window' (default) | 'Exponential weighting'

- 'Sliding window' — A window of length specified by `SpecifyWindowLength` is moved over the input data along each channel. For every sample the window moves by, the object computes the variance over the data in the window.
- 'Exponential weighting' — The object subtracts each sample of the data from the average, squares the difference, and multiplies the squared result with a weighting factor. The object then computes the variance by adding all the weighted data. The magnitude of the weighting factors decreases exponentially as the age of the data increases, never reaching zero.

For more details on these methods, see “Algorithms” on page 4-1358.

SpecifyWindowLength — Specify window length

true (default) | false

Flag to specify a window length, specified as a scalar Boolean.

- true — The length of the sliding window is equal to the value you specify in the `WindowLength` property.
- false — The length of the sliding window is infinite. In this mode, the variance is computed using the current sample and all past samples.

This property applies when you set `Method` to 'Sliding window'.

WindowLength — Length of the sliding window

4 (default) | positive scalar integer

Length of the sliding window, specified as a positive scalar integer. This property applies when you set `Method` to 'Sliding window' and `SpecifyWindowLength` to `true`.

ForgettingFactor — Exponential weighting factor

0.9 (default) | positive real scalar in the range (0,1]

Exponential weighting factor, specified as a positive real scalar in the range (0,1]. This property applies when you set `Method` to 'Exponential weighting'.

A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All the past samples are given an equal weight.

This property is tunable. You can change its value even when the object is locked.

Examples

Moving Variance of Noisy Square Wave Signal

Compute the moving variance of a noisy square wave signal with varying amplitude using the `dsp.MovingVariance` object.

Initialization

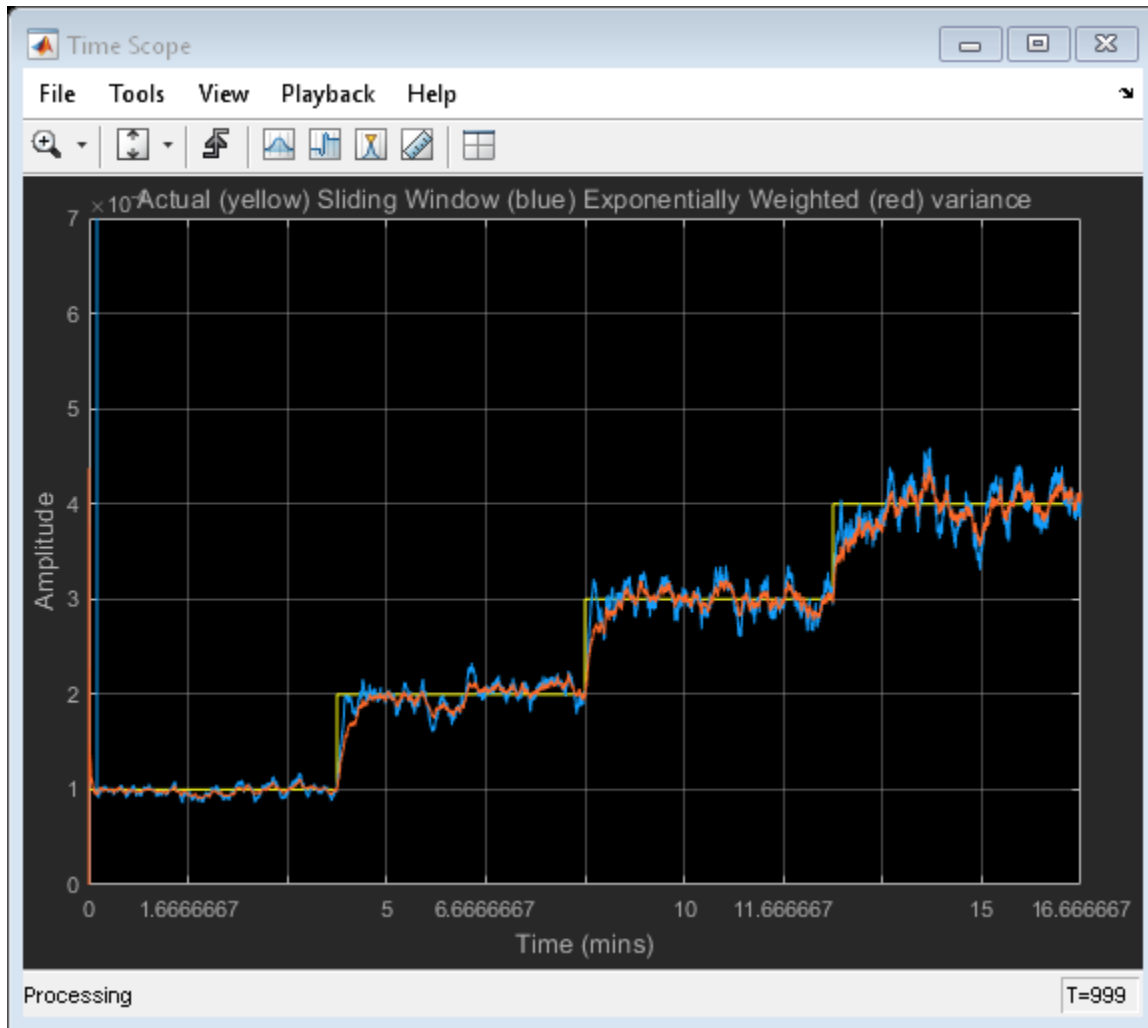

Set up `movvarWindow` and `movvarExp` objects. `movvarWindow` uses the sliding window method with a window length of 800. `movvarExp` uses the exponentially weighting method with a forgetting factor of 0.999. Create a time scope for viewing the output.

```
FrameLength = 100;
Fs = 100;
movvarWindow = dsp.MovingVariance(800);
movvarExp = dsp.MovingVariance('Method','Exponential weighting',...
    'ForgettingFactor',0.999);
scope = dsp.TimeScope('SampleRate',Fs,...
    'TimeSpanOverrunAction','Scroll',...
    'TimeSpan',1000,...
    'ShowGrid',true,...
    'BufferLength',1e7,...
    'YLimits',[0 7e-4]);
title = 'Actual (yellow) Sliding Window (blue) Exponentially Weighted (red) variance';
scope.Title = title;
```

Compute the Variance

Generate a noisy square wave signal. Vary the amplitude of the square wave after a given number of frames. Apply the sliding window method and the exponentially weighting method on this signal. The actual variance is np . This value is used while adding noise to the data. Compare the actual variance with the computed variances on the time scope.

```
count = 1;
noisepower = 1e-4 * [1 2 3 4];
index = 1;
for index = 1:length(noisepower)
    np = noisepower(index);
    yexp = np*ones(FrameLength,1);
    for i = 1:250
        x = 1 + sqrt(np) * randn(FrameLength,1);
        y1 = movvarWindow(x);
        y2 = movvarExp(x);
        scope([yexp,y1,y2]);
    end
end
```

Algorithms

Sliding Window Method

In the sliding window method, the output at the current sample is the variance of the current sample with respect to the data in the window. To compute the first $Len - 1$ outputs, when the window does not have enough data yet, the algorithm fills the window with zeros. As an example, to compute the variance when the second input sample comes in, the algorithm fills the window with $Len - 2$ zeros. Len is the length of the window. The data vector, x , is then the two data samples followed by $Len - 2$ zeros.

When you do not specify the window length, the algorithm chooses an infinite window length. In this mode, the output is the moving variance of the current sample with respect to all previous samples in the channel.

Consider an example of computing the moving variance of a streaming input data using the sliding window method. The algorithm uses a window length of 4. With each input sample that comes in, the window of length 4 moves along the data.

Exponential Weighting Method

In the exponential weighting method, the moving variance is computed recursively using these formulas:

$$s_{N,\lambda}^2 = \frac{1}{v_{N,\lambda}} \sum_{k=1}^N \lambda^{N-k} [x_k - \bar{x}_{N,\lambda}]^2,$$

$$v_{N,\lambda} = \frac{2\lambda(1-\lambda^{N-1})}{(1-\lambda)(1+\lambda)}$$

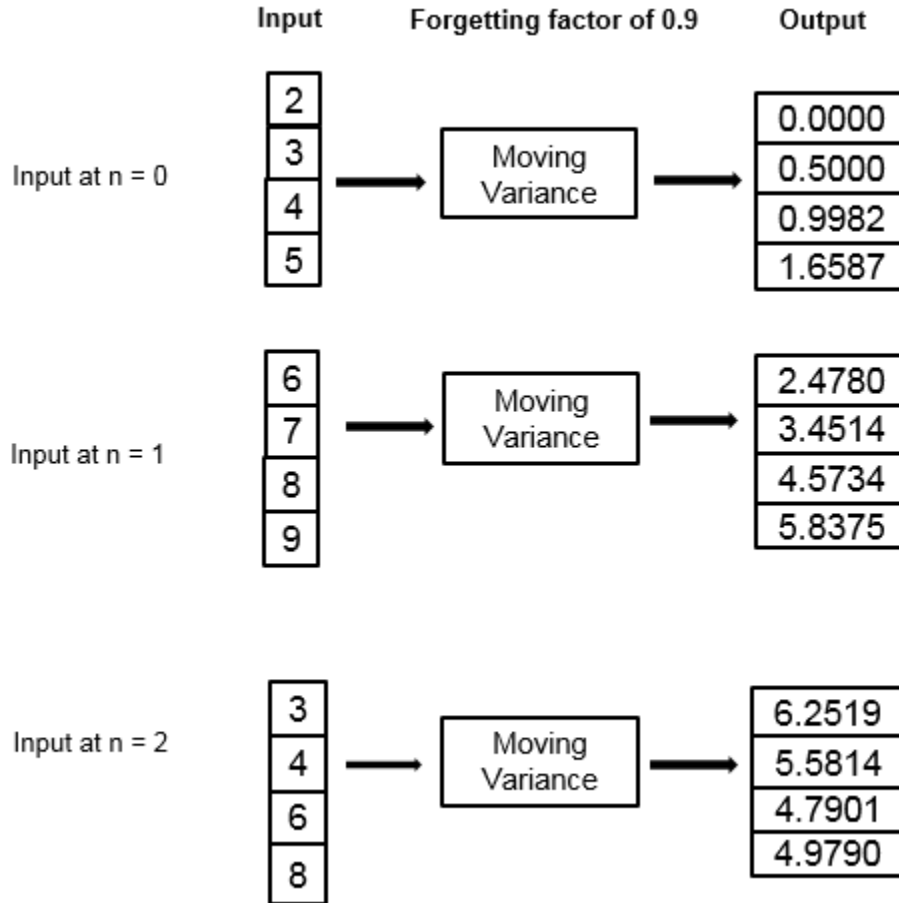

To compute the moving variance, the algorithm implements these equations recursively.

- $s_{N,\lambda}^2$ — Moving variance of the current data sample with respect to the rest of the data in the channel.
- $\bar{x}_{N,\lambda}$ — Moving average at the current sample. For details on computing the moving average, see `dsp.MovingAverage`.
- $[x_k - \bar{x}_{N,\lambda}]^2$ — Difference between each data sample and the average of the data, squared.
- $\sum_{k=1}^N \lambda^{N-k} [x_k - \bar{x}_{N,\lambda}]^2$ — Difference between each data sample and the average of the data, squared and multiplied with the forgetting factor. All the squared terms are added.
- $\frac{1}{v_{N,\lambda}}$ — Weighting factor applied to the sum.
- λ — Forgetting factor you can specify through the `ForgettingFactor` property.

As the age of the data increases, the magnitude of the weighting factor decreases exponentially, and never reaches zero. In other words, the recent data has more influence on the current variance, than the older data.

The value of the forgetting factor determines the rate of change of the weighting factors. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All the past samples are given an equal weight.

Consider an example of computing the moving variance using the exponential weighting method. The forgetting factor is 0.9.

Introduced in R2016b

reset

System object: dsp.MovingVariance

Package: dsp

Reset internal states of System object

Syntax

```
reset (movVar)
```

Description

`reset (movVar)` resets the states of the input object to their initial values. The initial state values correspond to the initial conditions for the difference equation defining the object. After you call the object using nonzero input data, the filter might have nonzero states. If you continue to pass nonzero input data to the object without first calling `reset`, the object might produce different outputs for an identical input.

Introduced in R2016b

step

System object: dsp.MovingVariance

Package: dsp

Moving Variance of input signal

Syntax

```
y = step(movVar, x)
```

Description

Note Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

`y = step(movVar, x)` computes the moving variance of the input signal, `x`, using either the sliding window method or exponential weighting method of the input `dsp.MovingVariance` System object, `movVar`. The input `x` can be a row vector, a column vector, or a matrix. If `x` is a matrix, each column is treated as an independent channel. The moving variance is computed along each channel. The input `x` can be complex and supports single and double data types.

Introduced in R2016b

dsp.NCO System object

Package: dsp

Generate real or complex sinusoidal signals

Description

The numerically controlled oscillator, or NCO, object generates real or complex sinusoidal signals. The amplitude of the generated signal is always 1.

To generate real or complex sinusoidal signals:

- 1 Define and set up your NCO System object. See “Construction” on page 4-1365.
- 2 Call `step` to generate the signals according to the properties of `dsp.NCO`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

Construction

`nco = dsp.NCO` returns an NCO System object, `nco`, that generates a multichannel real or complex sinusoidal signal, with independent frequency and phase in each output channel.

`nco = dsp.NCO('PropertyName', PropertyValue, ...)` returns an NCO System object, `nco`, with each specified property set to the specified value.

Properties

PhaseIncrementSource

Source of phase increment

Indicate how to specify the phase increment: `Property` or `Input port`. The default is `Input port`.

PhaseIncrement

Phase increment

Specify the phase increment as an integer scalar. This property applies only when you set the “`PhaseIncrementSource`” on page 4-0 property to `Property`. The default is 100.

PhaseOffsetSource

Source of phase offset

Specify the phase offset as `Property` or `Input port`. The default is `Property`.

PhaseOffset

Phase offset

Specify the phase offset as an integer scalar. This property applies only when you set the “`PhaseOffsetSource`” on page 4-0 property to `Property`. The default is 0.

Dither

Enable adding internal dithering to NCO algorithm

Set this property to `true` to add internal dithering to the NCO algorithm. Dithering is added using the PN Sequence Generator from the Communications System Toolbox product. The default is `true`.

NumDitherBits

Number of dither bits

Specify the number of dither bits as a positive integer. This property applies only when you set the `Dither` property to `true`. The default is 4.

PhaseQuantization

Enable quantization of accumulated phase

Set this property to `true` to enable quantization of the accumulated phase. The default is `true`.

NumQuantizerAccumulatorBits

Number of quantizer accumulator bits

Specify the number of quantizer accumulator bits as an integer scalar greater than 1 and less than the accumulator word length. This property determines the number of entries in the lookup table of sine values. This property applies only when you set the “PhaseQuantization” on page 4-0 property to `true`. The default is 12.

PhaseQuantizationErrorOutputPort

Enable output of phase quantization error

Set this property to `true` to output the phase quantization error. This property applies only when you set the “PhaseQuantization” on page 4-0 property to `true`. The default is `false`.

Waveform

Type of output signal

Specify the type of the output signal: `Sine`, `Cosine`, `Complex exponential` or `Sine and cosine`. The default is `Sine`.

SamplesPerFrame

Number of output samples per frame

Specify the number of samples per frame of the output signal. This property applies only when you set the “PhaseOffsetSource” on page 4-0 property to `Property`. The default is 1. When the `PhaseOffsetSource` property is `Input port`, and the “PhaseIncrementSource” on page 4-0 property is `Property`, the number of rows or frame size of the phase offset input determines the number of samples per frame of the output signal. When you set both the “PhaseOffsetSource” on page 4-0 and “PhaseIncrementSource” on page 4-0 properties to `Input port`, the number of rows in the inputs must be 1, and the samples per frame of the output signal is 1.

OutputDataType

Output data type

Specify the output data type as `double`, `single` or `Custom`. The default is `Custom`. When you select `Custom` you must also set the `CustomOutputDataType` property. You can find the `CustomOutputDataType` property described under `Fixed-Point Properties` on this page.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

This constant property has a value `Floor`.

OverflowAction

Overflow action for fixed-point operations

This constant property has a value `Wrap`.

AccumulatorDataType

Accumulator word and fraction lengths

This constant property has a value `Custom`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as an unscaled `numericType` object with a `Signedness` of `Auto`. The default is `numericType([], 16)`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the “`OutputDataType`” on page 4-0 property to `Custom`. The default is `numericType([], 16, 14)`.

Methods

- info Characteristic information about generated signal
- reset Reset accumulator of NCO object
- step Generate multichannel real or complex sinusoidal signal using NCO (Numerically Controlled Oscillator)

Common to All System Objects	
clone	Create System object with same property values
getNumInputs	Expected number of inputs to a System object
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Design an NCO Source

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject()` becomes `step(myObject)`.

Design an NCO source according to given specifications.

```
df = 0.05; % Frequency resolution = 0.05 Hz
minSFDR = 96; % Spurious free dynamic range >= 96 dB
Ts = 1/8000; % Sample period = 1/8000 sec
dphi = pi/2; % Desired phase offset = pi/2;
```

Calculate number of accumulator bits required for the given frequency resolution.

```
Nacc = ceil(log2(1/(df*Ts)));
```

Actual frequency resolution achieved.

```
actdf = 1/(Ts*2^Nacc);
```

Calculate number of quantized accumulator bits required from the SFDR requirement

```
Nqacc = ceil((minSFDR-12)/6);
```

Calculate the phase offset

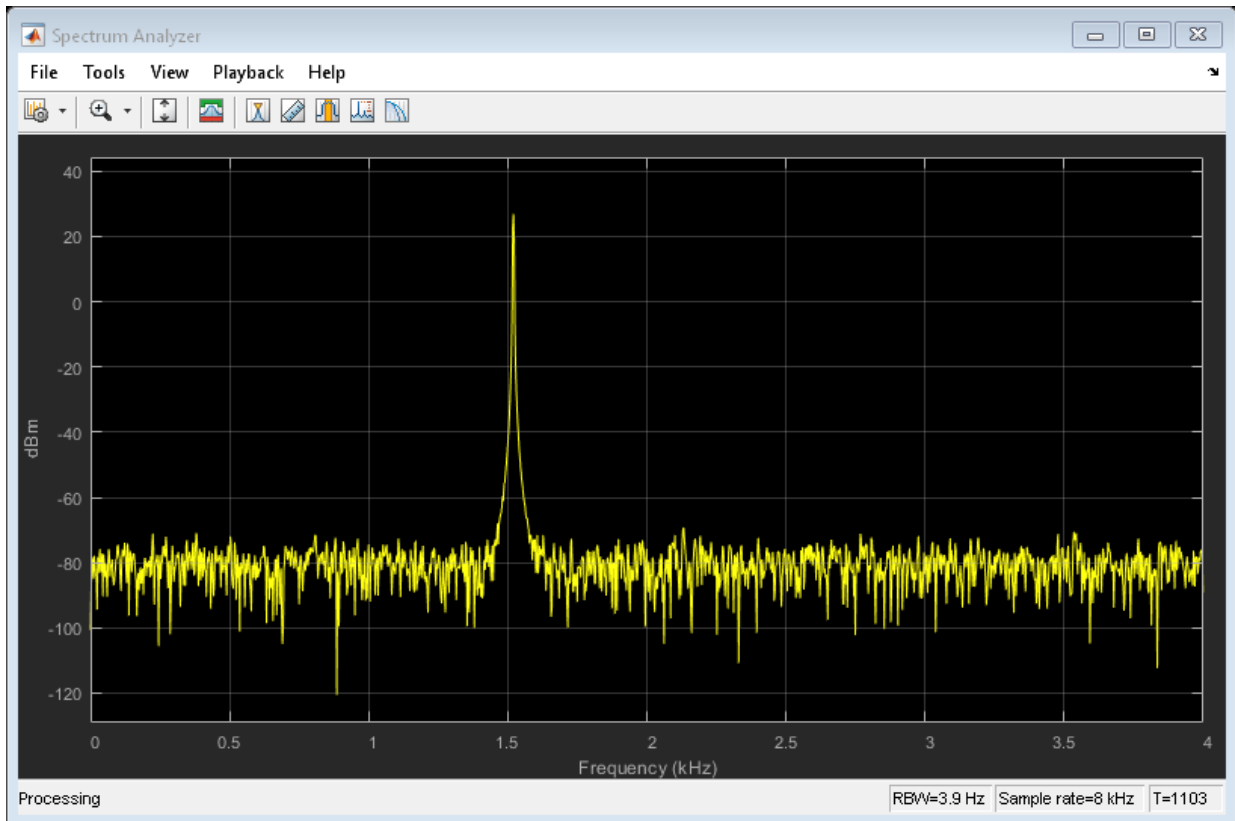

```
phOffset = 2^Nacc*dphi/(2*pi);
```

Design the NCO source.

```
nco = dsp.NCO('PhaseOffset', phOffset, ...  
            'NumDitherBits', 4, ...  
            'NumQuantizerAccumulatorBits', Nqacc, ...  
            'SamplesPerFrame', 1/Ts, ...  
            'CustomAccumulatorDataType', numerictype([],Nacc));  
san = dsp.SpectrumAnalyzer('SampleRate', 1/Ts, ...  
                          'PlotAsTwoSidedSpectrum', false);
```

View the output of the NCO source on a spectrum analyzer. Change the output frequency in the middle of the simulation from 510 Hz to 1520 Hz.

```
tic;  
while toc < 10  
  
    if toc < 5  
        F0 = 510;  
    else  
        F0 = 1520;  
    end  
    % Calculate the phase increment  
    phIncr = int32(round(F0*Ts*2^Nacc));  
    y = nco(phIncr);  
    san(y);  
end
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the NCO block reference page. The object properties correspond to the block properties, except: There is no object property that corresponds to the **Sample time** block parameter. The objects assumes a sample time of one second.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

See Also

`dsp.SineWave`

Introduced in R2012a

info

System object: dsp.NCO

Package: dsp

Characteristic information about generated signal

Syntax

```
S = info(nco)
```

Description

`S = info(nco)` returns a structure containing characteristic information, `S`, about the signal being generated by the NCO System object, `nco`. The number of fields of `S`, and their values vary depending on the property value settings of `nco`. For description of the possible fields and their values, see the following table.

Field	Value
NumPointsLUT	Number of data points for lookup table. The lookup table is implemented as a quarter-wave sine table.
SineLUTSize	Quarter-wave sine lookup table size in bytes.
TheoreticalSFDR	Theoretical spurious free dynamic range (SFDR) in dBc. This field applies when you set the <code>PhaseQuantization</code> property to <code>true</code> .
FrequencyResolution	Frequency resolution of the NCO in Hz. The sample time of the output signal is assumed to be 1 sec.

reset

System object: dsp.NCO

Package: dsp

Reset accumulator of NCO object

Syntax

```
reset(nco)
```

Description

`reset(nco)` resets the accumulator of the NCO System object, `nco`, to zero.

step

System object: dsp.NCO

Package: dsp

Generate multichannel real or complex sinusoidal signal using NCO (Numerically Controlled Oscillator)

Syntax

```
Y = step(nco, INC)
Y = step(nco)
Y = step(nco, OFFSET)
Y = step(nco, INC, OFFSET)
[Y, COSINE] = step(nco, ___)
[Y, QERR] = step(nco, ___)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

`Y = step(nco, INC)` returns a sinusoidal signal, `Y`, generated by the NCO with the specified phase increment, `INC`. `INC` must be a built-in integer or a `fi` object comprising either a scalar or a row vector, where each row element corresponds to a separate channel.

`Y = step(nco)` when the `PhaseIncrementSource` and `PhaseOffsetSource` properties are both `Property`, returns a sinusoidal signal, `Y`.

`Y = step(nco, OFFSET)` returns a sinusoidal signal, `Y`, with phase offset, `OFFSET`, when the `PhaseOffsetSource` property is `Input port`. `OFFSET` must be a built-in integer or a `fi` object. The number of rows of `OFFSET` determines the number of samples

per frame of the output signal. The number of columns of the `OFFSET` determines the number of channels of the output signal.

`Y = step(nco, INC, OFFSET)` returns a sinusoidal signal, `Y`, with phase increment, `INC`, and phase offset, `OFFSET`, when the `PhaseIncrementSource` and the `PhaseOffsetSource` properties are both `Input port`. `INC` and `OFFSET` must both be row vectors of the same length, where the length determines the number of channels in the output signal.

`[Y, COSINE] = step(nco, ___)` returns a sinusoidal signal, `Y`, and a cosinusoidal signal, `COSINE`, when the `Waveform` property is set to `Sine` and `cosine`. This syntax can include any of the input arguments in previous syntaxes.

`[Y, QERR] = step(nco, ___)` when the `PhaseQuantization` and the `PhaseQuantizationErrorOutputPort` properties are both `true`, returns a sinusoidal signal, `Y`, and output quantization error, `QERR`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.Normalize System object

Package: dsp

Vector normalization along specified dimension

Description

The `Normalize` object performs vector normalization along rows, columns, or specified dimension.

To perform vector normalization:

- 1 Define and set up your normalization object. See “Construction” on page 4-1377.
- 2 Call `step` to perform vector normalization according to the properties of `dsp.Normalize`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`norm = dsp.Normalize` returns a normalization object, `norm`, that normalizes the input over each column by the squared 2-norm of the column plus a bias term of $1e-10$ used to protect against divide-by-zero.

`norm = dsp.Normalize('PropertyName', PropertyValue, ...)` returns a normalization object, `norm`, with each property set to the specified value.

Properties

Method

Type of normalization to perform

Specify the type of normalization to perform as `2-norm` or `Squared 2-norm`. The `2-norm` mode supports floating-point signals only. The `Squared 2-norm` supports both fixed-point and floating-point signals. The default is `Squared 2-norm`.

Bias

Real number added in denominator to avoid division by zero

Specify the real number to add in the denominator to avoid division by zero. The default is `1e-10`. This property is tunable.

Dimension

Dimension to operate along

Specify whether to normalize along `Column`, `Row`, or `Custom`. The default is `Column`.

CustomDimension

Numerical dimension to operate along

Specify the one-based value of the dimension over which to normalize. The value of this parameter cannot exceed the number of dimensions in the input signal. This property applies when “Dimension” on page 4-0 property is `Custom`. The default is `1`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. The default is `Wrap`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of `Same as input` or `Custom`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numericType([], 32, 32)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `Same as product`, `Same as input`, `Custom`. The default is `Same as product`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of `Same as accumulator`, `Same as product`, `Same as input`, `Custom`. The default is `Same as product`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the “`OutputDataType`” on page 4-0 property to `Custom`. The default is `numerictype([], 32, 32)`.

Methods

`step` Normalize input along specified dimension

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

Normalize a Matrix

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
norm = dsp.Normalizer;  
x = magic(3);  
y = norm(x);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Normalization block reference page. The object properties correspond to the block parameters, except:

- **Treat sample-based row input as column** — The block allows you to input a row vector and normalize the row vector as a column vector. The normalization object always normalizes along the value of the “Dimension” on page 4-0 property.
- The normalization object does not support the **Minimum** and **Maximum** options for data output.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

See Also

`dsp.ArrayVectorMultiplier`

Introduced in R2012a

step

System object: dsp.Normalizer

Package: dsp

Normalize input along specified dimension

Syntax

```
Y = step(norm,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(norm,X)` returns a normalized output `Y`. The input `X` must be floating-point for the 2-norm mode, and either fixed-point and floating-point for the Squared 2-norm mode.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.NotchPeakFilter System object

Package: dsp

Second-order tunable notching and peaking IIR filter

Description

The `NotchPeakFilter` object filters each channel of the input using IIR filter implementation.

To filter each channel of the input:

- 1 Define and set up your NotchPeak filter. See “Construction” on page 4-1383.
- 2 Call `step` to filter each channel of the input according to the properties of `dsp.NotchPeakFilter`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`npFilter = dsp.NotchPeakFilter` returns a second-order notching and peaking IIR filter which independently filters each channel of the input over time, using a specified center frequency and 3 dB bandwidth. Both of these properties are specified in Hz and are tunable. Both of these values must be scalars between 0 and half the sample rate.

`npFilter = dsp.NotchPeakFilter('PropertyName',PropertyValue, ...)` returns a notch filter with each specified property name set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`npFilter = dsp.NotchPeakFilter('specification', 'Quality factor and center frequency')` specifies the quality factor (Q factor) of the notch or peak filter instead of the 3 dB bandwidth. The Q factor is defined as the center frequency divided by the bandwidth. A higher Q factor corresponds to a narrower notch or peak. The Q factor should be a scalar value greater than 0. The Q factor is tunable.

`npFilter = dsp.NotchPeakFilter('Specification', 'Coefficients')` specifies the coefficient values that affect bandwidth and center frequency directly, rather than specifying the design parameters in Hz. This removes the trigonometry calculations involved when the properties are tuned. The `CenterFrequencyCoefficients` should be a scalar between -1 and 1, with -1 corresponding to 0 Hz and 1 corresponding to the Nyquist frequency. The `BandwidthCoefficient` should be a scalar between -1 and 1, with -1 corresponding to the largest 3 dB bandwidth and 1 corresponding to the smallest 3 dB bandwidth. Both coefficient values are tunable.

Properties

Specification

Filter specification

Set the specification as one of 'Bandwidth and center frequency' | 'Quality factor and center frequency' | 'Coefficients'. The default is 'Bandwidth and center frequency'.

Bandwidth

3 dB bandwidth

Specify the filter's 3 dB bandwidth as a finite positive numeric scalar in Hertz. This property is applicable only if `specification` is 'Bandwidth and center frequency'. The default is 2205 Hz. This property is tunable.

CenterFrequency

Notch or Peak center frequency

Specify the filter's center frequency (for both the notch and the peak) as a finite positive numeric scalar in Hertz. This property is applicable only if `specification` is

'Bandwidth and center frequency' | 'Quality factor and center frequency'. The default is 11025 Hz. This property is tunable.

QualityFactor

Quality factor for notch or peak filter

Specify the quality factor (Q factor) for both the notch and the peak filters. The Q factor is defined as the center frequency divided by the bandwidth. This property is applicable only if specification is set to 'Quality factor and center frequency'. The default value is 5. This property is tunable.

SampleRate

Sample rate of input

Specify the sample rate of the input in Hertz as a finite numeric scalar. The default is 44100 Hz.

BandwidthCoefficient

Bandwidth coefficient

Specify the value that determines the filter's 3 dB bandwidth as a finite numeric scalar in the range $[-1 \ 1]$. Where -1 corresponds to the maximum 3 dB bandwidth ($\text{SampleRate}/4$), and 1 corresponds to the minimum 3 dB bandwidth (0 Hz, an allpass filter). The default is 0.72654. This property is only applicable if specification is set to 'Coefficients'. This property is tunable.

CenterFrequencyCoefficient

Center frequency coefficient

Specify the coefficient that determines the filter's center frequency as a finite numeric scalar between -1 and 1 . Where -1 corresponds to the minimum center frequency (0 Hz), and 1 corresponds to the maximum center frequency ($\text{SampleRate}/2$ Hz). This property is only applicable if specification is set to 'Coefficients'. The default is 0 which corresponds to $\text{SampleRate}/4$ Hz. This property is tunable.

Methods

getBandwidth	Get 3 dB bandwidth
getCenterFrequency	Get center frequency
getOctaveBandwidth	Bandwidth in number of octaves
getQualityFactor	Get quality factor
reset	Reset the internal states of notch or peak filter
step	Process input using the notch or peak filter algorithm
tf	Transfer function

Common to All System Objects	
clone	Create System object with same property values
getNumInputs	Expected number of inputs to a System object
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Notch filter

This example shows how to use `dsp.NotchPeakFilter` as a notch filter with center frequency of 5000 Hz and a 3 dB bandwidth of 500 Hz.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
npFilter = dsp.NotchPeakFilter('CenterFrequency',5000,'Bandwidth',500);
sa = dsp.SpectrumAnalyzer('SampleRate',44100,...
    'PlotAsTwoSidedSpectrum',false,'SpectralAverages',50);
for i=1:5000
```

```
y = npFilter(randn(1024,1));  
sa(y);  
if (i==2500)  
    % Tune center frequency to 10000  
    npFilter.CenterFrequency = 10000;  
end  
end  
release(npFilter)  
release(sa)
```

Algorithms

The design equations for this filter are:

$$H(z) = (1-b) \frac{1-z^{-2}}{1-2b \cos \omega_0 z^{-1} + (2b-1)z^{-2}}$$

The previous equation is for peak filter, and the following equation is for notch filter.

$$H(z) = b \frac{1-2 \cos \omega_0 z^{-1} + z^{-2}}{1-2b \cos \omega_0 z^{-1} + (2b-1)z^{-2}}$$

With

$$b = \frac{1}{1 + \tan(\Delta\omega / 2)}$$

where $\omega_0 = 2\pi f_0/f_s$ is the center frequency in radians/sample (f_0 is the center frequency in Hz and f_s is the sampling frequency in Hz). $\Delta\omega = 2\pi\Delta f/f_s$ is the 3 dB bandwidth in radians/sample (Δf is the 3 dB bandwidth in Hz). Note that the two filters are complementary:

$$H_{notch}(z) + H_{peak}(z) = 1$$

they can be written as:

$$H_{peak}(z) = \frac{1}{2}[1 - A(z)]$$

$$H_{notch}(z) = \frac{1}{2}[1 + A(z)]$$

where $A(z)$ is a 2nd order allpass filter.

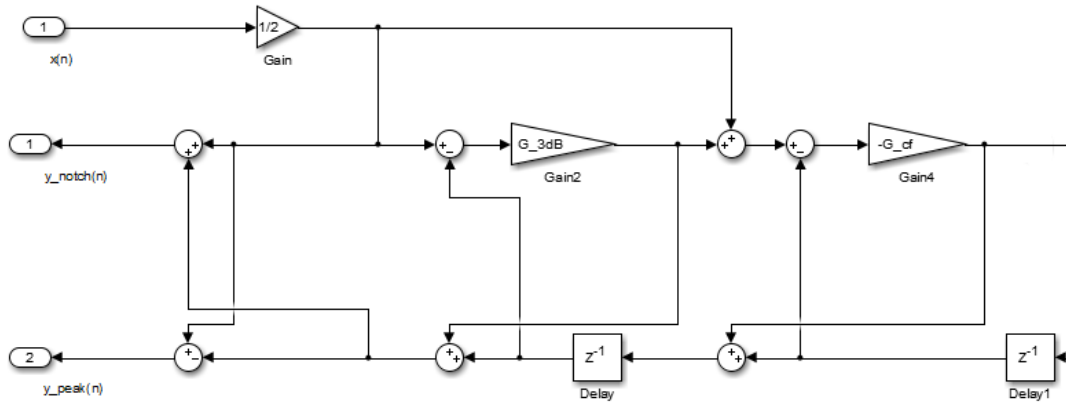

$$A(z) = \frac{a_2 + a_1 z^{-1} + z^{-2}}{1 + a_1 z^{-1} + a_2 z^{-2}}$$

and

$$a_1 = -2b \cos \omega_0$$

$$a_2 = 2b - 1$$

The filter is implemented as follows:

where

$$G_{3dB} = a_2 = 2b - 1$$

$$G_{cf} = \frac{a_1 - a_1 a_2}{1 - a_2^2} = -\cos w_0$$

Notice that G_{cf} depends only on the center frequency, and G_{3dB} depends only on the 3 dB bandwidth.

Notch-Peak Filter | dsp.BiquadFilter | iirnotch | iirpeak

Introduced in R2014a

getBandwidth

System object: dsp.NotchPeakFilter

Package: dsp

Get 3 dB bandwidth

Syntax

```
BW = getBandwidth(npFilter)
```

Description

`BW = getBandwidth(npFilter)` returns the 3 dB bandwidth for the notch or peak filter. If the `Specification` is set to 'Quality factor and center frequency', the 3 dB bandwidth is determined from the quality factor value. If the `Specification` property is set to 'Coefficients', the 3 dB bandwidth is determined from the `BandwidthCoefficient` value and the sample rate.

getCenterFrequency

System object: dsp.NotchPeakFilter

Package: dsp

Get center frequency

Syntax

```
CF= getCenterFrequency(npFilter)
```

Description

CF= `getCenterFrequency(npFilter)` returns the center frequency of the notch or peak filter. If the `Specification` property is set to 'Coefficients', the center frequency is determined from the `CenterFrequencyCoefficient` value and the sample rate.

getOctaveBandwidth

System object: dsp.NotchPeakFilter

Package: dsp

Bandwidth in number of octaves

Syntax

```
N = getOctaveBandwidth(npFilter)
```

Description

`N = getOctaveBandwidth(npFilter)` returns the bandwidth of the notch or peak filter, measured in number of octaves rather than Hz.

getQualityFactor

System object: dsp.NotchPeakFilter

Package: dsp

Get quality factor

Syntax

```
Q = getQualityFactor(npFilter)
```

Description

`Q = getQualityFactor(npFilter)` returns the quality factor (Q factor) for both the notch and the peak filters. The Q factor is defined as the center frequency divided by the bandwidth.

reset

System object: dsp.NotchPeakFilter

Package: dsp

Reset the internal states of notch or peak filter

Syntax

```
reset(npFilter)
```

Description

`reset(npFilter)` resets the internal states of System object, `npFilter`, to their initial values. System objects without states are unaffected by `reset`.

step

System object: dsp.NotchPeakFilter

Package: dsp

Process input using the notch or peak filter algorithm

Syntax

```
Y = step(npFilter,x)
[Yn,Yp] = step(npFilter,x)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(npFilter,x)` filters each channel of the input signal, `x`, using the notch peak filter, `npFilter`, to produce the notch filter output, `Y`.

`[Yn,Yp] = step(npFilter,x)` filters each channel of the input signal, `x`, using the notch peak filter, `npFilter`, to produce the notch filter output, `Yn`, and peak filter output, `Yp`.

Calling `step` on an object puts that object into a locked state. When locked, nontunable properties or any input characteristics (size, data type and complexity) cannot change without reinitializing (unlocking and relocking) the object.

tf

System object: `dsp.NotchPeakFilter`

Package: `dsp`

Transfer function

Syntax

```
[B,A] = tf(npFilter)
[B,A,B2,A2] = tf(npFilter)
```

Description

`[B,A] = tf(npFilter)` returns the vector of numerator coefficients, `B`, and the vector of denominators, `A`, for the equivalent transfer function corresponding to the notch filter.

In addition to `B` and `A`, `[B,A,B2,A2] = tf(npFilter)` returns the vector of numerator coefficients, `B2`, and the vector of denominator coefficients, `A2`, for the equivalent transfer function corresponding to the peak filter.

Examples

Determine the Transfer Function of Notch Peak Filter

Create a `dsp.NotchPeakFilter` System object™. Obtain the coefficients of the transfer function corresponding to the notch and peak filters.

```
notchpeak = dsp.NotchPeakFilter;
[Bnotch,Anotch,Bpeak,Apeak] = tf(notchpeak);
```

`Bnotch` and `Anotch` are the vector of numerator and denominator coefficients for the equivalent transfer function corresponding to the notch filter. `Bpeak` and `Apeak` are the vector of numerator and denominator coefficients for the equivalent transfer function corresponding to the peak filter.

dsp.ParametricEQFilter System object

Package: dsp

Tunable second-order parametric equalizer filter

Note The `dsp.ParametricEQFilter` object will be removed in a future release. Existing instances of the object continue to run. For new code, use the `multibandParametricEQ` object from Audio System Toolbox instead.

Description

The `ParametricEQFilter` object is a tunable, second-order parametric equalizer filter.

To apply the filter to each channel of the input:

- 1 Define and set up your equalizer filter. See “Construction” on page 4-1398.
- 2 Call `step` to filter each channel according to the properties of `dsp.ParametricEQFilter`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = dsp.ParametricEQFilter` returns a second-order parametric equalizer filter that independently filters each channel of the input over time, using the default values for `Bandwidth`, `CenterFrequency`, and `PeakGaindB`. The center frequency and bandwidth are specified in Hz and are tunable. The peak gain (dip) is specified in dB

and is also tunable. The bandwidth is measured at the arithmetic mean between the peak gain in absolute power units and one.

`H = dsp.ParametricEQFilter('Specification', 'Quality factor and center frequency')` specifies the quality factor (Q factor) of the filter. The Q factor is defined as the center frequency/bandwidth. A higher Q factor corresponds to a narrower peak/dip. The Q factor should be a scalar value greater than 0. The Q factor is tunable.

`H = dsp.ParametricEQFilter('Specification', 'Coefficients')` specifies the gain values for the bandwidth and center frequency. This removes the trigonometry calculations involved when the properties are tuned. The `CenterFrequencyCoefficient` should be a scalar between -1 and 1, with -1 corresponding to 0 Hz, and 1 corresponding to the Nyquist frequency. The `BandwidthCoefficient` should be a scalar between -1 and 1, with -1 corresponding to the largest bandwidth, and 1 corresponding to the smallest bandwidth. In this mode, the peak gain is specified in linear units rather than dB.

`H = dsp.ParametricEQFilter('Name', Value, ...)` returns a parametric equalizer filter with each specified property name set to the specified value. You can specify several name-value pair arguments in any order as `('Name1',Value1,...,'NameN',ValueN)`.

Properties

Specification

Design parameters or coefficients that specify the filter

Choose one of the following Specification values. Use the corresponding tunable properties to specify the filter:

- Bandwidth and center frequency — Use `Bandwidth`, `CenterFrequency`, and `PeakGaindB`.
- Quality factor and center frequency — Use `QualityFactor`, `CenterFrequency`, and `PeakGaindB`.
- Coefficients — Use `BandwidthCoefficient`, `CenterFrequencyCoefficient`, and `PeakGain`.

The default value is `Bandwidth` and `center frequency`.

Using `Coefficients` specifies gain values for the bandwidth and center frequency. This approach does not require the trigonometric calculations of the other two approaches where design parameters are specified in Hz.

Bandwidth

bandwidth of filter

Specify the bandwidth of the filter as a finite positive numeric scalar that is less than half the sample rate of the input signal, in Hz. This property is applicable if `Specification` is set to `Bandwidth` and `center frequency`. The default is 2205 Hz. This property is tunable.

BandwidthCoefficient

Coefficient for bandwidth of filter

Specify the value that determines the filter's bandwidth as a finite numeric scalar in the range `[-1 1]`:

- `-1` corresponds to the maximum bandwidth (`SampleRate/4`).
- `1` corresponds to the minimum bandwidth (0 Hz, that is, an allpass filter).

This property is only applicable if `Specification` is set to `Coefficients`. The default is 0.72654. This property is tunable.

CenterFrequency

Center frequency of the filter

Specify the filter's center frequency as a finite positive numeric scalar that is less than half the sample rate of the input signal, in Hz. This property is only applicable if `Specification` is set to `Bandwidth` and `center frequency` or `Quality factor` and `center frequency`. The default is 11025 Hz. This property is tunable.

CenterFrequencyCoefficient

Coefficient for center frequency of filter

Specify the value that determines the filter's center frequency as a finite numeric scalar between -1 and 1:

- -1 corresponds to the minimum center frequency (0 Hz).
- 1 corresponds to the maximum center frequency ($\text{SampleRate}/2$ Hz).

This property is only applicable if `Specification` is set to `Coefficients`. The default is 0, which corresponds to $\text{SampleRate}/4$ Hz.

This property is tunable.

PeakGain

Peak or dip gain of the filter in linear units

Specify the filter's peak or dip gain in linear units. A value greater than one boosts the signal. A value less than one attenuates the signal. The default is 2 (6.0206 dB). This property is tunable.

PeakGaindB

Peak or dip gain of the filter in dB

Specify the filter's peak or dip gain in dB. A positive value boosts the signal. A negative value attenuates the signal. The default is 6.0206 dB. This property is tunable.

QualityFactor

Quality factor of the parametric EQ filter

Specify the Quality factor (Q factor) of the filter. The Q factor is defined as the center frequency divided by the bandwidth. A higher Q factor corresponds to a narrower peak or dip. This property is only applicable if `Specification` is set to `Quality factor and center frequency`. The default value is 5. This property is tunable.

SampleRate

Input sample rate

Specify the sample rate of the input as a finite numeric scalar, in Hz. The default is 44100 Hz.

Methods

<code>getBandwidth</code>	Convert quality factor or bandwidth coefficient to bandwidth in Hz
<code>getCenterFrequency</code>	Convert center frequency coefficient to frequency in Hz
<code>getOctaveBandwidth</code>	Measure bandwidth of parametric equalizer filter in octaves
<code>getPeakGain</code>	Convert peak or notch gain from dB to absolute units
<code>getPeakGaindB</code>	Convert peak or notch gain from absolute units to dB
<code>getQualityFactor</code>	Convert bandwidth to quality factor
<code>reset</code>	Reset states of <code>ParametricEQFilter</code> object
<code>step</code>	Filter input with <code>ParametricEQFilter</code> object
<code>tf</code>	Compute transfer function

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

Tune Equalizer Filter

Create a `ParametricEQFilter` object where the center frequency and bandwidth of the equalizer filter are 5000 Hz and 500 Hz respectively. The sample rate for the filter is the default, 44,100 Hz.

```
h = dsp.ParametricEQFilter('CenterFrequency', 5000, ...
    'Bandwidth', 500);
```

Create objects to estimate and display the transfer function of the filter.

```

htf = dsp.TransferFunctionEstimator('FrequencyRange','onesided',...
    'SpectralAverages',50);
hplot = dsp.ArrayPlot('PlotType','Line','YLimits',[-15 15],...
    'SampleIncrement',44100/1024);

```

Generate a random signal and filter the signal.

```

for i=1:1000
    x = randn(1024,1);           % Random signal
    y = h(x);                   % Filter signal
    H = htf(x,y);               % Estimate transfer function
    magdB = 20*log10(abs(H)); % Convert to dB
    hplot(magdB);               % Display transfer function

    if (i==1)                   % Pause to display initial transfer function
        pause;
    end
    if (i==500)                  % Tune filter
        h.CenterFrequency = 10000;
        h.Bandwidth = 2000;
        h.PeakGaindB = -10;
    end
end
end

```

The software displays the initial transfer function estimate.

To continue, press any key.

At $i=500$, the filter is tuned. The center frequency, bandwidth, and peak gain of the filter now have different values. The software displays the new transfer function.

Algorithm

The parametric equalizer is formed by a linear combination of a peak and a notch filter. See the **Algorithm** section of `dsp.NotchPeakFilter` for details.

$$H(z) = H_{notch}(z) + GH_{peak}(z)$$

Here is a graph of the two cases (boost and cut) of the magnitude squared of the transfer functions:

The transfer function can be written as:

$$H(z) = \frac{\left(\frac{1+G\gamma}{1+\gamma}\right) - 2\left(\frac{\cos\omega_0}{1+\gamma}\right)z^{-1} + \left(\frac{1-G\gamma}{1+\gamma}\right)z^{-2}}{1 - 2\left(\frac{\cos\omega_0}{1+\gamma}\right)z^{-1} + \left(\frac{1-\gamma}{1+\gamma}\right)z^{-2}}$$

where

$$\gamma = \tan\left(\frac{\Delta\omega}{2}\right)$$

and

$$G_B^2 = \frac{1+G^2}{2}$$

G is the parametric equalizer gain, and G_B is the bandwidth gain, that is, the gain level at which the bandwidth $\Delta\omega$ is measured.

The `dsp.NotchPeakFilter` that does most of the work is implemented in a decoupled way so that the center frequency can be tuned independently from the bandwidth. Note that the Q factor is defined as center frequency/bandwidth.

Parametric EQ Filter

`iirparameq`

DSP System Toolbox

DSP System Toolbox

Introduced in R2014a

getBandwidth

System object: `dsp.ParametricEQFilter`

Package: `dsp`

Convert quality factor or bandwidth coefficient to bandwidth in Hz

Note The `dsp.ParametricEQFilter` object will be removed in a future release. Existing instances of the object continue to run. For new code, use the `multibandParametricEQ` object from Audio System Toolbox instead.

Syntax

`BW = getBandwidth(H)`

Description

`BW = getBandwidth(H)` returns the bandwidth of the parametric equalizer filter. The bandwidth is measured halfway between 1 and the peak (or notch) gain of the filter. The gain is specified in absolute power units (filter magnitude squared). If the `Specification` property is set to `Quality factor` and center frequency, the bandwidth is determined from the quality factor of the filter. If the `Specification` property is set to `Coefficients`, the bandwidth is determined from the `BandwidthCoefficient` value and the sample rate of the filter.

getCenterFrequency

System object: dsp.ParametricEQFilter

Package: dsp

Convert center frequency coefficient to frequency in Hz

Note The `dsp.ParametricEQFilter` object will be removed in a future release. Existing instances of the object continue to run. For new code, use the `multibandParametricEQ` object from Audio System Toolbox instead.

Syntax

`CF = getCenterFrequency(H)`

Description

`CF = getCenterFrequency(H)` returns the center frequency of the parametric equalizer filter. If the `Specification` property is set to `Coefficients`, the center frequency is determined from the `CenterFrequencyCoefficient` value and the sample rate of the filter.

getOctaveBandwidth

System object: `dsp.ParametricEQFilter`

Package: `dsp`

Measure bandwidth of parametric equalizer filter in octaves

Note The `dsp.ParametricEQFilter` object will be removed in a future release. Existing instances of the object continue to run. For new code, use the `multibandParametricEQ` object from Audio System Toolbox instead.

Syntax

`N = getOctaveBandwidth(H)`

Description

`N = getOctaveBandwidth(H)` returns the bandwidth of the parametric equalizer filter in octaves instead of Hz.

getPeakGain

System object: dsp.ParametricEQFilter

Package: dsp

Convert peak or notch gain from dB to absolute units

Note The `dsp.ParametricEQFilter` object will be removed in a future release. Existing instances of the object continue to run. For new code, use the `multibandParametricEQ` object from Audio System Toolbox instead.

Syntax

`G = getPeakGain(H)`

Description

`G = getPeakGain(H)` returns the peak or notch gain of the parametric equalizer filter in absolute units.

getPeakGaindB

System object: dsp.ParametricEQFilter

Package: dsp

Convert peak or notch gain from absolute units to dB

Note The `dsp.ParametricEQFilter` object will be removed in a future release. Existing instances of the object continue to run. For new code, use the `multibandParametricEQ` object from Audio System Toolbox instead.

Syntax

`G = getPeakGaindB(H)`

Description

`G = getPeakGaindB(H)` returns the peak or notch gain of the parametric equalizer filter in dB.

getQualityFactor

System object: dsp.ParametricEQFilter

Package: dsp

Convert bandwidth to quality factor

Note The `dsp.ParametricEQFilter` object will be removed in a future release. Existing instances of the object continue to run. For new code, use the `multibandParametricEQ` object from Audio System Toolbox instead.

Syntax

`Q = getQualityFactor(H)`

Description

`Q = getQualityFactor(H)` returns the quality factor (Q factor) for the parametric equalizer filter. The Q factor is defined as the center frequency divided by the bandwidth.

reset

System object: `dsp.ParametricEQFilter`

Package: `dsp`

Reset states of `ParametricEQFilter` object

Note The `dsp.ParametricEQFilter` object will be removed in a future release. Existing instances of the object continue to run. For new code, use the `multibandParametricEQ` object from Audio System Toolbox instead.

Syntax

`reset(H)`

Description

`reset(H)` resets the filter states of the `ParametricEQFilter` object, `H`, to the specified initial conditions. After the `step` method applies the `ParametricEQFilter` object to nonzero input data, the states can change. Invoking the `step` method again without first invoking the `reset` method can produce different outputs for an identical input.

step

System object: dsp.ParametricEQFilter

Package: dsp

Filter input with ParametricEQFilter object

Note The dsp.ParametricEQFilter object will be removed in a future release. Existing instances of the object continue to run. For new code, use the multibandParametricEQ object from Audio System Toolbox instead.

Syntax

$Y = \text{step}(H, X)$

Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

$Y = \text{step}(H, X)$ filters the real or complex input signal X using the specified filter to produce the equalized filter output Y . The filter processes each channel of the input signal (each column of X) independently over time.

Note obj specifies the System object on which to run this step method.

The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable

property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

tf

System object: dsp.ParametricEQFilter

Package: dsp

Compute transfer function

Note The `dsp.ParametricEQFilter` object will be removed in a future release. Existing instances of the object continue to run. For new code, use the `multibandParametricEQ` object from Audio System Toolbox instead.

Syntax

`[B,A] = tf(H)`

Description

`[B,A] = tf(H)` returns the vector of numerator coefficients `B` and the vector of denominator coefficients `A` for the equivalent transfer function of the parametric equalizer filter.

dsp.PeakFinder System object

Package: dsp

Identify peak values in input signal

Description

The `dsp.PeakFinder` System object counts the number of peak values (maxima, minima, or both) in each column of the real-valued input signal. To qualify as a peak, a point has to be larger (or smaller) than both of its neighboring points. The end points are not considered as peak values. The object can also output the indices and values of the peaks, and a binary array that indicates whether a peak is a maxima or a minima.

To output the peak indices and peak values, set “PeakIndicesOutputPort” on page 4-0 and “PeakValuesOutputPort” on page 4-0 to `true`, respectively. In addition, you can determine which of the peak values is a maxima or a minima using the polarity matrix. The polarity matrix is a logical array in which a 1 indicates a maxima, and a 0 indicates a minima. To view the polarity matrix, set “PeakType” on page 4-0 to 'Maxima and Minima' and access the fourth output.

Use the “MaximumPeakCount” on page 4-0 property to specify how many peak values to look for in each input signal. The object stops searching the input signal once this maximum number of peak values has been found.

If you set “IgnoreSmallPeaks” on page 4-0 to `true`, the object no longer detects low amplitude peaks and ignores noise within a threshold value that you define. In this mode, the current value is a maximum if $(current - previous) > threshold$ and $(current - next) > threshold$. The current value is a minimum if $(current - previous) < -threshold$ and $(current - next) < -threshold$.

To determine the peak values in an input signal:

- 1 Create the `dsp.PeakFinder` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects? \(MATLAB\)](#).

Creation

Syntax

```
pkFind = dsp.PeakFinder
pkFind = dsp.PeakFinder(Name,Value)
```

Description

`pkFind = dsp.PeakFinder` creates a peak finder System object that identifies the peak values (maxima, minima, or both) in an input signal.

`pkFind = dsp.PeakFinder(Name,Value)` creates a peak finder System object with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `delay = dsp.PeakFinder('PeakType','Maxima');`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects (MATLAB).

PeakType — Type of peaks to identify

'Maxima and Minima' (default) | 'Maxima' | 'Minima'

Type of peaks to identify, specified as one of the following:

- 'Maxima' — If “IgnoreSmallPeaks” on page 4-0 is set to `true`, the current value is identified as a maximum if $(current - previous) > threshold$ and $(current - next) > threshold$. Specify *threshold* in “PeakThreshold” on page 4-0 property. If

`IgnoreSmallPeaks` is set to `false`, the current value must be larger than both its neighboring points.

- 'Minima' — If `IgnoreSmallPeaks` is set to `true`, the current value is identified as a minimum if $(current - previous) < -threshold$ and $(current - next) < -threshold$. If `IgnoreSmallPeaks` is set to `false`, the current value must be smaller than both its neighboring points.
- 'Maxima and Minima' — The object identifies both the maxima and the minima points.

PeakIndicesOutputPort — Enable output of peak indices

`false` (default) | `true`

Enable output of the peak indices, specified as either:

- `true` — The object returns the indices of the input signal peak values.
- `false` — The object does not return the indices of the input signal peak values.

PeakValuesOutputPort — Enable output of peak values

`false` (default) | `true`

Enable output of the peak values, specified as either:

- `true` — The object returns the peak values of the input signal.
- `false` — The object does not return the peak values of the input signal.

MaximumPeakCount — Maximum number of peak values to identify

10 (default) | integer greater than or equal to 1

Maximum number of peak values to identify in each input signal, specified as an integer greater than or equal to 1. The object stops searching the input signal for peaks once it identifies the maximum number.

Example: 5

Example: 50

IgnoreSmallPeaks — Ignore peaks below a threshold

`false` (default) | `true`

Ignore peaks below a threshold, specified as either:

- `false` — The object identifies the current value as a peak, if the current value is larger (or smaller) than both of its neighboring points.
- `true` — The object identifies the current value as a maximum if $(current - previous) > threshold$ and $(current - next) > threshold$. The object identifies the current value as a minimum if $(current - previous) < -threshold$ and $(current - next) < -threshold$.

PeakThreshold — Threshold below which peaks are ignored

0 (default) | positive real scalar | vector

Threshold below which peaks are ignored, specified as a real scalar greater than or equal to 0 or a vector with all elements greater than or equal to 0. The length of the vector must be equal to the number of channels.

This property identifies the current input value to be a maximum if $(current\ input\ value - previous\ input\ value) > threshold$ and $(current\ input\ value - next\ input\ value) > threshold$. The current value is a minimum if $(current\ input\ value - previous\ input\ value) < -threshold$ and $(current\ input\ value - next\ input\ value) < -threshold$.

Example: 0.2

Example: [0.3 2.4]

Example: [3; 0.4]

Dependencies

This property applies only when you set `IgnoreSmallPeaks` to `true`.

Fixed-Point Properties

RoundingMethod — Rounding method

'Floor' (default)

Rounding method, specified as 'Floor', which is equivalent to truncation. The setting rounds the result of a calculation to the closest representable number in the direction of negative infinity.

OverflowAction — Overflow action

'Wrap' (default) | 'Saturate'

The overflow action for fixed-point operations, specified as one of the following:

- 'Wrap' — The object wraps the result of its fixed-point operations.

- 'Saturate' — The object saturates the result of its fixed-point operations.

For more details on overflow actions, see overflow mode for fixed-point operations.

Usage

Syntax

```
cnt = pkFind(input)
[cnt,idx] = pkFind(input)
[ ___,val] = pkFind(input)
[ ___,pol] = pkFind(input)
```

Description

`cnt = pkFind(input)` returns the number of peak values (minima, maxima, or both) in the input signal. Each column of the input is treated as a separate channel.

`[cnt,idx] = pkFind(input)` returns the number of peak values, `cnt`, and peak indices, `idx`, in the input signal.

To access the peak indices output, set the `PeakIndicesOutputPort` property to `true`.

```
pkFind = dsp.PeakFinder('PeakType','Maxima', ...
'PeakIndicesOutputPort',true);
...
[cnt,idx] = pkFind(input);
```

`[___,val] = pkFind(input)` returns the peak values `val` in the input signal.

To access the peak values output, set the `PeakValuesOutputPort` property to `true`.

```
pkFind = dsp.PeakFinder('PeakType','Maxima', ...
'PeakValuesOutputPort',true);
...
[cnt,idx,val] = pkFind(input);
```

`[___,pol] = pkFind(input)` returns the peak value polarity `pol` in input signal. The polarity is 1 for maxima and 0 for minima.

To access the polarity output, set the `PeakType` property to 'Maxima and Minima', and the `PeakIndicesOutputPort` property to `true`.

```
pkFind = dsp.PeakFinder('PeakType','Maxima and Minima', ...
    'PeakIndicesOutputPort',true);
...
[cnt,idx,val,pol] = pkFind(input);
```

Input Arguments

input — Data input

column vector of at least three rows | matrix with at least three rows

Data input whose peak values are detected by the object, specified as a vector or matrix containing at least three rows.

Example: [9 6 10 3 5 5 0 12; 9 6 1 13 4 1 0 12]'

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments

cnt — Number of peak values

scalar | row vector

Number of peak values, returned as a scalar or a row vector of length equal to the number of channels in the data input.

Example: [4 3]

Data Types: `uint32`

idx — Indices of the peak values

column vector | matrix

Indices of the peak values in the input signal, returned as a column vector or matrix. The size of the peak indices output is the same as that of the input. All nonzero elements represent peak indices.

Example: [1 2 3 6 0 0 0 0 0; 2 3 6 0 0 0 0 0]'

Dependencies

To enable this output, set the `PeakIndicesOutputPort` property to `true`.

Data Types: `uint32`

va1 — Peak values

column vector | matrix

Peak values in the input signal, returned as a column vector or matrix.

Example: `[6 10 3 0 0 0 0 0 0; 1 13 0 0 0 0 0 0 0]`'

Dependencies

To access the peak values output, set the `PeakValuesOutputPort` property to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

po1 — Peak value polarity

column vector | matrix

Peak value polarity in input signal, returned as a column vector or matrix of logical 1s and 0s. The polarity is 1 for maxima and 0 for minima.

Example: `[0 1 0 0 0 0 0 0 0; 0 1 0 0 0 0 0 0 0]`'

Data Types: `logical`

Note For versions earlier than R2016b, use the `step` function to run the System object™ algorithm. The arguments to `step` are the object you created, followed by the arguments shown in this section.

For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
clone	Create duplicate System object
getNumInputs	Number of inputs required to call the System object
getNumOutputs	Number of outputs from calling the System object
isLocked	Determine if System object is locked
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Determine Local Maxima and Minima

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Determine whether each value of an input signal is a local maximum or minimum.

```
pkFind = dsp.PeakFinder;
pkFind.PeakIndicesOutputPort = true;
pkFind.PeakValuesOutputPort = true;
```

```
x1 = [9 6 10 3 4 5 0 12]';
```

Find the peaks of each input `[prev;cur;next]: {[9;6;10],[6;10;3],...}`

```
[cnt1, idx1, val1, poll] = pkFind(x1)
```

```
cnt1 =

Peak Value For a Fixed-Point Signal

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Determine peak values for a fixed-point input signal.

```
pkFind = dsp.PeakFinder('PeakType', 'Maxima', ...
    'PeakValuesOutputPort', true, ...
    'MaximumPeakCount', 2, ...
    'IgnoreSmallPeaks', true, ...
    'PeakThreshold', 0.25, ...
    'OverflowAction', 'Saturate');
x2 = fi([-1;0.5;0],true,16,15);
[cnt2, val2] = pkFind(x2)

cnt2 =

    uint32
     1

val2 =

    0.5000
     0

    DataTypeMode: Fixed-point: binary point scaling
    Signedness: Signed
    WordLength: 16
    FractionLength: 15
```

dsp.PeakToPeak System object

Package: dsp

Peak-to-peak value

Description

The `PeakToPeak` object computes the peak-to-peak value of an input.

To obtain the peak-to-peak value:

- 1 Define and set up your peak-to-peak calculation. See “Construction” on page 4-1429.
- 2 Call `step` to compute the peak-to-peak value for an input vector according to the properties of `dsp.PeakToPeak`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`ptp = dsp.PeakToPeak` creates a peak-to-peak System object, `ptp`, that computes the difference between the maximum and minimum value in an input or a sequence of inputs.

`ptp = dsp.PeakToPeak('PropertyName',PropertyValue,...)` returns an `PeakToPeak` System object, `ptp`, with each specified property set to the specified value.

Properties

CustomDimension

Dimension to operate along. Specify the dimension as a positive integer along which the peak-to-peak difference is computed. The value of this property cannot exceed the number of dimensions in the input signal. This property applies when the `Dimension` property is 'Custom'.

Default: 1

Dimension

Dimension to operate along. Specify the dimension along which to calculate the peak-to-peak ratio as one of 'All', 'Row', 'Column', or 'Custom'. This property applies when the `RunningPeakToPeak` property is false. If you set this property to 'Custom', specify the dimension using the `CustomDimension` property.

Default: 'Column'

ResetCondition

Reset condition for running peak-to-peak mode. Specify the event to reset the running peak-to-peak as one of 'Rising edge', 'Falling edge', 'Either edge', or 'Non-zero'. This property applies when the `ResetInputPort` property is true.

ResetInputPort

Enables resetting in running peak-to-peak mode. Set this property to `true` to enable resetting the running peak-to-peak. When the property is set to `true`, a reset input must be specified to the call of `step` to reset the running peak-to-peak difference. This property applies when the `RunningPeakToPeak` property is `true`.

Default: false

RunningPeakToPeak

Calculation over successive calls to `step`. Set this property to `true` to enable the calculation of the peak-to-peak difference over successive calls to the `step`.

Default: false

Methods

reset Reset the running peak-to-peak object
 step Compute peak-to-peak value

Common to All System Objects	
clone	Create System object with same property values
getNumInputs	Expected number of inputs to a System object
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Peak-to-Peak Value of Vector

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Determine the peak-to-peak value for a vector input.

```
in = (1:10)';
ptp = dsp.PeakToPeak;
y = ptp(in)
```

```
y = 9
```

Peak-to-Peak Value of Matrix Input

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Determine the peak-to-peak value of a matrix input.

```
in = magic(4);
ptp = dsp.PeakToPeak;
ptp.Dimension = 'All';
y = ptp(in)

y = 15
```

`dsp.Maximum` | `dsp.PeakToRMS`

Introduced in R2012a

reset

System object: dsp.PeakToPeak

Package: dsp

Reset the running peak-to-peak object

Syntax

`reset (ptp)`

Description

`reset (ptp)` resets the running peak-to-peak value for the object `ptp`.

step

System object: dsp.PeakToPeak

Package: dsp

Compute peak-to-peak value

Syntax

`Y = step(ptp,X)`

`Y = step(ptp,X,R)`

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(ptp,X)` computes the peak-to-peak value, `Y`, of the floating-point input vector `X`. When the `RunningPeakToPeak` property is `true`, `Y` corresponds to the peak-to-peak value of the input elements over successive calls to the `step` method.

`Y = step(ptp,X,R)` computes the peak-to-peak value of the input elements over successive calls to the `step` method. The object optionally resets its state based on the reset input signal, `R`, and the value of the `ResetCondition` property. This is possible when you set both the `RunningPeakToPeak` and the `ResetInputPort` properties to `true`.

dsp.PeakToRMS System object

Package: dsp

Peak-to-root-mean-square value of vector

Description

The `PeakToRMS` object calculates the peak-to-root-mean-square ratio of a vector.

To compute the peak-to-root-mean-square ratio:

- 1 Define and set up your peak-to-root-mean-square calculation. See “Construction” on page 4-1435.
- 2 Call `step` to calculate the peak-to-root-mean-square value for an input vector according to the properties of `dsp.PeakToRMS`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`ptr = dsp.PeakToRMS` creates a peak-to-root-mean-square System object, `ptr`, that returns the ratio of the maximum magnitude (peak) to the root-mean-square (RMS) value in an input or a sequence of inputs.

`ptr = dsp.PeakToRMS('PropertyName', PropertyValue, ...)` returns an `PeakToRMS` System object, `ptr`, with each specified property set to the specified value.

Properties

CustomDimension

Numerical dimension to operate along. Specify the dimension as a positive integer along which the peak-to-RMS ratio is computed. The value of this property cannot exceed the number of dimensions in the input signal. This property applies when `Dimension` property is 'Custom'.

Default: 1

DecibelScaledOutput

Report output in decibels (dB). Set this property to `true` to enable output in dB. Set this property to `false` to report output as a ratio.

Default: `true`

Dimension

Dimension to operate along. Specify the dimension along which to calculate the peak-to-RMS ratio as one of 'All', 'Row', 'Column', or 'Custom'. This property applies when the `RunningPeakToRMS` property is `false`. If you set this property to 'Custom', specify the dimension using the `CustomDimension` property.

Default: 'Column'

ResetCondition

Reset condition for running peak-to-RMS mode. Specify the event to reset the running peak-to-RMS as one of 'Rising edge', 'Falling edge', 'Either edge', or 'Non-zero'. This property applies when the `ResetInputPort` property is `true`.

ResetInputPort

Enables resetting in running peak-to-RMS mode. Set this property to `true` to enable resetting. When the property is set to `true`, a reset input must be specified in the call to `step` to reset the running peak-to-RMS ratio. This property applies when the `RunningPeakToRMS` property is `true`.

Default: `false`

RunningPeakToRMS

Calculation over successive calls to `step`. Set this property to `true` to enable the calculation of the peak-to-RMS ratio over successive calls to the `step`.

Default: `false`

Methods

`reset` Reset the running peak-to-root-mean-square object
`step` Compute peak-to-RMS ratio

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)

Examples

Peak-to-RMS Ratio of Vector Input

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Determine the peak-to-RMS ratio of a vector input.

```
in = (1:10)';
ptr = dsp.PeakToRMS;
y = ptr(in)
```

```
y = 1.6116
```

Peak-to-RMS Ratio of Matrix Input

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Determine the peak-to-RMS ratio of a matrix input.

```
in = magic(4);  
ptr = dsp.PeakToRMS;  
ptr.Dimension = 'All';  
y = ptr(in)
```

```
y = 1.6547
```

Definitions

Peak-magnitude-to-RMS Level

The peak-magnitude-to-RMS level is

$$\frac{\|X\|_{\infty}}{\sqrt{\frac{1}{N} \sum_{n=1}^N |X_n|^2}}$$

where the l -infinity norm and RMS values are computed along the specified dimension.

Package: dsp

Compute peak-to-RMS ratio

Syntax

`Y = step(ptr,X)`

`Y = step(ptr,X,R)`

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(ptr,X)` computes the peak-to-RMS ratio, `Y`, of the floating-point input vector `X`. When the `RunningPeakToRMS` property is `true`, `Y` corresponds to the peak-to-RMS ratio of the input elements over successive calls to the `step` method.

`Y = step(ptr,X,R)` computes the peak-to-RMS ratio of the input elements over successive calls to the `step` method. The object optionally resets its state based on the reset input signal, `R`, and the value of the `ResetCondition` property. This is possible when you set both the `RunningPeakToRMS` and the `ResetInputPort` properties to `true`.

dsp.PhaseExtractor System object

Package: dsp

Extract the unwrapped phase of a complex input

Description

The `PhaseExtractor` object extracts the unwrapped phase of a complex input.

To extract the unwrapped phase of a signal input:

- 1 Define and set up your `dsp.PhaseExtractor` System object. See “Construction” on page 4-1442.
- 2 Call `step` with your input signal to extract the signal phase according to the properties of this System object. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`phase = dsp.PhaseExtractor` returns a System object, `phase`, that extracts the unwrapped phase of an input signal.

`phase = dsp.PhaseExtractor('PropertyName', PropertyValue, ...)` returns a System object, `phase`, with each specified property set to the specified value.

Properties

TreatFramesIndependently

Specify if you want to reset the unwrapped phase at the end of a frame.

If you set this property to:

- `true`: The object treats each frame of data independently. It resets the initial cumulative unwrapped phase to zero each time a new input frame is received.
- `false`: The object ignores boundaries between frames when returning the unwrapped phase.

The default value is `false`.

Methods

`reset` Reset internal states of object
`step` Extract phase of signal input

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

Plot Unwrapped Phase Of a Sine Wave

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Create a `dsp.SineWave` System object™. Specify that the object generates an exponential output with a complex exponent.

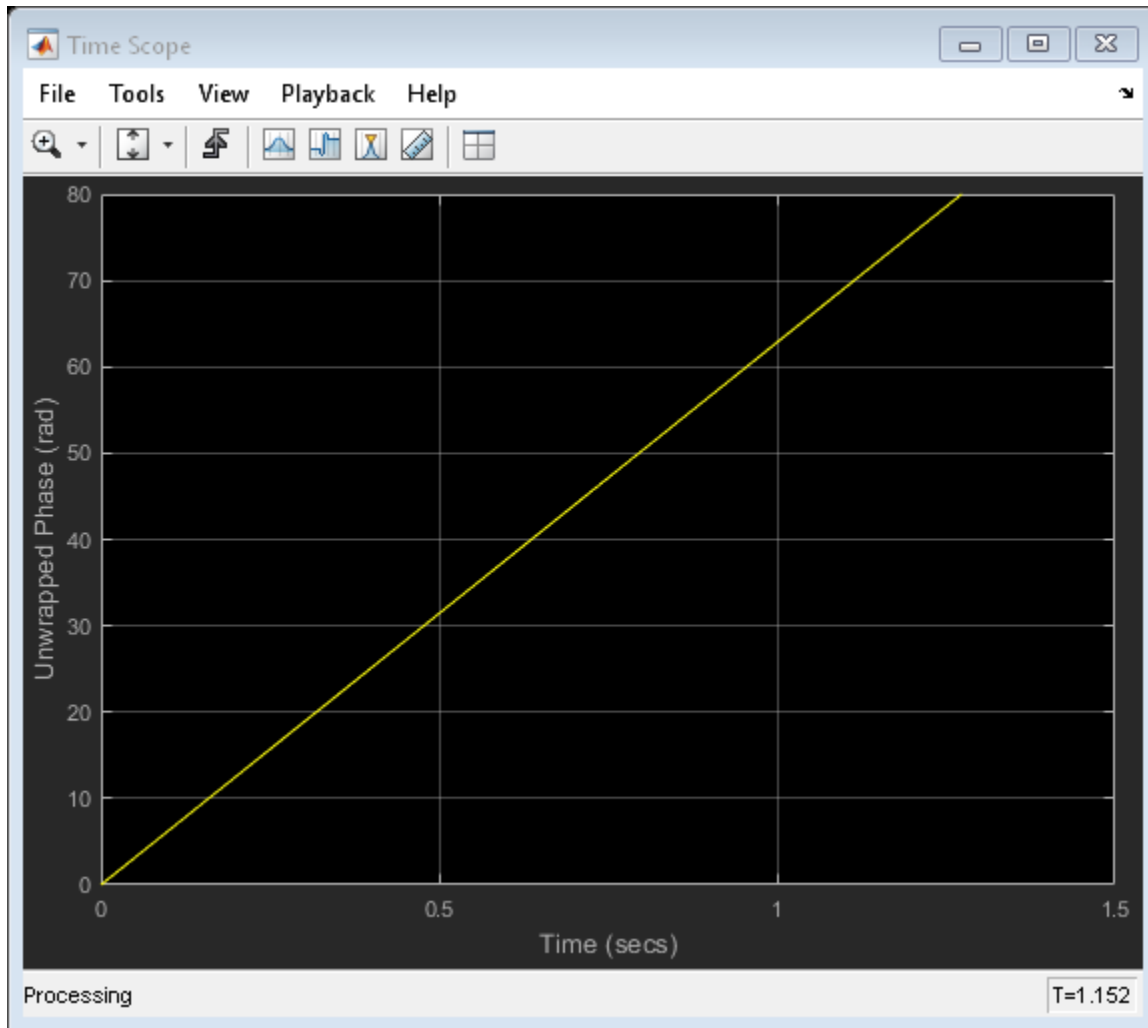

```
sine = dsp.SineWave('Frequency',10,...  
    'ComplexOutput',true,'SamplesPerFrame',128);
```

Create a `dsp.PhaseExtractor` System object™. Specify that the object ignores frame boundaries when returning the unwrapped phase.

```
phase = dsp.PhaseExtractor('TreatFramesIndependently',false);
```

Extract the unwrapped phase of a sine wave. Plot the phase versus time using a `dsp.TimeScope` System object™.

```
timeplot = dsp.TimeScope('PlotType','Line','SampleRate',1000,...  
    'TimeSpan',1.5,'YLimits',[0 80],...  
    'ShowGrid',true,...  
    'YLabel','Unwrapped Phase (rad)');  
for ii = 1:10  
    sineOutput = sine();  
    phaseOutput = phase(sineOutput);  
    timeplot(phaseOutput)  
end
```

Plot Phase Response of Third-Order IIR Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Create a `dsp.TransferFunctionEstimator` System object™.

```
tfe = dsp.TransferFunctionEstimator('FrequencyRange','centered');
```

Create a `dsp.PhaseExtractor` System object™. Specify that the object must treat each frame of data independently.

```
phase = dsp.PhaseExtractor('TreatFramesIndependently',true);
```

Create a `dsp.IIRFilter` System object™. Compute the transfer function of a third-order IIR filter. Use the `butter` function to generate coefficients for the filter.

```
[b,a] = butter(3,.3);  
iir = dsp.IIRFilter('Numerator',b,'Denominator',a);
```

Extract the phase response of the transfer function. Plot using a `dsp.ArrayPlot` System object™.

```
sampleRate = 1e3;  
phaseplot = dsp.ArrayPlot('PlotType','Line','XOffset',-sampleRate/2,...  
    'YLimits',[-15 0],...  
    'YLabel','Phase Response (rad)',...  
    'XLabel','Frequency (Hz)',...  
    'Title','System Phase response');  
for ii = 1:100  
    % Generate input  
    input = 0.05*randn(1000,1);  
    % Pass through IIR filter  
    filterOutput = iir(input);  
    % Estimate transfer function  
    transferFunction = tfe(input,filterOutput);  
    % Plot transfer function phase  
    phaseOutput = phase(transferFunction);  
    phaseplot(phaseOutput);  
end
```

Algorithms

Consider an input frame of length N :

$$\begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_N \end{pmatrix}$$

The `step` method acts on this frame and produces this output:

$$\begin{pmatrix} \Phi_1 \\ \Phi_2 \\ \vdots \\ \Phi_N \end{pmatrix}$$

where:

$$\Phi_i = \Phi_{i-1} + \text{angle}(x_{i-1}^* x_i)$$

Here, i runs from 1 to N . The `angle` function returns the phase angle in radians.

If the input signal consists of multiple frames:

- If you set `TreatFramesIndependently` to `true`, the `step` method treats each frame independently. Therefore, in each frame, the `step` method calculates the phase using the preceding formula where:
 - Φ_0 is 0.
 - x_0 is 1.
- If you set `TreatFramesIndependently` to `false`, the `step` method ignores boundaries between frames. Therefore, in each frame, the `step` method calculates the phase using the preceding formula where:
 - Φ_0 is the last unwrapped phase from the previous frame.
 - x_0 is the last sample from the previous frame.

Extended Capabilities

Blocks

Phase Extractor

Introduced in R2014b

reset

System object: dsp.PhaseExtractor

Package: dsp

Reset internal states of object

Syntax

`reset (phase)`

Description

`reset (phase)` resets the values of internal variables Φ_0 to 0 and x_0 to 1. For more information on how the internal variables are used, see the algorithm used by the `dsp.PhaseExtractor` object.

step

System object: dsp.PhaseExtractor

Package: dsp

Extract phase of signal input

Syntax

```
Y = step(phase,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(phase,X)` returns a vector containing the unwrapped phase of the input signal `X` in radians. The method treats each column of `X` as an independent channel. The data types of input signals must be either single or double-precision floating point.

If the property `TreatFramesIndependently` of the `dsp.PhaseExtractor` object `phase` is set to:

- `true`, the object treats each frame of data independently. It resets the initial cumulative unwrapped phase to zero each time a new input frame is received.
- `false`, the object ignores boundaries between frames when returning the unwrapped phase.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.PhaseUnwrapper System object

Package: dsp

Unwrap signal phase

Description

The `PhaseUnwrapper` object unwraps the signal phase input specified in radians.

To unwrap the signal phase input:

- 1 Define and set up your System object. See “Construction” on page 4-1453.
- 2 Call `step` to unwrap the signal phase according to the properties of `dsp.PhaseUnwrapper`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`phUnwrap = dsp.PhaseUnwrapper` returns a System object, `phUnwrap`. This System object adds or subtracts appropriate multiples of 2π to each input element to remove phase discontinuities (unwrap).

`phUnwrap = dsp.PhaseUnwrapper('PropertyName', PropertyValue, ...)` returns an unwrapped System object, `phUnwrap`, with each specified property set to the specified value.

Properties

InterFrameUnwrap

Enable unwrapping of phase discontinuities between successive frames

Set this property to `false` to unwrap phase discontinuities only within the frame. Set this property to `true` to also unwrap phase discontinuities between successive frames. The default is `true`.

Tolerance

Jump size as true phase discontinuity

Specify the jump size that the phase unwrapper recognizes as a true phase discontinuity. The default is set to π (rather than a smaller value) to avoid altering legitimate signal features. To increase the phase wrapper sensitivity, set the `Tolerance` property to a value slightly less than π .

Methods

`reset` Reset internal states of Phase Unwrapper System object

`step` Unwrap input phase signal input

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

Unwrap input phase data

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
phUnwrap = dsp.PhaseUnwrapper;
p = [0 2/5 4/5 -4/5 -2/5 0 2/5 4/5 -4/5 -2/5 0 2/5 ...
     4/5 -4/5, -2/5]*pi;
y = phUnwrap(p');
figure,stem(p); hold

Current plot held

stem(y, 'r');
legend('Input (blue)', 'Unwrapped data (red)');
hold off;
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Unwrap block reference page. The object properties correspond to the Simulink block parameters.

Syntax

`reset(phUnwrap)`

Description

`reset(phUnwrap)` resets the 2π multiplier k to 0 for the phase unwrapper object `phUnwrap`. See “Frame-Based Processing” on page 2-1706 for details.

step

System object: dsp.PhaseUnwrapper

Package: dsp

Unwrap input phase signal input

Syntax

`Y = step(phUnwrap,X)`

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(phUnwrap,X)` unwraps the input signal `X` in radians for the root mean square (RMS) object `phUnwrap`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.PulseMetrics System object

Package: dsp

Pulse metrics of bilevel waveforms

Description

The `PulseMetrics` object computes rise times, fall times, pulse widths, and cycle metrics including pulse period, pulse separation, and duty cycle for bilevel waveforms.

To obtain pulse metrics for a bilevel waveform:

- 1 Define and set up your pulse metrics. See “Construction” on page 4-1460.
- 2 Call `step` to compute the pulse metrics according to the properties of `dsp.PulseMetrics`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`pm = dsp.PulseMetrics` creates a pulse metrics System object, `pm`. The object computes the rise time, fall time, and width of a pulse. `dsp.PulseMetrics` also computes cycle metrics such as pulse separations, periods, and duty cycles. Because a pulse contains two transitions, the object contains a superset of the capability defined in `dsp.TransitionMetrics`.

`pm = dsp.PulseMetrics('PropertyName',PropertyValue,...)` returns a `PulseMetrics` System object, `pm`, with each specified property set to the specified value.

Properties

CycleOutputPort

Enable cycle metrics. If `CycleOutputPort` is `true`, cycle metrics are reported for each pulse period.

Default: `false`

MaximumRecordLength

Maximum samples to preserve between calls to `step`. This property requires a positive integer that specifies the maximum number of samples to save between calls to the `step` method. When the number of samples to be saved exceeds this length, the oldest excess samples are discarded. This property applies when the `RunningMetrics` property is `true` and is tunable.

Default: `1000`

PercentReferenceLevels

Lower-, middle-, and upper-percent reference levels. This property contains a three-element numeric row vector that contains the lower-, middle-, and upper-percent reference levels. These reference levels are used as an offset between the lower and upper states of the waveform when computing the duration of each transition.

Default: `[10 50 90]`

PercentStateLevelTolerance

Tolerance of the state level (in percent). This property requires a scalar that specifies the maximum deviation from either the low or high state before it is considered to be outside that state. The tolerance is expressed as a percentage of the waveform amplitude.

Default: `2`

Polarity

Polarity of pulse to extract. This property specifies the type of pulse to extract by the polarity of the leading transition. Valid values for this property are `'positive'` or `'negative'`.

Default: 'positive'

PostshootOutputPort

Enable posttransition aberration metrics. If this property is set to `true`, overshoot and undershoot metrics are reported for a region defined immediately after each transition. The posttransition aberration region is defined as the waveform interval that begins at the end of each transition and whose duration is the value of `PostshootSeekFactor` times the computed transition duration. If a complete subsequent transition is detected before the interval is over, the region is truncated at the start of the subsequent transition. The metrics are computed for each transition that has a complete posttransition aberration region.

Default: `false`

PostshootSeekFactor

Corresponds to the duration of time to search for the overshoot and undershoot metrics immediately following each transition. The duration is expressed as a factor of the duration of the transition. This property is enabled only when the `PostshootOutputPort` property is set to `true` and is tunable.

Default: 3

PreshootOutputPort

Enable pretransition aberration metrics. If `PreshootOutputPort` is set to `true`, overshoot and undershoot metrics are reported for a region defined immediately before each transition. The pretransition aberration region is defined as the waveform interval that ends at the start of each transition and whose duration is `PreshootSeekFactor` times the computed transition duration.

Default: 'false'

PreshootSeekFactor

Corresponds to the duration of time to search for the overshoot and undershoot metrics immediately preceding each transition. The duration is expressed as a factor of the duration of the transition. This property is enabled only when the `PreshootOutputPort` property is set to `true` and is tunable.

Default: 3

RunningMetrics

Enable metrics over all calls to `step`. If `RunningMetrics` is set to `false`, metrics are computed for each call to `step` independently. If `RunningMetrics` is set to `true`, metrics are computed across subsequent calls to `step`. If there are not enough samples to compute metrics associated with the last transition, posttransition aberration region, or settling seek duration in the current record, the object will defer reporting all transition, aberration, and settling metrics associated with the last transition until a subsequent call to `step` is made with enough data to compute all enabled metrics for that transition.

Default: `false`

SampleRate

Sampling rate of uniformly-sampled signal. Specify the sample rate in hertz as a positive scalar. This property is used to construct the internal time values that correspond to the input sample values. Time values start with zero. This property applies when the `TimeInputPort` property is set to `false`.

Default: 1

SettlingOutputPort

Enable settling metrics. If the `SettlingOutputPort` property is set to `true`, settling metrics are reported for each transition. The region used to compute the settling metrics starts at the midcrossing and lasts until the `SettlingSeekDuration` has elapsed. If an intervening transition occurs, or the signal has not settled within the `PercentStateLevelTolerance` of the final level, `NaN` is returned for each metric. If there are not enough samples after the last transition to complete the `SettlingSeekDuration`, no metrics are reported for the last transition. The metrics are reported for the transition the next time `step` is called if the `RunningMetrics` property is set to `true`.

Default: `false`

SettlingSeekDuration

Duration of time over which to search for settling. This property value is a scalar that specifies the amount of time to inspect from the mid-reference level crossing (in seconds). If the transition has not yet settled, or a subsequent complete transition is detected within this duration, the `PulseMetrics` object will report `NaN` for all settling metrics.

This property is tunable and applies only when you set the `SettlingOutputPort` property to `true`.

Default: `0.02`

StateLevels

Low- and high-state levels. This property is a 2–element numeric row vector that contains the low- and high-state levels respectively. These state levels correspond to the nominal logic low and high levels of the pulse waveform. This property is tunable.

Default: `[0 2.3]`

StateLevelsSource

Auto or manual state-level computation. If `StateLevelsSource` is set to `'Auto'`, the first record sent to `step` is sent to `dsp.StateLevels` with the default settings to determine the state levels of the incoming waveform. If this property is set to `'Property'`, the object uses the values the user specifies in the `StateLevels` property.

Default: `'Property'`

TimeInputPort

Add input to specify sample instants. Set `TimeInputPort` to `true` to enable an additional real input column vector to `step` to specify the sample instants that correspond to the sample values. If this property is `false`, the sample instants are built internally. The sample instants start at zero and increment by the reciprocal of the `SampleRate` property for subsequent samples. The sample instants continue to increment if the `RunningMetrics` property is set to `true` and no intervening calls to the `reset` or `release` methods are encountered.

Default: `false`

TransitionOutputPort

Enable transition metrics. If the `TransitionOutputPort` property is set to `true`, transition metrics are reported for the initial and final transitions of each pulse.

Default: `false`

Methods

plot Plots signal and metrics computed in last call to `step`
reset Reset the running pulse metrics object
step Pulse metrics of bilevel waveforms

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

Width, Period, and Duty Cycle

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Determine the width, period, and duty cycle of a 5 V pulse sampled at 4 MHz.

```
load('pulseex.mat', 'x', 't');
```

Construct the `dsp.PulseMetrics` object. Set the `TimeInputPort` property to `true` to specify the sampling instants as an input. Set the `CycleOutputPort` property to `true` to obtain metrics for each pulse. Because the input is a 5V pulse, set the `StateLevels` property to `[0 5]`.

```
pm = dsp.PulseMetrics('TimeInputPort',true, ...
                    'CycleOutputPort', true, ...
                    'StateLevels',[0 5])
```

```
pm =
  dsp.PulseMetrics with properties:

        Polarity: 'Positive'
    StateLevelsSource: 'Property'
        StateLevels: [0 5]
PercentStateLevelTolerance: 2
    PercentReferenceLevels: [10 50 90]
        RunningMetrics: false
        TimeInputPort: true
        CycleOutputPort: true
    TransitionOutputPort: false
    PreshootOutputPort: false
    PostshootOutputPort: false
    SettlingOutputPort: false
```

Call `step` to compute the cycle metrics and plot the result.

```
[pulse, cycle] = pm(x,t);
plot(pm)
text(t(2),-0.5,['Duty Cycle: ',num2str(cycle.DutyCycle)]);
```

Slew Rates for 2.3 V Digital Clock

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Find the slew rates of the leading and trailing edges of a 2.3 V digital clock sampled at 4 MHz.

```
load('pulseex.mat', 'x', 't');
```

Construct the `dsp.PulseMetrics` object. Set the `TransitionOutputPort` property to `true` to report transition metrics for the initial and final transitions. Set the `StateLevelsSource` property to `'Auto'` to estimate the state levels from the data.

```
pm = dsp.PulseMetrics('SampleRate',4e6, ...
                    'TransitionOutputPort', true, ...
                    'StateLevelsSource','Auto');
```

Compute the pulse and transition metrics and plot the result.

```
[pulse, transition] = pm(x);
plot(pm);
```

`dsp.StateLevels` | `dsp.TransitionMetrics`

Introduced in R2012a

plot

System object: dsp.PulseMetrics

Package: dsp

Plots signal and metrics computed in last call to `step`

Syntax

```
plot(pm)
```

Description

`plot(pm)` plots the signal and metrics resulting from the last call of the `step` method.

By default `plot` displays

- the low and high state levels and the state-level boundaries defined by the `PercentStateLevelTolerance` property.
- the lower-, middle-, and upper-reference levels.
- the locations of the mid-reference level crossings of the positive (+) and negative (-) transitions of each detected pulse.

When the `TransitionOutputPort` property is set to `true`, the locations of the upper and lower crossings are also plotted. When the `PreshootOutputPort` or `PostShootOutputPort` properties are set to `true`, the corresponding overshoots and undershoots are plotted as inverted or noninverted triangles. When the `SettlingOutputPort` property is set to `true`, the locations where the signal enters and remains within the lower and upper state boundaries over the specified seek duration are plotted.

reset

System object: dsp.PulseMetrics

Package: dsp

Reset the running pulse metrics object

Syntax

reset (pm)

Description

reset (pm) clears information from previous calls to step.

step

System object: dsp.PulseMetrics

Package: dsp

Pulse metrics of bilevel waveforms

Syntax

```
PULSE = step(pm,X)
[PULSE,CYCLE] = step(pm,X)
[PULSE,TRANSITION] = step(pm,X)
[PULSE,PRESHOOT] = step(pm,X)
[PULSE,POSTSHOOT] = step(pm,X)
[PULSE,SETTLING] = step(pm,X)
[...] = step(pm,X,T)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`PULSE = step(pm,X)` returns a structure array, `PULSE`, whose fields contain real-valued column vectors. The number of rows of each field corresponds to the number of complete pulses found in the real-valued column vector input, `X`. Each pulse starts with a transition of the polarity specified by the `Polarity` property and ends with a transition of the opposite polarity.

`PULSE` fields:

- `PositiveCross` — Instants where the positive-going transitions cross the mid-reference level of each pulse

- `NegativeCross` — Instants where the negative-going transitions cross the mid-reference level of each pulse
- `Width` — Absolute difference between `PositiveCross` and `NegativeCross` of each pulse
- `RiseTime` — Duration between the linearly-interpolated instants when the positive-going (rising) transition of each pulse crosses the lower- and upper-reference levels
- `FallTime` — Duration between the linearly-interpolated instants when the negative-going (falling) transition of each pulse crosses the upper- and lower-reference levels

`[PULSE, CYCLE] = step(pm, X)` returns a structure array, `CYCLE`, whose fields contain real-valued column vectors when you set the `CycleOutputPort` property to `true`. The number of rows of each field corresponds to the number of complete pulse periods found in the real-valued column vector input, `X`. You need at least three consecutive alternating polarity transitions that start and end with the same polarity as the value of the `Polarity` property if you want to compute cycle metrics. If the last transition found in the input `X` does not match the polarity of the `Polarity` property, the pulse separation, period, frequency, and duty cycle are not reported for the last pulse. If the `RunningMetrics` property is set to `true` when this occurs, all pulse, cycle, transition, preshoot, postshoot, and settling metrics associated with the last pulse are deferred until a subsequent call to `step` detects the next transition.

`CYCLE` fields:

- `Period` — Duration between the first transition of the current pulse and the first transition of the next pulse
- `Frequency` — Reciprocal of the period
- `Separation` — Durations between the mid-reference level crossings of the second transition of each pulse and the first transition of the next pulse
- `Width` — Durations between the mid-reference level crossings of the first and second transitions of each pulse. This is equivalent to the width parameter of the `PULSE` structure.
- `DutyCycle` — Ratio of the width to the period for each pulse

`[PULSE, TRANSITION] = step(pm, X)` returns a structure array, `TRANSITION`, when you set the `TransitionOutputPort` property to `true`. The fields of `TRANSITION` contain real-valued matrices with two columns which correspond to the metrics of the first and second transitions. The number of rows corresponds to the number of pulses found in the input waveform.

TRANSITION fields:

- `Duration` — Amount of time between the interpolated instants where the transition crosses the lower- and upper-reference levels
- `SlewRate` — Ratio of absolute difference between the upper and lower reference levels to the transition duration
- `MiddleCross` — Linearly-interpolated instant in time where the transition first crosses the mid-reference level
- `LowerCross` — Linearly-interpolated instant where the signal crosses the lower-reference level
- `UpperCross` — Linearly-interpolated instant where the signal crosses the upper-reference level

`[PULSE, PRESHOOT] = step(pm, X)` returns a structure array, `PRESHOOT`, when you set the `PreshootOutputPort` property to `true`. The fields of `PRESHOOT` contain real-valued 2-column matrices whose row length corresponds to the number of transitions found in the input waveform. The field names are identical to those of the `POSTSHOOT` structure array.

`[PULSE, POSTSHOOT] = step(pm, X)` returns a structure, `POSTSHOOT`, when you set the `PostshootOutputPort` property to `true`. The fields of `POSTSHOOT` contain real-valued 2-column matrices whose row length corresponds to the number of transitions found in the input waveform.

PRESHOOT and POSTSHOOT fields:

- `Overshoot` — Overshoot of the region of interest expressed as a percentage of the waveform amplitude
- `Undershoot` — Undershoot of the region of interest expressed as a percentage of the waveform amplitude
- `OvershootLevel` — Level of the overshoot
- `UndershootLevel` — Level of the undershoot
- `OvershootInstant` — Instant that corresponds to the overshoot
- `UndershootInstant` — Instant that corresponds to the undershoot

`[PULSE, SETTTLING] = step(pm, X)` returns a structure array, `SETTLING`, when you set the `SettlingOutputPort` property to `true`. The fields of `SETTLING` correspond to the

settling metrics for each transition. Each field is a column vector whose elements correspond to the individual settling durations, levels, and instants.

SETTLING fields:

- **Duration** — Amount of time from when the signal crosses the mid-reference level to the time where the signal enters and remains within the specified `PercentStateLevelTolerance` of the waveform amplitude over the specified settling seek duration
- **Instant** — Instant in time where the signal enters and remains within the specified tolerance
- **Level** — Level of the waveform where it enters and remains within the specified tolerance

The above operations can be used simultaneously, provided the `System` object properties are set appropriately. One example of providing all possible inputs and returning all possible outputs is :

```
[PULSE, CYCLE, TRANSITION, PRESHOOT, POSTSHOOT, SETTLING] = step(pm, X)
```

which returns the `PULSE`, `CYCLE`, `TRANSITION`, `PRESHOOT`, `POSTSHOOT`, and `SETTLING` structures when the `CycleOutputPort`, `PreshootOutputPort`, `PostshootPort`, and `SettlingOutputPort` properties are `true`. You may enable or disable any combination of output ports. However, the output arguments are defined in the order shown here.

`[...] = step(pm, X, T)` performs the above metrics with respect to a sampled signal, whose sample values, `X`, and sample instants, `T`, are real-valued column vectors of the same length. The additional input `T` applies only when you set the `TimeInputPort` property to `true`.

dsp.RCToAutocorrelation System object

Package: dsp

Convert reflection coefficients to autocorrelation coefficients

Description

The `RCToAutocorrelation` object converts reflection coefficients to autocorrelation coefficients.

To convert reflection coefficients to autocorrelation coefficients:

- 1 Define and set up your System object. See “Construction” on page 4-1476.
- 2 Call `step` to convert reflection coefficients according to the properties of `dsp.RCToAutocorrelation`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`rc2ac = dsp.RCToAutocorrelation` returns an `RCToAutocorrelation` System object, `rc2ac`. This object converts reflection coefficients to autocorrelation coefficients, assuming an error power of 1.

`rc2ac = dsp.RCToAutocorrelation('PropertyName',PropertyValue,...)` returns an object, `rc2ac`, that converts reflection coefficients into autocorrelation coefficients, with each specified property set to the specified value.

Properties

PredictionErrorInputPort

Enable prediction error power input

Choose how to select the prediction error power. When you set this property to `true`, you must specify the prediction error power as a second input to the `step` method. When you set this property to `false`, the object assumes a prediction error power of 1. The default is `false`.

Methods

`step` Convert columns of reflection coefficients to autocorrelation coefficients

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

Convert Reflection Coefficients to Autocorrelation Coefficients

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
k = [-0.8091 0.2525 -0.5044 0.4295 -0.2804 0.0711].';
rc2ac = dsp.RCToAutocorrelation;
ac = rc2ac(k);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the LPC/RC to Autocorrelation block reference page. The object properties correspond to the block parameters, except:

- There is no object property that corresponds to the **Type of conversion** block parameter.
- **PredictionErrorInputPort** is a pop-up menu choice on the block. Setting the `PredictionErrorInputPort` object property to `false` corresponds to selecting `Assume P = 1` in the pop-up menu. Setting `PredictionErrorInputPort` to `true` corresponds to selecting `Via input port` from the pop-up menu.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

Introduced in R2012a

step

System object: dsp.RCToAutocorrelation

Package: dsp

Convert columns of reflection coefficients to autocorrelation coefficients

Syntax

```
AC = step(rc2ac,K)
```

```
AC = step(rc2ac,K,P)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

`AC = step(rc2ac,K)` converts the columns of the reflection coefficients, K , to autocorrelation coefficients, AC .

`AC = step(rc2ac,K,P)` when you set the `PredictionErrorInputPort` property to `true`, converts the columns of the reflection coefficients, K , to autocorrelation coefficients, AC , using P as the prediction error power. P must be a row vector with same number of columns as in K .

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.RCToLPC System object

Package: dsp

Convert reflection coefficients to linear prediction coefficients

Description

The `RCToLPC` object converts reflection coefficients to linear prediction coefficients.

To convert reflection coefficients to LPC:

- 1 Define and set up your RC to LPC System object. See “Construction” on page 4-1481.
- 2 Call `step` to convert RC to LPC according to the properties of `dsp.RCToLPC`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`rc2lpc = dsp.RCToLPC` returns an RC to LPC System object, `rc2lpc`, that converts reflection coefficients (RC) to linear prediction coefficients (LPC).

`rc2lpc = dsp.RCToLPC('PropertyName',PropertyValue,...)` returns an RC to LPC conversion object, `rc2lpc`, with each specified property set to the specified value.

Properties

PredictionErrorOutputPort

Enable normalized prediction error power output

Set this property to `true` to return the normalized error power as a vector with one element per input channel. Each element varies between 0 and 1. The default is `true`.

ExceptionOutputPort

Produce output with stability status of filter represented by LPC coefficients

Set this property to `true` to return the stability of the filter. The output is a vector of a length equal to the number of channels. A logical value of 1 indicates a stable filter. A logical value of 0 indicates an unstable filter. The default is `false`.

Methods

`step` Convert columns of reflection coefficients to linear prediction coefficients

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

Convert RC to LPC Coefficients

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Convert reflection coefficients to linear prediction coefficients.

```
levinson = dsp.LevinsonSolver;
ac = dsp.Autocorrelator;
```

```
ac.MaximumLagSource = 'Property';
ac.MaximumLag = 10; % Compute autocorrelation
% lags between [0:10]
rc2lpc = dsp.RCToLPC;
x = (1:100)';
a = ac(x);
k = levinson(a); % Compute reflection coefficients
[A, P] = rc2lpc(k);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the LPC to/from RC block reference page. The object properties correspond to the block parameters, except:

There is no object property that corresponds to the **Type of conversion** block parameter. The object always converts LPC to RC.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

step

System object: dsp.RCToLPC

Package: dsp

Convert columns of reflection coefficients to linear prediction coefficients

Syntax

```
[A,P] = step(rc2lpc,K)
A = step(rc2lpc,K)
[... , S] = step(rc2lpc,K)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[A,P] = step(rc2lpc,K)` converts the columns of the reflection coefficients, `K`, to linear prediction coefficients, `A`, and outputs the normalized prediction error power, `P`.

`A = step(rc2lpc,K)` when the `PredictionErrorOutputPort` property is `false`, converts the columns of the reflection coefficients, `K`, to linear prediction coefficients, `A`.

`[... , S] = step(rc2lpc,K)` also outputs the LPC filter stability, `S`, when the `ExceptionOutputPort` property is `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable

property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.RLSFilter System object

Package: dsp

Compute output, error and coefficients using Recursive Least Squares (RLS) algorithm

Description

The `RLSFilter` object filters each channel of the input using RLS filter implementations.

To filter each channel of the input:

- 1 Define and set up your RLS filter. See “Construction” on page 4-1486.
- 2 Call `step` to filter each channel of the input according to the properties of `dsp.RLSFilter`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`rlsFilt = dsp.RLSFilter` returns an adaptive RLS filter System object, `rlsFilt`. This System object computes the filtered output, filter error and the filter weights for a given input and desired signal using the RLS algorithm.

`rlsFilt = dsp.RLSFilter('PropertyName', PropertyValue, ...)` returns an RLS filter System object, `rlsFilt`, with each specified property set to the specified value.

`rlsFilt = dsp.RLSFilter(LEN, 'PropertyName', PropertyValue, ...)` returns an RLS filter System object, `rlsFilt`. This System object has the `Length` property set to `LEN`, and other specified properties set to the specified values.

Properties

Method

Method to calculate the filter coefficients

You can specify the method used to calculate filter coefficients as one of | `Conventional RLS` [1] [2] | `Householder RLS` [3] [4] | `Sliding-window RLS` [5][1][2] | `Householder sliding-window RLS` [4] | `QR decomposition` [1] [2]. The default value is `Conventional RLS`. This property is nontunable.

Length

Length of filter coefficients vector

Specify the length of the RLS filter coefficients vector as a scalar positive integer value. The default value is 32. This property is nontunable.

SlidingWindowBlockLength

Width of the sliding window

Specify the width of the sliding window as a scalar positive integer value greater than or equal to the `Length` property value. This property is applicable only when the `Method` property is set to `Sliding-window RLS` or `Householder sliding-window RLS`. The default value is 48. This property is nontunable.

ForgettingFactor

RLS forgetting factor

Specify the RLS forgetting factor as a scalar positive numeric value less than or equal to 1. Setting this property value to 1 denotes infinite memory, while adapting to find the new filter. The default value is 1. This property is tunable.

InitialCoefficients

Initial coefficients of the filter

Specify the initial values of the FIR adaptive filter coefficients as a scalar or a vector of length equal to the `Length` property value. The default value is 0. This property is tunable.

InitialInverseCovariance

Initial inverse covariance

Specify the initial values of the inverse covariance matrix of the input signal. This property must be either a scalar or a square matrix, with each dimension equal to the `Length` property value. If you set a scalar value, the `InverseCovariance` property is initialized to a diagonal matrix with diagonal elements equal to that scalar value. This property applies only when the `Method` property is set to `Conventional RLS` or `Sliding-window RLS`. The default value is `1000`. This property is tunable.

InitialSquareRootInverseCovariance

Initial square root inverse covariance

Specify the initial values of the square root inverse covariance matrix of the input signal. This property must be either a scalar or a square matrix with each dimension equal to the `Length` property value. If you set a scalar value, the `SquareRootInverseCovariance` property is initialized to a diagonal matrix with diagonal elements equal to that scalar value. This property applies only when the `Method` property is set to `Householder RLS` or `Householder sliding-window RLS`. The default value is `sqrt(1000)`. This property is tunable.

InitialSquareRootCovariance

Initial square root covariance

Specify the initial values of the square root covariance matrix of the input signal. This property must be either a scalar or a square matrix with each dimension equal to the `Length` property value. If you set a scalar value, the `SquareRootCovariance` property is initialized to a diagonal matrix with diagonal elements equal to the scalar value. This property applies only when the `Method` property is set to `QR-decomposition RLS`. The default value is `sqrt(1/1000)`. This property is tunable.

LockCoefficients

Lock coefficient updates

Specify whether the filter coefficient values should be locked. When you set this property to `true`, the filter coefficients are not updated and their values remain the same. The default value is `false` (filter coefficients continuously updated). This property is tunable.

Methods

msesim	Mean-square error for RLS filter
reset	Reset the internal states of a System object
step	Process inputs using RLS filter

Common to All System Objects	
clone	Create System object with same property values
getNumInputs	Expected number of inputs to a System object
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

System Identification of an FIR Filter

Use the RLS filter System object™ to determine the signal value.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent step syntax. For example, myObject(x) becomes step(myObject,x).

```

rls1 = dsp.RLSFilter(11, 'ForgettingFactor', 0.98);
filt = dsp.FIRFilter('Numerator', fir1(10, .25)); % Unknown System
x = randn(1000,1); % input signal
d = filt(x) + 0.01*randn(1000,1); % desired signal
[y,e] = rls1(x, d);
w = rls1.Coefficients;
subplot(2,1,1), plot(1:1000, [d,y,e]);
title('System Identification of an FIR filter');
legend('Desired', 'Output', 'Error');
xlabel('time index'); ylabel('signal value');
subplot(2,1,2); stem([filt.Numerator; w].');

```

```

legend('Actual', 'Estimated');
xlabel('coefficient #'); ylabel('coefficient value');

```

Noise Cancellation

```

rls2 = dsp.RLSFilter('Length', 11, 'Method', 'Householder RLS');
filt2 = dsp.FIRFilter('Numerator', fir1(10, [.5, .75]));
x = randn(1000,1); % Noise
d = filt2(x) + sin(0:.05:49.95)'; % Noise + Signal
[y, err] = rls2(x, d);
subplot(2,1,1), plot(d), title('Noise + Signal');
subplot(2,1,2), plot(err), title('Signal');

```

Algorithms

The `dsp.RLSFilter` System object, when `Conventional` RLS is selected, recursively computes the least squares estimate (RLS) of the FIR filter weights. The System object estimates the filter weights or coefficients, needed to convert the input signal into the desired signal. The input signal can be a scalar or a column vector. The desired signal must have the same data type, complexity, and dimensions as the input signal. The corresponding RLS filter is expressed in matrix form as $\mathbf{P}(n)$:

$$\mathbf{k}(n) = \frac{\lambda^{-1} \mathbf{P}(n-1) \mathbf{u}(n)}{1 + \lambda^{-1} \mathbf{u}^H(n) \mathbf{P}(n-1) \mathbf{u}(n)}$$

$$y(n) = \mathbf{w}^T(n-1) \mathbf{u}(n)$$

$$e(n) = d(n) - y(n)$$

$$\mathbf{w}(n) = \mathbf{w}(n-1) + \mathbf{k}(n)e(n)$$

$$\mathbf{P}(n) = \lambda^{-1} \mathbf{P}(n-1) - \lambda^{-1} \mathbf{k}(n) \mathbf{u}^H(n) \mathbf{P}(n-1)$$

where λ^{-1} denotes the reciprocal of the exponential weighting factor. The variables are as follows:

Variable	Description
n	The current time index
$\mathbf{u}(n)$	The vector of buffered input samples at step n
$\mathbf{P}(n)$	The inverse correlation matrix at step n
$\mathbf{k}(n)$	The gain vector at step n
$\mathbf{w}(n)$	The vector of filter tap estimates at step n
$y(n)$	The filtered output at step n
$e(n)$	The estimation error at step n
$d(n)$	The desired response at step n
λ	The forgetting factor

\mathbf{u} , \mathbf{w} , and \mathbf{k} are all column vectors.

Introduced in R2013a

msesim

System object: dsp.RLSFilter

Package: dsp

Mean-square error for RLS filter

Syntax

```
MSE = msesim(sysObj,X,D)
[MSE,MEANW,W,TRACEK] = msesim(sysObj,X,D)
[...] = msesim(sysObj,X,D,M)
```

Description

`MSE = msesim(sysObj,X,D)` returns a sequence of mean-square errors. This column vector contains estimates of the mean-square error of the adaptive filter at each time instant. The length of `MSE` is equal to `SIZE(X,1)`. The columns of the matrix `X` contain individual input signal sequences, and the columns of the matrix `D` contain corresponding desired response signal sequences.

`[MSE,MEANW,W,TRACEK] = msesim(sysObj,X,D)` calculates three parameters corresponding to the simulated behavior of the adaptive filter defined by `sysObj`. `MEANW` is a sequence of coefficient vector means. The columns of this matrix contain estimates of the mean values of the adaptive filter coefficients at each time instant. The dimensions of `MEANW` are `(SIZE(X,1))` by `(sysObj.length)`. `W` is an estimate of the final values of the adaptive filter coefficients for the algorithm corresponding to `sysObj`. `TRACEK` is a sequence of total coefficient error powers. This column vector contains estimates of the total coefficient error power of the adaptive filter at each time instant. The length of `TRACEK` is equal to `SIZE(X,1)`.

`[...] = msesim(sysObj,X,D,M)` specifies an optional decimation factor for computing `MSE`, `MEANW`, and `TRACEK`. If `M > 1`, every `Mth` predicted value of each of these sequences is saved. If omitted, the value of `M` is the default, which is 1.

reset

System object: dsp.RLSFilter

Package: dsp

Reset the internal states of a System object

Syntax

```
reset(rlsFilt)
```

Description

`reset(rlsFilt)` resets the internal states of the System object, `rlsFilt`, to their initial values.

For many System objects, this method is nonoperational. Objects that have internal states describe in their **help** what the reset method does for that object. The `reset` method is always nonoperational for unlocked System objects, as states may not be allocated when the object is not locked.

step

System object: dsp.RLSFilter

Package: dsp

Process inputs using RLS filter

Syntax

```
y = step(rlsFilt,x,d)
[y,e] = step(rlsFilt,x,d)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`y = step(rlsFilt,x,d)` recursively adapts the reference input, `x`, to match the desired signal, `d`, using the System object, `rlsFilt`. The desired signal, `d` is the signal desired plus some undesired noise. `[y,e] = step(rlsFilt,x,d)` shows the output of the RLS filter along with the error, `e`, between the reference input and the desired signal. The filter adapts its coefficients until the error, `e` is minimized. You can access these coefficients by accessing the 'Coefficients' property of the object. You must access this property after calling the `step` method on the object. For example, you can access the optimized coefficients of `rlsFilt` filter object through `rlsFilt.Coefficients`, after calling the `step` method on this object.

dsp.RMS System object

Package: dsp

Root mean square of vector elements

Description

The RMS object computes the root mean square (RMS) value.

To compute the RMS value of your input:

- 1 Define and set up your RMS calculation. See “Construction” on page 4-1497.
- 2 Call `step` to compute the RMS value for an input according to the properties of `dsp.RMS`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Note The Running mode in the `dsp.RMS` System object will be removed in a future release. To compute the running RMS in MATLAB, use the `dsp.MovingRMS` System object instead.

Construction

`rms = dsp.RMS` returns a System object, `rms`, that computes the root mean square (RMS) of an input or a sequence of inputs over the specified `Dimension`.

`rms = dsp.RMS('PropertyName', PropertyValue, ...)` returns an RMS System object, `rms`, with each specified property set to the specified value.

Properties

RunningRMS

Enable calculating RMS over time

Set this property to `true` to enable calculating the RMS over successive calls to the `step` method.

Default: `false`

ResetInputPort

Enable resetting in running RMS mode

Set this property to `true` to enable resetting the running RMS. When the property is set to `true`, you must specify a reset input to the `step` method to reset the running RMS. This property applies when you set the `RunningRMS` property to `true`.

Default: `false`

ResetCondition

Reset condition for running RMS mode

Specify the event to reset the running RMS as one of `Rising edge`, `Falling edge`, `Either edge`, or `Non-zero`. `Non-zero` resets the running RMS each time a nonzero sample is acquired. See “Rising and Falling Edges” on page 4-1501 for definitions of rising and falling edges. This property applies when you set the “ResetInputPort” on page 4-0 property to `true`.

Default: `Non-zero`

Dimension

Dimension to compute RMS value along

Specify the dimension along which to calculate the RMS as one of `All`, `Row`, `Column`, or `Custom`. This property applies only when you set the `RunningRMS` property to `false`. Specifying the `Dimension` property as `All` computes the RMS value over the entire input.

Default: Column

CustomDimension

Numerical dimension to operate along

Specify the dimension (one-based scalar integer value) of the input signal, along which the RMS is computed. The cannot exceed the number of dimensions in the input signal. This property applies when you set the “Dimension” on page 4-0 property to Custom.

Default: 1

Methods

reset Reset the running root mean square object
 step Root mean square of input

Common to All System Objects	
clone	Create System object with same property values
getNumInputs	Expected number of inputs to a System object
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

RMS Value of Vector Input

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Compute the RMS value of a vector consisting of the integers 1 to 10.

```
x = 1:10;
rms = dsp.RMS('Dimension','row');
rmsval = rms(x)

rmsval = 6.2048
```

RMS Value of Matrix Input

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Compute the RMS value of a matrix with the `Dimension` property set to `'All'`.

```
in2 = magic(4);
rms2d = dsp.RMS;
rms2d.Dimension = 'All';
y_rms2 = rms2d(in2)

y_rms2 = 9.6695
```

The output is equivalent to reshaping the 4-by-4 matrix into a 16-by-1, or 1-by-16 vector and computing the RMS value for the vector.

Definitions

Root-Mean-Square Level

The root-mean-square level of a vector, X , is

$$x_{\text{RMS}} = \sqrt{\frac{1}{N} \sum_{n=1}^N |x_n|^2},$$

with the summation performed along the specified dimension.

Rising and Falling Edges

A rising edge:

- Rises from a negative value to a positive value or zero.
- Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.

A falling edge:

- Falls from a positive value to a negative value or zero.
- Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.

Algorithms

This object implements the algorithm, inputs, and outputs described on the RMS block reference page. The object properties correspond to the Simulink block parameters, except:

- **Treat sample-based row input as a column** block parameter is not supported by the `dsp.RMS` object.
- **Reset Port** block parameter corresponds to both the `ResetCondition` and the `ResetInputPort` object properties.

Extended Capabilities

reset

System object: dsp.RMS

Package: dsp

Reset the running root mean square object

Syntax

```
reset(rms)
```

Description

`reset(rms)` resets the running root mean square (RMS) for the object `rms`.

step

System object: dsp.RMS

Package: dsp

Root mean square of input

Syntax

`Y = step(rms,X)`

`Y = step(rms,X,R)`

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(rms,X)` computes the root mean square (RMS) output, `Y`, of input vector `X`. When the `RunningRMS` property is true, `Y` corresponds to the RMS of the input elements over successive calls to the `step` method.

`Y = step(rms,X,R)` resets the running RMS state based on the value of `R`, the reset signal, and the `ResetCondition` property. This computation is possible when you set both the `RunningRMS` and the `ResetInputPort` properties to true.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.SampleRateConverter System object

Package: dsp

Multistage sample rate converter

Description

The `SampleRateConverter` System object converts the sample rate of an incoming signal.

To convert the sample rate of a signal:

- 1 Define and set up your sample rate converter. See “Construction” on page 4-1506.
- 2 Call `step` to convert the sample rate according to the properties of `dsp.SampleRateConverter`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`src = dsp.SampleRateConverter` creates a multistage FIR sample rate converter System object, `src`, that converts the sample rate of each channel of an input signal.

`src = dsp.SampleRateConverter(Name,Value)` returns a multistage FIR sample rate converter System object, `src`, with properties and options specified by one or more `Name,Value` pair arguments.

Properties

Bandwidth — Two-sided bandwidth of interest

40 kHz (default) | positive scalar

Specify the two-sided bandwidth of interest (after rate conversion) as a positive scalar expressed in hertz. This property is the two-sided bandwidth of the information-carrying portion of the signal that you wish to retain. The default is 40 kHz.

InputSampleRate — Sample rate of input signal

192 kHz (default) | positive scalar

Specify the sample rate of the input signal as a positive scalar expressed in hertz. The input sample rate must be greater than the bandwidth of interest. The default is 192 kHz.

OutputRateTolerance — Maximum allowed tolerance for output sample rate

0 (default) | positive scalar

Specify the maximum allowed tolerance for the sample rate of the output signal as a positive scalar between 0 and 1. The default is 0.

The output rate tolerance allows for a simpler design in many cases. The actual output sample rate varies but is within the specified range. For example, if `OutputRateTolerance` is specified as 0.01, then the actual output sample rate is in the range given by `OutputSampleRate ± 1%`.

OutputSampleRate — Sample rate of output signal

44.1 kHz (default) | positive scalar

Specify the sample rate of the output signal as a positive scalar expressed in hertz. The output sample rate must be greater than the bandwidth of interest. The default is 44.1 kHz.

StopbandAttenuation — Minimum dB attenuation for aliased components

80 dB (default) | positive scalar

Specify the stopband attenuation as a positive scalar expressed in decibels. This property is the minimum amount by which any aliasing involved in the process is attenuated. The default is 80 dB.

Methods

<code>cost</code>	Compute implementation cost
<code>freqz</code>	Frequency response
<code>getFilters</code>	Obtain single-stage filters
<code>getActualOutputRate</code>	Get actual output rate
<code>getRateChangeFactors</code>	Overall interpolation and decimation factors

Examples

Convert Sample Rate of Audio Signal

Convert the sample rate of an audio signal from 44.1 kHz (CD quality) to 96 kHz (DVD quality).

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
fs1 = 44.1e3;
fs2 = 96e3;
```

```

SRC = dsp.SampleRateConverter('Bandwidth',40e3,...
    'InputSampleRate',fs1,'OutputSampleRate',fs2);

[L,M] = getRateChangeFactors(SRC);
FrameSize = 10*M;

AR = dsp.AudioFileReader('guitar10min.ogg', ...
    'SamplesPerFrame',FrameSize);
AW = dsp.AudioFileWriter('guitar10min_96k.wav', ...
    'SampleRate',fs2);

```

Run the system for 15 s. Release all objects.

```

tic
while toc < 15
    x = AR();
    y = SRC(x);
    AW(y);
end

release(AR);
release(AW);
release(SRC);

```

Plot the input and output signals. Use a different set of axes for each signal. Shift the output to compensate for the delay introduced by the filter.

```

t1 = 0:1/fs1:1/30-1/fs1;
t2 = 0:1/fs2:1/30-1/fs2;

delay = 114;

e11 = 1:length(t1)-delay;

e12 = 1:length(t2);
e12(1:delay) = [];

subplot(2,1,1)
plot(t1(1:length(e11)),x(e11,1))
hold on
plot(t1(1:length(e11)),x(e11,2))
title('Input')

subplot(2,1,2)

```

```

plot(t2(1:length(e12)),y(e12,1))
hold on
plot(t2(1:length(e12)),y(e12,2))
xlabel('Time (s)')
title('Output')

```

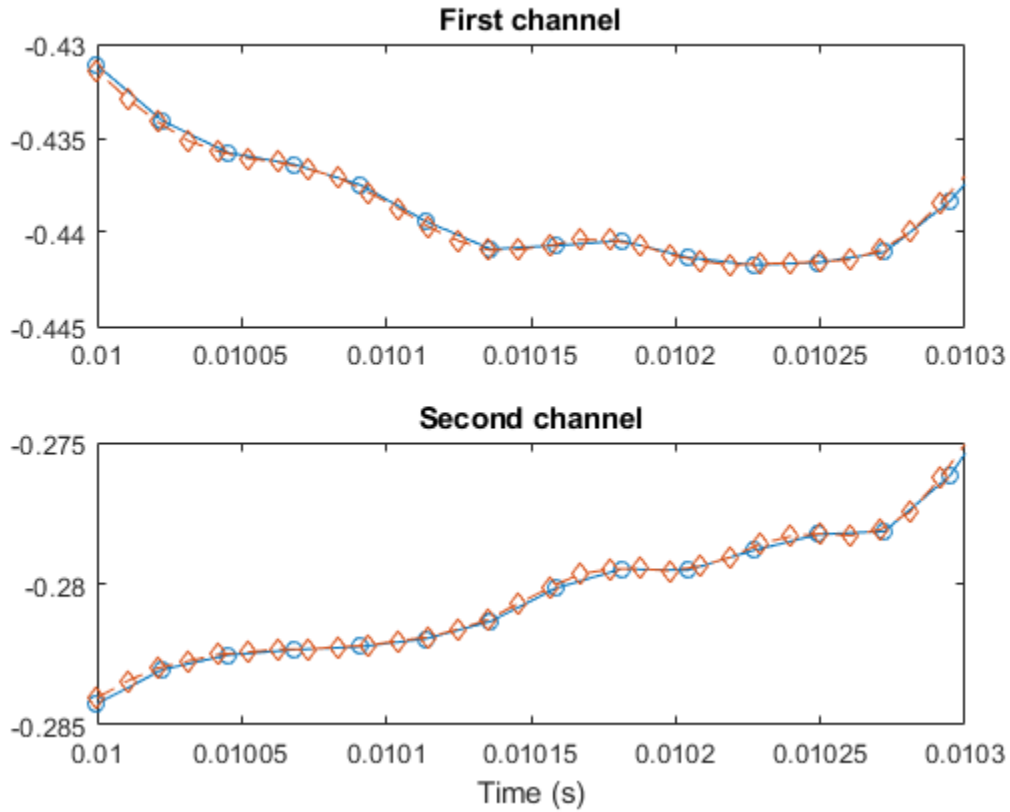

Zoom in to see the difference in sample rates. Use a different set of axes for each channel.

```

figure
subplot(2,1,1)
plot(t1(1:length(e11)),x(e11,1),'o-')
hold on
plot(t2(1:length(e12)),y(e12,1),'d--')

```

```
xlim([0.01 0.0103])  
title('First channel')  
  
subplot(2,1,2)  
plot(t1(1:length(e11)),x(e11,2),'o-')  
hold on  
plot(t2(1:length(e12)),y(e12,2),'d--')  
xlim([0.01 0.0103])  
xlabel('Time (s)')  
title('Second channel')
```

Tolerance Cost in Sample Rate Conversion

A signal output from an A/D converter is sampled at 98.304 MHz. The signal has a bandwidth of 20 MHz. Reduce the sample rate of the signal to 22 MHz, which is the bandwidth of 802.11 channels. Make the conversion exactly and then redo it with an output rate tolerance of 1%.

```
SRC1 = dsp.SampleRateConverter('Bandwidth',20e6, ...  
    'InputSampleRate',98.304e6, 'OutputSampleRate',22e6, ...  
    'OutputRateTolerance',0);  
SRC2 = dsp.SampleRateConverter('Bandwidth',20e6, ...  
    'InputSampleRate',98.304e6, 'OutputSampleRate',22e6, ...  
    'OutputRateTolerance',0.01);
```

Use the `cost` method to determine the cost of each sample rate conversion. The zero-tolerance process requires more than 500 times as many coefficients as the 1% process.

```
c1 = cost(SRC1)  
c2 = cost(SRC2)
```

```
c1 =  
  
    struct with fields:  
  
        NumCoefficients: 84779  
        NumStates: 133  
        MultiplicationsPerInputSample: 27.0422  
        AdditionsPerInputSample: 26.0684
```

```
c2 =  
  
    struct with fields:  
  
        NumCoefficients: 150  
        NumStates: 127  
        MultiplicationsPerInputSample: 22.6667  
        AdditionsPerInputSample: 22.1111
```

Find the integer upsampling and downsampling factors used in each conversion.

```
[L1,M1] = getRateChangeFactors(SRC1)  
[L2,M2] = getRateChangeFactors(SRC2)
```

```
L1 =  
    1375
```

```
M1 =  
    6144
```

```
L2 =  
     2
```

```
M2 =  
     9
```

Compute the actual sample rate of the output signal when the sample rate conversion has a tolerance of 1%.

```
getActualOutputRate(SRC2)
```

```
ans =  
    2.1845e+07
```

Algorithms

- The general multistage sample rate converter performs a multistage decimation, a single-stage sample rate conversion, and a multistage interpolation, in that order. Actual designs include at most two of those steps.
- The procedure determines automatically the optimal number of decimation or interpolation stages. In special cases, the decimation or the interpolation can be performed in a single stage.
- The algorithm always attempts to start by reducing the sample rate. This decreases the amount of computation required. The decimation step is designed so that no

intermediate sample rate goes below the bandwidth of interest. This ensures that no information is filtered out.

- Each individual stage uses halfband or Nyquist filters to minimize the number of nonzero coefficients.
- Transition-band aliasing is allowed because it decreases the implementation cost. The signal within the bandwidth of interest is kept alias free up to the value specified by the `StopbandAttenuation` property.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Introduced in R2014b

cost

System object: dsp.SampleRateConverter

Package: dsp

Compute implementation cost

Syntax

```
c = cost(src)
```

Description

`c = cost(src)` returns a structure, `c`, whose fields contain information about the computational cost of implementing a multistage sample rate converter, `src`.

Input Arguments

src — Multistage sample rate converter

SampleRateConverter System object

Multistage sample rate converter, specified as a SampleRateConverter System object.

Output Arguments

c — Output structure

structure

Output structure with information about the computational cost of `src`:

- The number of coefficients,
- The number of states,
- The number of multiplications per unit sample, and

- The number of additions per unit sample.

Examples

Computational Cost of a Sample Rate Converter

Create `src`, a multistage sample rate converter with default values. `src` combines three filter stages to convert from 192 kHz to 44.1 kHz. Determine its computational cost: the number of coefficients, the number of states, the number of multiplications per unit sample, and the number of additions per unit sample.

```
src = dsp.SampleRateConverter;
cst = cost(src)

cst =

    struct with fields:

        NumCoefficients: 8631
        NumStates: 138
        MultiplicationsPerInputSample: 27.6672
        AdditionsPerInputSample: 26.6875
```

Repeat the computation allowing a tolerance of 10% in the output sample rate.

```
src.OutputRateTolerance = 0.1;
ctl = cost(src)

ctl =

    struct with fields:

        NumCoefficients: 44
        NumStates: 80
        MultiplicationsPerInputSample: 14.2500
        AdditionsPerInputSample: 13.5000
```

freqz

System object: `dsp.SampleRateConverter`

Package: `dsp`

Frequency response

Syntax

```
[h, f] = freqz(src, n, range)
```

```
[h, f] = freqz(src, f)
```

Description

`[h, f] = freqz(src, n, range)` returns the complex frequency response, `h`, of the multistage sample rate converter, `src`, evaluated at the `n` frequencies returned in `f`. `range` is the frequency range over which the response is computed. The sample rate is taken to be the largest of `InputSampleRate` and `OutputSampleRate`.

`[h, f] = freqz(src, f)` returns the complex frequency response evaluated at the frequency points specified in the vector `f`. `f` is assumed to be expressed in hertz.

Input Arguments

src — Multistage sample rate converter

`SampleRateConverter` System object

Multistage sample rate converter, specified as a `SampleRateConverter` System object.

n — Number of evaluation points

512 (default) | positive integer

Number of frequencies for response evaluation, specified as a positive integer scalar. If `n` is not specified, it defaults to 512.

range — Range of frequencies

'half' (default) | 'whole'

Range considered when computing the frequency response, specified as either 'half' (from 0 to π) or 'whole' (from 0 to 2π). If range is not specified, it defaults to 'half'.

Output Arguments

h — Complex frequency response

vector

Complex frequency response, returned as a vector.

f — Frequencies

vector

Frequencies at which the response is evaluated, returned as a vector.

Examples

Frequency Response of Default Converter

Create a multistage sample rate converter with default properties, corresponding to the combined three filter stages used to convert from 192 kHz to 44.1 kHz. Compute and display the frequency response.

```
src = dsp.SampleRateConverter;  
[H,f] = freqz(src);  
plot(f,20*log10(abs(H)))
```

Compute and display the frequency response over the range between 20 Hz and 44.1 kHz.

```
f = 20:10:44.1e3;  
[H,f] = freqz(src,f);  
plot(f,20*log10(abs(H)))
```

getFilters

System object: dsp.SampleRateConverter

Package: dsp

Obtain single-stage filters

Syntax

```
c = getFilters(src)
```

Description

`c = getFilters(src)` returns the multirate filters cascaded together in `src` to perform the overall sample rate conversion. The result is a `FilterCascade` structure, `c`. Each field of `c` holds the filter used at a particular stage and gives access to its coefficients and rate-change factors.

Input Arguments

src — Multistage sample rate converter

`SampleRateConverter` System object

Multistage sample rate converter, specified as a `SampleRateConverter` System object.

Output Arguments

c — Single-stage filters

`FilterCascade` structure

Single-stage filters, returned as a `FilterCascade` structure.

Examples

Single-Stage Filters

Create `src`, a multistage sample rate converter with default properties. `src` converts between 192 kHz and 44.1 kHz. Find the individual filters that are cascaded together to perform the conversion.

```
src = dsp.SampleRateConverter;  
c = getFilters(src);
```

Visualize the frequency response of the decimator used in the first stage of the process.

```
m = c.Stage1;  
  
[h,w] = freqz(m);  
plot(w/pi,20*log10(abs(h)))  
xlabel('\omega / \pi')  
ylabel('Magnititude (dB)')
```

getActualOutputRate

System object: `dsp.SampleRateConverter`

Package: `dsp`

Get actual output rate

Syntax

```
fsout = getActualOutputRate(src)
```

Description

`fsout = getActualOutputRate(src)` returns the actual output sample rate yielded by a `SampleRateConverter` System object. The computation takes into account the `OutputRateTolerance` parameter.

Input Arguments

src — Multistage sample rate converter

`SampleRateConverter` System object

Multistage sample rate converter, specified as a `SampleRateConverter` System object.

Output Arguments

fsout — Actual output sample rate

scalar

Actual output sample rate, returned as a scalar expressed in hertz.

Examples

Output Sample Rate with Given Tolerance

Get the actual output sample rate for conversion between 192 kHz and 44.1 kHz when given a tolerance of 1%.

```
src = dsp.SampleRateConverter;  
src.OutputRateTolerance = 0.01;  
FsOut = getActualOutputRate(src)
```

```
FsOut = 4.4308e+04
```

getRateChangeFactors

System object: `dsp.SampleRateConverter`

Package: `dsp`

Overall interpolation and decimation factors

Syntax

```
[L,M] = getRateChangeFactors(src)
```

Description

`[L,M] = getRateChangeFactors(src)` returns the overall interpolation factor, `L`, and the overall decimation factor, `M`, corresponding to the multistage sample rate converter, `src`. The overall decimation factor affects the allowable frame size of the input signal, which must be an integer multiple of `M`.

Input Arguments

src — Multistage sample rate converter

`SampleRateConverter` System object

Multistage sample rate converter, specified as a `SampleRateConverter` System object.

Output Arguments

L — Overall interpolation factor

scalar

Overall interpolation factor, returned as a scalar.

M — Overall decimation factor

scalar

Overall decimation factor, returned as a scalar.

Examples

Default Resampling Factors

Create `src`, a multistage sample rate converter with default properties. `src` combines three filter stages to convert from 192 kHz to 44.1 kHz. Determine its overall interpolation and decimation factors.

```
src = dsp.SampleRateConverter;  
[L,M] = getRateChangeFactors(src)
```

```
L = 147
```

```
M = 640
```

info

System object: `dsp.SampleRateConverter`

Package: `dsp`

Display information about sample rate converter

Syntax

```
info(src)
```

Description

`info(src)` displays information about the multistage `SampleRateConverter` System object, `src`.

Input Arguments

src — **Multistage sample rate converter**

`SampleRateConverter` System object

Multistage sample rate converter, specified as a `SampleRateConverter` System object.

Examples

Default Multistage Sample Rate Converter

Create a multistage sample rate converter with default properties, corresponding to the combined three filter stages used to convert from 192 kHz to 44.1 kHz. Display information about the design.

```
src = dsp.SampleRateConverter
```

```
src =
  dsp.SampleRateConverter with properties:

      InputSampleRate: 192000
      OutputSampleRate: 44100
      OutputRateTolerance: 0
          Bandwidth: 40000
      StopbandAttenuation: 80

info(src)

ans =
'Overall Interpolation Factor      : 147

```

reset

System object: dsp.SampleRateConverter

Package: dsp

Reset internal states of multistage sample rate converter

Syntax

```
reset(src)
```

Description

`reset(src)` resets the internal states of a multistage `SampleRateConverter` System object, `src`, to their initial values.

Input Arguments

src — Multistage sample rate converter

`SampleRateConverter` System object

Multistage sample rate converter, specified as a `SampleRateConverter` System object.

Examples

Reset a Sample Rate Converter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Create a multistage sample rate converter with default properties, corresponding to the combined three filter stages used to convert from 192 kHz to 44.1 kHz. Determine its overall decimation and interpolation factors.

```
src = dsp.SampleRateConverter;  
  
[L,M] = getRateChangeFactors(src);
```

Create a two-channel random signal. Specify a number of samples equal to the decimation factor. Apply the `step` method twice on the signal.

```
x = randn(M,2);  
  
y1 = src(x);  
y2 = src(x);  
  
no = all(y2==y1)
```

```
no =  
  
    1x2 logical array  
  
     0     0
```

The output is different because the internal states of `src` have changed. Use `reset` to reset the converter and call the converter again. Verify that the output is unchanged.

```
reset(src)  
  
y3 = src(x);  
  
yes = all(y3==y1)  
  
yes =  
  
    1x2 logical array  
  
     1     1
```

step

System object: `dsp.SampleRateConverter`

Package: `dsp`

Convert sample rate of signal

Syntax

```
y = step(src,x)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`y = step(src,x)` returns a signal, `y`, corresponding to the input signal, `x`, with sample rate converted by `src`.

Input Arguments

src — Multistage sample rate converter

`SampleRateConverter` System object

Multistage sample rate converter, specified as a `SampleRateConverter` System object.

x — Input signal

vector | matrix

Input signal, specified as a vector or matrix. The row length of `x` must be a multiple of the overall decimation factor. Each column of `x` is treated as a separate channel.

Output Arguments

y — Resampled signal

vector | matrix

Resampled signal, returned as a vector or matrix.

Examples

Convert the Sample Rate of a Sinusoid

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Create a multistage sample rate converter with default properties. The converter converts from 192 kHz to 44.1 kHz in three stages.

```
src = dsp.SampleRateConverter;
```

Use `src` to convert the sample rate of a noisy sinusoid. The sinusoid has a frequency of 20 kHz and is sampled for 0.1 s.

```
f = 20e3;
```

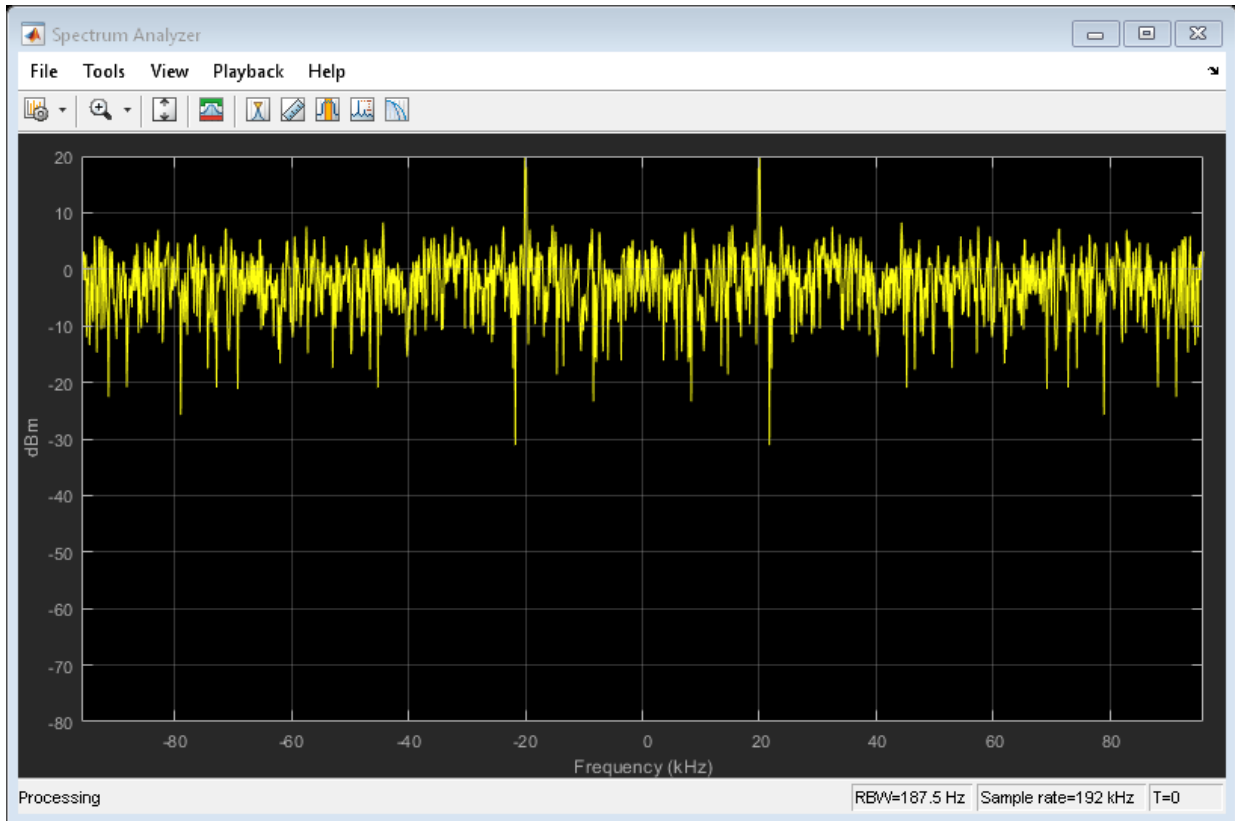

```
FsIn = src.InputSampleRate;  
FsOut = src.OutputSampleRate;
```

```
t1 = (0:1/FsIn:0.1-1/FsIn)';
```

```
sIn = sin(2*pi*f*t1) + randn(size(t1));
```

Estimate the power spectral density of the input.

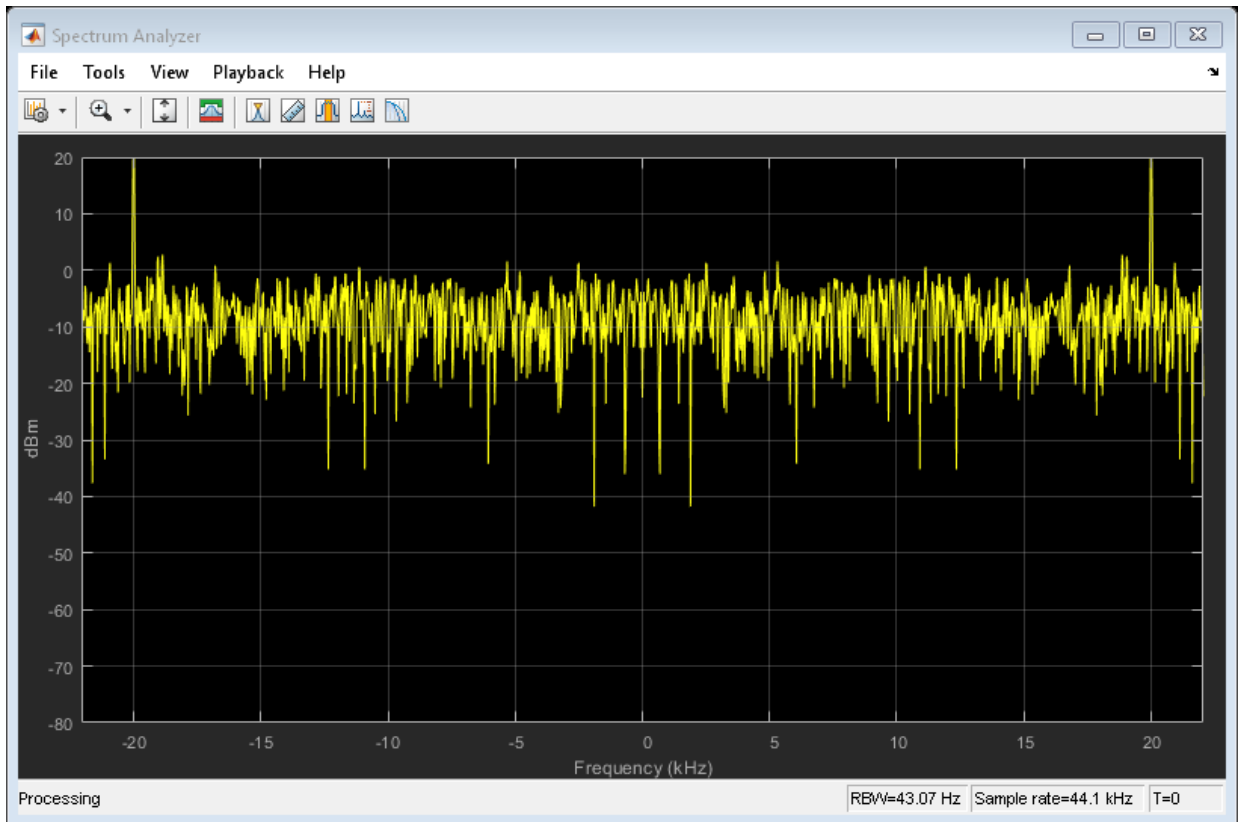

```
hsa = dsp.SpectrumAnalyzer('SampleRate',FsIn);  
hsa(sIn)
```

Convert the sample rate of the signal. Estimate the power spectral density of the output.

```
sOut = src(sIn);
```

```
hsb = dsp.SpectrumAnalyzer('SampleRate',FsOut);  
hsb(sOut)
```

visualizeFilterStages

System object: `dsp.SampleRateConverter`

Package: `dsp`

Visualize filter stages

Syntax

```
visualizeFilterStages(src)
```

Description

`visualizeFilterStages(src)` shows the response of each individual filter stage of `src` using `FVTool`.

Input Arguments

src — Multistage sample rate converter

`SampleRateConverter` System object

Multistage sample rate converter, specified as a `SampleRateConverter` System object.

Examples

Sample Rate Converter Stages

Create a multistage sample rate converter with default properties, corresponding to the combined three filter stages used to convert from 192 kHz to 44.1 kHz. Visualize the stages.

```
src = dsp.SampleRateConverter;  
visualizeFilterStages(src)
```

dsp.ScalarQuantizerDecoder System object

Package: dsp

Convert each index value into quantized output value

Description

The `ScalarQuantizerDecoder` object converts each index value into a quantized output value. The specified codebook defines the set of all possible quantized output values or codewords. Input index values less than 0 are set to 0 and index values greater $N - 1$ are set to $N - 1$. N is the length of the codebook vector.

To convert an index value into a quantized output value:

- 1 Define and set up your scalar quantizer decoder. See “Construction” on page 4-1538.
- 2 Call `step` to convert the index value according to the properties of `dsp.ScalarQuantizerDecoder`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

Construction

`sqdec = dsp.ScalarQuantizerDecoder` returns a scalar quantizer decoder System object, `sqdec`, that transforms zero-based input index values into quantized output values.

`sqdec = dsp.ScalarQuantizerDecoder('PropertyName', PropertyValue, ...)` returns a scalar quantizer decoder object, `sqdec`, with each specified property set to the specified value.

Properties

CodebookSource

How to specify codebook values

Specify how to determine the codebook values as `Property` or `Input port`. The default is `Property`.

Codebook

Codebook

Specify the codebook as a vector of quantized output values that correspond to each index value. The default is `1:10`. This property is tunable.

OutputDataType

Data type of codebook and quantized output

Specify the data type of the codebook and quantized output values as `Same as input`, `double`, `single` or `Custom`. The default is `double`.

Fixed-Point Properties

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a signed or unsigned `numericType` object. This property applies only when you set the “`OutputDataType`” on page 4-0 property to `Custom`. The default is `numericType(true,16)`.

Methods

`step` Decode using scalar quantization

Common to All System Objects	
<code>clone</code>	Create System object with same property values

Common to All System Objects	
getNumInputs	Expected number of inputs to a System object
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Quantize a Signal

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Given a codebook and index values as inputs, determine the corresponding output quantized values.

```
codebook = single([-2.1655 -1.3238 -0.7365 -0.2249 0.2726, ...  
    0.7844 1.3610 2.1599]);  
indices = uint8([1 3 5 7 6 4 2 0]);  
sqdec = dsp.ScalarQuantizerDecoder;  
sqdec.CodebookSource = 'Input port';  
gout = sqdec(indices, codebook);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Scalar Quantizer Decoder block reference page. The object properties correspond to the block parameters, except:

There is no object property that directly corresponds to the **Action for out of range index value** block parameter. The object sets any index values less than 0 to 0 and any index values greater than or equal to N to $N - 1$.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

`dsp.ScalarQuantizerEncoder` | `dsp.VectorQuantizerDecoder`

Introduced in R2012a

step

System object: dsp.ScalarQuantizerDecoder

Package: dsp

Decode using scalar quantization

Syntax

```
Q = step(sqdec, I)
```

```
Q = step(sqdec, I, C)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

`Q = step(sqdec, I)` returns the quantized output values `Q` corresponding to the input indices `I`. The data type of `I` can be `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`. The `OutputDataType` property determines the data type for `Q`.

`Q = step(sqdec, I, C)` uses input `C` as the codebook values when you set the `CodebookSource` property to `Input port`. The data type of `C` can be `double`, `single`, or fixed-point. The output `Q` has the same data type as the codebook input `C`.

dsp.ScalarQuantizerEncoder System object

Package: dsp

Associate input value with index value of quantization region

Description

The `ScalarQuantizerEncoder` object encodes each input value by associating that value with the index value of the quantization region. Then, the object outputs the index of the associated region.

To encode an input value by associating it with an index value of the quantization region:

- 1 Define and set up your scalar quantizer encoder. See “Construction” on page 4-1543.
- 2 Call `step` to encode the input value according to the properties of `dsp.ScalarQuantizerEncoder`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`sqenc = dsp.ScalarQuantizerEncoder` returns a scalar quantizer encoder System object, `sqenc`. This object maps each input value to a quantization region by comparing the input value to the user-specified boundary points.

`sqenc = dsp.ScalarQuantizerEncoder('PropertyName',PropertyValue,...)` returns a scalar quantizer encoder object, `sqenc`, with each specified property set to the specified value.

Properties

BoundaryPointsSource

Source of boundary points

Specify how to determine the boundary points and codebook values as `Property` or `Input port`. The default is `Property`.

Partitioning

Quantizer is bounded or unbounded

Specify the quantizer as `Bounded` or `Unbounded`. The default is `Bounded`.

BoundaryPoints

Boundary points of quantizer regions

Specify the boundary points of quantizer regions as a vector. The vector values must be in ascending order. Let $[p_0 \ p_1 \ p_2 \ p_3 \ \dots \ p_N]$ denote the boundary points property in the quantizer. If the quantizer is bounded, the object uses this property to specify $[p_0 \ p_1 \ p_2 \ p_3 \ \dots \ p_N]$. If the quantizer is unbounded, the object uses this property to specify $[p_1 \ p_2 \ p_3 \ \dots \ p_{(N-1)}]$ and sets $p_0 = -\text{Inf}$ and $p_N = +\text{Inf}$. This property applies when you set the `BoundaryPointsSource` property to `Property`. The default is `1:10`. This property is tunable.

SearchMethod

Find quantizer index by linear or binary search

Specify whether to find the appropriate quantizer index using a linear search or a binary search as one of `Linear` or `Binary`. The computational cost of the linear search method is of the order P and the computational cost of the binary search method is of the order $\log_2(P)$

where P is the number of boundary points. The default is `Linear`.

TiebreakerRule

Behavior when input equals boundary point

Specify whether the input value is assigned to the lower indexed region or higher indexed region when the input value equals boundary point by selecting `Choose the lower index` or `Choose the higher index`. The default is `Choose the lower index`.

CodewordOutputPort

Enable output of codeword value

Set this property to `true` to output the codeword values that correspond to each index value. The default is `false`.

QuantizationErrorOutputPort

Enable output of quantization error

Set this property to `true` to output the quantization error for each input value. The quantization error is the difference between the input value and the quantized output value. The default is `false`.

Codebook

Codebook

Specify the codebook as a vector of quantized output values that correspond to each region. If the `Partitioning` property is `Bounded` and the boundary points vector has length N , you must set this property to a vector of length $N-1$. If the `Partitioning` property is `Unbounded` and the boundary points vector has length N , you must set this property to a vector of length $N+1$. This property applies when you set the `BoundaryPointsSource` property to `Property` and either the `CodewordOutputPort` property or the `QuantizationErrorOutputPort` property is `true`. The default is `1.5:9.5`. This property is tunable.

ClippingStatusOutputPort

Enable output of clipping status

Set this property to `true` to output the clipping status. The output is a 1 when an input value is outside the range defined by the `BoundaryPoints` property. When the value is inside the range, the exception output is a 0. This property applies when you set the `Partitioning` property to `Bounded`. The default is `false`.

OutputIndexDataType

Data type of the index output

Specify the data type of the index output from the object as: `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`. The default is `int32`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest` or `Zero`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

Methods

`step` Encode using scalar quantization

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

Quantize the Varying Fractional Inputs

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Quantize the varying fractional inputs between zero and five to the closest integers, and then plot the results.

```
sqenc = dsp.ScalarQuantizerEncoder;
sqenc.BoundaryPoints = [-.001 .499 1.499 ...
    2.499 3.499 4.499 5.001];
sqenc.CodewordOutputPort = true;
sqenc.Codebook = [0 1 2 3 4 5];
input = (0:0.02:5)';
[index, quantizedValue] = sqenc(input);
plot(1:length(input), [input quantizedValue]);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Scalar Quantizer Encoder block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

See Also

`dsp.ScalarQuantizerDecoder` | `dsp.VectorQuantizerEncoder`

Introduced in R2012a

step

System object: dsp.ScalarQuantizerEncoder

Package: dsp

Encode using scalar quantization

Syntax

```
INDEX= step(sqenc, INPUT)
[...] = step(sqenc, INPUT, BPOINTS)
[...] = step(sqenc, INPUT, BPOINTS, CODEBOOK)
[... , CODEWORD] = step(sqenc, ...)
[... , QERR] = step(sqenc, ...)
[... , CLIPSTATUS] = step(sqenc, ...)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

`INDEX= step(sqenc, INPUT)` returns the `INDEX` of the quantization region to which the `INPUT` belongs. The input data, boundary points, codebook values, quantized output values, and the quantization error must have the same data type whenever they are present.

`[...] = step(sqenc, INPUT, BPOINTS)` when the `BoundaryPointsSource` property is `Input port`, uses input `BPOINTS` as the boundary points .

`[...] = step(sqenc, INPUT, BPOINTS, CODEBOOK)` uses input `BPOINTS` as the boundary points and input `CODEBOOK` as the codebook when the `BoundaryPointsSource` property is `Input port` and either the

CodewordOutputPort property or the QuantizationErrorOutputPort property is true.

[..., CODEWORD] = step(sqenc, ...) outputs the CODEWORD values that corresponds to each index value when the CodewordOutputPort property is true.

[..., QERR] = step(sqenc, ...) outputs the quantization error QERR for each input value when the QuantizationErrorOutputPort property is true.

[..., CLIPSTATUS] = step(sqenc, ...) also returns output CLIPSTATUS as the clipping status output port for each input value when the Partitioning property is Bounded and the ClippingStatusOutputPort property is true. If an input value is outside the range defined by the BoundaryPoints property, CLIPSTATUS is true. If an input value is inside the range, CLIPSTATUS is false.

Note obj specifies the System object on which to run this step method.

The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

dsp.SignalSink System object

Package: dsp

Log simulation data in buffer

Description

The `SignalSink` object logs MATLAB simulation data. This object accepts any numeric data type.

To log MATLAB simulation data :

- 1 Define and set up your signal sink. See “Construction” on page 4-1552.
- 2 Call `step` to log the simulation data according to the properties of `dsp.SignalSink`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = dsp.SignalSink` returns a signal sink, `H`, that logs 2-D input data in the object.

`H = dsp.SignalSink('PropertyName', PropertyValue, ...)` returns a signal sink, `H`, with each specified property set to the specified value.

Properties

BufferLength

Maximum number of input frames to log

Specify the maximum number of frames to log. The object always preserves the most recent data in the buffer. When you specify a buffer length that is greater than the input length, the object pads the end of the logged data with zeros. To capture all input data without extra padding, set the `BufferLength` property to `inf`. The default is `inf`.

Decimation

Decimation factor

Setting this property to any positive integer d causes the signal sink to write data at every d th sample. The default is 1.

FrameHandlingMode

Output dimensionality for frame-based inputs

Set the dimension of the output array for frame-based inputs as 2-D array (concatenate) or 3-D array (separate). Concatenation occurs along the first dimension for 2-D array (concatenate). The default is 2-D array (concatenate).

Buffer

Logged Data (read only)

The signal sink writes simulation data into a buffer. Specify the maximum length of the buffer with the `BufferLength` property.

Methods

`reset` Reset internal states of signal logger object
`step` Store signal in buffer

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object

Common to All System Objects	
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Log Input Data

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
hlog = dsp.SignalSink;
for i=1:10
    y = sin(i);
    hlog(y);
end
log = hlog.Buffer;
display(log);
```

```
log =
    0.8415
    0.9093
    0.1411
   -0.7568
   -0.9589
   -0.2794
    0.6570
    0.9894
    0.4121
   -0.5440
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the To Workspace block reference page. The object properties correspond to the block properties, except:

The object always generates fixed-point output for fixed-point input.

`dsp.SignalSource`

Introduced in R2012b

reset

System object: dsp.SignalSink

Package: dsp

Reset internal states of signal logger object

Syntax

`reset(H)`

Description

`reset(H)` sets the internal states of the `SignalSink` object `H` to their initial values.

step

System object: dsp.SignalSink

Package: dsp

Store signal in buffer

Syntax

`step(H, Y)`

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

`step(H, Y)` buffers the signal `Y`. The buffer may be accessed at any time from the `Buffer` property of `H`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.SignalSource System object

Package: dsp

Import variable from workspace

Description

The `SignalSource` object imports a variable from the MATLAB workspace.

To import a variable from the MATLAB workspace:

- 1 Define and set up your signal source. See “Construction” on page 4-1558.
- 2 Call `step` to import the variable according to the properties of `dsp.SignalSource`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

Construction

`src = dsp.SignalSource` returns a signal source System object, `src`, that outputs the variable one sample or frame at a time.

`src = dsp.SignalSource('PropertyName', PropertyValue, ...)` returns a signal source object, `src`, with each specified property set to the specified value.

`src = dsp.SignalSource(signal, spf, 'PropertyName', PropertyValue, ...)` returns a signal source object, `src`, with the `Signal` property set to `signal`, the “SamplesPerFrame” on page 4-0 property set to `spf`, and other specified properties set to the specified values.

Properties

Signal

Variable or expression containing the signal

Specify the name of the workspace variable from which to import the signal, or a valid expression specifying the signal. The default is `[1:10]`.

SamplesPerFrame

Number of samples per output frame

Specify the number of samples to buffer into each output frame. This property must be 1 when you specify a 3-D array in the `Signal` property. The default is 1.

SignalEndAction

Action after final signal values are generated

Specify the output after all of the specified signal samples have been generated as one of `Set to zero`, `Hold final value`, or `Cyclic repetition`. The default is `Set to zero`.

Methods

`isDone` End-of-file status for signal reader object
`reset` Reset internal states of signal reader object
`step` Read one sample or frame of signal

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object

Common to All System Objects	
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Create a Signal Source

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject()` becomes `step(myObject)`.

Create a signal source to output one sample at a time.

```
src1 = dsp.SignalSource;
src1.Signal = randn(1024, 1);
y1 = zeros(1024,1);
idx = 1;
while(~isDone(src1))
    y1(idx) = src1();
    idx = idx+1;
end
```

Create a signal source to output vectors.

```
src2 = dsp.SignalSource(randn(1024, 1), 128);
y2 = src2(); % y2 is a 128-by-1 frame of samples
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Signal From Workspace block reference page. The object properties correspond to the block parameters, except:

The object does not have properties that correspond to the **Sample time** or **Warn when frame size does not evenly divide input length** block parameters.

Extended Capabilities

Syntax

```
isDone(src)
```

Description

`isDone(src)` returns a logical value indicating whether or not the `SignalSource` object, `src`, has reached the end of the imported signal. If the `SignalEndAction` property is set to `Cyclic` repetition, this method will return `true` every time the reader reaches the end.

reset

System object: dsp.SignalSource

Package: dsp

Reset internal states of signal reader object

Syntax

```
reset(src)
```

Description

`reset(src)` resets the signal reader object `src`, to start reading from the beginning of the imported signal.

step

System object: dsp.SignalSource

Package: dsp

Read one sample or frame of signal

Syntax

```
Y = step(src)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

`Y = step(src)` outputs one sample or frame of data, `Y`, from each column of the imported signal. The imported signal is the variable or expression you specify for the `Signal` property of the `SignalSource` System object `src`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.SineWave System object

Package: dsp

Generate discrete sine wave

Description

The `dsp.SineWave` System object generates a real or complex, multichannel sinusoidal signal with independent amplitude, frequency, and phase in each output channel.

For both real and complex sinusoids, the “Amplitude” on page 4-0 , “Frequency” on page 4-0 , and “PhaseOffset” on page 4-0 properties can be scalars or length- N vectors, where N is the number of channels in the output. When you specify at least one of these properties as a length- N vector, scalar values specified for the other properties are applied to each of the N channels.

To generate a discrete-time sinusoidal signal:

- 1 Create the `dsp.SineWave` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#) (MATLAB).

Creation

Syntax

```
sine = dsp.SineWave
sine = dsp.SineWave(Name, Value)
sine = dsp.SineWave(amp, freq, phase, Name, Value)
```

Description

`sine = dsp.SineWave` creates a sine wave object that generates a real-valued sinusoid with an amplitude of 1, a frequency of 100 Hz, and a phase offset of 0. By default, the sine wave object generates only one sample.

`sine = dsp.SineWave(Name, Value)` creates a sine wave object with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `sine = dsp.SineWave('Amplitude',2);`

`sine = dsp.SineWave(amp, freq, phase, Name, Value)` creates a sine wave object with the “Amplitude” on page 4-0 property set to `amp`, “Frequency” on page 4-0 property set to `freq`, “PhaseOffset” on page 4-0 property set to `phase`, and anyother specified properties set to the specified values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects \(MATLAB\)](#).

Amplitude — Amplitude of sine wave

1 (default) | scalar | vector

Amplitude of the sine wave, specified as one of the following:

- scalar — A scalar applies to all channels.
- vector — A length- N vector contains the amplitudes of the sine waves in each of the N output channels. The vector length must be the same as that specified for the “Frequency” on page 4-0 and “PhaseOffset” on page 4-0 properties.

Tunable: Yes

Dependencies

This property is tunable only when you set “Method” on page 4-0 to either 'Trigonometric function' or 'Differential'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Frequency — Frequency of sine wave

100 (default) | scalar | vector

Frequency of the sine wave in Hz, specified as one of the following:

- scalar — A scalar applies to all channels.
- vector — A length- N vector contains the frequencies of the sine waves in each of the N output channels. The vector length must be the same as that specified for the “Amplitude” on page 4-0 and “PhaseOffset” on page 4-0 properties.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

PhaseOffset — Phase offset of sine wave

0 (default) | scalar | vector

Phase offset of the sine wave in radians, specified as one of the following:

- scalar — A scalar applies to all channels.
- vector — A length- N vector contains the phase offsets of the sine waves in each of the N output channels. The vector length must be the same as that specified for the “Amplitude” on page 4-0 and “Frequency” on page 4-0 properties.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

ComplexOutput — Flag that indicates whether waveform is real or complex

false (default) | true

Flag that indicates whether the waveform is real or complex, specified as either:

- false — The waveform output is real.
- true — The waveform output is complex.

Method — Method used to generate sinusoids

'Trigonometric function' (default) | 'Table lookup' | 'Differential'

Method used to generate sinusoids, specified as one of the following:

- 'Trigonometric function' — The object computes the sinusoid by sampling the continuous-time function.
- 'Table lookup' — The object precomputes the unique samples of every output sinusoid at the start of the simulation, and recalls the samples from memory as needed.
- 'Differential' — The object uses an incremental algorithm. This algorithm computes the output samples based on the output values computed at the previous sample time and precomputed update terms.

TableOptimization — Optimize table of sine values for speed or memory

'Speed' (default) | 'Memory'

Optimize table of sine values for speed or memory, specified as either:

- 'Speed' — The table contains k elements, where k is the number of input samples in one full period of the sine wave. The period of each sinusoid must be an integer multiple of $1/F_s$, where F_s is the value of the “SampleRate” on page 4-0 property value. That is, each element of the “Frequency” on page 4-0 property must be of the form F_s/m , where m is an integer greater than 1.
- 'Memory' — The table contains $k/4$ elements.

Dependencies

This property applies only when you set the Method property to 'Table lookup'.

SampleRate — Sample rate of output signal

1000 (default) | positive scalar

Sample rate of output signal in Hz, specified as a positive scalar.

Example: 44100

Example: 22050

SamplesPerFrame — Number of samples per frame

1 (default) | positive integer

Number of consecutive samples from each sinusoid to buffer into the output frame, specified as a positive integer.

Example: 1000

Example: 5000

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

OutputDataType — Data type of the sine wave output

`'double'` (default) | `'single'` | `'Custom'`

Data type of the sine wave output, specified as `'double'`, `'single'`, or `'Custom'`.

Fixed-Point Properties

CustomOutputDataType — Output word and fraction lengths

`numericType([],16)` (default) | `numericType([],32,30)`

Output word and fraction lengths, specified as an autosigned numeric type with a word length of 16.

Example: `numericType([],32,30)`

Example: `numericType([],16,15)`

Dependencies

This property applies only when you set the “Method” on page 4-0 property to `'Table lookup'` and the “OutputDataType” on page 4-0 property to `'Custom'`.

Usage

Syntax

```
sineOut = sine()
```

Description

`sineOut = sine()` creates the sine wave output, `sineOut`.

Output Arguments

sineOut — Sine wave output

vector | matrix

Sine wave output, returned as a vector or matrix. The “SamplesPerFrame” on page 4-0 property determines the number of rows in the output matrix. If the “Frequency” on page 4-0 or the “PhaseOffset” on page 4-0 property is a vector, the length of the vector determines the number of columns (channels) in the output matrix. If the Frequency or the PhaseOffset properties is a scalar, then the number of channels in the output matrix is 1.

The “OutputDataType” on page 4-0 property sets the data type of the output.

Data Types: `single` | `double` | `fi`

Note For versions earlier than R2016b, use the `step` function to run the System object™ algorithm. The arguments to `step` are the object you created, followed by the arguments shown in this section.

For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>clone</code>	Create duplicate System object
<code>getNumInputs</code>	Number of inputs required to call the System object
<code>getNumOutputs</code>	Number of outputs from calling the System object
<code>isLocked</code>	Determine if System object is locked
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Generate a Sine Wave Signal

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Generate a sine wave with an amplitude of 2, frequency of 10 Hz, and an initial phase of 0.

```
sine1 = dsp.SineWave(2,10);  
sine1.SamplesPerFrame = 1000;  
y = sine1();  
plot(y)
```

Generate two sine waves offset by a phase of $\pi/2$ radians.

```
sine2 = dsp.SineWave;  
sine2.Frequency = 10;  
sine2.PhaseOffset = [0 pi/2];  
sine2.SamplesPerFrame = 1000;  
y = sine2();  
plot(y)
```

Definitions

Sinusoid

A real-valued, discrete-time sinusoid is defined as:

$$y(n) = A \sin(2\pi fn + \phi)$$

where A is the amplitude, f is the frequency in Hz, and ϕ is the initial phase, or phase offset, in radians.

A complex sinusoid is defined as:

$$y(n) = Ae^{j(2\pi fn + \phi)}$$

Algorithms

Trigonometric Function

The trigonometric function method computes the sinusoid in the i th channel, y_i , by sampling the continuous function

$$y_i = A_i \sin(2\pi f_i t + \phi_i) \quad (\text{real})$$

or

$$y_i = A_i e^{j(2\pi f_i t + \phi_i)} \quad (\text{complex})$$

with a period of T_s , where you specify T_s in the sample time.

At each sample time, the algorithm evaluates the sine function at the appropriate time value *within the first cycle* of the sinusoid. By constraining trigonometric evaluations to the first cycle of each sinusoid, the algorithm avoids the imprecision of computing the sine of very large numbers. This constraint also eliminates the possibility of discontinuity during extended operations, when an absolute time variable might overflow. This method therefore avoids the memory demands of the table lookup method at the expense of many more floating-point operations.

Table Lookup

The table lookup method precomputes the *unique* samples of every output sinusoid at the start of the simulation, and recalls the samples from memory as needed. Because a table of finite length can only be constructed when all output sequences repeat, the method requires that the period of every sinusoid in the output be evenly divisible by the sample period. That is, $1/(f_i T_s) = k_i$ must be an integer value for every channel $i = 1, 2, \dots, N$.

When the algorithm optimizes the table of sine values for `Speed`, the table constructed for each channel contains k_i elements. When the optimization is for `Memory`, the table constructed for each channel contains $k_i/4$ elements.

For long output sequences, the table lookup method requires far fewer floating-point operations than any of the other methods. However, the method can demand considerably more memory, especially for high sample rates (long tables). This method is recommended for models that are intended to emulate or generate code for DSP hardware, which need to be optimized for execution speed.

Note The lookup table for this object is constructed from double-precision floating-point values. When you use the `Table Lookup` computation mode, the maximum amount of precision you can achieve in your output is 53 bits. Setting the word length of the output data type to values greater than 53 bits does not improve the precision of your output.

Differential

The differential method uses an incremental algorithm. This algorithm computes the output samples based on the output values computed at the previous sample time (and precomputed update terms) by making use of the following identities.

$$\begin{aligned}\sin(t + T_s) &= \sin(t)\cos(T_s) + \cos(t)\sin(T_s) \\ \cos(t + T_s) &= \cos(t)\cos(T_s) - \sin(t)\sin(T_s)\end{aligned}$$

The update equations for the sinusoid in the i th channel, y_i , can therefore be written in matrix form as

$$\begin{bmatrix} \sin\{2\pi f_i(t + T_s) + \phi_i\} \\ \cos\{2\pi f_i(t + T_s) + \phi_i\} \end{bmatrix} = \begin{bmatrix} \cos(2\pi f_i T_s) & \sin(2\pi f_i T_s) \\ -\sin(2\pi f_i T_s) & \cos(2\pi f_i T_s) \end{bmatrix} \begin{bmatrix} \sin(2\pi f_i t + \phi_i) \\ \cos(2\pi f_i t + \phi_i) \end{bmatrix}$$

where you specify T_s in the sample time. Since T_s is constant, the right-hand matrix is a constant and can be computed once at the start of the simulation. The value of $A_i \sin[2\pi f_i(t + T_s) + \phi_i]$ is then computed from the values of $\sin(2\pi f_i t + \phi_i)$ and $\cos(2\pi f_i t + \phi_i)$ by a simple matrix multiplication at each time step.

This mode offers reduced computational load, but is subject to drift over time due to cumulative quantization error. Because the method is not contingent on an absolute time value, there is no danger of discontinuity during extended operations, when an absolute time variable might overflow.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- This object has no tunable properties for code generation.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Introduced in R2012a

dsp.SpectrumAnalyzer System object

Package: dsp

Display frequency spectrum of time-domain signals

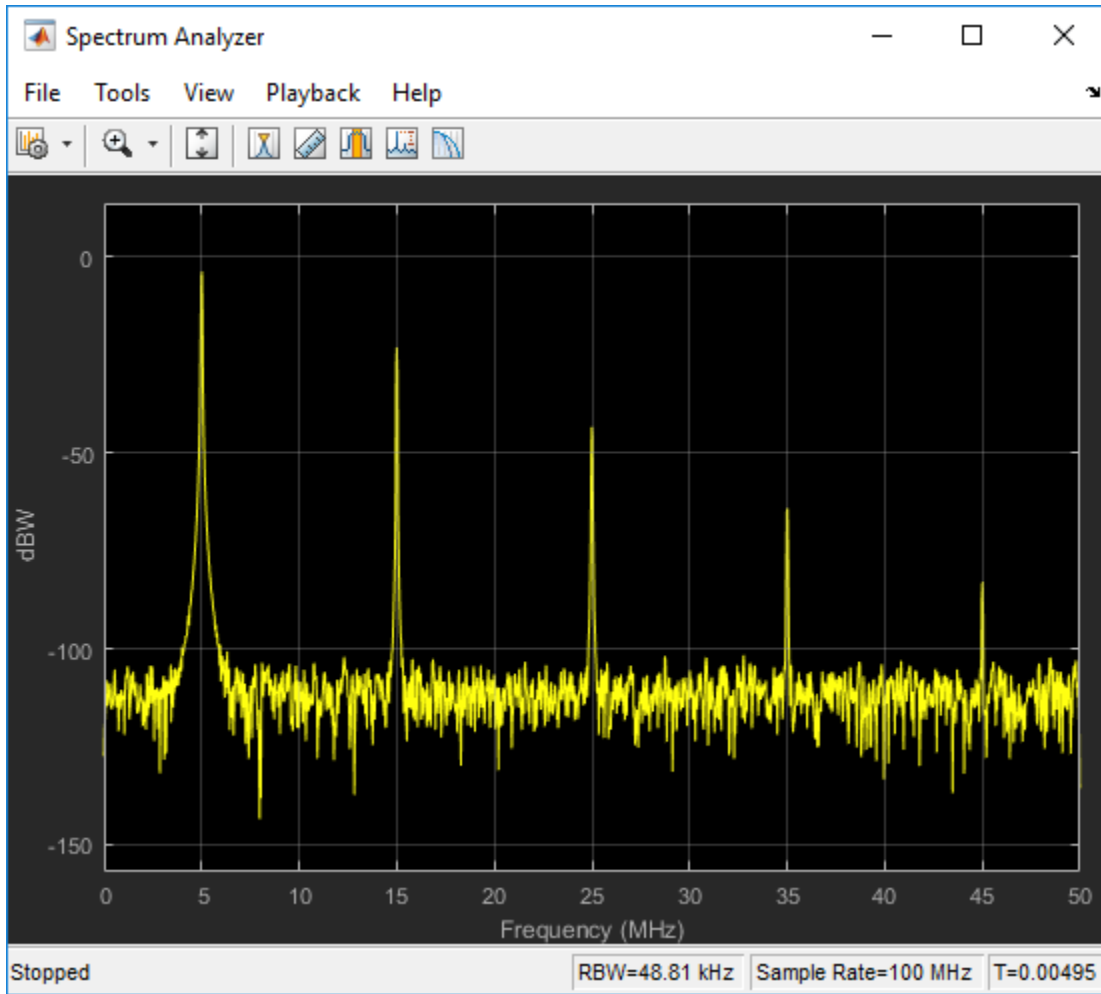

Description

The Spectrum Analyzer System object displays the frequency spectrum of time-domain signals. This scope supports variable-size input, which allows the input frame size to change. Frame size is the first dimension of the input vector. The number of input channels must remain constant.

To display the spectra of signals in the Spectrum Analyzer:

- 1** Create the dsp.SpectrumAnalyzer object and set its properties.
- 2** Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#) (MATLAB).

Creation

Syntax

```
scope = dsp.SpectrumAnalyzer
```

```
scope = dsp.SpectrumAnalyzer(ports)
scope = dsp.SpectrumAnalyzer(Name,Value)
```

Description

`scope = dsp.SpectrumAnalyzer` creates a Spectrum Analyzer System object. This object displays the frequency spectrum of real- and complex-valued floating- and fixed-point signals.

`scope = dsp.SpectrumAnalyzer(ports)` creates a Spectrum Analyzer object and sets the `NumInputPorts` property to the value of `ports`.

`scope = dsp.SpectrumAnalyzer(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects \(MATLAB\)](#).

Frequently Used

NumInputPorts — Number of input ports

1 (default) | integer between [1, 96]

Number of input ports, specified as a positive integer. Each signal coming through an input port becomes a separate channel in the scope. You must invoke the scope with the same number of inputs as the value of this property.

sampleRate — Sample rate of input

10e3 (default) | finite scalar

Specify the sample rate, in hertz, of the input signals as a finite numeric scalar.

UI Use

Open the **Spectrum Settings**. In the **Main options** section, set **Sample rate (Hz)**.

SpectrumType — Type of spectrum to show

'Power' (default) | 'Power density' | 'RMS'

Specify the spectrum type to display.

'Power' - Power spectrum

'Power density' - Power spectral density. The power spectral density is the magnitude squared of the spectrum normalized to a bandwidth of 1 hertz.

'RMS' - Root mean squared. The root mean squared shows the square root of the sum of the squared means. This option is useful when viewing the frequency of voltage or current signals.

Tunable: Yes

UI Use

Open the **Spectrum Settings**. In the **Main options** section, set **Type**.

ViewType — Viewer type

'Spectrum' (default) | 'Spectrogram' | 'Spectrum and spectrogram'

Specify the spectrum type as one of 'Spectrum', 'Spectrogram', or 'Spectrum and spectrogram'.

- 'Spectrum' — shows the power spectrum.
- 'Spectrogram' — shows frequency content over time. Each line of the spectrogram is one periodogram. Time scrolls from the bottom to the top of the display. The most recent spectrogram update is at the bottom of the display.
- 'Spectrum and Spectrogram' — shows a dual view of a spectrum and spectrogram.

Tunable: Yes

UI Use

Open the **Spectrum Settings**. In the **Main options** section, set **View**.

Method — Spectrum estimation method`'Welch'` (default) | `'Filter Bank'`

Specify the spectrum estimation method as `Welch` or `Filter bank`.

UI Use

Open the **Spectrum Settings**. In the **Main options** section, set **Method**.

NumTapsPerBand — Number of filter taps per frequency band`12` (default) | positive scalar

Specify the number of filter taps or coefficients for each frequency band. This corresponds to the number of filter coefficients per polyphase branch. The total number of filter coefficients is equal to `NumTapsPerBand + FFTLength`.

Dependency

To enable this property, set `Method` to `'Filter Bank'`

UI Use

Open the **Spectrum Settings**. In the **Main options** section, set **Taps per band**.

SpectralAverages — Number of spectral averages`1` (default) | positive integer

The Spectrum Analyzer computes the current power spectrum estimate by computing a running average of the last N power spectrum estimates. This property defines N .

Tunable: Yes

Dependency

To enable this property, set `ViewType` to `'Spectrum'`.

UI Use

Open the **Spectrum Settings**. In the **Trace options** section, set **Averages**.

PlotAsTwoSidedSpectrum — Two-sided spectrum flag`true` (default) | `false`

- `true` - Compute and plot two-sided spectral estimates. When the input signal is complex valued, you must set this property to `true`.

- `false` - Compute and plot one-sided spectral estimates. If you set this property to `false`, then the input signal must be real valued.

When this property is `false`, Spectrum Analyzer uses power-folding. The *y*-axis values are twice the amplitude that they would be if this property were set to `true`, except at 0 and the Nyquist frequency. A one-sided power spectral density (PSD) contains the total power of the signal in the frequency interval from DC to half of the Nyquist rate. For more information, see `pwelch`.

UI Use

Open the **Spectrum Settings**. In the **Trace options** section, select **Two-sided spectrum**.

FrequencyScale — Frequency scale

'Linear' (default) | 'Log'

- 'Log' - displays the frequencies on the *x*-axis on a logarithmic scale. To use the 'Log' setting, you must also set the `PlotAsTwoSidedSpectrum` property to `false`.
- 'Linear' - displays the frequencies on the *x*-axis on a linear scale. To use the 'Linear' setting, you must also set the `PlotAsTwoSidedSpectrum` property to `true`.

Tunable: Yes

UI Use

Open the **Spectrum Settings**. In the **Trace options** section, set **Scale**.

AxesScaling — Axes scaling mode

'Auto' (default) | 'Manual' | 'OnceAtStop' | 'Updates'

Specify when the scope automatically scales the axes. Valid values are:

- 'Auto' — The scope scales the axes as needed to fit the data, both during and after simulation.
- 'Manual' — The scope does not scale the axes automatically.
- 'OnceAtStop' — The scope scales the axes when the simulation stops.
- 'Updates' — The scope scales the axes once after 10 updates.

UI Use

Select **Tools > Axes Scaling**.

Advanced**FrequencyResolutionMethod — Frequency resolution method**

'RBW' (default) | 'WindowLength' | 'NumFrequencyBands'

Specify the frequency resolution method of the Spectrum Analyzer.

- 'RBW' - the RBWSource and RBW properties control the frequency resolution (in Hz) of the analyzer. The FFT length is the window length that results from achieving the specified RBW value or 1024, whichever is larger.
- 'WindowLength' - applies only when the Method property is set to 'Welch'. The WindowLength property controls the frequency resolution. You can control the number of FFT points only when the FrequencyResolutionMethod property is 'WindowLength'.
- 'NumFrequencyBands' - applies only when the Method property is set to 'Filter Bank'. The FFTLengthSource and FFTLength properties control the frequency resolution.

Tunable: Yes

UI Use

Open the **Spectrum Settings**. In the **Main options** section, set the frequency resolution method by selecting the **RBW (Hz)** dropdown.

AxesLayout — Orientation of the spectrum and spectrogram

'Vertical' (default) | 'Horizontal'

Specify the layout type as 'Horizontal' or 'Vertical'. A vertical layout stacks the spectrum above the spectrogram. A horizontal layout puts the two views side-by-side.

Tunable: Yes

Dependency

To enable this property, set ViewType to 'Spectrum and spectrogram'.

UI Use

Open the **Spectrum Settings**. Set **Axes layout**.

RBWSource — Source of resolution bandwidth value

'Auto' (default) | 'Property'

Specify the source of the resolution bandwidth (RBW) as either 'Auto' or 'Property'.

- 'Auto' - The Spectrum Analyzer adjusts the spectral estimation resolution to ensure that there are 1024 RBW intervals over the defined frequency span.
- 'Property' - Specify the resolution bandwidth directly using the RBW property.

Tunable: Yes

Dependency

To enable this property, set the FrequencyResolutionMethod property to 'RBW'.

UI Use

Open the **Spectrum Settings**. In the **Main options** section, set **RBW (Hz)**.

RBW — Resolution bandwidth

9.76 (default) | real positive scalar

RBW controls the spectral resolution of Spectrum Analyzer. Specify the resolution bandwidth in hertz as a real positive scalar. You must specify a value to ensure that there are at least two RBW intervals over the specified frequency span. Thus, the ratio of the overall span to RBW must be greater than two:

$$\frac{\text{span}}{\text{RBW}} > 2$$

You can specify the overall span in different ways based on how you set the FrequencySpan property.

Tunable: Yes

Dependency

To enable, set:

- FrequencyResolutionMethod to 'RBW'

- RBWSource to 'Property'

UI Use

Open the **Spectrum Settings**. In the **Main options** section, set **RBW (Hz)**.

WindowLength — Window length

1024 (default) | integer greater than 2

Control the frequency resolution by specifying the window length, in samples used to compute the spectral estimates. The window length must be an integer scalar greater than 2.

Tunable: Yes

Dependencies

To enable this property, set:

- FrequencyResolutionMethod to 'WindowLength', which controls the frequency resolution based on your window length setting
- Method to 'Welch'

UI Use

Open the **Spectrum Settings**. Change the **RBW (Hz)** dropdown to Window length.

FFTLengthSource — Source of the FFT length

'Auto' (default) | 'Property'

- 'Auto' - sets the FFT length to the window length specified in the WindowLength property or 1024, whichever is larger.
- 'Property' - number of FFT points using the FFTLength property. FFTLength must be greater than WindowLength.

Tunable: Yes

Dependency

To enable this property, set FrequencyResolutionMethod to 'WindowLength'.

UI Use

Open the **Spectrum Settings**. In the **Main options** section, next to the **RBW (Hz)** option, enter a number or select `Auto`.

FFTLength — Length of FFT

1024 (default) | positive integer

Specify the length of the FFT that the Spectrum Analyzer uses to compute spectral estimates.

If `FrequencyResolutionMethod` is 'RBW', the FFT length is set as the window length required to achieve the specified resolution bandwidth value or 1024, whichever is larger.

Tunable: Yes

Dependencies

To use this property, the following must be true:

- `FFTLength` is greater than or equal to the `WindowLength`.
- `FrequencyResolutionMethod` is set to 'WindowLength' or 'NumFrequencyBands'
- `FFTLengthSource` is set to 'Property'.

UI Use

Open the **Spectrum Settings**. In the **Main options** section, next to the **RBW (Hz)** option, enter a number or select `Auto`.

FrequencyOffset — Frequency offset

0 (default) | scalar | vector

- scalar - Apply the same frequency offset to all channels, specified in hertz.
- vector - apply a specific frequency offset for each channel, specify a vector of frequencies. The vector length must be equal to number of input channels.

The Frequency-axis values are offset by the values specified in this property. The overall span must fall within the “Nyquist frequency interval” on page 4-1616. You can control the overall span in different ways based on how you set the `FrequencySpan` property.

Tunable: Yes

UI Use

Open the **Spectrum Settings**. In the **Trace options** section, set **Offset (Hz)**.

FrequencySpan — Frequency span mode

'Full' (default) | 'Span and center frequency' | 'Start and stop frequencies'

- 'Full' - The Spectrum Analyzer computes and plots the spectrum over the entire “Nyquist frequency interval” on page 4-1616.
- 'Span and center frequency' - The Spectrum Analyzer computes and plots the spectrum over the interval specified by the Span and CenterFrequency properties.
- 'Start and stop frequencies' - The Spectrum Analyzer computes and plots the spectrum over the interval specified by the StartFrequency and StopFrequency properties.

Tunable: Yes

UI Use

Open the **Spectrum Settings**. In the **Main options** section, select **Full frequency span** for 'Full'. Otherwise, clear the **Full frequency span** check box and choose between Span or FStart.

StartFrequency — Start frequency to compute spectrum

-5e3 (default) | real scalar

Start of the frequency interval over which spectrum is computed, specified in hertz as a real scalar. The overall span, which is defined by this property and StopFrequency, must fall within the “Nyquist frequency interval” on page 4-1616.

Tunable: Yes

Dependency

To enable this property, set FrequencySpan to 'Start and stop frequencies'.

UI Use

Open the **Spectrum Settings**. In the **Main options** section, clear the **Full frequency span** and change Span to FStart. Set **FStart (Hz)**.

StopFrequency — Stop frequency to compute spectrum

5e3 (default) | real scalar

End of the frequency interval over which spectrum is computed, specified in hertz as a real scalar. The overall span, which is defined by this property and the StartFrequency property, must fall within the Nyquist frequency interval on page 4-1616.

Tunable: Yes

Dependency

To enable this property, set FrequencySpan to 'Start and stop frequencies'.

UI Use

Open the **Spectrum Settings**. In the **Main options** section, clear the **Full frequency span** and change Span to FStart. Set **FStop (Hz)**.

CenterFrequency — Center of frequency span

0 (default) | real scalar

Specify in hertz the center frequency of the span over which the Spectrum Analyzer computes and plots the spectrum. The overall frequency span, defined by the Span and this property, must fall within the “Nyquist frequency interval” on page 4-1616.

Tunable: Yes

Dependency

To enable this property, set FrequencySpan to 'Span and center frequency'.

UI Use

Open the **Spectrum Settings**. In the **Main**, clear **Full frequency span** and set **CF (Hz)**.

Span — Frequency span to compute spectrum

10e3 (default) | real positive scalar

Specify the frequency span, in hertz, over which the Spectrum Analyzer computes and plots the spectrum. The overall span, defined by this property and the CenterFrequency property, must fall within the “Nyquist frequency interval” on page 4-1616.

Tunable: Yes

Dependency

To enable this property, set `FrequencySpan` to `'Span and center frequency'`.

UI Use

Open the **Spectrum Settings**. In the **Main options** section, clear the **Full frequency span** check box and set `Span`.

TimeResolutionSource — Source of the time resolution value

`'Auto'` (default) | `'Property'`

Specify the source for the time resolution of each spectrogram line as either `'Auto'` or `'Property'`. The `TimeResolution` property shows the time resolution for the different frequency resolution methods and time resolution properties.

Tunable: Yes

Dependency

To enable this property, set `ViewType` to `'Spectrogram'` or `'Spectrum and spectrogram'`.

UI Use

Open the **Spectrum Settings**. In the **Spectrogram options** section, set **Time res (s)**.

TimeResolution — Time resolution

`0.001` (default) | positive scalar

Specify the time resolution of each spectrogram line as a positive scalar, expressed in seconds.

The time resolution value is determined based on frequency resolution method, the RBW setting, and the time resolution setting.

Method	Frequency Resolution Method	Frequency Resolution Setting	Time Resolution Setting	Resulting Time Resolution in Seconds
Welch or Filter Bank	RBW (Hz)	Auto	Auto	1/RBW

Method	Frequency Resolution Method	Frequency Resolution Setting	Time Resolution Setting	Resulting Time Resolution in Seconds
Welch or Filter Bank	RBW (Hz)	Auto	Manually entered	Time Resolution
Welch or Filter Bank	RBW (Hz)	Manually entered	Auto	1/RBW
Welch or Filter Bank	RBW (Hz)	Manually entered	Manually entered	Must be equal to or greater than the minimum attainable time resolution, 1/RBW. Several spectral estimates are combined into one spectrogram line to obtain the desired time resolution. Interpolation is used to obtain time resolution values that are not integer multiples of 1/RBW.
Welch	Window length	—	Auto	1/RBW
Welch	Window length	—	Manually entered	Must be equal to or greater than the minimum attainable time resolution. Several spectral estimates are combined into one spectrogram line to obtain the desired time resolution. Interpolation is used to obtain time resolution values that are not integer multiples of 1/RBW.

Method	Frequency Resolution Method	Frequency Resolution Setting	Time Resolution Setting	Resulting Time Resolution in Seconds
Filter Bank	Number of frequency bands	—	Auto	1/RBW
Filter Bank	Number of frequency bands	—	Manually entered	Must be equal to or greater than the minimum attainable time resolution, 1/RBW.

Tunable: Yes

Dependency

To enable this property, set:

- ViewType to 'Spectrogram' or 'Spectrum and spectrogram'
- TimeResolutionSource to 'Property'.

UI Use

Open the **Spectrum Settings**. In the **Spectrogram options** section, in the **Time res (s)** box, enter a number.

TimeSpanSource — Source of time span value

'Auto' (default) | 'Property'

Specify the source for the time span of the spectrogram as either 'Auto' or 'Property'. If you set this property to 'Auto', the spectrogram displays 100 spectrogram lines at any given time. If you set this property to 'Property', the spectrogram uses the time duration you specify in seconds in the TimeSpan property.

Tunable: Yes

Dependency

To enable this property, set ViewType to 'Spectrogram' or 'Spectrum and spectrogram'.

UI Use

Open the **Spectrum Settings**. In the **Spectrogram options** section, set **Time span (s)**.

TimeSpan — Time span

0.1 (default) | positive scalar

Specify the time span of the spectrogram display in seconds. You must set the time span to be at least twice as large as the duration of the number of samples required for a spectral update.

Tunable: Yes

Dependency

To enable this property, set:

- ViewType to 'Spectrogram' or 'Spectrum and spectrogram'.
- TimeSpanSource to 'Property'.

UI Use

Open the **Spectrum Settings**. In the **Spectrogram options** section, in the **Time span (s)** box, enter a number.

OverlapPercent — Overlap percentage

0 (default) | real, scalar value

The percentage overlap between the previous and current buffered data segments, specified as a real, scalar value. The overlap creates a window segment that is used to compute a spectral estimate. The value must be greater than or equal to zero and less than 100.

Tunable: Yes

UI Use

Open the **Spectrum Settings**. In the **Window options** section, set **Overlap (%)**.

window — Window function

'Hann' (default) | 'Rectangular' | 'Chebyshev' | 'Flat Top' | 'Hamming' | 'Kaiser' | 'Blackman-Harris' | 'Custom'

Specify a window function for the spectral estimator. The following table shows preset windows. For more information, follow the link to the corresponding function reference in the Signal Processing Toolbox documentation.

Window Option	Corresponding Signal Processing Toolbox Function
'Rectangular'	rectwin
'Chebyshev'	chebwin
'Flat Top'	flattopwin
'Hamming'	hamming
'Hann'	hann
'Kaiser'	kaiser
'Blackman-Harris'	blackmanharris

To set your own spectral estimation window, set this property to 'Custom' and specify a custom window function in the CustomWindow property.

Tunable: Yes

UI Use

Open the **Spectrum Settings**. In the **Window options** section, set **Window**.

CustomWindow — Custom window function

'hann' (default) | character array

Specify a custom window function as a character array. The custom window function name must be on the MATLAB path. This property is useful if you want to customize the window using additional properties available with the Signal Processing Toolbox version of the window function.

Tunable: Yes

Example

Define and use a custom window function.

```
function w = my_hann(L)
    w = hann(L, 'periodic')
end
```

```
scope.Window = 'Custom';
scope.CustomWindow = 'my_hann'
```

Dependency

To use this property, set Window to 'Custom'.

UI Use

Open the **Spectrum Settings**. In the **Window options** section, in the **Window** option box, enter a custom window function name.

SidelobeAttenuation — Sidelobe attenuation of window

60 (default) | real positive scalar

The window sidelobe attenuation, in decibels (dB). The value must be greater than or equal to 45.

Tunable: Yes

Dependency

To enable this property, set Window to 'Chebyshev' or 'Kaiser'.

UI Use

Open the **Spectrum Settings**. In the **Window options** section, set **Attenuation (dB)**.

SpectrumUnits — Units of the spectrum

'dBm' (default) | 'dBFS' | 'dBW' | 'Watts' | 'Vrms' | 'dBV'

Specify the units in which the Spectrum Analyzer displays power values.

Tunable: Yes

Dependency

The available spectrum units depends on the value of SpectrumType.

SpectrumType	Allowed SpectrumUnits
Power or Power density	'dBFS', 'dBm', 'dBW', 'Watts'
RMS	'Vrms', 'dBV'

UI Use

Open the **Spectrum Settings**. In the **Trace options** section, set **Units**.

FullScaleSource — Source of full scale

'Auto' (default) | 'Property'

Specify the source of the dBFS scaling factor as either 'Auto' or 'Property'.

- 'Auto' - The Spectrum Analyzer adjusts the scaling factor based on the input data.
- 'Property' - Specify the full-scale scaling factor using the FullScale property.

Dependency

To enable this property, set SpectrumUnits to 'dBFS'.

UI Use

Open the **Spectrum Settings**. In the **Trace options** section, set **Full scale** to Auto or enter a number.

FullScale — Full scale

1 (default) | positive scalar

Specify a real positive scalar for the dBFS full scale.

Tunable: Yes

Dependency

To enable this option set:

- SpectrumUnits to 'dBFS'
- FullScaleSource to 'Property'

UI Use

Open the **Spectrum Settings**. In the **Trace options** section, set **Full scale** to Auto or enter a number.

ReferenceLoad — Reference load

1 (default) | real positive scalar

The load the scope uses as a reference to compute power levels.

Tunable: Yes

UI Use

Open the **Spectrum Settings**. In the **Trace options** section, set **Reference load**.

PlotNormalTrace — Normal trace flag

`true` (default) | `false`

Set this property to `false` to remove the display of the normal traces. These traces display the free-running spectral estimates. Even when the traces are removed from the display, the Spectrum Analyzer continues its spectral computations.

Tunable: Yes

Dependency

To enable this property, set `ViewType` to `'Spectrum'` or `'Spectrum and spectrogram'`.

UI Use

Open the **Spectrum Settings**. In the **Trace options** section, select **Normal trace**.

PlotMaxHoldTrace — Max-hold trace flag

`false` (default) | `true`

To compute and plot the maximum-hold spectrum of each input channel, set this property to `true`. The maximum-hold spectrum at each frequency bin is computed by keeping the maximum value of all the power spectrum estimates. When you toggle this property, the Spectrum Analyzer resets its maximum-hold computations.

Tunable: Yes

Dependency

To enable this property, set `ViewType` to `'Spectrum'` or `'Spectrum and spectrogram'`.

UI Use

Open the **Spectrum Settings**. In the **Trace options** section, select **Max-hold trace**.

PlotMinHoldTrace — Min-hold trace flag`false` (default) | `true`

To compute and plot the minimum-hold spectrum of each input channel, set this property to `true`. The minimum-hold spectrum at each frequency bin is computed by keeping the minimum value of all the power spectrum estimates. When you toggle this property, the Spectrum Analyzer resets its minimum-hold computations.

Tunable: Yes**Dependency**

To enable this property, set `ViewType` to `'Spectrum'` or `'Spectrum and spectrogram'`.

UI Use

Open the **Spectrum Settings**. In the **Trace options** section, select **Min-hold trace**.

SpectralMask — Spectral mask lines`SpectralMaskSpecification` object

Specify whether to display upper and lower spectral masks lines on a spectrum plot. This property uses `SpectralMaskSpecification` properties to enable and configure the spectral masks. The `SpectralMaskSpecification` properties are:

- `EnabledMasks` — Masks to enable, specified as a character vector. Valid values are `'None'`, `'Upper'`, `'Lower'`, or `'Upper and lower'`.

Default: `'None'`

- `UpperMask` — Upper limit spectral mask, specified as a scalar or two-column matrix. If `UpperMask` is a scalar, the upper limit mask uses the power value of the scalar for all frequency values applicable to the Spectrum Analyzer. If `UpperMask` is a matrix, the first column contains the frequency values (Hz), which correspond to the *x*-axis values. The second column contains the power values, which correspond to the associated *y*-axis values. To apply offsets to the power and frequency values, use `ReferenceLevel` and `MaskFrequencyOffset` property values, respectively.

Default: `Inf`

- `LowerMask` — Lower limit spectral mask, specified as a scalar or two-column matrix. If `LowerMask` is a scalar, the lower limit mask uses the power value of the scalar for

all frequency values applicable to the Spectrum Analyzer. If `LowerMask` is a matrix, the first column contains the frequency values (Hz), which correspond to the *x*-axis values. The second column contains the power values, which correspond to the associated *y*-axis values. To apply offsets to the power and frequency values, use `ReferenceLevel` and `MaskFrequencyOffset` property values, respectively.

Default: `-Inf`

- `ReferenceLevel` — Reference level for mask power values, specified as either 'Custom' or 'Spectrum peak'. When `ReferenceLevel` is 'Custom', the `CustomReferenceLevel` property value is used as the reference to the power values, in dB, in the `UpperMask` and `LowerMask` properties. When `ReferenceLevel` is 'Spectrum peak', the peak value of the current spectrum of the `SelectedChannel` is used.

Default: 'Custom'

- `CustomReferenceLevel` — Custom reference level, specified as a real value, in the same units as the power units. The reference level is the value to which to reference the power values in the `UpperMask` and `LowerMask` properties. This property applies when `ReferenceLevel` is set to 'Custom'. This property uses the same units as the `PowerUnits` property of the Spectrum Analyzer.

Default: 0

- `SelectedChannel` — Input channel with peak spectrum to use as the mask reference level, specified as an integer. This property applies when `ReferenceLevel` is set to 'Spectrum peak'.

Default: 1

- `MaskFrequencyOffset` — Frequency offset, specified as a finite, numeric scalar. Frequency offset is the amount of offset to apply to frequency values in the `UpperMask` and `LowerMask` properties.

Default: 0

All `SpectralMaskSpecification` properties are tunable.

Masks are overlaid on the spectrum. If the mask is green, the signal is passing. If the mask is red, the signal is failing.

You can check the status of the spectral mask using one of the following methods:

- To modify the spectral mask and see the spectral mask status, in the scope toolbar select the spectral mask button, . In the Spectral Mask panel that opens, you can modify the masks and see details about what percentage of the time the mask is succeeding, which mask is failing, how many times the mask failed, and which channels are causing the failure.
- To get the current status of the spectral masks, call the function `getSpectralMaskStatus`.
- To perform an action every time the mask fails, use the `MaskTestFailed` event. To trigger a function when the mask fails, create a listener to the `MaskTestFailed` event and define a callback function to trigger. For more details about using events, see “Events” (MATLAB).

Tunable: Yes

UI Use

Open the **Spectral Mask** panel and modify the **Settings** options.

Visualization

Name — Display name

'Spectrum Analyzer' (default) | character vector

Title of the scope window, specified as a character vector.

Tunable: Yes

Position — Window position

screen center (default) | [left bottom width height]

Spectrum Analyzer window position in pixels, specified by the size and location of the scope window as a 4-element double vector of the form [left bottom width height]. You can place the scope window in a specific position on your screen by modifying the values to this property.

By default, the window appears in the center of your screen with a width of 800 pixels and height of 450 pixels. The exact center coordinates depend on your screen resolution.

Tunable: Yes

PlotType — Plot type for normal traces

'Line' (default) | 'Stem'

Specify the type of plot to use for displaying normal traces as either 'Line' or 'Stem'. Normal traces are traces that display free-running spectral estimates.

Tunable: Yes

Dependency

To enable this property, set:

- ViewType to 'Spectrum' or 'Spectrum and spectrogram'
- PlotNormalTrace to true

UI Use

Open the **Style** properties and set **Plot type**.

ReducePlotRate — Improve performance with reduced plot rate

true (default) | false

The simulation speed is faster when this property is set to true.

- true - the scope logs data for later use and updates the display at fixed intervals of time. Data occurring between these fixed intervals might not be plotted.
- false - the scope updates every time it computes the power spectrum. Use the false setting when you do not want to miss any spectral updates at the expense of slower simulation speed.

Tunable: Yes

UI Use

Select **Playback** > **Reduce plot rate to improve performance**.

Title — Display title

'' (default) | character vector | string

Specify the display title as a character vector or string. Enter %<SignalLabel> to use the signal labels as the axes titles.

Tunable: Yes

UI Use

Open the **Configuration Properties**. On the **Display** tab, set **Title**.

ShowLegend — Show legend

false (default) | true

To show a legend with the input names, set this property to `true`.

From the legend, you can control which signals are visible. This control is equivalent to changing the visibility in the **Style** dialog box. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again. To show only one signal, right-click the signal name. To show all signals, press **Esc**.

Tunable: Yes

UI Use

Open the **Configuration Properties**. On the **Display** tab, select **Show legend**.

ChannelNames — Channel names

empty cell (default) | cell array of character vectors | cell array of strings

Specify the input channel names as a cell array of character vectors or strings. The names appear in the legend, **Style** dialog box, and **Measurements** panels. If you do not specify names, the channels are labeled as `Channel 1`, `Channel 2`, etc.

Tunable: Yes

Dependency

To see channel names, set `ShowLegend` to `true`.

UI Use

Show the legend and double-click the channel name.

ShowGrid — Grid visibility

false (default) | true

Set this property to `true` to show gridlines on the plot.

Tunable: Yes

UI Use

Open the **Configuration Properties**. On the **Display** tab, set **Show grid**.

YLimits — Y-axis limits

`[-80, 20]` (default) | `[ymin ymax]`

Specify the *y*-axis limits as a 2-element numeric vector, `[ymin ymax]`.

Example: `scope.YLimits = [-10,20]`

Tunable: Yes

Dependencies

- To enable this property, set the `ViewType` property to 'Spectrum' or 'Spectrum and spectrogram'.
- The units directly depend upon the `SpectrumUnits` property.

UI Use

Open the **Configuration Properties**. Set **Y-limits (maximum)** and **Y-limits (minimum)**.

ColorLimits — Scale spectrogram color limits

`[-80, 20]` (default) | `[colorMin colorMax]`

Control the color limits of the spectrogram using a 2-element numeric vector, `[colorMin colorMax]`.

Example: `scope.ColorLimits = [-10,20]`

Dependencies

- To enable this property, set the `ViewType` property to 'Spectrogram' or 'Spectrum and spectrogram'.
- The units directly depend upon the `SpectrumUnits` property.

UI Use

Open the **Configuration Properties**. Set **Color-limits (minimum)** and **Color-limits (maximum)**.

YLabel — Y-axis label`' '` (default) | character vector

Specify the text for the scope to display to the left of the y -axis.

Regardless of this property, Spectrum Analyzer always displays power units as one of the SpectrumUnits values.

Tunable: Yes

Dependency

To enable this property, set ViewType to 'Spectrum' or 'Spectrum and spectrogram'.

UI Use

Open the **Configuration Properties**. Set **Y-label**.

AxesLayout — Orientation of the spectrum and spectrogram`'Vertical'` (default) | 'Horizontal'

Specify the layout type as 'Horizontal' or 'Vertical'. A vertical layout stacks the spectrum above the spectrogram. A horizontal layout puts the two views side-by-side.

Tunable: Yes

Dependency

To enable this property, set ViewType to 'Spectrum and spectrogram'.

UI Use

Open the **Spectrum Settings**. Set **Axes layout**.

Usage

Note For versions earlier than R2016b, use the `step` function to run the System object™ algorithm. The arguments to `step` are the object you created, followed by the arguments shown in this section.

For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Syntax

```
scope(signal)  
scope(signal1,signal2,...,signalN)
```

Description

`scope(signal)` updates the spectrum of the signal in the spectrum analyzer.

`scope(signal1,signal2,...,signalN)` displays multiple signals in the spectrum analyzer. The signals must have the same frame length, but can vary in number of channels. You must set the `NumInputPorts` property to enable multiple input signals.

Input Arguments

signal — Input signal or signals to visualize

scalar | vector | matrix

Specify one or more input signals to visualize in the `dsp.SpectrumAnalyzer`. Signals can have a different number of channels, but must have the same frame length.

Example: `scope(signal1, signal2)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `string` | `struct` | `table` | `cell` | `categorical` | `datetime` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.SpectrumAnalyzer`

<code>getSpectralMaskStatus</code>	Get test results of current spectral mask
<code>getSpectrumData</code>	Save spectrum data shown in spectrum analyzer
<code>isNewDataReady</code>	Check spectrum analyzer for new data

Specific to Scopes

show Display scope window
hide Hide scope window

Common to All System Objects

step Run System object algorithm
clone Create duplicate System object
getNumInputs Number of inputs required to call the System object
getNumOutputs Number of outputs from calling the System object
isLocked Determine if System object is locked
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

Examples

Spectrum Analyzer for One-Sided Power Spectrum

View a one-sided power spectrum made from the sum of fixed real sine waves with different amplitudes and frequencies.

```

Fs = 100e6;    % Sampling frequency
fSz = 5000;    % Frame size

sin1 = dsp.SineWave(1e0, 5e6, 0, 'SamplesPerFrame', fSz, 'SampleRate', Fs);
sin2 = dsp.SineWave(1e-1, 15e6, 0, 'SamplesPerFrame', fSz, 'SampleRate', Fs);
sin3 = dsp.SineWave(1e-2, 25e6, 0, 'SamplesPerFrame', fSz, 'SampleRate', Fs);
sin4 = dsp.SineWave(1e-3, 35e6, 0, 'SamplesPerFrame', fSz, 'SampleRate', Fs);
sin5 = dsp.SineWave(1e-4, 45e6, 0, 'SamplesPerFrame', fSz, 'SampleRate', Fs);

scope = dsp.SpectrumAnalyzer;
scope.SampleRate = Fs;
scope.SpectralAverages = 1;
scope.PlotAsTwoSidedSpectrum = false;
scope.RBWSource = 'Auto';
scope.PowerUnits = 'dBW';
for idx = 1:1e2
    y1 = sin1();
    y2 = sin2();

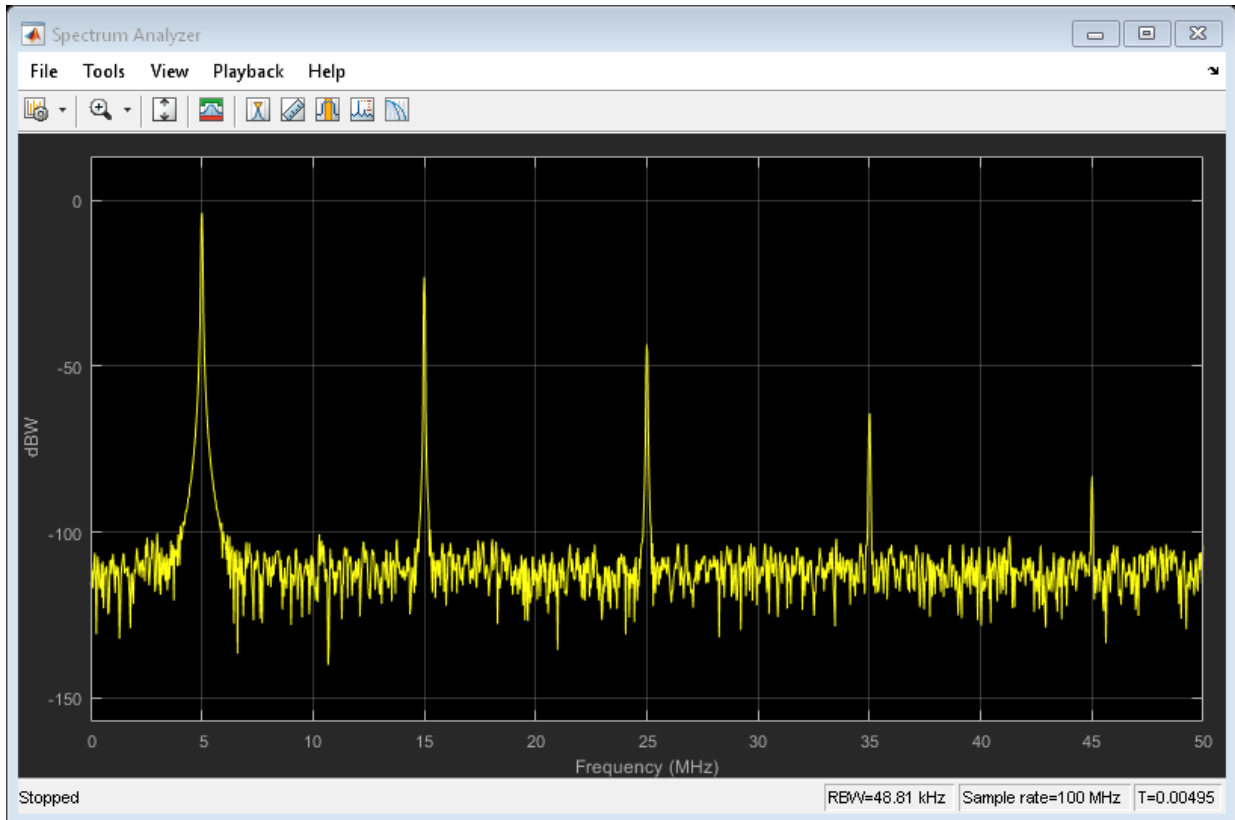

```

```
y3 = sin3();  
y4 = sin4();  
y5 = sin5();  
scope(y1+y2+y3+y4+y5+0.0001*randn(fSz,1));  
end
```

Run the `release` method to let property values and input characteristics change. The scope automatically scales the axes.

```
release(scope)
```

Run the `clear` function to close the Spectrum Analyzer window.

```
clear('scope');
```

Spectrogram of Chirp Signal

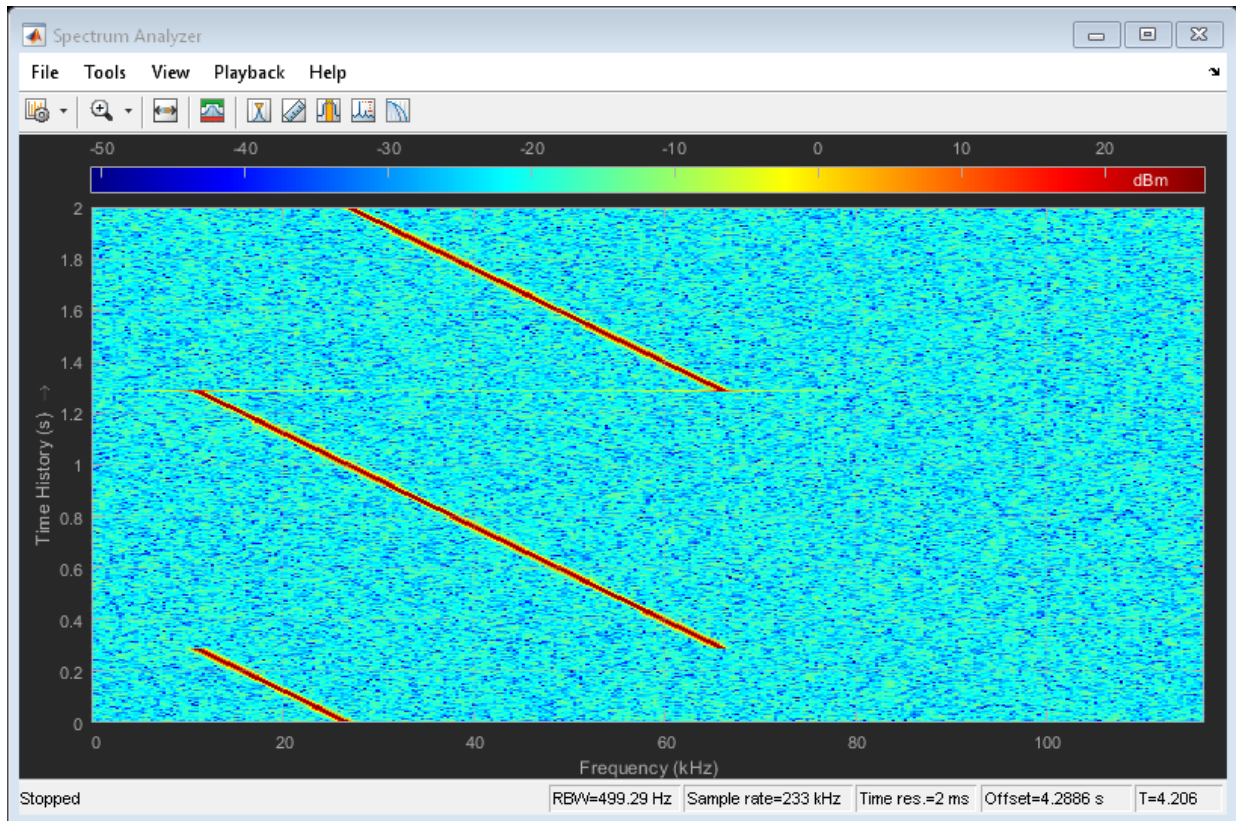

This example shows the spectrogram for a chirp signal with added random noise.

```
Fs = 233e3;  
frameSize = 20e3;  
chirp = dsp.Chirp('SampleRate',Fs,...  
    'SamplesPerFrame',frameSize,...  
    'InitialFrequency',11e3,...
```

```
    'TargetFrequency',11e3+55e3);

scope = dsp.SpectrumAnalyzer('SampleRate',Fs);
scope.SpectrumType = 'Spectrogram';
scope.RBWSource = 'Property';
scope.RBW = 500;
scope.TimeSpanSource = 'Property';
scope.TimeSpan = 2;
scope.PlotAsTwoSidedSpectrum = false;

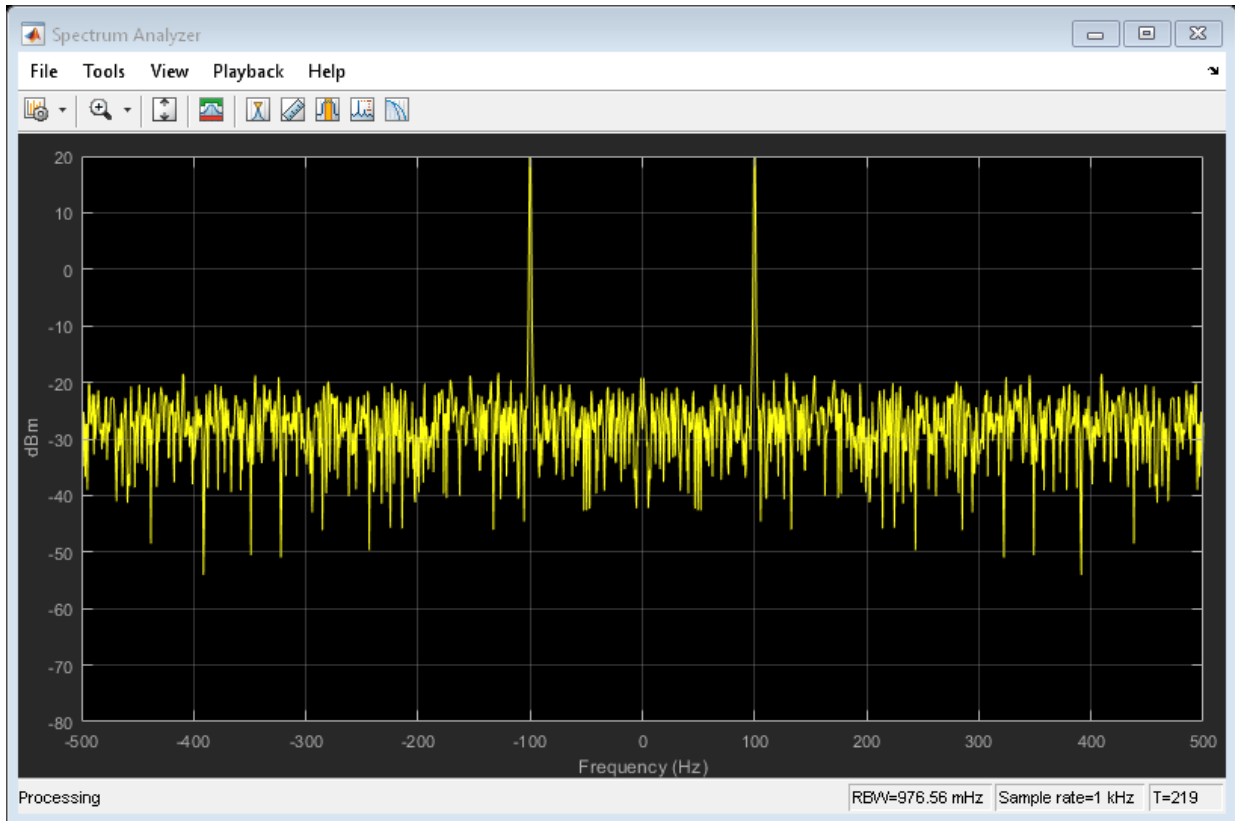

for idx = 1:50
    y = chirp()+ 0.05*randn(frameSize,1);
    scope(y);
end
release(scope)
```

Spectrum Analyzer For Two-Sided Power Spectrum

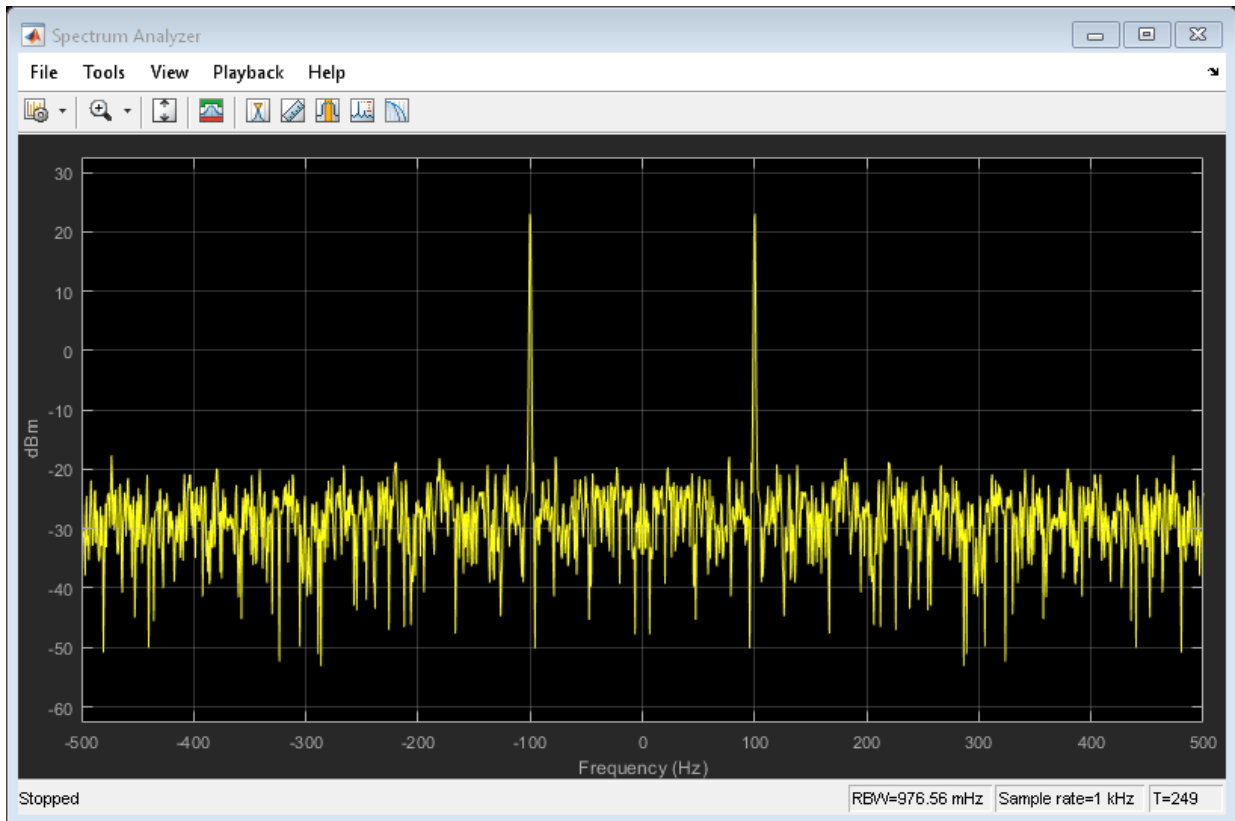

View a two-sided power spectrum of a sine wave with noise on the Spectrum Analyzer.

```
sin = dsp.SineWave('Frequency',100,'SampleRate',1000);  
sin.SamplesPerFrame = 1000;  
scope = dsp.SpectrumAnalyzer('SampleRate',sin.SampleRate);  
for ii = 1:250  
    x = sin() + 0.05*randn(1000,1);  
    scope(x);  
end
```

Run the `release` method to change property values and input characteristics. The scope automatically scales the axes. It updates the display one more time if any data is in the internal buffer.

```
release(scope);
```

Run the MATLAB `clear` function to close the Spectrum Analyzer window.

```
clear('scope');
```

- “Estimate the Power Spectrum in MATLAB”
- “Spectral Analysis”

Tips

- To close the scope window and clear its associated data, use the MATLAB `clear` function.

- To hide or show the scope window, use the `hide` and `show` functions.
- Use the `MATLAB mcc` function to compile code containing a Spectrum Analyzer.

You cannot open Spectrum Analyzer configuration dialogs if you have more than one compiled component in your application.

Algorithms

Welch's Method

When you set the **Method** property to `Welch`, the following algorithms apply. The Spectrum Analyzer uses the `RBW` or the `Window Length` setting in the **Spectrum Settings** pane to determine the data window length. Then, it partitions the input signal into a number of windowed data segments. Finally, Spectrum Analyzer uses the modified periodogram method to compute spectral updates, averaging the windowed periodograms for each segment.

Spectrum Analyzer requires that a minimum number of samples to compute a spectral estimate. This number of input samples required to compute one spectral update is shown as **Samples/update** in the **Main options** pane. This value is directly related to resolution bandwidth, RBW , by the following equation, or to the window length, by the equation shown in step 2.

$$N_{samples} = \frac{\left(1 - \frac{O_p}{100}\right) \times NENBW \times F_s}{RBW}$$

The normalized effective noise bandwidth, $NENBW$, is a factor that depends on the windowing method. Spectrum Analyzer shows the value of $NENBW$ in the **Window Options** pane of the **Spectrum Settings** pane. Overlap percentage, O_p , is the value of the **Overlap %** parameter in the **Window Options** pane of the **Spectrum Settings** pane. F_s is the sample rate of the input signal. Spectrum Analyzer shows sample rate in the **Main Options** pane of the **Spectrum Settings** pane.

- 1 When in **RBW (Hz)** mode, the window length required to compute one spectral update, N_{window} , is directly related to the resolution bandwidth and normalized effective noise bandwidth:

$$N_{window} = \frac{NENBW \times F_s}{RBW}$$

When in **Window Length** mode, the window length is used as specified.

- The number of input samples required to compute one spectral update, $N_{samples}$, is directly related to the window length and the amount of overlap by the following equation.

$$N_{samples} = \left(1 - \frac{O_p}{100}\right) N_{window}$$

When you increase the overlap percentage, fewer new input samples are needed to compute a new spectral update. For example, if the window length is 100, then the number of input samples required to compute one spectral update is given as shown in the following table.

O_p	$N_{samples}$
0%	100
50%	50
80%	20

- The normalized effective noise bandwidth, $NENBW$, is a window parameter determined by the window length, N_{window} , and the type of window used. If $w(n)$ denotes the vector of N_{window} window coefficients, then $NENBW$ is given by the following equation.

$$NENBW = N_{window} \frac{\sum_{n=1}^{N_{window}} w^2(n)}{\left[\sum_{n=1}^{N_{window}} w(n)\right]^2}$$

- When in **RBW (Hz)** mode, you can set the resolution bandwidth using the value of the **RBW (Hz)** parameter on the **Main options** pane of the **Spectrum Settings** pane. You must specify a value to ensure that there are at least two RBW intervals over the specified frequency span. The ratio of the overall span to RBW must be greater than two:

$$\frac{span}{RBW} > 2$$

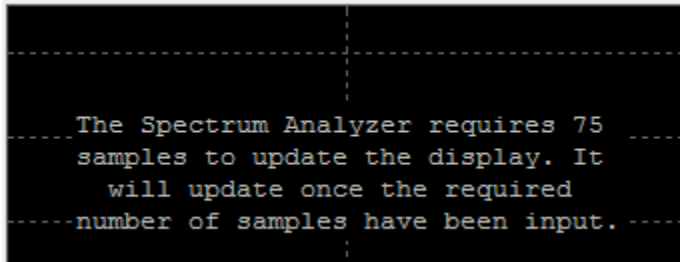

By default, the **RBW (Hz)** parameter on the **Main options** pane is set to `Auto`. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 RBW intervals over the specified frequency span. When you set **RBW (Hz)** to `Auto`, *RBW* is calculated as:

$$RBW_{auto} = \frac{span}{1024}$$

- 5 When in **Window Length** mode, you specify N_{window} and the resulting *RBW* is:

$$\frac{NENBW * F_s}{N_{window}}$$

Sometimes, the number of input samples provided are not sufficient to achieve the resolution bandwidth that you specify. When this situation occurs, Spectrum Analyzer displays a message:

Spectrum Analyzer removes this message and displays a spectral estimate when enough data has been input.

Note The number of FFT points (N_{fft}) is independent of the window length (N_{window}). You can set them to different values if N_{fft} is greater than or equal to N_{window} .

Filter Bank

When you set the **Method** property to `Filter Bank`, the following algorithms apply. The Spectrum Analyzer uses the **RBW (Hz)** or the **Number of frequency band** property in the **Spectrum Settings** pane to determine the input frame length.

Spectrum Analyzer requires a minimum number of samples to compute a spectral estimate. This number of input samples required to compute one spectral update is shown as **Samples/update** in the **Main options** pane. This value is directly related to resolution bandwidth, RBW , by the following equation.

$$N_{samples} = \frac{F_s}{RBW}$$

F_s is the sample rate of the input signal. Spectrum Analyzer shows sample rate in the **Main Options** pane of the **Spectrum Settings** pane.

- 1 When in **RBW (Hz)** mode, you can set the resolution bandwidth using the value of the **RBW (Hz)** parameter on the **Main options** pane of the **Spectrum Settings** pane. You must specify a value to ensure that there are at least two RBW intervals over the specified frequency span. The ratio of the overall span to RBW must be greater than two:

$$\frac{span}{RBW} > 2$$

By default, the **RBW** parameter on the **Main options** pane is set to `Auto`. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 RBW intervals over the specified frequency span. Thus, when you set **RBW**

to `Auto`, it is calculated by the following equation. $RBW_{auto} = \frac{span}{1024}$

- 2 When in **Number of frequency bands** mode, you specify the input frame size. When the number of frequency bands is `Auto`, the resulting RBW is:

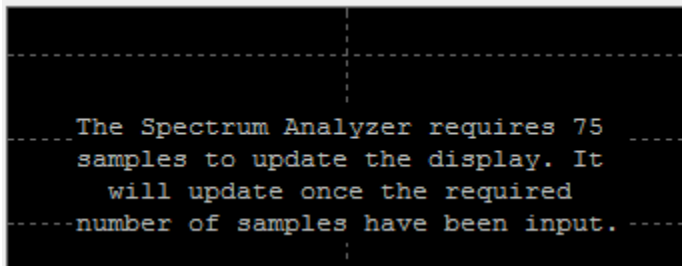

$$RBW = \frac{F_s}{\text{Input Frame Size}}$$

When the number of frequency bands is manually specified, the resulting RBW is:

$$RBW = \frac{F_s}{FFTL\text{Length}}$$

For more information about the filter bank algorithm, see “Polyphase Implementation” on page 2-196.

Sometimes, the number of input samples provided are not sufficient to achieve the resolution bandwidth that you specify. When this situation occurs, Spectrum Analyzer displays a message:

Spectrum Analyzer removes this message and displays a spectral estimate when enough data has been input.

Nyquist frequency interval

When the `PlotAsTwoSidedSpectrum` property is set to `true`, the interval is

$$\left[-\frac{\text{SampleRate}}{2}, \frac{\text{SampleRate}}{2} \right] + \text{FrequencyOffset} \text{ hertz.}$$

When the `PlotAsTwoSidedSpectrum` property is set to `false`, the interval is

$$\left[0, \frac{\text{SampleRate}}{2} \right] + \text{FrequencyOffset} \text{ hertz.}$$

Periodogram and Spectrogram

Spectrum Analyzer calculates and plots the power spectrum, power spectrum density, and RMS computed by the modified Periodogram estimator. For more information about the Periodogram method, see `periodogram`.

Power Spectral Density — The power spectral density (PSD) is given by the following equation.

$$PSD(f) = \frac{1}{P} \sum_{p=1}^P \frac{\left| \sum_{n=1}^{N_{FFT}} x^{(p)}[n] e^{-j2\pi f(n-1)T} \right|^2}{F_s \times \sum_{n=1}^{N_{window}} w^2[n]}$$

In this equation, $x[n]$ is the discrete input signal. On every input signal frame, Spectrum Analyzer generates as many overlapping windows as possible, with each window denoted as $x^{(p)}[n]$, and computes their periodograms. Spectrum Analyzer displays a running average of the P most current periodograms.

Power Spectrum — The power spectrum is the product of the power spectral density and the resolution bandwidth, as given by the following equation.

$$P_{spectrum}(f) = PSD(f) \times RBW = PSD(f) \times \frac{F_s \times NENBW}{N_{window}} = \frac{1}{P} \sum_{p=1}^P \frac{\left| \sum_{n=1}^{N_{FFT}} x^{(p)}[n] e^{-j2\pi f(n-1)T} \right|^2}{\left[\sum_{n=1}^{N_{window}} w[n] \right]^2}$$

Spectrogram — You can plot any power as a spectrogram. Each line of the spectrogram is one periodogram. The time resolution of each line is $1/RBW$, which is the minimum attainable resolution. Achieving the resolution you want may require combining several periodograms. You then use interpolation to calculate noninteger values of $1/RBW$. In the spectrogram display, time scrolls from bottom to top, so the most recent data is shown at the bottom of the display. The offset shows the time value at which the center of the most current spectrogram line occurred.

Occupied BW

The *Occupied BW* is calculated as follows.

- 1 Calculate the total power in the measured frequency range.
- 2 Determine the lower frequency value. Starting at the lowest frequency in the range and moving upward, the power distributed in each frequency is summed until this result is

$$\frac{100 - \text{Occupied BW \%}}{2}$$

2

- of the total power.
- 3 Determine the upper frequency value. Starting at the highest frequency in the range and moving downward, the power distributed in each frequency is summed until the result reaches

$$\frac{100 - \text{Occupied BW } \%}{2}$$
 of the total power.
 - 4 The bandwidth between the lower and upper power frequency values is the occupied bandwidth.
 - 5 The frequency halfway between the lower and upper frequency values is the center frequency.

Distortion Measurements

The *Distortion Measurements* are computed as follows.

- 1 Spectral content is estimated by finding peaks in the spectrum. When the algorithm detects a peak, it records the width of the peak and clears all monotonically decreasing values. That is, the algorithm treats all these values as if they belong to the peak. Using this method, all spectral content centered at DC (0 Hz) is removed from the spectrum and the amount of bandwidth cleared (W_0) is recorded.
- 2 The fundamental power (P_1) is determined from the remaining maximum value of the displayed spectrum. A local estimate (Fe_1) of the fundamental frequency is made by computing the central moment of the power in the vicinity of the peak. The bandwidth of the fundamental power content (W_1) is recorded. Then, the power from the fundamental is removed as in step 1.
- 3 The power and width of the higher-order harmonics (P_2, W_2, P_3, W_3 , etc.) are determined in succession by examining the frequencies closest to the appropriate multiple of the local estimate (Fe_1). Any spectral content that decreases monotonically about the harmonic frequency is removed from the spectrum first before proceeding to the next harmonic.
- 4 Once the DC, fundamental, and harmonic content is removed from the spectrum, the power of the remaining spectrum is examined for its sum ($P_{\text{remaining}}$), peak value (P_{maxspur}), and median value (P_{estnoise}).
- 5 The sum of all the removed bandwidth is computed as $W_{\text{sum}} = W_0 + W_1 + W_2 + \dots + W_n$.

The sum of powers of the second and higher-order harmonics are computed as $P_{\text{harmonic}} = P_2 + P_3 + P_4 + \dots + P_n$.

- 6 The sum of the noise power is estimated as:

$$P_{noise} = (P_{remaining} \cdot dF + P_{est.noise} \cdot W_{sum}) / RBW$$

Where dF is the absolute difference between frequency bins, and RBW is the resolution bandwidth of the window.

- 7 The metrics for SNR, THD, SINAD, and SFDR are then computed from the estimates.

$$THD = 10 \cdot \log_{10} \left(\frac{P_{harmonic}}{P_1} \right)$$

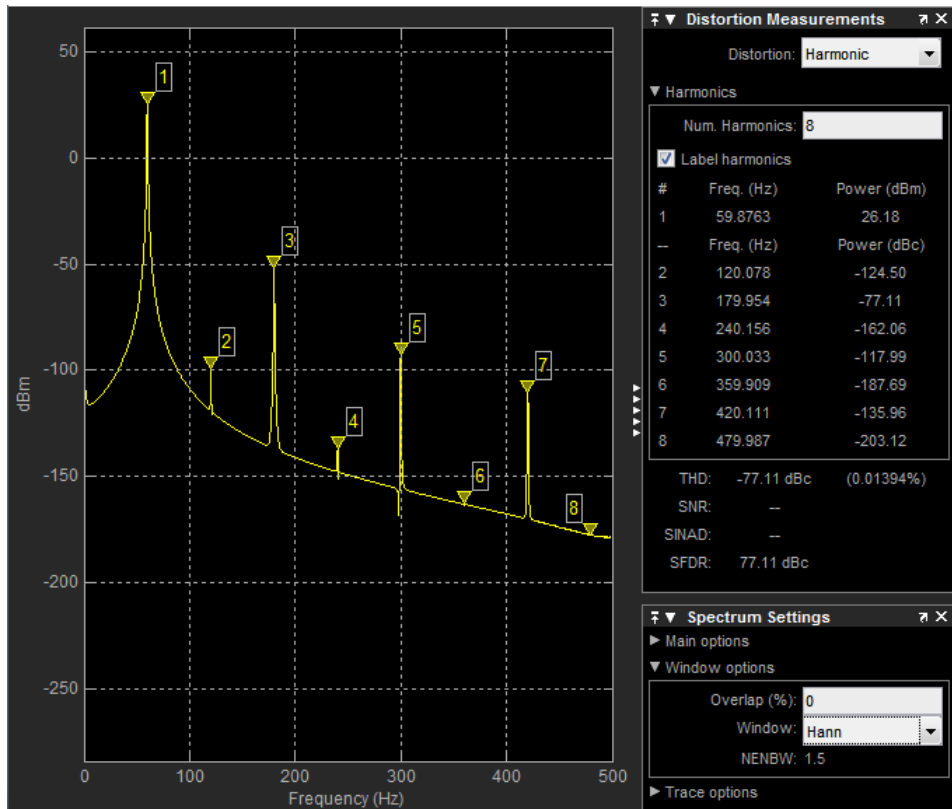

$$SINAD = 10 \cdot \log_{10} \left(\frac{P_1}{P_{harmonic} + P_{noise}} \right)$$

$$SNR = 10 \cdot \log_{10} \left(\frac{P_1}{P_{noise}} \right)$$

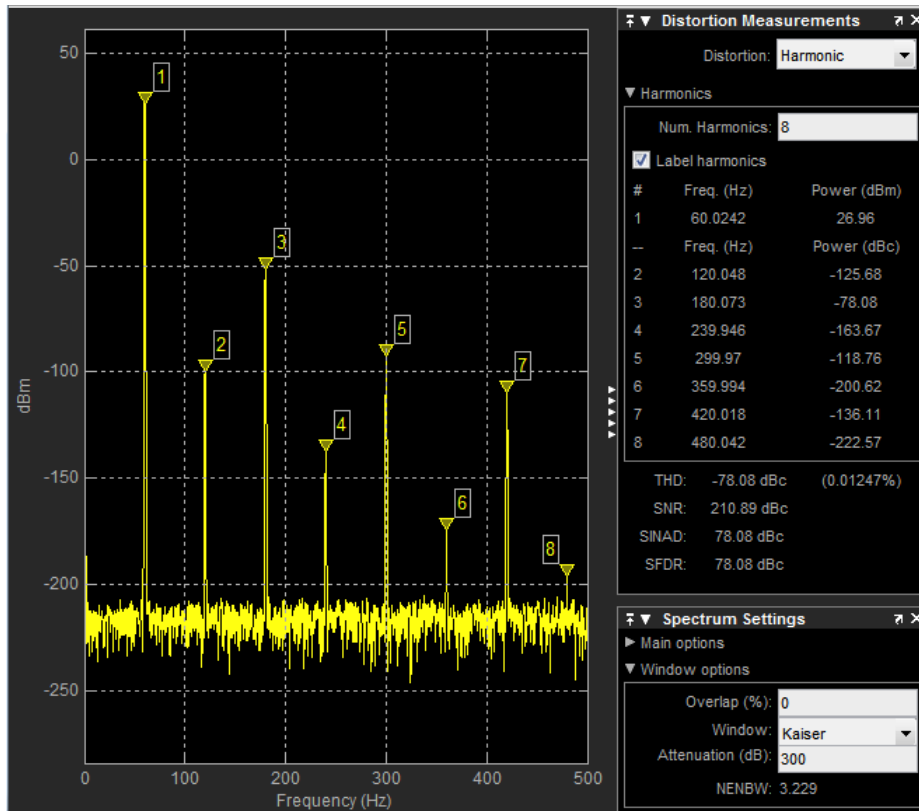

$$SFDR = 10 \cdot \log_{10} \left(\frac{P_1}{\max(P_{maxspur}, \max(P_2, P_3, \dots, P_n))} \right)$$

Harmonic Measurements

- 1 The harmonic distortion measurements use the spectrum trace shown in the display as the input to the measurements. The default Hann window setting of the Spectrum Analyzer may exhibit leakage that can completely mask the noise floor of the measured signal.

The harmonic measurements attempt to correct for leakage by ignoring all frequency content that decreases monotonically away from the maximum of harmonic peaks. If the window leakage covers more than 70% of the frequency bandwidth in your spectrum, you may see a blank reading (–) reported for **SNR** and **SINAD**. If your application can tolerate the increased equivalent noise bandwidth (ENBW), consider using a Kaiser window with a high attenuation (up to 330 dB) to minimize spectral leakage.

- 2 The DC component is ignored.
- 3 After windowing, the width of each harmonic component masks the noise power in the neighborhood of the fundamental frequency and harmonics. To estimate the noise power in each region, Spectrum Analyzer computes the median noise level in the nonharmonic areas of the spectrum. It then extrapolates that value into each region.
- 4 N th order intermodulation products occur at $A * F1 + B * F2$,

where $F1$ and $F2$ are the sinusoid input frequencies and $|A| + |B| = N$. A and B are integer values.

- 5 For intermodulation measurements, the third-order intercept (TOI) point is computed as follows, where P is power in decibels of the measured power referenced to 1 milliwatt (dBm):

- $TOI_{lower} = P_{F1} + (P_{F2} - P_{(2F1-F2)})/2$
- $TOI_{upper} = P_{F2} + (P_{F1} - P_{(2F2-F1)})/2$
- $TOI = + (TOI_{lower} + TOI_{upper})/2$

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Supports MEX code generation by treating the calls to the object as extrinsic. Does not support code generation for standalone applications.

dsp.SpectrumEstimator System object

Package: dsp

Estimate power spectrum or power density spectrum

Description

The `dsp.SpectrumEstimator` computes the power spectrum or the power density spectrum of a signal, using the Welch algorithm and the filter bank approach.

When you choose the Welch method, the object computes the averaged modified periodograms to compute the spectral estimate. When you choose the filter bank approach, an analysis filter bank splits the broadband input signal into multiple narrow subbands. The object computes the power in each narrow frequency band and the computed value is the spectral estimate over the respective frequency band. For signals with relatively small FFT lengths, the filter bank approach produces a spectral estimate with a higher resolution, a more accurate noise floor, and peaks more precise than the Welch method, with low or no spectral leakage. These advantages come at the expense of increased computation and slower tracking.

The spectrum can be expressed in Watts or in decibels. This object can also estimate the max-hold and min-hold spectra of the signal.

To estimate the power density spectrum:

- 1 Define and set up your spectrum estimator object. See “Construction” on page 4-1624.
- 2 Call `step` to estimate the power density spectrum according to the properties of the object.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`SE = dsp.SpectrumEstimator` returns a System object, SE, that computes the frequency power spectrum or the power density spectrum of real or complex signals. This System object uses the Welch's averaged modified periodogram method and filter bank based spectral estimation method.

`SE = dsp.SpectrumEstimator('PropertyName', PropertyValue, ...)` returns a Spectrum Estimator System object, SE, with each specified property name set to the specified value. You can specify additional name-value pair arguments in any order as (Name1, Value1, ..., NameN, ValueN).

Properties

SampleRate

Sample rate of input

Specify the sample rate of the input in, hertz, as a finite numeric scalar. The default value is 1 Hz. The sample rate is the rate at which the signal is sampled in time.

SpectrumType

Spectrum type

Specify the spectrum type as one of 'Power' | 'Power density'. When the spectrum type is 'Power', the power density spectrum is scaled by the equivalent noise bandwidth of the window (in Hz). The default value is 'Power'. This property is tunable.

SpectralAverages

Number of spectral averages

Specify the number of spectral averages as a positive, integer scalar. The Spectrum Estimator computes the current power spectrum or power density spectrum estimate by averaging the last N estimates. N is the number of spectral averages defined in the SpectralAverages property. The default value is 8.

FFTLengthSource

Source of the FFT length value

Specify the source of the FFT length value as one of `'Auto'` | `'Property'`. The default value is `'Auto'`. If you set this property to `'Auto'`, the Spectrum Estimator sets the FFT length to the input frame size. If you set this property to `'Property'`, then you specify the number of FFT points using the `FFTLength` property.

FFTLength

FFT Length

Specify the length of the FFT that the Spectrum Estimator uses to compute spectral estimates as a positive, integer scalar. This property applies when you set the `FFTLengthSource` property to `'Property'`. The default value is 128.

Method

Welch or filter bank

Specify the spectral estimation method as one of `'Welch'` | `'Filter bank'`.

- `'Welch'` — The object uses Welch's averaged modified periodograms method.
- `'Filter bank'` — An analysis filter bank splits the broadband input signal into multiple narrow subbands. The object computes the power in each narrow frequency band and the computed value is the spectral estimate over the respective frequency band.

The default is `'Welch'`.

NumTapsPerBand

Number of filter taps per frequency band

Specify the number of filter coefficients, or taps, for each frequency band. This value corresponds to the number of filter coefficients per polyphase branch. The total number of filter coefficients is given by $\text{NumTapsPerBand} \times \text{FFTLength}$. This property applies when you set `Method` to `'Filter bank'`. The default is 12.

Window

Window function

Specify a window function for the spectral estimator as one of 'Rectangular' | 'Chebyshev' | 'Flat Top' | 'Hamming' | 'Hann' | 'Kaiser'. The default value is 'Hann'.

SidelobeAttenuation

Side lobe attenuation of window

Specify the side lobe attenuation of the window as a real, positive scalar, in decibels (dB). This property applies when you set the Window property to 'Chebyshev' or 'Kaiser'. The default value is 60 dB.

FrequencyRange

Frequency range of the spectrum estimate

Specify the frequency range of the spectrum estimator as one of 'twosided' | 'onesided' | 'centered'.

If you set the FrequencyRange to 'onesided', then the Spectrum Estimator computes the one-sided spectrum of a real input signal. When the FFT length, N_{FFT} , is even, the spectrum estimate has length $(N_{FFT}/2) + 1$ and is computed over the frequency range $[0 \text{ SampleRate}/2]$, where SampleRate is the sample rate of the input signal. When N_{FFT} is odd, the spectrum estimate has length $(N_{FFT} + 1)/2$ and is computed over the frequency range $[0 \text{ SampleRate}/2)$.

If you set the FrequencyRange to 'twosided', then the Spectrum Estimator computes the two-sided spectrum of a complex or real input signal. The length of the spectrum estimate is equal to the FFT length. The spectrum estimate is computed over the frequency range $[0 \text{ SampleRate})$, where SampleRate is the sample rate of the input signal.

If you set the FrequencyRange to 'centered', then the Spectrum Estimator computes the centered two-sided spectrum of a complex or real input signal. The length of the spectrum estimate is equal to the FFT length. The spectrum estimate is computed over the frequency range $(-\text{SampleRate}/2 \text{ SampleRate}/2]$ when the FFT length is even and $(-\text{SampleRate}/2 \text{ SampleRate}/2)$ when the FFT length is odd.

The default value is `'twosided'`.

PowerUnits

Power units

Specify the units used to measure power as one of `'Watts'` | `'dBW'` | `'dBm'`. The default value is `'Watts'`.

ReferenceLoad

Reference load

Specify the load that the spectrum estimator uses as a reference to compute power values as a real, positive scalar in ohms. The default value is `1 ohm`.

OutputMaxHoldSpectrum

Output max-hold spectrum

Set this property to `true` so that the Spectrum Estimator computes and outputs the max-hold spectrum of each input channel. The max-hold spectrum is computed by keeping, at each frequency bin, the maximum value of all the power spectrum estimates. The default is `false`.

OutputMinHoldSpectrum

Output min-hold spectrum

Set this property to `true` so that the Spectrum Estimator computes and outputs the min-hold spectrum of each input channel. The min-hold spectrum is computed by keeping, at each frequency bin, the minimum value of all the power spectrum estimates. The default is `false`.

Methods

<code>getFrequencyVector</code>	Get the vector of frequencies at which the spectrum is estimated
<code>getRBW</code>	Get the resolution bandwidth of the spectrum
<code>reset</code>	Reset the internal states of the spectrum estimator
<code>step</code>	Estimate the power spectrum or power-density spectrum of a signal

Common to All System Objects	
<code>clone</code>	Create System object with same property values
<code>getNumInputs</code>	Expected number of inputs to a System object
<code>getNumOutputs</code>	Expected number of outputs of a System object
<code>isLocked</code>	Check locked states of a System object (logical)
<code>release</code>	Allow System object property value changes

Examples

Spectral Estimation Using Filter Bank

Compare spectral estimates of sinusoids embedded in white Gaussian noise using a Hann window based Welch method and filter bank method.

Initialization

Initialize two `dsp.SpectrumEstimator` objects. Specify one estimator to use the Welch-based spectral estimation technique with a Hann window. Specify the other estimator to use an analysis filter bank to perform the spectral estimation. Specify a noisy sine wave input signal with 4 sinusoids at 0.16, 0.2, 0.205, and 0.25 cycles/sample. View the spectral estimate using an array plot.

```
FrameSize = 420;  
Fs = 1;  
sinegen = dsp.SineWave('SampleRate',Fs,...  
    'SamplesPerFrame',FrameSize,...
```

```

    'Frequency',[0.16 0.2 0.205 0.25],...
    'Amplitude',[2e-5 1 0.05 0.5]);
NoiseVar = 1e-10;
numAvg = 8;

hannEstimator = dsp.SpectrumEstimator('PowerUnits','dBm',...
    'Window','Hann','FrequencyRange','onesided',...
    'SpectralAverages',numAvg,'SampleRate',Fs);

filterBankEstimator = dsp.SpectrumEstimator('PowerUnits','dBm',...
    'Method','Filter bank','FrequencyRange','onesided',...
    'SpectralAverages',numAvg,'SampleRate',Fs);

spectrumPlotter = dsp.ArrayPlot(...
    'PlotType','Line','SampleIncrement',Fs/FrameSize,...
    'YLimits',[-250,50],'YLabel','dBm',...
    'ShowLegend',true,'ChannelNames',{'Hann window','Filter bank'});

```

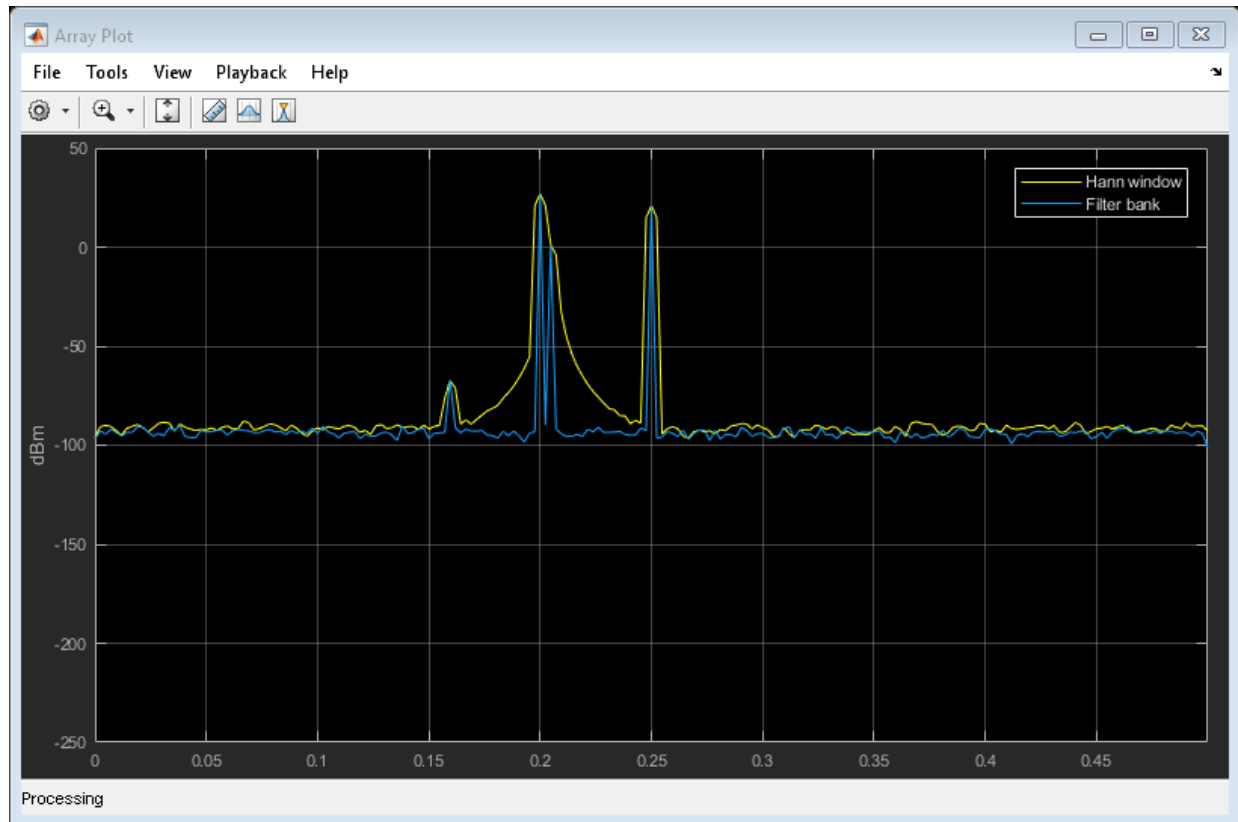

Streaming

Stream the input. Compare the spectral estimates computed using the Hann window and the analysis filter bank

```

for i = 1:1000
    x = sum(sinegen(),2) + sqrt(NoiseVar)*randn(FrameSize,1);
    Pse_hann = hannEstimator(x);
    Pfb = filterBankEstimator(x);
    spectrumPlotter([Pse_hann,Pfb]);
end

```

The Hann window misses the peak at 0.205 cycles/sample. In addition, the window has a significant spectral leakage that makes the peak at 0.16 cycles/sample hard to distinguish, and the noise floor is not correct.

The filter bank estimate has a very good resolution with no spectral leakage.

Power and Max-Hold Spectra of Noisy Sine Wave

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Generate a sine wave.

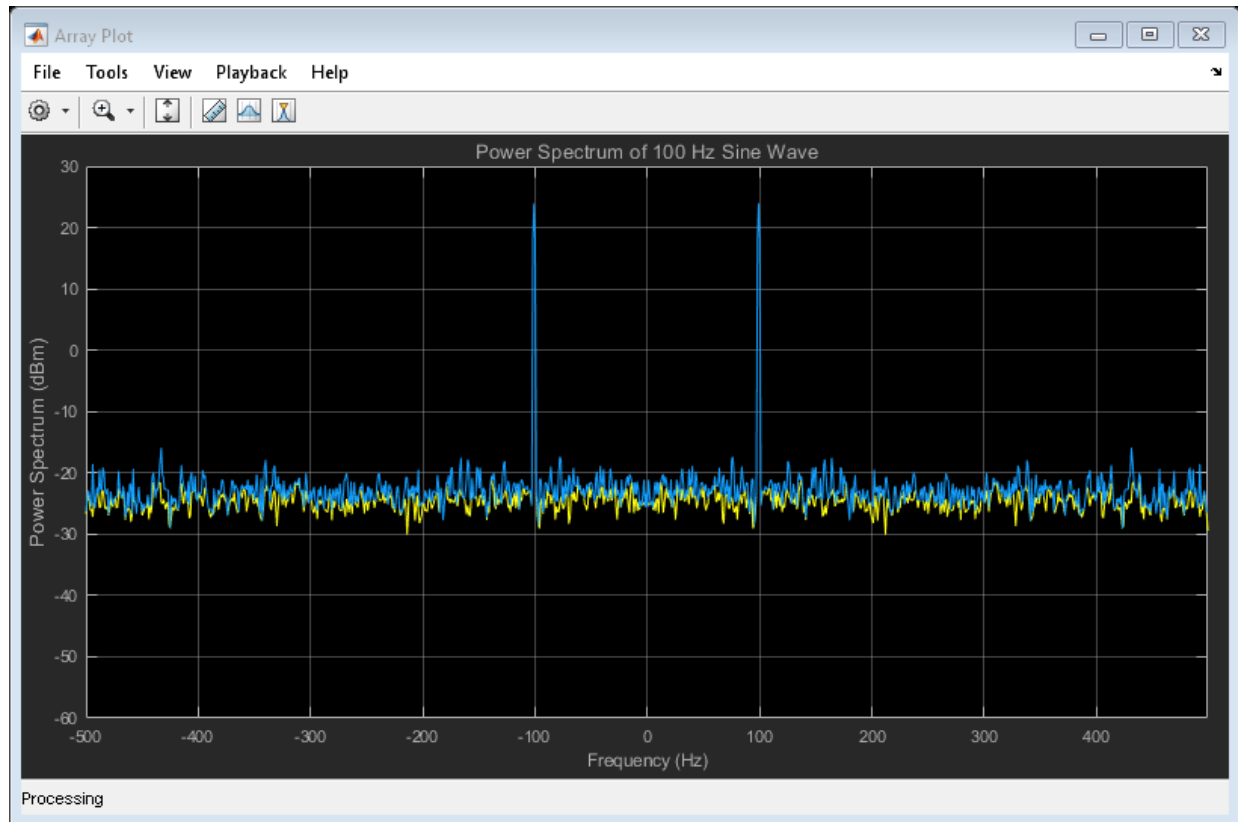

```
SINE = dsp.SineWave('Frequency',100,'SampleRate',1000, ...  
    'SamplesPerFrame',1000);
```

Use the Spectrum Estimator to compute the power spectrum and the max-hold spectrum of the sine wave. Use the Array Plot to display the spectra.

```
SE = dsp.SpectrumEstimator('SampleRate',SINE.SampleRate, ...  
    'SpectrumType','Power','PowerUnits','dBm', ...  
    'FrequencyRange','centered','OutputMaxHoldSpectrum',true);  
PLOTTER = dsp.ArrayPlot('PlotType','Line','XOffset',-500, ...  
    'YLimits',[-60 30], 'Title','Power Spectrum of 100 Hz Sine Wave', ...  
    'YLabel','Power Spectrum (dBm)','XLabel','Frequency (Hz)');
```

Add random noise to the sine wave. Stream in the data, and plot the power spectrum of the signal.

```
for ii = 1:10  
    x = SINE() + 0.05*randn(1000,1);  
    [Pxx,Pmax] = SE(x);  
    PLOTTER([Pxx Pmax]);  
end
```

Algorithms

Welch's Method of Averaged Modified Periodograms

When you choose the Welch method, the power spectrum estimate is averaged modified periodograms.

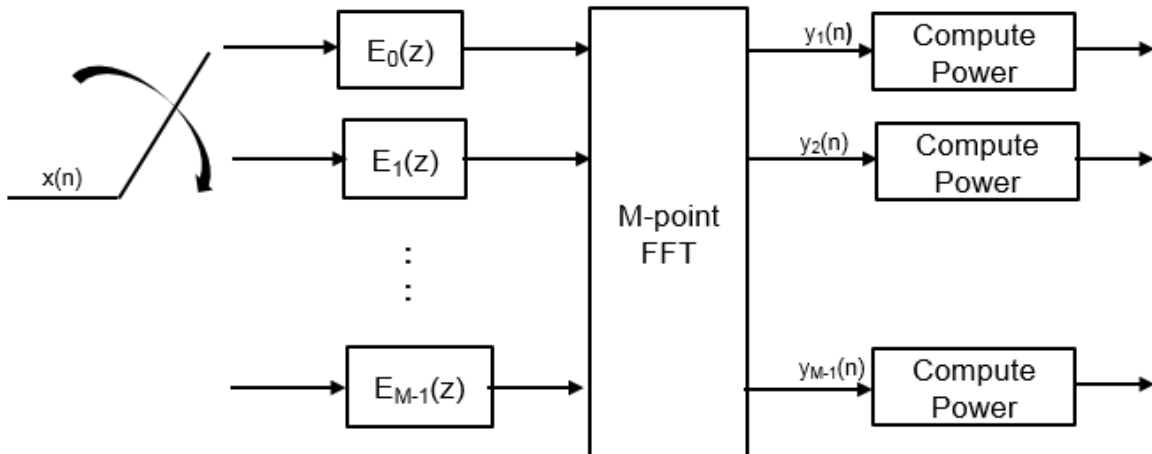

Let x be the input frame. Multiply x by the window and scale the result by the window power. Take the FFT of the signal, Y , and take the square magnitude using $Z = Y \cdot \text{conj}(Y)$. Compute the current power spectrum estimate by averaging the last N Z s and scaling the answer by the sample rate. N is the number of spectral averages.

For further information refer to the “Algorithms” on page 2-1551 section in Spectrum Analyzer, which uses the same algorithm.

Filter Bank

The spectrum estimator uses an analysis filter bank to estimate the power spectrum. The number of taps per frequency band specifies the number of filter coefficients for each frequency band of the filter bank. The total number of filter coefficients is equal to number of taps per band times the FFT length.

The filter-bank-based spectrum estimator splits the broadband input signal, $x(n)$, into multiple narrow bands and computes the power in each band. Each value becomes the estimate of the power over that narrow frequency band. The power in all the narrow bands forms the spectral estimate vector.

For more information on the analysis filter bank and how it is implemented, see the “Definitions” on page 4-290 and the “Algorithm” on page 4-293 sections in dsp.Channelizer.

System Objects

`dsp.CrossSpectrumEstimator` | `dsp.SpectrumAnalyzer` |
`dsp.TransferFunctionEstimator`

Blocks

Spectrum Estimator

Introduced in R2013b

getFrequencyVector

System object: dsp.SpectrumEstimator

Package: dsp

Get the vector of frequencies at which the spectrum is estimated

Syntax

```
getFrequencyVector(SE)
```

Description

`getFrequencyVector(SE)` returns the vector of frequencies at which the spectrum is estimated.

If you set the `FrequencyRange` to 'onesided' and the FFT length, `NFFT`, is even, the frequency vector is of length $NFFT/2+1$, and covers the interval $[0, SampleRate/2]$. If you set the `FrequencyRange` to 'onesided' and `NFFT` is odd, the frequency vector is of length $(NFFT+1)/2$ and covers the interval $[0, SampleRate/2]$. If you set the `FrequencyRange` to 'twosided', the frequency vector is of length `NFFT` and covers the interval $[0, SampleRate]$. If you set the `FrequencyRange` to 'centered', the frequency vector is of length `NFFT` and covers the range $[-SampleRate/2, SampleRate/2]$ and $[-SampleRate/2, SampleRate/2]$ for even and odd length `NFFT`, respectively.

getRBW

System object: dsp.SpectrumEstimator

Package: dsp

Get the resolution bandwidth of the spectrum

Syntax

```
getRBW(SE)
```

Description

`getRBW(SE)` returns the resolution bandwidth of the spectrum.

The resolution bandwidth, RBW , is the smallest positive frequency, or frequency interval, that can be resolved. It is equal to $ENBW * SampleRate / L$, where L is the input length, and $ENBW$ is the two-sided equivalent noise bandwidth of the window (in Hz). For example, if `SampleRate=100`, `L=1024`, and `Window='Hann'`, $RBW=enbw(hann(1024)) * 100 / 1024$.

reset

System object: dsp.SpectrumEstimator

Package: dsp

Reset the internal states of the spectrum estimator

Syntax

```
reset(sysObj)
```

Description

`reset(sysObj)` resets the internal states of the System object, `sysObj`, to their initial values. The reset method is always a no-op for unlocked System objects, as the states may not be allocated when the object is not locked.

step

System object: dsp.SpectrumEstimator

Package: dsp

Estimate the power spectrum or power-density spectrum of a signal

Syntax

```
pxx = step(SE,x)
[pxx, pmax] = step(SE,x)
[pxx, pmin] = step(SE,x)
[pxx, pmax, pmin] = step(SE,x)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`pxx = step(SE,x)` computes the power spectrum or power-density spectrum, `pxx`, of the input signal, `x`. The System object treats the columns of `x` as independent channels.

`[pxx, pmax] = step(SE,x)` also computes the max-hold frequency spectrum, `pmax`, of `x`. To determine the max-hold spectrum, the method keeps the maximum of all the power spectrum estimates computed at each frequency bin. Set `OutputMaxHoldSpectrum` to `true` to obtain the max-hold spectrum.

`[pxx, pmin] = step(SE,x)` also computes the min-hold frequency spectrum, `pmin`, of `x`. To determine the min-hold spectrum, the method keeps the minimum of all the power spectrum estimates computed at each frequency bin. Set `OutputMinHoldSpectrum` to `true` to obtain the min-hold spectrum.

`[pxx, pmax, pmin] = step(SE, x)` computes the power spectrum or power-density spectrum, the max-hold spectrum, and the min-hold spectrum of `x`. Set `OutputMaxHoldSpectrum` and `OutputMinHoldSpectrum` to `true` to obtain the max-hold and min-hold spectra.

Input Arguments

SE — Frequency spectrum estimator

`SpectrumEstimator` System object

Frequency spectrum estimate, specified as a `SpectrumEstimator` System object

x — Input signal

vector | matrix

Input signal, specified as a vector or matrix with floating point or fixed-point precision. The row length of `x` is the frame size or channel length. Each column of `x` is treated as a separate channel. The column length of `x` is the number of channels.

Output Arguments

p_{xx} — Power or power-density spectrum estimate

vector | matrix

Power or power-density spectrum estimate, returned as a vector or matrix of the same size, data type, and complexity as the input signal, `x`. By default, the unit is 'Watts'. You can also specify the spectrum to be in 'dBm' or 'dBW' through the `PowerUnits` property of the `SpectrumEstimator` System object.

p_{max} — Max-hold spectrum estimate

vector | matrix

Max-hold spectrum estimate, returned as a vector or matrix of the same size, data type, and complexity as the input signal, `x`.

p_{min} — Min-hold spectrum estimate

vector | matrix

Min-hold spectrum estimate, returned as a vector or matrix of the same size, data type, and complexity as the input signal, x .

Examples

Power Spectrum of Multichannel Sinusoidal Signal

Generate a three-channel sinusoid sampled at 1 kHz. Specify sinusoidal frequencies of 100, 200, and 300 Hz. The second and third channels have their phases offset from the first by $\pi/2$ and $\pi/4$, respectively.

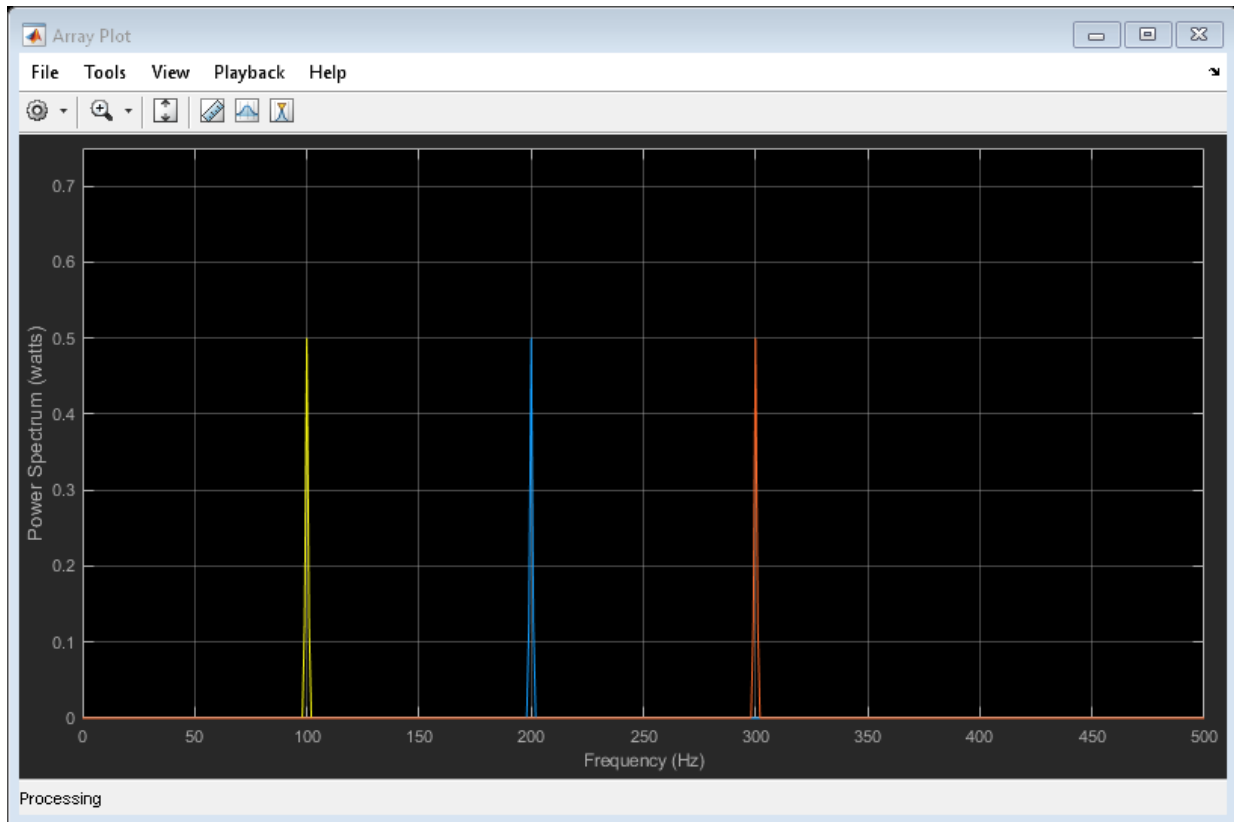

```
SINE = dsp.SineWave('SamplesPerFrame',1000,'SampleRate',1000, ...  
    'Frequency',[100 200 300],'PhaseOffset',[0 pi/2 pi/4]);
```

Estimate and plot the one-sided spectrum of the signal. Use the Spectrum Estimator for the computation and the Array Plot for the plotting.

```
SE = dsp.SpectrumEstimator('FrequencyRange','onesided');  
PLOTTER = dsp.ArrayPlot('PlotType','Line','YLimits',[0 0.75], ...  
    'YLabel','Power Spectrum (watts)','XLabel','Frequency (Hz)');
```

Step through to obtain the data streams and display the spectra of the three channels.

```
y = step(SINE);  
pxx = step(SE,y);  
step(PLOTTER,pxx)
```

dsp.StandardDeviation System object

Package: dsp

Standard deviation of input or sequence of inputs

Description

The `dsp.StandardDeviation` object computes the standard deviation for an input or sequence of inputs.

To compute the standard deviation for an input or sequence of inputs:

- 1 Define and set up your standard deviation object. See “Construction” on page 4-1642.
- 2 Call `step` to compute the standard deviation according to the properties of `dsp.StandardDeviation`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Note The Running mode in the `dsp.StandardDeviation` System object will be removed in a future release. To compute the running standard deviation in MATLAB, use the `dsp.MovingStandardDeviation` System object instead.

Construction

`std = dsp.StandardDeviation` returns a standard deviation System object, `std`, that computes the standard deviation for the columns of input.

`std = dsp.StandardDeviation('PropertyName', PropertyValue, ...)` returns a standard deviation System object, `std`, with each specified property set to the specified value.

Properties

RunningStandardDeviation

Enable calculation over successive calls to the `step` method

Set this property to `true` to enable the calculation of standard deviation over successive calls to the `step` method. The default is `false`.

ResetInputPort

Enable resetting in running standard deviation mode

Set this property to `true` to enable resetting for the running standard deviation. When the property is set to `true`, you must specify a reset input to the `step` method to reset the running standard deviation. This property applies only when you set the `RunningStandardDeviation` property to `true`. The default is `false`.

ResetCondition

Reset condition for running standard deviation mode

Specify event to reset the running standard deviation as one of `| Rising edge | Falling edge | Either edge | Non-zero |`. This property applies only when you set the “ResetInputPort” on page 4-0 property to `true`. The default is `Non-zero`.

Dimension

Dimension to operate along

Specify how the standard deviation calculation is performed over the data as one of `| All | Row | Column | Custom |`. This property applies only when you set the `RunningStandardDeviation` property to `false`. The default is `Column`.

CustomDimension

Numerical dimension to operate along

Specify the dimension (one-based value) of the input signal, over which the object computes the standard deviation. The cannot exceed the number of dimensions for the input signal. This property applies when you set the “Dimension” on page 4-0 property to `Custom`. The default is `1`.

Methods

- reset Reset states for running standard deviation computation
- step Calculate standard deviation of input

Common to All System Objects	
clone	Create System object with same property values
getNumInputs	Expected number of inputs to a System object
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Running Standard Deviation

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Compute the running standard deviation of a signal using `dsp.StandardDeviation` object. To activate this mode, set the `RunningStandardDeviation` property to `true`.

```
std2 = dsp.StandardDeviation;  
std2.RunningStandardDeviation = true;  
x = randn(100,1);  
y = std2(x);
```

`y(i)` is the standard deviation of the `i`th input sample with respect to all the past input samples.

Algorithms

This object implements the algorithm, inputs, and outputs described on the Standard Deviation block reference page. The object properties correspond to the block parameters, except:

- The **Reset port** block parameter corresponds to the `ResetInputPort` and `ResetCondition` object properties.

```

Description

`reset(std)` sets the internal states of the `StandardDeviation` object `std` to their initial values when computing the running standard deviation.

step

System object: dsp.StandardDeviation

Package: dsp

Calculate standard deviation of input

Syntax

```
Y = step(std,X)
```

```
Y = step(std,X,R)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(std,X)` computes the standard deviation, `Y`, of input `X`. The object computes the standard deviation over successive calls to the `step` method when the `RunningStandardDeviation` property is `true`.

`Y = step(std,X,R)` resets its state based on the value of reset signal `R` and the `ResetCondition` property. You can use this option only when the `RunningStandardDeviation` property is `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.StateLevels System object

Package: dsp

State-level estimation for bilevel rectangular waveform

Description

The `StateLevels` object estimates the state levels of a bilevel rectangular waveform.

To estimate the state levels of a bilevel waveform:

- 1 Define and set up your state-level estimation. See “Construction” on page 4-1649.
- 2 Call `step` to estimate the state levels for an input vector according to the properties of `dsp.StateLevels`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`s1 = dsp.StateLevels` creates a state-level estimation System object, `s1`, that estimates state levels in a bilevel rectangular waveform using the histogram method with 100 bins.

`s1 = dsp.StateLevels('PropertyName',PropertyValue,...)` returns an `StateLevels` System object, `s1`, with each specified property set to the specified value.

Properties

HistogramBounds

Minimum and maximum levels of the histogram. Specify the range of the histogram as a 2-element real-valued row vector. Signal values outside the range defined by this property are ignored. This property applies when you set the `Method` property to 'Histogram mode' or 'Histogram mean', and either `RunningStateLevels` is true, or the `HistogramBoundsSource` property is set to 'Property'.

Default: [0 5]

HistogramBoundsSource

Source of histogram bounds. Specify how to determine the histogram bounds as one of 'Auto' or 'Property'. When you set this property to 'Auto', the histogram bounds are determined by the minimum and maximum input values. When you set this property to 'Property', the histogram bounds are determined by the value of the `HistogramBounds` property. This property applies when you set the `Method` property to 'Histogram mode' or 'Histogram mean', and the `RunningStateLevels` property is false.

Default: 'Auto'

HistogramNumBins

Number of bins in the histogram. Specify the number of bins in the histogram. This property applies when you set the `Method` property to 'Histogram mode' or 'Histogram mean'.

Default: 100

HistogramOutputPort

Enable histogram output. Set this property to true to output the histogram used in the computation of the state levels. This property applies when you set the `Method` property to 'Histogram mode' or 'Histogram mean'.

Default: false

Method

Algorithm used to compute state levels. Specify the method used to compute state levels as one of 'Histogram mean', 'Histogram mode', or 'Peak to peak'.

Default: 'Histogram mode'

RunningStateLevels

Calculation over successive calls to `step`. Set this property to `true` to enable computation of the state levels over successive calls to the `step`. Otherwise, compute the state levels of the current input. When you set the `RunningStateLevels` property to `false` and you are using a histogram to compute your state levels, you must set the `HistogramBoundsSource` property to 'Property'.

State

A particular level, which can be associated with an upper and lower state boundary. States are ordered from the most negative to the most positive. In a bilevel waveform, the most negative state is the low state. The most positive state is the high state.

State-Level Tolerances

Each state level can have associated lower- and upper-state boundaries. These state boundaries are defined as the state level plus or minus a scalar multiple of the difference between the high state and low state. To provide a useful tolerance region, the scalar is typically a small number such as 2/100 or 3/100. In general, the $\alpha\%$ tolerance region for the low state is defined as

$$S_1 \pm \frac{\alpha}{100}(S_2 - S_1)$$

where S_1 is the low-state level and S_2 is the high-state level. Replace the first term in the equation with S_2 to obtain the $\alpha\%$ tolerance region for the high state.

The following figure illustrates lower and upper 2% state boundaries (tolerance regions) for a positive-polarity bilevel waveform. The estimated state levels are indicated by a dashed red line.

Methods

- plot Plot signal, state levels, and histogram
- reset Reset internal states of state levels object
- step Estimate state levels for bilevel rectangular waveform

Common to All System Objects	
clone	Create System object with same property values
getNumInputs	Expected number of inputs to a System object
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

State Levels of 2.3 V Underdamped Noisy Clock

Compute and plot the state levels of a 2.3 V underdamped noisy clock. Load the clock data in the variable, `x`, and the sampling instants in the variable `t`.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
load('clockex.mat', 'x', 't');
```

Estimate the state levels.

```
s1 = dsp.StateLevels;  
levels = s1(x);
```

Plot the clock data along with the estimated state levels and histograms.

```
plot(s1)
```

Algorithms

The `StateLevels` System object uses the histogram method to estimate the states of a bilevel waveform. The histogram method is described in [1]. To summarize the method:

- 1 Determine the maximum and minimum amplitudes and amplitude range of the data.
- 2 For the specified number of histogram bins, determine the bin width as the ratio of the amplitude range to the number of bins.
- 3 Sort the data values into the histogram bins.

- 4 Identify the lowest-indexed histogram bin, i_{low} , and highest-indexed histogram bin, i_{high} , with nonzero counts.
- 5 Divide the histogram into two subhistograms. The lower-histogram bins are $i_{low} \leq i \leq 1/2(i_{high} - i_{low})$.
The upper-histogram bins are $i_{low} + 1/2(i_{high} - i_{low}) \leq i \leq i_{high}$.
- 6 Compute the state levels by determining the mode or mean of the lower and upper histograms.

`dsp.PulseMetrics` | `dsp.TransitionMetrics`

Introduced in R2012a

plot

System object: dsp.StateLevels

Package: dsp

Plot signal, state levels, and histogram

Syntax

```
plot(s1)
```

Description

`plot(s1)` plots the signal and state levels computed in the last call to the `step` method. If the `Method` property of the state levels object is set to 'Histogram mode' or 'Histogram Mean', the histogram is plotted in a subplot below the signal.

reset

System object: dsp.StateLevels

Package: dsp

Reset internal states of state levels object

Syntax

```
reset(s1)
```

Description

`reset(s1)` resets the state levels object, `s1`, to clear information accumulated from previous calls to `step`.

step

System object: dsp.StateLevels

Package: dsp

Estimate state levels for bilevel rectangular waveform

Syntax

```
LEVELS = step(sl,X)  
[LEVELS,HISTOGRAM] = step(sl,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`LEVELS = step(sl,X)` returns a 2-element row vector, `LEVELS`, containing the estimated state levels for `X`. `X` is a real-valued column vector.

`[LEVELS,HISTOGRAM] = step(sl,X)` returns a double-precision column vector, `HISTOGRAM`, containing the histogram of the sample values in `X`. You can obtain this output only when you set the `Method` property to either `'Histogram mean'` or `'Histogram mode'`, and you set the `HistogramOutputPort` property to `true`.

dsp.SubbandAnalysisFilter System object

Package: dsp

Decompose signal into high-frequency and low-frequency subbands

Description

The `SubbandAnalysisFilter` object decomposes a signal into high-frequency and low-frequency subbands.

To decompose a signal into high-frequency and low-frequency subbands:

- 1 Define and set up your two-channel subband analysis filter. See “Construction” on page 4-1659.
- 2 Call `step` to decompose the signal according to the properties of `dsp.SubbandAnalysisFilter`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`subAna = dsp.SubbandAnalysisFilter` returns a two-channel subband analysis filter, `subAna`, that decomposes the input signal into a high-frequency subband and a low-frequency subband, each with half the bandwidth of the input.

`subAna = dsp.SubbandAnalysisFilter('PropertyName', PropertyValue, ...)` returns a two-channel subband analysis filter, `subAna`, with each specified property set to the specified value.

`subAna = dsp.SubbandAnalysisFilter(lpc, hpc,`

`'PropertyName', PropertyValue, ...)` returns a two-channel subband analysis filter, `subAna`, with the “LowpassCoefficients” on page 4-0 property set to `lpc`, the `HighpassCoefficients` property set to `hpc`, and other specified properties set to the specified values.

Properties

LowpassCoefficients

Lowpass FIR filter coefficients

Specify a vector of lowpass FIR filter coefficients, in descending powers of z . For the lowpass filter, use a half-band filter that passes the frequency band stopped by the filter specified in the `HighpassCoefficients` property. The default values of this property specify a filter based on a third-order Daubechies wavelet.

HighpassCoefficients

Highpass FIR filter coefficient

Specify a vector of highpass FIR filter coefficients, in descending powers of z . For the highpass filter, use a half-band filter that passes the frequency band stopped by the filter specified in the “LowpassCoefficients” on page 4-0 property. The default values of this property specify a filter based on a third-order Daubechies wavelet.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |. The default is Floor. This property applies only if the object is not in full precision mode.

OverflowAction

Action to take when integer input is out of range

Specify the overflow action as one of | Wrap | Saturate |. The default is Wrap. This property applies only if the object is not in full precision mode.

CoefficientsDataType

Data type of the coefficients

Specify the FIR filter coefficients fixed-point data type as one of | Same word length as input | Custom |. The default is Same word length as input.

CustomCoefficientsDataType

Coefficients word and fraction lengths

Specify the FIR filter coefficients fixed-point type as a `numerictype` object with a Signedness of Auto. This property applies only when you set the `CoefficientsDataType` property to Custom. The default is `numerictype([],16,15)`.

ProductDataType

Data type of product

Specify the product data type as one of | Full precision | Same as input | Custom |. The default is Full precision.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `ProductDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

AccumulatorDataType

Data type of accumulator

Specify the accumulator data type as one of `Full precision` | `Same as input` | `Same as product` | `Custom` |. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

OutputDataType

Data type of output

Specify the output data type as one of | `Same as accumulator` | `Same as product` | `Same as input` | `Custom` |. The default is `Same as accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the “`OutputDataType`” on page 4-0 property to `Custom`. The default is `numericType([], 16, 14)`.

Methods

- `reset` Reset filter states of subband analysis filter object
- `step` Decompose signal into high- and low-frequency subbands

Common to All System Objects	
clone	Create System object with same property values
getNumInputs	Expected number of inputs to a System object
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Decompose and Reconstruct a Signal

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Decompose a signal into low frequency and high frequency subbands using the subband analysis filter. Reconstruct the signal using the subband synthesis filter.

```
load dspwlets; % load the filter coefficients lod, hid, lor and hir
subAna = dsp.SubbandAnalysisFilter(lod, hid);
subSynth = dsp.SubbandSynthesisFilter(lor, hir);
u = randn(128,1);

[hi, lo] = subAna(u); % Two channel analysis
y = subSynth(hi, lo); % Two channel synthesis
```

Plot difference between original and reconstructed signals with filter latency compensated.

```
plot(u(1:end-7)-y(8:end));
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Two-Channel Analysis Subband Filter block reference page. The object properties correspond to the block parameters, except:

- The `SubbandAnalysisFilter` object does not have a property that corresponds to the **Input processing** parameter of the Two-Channel Analysis Subband Filter block. The object assumes the input is frame based and always maintains the input frame rate.

- The **Rate options** block parameter is not supported by the `dsp.SubbandAnalysisFilter` object.

Extended Capabilities

reset

System object: dsp.SubbandAnalysisFilter

Package: dsp

Reset filter states of subband analysis filter object

Syntax

```
reset(subAna)
```

Description

`reset(subAna)` sets the filter states of the `SubbandAnalysisFilter` object `subAna` to 0.

step

System object: dsp.SubbandAnalysisFilter

Package: dsp

Decompose signal into high- and low-frequency subbands

Syntax

```
[HI,LO] = step(subAna,SIG)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[HI,LO] = step(subAna,SIG)` decomposes the input signal, `SIG`, into a high-frequency subband, `HI`, and a low-frequency subband, `LO`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.SubbandSynthesisFilter System object

Package: dsp

Reconstruct signal from high-frequency and low-frequency subbands

Description

The `SubbandSynthesisFilter` object reconstructs a signal from high-frequency and low-frequency subbands.

To reconstruct a signal from high-frequency and low-frequency subbands:

- 1 Define and set up your two-channel subband synthesis filter. See “Construction” on page 4-1668.
- 2 Call `step` to reconstruct the signal according to the properties of `dsp.SubbandSynthesisFilter`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`subSyn = dsp.SubbandSynthesisFilter` returns a two-channel subband synthesis filter, `subSyn`, that reconstructs a signal from its high-frequency subband and low-frequency subband. Each subband contains half the bandwidth of the original signal.

`subSyn = dsp.SubbandSynthesisFilter('PropertyName', PropertyValue, ...)` returns a two-channel subband synthesis filter, `subSyn`, with each specified property set to the specified value.

`subSyn = dsp.SubbandSynthesisFilter(lpc, hpc,`

`'PropertyName', PropertyValue, ...)` returns a two-channel subband synthesis filter, `subSyn`. The object has the “LowpassCoefficients” on page 4-0 property set to `lpc`, the `HighpassCoefficients` property set to `hpc`, and other specified properties set to the specified values.

Properties

LowpassCoefficients

Lowpass FIR filter coefficients

Specify a vector of lowpass FIR filter coefficients, in descending powers of z . For the lowpass filter, use a half-band filter that passes the frequency band stopped by the filter specified in the `HighpassCoefficients` property. The default values of this property specify a filter based on a third-order Daubechies wavelet.

HighpassCoefficients

Highpass FIR filter coefficients

Specify a vector of highpass FIR filter coefficients, in descending powers of z . For the highpass filter, use a half-band filter that passes the frequency band stopped by the filter specified in the `LowpassCoefficients` property. The default values of this property specify a filter based on a third-order Daubechies wavelet.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |. The default is `Floor`. This property applies only if the object is not in full precision mode.

OverflowAction

Action to take when integer input is out of range

Specify the overflow action as one of | `Wrap` | `Saturate` |. The default is `Wrap`. This property applies only if the object is not in full precision mode.

CoefficientsDataType

Data type of the coefficients

Specify the FIR filter coefficients fixed-point data type as one of | `Same word length as input` | `Custom` |. The default is `Same word length as input`.

CustomCoefficientsDataType

Coefficient word and fraction lengths

Specify the FIR filter coefficients fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `CoefficientsDataType` property to `Custom`. The default is `numerictype([],16,15)`.

ProductDataType

Data type of product

Specify the product data type as one of | `Full precision` | `Same as input` | `Custom` |. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `ProductDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

AccumulatorDataType

Data type of accumulator

Specify the accumulator data type as one of `| Full precision | Same as input | Same as product | Custom |`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

OutputDataType

Data type of output

Specify the output data type as one of `| Same as accumulator | Same as product | Same as input | Custom |`. The default is `Same as accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when you set the `OutputDataType` property to `Custom`. The default is `numericType([], 16, 14)`.

Methods

- `reset` Reset internal states of subband synthesis filter object
- `step` Reconstruct signal from high- and low-frequency subbands

Common to All System Objects	
clone	Create System object with same property values
getNumInputs	Expected number of inputs to a System object
getNumOutputs	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Decompose and Reconstruct a Signal

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Decompose a signal into low frequency and high frequency subbands using the subband analysis filter. Reconstruct the signal using the subband synthesis filter.

```
load dspwlets; % load the filter coefficients lod, hid, lor and hir
subAna = dsp.SubbandAnalysisFilter(lod, hid);
subSynth = dsp.SubbandSynthesisFilter(lor, hir);
u = randn(128,1);

[hi, lo] = subAna(u); % Two channel analysis
y = subSynth(hi, lo); % Two channel synthesis
```

Plot difference between original and reconstructed signals with filter latency compensated.

```
plot(u(1:end-7)-y(8:end));
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Two-Channel Synthesis Subband Filter block reference page. The object properties correspond to the block parameters, except:

- The `SubbandSynthesisFilter` object does not have a property that corresponds to the **Input processing** parameter of the Two-Channel Synthesis Subband Filter block. The object only performs sample-based processing and always maintains the input frame rate.

- The **Rate options** block parameter is not supported by the `SubbandSynthesisFilter` object.

Extended Capabilities

```
reset(subSyn)
```

Description

`reset(subSyn)` sets the internal states of the `SubbandSynthesisFilter` object `subSyn` to their initial values.

step

System object: dsp.SubbandSynthesisFilter

Package: dsp

Reconstruct signal from high- and low-frequency subbands

Syntax

```
Y = step(subSyn, HI, LO)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

`Y = step(subSyn, HI, LO)` reconstructs a signal from a high-frequency subband, `HI`, and a low-frequency subband, `LO`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.TimeScope System object

Package: dsp

Time domain signal display and measurement

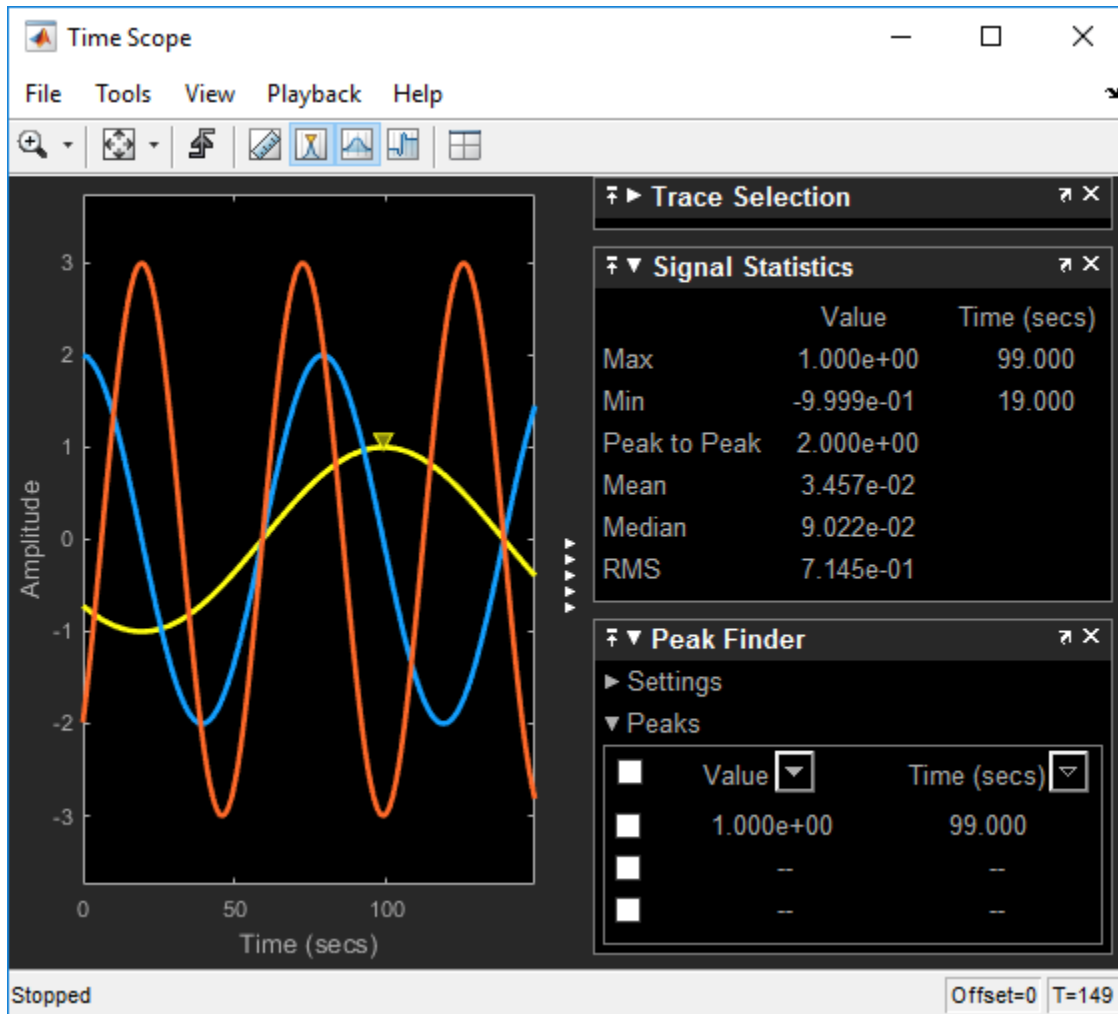

Description

The `dsp.TimeScope` System object displays time-domain signals. You can use the scope to measure signal values, find peaks, display bilevel measurements and statistics.

To see time-domain signals in the scope:

- 1 Create the `dsp.TimeScope` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#) (MATLAB).

Oscilloscope features:

- Triggers — Set triggers to sync repeating signals and pause the display when events occur.
- Cursor Measurements — Measure signal values using vertical and horizontal cursors.
- Signal Statistics — Display the maximum, minimum, peak-to-peak difference, mean, median, and RMS values of a selected signal.

- Peak Finder — Find maxima, showing the x -axis values at which they occur.
- Bilevel Measurements — Measure transitions, overshoots, undershoots, and cycles.

For information on measurements and triggers, see “Configure Time Scope”.

Scope display features:

- Multiple signals — Plot multiple signals on the same y -axis (display) using multiple input ports.
- Multiple y -axes (displays) — Display multiple y -axes. All the y -axes have a common time range on the x -axis.
- Modify parameters — Modify scope parameter values before and during a simulation.
- Axis autoscaling — Autoscaling during or at the end of a simulation. Margins are drawn at the top and bottom of the axes.

Creation

Syntax

```
scope = dsp.TimeScope
scope = dsp.TimeScope(numInputs, sampleRate)
scope = dsp.TimeScope( ____, Name, Value)
```

Description

`scope = dsp.TimeScope` returns a Time Scope System object, `scope`. This object displays real- and complex-valued floating and fixed-point signals in the time domain.

`scope = dsp.TimeScope(numInputs, sampleRate)` creates a Time Scope and sets the `NumInputPorts` property to `numInputs` and the `SampleRate` property to `sampleRate`.

`scope = dsp.TimeScope(____, Name, Value)` sets properties specified as `Name, Value` pairs.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects \(MATLAB\)](#).

Frequently Used

NumInputPorts — Number of input ports

1 (default) | integer between [1, 96]

Number of input ports, specified as a positive integer. Each signal coming through an input port becomes a separate channel in the scope. You must invoke the scope with the same number of inputs as the value of this property.

SampleRate — Sample rate of inputs

1 (default) | scalar | vector

Specify the sample rate, in hertz, of the input signals.

You can specify a scalar or a numeric vector with length equal to the value of `NumInputPorts`. The inverse of the sample rate determines the spacing between points on the time axis in the displayed signal. When you set `SampleRate` to a scalar value and `NumInputPorts` is greater than 1, the object uses the same sample rate for all inputs.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

TimeSpan — Time span

10 (default) | positive scalar

Specify the time span, in seconds, as a positive, numeric scalar value. The time-axis limits are calculated as follows.

- Minimum time-axis limit = `min(TimeDisplayOffset)`

- Maximum time-axis limit = $\max(\text{TimeDisplayOffset}) + \text{TimeSpan}$

Tunable: Yes

Dependencies

To use this property, set `FrameBasedProcessing` to `false`, or set `FrameBasedProcessing` to `true` and `TimeSpanSource` to `'Property'`.

UI Use

Open the **Configuration Properties**. On the **Main** tab, set **Time Span**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

TimeSpanOverrunAction — Wrap or scroll when **TimeSpan** is overrun

`'Wrap'` (default) | `'Scroll'`

Specify how the scope displays new data beyond the visible time span.

- `Wrap` — In this mode, the scope displays new data until the data reaches the maximum time-axis limit. When the data reaches the maximum time-axis limit of the scope window, the scope clears the display. The scope then updates the time offset value and begins displaying subsequent data points starting from the minimum time-axis limit.
- `Scroll` — In this mode, the scope scrolls old data to the left to make room for new data on the right side of the scope display. This mode is graphically intensive and can affect run-time performance. However, it is beneficial for debugging and monitoring time-varying signals.

Tunable: Yes

UI Use

Open the **Configuration Properties**. On the **Main** tab, set **Time Span overrun action**.

TimeSpanSource — Source of time span

`'Property'` (default) | `'Auto'`

Specify the source of the time span for frame-based input signals as:

- 'Property' — The object derives the *x*-axis limits from the `TimeDisplayOffset` and `TimeSpan` properties.
- 'Auto' — The time-axis limits are derived from the `TimeDisplayOffset` and `SampleRate` properties and the `FrameSize` (number of rows in each input signal). The limits are calculated as:
 - Minimum time-axis limit = `min(TimeDisplayOffset)`
 - Maximum time-axis limit = `max(TimeDisplayOffset) + max(1/SampleRate.*FrameSize)`

Tunable: Yes

Dependencies

To use this property, set `FrameBasedProcessing` to true.

UI Use

Open the **Configuration Properties**. On the **Main** tab, set **Time Span**.

AxesScaling — Axes scaling mode

'OnceAtStop' (default) | 'Auto' | 'Manual' | 'Updates'

Specify when the scope scales the axes. Valid values are:

- 'Auto' — The scope scales the axes as needed to fit the data, both during and after simulation.
- 'Manual' — The scope does not scale the axes automatically.
- 'OnceAtStop' — The scope scales the axes when the simulation stops.
- 'Updates' — The scope scales the axes once and only once after 10 updates.

UI Use

Select **Tools > Axes Scaling**.

Advanced

Name — Window name

'Time Scope' (default) | character vector | string

Specify the name of the scope as a character vector or string. This name appears as the title of the scope's figure window. To specify a title of a scope plot, use the Title property.

Tunable: Yes

Data Types: `char` | `string`

Position — Window position

`screen center (default)` | `[left bottom width height]`

Scope window position in pixels, specified by the size and location of the scope window as a 4-element vector of the form `[left bottom width height]`. You can place the scope window in a specific position on your screen by modifying the values to this property.

By default, the window appears in the center of your screen with a width of 410 pixels and height of 300 pixels. The exact position value depends on your screen resolution.

Tunable: Yes

ReduceUpdates — Reduce updates to improve performance

`true (default)` | `false`

- `true` — The scope logs data for later use and updates the window periodically.
- `false` — The scope updates every time the scope is called.

The simulation speed is faster when this property is set to `true`.

Tunable: Yes

UI Use

Select **Simulation > Reduce Updates to Improve Performance**.

LayoutDimensions — Display layout grid dimentions

`[1,1] (default)` | `[numberOfRows, numberOfColumns]`

Specify the layout grid dimensions as a 2-element vector: `[numberOfRows, numberOfColumns]`. You can use up to 16 rows and 16 columns.

Example: `scope.LayoutDimensions = [2,4]`

Tunable: Yes

UI Use

Select **View > Layout**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

PlotType — Control the type of plot

'Line' (default) | 'Stairs'

Specify the type of plot to use.

- `Line` — Line graph, similar to the `line` or `plot` function.
- `Stairs` — Stair-step graph, similar to the `stairs` function. Stair-step graphs are useful for drawing time history graphs of digitally sampled data.

Tunable: Yes

UI Use

Open the **Style** properties. Set **Plot type**.

BufferLength — Length of buffer used for each input signal

5000 (default) | scalar

Specify the size of the buffer that the scope holds in its memory cache. Memory is limited by available memory on your system. If your signal has M rows of data and N data points in each row, $M \times N$ is the number of data points per time step. Multiply this result by the number of time steps for your model to obtain the required buffer length. For example, if you have 10 rows of data with each row having 100 data points and your run will be 10 time steps, you should enter 10,000 ($10 \times 100 \times 10$) as the buffer length.

UI Use

Open the **Data History Properties**. Set **Buffer length**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

FrameBasedProcessing — Process input in frames

`true` (default) | `false`

- `true` — Enable frame-based processing.

- `false` — Enable sample-based processing.

UI Use

Open the **Configuration Properties**. On the **Main** tab, set **Input processing**.

TimeUnits — Units of time axis

'Metric' (default) | 'Seconds' | 'None'

Specify the units used to describe the time axis. You can select one of the following options:

- `Metric` — In this mode, the scope converts the times on the time axis to the most appropriate measurement units. These units include milliseconds, microseconds, nanoseconds, minutes, days, etc. The scope chooses the appropriate measurement units based on the minimum time-axis limit and the maximum time-axis limit of the scope window.
- `Seconds` — In this mode, the scope always displays the units on the time axis as seconds.
- `None` — In this mode, the scope does not display any units on the time axis. The scope only shows the word `Time` on the time axis.

Tunable: Yes

UI Use

Open the **Configuration Properties**. On the **Main** tab, set **Time units**.

TimeDisplayOffset — Offset x-axis limits

0 (default) | scalar | vector

Specify, in seconds, how far to move the data on *x*-axis. The signal value does not change, only the displayed *x*-axis.

If you specify this property as a scalar, then that value is the time display offset for all channels.

If you specify a vector, each vector element is the time offset for the corresponding channel. For vectors with length less than the number of input channels, the time display offsets for the remaining channels are set to 0. If a vector has a length greater than the number of input channels, the extra vector elements are ignored.

Tunable: Yes

UI Use

Open the **Configuration Properties**. On the **Main** tab, set **Time display offset**.

TimeAxisLabels — Time-axis labels

'All' (default) | 'Bottom' | 'None'

Specify how time-axis labels should appear in the scope displays as:

- 'All' — Time-axis labels appear in all displays.
- 'Bottom' — Time-axis labels appear in the bottom display of each column.
- 'None' — No labels appear in any display.

Tunable: Yes

UI Use

Open the **Configuration Properties**. On the **Main** tab, set **Time-axis labels**.

MaximizeAxes — Maximize axes control

'Auto' (default) | 'On' | 'Off'

Specify whether to display the scope in maximized-axes mode. In this mode, the axes are expanded to fit into the entire display. To conserve space, labels do not appear in each display. Instead, tick-mark values appear on top of the plotted data. You can select one of the following options:

- 'Auto' — The axes appear maximized in all displays only if the Title and YLabel properties are empty for every display. If you enter any value in any display for either of these properties, the axes are not maximized.
- 'On' — The axes appear maximized in all displays. Any values entered into the Title and YLabel properties are hidden.
- 'Off' — None of the axes appear maximized.

Tunable: Yes

UI Use

Open the **Configuration Properties**. On the **Main** tab, set **Maximize axes**.

Display

ActiveDisplay — Active display for setting properties

1 (default) | integer

Specify the active display, by integer display number, to get and set relevant properties. The number of a display corresponds to its column-wise placement index. Set this property to control which display has its axes colors, line properties, marker properties, and visibility changed.

Tunable: Yes

UI Use

Open the **Configuration Properties**. On the **Display** tab, set **Active Display**.

Title — Display title

' ' (default) | character vector | string

Specify the display title as a character vector or string. Enter %<SignalLabel> to use the signal labels as the axes titles.

Tunable: Yes

UI Use

Open the **Configuration Properties**. On the **Display** tab, set **Title**.

ShowLegend — Show legend

false (default) | true

To show a legend with the input names, set this property to `true`.

From the legend, you can control which signals are visible. This control is equivalent to changing the visibility in the **Style** dialog box. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again. To show only one signal, right-click the signal name. To show all signals, press **Esc**.

Tunable: Yes

UI Use

Open the **Configuration Properties**. On the **Display** tab, select **Show legend**.

ShowTimeAxisLabel — Show legend on display

`true` (default) | `false`

When you set this property to `true`, the scope displays the time-axis label. When you set this property to `false`, the scope does not display the time-axis label, but still displays tick marks and other time-axis items. This property applies only if the `TimeAxisLabels` property is `All` or `Bottom`.

Tunable: Yes

Dependency

To control which display's axis is labeled, use the `ActiveDisplay` property.

UI Use

Open the **Configuration Properties**. On the **Main** tab, set **Show time-axis label**.

ChannelNames — Channel names

empty cell (default) | cell array of character vectors | cell array of strings

Specify the input channel names as a cell array of character vectors or strings. The names appear in the legend, **Style** dialog box, and **Measurements** panels. If you do not specify names, the channels are labeled as `Channel 1`, `Channel 2`, etc.

Tunable: Yes

Dependency

To see channel names, set `ShowLegend` to `true`.

UI Use

Show the legend and double-click the channel name.

ShowGrid — Grid visibility

`false` (default) | `true`

Set this property to `true` to show gridlines on the plot.

Tunable: Yes

UI Use

Open the **Configuration Properties**. On the **Display** tab, set **Show grid**.

PlotAsMagnitudePhase — Plot signal as magnitude and phase`false` (default) | `true`

When you set this property to `true`, the scope plots the magnitude and phase of the input signal on two separate axes within the same active display. When you set this property to `false`, the scope plots the real and imaginary parts of the input signal on two separate axes within the same active display.

This property is useful for complex-valued input signals. Turning on this property affects the phase for real-valued input signals. When the amplitude of the input signal is nonnegative, the phase is 0 degrees. When the amplitude of the input signal is negative, the phase is 180 degrees.

Tunable: Yes

UI Use

Open the **Configuration Properties**. On the **Display** tab, select **Plot signals as magnitude and phase**.

YLimits — Y-axis limits`[-10,10]` (default) | `[ymin, ymax]`

Specify the *y*-axis limits as a two-element numeric vector, `[ymin, ymax]`.

If `PlotAsMagnitudePhase` is `false`, the default is `[-10,10]`. If `PlotAsMagnitudePhase` is `true`, the default is `[0,10]`.

Tunable: Yes

Dependencies

When `PlotAsMagnitudePhase` is `true`, this property specifies the *y*-axis limits of only the magnitude plot. The *y*-axis limits of the phase plot are always `[-180,180]`.

UI Use

Open the **Configuration Properties**. On the **Display** tab, set **Y-limits (Minimum)** and **Y-limits (Maximum)**.

YLabel — Y-axis label`'Amplitude'` (default) | character vector | string

Specify the text for the scope to display to the left of the y -axis.

Tunable: Yes

Dependencies

This property applies only when `PlotAsMagnitudePhase` is false. When `PlotAsMagnitudePhase` is true, the two y -axis labels are read-only values. The y -axis labels are set to 'Magnitude' and 'Phase' for the magnitude plot and the phase plot, respectively.

UI Use

Open the **Configuration Properties**. On the **Display** tab, set **Y-Label**.

Data Types: `char` | `string`

Usage

Note For versions earlier than R2016b, use the `step` function to run the System object™ algorithm. The arguments to `step` are the object you created, followed by the arguments shown in this section.

For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Syntax

```
scope(signal)
scope(signal, signal2, ..., signalN)
```

Description

`scope(signal)` displays the signal, `signal`, in the time scope display.

`scope(signal, signal2, ..., signalN)` displays the signals `signal`, `signal2`, ..., `signalN` in the time scope display when you set the `NumInputPorts` property to `N`. In this case, `signal1`, `signal2`, ..., `signalN` can have different data types and dimensions.

Input Arguments

signal — Input signal or signals to visualize

scalar | vector | matrix

Specify one or more input signals to visualize in the `dsp.TimeScope`. Signals can have different data types and dimensions.

Example: `scope(signal1,signal2)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `string` | `struct` | `table` | `cell` | `categorical` | `datetime` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to Scopes

`show` Display scope window

`hide` Hide scope window
