matlab.DiscreteEventSystem class

Package: matlab

Superclasses:

Base class for discrete-event system objects

Description

`matlab.DiscreteEventSystem` is the base class for discrete-event System objects. In your class definition file, you must subclass your object from this base class (or from another class that derives from this base class). Subclassing allows you to use the implementation and service methods provided by this base class to build your object. Type this syntax as the first line of your class definition file to directly inherit from the `matlab.DiscreteEventSystem` base class, where `ObjectName` is the name of your object:

```
classdef ObjectName < matlab.DiscreteEventSystem
```

Define as public these methods:

- `blocked`
- `destroy`
- `entry`
- `exit`
- `generate`
- `iterate`
- `setupEvents`
- `timer`

For other methods, set `Access = protected`.

Methods

This list contains the methods to implement and the utility methods.

blocked	Event action when entity forward fails
cancelDestroy	Cancel previously scheduled entity destroy event
cancelForward	Cancel previously scheduled forward events
cancelGenerate	Cancel previously scheduled entity generation event
cancelIterate	Cancel previously scheduled iterate event
cancelTimer	Cancel previously scheduled timer event
destroy	Event action upon entity destruction
entityType	Define entity type
entry	Event action when entity enters storage element
eventDestroy	Create entity destroy event
eventForward	Create entity forward event
eventGenerate	Create entity generate event
eventIterate	Create entity iterate event
eventTimer	Create entity timer event
exit	Event action before entity exit from storage
generate	Event action upon entity creation
getEntityPortsImpl	Define input ports and output ports of discrete-event system
getEntityStorageImpl	Define entity storage elements of discrete-event system
getEntityTypesImpl	Define entity types of discrete-event system
initEventArray	Initialize event array
iterate	Event action when entity iterates
queueFIFO	Define first-in first-out (FIFO) queue storage
queueLIFO	Define last-in last-out (LIFO) queue storage
queuePriority	Define priority queue storage
queueSysPriority	Define system priority queue storage
setupEvents	Initialize entity generation events
timer	Event action when timer completes

Inherited Methods

The `matlab.DiscreteEventSystem` class inherits a subset of the `matlab.System` class.

<code>getIconImpl</code>	Name to display as block icon
<code>getHeaderImpl</code>	Header for System object display
<code>getPropertyGroupsImpl</code>	Property groups for System object display
<code>isInactivePropertyImpl</code>	Inactive property status
<code>validatePropertiesImpl</code>	Validate property values
<code>processTunedPropertiesImpl</code>	Action when tunable properties change
<code>getNumInputsImpl</code>	Number of inputs to step method
<code>getInputNamesImpl</code>	Names of System block input ports
<code>getNumOutputsImpl</code>	Number of outputs from step method
<code>getOutputNamesImpl</code>	Names of System block output ports
<code>getOutputSizeImpl</code>	Sizes of output ports
<code>getOutputDataTypeImpl</code>	Data types of output ports
<code>isOutputComplexImpl</code>	Complexity of output ports
<code>getDiscreteStateSpecificationImpl</code>	Discrete state size, data type, and complexity
<code>getDiscreteStateImpl</code>	Discrete state property values
<code>matlab.DiscreteEventSystem.initEventArray</code>	Initialize event array
<code>setupImpl</code>	Initialize System object
<code>resetImpl</code>	Reset System object states
<code>releaseImpl</code>	Release resources
<code>loadObjectImpl</code>	Load System object from MAT file
<code>saveObjectImpl</code>	Save System object in MAT file
<code>infoImpl</code>	Information about System object
<code>isDoneImpl</code>	End-of-data flag

Introduced in R2016a

blocked

Class: matlab.DiscreteEventSystem

Package: matlab

Event action when entity forward fails

Syntax

```
[entity,events]=blocked(obj,storage,entity,destination)
[entity,events,out1,...]=blocked(obj,storage,entity,destination,
in1,...)
```

Description

`[entity,events]=blocked(obj,storage,entity,destination)` specifies event actions of the object when an entity forward fails because the destination storage element has reached its maximum capacity.

`[entity,events,out1,...]=blocked(obj,storage,entity,destination,in1,...)` specifies such event actions of the object when the block has one or more input signal ports and/or signal output ports.

Input Arguments

obj — Discrete-event System object™

MATLAB® object

Discrete-event System object.

storage — Storage

double

Index of the storage element.

entity — Entity

MATLAB structure

Entity leaving storage element.

destination — Destination

MATLAB structure

Destination of entity, such as an output port or a storage element.

in1 — Signal inputs

any value

Any data inputs of the object. These input arguments exist only when the object has data inputs.

Output Arguments

entity — Entity

MATLAB structure

Entity leaving storage, possibly with changed data.

events — Events

vector of MATLAB structures

Events to be scheduled after the method returns.

out1 — Signal output

any value

Data outputs of the object. You must specify these output arguments when the object has data outputs.

Examples

Cancel Current Forward Event

Cancel the current forward event upon blocking. Schedule an event to forward the entity to the next location. Destroy the entity if no storage can accept the entity.

```
function [entity,events] = blocked(obj,storage,entity,dst)
    % Cancel the current forward event. Schedule an event to
    % forward the entity to the next location. Destroy the entity
    % if no storage can accept the entity.
    if dst.index < obj.numStorage
        events = [...
            obj.cancelForward(dst.type, dst.index), ...
            obj.eventForward('storage', dst.index+1, 0)];
    else
        events = [...
            obj.cancelForward(dst.type, dst.index), ...
            obj.eventDestroy()];
    end
end
```

cancelDestroy

Class: matlab.DiscreteEventSystem

Package: matlab

Cancel previously scheduled entity destroy event

Syntax

```
event=cancelDestroy()
```

Description

`event=cancelDestroy()` cancels a previously scheduled destroy event of the current entity. You can then schedule this event by returning it as the output argument when implementing an event action method, such as `matlab.DiscreteEventSystem.entry` or `matlab.DiscreteEventSystem.exit`.

Output Arguments

event — Event

MATLAB structure

Event for cancelling entity destroy.

Examples

Cancel Previously Scheduled Destroy Event

Cancel the previously scheduled destroy event of the entity in the current event action context.

```
function [entity,events] = timer(obj,storage,entity,tag)
    % Cancel the previously scheduled destroy event of the entity in
```

```
% current event action context.  
event = obj.cancelDestroy();  
end
```

cancelForward

Class: matlab.DiscreteEventSystem

Package: matlab

Cancel previously scheduled forward events

Syntax

```
event=cancelForward(destinationType,destinationID)
```

Description

`event=cancelForward(destinationType,destinationID)` cancel previously scheduled forward events on the current entity. You can then schedule this event by returning it as the output argument when implementing an event action method, such as `matlab.DiscreteEventSystem.entry` or `matlab.DiscreteEventSystem.exit`.

Input Arguments

destinationType — Destination type

character vector

Destination type. Its value can be either:

- `storage`, if destination of the forward event is a storage element.
- `output`, if destination of forward event is an output port.

destinationID — Destination index

double

Destination index, specified as a double. Its value can be either:

- Storage index, when `destinationType` is `storage`.

- Output port index, when `destinationType` is output.

Output Arguments

event — Event

MATLAB structure

Event for cancelling an entity forward.

Examples

Cancel Previously Schedule Forward Event

Cancel a previously scheduled forward event of the entity in the current event action context.

```
function [entity,events] = timer(obj,storage,entity,tag)
    % Cancel a previously scheduled forward event of the entity in
    % current event action context. The entity was scheduled to go to
    % storage element 2.
    event1 = obj.cancelForward('storage', 2);

    % Cancel a previously scheduled forward event of the entity in
    % current event action context. The entity was scheduled to go to
    % output port 1.
    event2 = obj.cancelForward('output', 1);
end
```

cancelGenerate

Class: matlab.DiscreteEventSystem

Package: matlab

Cancel previously scheduled entity generation event

Syntax

```
event=cancelGenerate(storageID,tag)
```

Description

`event=cancelGenerate(storageID,tag)` cancels a previously scheduled generation event. You can then schedule this event by returning it as the output argument when implementing an event action method, such as `matlab.DiscreteEventSystem.entry` or `matlab.DiscreteEventSystem.exit`.

Input Arguments

storageID — Storage index

double

Storage index of the to-be-cancelled entity generation event.

tag — Tag

character vector

Tag of the to-be-cancelled entity generation event.

Output Arguments

event — Event

MATLAB structure

Event for cancelling an entity generation.

Examples

Cancel Previously Scheduled Entity Generation Event

Cancel a previously scheduled entity generation event.

```
function [entity,event] = entry(obj,storage,entity,src)
    % Cancel a previously scheduled entity generation event. The event
    % was scheduled for storage element 3, with a custom tag 'seed'.
    event = obj.cancelGenerate(3, 'seed');
end
```

cancelIterate

Class: matlab.DiscreteEventSystem

Package: matlab

Cancel previously scheduled iterate event

Syntax

```
event=cancelIterate(storageID,tag)
```

Description

`event=cancelIterate(storageID,tag)` cancels a previously scheduled iterate event. You can commit the cancellation by returning it as the output argument when implementing an event action method, such as `matlab.DiscreteEventSystem.entry`.

Input Arguments

storageID — Storage index

double

Storage index of the to-be-cancelled iterate event.

tag — Tag

character vector

Tag of the to-be-cancelled iterate event.

Output Arguments

event — Event

MATLAB structure

Event for cancelling the specified iterate event.

Examples

Cancel Previously Scheduled Iterate Event

Cancel a previously scheduled iterate event.

```
function [entity,event] = entry(obj,storage,entity,src)
    % Cancel a previously scheduled iterate event. The event was
    % scheduled for storage element 2, with a custom tag 'search'.
    event = obj.cancelIterate(2, 'search');
end
```

cancelTimer

Class: matlab.DiscreteEventSystem

Package: matlab

Cancel previously scheduled timer event

Syntax

```
event=cancelTimer(tag)
```

Description

`event=cancelTimer(tag)` cancels a previously scheduled timer event of the current entity. You can commit the cancellation by returning it as the output argument when implementing an event action method, such as `matlab.DiscreteEventSystem.entry`.

Input Arguments

tag — Tag

character vector

Tag of the to-be-cancelled timer event.

Output Arguments

event — Event

MATLAB structure

Event for cancelling the specified timer.

Examples

Cancel Previously Scheduled Timer Event

Cancel a previously scheduled timer event of the entity in the current event action context.

```
function [entity,event] = entry(obj,storage,entity,src)
    % Cancel a previously scheduled timer event of the entity in
    % current event action context. The event was scheduled with a
    % custom tag 'timeout'.
    event = obj.cancelTimer('timeout');
end
```

destroy

Class: matlab.DiscreteEventSystem

Package: matlab

Event action upon entity destruction

Syntax

```
[events]=destroy(obj,storage,entity)  
[events,out1,...]=destroy(obj,storage,entity,in1,...)
```

Description

`[events]=destroy(obj,storage,entity)` specifies event actions of the object before an entity is destroyed.

`[events,out1,...]=destroy(obj,storage,entity,in1,...)` specifies such event actions of the object when the block has one or more input signal ports and/or signal output ports.

Input Arguments

obj — Discrete-event System object

MATLAB object

Discrete-event System object.

storage — Storage

double

Index of the storage element.

entity — Entity

MATLAB structure

Entity leaving storage element.

in1 — Signal input

any value

Any data inputs of the object. These input arguments exist only when the object has data inputs.

Output Arguments

events — Events

vector of MATLAB structures

Events to be scheduled.

out1 — Signal output

any value

Data outputs of the object. You must specify these output arguments when the object has data outputs.

Examples

Event Action Upon Entity Destruction

Specify event action upon entity destruction in storage.

```
function events = destroy(obj,storage,entity)
    % Upon destroy of an entity, display its ID and schedule to
    % generate a new entity.
    disp(['Entity of ID ' num2str(entity.sys.id) ' is destroyed']);
    events = obj.eventGenerate(storage, 'Refill', 1, entity.sys.priority);
end
```

entityType

Class: matlab.DiscreteEventSystem

Package: matlab

Define entity type

Syntax

```
entitytype=entityType(name)  
entitytype=entityType(name,datatype)  
entitytype=entityType(name,datatype,dimensions,complexity)
```

Description

`entitytype=entityType(name)` defines a named entity type.

`entitytype=entityType(name,datatype)` defines a named entity type with a specified data type.

`entitytype=entityType(name,datatype,dimensions,complexity)` defines a named entity type with a specified data type, dimensions, and complexity.

Input Arguments

name — Entity type name

character vector

Entity type name.

datatype — Data type

character vector

Data type that specifies the data type of the entity. The data type must be a built-in data type or a bus object.

dimensions — Dimensions

vector of doubles

Dimensions, specified as a vector of doubles, specifying the dimensions of the entity.

complexity — Complexity

logical | double

Complexity, specified as a logical or double value, specifying the complexity of the entity:

- `false` or `0` — If the entity contains real values.
- `true` or any positive number — If the entity contains complex values.

Output Arguments

entitytype — Entity type

MATLAB structure

Entity type, specified as a MATLAB structure.

Examples

Define Entity Type

Define entity types `type1`, `type2`, and `type3`.

```
function entityTypes = getEntityTypesImpl(obj)
    % Define entity type 'type1' with inherited data type, dimension
    % and complexity
    t1 = obj.entityType('type1');

    % Define entity type 'type2' with specified data type ('mybus'),
    % default dimension and complexity (i.e. scalar real values)
    t2 = obj.entityType('type2', 'mybus');

    % Define entity type 'type3' with specified data type ('double'),
    % dimension (2 by 3 matrix), and complexity (complex)
    t3 = obj.entityType('type3', 'double', [2 3], true);
```

```
    entityType = [t1, t2, t3];  
end
```

entry

Class: matlab.DiscreteEventSystem

Package: matlab

Event action when entity enters storage element

Syntax

```
[entity,events]=entry(obj,storage,entity,source)
[entity,events,out1,...]=entry(obj,storage,entity,source,in1,...)
```

Description

`[entity,events]=entry(obj,storage,entity,source)` specifies event actions of the object when an entity enters a storage.

`[entity,events,out1,...]=entry(obj,storage,entity,source,in1,...)` such event actions of the object when the block has one or more input signal ports and/or signal output ports.

Input Arguments

obj — Discrete-event System object

MATLAB object

Discrete-event System object.

storage — Storage

double

Index of the storage element.

entity — Entity

MATLAB structure

Entity entering storage component.

source — Source location

MATLAB structure

Source location of entity, such as an input port or a storage element.

in1 — Signal input

any value

Any data inputs of the object. These input arguments exist only when the object has data inputs.

Output Arguments

entity — Entity

MATLAB structure

Entity entering storage, possibly with changed data.

events — Events

vector of MATLAB structures

Events to be scheduled.

out1 — Signal output

any value

Data outputs of the object. You must specify these output arguments when the object has data outputs.

Examples

Event Action Upon Entity Entry

Event action for entity entry to storage.

```
function [entity,events] = entry(obj,storage,entity,src)
    % Specify event actions when entity entered storage.
```

```
disp(['Entity of ID ' num2str(entity.sys.id) ...
     ' has entered storage element ' num2str(storage)]);
switch src.type
    case 'input'
        disp(['Entity came from input port ' num2str(src.index)]);
    case 'storage'
        disp(['Entity came from storage element ' num2str(src,index)]);
end
events = [ ...
    obj.eventDestroy(), ... % Destroy the newly entered entity
    obj.eventIterate(2, '')]; % Iterate entities in storage element 2
end
```

eventDestroy

Class: matlab.DiscreteEventSystem

Package: matlab

Create entity destroy event

Syntax

```
event=eventDestroy()
```

Description

`event=eventDestroy()` creates an event to destroy an entity. You can then schedule this event by returning it as an output argument when implementing an event action method, such as `matlab.DiscreteEventSystem.timer`.

Output Arguments

event — Event

MATLAB structure

Event that destroys the entity in current event action context.

Examples

Destroy Entity in Current Event Action Context

Define an event to destroy the entity in current event action context.

```
function [entity,event] = entry(obj,storage,entity,src)
    % Define an event to destroy the entity in current event action
    % context.
```

```
        event = obj.eventDestroy();  
end
```

```

Description

`event=eventForward(locationType,locationIndex,delay)` creates an event to forward an entity from the current location to a new location. You can then schedule this event by returning it as the output argument when implementing an event action method, such as `matlab.DiscreteEventSystem.entry`.

Input Arguments

locationType — Location type

character vector

Type of the new location. Specify 'storage' if the new location is a storage element of the discrete-event system. Specify 'output' if you want the entity to exit from an output port of the discrete-event system.

locationIndex — Location index

double

Index of the new location. If location type is 'storage', it indicates the index of a storage element. If location type is 'output', it indicates the index of an output port.

delay — Delay

double

Time delay between current simulation time and the time the entity will be forwarded.

Output Arguments

event — Event

MATLAB structure

Event that forwards the entity in current event action context to a new location.

Examples

Forward Current Entity to Storage

Define an event that forwards the current entity to storage.

```
function [entity,events] = entry(obj,storage,entity,src)
    % Define an event that forwards the current entity to storage
    % element 2. Event shall be scheduled to execute 0.8 second later.
    event1 = obj.eventForward('storage', 2, 0.8);

    % Define an event that forwards the current entity to output port 1.
    % Event shall be scheduled to execute at current simulation clock time.
    event2 = obj.eventForward('output', 1, 0);
end
```

Introduced in R2016a

eventGenerate

Class: matlab.DiscreteEventSystem

Package: matlab

Create entity generate event

Syntax

```
event=eventGenerate(storageID,tag,delay,priority)
```

Description

`event=eventGenerate(storageID,tag,delay,priority)` creates an event to generate an entity. You can then schedule this event by returning it as the output argument when implementing an event action method, such as `matlab.DiscreteEventSystem.entry`.

Input Arguments

storageID — Storage index

double

Index of the storage element, where a new entity will be generated.

tag — Tag

character vector

Custom tag of this entity generate event.

delay — Delay

double

Time delay between current simulation time and the time the entity will be generated.

priority — Priority

double

Positive integer value indicating system priority of the new entity. A smaller numeric value indicates a higher priority.

Output Arguments

event — Event

MATLAB structure

Event that generates an new entity in the specified storage element.

Examples

Define Entity Generation Event

Define entity generation event in storage element 3.

```
function event = setupEvents(obj)
    % Define an entity generation event
    % - A new entity shall be created in storage element 3
    % - The event has a custom tag 'seed'
    % - The event shall be executed 0.5 second later
    % - The new entity shall be initialized with a priority of 200
    event = obj.eventGenerate(3, 'seed', 0.5, 200);
end
```

eventIterate

Class: matlab.DiscreteEventSystem

Package: matlab

Create entity iterate event

Syntax

```
event=eventIterate(storageID,tag,priority)
```

Description

`event=eventIterate(storageID,tag,priority)` creates an event to repeatedly process entities of a storage element. You can then schedule this event by returning it as the output argument when implementing an event action method, such as `matlab.DiscreteEventSystem.exit`.

Input Arguments

storageID — Storage index

double

Index of a storage element. Entities inside this storage element will be iterated.

tag — Tag

character vector

Custom tag of this entity iterate event.

priority — Priority

double

Priority of the entity iterate event. This value must be a positive integer, where a smaller value indicates a higher event priority.

Output Arguments

event — Event

MATLAB structure

Event that processes entities of a specific storage element.

Examples

Iterate Entities of a Storage Element

Define an event to iterate entities of a storage element..

```
function event = exit(obj,storage,entity,dst)
    % Define an event to iterate entities of a storage element
    % - The event is regarding to storage element 2
    % - The event has a custom tag 'search'
    % - The event shall be executed at current simulation clock time
    % - The event has a priority of 10 (a smaller numeric value
    %   indicates a higher event priority)
    event = obj.eventIterate(2, 'search', 10);
end
```

eventTimer

Class: matlab.DiscreteEventSystem

Package: matlab

Create entity timer event

Syntax

```
event=eventTimer(tag, delay)
```

Description

`event=eventTimer(tag, delay)` creates an event to delay an entity for a period of time. You can then schedule the timer by returning it as the output argument when implementing an event action method, such as `matlab.DiscreteEventSystem.entry`.

Input Arguments

tag — Tag

character vector

Custom tag of this entity timer event.

delay — Delay

double

Time delay between current simulation time and the time that this timer event will be executed.

Output Arguments

event — Event

MATLAB structure

Event that delays the entity in current event action context for a period of time.

Examples

Define Timer Event

Define a timer event.

```
function [entity,event] = entry(obj,storage,entity,src)
    % Define a timer event
    % - The event is regarding the entity in current event action context
    % - The event has a custom tag 'timeout'
    % - The event will be executed 3.0 seconds later
    event = obj.eventTimer('timeout', 3.0);
end
```

exit

Class: matlab.DiscreteEventSystem

Package: matlab

Event action before entity exit from storage

Syntax

```
[events]=exit(obj,storage,entity,destination)  
[events,out1,...]=exit(obj,storage,entity,destination,in1,...)
```

Description

[events]=exit(obj,storage,entity,destination) specifies event actions of the object when an entity exits a storage.

[events,out1,...]=exit(obj,storage,entity,destination,in1,...) specifies such event actions of the object when the block has one or more input signal ports and/or signal output ports.

Input Arguments

obj — Discrete-event System object

MATLAB object

Discrete-event System object.

storage — Storage

double

Index of the storage element.

entity — Entity

MATLAB structure

Entity leaving storage element.

destination — Destination

MATLAB structure

Destination of entity, such as an output port or a storage element.

in1 — Data inputs

any value

Any data inputs of the object. These input arguments exist only when the object has data inputs.

Output Arguments

events — Events

vector of MATLAB structures

Events to be scheduled after the method returns.

out1 — Signal output

any value

Data outputs of the object. You must specify these output arguments when the object has data outputs.

Examples

Refill Upon Entity Exit Storage

Create a new entity when an existing entity exits the storage element.

```
function events = exit(obj,storage,entity,dst)
    % Upon exit of an entity, display its ID and schedule to
    % generate a new entity.
    disp(['Entity of ID ' num2str(entity.sys.id) ' has exited']);
    events = obj.eventGenerate(storage, 'Refill', 1, entity.sys.priority);
```

generate

Class: matlab.DiscreteEventSystem

Package: matlab

Event action upon entity creation

Syntax

```
[entity,events]=generate(obj,storage,entity,tag)  
[entity,events,out1,...]=generate(obj,storage,entity,tag,in1,...)
```

Description

`[entity,events]=generate(obj,storage,entity,tag)` specifies event actions of the object when an entity is created inside a storage component.

`[entity,events,out1,...]=generate(obj,storage,entity,tag,in1,...)` specifies such event actions of the object when the block has one or more input signal ports and/or signal output ports.

Input Arguments

obj — Discrete-event System object

MATLAB object

Discrete-event System object.

storage — Storage

double

Index of the storage element.

entity — Entity

MATLAB structure

Entity to create inside storage element.

tag — Tag

character vector

Tag of the current entity generation event.

in1 — Input

any value

Any data inputs of the object. These input arguments exist only when the object has data inputs.

Output Arguments

entity — Entity

MATLAB structure

Entities created with possibly changed values.

events — Events

vector of MATLAB structures

Events to be scheduled for just after entities are created.

out1 — Data output

any value

Data outputs of the object. You must specify these output arguments when the object has data outputs.

Examples

Set Initial Values When Entity is Generated

Initialize attribute values when entity is generated in a storage element.

```
function [entity,events] = generate(obj,storage,entity,tag)
    % Specify event actions when entity generated in storage.
```

```
% - For entity generation event of tag 'Adam', initialize the
% entity so that its attribute 'gender' has value '0', and its
% priority is '200'.
% - For entity generation event of tag 'Eve', initialize the
% entity so that its attribute 'gender' has value '1', and its
% priority is '100'.
% - An event is returned to forward the entity to storage
% element 2 with a time delay of 0.6.
switch tag
    case 'Adam'
        entity.data.gender = 0;
        entity.sys.priority = 200;
    case 'Eve'
        entity.data.gender = 1;
        entity.sys.priority = 100;
end
events = obj.eventForward('storage',2,0.6);
end
```

getEntityPortsImpl

Class: matlab.DiscreteEventSystem

Package: matlab

Define input ports and output ports of discrete-event system

Syntax

```
[inputTypes,outputTypes]=getEntityPortsImpl(obj)
```

Description

[inputTypes,outputTypes]=getEntityPortsImpl(obj) defines input ports and output ports of a discrete-event system.

Input Arguments

obj — Discrete-event System object

MATLAB object

Discrete-event System object.

Output Arguments

inputTypes — Input types

cell vector of character vectors

Input port types of a discrete-event system, specified as a cell vector of character vectors with a length that is the same as the number of input ports.

The *N*th element of the vector that specifies the type of the *N*th input port.

- If the port is an entity port, the character vector indicates the entity type name of this port. The name must match one of the entity types specified in `matlab.DiscreteEventSystem.getEntityTypesImpl`.
- If the port is a signal port, the character vector must be empty ('').

outputTypes — Output types

cell vector of character vectors

Output port types of a discrete-event system, specified as a cell vector with a length that is the same as the number of output ports.

The *N*th element of the vector that specifies type of the *N*th output port.

- If the port is an entity port, the character vector indicates the entity type name of this port. The name must match one of the entity types specified in `matlab.DiscreteEventSystem.getEntityTypesImpl`.
- If the port is a signal port, the character vector must be empty ('').

Examples

Get Entity Inputs and Outputs for Discrete-Event System

Get entity input and output port types for discrete-event system.

```
function [inputTypes,outputTypes] = getEntityPortsImpl(obj)
    % Specify input and output port types.
    %
    % This implementation further specifies port type and entity
    % type at these inputs and outputs:
    % Inputs:
    % 1. Signal port
    % 2. Entity port receiving entities of type 'entity1'
    % 3. Entity port receiving entities of type 'entity2'
    % Outputs:
    % 1. Signal port
    % 2. Entity port sending entities of type 'entity2'
    %
    % The discrete-event system must have already defined:
    % - 3 inputs (by method 'getNumInputsImpl') and
    % - 2 outputs (by method 'getNumOutputsImpl')
```

```
inputTypes = {'', 'entity1', 'entity2'};  
outputTypes = {'', 'entity2'};  
end
```

getEntityStorageImpl

Class: matlab.DiscreteEventSystem

Package: matlab

Define entity storage elements of discrete-event system

Syntax

```
[storageSpecs,I,O]=getEntityStorageImpl(obj)
```

Description

`[storageSpecs,I,O]=getEntityStorageImpl(obj)` defines entity storage elements of a discrete-event system.

Input Arguments

obj — Discrete-event System object

MATLAB object

Discrete-event System object.

Output Arguments

storageSpecs — Storage specifications

vector of MATLAB structures

Entity storage specifications of a discrete-event system, specified as a vector of MATLAB structures with its length indicating number of entity storage elements of the discrete-event system. The N th element of the vector defines an entity storage element with index N . Use utility methods such as `queueFIFO` to create such definition as a MATLAB structure.

i — Connections between input ports and entity storage elements

cell array

Define connections between input ports and entity storage elements as a cell array. The length of the cell array must match the number of input ports of this discrete-event system. The N th element of the cell array defines the connection between the N th input port and any entity storage element. If the input port is an entity port, a valid entity storage index must be specified. If the input port is a signal port, the element takes a value of zero.

You can connect multiple entity input ports to a common storage element.

o — Connections between output ports and entity storage elements

cell array

Define connections between output ports and entity storage elements as a cell array. The length of the cell array must match the number of output ports of this discrete-event system. The M th element of the cell array defines the connections between the M th output port and any entity storage elements. If the output port is an entity port, specify one of these:

- A scalar indicating a single connection from a storage element to the output port.
- A vector indicating multiple connections from multiple storage elements to the output port.

If the output port is a signal port, the element takes a value of zero.

You can connect multiple entity output ports to a common storage element.

Examples

Specify Entity Storage Elements

Specify entity storage elements and connections between entity input ports and storage elements for the discrete-event system object.

```
function [storageSpecs, I] = getEntityStorageImpl(obj)
    % Specify entity storage elements and connections between
    % entity input ports and storage elements.
```

```

%
% The implementation specifies two storage elements for the
% discrete-event system:
% 1. A priority queue
% - Stores entities of type 'student'
% - Has maximal capacity of 25
% - Sort entities by an attribute named 'age', in ascending
%   direction
% 2. A FIFO queue
% - Stores entities of type 'student'
% - Has maximal capacity of 10
% - Sort entities in a First-In-First-Out order
%
% The implementation also specifies that the entity input port
% of the discrete-event system is connected to the 2nd storage
% element.
%
% Other methods of the discrete-event system must have defined:
% - An entity type named 'student' (by method 'getEntityTypesImpl')
% - An entity input port (by method 'getEntityPortsImpl')
%
storageSpecs = [...
    obj.queuePriority('student', 25, 'age', 'ascending'), ...
    obj.queueFIFO('student', 10)];
I = 2;
end

```

getEntityTypesImpl

Class: matlab.DiscreteEventSystem

Package: matlab

Define entity types of discrete-event system

Syntax

```
entityTypes=getEntityTypesImpl(obj)
```

Description

`entityTypes=getEntityTypesImpl(obj)` defines entity types of a discrete-event system.

Input Arguments

obj — Discrete-event System object

MATLAB object

Discrete-event System object.

Output Arguments

entityTypes — Entity types

vector of MATLAB structures

Entity types returned as a vector whose length is the same as the number of entity types. Each vector element is a structure containing the entity type properties:

- Name
- Data dimension

- Data type
- Complexity

Examples

Get Entity Types

Get entity types *entity1* and *entity2* for discrete-event system, *obj*.

```
function entityTypes = getEntityTypesImpl(obj)
    % Define entity type 'type1' with inherited data type, dimension
    % and complexity
    t1 = obj.entityType('type1');

    % Define entity type 'type2' with specified data type ('mybus'),
    % default dimension and complexity (i.e. scalar real values)
    t2 = obj.entityType('type2', 'mybus');

    % Define entity type 'type3' with specified data type ('double'),
    % dimension (2 by 3 matrix), and complexity (complex)
    t3 = obj.entityType('type3', 'double', [2 3], true);

    entityTypes = [t1, t2, t3];
end
```

initEventArray

Class: matlab.DiscreteEventSystem

Package: matlab

Initialize event array

Syntax

```
event = initEventArray()
```

Description

`event = initEventArray()` creates an empty array of event structures, to initialize the return of an event action method such as `matlab.DiscreteEventSystem.entry`. This method enables you to append elements to the array in the MATLAB Discrete-Event System block simulation using code generation mode.

Output Arguments

event — Array of event structures

Array

Array of event structures, specified as a MATLAB structures.

Examples

Initialize Returned Event Array

Initialize returned event array for the `exit` method.

```
function events = exit(~, ~, entity, ~)
    events = obj.initEventArray;
    if entity.data == 1
        events = obj.eventTimer('exit', 0);
    end
end
```

iterate

Class: matlab.DiscreteEventSystem

Package: matlab

Event action when entity iterates

Syntax

```
[entity,events,next]=iterate(obj,storage,entity,tag,cur)
[entity,events,next,out1,...]=iterate(obj,storage,entity,tag,cur,
in1,...)
```

Description

`[entity,events,next]=iterate(obj,storage,entity,tag,cur)` specifies event actions for when an entity is processed as a part of an iterate event.

`[entity,events,next,out1,...]=iterate(obj,storage,entity,tag,cur,in1,...)` specifies such event actions when the block has one or more input signal ports and/or signal output ports.

Input Arguments

obj — Discrete-event System object

MATLAB object

Discrete-event System object.

storage — Storage

double

Index of the storage element.

entity — Entity

MATLAB structure

Entity currently being processed.

tag — Tag

character vector

Tag of the current entity iterate event.

cur — Current state

MATLAB structure

MATLAB structure indicating current state of iteration. The structure has these fields:

- `size`

Total number of entities the storage has

- `position`

Position of the current iterating entity

in1 — Signal input

any value

Any data inputs of the object. These input arguments exist only when the object has data inputs.

Output Arguments

entity — Entity

MATLAB structure

Entity being processed, possibly with changed data.

events — Events

vector of MATLAB structures

Events to be scheduled after the method returns.

next — Iteration

logical | double

- True

Continue to process the next entity in the storage element.

- False

Terminate the iterate event, and leave the rest of the entities of the storage element unprocessed.

out1 — Signal output

any value

Data outputs of the object. You must specify these output arguments when the object has data outputs.

Examples

Forward the First Entity

Forward the first entity with matching data value to output port 1 of the discrete-event system.

```
function [entity,events,next] = iterate(obj,storage,entity,tag,status)
    % Forward the first entity with matching data value to output
    % port 1 of the discrete-event system.
    disp(['Searching in storage element ' num2str(storage)]);
    disp(['    Total size = ' num2str(status.size)]);
    disp(['    Current position = ' num2str(status.position)]);
    if (entity.data == obj.dataToSearch)
        events = obj.eventForward('output', 1, 0);
        next = false;    % Found -- early terminate
    else
        events = [];
        next = true;    % Not yet found -- continue
    end
end
```

queueFIFO

Class: matlab.DiscreteEventSystem

Package: matlab

Define first-in first-out (FIFO) queue storage

Syntax

```
storage=queueFIFO(entityType,capacity)
```

Description

`storage=queueFIFO(entityType,capacity)` defines a FIFO queue storage element. Use this function when implementing the `matlab.DiscreteEventSystem.getEntityStorageImpl` method.

Input Arguments

entityType — Entity type

character vector

Type of entities that the new storage element works with.

capacity — Maximum number of entities

double

Maximum number of entities that the storage can contain, specified as a double.

Output Arguments

storage — Storage

MATLAB structure

Queue storage that contains entities and sorts them in FIFO order.

Examples

Specify FIFO Queue Entity Storage

Specify FIFO queue entity storage for the discrete-event system object.

```
% Define a storage element as a FIFO queue
% - Entities in the queue are sorted in First-In-First-Out (FIFO) order
% - Queue can store entities of type 'myEntity'
% - Queue can store no more than 25 entities
storage = obj.queueFIFO('myEntity', 25);
```

queueLIFO

Class: matlab.DiscreteEventSystem

Package: matlab

Define last-in last-out (LIFO) queue storage

Syntax

```
storage=queueLIFO(entityType,capacity)
```

Description

`storage=queueLIFO(entityType,capacity)` defines a LIFO queue storage element. Use this function when implementing the `matlab.DiscreteEventSystem.getEntityStorageImpl` method.

Input Arguments

entityType — Entity type

character vector

Type of entities that the new storage element works with.

capacity — Capacity

double

Maximum number of entities that the storage can contain, specified as a double.

Output Arguments

storage — Storage

MATLAB structure

Queue storage that contains entities and sorts them in a LIFO order.

Examples

Define LIFO Queue Storage

Define LIFO queue storage.

```
% Define a storage element as a LIFO queue
% - Entities in the queue are sorted in Last-In-First-Out (LIFO) order
% - Queue can store entities of type 'myEntity'
% - Queue can store no more than 25 entities
storage = obj.queueLIFO('myEntity', 25);
```

queuePriority

Class: matlab.DiscreteEventSystem

Package: matlab

Define priority queue storage

Syntax

```
storage=queuePriority(entityType,capacity,key,order)
```

Description

`storage=queuePriority(entityType,capacity,key,order)` defines a priority queue that sorts entities by custom attribute. Use this function when implementing the `matlab.DiscreteEventSystem.getEntityStorageImpl` method.

Input Arguments

entityType — Entity type

character vector

Type of entities that the new storage element works with.

capacity — Capacity

double

Maximum number of entities that the storage can contain, specified as a double.

key — Key

character vector

Name of the attribute that is used as the key for sorting.

order — Sorting order

character vector

Direction of sorting. Specify 'ascending' if you want entities with smaller key values to appear in front of the queue. Specify 'descending' if you want entities with greater key values to appear in front of the queue.

Output Arguments

storage — Storage
MATLAB structure

Queue storage element that contains entities and sorts them using a custom attribute.

Examples

Define Storage Element as a Priority Queue

Define storage element as a priority queue.

```
% Define a storage element as a priority queue
% - Queue sorts entities using a specific attribute of the entities
% - Queue can store entities of type 'myEntity'
% - Queue can store no more than 25 entities
% - Queue uses the attribute 'age' to sort entities
% - Sorting direction is 'ascending', resulting entities with
%   smaller 'age' attribute values to appear in front of the queue
storage = obj.queuePriority('myEntity', 25, 'age', 'ascending');
```

“Create Custom Blocks Using MATLAB Discrete-Event System Block”

Introduced in R2016a

queueSysPriority

Class: matlab.DiscreteEventSystem

Package: matlab

Define system priority queue storage

Syntax

```
storage=queueSysPriority(entityType,capacity,order)
```

Description

`storage=queueSysPriority(entityType,capacity,order)` defines a priority queue storage element that sorts entities by their system priorities. Use this method when implementing the `matlab.DiscreteEventSystem.getEntityStorageImpl` method.

Input Arguments

entityType — Entity type

character vector

Type of entities that the new storage element works with.

capacity — Capacity

double

Maximum number of entities that the storage can contain, specified as a double.

order — Sorting order

character vector

Direction of sorting. Specify 'ascending' if you want entities with smaller system priority values (higher priority) to appear in front of the queue. Use 'descending' if

you want entities with higher system priority values (lower priority) to appear in front of the queue.

Output Arguments

storage — Storage

MATLAB structure

Queue storage element that contains entities and sorts them by the entities' system priorities.

Examples

Define Storage Element as System Priority Queue

Define a storage element that uses an entity system priority for sorting.

```
% - Queue sorts entities using entity priority (i.e.
%   the field 'entVar.sys.priority' on a MATLAB variable 'entVar'
%   representing a SimEvents entity)
% - Queue can store entities of type 'myEntity'
% - Queue can store no more than 25 entities
% - Sorting direction is 'ascending', resulting entities with
%   higher priority (or smaller entity priority values) to appear
%   in the front of the queue
storage = obj.queueSysPriority('myEntity', 25, 'ascending');
```

setupEvents

Class: matlab.DiscreteEventSystem

Package: matlab

Initialize entity generation events

Syntax

```
events=setupEvents(obj)  
[events,out1,...]=setupEvents(obj)
```

Description

`events=setupEvents(obj)` sets up the first set of entity generation events at the start of simulation.

`[events,out1,...]=setupEvents(obj)` specifies such event actions of the object when the block has one or more signal output ports.

Input Arguments

obj — Discrete-event System object
MATLAB object

Discrete-event System object.

Output Arguments

events — Events
vector of MATLAB structures

A vector of events to create initial entities. The discrete-event system schedules these events at the start of simulation.

out1 — Data output

any value

Data outputs of the object. You must specify these output arguments when the object has data outputs.

Examples

Schedule Two Entity Generation Events

Schedules two entity generation events at the start of the simulation

```
function events = setupEvents(obj)
    % Schedules two entity generation events at the start of the
    % simulation
    % - An event with tag 'Adam' to generate an entity in storage element 1.
    % - An event with tag 'Eve' to generate an entity in storage element 2.
    events = [...
        obj.eventGenerate(1, 'Adam', 0.5, 200), ...
        obj.eventGenerate(2, 'Eve', 0.8, 100)];
end
```

timer

Class: matlab.DiscreteEventSystem

Package: matlab

Event action when timer completes

Syntax

```
[entity,events]=timer(obj,storage,entity,tag)  
[entity,events,out1,...]=timer(obj,storage,entity,tag,in1,...)
```

Description

[entity,events]=timer(obj,storage,entity,tag) specifies event actions for when scheduled timer completes.

[entity,events,out1,...]=timer(obj,storage,entity,tag,in1,...) specifies such event actions when the block has one or more input signal ports and/or signal output ports.

Input Arguments

obj — Discrete-event System object

MATLAB object

Discrete-event System object.

storage — Storage

double

Index of the storage element.

entity — Entity

MATLAB structure

Entity for the timer event.

tag — Tag

character vector

Tag of the currently executing timer event.

in1 — Signal input

any value

Any data inputs of the object. These input arguments exist only when the object has data inputs.

Output Arguments

entity — Entity

MATLAB structure

Entity with changed value.

events — Events

vector of MATLAB structures

Events to be scheduled after the method returns.

out1 — Signal output

any value

Data outputs of the object. You must specify these output arguments when the object has data outputs.

Examples

Event Action When Timer Completes

Forward entity when timer completes for discrete-event system object *obj*.

```
function [entity,events] = timer(obj,storage,entity,tag)
    % Check which timer of the entity has expired, and forward the
```

```
% entity to the next location accordingly.
switch tag
    case 'ServiceComplete'
        entity.done = 1;
        events = obj.eventForward('output', 1, 0);
    case 'Timeout'
        entity.done = 0;
        events = obj.eventForward('storage', 2, 0);
end
end
```

simevents

Open SimEvents library

Syntax

```
simevents  
simevents('1')  
simevents('2')  
simevents('3')  
simevents('4')  
simevents('5')
```

Description

`simevents` opens the main SimEvents library.

`simevents('1')` opens version 1.2 of the SimEvents library.

`simevents('2')` and `simevents('3')` open version 3.1.2 of the SimEvents library.

`simevents('4')` opens version 4.4.1 of the SimEvents library.

`simevents('5')` opens version 5.0 of the SimEvents library.

Introduced in R2011b

simeventslib

Open SimEvents library

Syntax

```
simeventslib
```

Description

`simeventslib` opens the main SimEvents library.

Introduced before R2006a

simevents.SimulationObserver class

Package: simevents

Superclasses:

Interface to create your custom visualization for models with SimEvents blocks

Description

This class is an interface for creating custom visualizations for models with SimEvents blocks. Subclass this class to create your own visualization, using the methods below. Some utility functions are also provided to interact with event calendars, blocks, and entities. Do not overwrite these utility functions.

Construction

`obj = SimulationObserver(modelName)` returns an object of the `SimulationObserver` class, used to create a model observer for a SimEvents model.

Input Arguments

modelName — Model to observe

character vector

The name of the model to observe.

Methods

Public Methods to Implement

`simevents.SimulationObserver.simStarted`

Specify behavior when simulation starts

`simevents.SimulationObserver.simPaused`

Specify behavior when simulation pauses

<code>simevents.SimulationObserver.simResumed</code>	Specify behavior when simulation resumes
<code>simevents.SimulationObserver.simTerminating</code>	Define observer behavior when simulation is terminating
<code>simevents.SimulationObserver.getBlocksToNotify</code>	Specify list of blocks to be notified of entity entry and exit events
<code>simevents.SimulationObserver.notifyEventCalendarEvents</code>	Specify whether you want notification for all events in event calendar
<code>simevents.SimulationObserver.postEntry</code>	Specify behavior after an entity enters a block that has entity storage
<code>simevents.SimulationObserver.preExit</code>	Specify behavior before an entity exits a block with entity storage
<code>simevents.SimulationObserver.preExecute</code>	Specify behavior before execution of an event

Utility Functions

<code>simevents.SimulationObserver.addBlockNotification</code>	Add block to list of blocks to be notified
<code>simevents.SimulationObserver.removeBlockNotification</code>	Remove block from list of blocks being notified
<code>simevents.SimulationObserver.getEventCalendars</code>	Get handles to event calendars
<code>simevents.SimulationObserver.getAllBlockWithStorages</code>	Get list of blocks that store entities
<code>simevents.SimulationObserver.getHandleToBlock</code>	Return block handle for a given block path
<code>simevents.SimulationObserver.getHandlesToBlockStorages</code>	Return storage handles of specified block

Examples

Construct Animator

Construct an animator.

```
function this = seExampleRestaurantAnimator
    % Constructor
    modelname = 'seExampleCustomVisualization';
    this@simevents.SimulationObserver(modelname);
    this.mModel = modelname;
end
```

addBlockNotification

Class: simevents.SimulationObserver

Package: simevents

Add block to list of blocks to be notified

Syntax

```
addBlockNotification(obj,blkPath)
```

Description

`addBlockNotification(obj,blkPath)` is a utility function for adding a block to the list of blocks to be notified. Specify the full path of the block to be added in `blkPath`.

Input Arguments

obj — **SimulationObserver object**

character vector

Object of class SimulationObserver

blkPath — **Full path of the block to be notified**

character vector

Full path of the block to be added to the list of blocks to be notified.

Examples

Add Block to List of Blocks for Notification

Add block to list of blocks for notification.

```
function postEntry(obj,eventSource,eventData)
    if someConditionIsTrue
        addBlockNotification(obj,[this.mModel '/Patron Enter']);
    end
end
```

getAllBlockWithStorages

Class: simevents.SimulationObserver

Package: simevents

Get list of blocks that store entities

Syntax

```
getAllBlockWithStorages (obj)
```

Description

`getAllBlockWithStorages (obj)` is a utility function that returns the paths of all blocks that store entities.

Input Arguments

obj — **SimulationObserver object**

character vector

Object of class SimulationObserver

Output Arguments

allBlkPaths — **Paths of all blocks that store entities**

cell array of character vectors

Cell array of all blocks that store entities, provided as full block paths.

Examples

Return Paths of All Blocks that Store Entities

Return the paths of all blocks that store entities.

```
function blks=getBlocksToNotify(obj)
    blks=getAllBlockWithStorages(obj);
end
```

getBlocksToNotify

Class: simevents.SimulationObserver

Package: simevents

Specify list of blocks to be notified of entity entry and exit events

Syntax

```
getBlocksToNotify(obj)
```

Description

`getBlocksToNotify(obj)` is used to specify a cell array of block paths that are notified by the `SimulationObserver` object. These blocks have to be discrete event blocks with entity storages. Override this function in your subclass to specify a cell array of blocks for which `simevents.SimulationObserver.preExit` and `simevents.SimulationObserver.postEntry` methods will be called. Specify 'ALL' to run these methods on all the discrete-event blocks with entity storages in the model. If you do not want any blocks to be notified, specify an empty cell array, `{}`.

Input Arguments

obj — **SimulationObserver object**

character vector

Object of class `SimulationObserver`

Output Arguments

blks — **List of blocks being notified of runtime events**

`{}` (default) | cell array of character vectors

Cell array of full block paths of all blocks being notified of runtime events

Examples

Blocks to Observe in Model

Return the list of blocks you want to observe in the model.

```
function blks = getBlocksToNotify(this)
    % Return list of blocks to observe in the model
    %
    % For this example, we are only interested in the following
    % blocks as they are sufficient for us to know all events of
    % interest
    blks = { ...
        [this.mModel '/Patron Enter'], ...
        [this.mModel '/Have Dinner'], ...
        [this.mModel '/Patron Leave'] ...
    };
end
```

getEventCalendars

Class: simevents.SimulationObserver

Package: simevents

Get handles to event calendars

Syntax

```
getEventCalendars(obj)
```

Description

`getEventCalendars(obj)` is a utility method that returns handles to all event calendars in your model.

Input Arguments

obj — **SimulationObserver object**
character vector

Object of class SimulationObserver

Output Arguments

evCa1 — **Array of event calendars in model**
array of handles to EventCalendar objects

Array of handles to the event calendars in your model.

Examples

Get Handles to Event Calendars in Model

Get handles to all event calendars in your model.

```
function postEntry(obj, evSrc, evData)
    % Print simulation time
    evcal=getEventCalendars(obj);
    tNow=evcal(1).TimeNow;
    disp(tNow);
end
```

getHandlesToBlockStorages

Class: simevents.SimulationObserver

Package: simevents

Return storage handles of specified block

Syntax

```
getHandlesToBlockStorages (obj, blkPath)
```

Description

`getHandlesToBlockStorages (obj, blkPath)` returns the storage handles for the block specified by `blkPath`. If the block does not store entities, this method returns a 0x0 array of `simevents.Storage` objects.

Input Arguments

obj — **SimulationObserver object**

character vector

Object of class `SimulationObserver`

blkPath — **Full path to block**

character vector

Full path to the block that stores entities

Output Arguments

storagesForBlock — **Storage handles for the block**

array of handles to `simevents.Storage` objects

Array of storage handles of the block. If the block does not store entities, output is a 0x0 array of storage.

Examples

Get Handles for All Block Storage Elements

Get handles for all block storage elements in the model.

```
function postEntry(obj, evSrc, evData)
    % Number of entities in server;
    storage=getHandlesToBlockStorages(obj, [this.mModel '/Have Dinner']);
    disp(length(storage.Entity));
end
```

getHandleToBlock

Class: simevents.SimulationObserver

Package: simevents

Return block handle for a given block path

Syntax

```
getHandleToBlock(obj, blkPath)
```

Description

`getHandleToBlock(obj, blkPath)` is a utility function that returns the handle to the block whose full path is specified by `blkPath`.

Input Arguments

obj — SimulationObserver object

character vector

Object of class SimulationObserver

blkPath — Full path to block

character vector

Output Arguments

blkHandle — Handle to block

handle to block

Handle to the block specified in `blkPath`.

Examples

Return Handle to Specified Block

Return handle to specified block.

```
function postEntry(obj, evSrc, evData)
    hdl=getHandleToBlock(obj, [this.mModel '/Have Dinner']);
    ...
end
```

notifyEventCalendarEvents

Class: simevents.SimulationObserver

Package: simevents

Specify whether you want notification for all events in event calendar

Syntax

```
notifyEventCalendarEvents (obj)
```

Description

`notifyEventCalendarEvents (obj)` is specifies whether you want notification for all events in the event calendar before they are executed. Set the output of this method to `true` to call the `simevents.SimulationObserver.preExecute` method for all events in the event calendar.

Input Arguments

obj — **SimulationObserver object**

character vector

Object of class `SimulationObserver`

Output Arguments

n — **Boolean specifying whether all events in event calendar are notified before executing**

`false` (default) | `true`

Boolean that specifies whether you are notified of all events in the event calendar before executing. If set to `true`, the `simevents.SimulationObserver.preExecute` method is called for every event before its execution.

Examples

Specify Notification for All Events in Event Calendar

Specify whether you want notification for all events in event calendar.

```
function status=notifyEventCalendarEvents(obj)
    status=false;
end
```

postEntry

Class: simevents.SimulationObserver

Package: simevents

Specify behavior after an entity enters a block that has entity storage

Syntax

```
postEntry(obj, evSrc, evData)
```

Description

`postEntry(obj, evSrc, evData)` is used to specify behavior after an entity enters a block that has entity storage. The simulation observer uses this method as a callback for post-entry event notification and provides handles to the entity, the block and its storage, and the event.

Input Arguments

obj — **SimulationObserver object**

character vector

Object of class SimulationObserver

evSrc — **Handle to block storage**

handle to simevents.Storage object

Handle to block storage in which the entity entered. The handle will be populated by the simulation observer.

evData — **List of handles for block, storage, and entities, and event type**

cell array of handles

List of handles for block, storage, and entities. The list will be populated by the simulation observer.

Examples

Specify Listener for Storage Entry

Specify listener to execute when entity enters a storage element such as a queue or server.

```
function postEntry(this, evSrc, evData)
    % Override to specify listener for entry into a storage (queue/server)

    entity = evData.CurrentEntity;

    if strcmp(evData.Block.BlockPath, [this.mModel '/Have Dinner'])

        % Identify which table the customer is going to
        tblId = this.occupyTable(entity);

        % Schedule motion for this customer to the appropriate
        % table
        target = this.cTablePos(tblId, :);
        this.scheduleMotion(entity, target);

        % Decrement the waiting statistic
        this.updateStats(this.mTxtWaiting, this.DECREMENT);

    elseif strcmp(evData.Block.BlockPath, [this.mModel '/Patron Leave'])
        % Schedule motion for this entity from its current position
        % to the exit position
        if isKey(this.mEntityGlyphs, num2str(entity.ID))
            this.scheduleMotion(entity, this.cExitPos);
        end

        % Schedule for the entity dot to be destroyed when it has
        % completed its pending motion
        this.scheduleMotion(entity, [NaN, NaN]);

    end
end
```

preExecute

Class: simevents.SimulationObserver

Package: simevents

Specify behavior before execution of an event

Syntax

```
preExecute(obj, evSrc, evData)
```

Description

`preExecute(obj, evSrc, evData)` is used to specify behavior before the execution of an event in the event calendar. The simulation observer uses this method as a callback for pre-execute event notifications and provides a handle to the event calendar.

Input Arguments

obj — **SimulationObserver object**

character vector

Object of class SimulationObserver

evSrc — **Handle to event calendar**

handle to simevents.EventCalendar object

Handle to event calendar. The handle will be populated by the simulation observer.

evData — **Event name and handle to event calendar**

cell array of handles

Event name and handle to event calendar

Examples

Specify Behavior Before Execution of Event

Specify behavior before the execution of an event in the event calendar.

```
function preExecute(obj, evSrc, evData)
    fprintf('Specify behavior before the execution of an event in the event calendar. ');
end
```

preExit

Class: simevents.SimulationObserver

Package: simevents

Specify behavior before an entity exits a block with entity storage

Syntax

```
preExit(obj, evSrc, evData)
```

Description

`preExit(obj, evSrc, evData)` is used to specify behavior before an entity exits a block that stores entities. The simulation observer uses this method as a callback for pre-exit event notification and provides handles to the entity, the block and its storage, and the event.

Input Arguments

obj — **SimulationObserver object**

character vector

Object of class SimulationObserver

evSrc — **Handle to event calendar**

handle to simevents.EventCalendar object

Handle to event calendar. The handle will be populated by the simulation observer.

evData — **List of handles of block, storage, and entities, and event type**

cell array of handles

List of handles of block, storage, and entities. The list will be populated by the simulation observer.

Examples

Specify Listener for Storage Exit

Specify listener to execute when entity exits a storage element such as a queue or server.

```
function preExit(this, ~, evData)
    % Override to specify listener for exit from a storage (queue/server)
    % evData contains block, storage, and entity handles

    entity = evData.CurrentEntity;

    if strcmp(evData.Block.BlockPath, [this.mModel '/Patron Enter'])
        % Create a new "dot" on the figure at the entry position
        h = plot(this.cEntryPos(1), this.cEntryPos(2), '.');
        set(h, 'MarkerSize', 32);

        % Add a mouse-click function to the dot so we can retrieve
        % attribute data when user clicks on this customer
        set(h, 'ButtonDownFcn', @(h,e)entityClickFcn(this,h,e));

        % Cache away the entity identifier on this dot
        set(h, 'Tag', num2str(entity.ID));

        % Cache away this dot handle so that we can move it in
        % future events
        this.mEntityGlyphs(num2str(entity.ID)) = h;

        % Cache away the entity handle
        this.mEntities(num2str(entity.ID)) = entity;

        % Increment the entry statistics
        this.updateStats(this.mTxtEntry, this.INCREMENT);

        % Schedule motion for this entity from its current position
        % to a random position in the waiting area
        this.scheduleMotion(entity, this.getRandWaitingPos());

        % Increment waiting statistic
        this.updateStats(this.mTxtWaiting, this.INCREMENT);
    elseif strcmp(evData.Block.BlockPath, [this.mModel '/Have Dinner'])
        this.releaseTable(entity);
    end
```

```
end
```

```
end
```

removeBlockNotification

Class: simevents.SimulationObserver

Package: simevents

Remove block from list of blocks being notified

Syntax

```
removeBlockNotification(obj,blkPath)
```

Description

`removeBlockNotification(obj,blkPath)` is a utility function used to remove a block from the list of blocks being notified. Specify the full path of the block to be added in `blkPath`.

Input Arguments

obj — **SimulationObserver object**

character vector

Object of class SimulationObserver

blkPath — **Full path of the block to be notified**

character vector

Full path of the block to be added to the list of blocks being notified.

Examples

Remove Block

Remove block from list of blocks being notified.

```
function postEntry(obj,eventSource,eventData)
  if someConditionIsTrue
    removeBlockNotification(obj,[this.mModel '/Patron Enter']);
  end
end
```

simPaused

Class: simevents.SimulationObserver

Package: simevents

Specify behavior when simulation pauses

Syntax

```
simPaused(obj)
```

Description

`simPaused(obj)` determines the behavior when the simulation is paused. Override this function to specify the behavior of your visualization when the simulation pauses, as determined by the `SimulationStatus` parameter.

Input Arguments

obj — SimulationObserver object

character vector

Object of class SimulationObserver

Examples

Call Method When Pausing Model

Call this method when model is paused.

```
function simPaused(this)
    % Called when model is paused
```

```
        % Schedule the timer to stop when all pending animation is
        % completed
        this.mTimerRequestPause = true;
    end
```

simResumed

Class: simevents.SimulationObserver

Package: simevents

Specify behavior when simulation resumes

Syntax

```
simResumed(obj)
```

Description

`simResumed(obj)` determines the behavior when the simulation resumes after pausing. Override this function to specify the behavior of your visualization when the simulation resumes, as determined by the `SimulationStatus` parameter.

Input Arguments

obj — SimulationObserver object

character vector

Object of class SimulationObserver

Examples

Call Method When Model Continues

Call this method when model continues after pausing.

```
function simResumed(this)
    % Called when model continues from being paused
```

```
        % Restart the timer
        this.mTimerRequestPause = false;
        start(this.mTimer);
    end
```

simStarted

Class: simevents.SimulationObserver

Package: simevents

Specify behavior when simulation starts

Syntax

```
simStarted(obj)
```

Description

`simStarted(obj)` determines the behavior when the simulation starts. Override this function to specify the behavior of your visualization when the simulation starts, as determined by the `SimulationStatus` parameter.

Input Arguments

obj — SimulationObserver object

character vector

Object of class SimulationObserver

Examples

Initialize Animation Canvas

Initialize the animation canvas.

```
function simStarted(this)
    % Initialize the animation canvas

    % Re-initialize runtime work variables for simulation
    this.mEntityGlyphs = containers.Map('keytype', 'char', 'valuetype', 'any');
```

```

this.mEntities = containers.Map('keytype', 'char', 'valuetype', 'any');
this.mCombineMap = containers.Map('keytype', 'char', 'valuetype', 'char');
this.mCachePostRun = containers.Map('keytype', 'char', 'valuetype', 'char');

simTerminating

Class: simevents.SimulationObserver

Package: simevents

Define observer behavior when simulation is terminating

Syntax

```
simTerminating(obj)
```

Description

`simTerminating(obj)` determines the behavior when the simulation is terminating. Override this function to specify the behavior of your visualization when the simulation is terminating, as determined by the `SimulationStatus` parameter.

Input Arguments

obj — SimulationObserver object

character vector

Object of class SimulationObserver

Examples

Call Method When Simulation is Terminating

Call this method when simulation is terminating.

```
function simTerminating(this)
    % Called when simulation is terminating
    %
```

```
% After the simulation terminates, in order to support clicking
% on entity to see attributes, we gather up all of the entities
% that exist in the model and save their attribute information

ents = this.mEntityGlyphs.keys;
for idx = 1 : length(ents)
    ent = ents{idx};
    try
        enStruct = this.mEntities(ent);
        str = evalc('disp(enStruct.Attributes)');
        this.mCachePostRun(ent) = str;
    catch me
    end
end

% If animation timer is still running, schedule a stop
if strcmp(this.mTimer.Running, 'on')
    this.mTimerRequestStop = true;
else
    % If timer is not running, delete it
    delete(this.mTimer);
end
end
```

Blocks — Alphabetical List

Attribute Function (Obsolete)

Access and modify attributes using MATLAB code

Library

Attributes

Description

This block accepts an entity, assigns data to it, and then outputs it. Assigned data is stored in attributes of the entity, where each attribute has a name and a value.

This block corresponds to a function that you write in an editor window that opens when you double-click the block. Your function names the attributes you want to access, modify, or create. When writing your function, you can use any part of the MATLAB language that is suitable for code generation, subject to the argument-naming rules described in “Write Functions to Manipulate Attributes” and the attribute support described in “Attribute Value Support”.

Note If you attach large arrays to entities in a model that contains a server or a queue block with large capacity, the simulation could run out of memory.

Timing and Connections

In most cases, it is not necessary to introduce a storage block between the Attribute Function block and subsequent blocks that use attributes (for example, Attribute Scope). However, the next table indicates exceptional cases in which you should insert a Single Server block between the Attribute Function block and the block performing the subsequent operation.

Subsequent Operation	Block
Switching based on the same attribute that the Attribute Function block created or modified	Output Switch block with Switching criterion=From attribute
Preemption based on the same attribute that the Attribute Function block created or modified	Single Server block with Permit preemption based on attribute selected

Ports

Entity Input Ports

Label	Description
IN	Port for arriving entities.

Entity Output Ports

Label	Description
OUT	Port for entities whose attributes the block accessed, created, or modified.

Examples

- “Set Attributes”
- “Incorporate Legacy Code”

See Also

Set Attribute (Obsolete), Get Attribute (Obsolete)

“Write Functions to Manipulate Attributes”

Introduced in R2007b

Attribute Scope (Obsolete)

Plot data from attribute of arriving entities

Library

SimEvents Sinks

Description

This block creates a plot using data from a real scalar-valued attribute of arriving entities. Use the **Y attribute name** parameter to specify which attribute to plot along the vertical axis.

Use the **Enable entity OUT port** option to choose whether the entity advances to a subsequent block or whether the block absorbs the arriving entity.

The **Plot type** parameter on the **Plotting** tab determines whether and how the block connects the points that it plots.

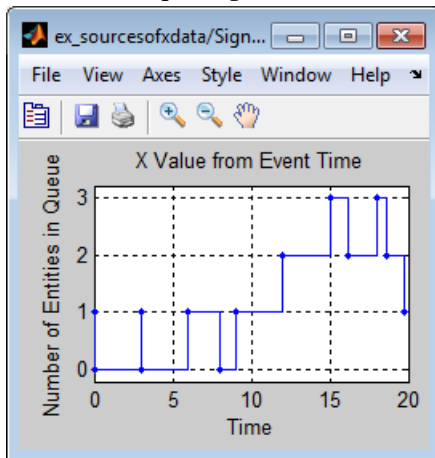

Selecting Data for the Horizontal Axis

Use the **X value from** parameter to select the type of data for the horizontal axis. The table below describes the choices.

Source of X Data	Description of Plot
Event time	Plot of the specified attribute versus simulation time.

Source of X Data	Description of Plot
Index	Plot of the successive values of the specified attribute against a horizontal axis that represents the index of the values. The first entity's attribute value has an index of 1, the second entity's attribute value has an index of 2, and so on. For example, you might use this option when multiple entities might arrive simultaneously, to help determine the exact sequence among the simultaneous attribute values.

The figures below illustrate the different sources of data for the horizontal axis. The plots look similar, except that the second plot has uniform horizontal spacing rather than time-based spacing between successive points.

Ports

Entity Input Ports

Label	Description
IN	Port for arriving entities, whose attributes contain the data to plot.

Entity Output Ports

Label	Description
OUT	Port for departing entities. You see this port only if you select Enable entity OUT port .

Signal Output Ports

Label	Description
#a	Number of entities that have arrived at the block since the start of the simulation.

The initial output value is 0. This value is in effect from the start of the simulation until the first update by the block.

Parameters

Plotting Tab

Plot type

The presentation format for the data.

Y attribute name

Name of the attribute to plot along the vertical axis.

X value from

Source of data for the plot's horizontal axis. See “Selecting Data for the Horizontal Axis” on page 2-4 for details.

Enable entity OUT port

Causes the block to have an entity output port labeled **OUT**, through which the arriving entity departs. If you clear this box, the block absorbs arriving entities.

Open scope at start of simulation

Selecting this option causes the plot window to open when you start the simulation. If you clear this box, you can open the plot window by double-clicking the block icon.

Axes Tab

Initial X axis lower limit, Initial X axis upper limit

The interval shown on the X axis at the beginning of the simulation. The interval might change from this initial setting due to zooming, autoscaling, or the **If X value is beyond limit** setting.

If X value is beyond limit

Determines how the plot changes if one or more X values are not within the limits shown on the X axis.

Initial Y axis lower limit, Initial Y axis upper limit

The interval shown on the Y axis at the beginning of the simulation. The interval might change from this initial setting due to zooming, autoscaling, or the **If Y value is beyond limit** setting.

If Y value is beyond limit

Determines how the plot changes if one or more attribute values are not within the limits shown on the Y axis.

Show grid

Toggles the grid on and off.

Figure Tab

Title

Text that appears as the title of the plot, above the axes.

Y label

Text that appears to the left of the vertical axis.

X label

Text that appears below the horizontal axis.

Position

A four-element vector of the form `[left bottom width height]` specifying the position of the scope window. (0,0) is the lower left corner of the display.

Show number of entities

Displays the number of plotted points using an annotation in the plot window.

Data History Tab

Store data when scope is closed

Select `Unlimited` to have the block cache all data for future viewing, `Limited` to cache a portion of the most recent data, and `Disabled` to avoid caching undisplayed data.

Limit data points to

The number of data points the block caches, using the most recent data. You see this field only if you set **Store data when scope is closed** to `Limited`.

Statistics Tab

These parameters determine whether the block produces data at signal output ports or omits those ports. For descriptions of the data and ports, see the preceding table, “Signal Output Ports”.

Number of entities arrived

Allows you to use the signal output port labeled **#a**.

Examples

- “Set Attributes”

See Also

X-Y Attribute Scope (Obsolete), Signal Scope (Obsolete)

“Manipulate Entity Attributes”

Introduced before R2006a

Cancel Timeout (Obsolete)

Cancel timeout event for each entity

Library

Timing

Description

This block cancels a named timeout event that the Schedule Timeout (Obsolete) block previously scheduled for the arriving entity. Timeout events enable you to limit the time that an entity spends on designated entity paths during the simulation. Topologically, this block designates an end of an entity path that is relevant to the time limit. The ability to cancel timeout events before they occur lets you apply the time limit to an entity path that does not end with a sink block.

The **Timeout tag** parameter of this block is the name of the timeout event and corresponds to the **Timeout tag** parameter of a Schedule Timeout block in the model. If the arriving entity is not associated with a timeout event of that name, then you can configure the block to produce an error or warning, or to ignore the absence of the timeout event.

Using the **Residual time** and **Average residual time** parameters, you can configure the block to report the following statistics via the **rt** and **w** signal output ports, respectively:

- The residual time for the named timeout event associated with the arriving entity, which is the amount of time between the entity's arrival time at this block and the scheduled time of the named timeout event
- The average among the **rt** values among all entities that have arrived at this block during the simulation and been associated with timeouts of the specified name

Ports

Entity Input Ports

Label	Description
IN	Port for arriving entities.

Entity Output Ports

Label	Description
OUT	Port for entities whose timeout event the block has just canceled.

Signal Output Ports

Label	Description	Time of Update When Statistic is On	Order of Update
#d	Number of entities that have departed from this block since the start of the simulation	After entity departure	3
#t	Number of entities that have departed from this block and been associated with a timeout of the specified name.	After entity departure	2
rt	Amount of time between arrival time at this block and the scheduled time of the named timeout event.	After entity departure	2
w	Average among the rt values among all entities that have arrived at this block and been associated with timeouts of the specified name.	After entity departure	1

Output signals having the same number in the Order of Update column in the table above are updated in an arbitrary sequence relative to each other; you should not rely on a specific sequence for your simulation results.

The initial output value, which is in effect from the start of the simulation until the first update by the block, is 0 for all signals

Parameters

Cancel Timeout Tab

Timeout tag

Name of the timeout event to cancel, corresponding to the **Timeout tag** parameter of a Schedule Timeout block in the model.

If tagged timeout is not scheduled

Behavior of the block if an arriving entity is not associated with a timeout event with the specified timeout tag.

Statistics Tab

These parameters determine whether the block produces data at signal output ports or omits those ports.

Number of entities departed

Allows you to use the signal output port labeled **#d**.

Number of entities departed with specified tag

Allows you to use the signal output port labeled **#t**.

Residual time

Allows you to use the signal output port labeled **rt**.

Average residual time

Allows you to use the signal output port labeled **w**.

See Also

Schedule Timeout (Obsolete)

Introduced in R2007a

Conn (Obsolete)

Provide entity input port or entity output port for virtual subsystem

Library

SimEvents Ports and Subsystems

Description

The Conn block, placed inside a subsystem containing blocks with entity ports, creates an entity port on the boundary of the subsystem. When you connect the Conn block, the port changes its appearance and becomes either an entity input port or an entity output port:

- Conn represents an input port if connected to another block's input port.
- Conn represents an output port if connected to another block's output port.

To create a new virtual subsystem, select one or more blocks in the model and select **Diagram > Subsystem & Model Reference > Create Subsystem from Selection** from the model window's menu. The application automatically inserts and connects appropriate input and output ports. To add more ports to the subsystem along entity paths, insert and connect this block in the subsystem window.

Parameters

Port number

Labels the subsystem connector port created by this block. Each connector port on the boundary of a single subsystem requires a unique number as a label.

Port location on parent subsystem

Use this parameter to choose on which side of the parent subsystem boundary the port appears. The choices are `Left` and `Right`. The choice of port location is unrelated to whether the block represents an entity input port or an entity output port.

Introduced in R2007b

Discrete Event Signal to Workspace (Obsolete)

Write event-based signal to workspace

Library

SimEvents Sinks

Description

This block writes its input to a structure or array in the base MATLAB workspace when the simulation stops or pauses. One way to pause a running simulation is to select **Simulation > Pause**. Suspending the simulation during a debugger session does not cause this block to write data to the workspace. This block logs data at each sample time hit.

This block is similar to the To Workspace block in the Simulink® Sinks library but is tailored for use with event-based signals.

Output Format

The **Save format** parameter determines the output format. The `Structure With Time` output format is most appropriate for event-based signals because it indicates when the signal assumes each value. Updates of event-based signals are typically aperiodic.

If the signal has an initial value, the value is the first data value in the workspace variable. (An example of a signal that has no initial value is a signal inside an Atomic Subsystem that has an event-based input signal.) Depending on the topology of your model, initial values of the signal might account for multiple data values in the workspace variable.

To identify the first data value that represents a sample time hit of the event-based signal, insert the Initial Value block before this block. Set the **Value until the first**

sample time hit parameter to a value you do not expect as a signal value at a sample time hit. To identify the initial value or values of the signal, remove the Initial Value block.

For scalar signals, you can convert a structure with time into a two-column matrix containing times in the first column and signal values in the second column. To do this, use an assignment like the one below. In place of `simout`, use the name specified in this block's **Variable name** parameter.

```
times_values = [simout.time, simout.signals.values];
```

For descriptions of all output formats, see the reference page for the To Workspace block.

Comparison with To Workspace Block

This block has no **Sample time** parameter because event-based signals do not have a true sample time.

The simulation times at which this block records data is typically unrelated to the variable that a model creates if you select **Time** in the **Save to workspace** section of the **Data Import/Export** tab of the Configuration Parameters dialog box. By default, this option is selected and the variable is called `tout`.

Ports

This block has one signal input port for the signal to write to the workspace.

The block has no entity ports, and no signal output port.

Parameters

Variable name

The name of the structure or array that holds the data.

Limit data points to last

The maximum number of input samples to be saved.

Decimation

A positive integer, n , that specifies the decimation factor. The block ignores the last $n-1$ out of every n input samples.

Save format

Format in which to save simulation output to the workspace. The recommended format for event-based signals is `Structure With Time`.

Examples

- “Send Queue Length to the Workspace”

See Also

To Workspace

“Save Simulation Data”

Introduced before R2006a

Enabled Gate (Obsolete)

Allow entity arrivals upon positive control signal

Library

Gates

Description

This block represents a gate that is open whenever the control signal at the **en** input port is positive, and closed whenever the signal is zero or negative. By definition, an open gate permits entity arrivals as long as the entities would be able to advance immediately to the next block, while a closed gate forbids entity arrivals. The **en** signal is a numerical signal of type `double`. Because the signal can remain positive for a time interval of arbitrary length, an enabled gate can remain open for a time interval of arbitrary length. The length can be zero or a positive number.

Ports

Entity Input Ports

Label	Description
IN	Port for arriving entities.

Signal Input Ports

Label	Description
en	The gate is open whenever this signal is positive. This signal must be an event-based signal.

Entity Output Ports

Label	Description
OUT	Port for departing entities.

Signal Output Ports

Label	Description	Time of Update When Statistic Is On
#d	Number of entities that have departed from this block since the start of the simulation	After entity departure

The initial output value is 0. This value is in effect from the start of the simulation until the first update by the block.

Dialog Box

Enabled Gate Tab

Resolve simultaneous signal updates according to event priority

Select this option to prioritize the gate-opening or gate-closing event explicitly, relative to other simultaneous events in the simulation. If you do not select this option, the event has priority `SYS1` on the event calendar.

Event priority

The priority of the gate-opening and gate-closing events, relative to other simultaneous events in the simulation. Gate opening and closing are distinct events that share the same event priority. You see this field only if you select **Resolve simultaneous signal updates according to event priority**.

Statistics Tab

These parameters determine whether the block produces data at signal output ports or omits those ports. For descriptions of the data and ports, see the preceding table, “Signal Output Ports”.

Number of entities departed

Allows you to use the signal output port labeled **#d**.

See Also

Release Gate (Obsolete)

Introduced before R2006a

Entity Batch Creator

Create batch of entities

Library

Routing

Description

The Entity Batch Creator receives the expected number of entities **Number of entities in batch** and creates a new batch entity that contains all these entities. The batched entity is an array of entities. The block releases any acquired resources before batching an input entity.

You can reference batched entity attributes in event actions. You cannot reference them in:

- Priority queues — Do not set **Priority source** parameter to `PriorityAttribute`.
- Entity Server block — Do not set **Service time source** parameter to `Attribute`.
- Output Switch block — Do not set **Switching criterion** parameter to `From attribute`.

To output the batch as a bus object, select the **Bus object** parameter. Consider creating a bus object for the batched entity when:

- Sending or receiving a batched entity to or from a MATLAB Discrete-Event System block.
- Sending or receiving a batched entity to or from a Discrete-Event Chart block.
- When passing full entity data to a Simulink Function block.
- When converting a batched entity to a signal using the Message Receive block.

Parameters

Number of entities in batch

Specify the number of input ports.

Entity type name

Specify the type name of the batched entity that is created after combining incoming entities.

Bus object

Specify whether to output the batched entity as a bus object.

Input entity name

Specify names to be attached to the input entities, which can be used for referencing these entities in the batched entity.

Event actions

Specify the behavior of the entity on certain events. Define the behavior in the **Event action** parameter. For example, the **Generate** action is called when an entity is generated.

Event action

Define the behavior for the event action specified in **Event actions**.

Number of entities arrived, a

Outputs the number of entities that have arrived at the block.

Number of entities departed, d

Outputs the number of entities that have departed the block.

Number of entities remaining for next batch, rem

Outputs the number of entities still in the block for the next batch of entities.

Pending entity in block, pe

Indicates whether there are entities present in the block that have yet to depart.

See Also

Entity Batch Splitter | Entity Generator

Introduced in R2016b

Entity Batch Splitter

Split batch entities

Library

Routing

Description

The Entity Batch Splitter block splits a batched entity into its individual entities and outputs each entity through the output port. A batched entity is the output of the Entity Batch Creator block.

Parameters

Event actions

Specify the behavior of the entity on certain events. Define the behavior in the **Event action** parameter. For example, the **Generate** action is called when an entity is generated.

Event action

Define the behavior for the event action specified in **Event actions**.

Number of entities arrived, a

Outputs the number of entities that have arrived at the block.

Number of entities departed, d

Outputs the number of entities that have departed the block.

Number of entities remaining to depart, rem

Outputs the number of entities still in the block that have yet to depart.

Pending entity in block, pe

Indicates whether there are entities present in the block that have yet to depart.

Entity Batch Creator | Entity Generator

Introduced in R2016b

Entity Combiner (Obsolete)

Generate one entity per set of entities arriving simultaneously

Library

Entity Management

Description

This block generates one new entity for each set of entities arriving simultaneously at multiple input ports. The arriving entities are called component entities. They might represent different parts within a larger item, such as a header, payload, and trailer that are parts of a packet. The Entity Combiner block and its preceding blocks automatically detect when all necessary component entities are ready for the combining operation to proceed. Your parameter choices in this block determine whether other blocks can access the attributes or timers of the component entities, and whether the combining operation is reversible. Some parameter choices require uniqueness of attribute names or timer tags in the component entities.

Timeout events, if any, corresponding to the component entities are canceled during the combining operation.

Waiting for Component Entities on Multiple Paths

The Entity Combiner block has multiple entity input ports and one entity output port. The combining operation occurs when all necessary component entities are ready and the resulting entity would be able to depart. More explicitly, when all the blocks that connect to the Entity Combiner block's entity input ports have a pending entity simultaneously and the port connecting to the Entity Combiner block's entity output port is available,

the Entity Combiner block accepts one entity arrival at each input port and outputs one entity. At all other times, the Entity Combiner block's input ports are unavailable.

Tip It is typical to connect a queue or other storage block to each entity input port of the Entity Combiner block. The storage blocks provide a place for pending entities to wait for other entity paths to have pending entities. Storage blocks are especially important if multiple component entities come from a single multiple-output block, such as a Replicate or Entity Splitter block.

Managing Information When Combining Entities

The entity that departs from the Entity Combiner block can optionally carry information about the component entities that the block combines. In some applications, you might consider the information to be more important than the entities that carry it. The table below indicates how different options of the block produce different requirements and behavior regarding

- Uniqueness of attribute names among the entities at all entity input ports of the Entity Combiner block
- Uniqueness of timer tags among the entities at all entity input ports of the Entity Combiner block
- Your ability to use the departing entity to access attributes and timers from the component entities
- Your ability to split the departing entity into its components using the Entity Splitter block

Note You can manage access to the set of attributes and the set of timers independently. The table treats attributes and timers together merely for conciseness.

Options for Managing Information When Combining Entities

<ul style="list-style-type: none"> <input checked="" type="checkbox"/> Retain structure in departing entity <input checked="" type="checkbox"/> Make attributes accessible in departing entity <input checked="" type="checkbox"/> Make timers accessible in departing entity <ul style="list-style-type: none"> • You can split the departing entity, which is called a composite entity. • Attribute names and timer tags must be unique. • You can access attributes and timers. 	<ul style="list-style-type: none"> <input type="checkbox"/> Retain structure in departing entity <input checked="" type="checkbox"/> Copy attributes to departing entity <input checked="" type="checkbox"/> Copy timers to departing entity <ul style="list-style-type: none"> • You cannot split the departing entity. • Attribute names and timer tags must be unique. • You can access attributes and timers.
<ul style="list-style-type: none"> <input checked="" type="checkbox"/> Retain structure in departing entity <input type="checkbox"/> Make attributes accessible in departing entity <input type="checkbox"/> Make timers accessible in departing entity <ul style="list-style-type: none"> • You can split the departing entity, which is called a composite entity. When you split the composite entity, attributes and timers of components become accessible. • Uniqueness of attribute names and timer tags is optional. • You cannot access attributes and timers via the departing entity. 	<ul style="list-style-type: none"> <input type="checkbox"/> Retain structure in departing entity <input type="checkbox"/> Copy attributes to departing entity <input type="checkbox"/> Copy timers to departing entity <ul style="list-style-type: none"> • You cannot split the departing entity. • Uniqueness of attribute names and timer tags is optional. • You cannot access attributes and timers.

If you do not select **Retain structure in departing entity**, you can think of the block as generating a new nonhierarchical entity, copying attribute or timer information to the new entity if necessary, and then discarding the component entities.

Ports

Entity Input Ports

Label	Description
IN1, IN2, IN3, and so on	Port for arriving entities. The Number of entity input ports parameter determines how many of these entity input ports the block has.

Entity Output Ports

Label	Description
OUT	Port for departing entities.

Signal Output Ports

Label	Description	Time of Update When Statistic Is On
#d	Number of entities that have departed from this block since the start of the simulation	After entity departure

The initial output value is 0. This value is in effect from the start of the simulation until the first update by the block.

Parameters

Entity Combiner Tab

Number of entity input ports

Determines how many entity input ports the block has.

Retain structure in departing entity

If you select this option, the departing entity carries information about the number of component entities and which attributes and timers each component entity possesses. Such information enables you to recover the component entities using the Entity Splitter block.

Make attributes accessible in departing entity

If you select this option, you can access attributes from the component entities via the departing entity. The name of this field depends on whether you select **Retain structure in departing entity**.

Make timers accessible in departing entity

If you select this option, you can access timers from the component entities via the departing entity. The name of this field depends on whether you select **Retain structure in departing entity**.

Statistics Tab

Number of entities departed

Allows you to use the signal output port labeled **#d**.

Examples

- “Manage Data in Composite Entities”

Limitations

In general, a composite entity can arrive at this block and become a component entity within a new nested composite entity. However, if you select **Retain structure in departing entity**, the depth of nesting is limited. This prevents the memory usage of nested composite entities from growing without bound in the case of a looped entity path.

See Also

Entity Splitter (Obsolete)

“Combine Entities”

Introduced in R2007a

Entity Departure Counter (Obsolete)

Count departures and write result to signal port or attribute

Library

Entity Management

Description

This block computes the number of entities that have departed since the start of the simulation or since the last reset, whichever occurred later. The block writes this number to a signal output port and/or an attribute of each departing entity. The count includes the departing entity.

Ports

Entity Input Ports

Label	Description
IN	Port for arriving entities.

Signal Input Ports

Label	Description
ts	When this signal has an update, the block resets its internal counter and the #d output signal to zero. This signal must be an event-based signal. You see this port only if you set Reset counter upon to <code>Sample time hit</code> from port <code>ts</code> .
tr	When this signal satisfies the specified trigger criteria, the block resets its internal counter and the #d output signal to zero. This signal must be an event-based signal. You see this port only if you set Reset counter upon to <code>Trigger</code> from port <code>tr</code> .
vc	When this signal satisfies the specified value-change criteria, the block resets its internal counter and the #d output signal to zero. This signal must be an event-based signal. You see this port only if you set Reset counter upon to <code>Change in signal</code> from port <code>vc</code> .
fcn	When this signal carries a function call, the block resets its internal counter and the #d output signal to zero. This signal must be an event-based function call. You see this port only if you set Reset counter upon to <code>Function call</code> from port <code>fcn</code> .

Entity Output Ports

Label	Description
OUT	Port for departing entities.

Signal Output Ports

Label	Description	Time of Update When Statistic Is On
#d	Number of entities that have departed from this block since the start of the simulation or since the last reset.	After entity departure

The initial output value is 0. This value is in effect from the start of the simulation until the first update by the block.

Parameters

Write count to signal port #d

Allows you to use the signal output port labeled **#d**. This parameter determines whether the block outputs the entity count through a signal output port under these circumstances:

- Throughout the simulation
- Only when you stop or pause the simulation
- Not at all

Write count to attribute

If you select this check box, the block assigns the entity count to the attribute specified in the **Attribute name** parameter.

Attribute name

The name of the attribute the block uses to record the entity count. You see this field only if you select the **Write count to attribute** check box.

Create attribute if not present

Selecting this option enables the block to define a new attribute for the entity count. Otherwise, the block issues an error if the attribute you name in the **Attribute name** parameter does not exist. You see this field only if select the **Write count to attribute** check box.

Reset counter upon

Determines whether, and under which circumstances, the block resets its internal counter and the **#d** output signal to zero:

Trigger type determines whether rising, falling, or either type of trigger edge causes the counter to reset. You see this field only if you set **Reset counter upon to** `Trigger from port tr`.

Type of change in signal value determines whether rising, falling, or either type of value change causes the counter to reset. You see this field only if you set **Reset counter upon to** `Change in signal from port vc`.

Resolve simultaneous signal updates according to event priority

Select this option to prioritize the reset event explicitly, relative to other simultaneous events in the simulation. If you do not select this option, the event has

priority `SYS1` on the event calendar. You see this field only if you set **Reset counter upon** to a value other than `Off`.

Event priority

The priority of the reset event, relative to other simultaneous events in the simulation. You see this field only if you set these parameters:

- **Reset counter upon** = A value other than `Off`
- Select **Resolve simultaneous signal updates according to event priority**

Examples

- “Set Attributes”

Instantaneous Entity Counting Scope (Obsolete)

“Count Entities”

Introduced before R2006a

Entity Departure Function-Call Generator (Obsolete)

Convert entity departure event into one or two function calls

Library

Generators/Function-Call Generators

Description

This block converts an entity departure event into one or two function calls that you can use to invoke function-call subsystems, Stateflow® blocks, or other blocks that accept function-call inputs. The block can suppress its output under certain conditions.

Criteria for Generating Function Calls

The primary criterion is the departure, or imminent departure, of an entity from the block. You can choose whether the block generates the function call before or after the departure.

To generate up to two function calls per event, select **Generate optional function call f2 after function call f1**. If you configure the block to generate the **f1** function call before the entity departure, you can independently choose whether the block generates the **f2** function call before or after that departure.

To make the **f1** or **f2** output function call contingent upon a secondary criterion, select **Suppress function call f1 if enable signal e1 is not positive** or **Suppress function call f2 if enable signal e2 is not positive**. The block acquires an additional signal input port, labeled **e1** or **e2**, to which you connect a control signal. If the control signal is zero or negative when the block is about to generate the function call, the block

suppresses the function call. The **e1** and **e2** ports operate independently of each other as secondary criteria for their respective function-call output ports.

Ports

Entity Input Ports

Label	Description
IN	Port for arriving entities.

Signal Input Ports

Label	Description
e1	When this signal is 0 or negative, the block does not generate a function call at the f1 output port. This signal must be an event-based signal. You see this input port only if you select Suppress function call f1 if enable signal e1 is not positive .
e2	When this signal is 0 or negative, the block does not generate a function call at the f2 output port. This signal must be an event-based signal. You see this input port only if you select Suppress function call f2 if enable signal e2 is not positive .

Entity Output Ports

Label	Description
OUT	Port for departing entities.

Signal Output Ports

Label	Description	Time of Update When Port Is Present	Order of Update
f1	Function-call signal, possibly contingent on e1 input signal.	Before or after entity departure, depending on Timing of function call f1 parameter	1
f2	Function-call signal, possibly contingent on e2 input signal.	Before entity departure if both Timing of function call... parameters are set to Before entity departure; otherwise, after entity departure	2
#d	Number of entities that have departed from this block since the start of the simulation.	After entity departure	4
#f1	Number of function calls the block has generated at the f1 port during the simulation.	After entity departure	3
#f2	Number of function calls the block has generated at the f2 port during the simulation.	After entity departure	3

Output signals having the same number in the Order of Update column in the table above are updated in an arbitrary sequence relative to each other; you should not rely on a specific sequence for your simulation results.

The initial output value for the numerical signals, which is in effect from the start of the simulation until the first update by the block, is 0.

Parameters

Function Call Tab

Timing of function call **f1**

Determines whether the **f1** function call occurs before or after the entity departure event.

Use of signals awaiting update during function call

You see this parameter only if you set **Timing of function call f1** to `Before entity departure`.

When you configure the block to generate a function-call before an entity departs the block, the function-call event might use signal values that are still awaiting update. If this situation arises, **Use of signals awaiting update during function call:** specifies the action that you want the software to take. If you do not also select the configuration parameter **Prevent duplicate events on multiport blocks and branched signals** in your model, the parameter does not function.

Suppress function call f1 if enable signal e1 is not positive

Selecting this option causes **f1** function calls to be contingent upon a positive value at the **e1** signal input port.

Generate optional function call f2 after function call f1

Selecting this option causes the block to generate a function call at the optional **f2** output port when appropriate criteria are satisfied.

Timing of function call f2

Determines whether the **f2** function call occurs before or after the entity departure event. You see this field only if you set **Timing of function call f1** to `Before entity departure` and select **Generate optional function call f2 after function call f1**.

Suppress function call f2 if enable signal e2 is not positive

Selecting this option causes **f2** function calls to be contingent upon a positive value at the **e2** signal input port. You see this field only if you select **Generate optional function call f2 after function call f1**.

Statistics Tab

Number of entities departed

Allows you to use the signal output port labeled **#d**.

Number of f1 function calls

Allows you to use the signal output port labeled **#f1**.

Number of f2 function calls

Allows you to use the signal output port labeled **#f2**. This field is active only if you select **Generate optional function call f2 after function call f1** on the **Function Call** tab of this dialog box.

Composite Entity Creator

Create composite entities

Library

Routing

Description

This block creates a composite entity for each set of entities arriving simultaneously at all input ports. The newly created entity can include information about the structure, attributes, and timers of the arriving entities.

Parameters

Number of input ports

Specify the number of input ports.

Entity type name

Specify the type name of the composite entity that is created after combining incoming entities.

Bus object

Specify whether to output the composite entity as a bus object.

Define input entity names

Specify names to be attached to the input entities, which can be used for referencing these entities in the composite entity.

Entity priority

Specify the priority of the composite entity created.

Discrete Event Chart

Discrete event chart

Library

User-Defined

Description

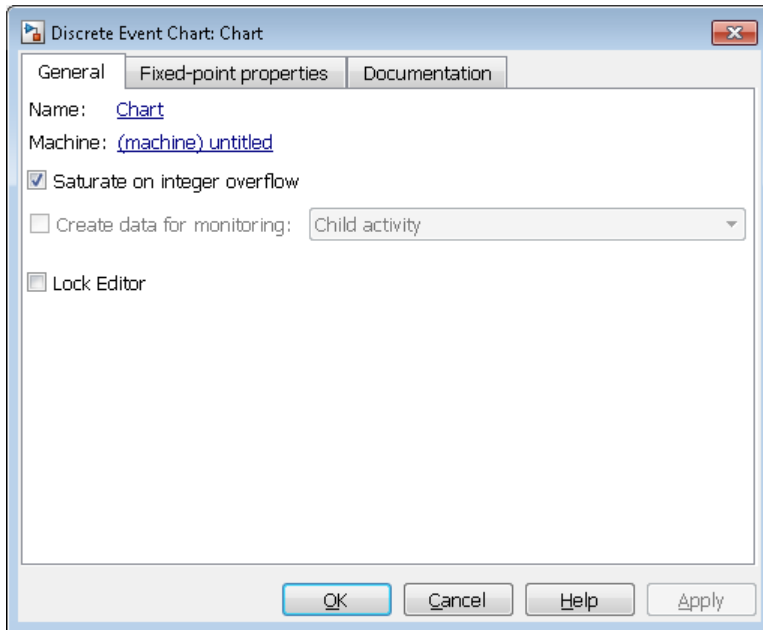

This block is similar to a Stateflow chart, but is used for discrete events. The block requires a Stateflow license.

The advantages of the discrete event chart are given below.

- **Precise timing:** The time resolution for occurrence of events can be arbitrarily precise, and are not limited by the sample time of the model.
- **Trigger on Arrival:** A discrete event chart executes immediately on arrival of a message. It does not execute on the next sample time hit.
- **Dynamic Scheduling:** A discrete event chart can execute zero or multiple times in a single time step. It does not have a fixed sorted execution order. The order of execution depends on the run-time conditions of the model.

The Discrete Event Chart can be used in a similar fashion to the Stateflow Chart.

To access the properties of the chart, right-click the chart and select **Properties**. For more information on properties, see “Discrete Event Chart Properties”.

MATLAB Discrete-Event System

MATLAB discrete-event system

Library

SimEvents Library: User-Defined

Description

This block allows you to create and author discrete-event systems in MATLAB using the MATLAB System block. With this block, you can author an event-driven entity-flow system using MATLAB, and use it in your Simulink model.

Parameters

System object name

Specify the full name of the user-defined discrete-event System object class without the file extension. This entry is case sensitive. The class name must exist on the MATLAB path.

You can specify a discrete-event System object name in one of these ways:

- Enter the name in the text box.
- Click the list arrow attached to the text box. If valid System objects exist in the current folder, the names appear in the list. Select a System object from this list.
- Browse to a folder that contains a valid discrete-event System object. If the folder is not on your MATLAB path, the software prompts you to add it.

If you need to create a discrete-event System object, you can create one from a template by clicking **New**.

After you save the SimEvents System object, the name appears in the **System object name** text box.

Use the full name of the user-defined discrete-event System object class name. The block does not accept a MATLAB variable that you have assigned to a discrete-event System object class name.

New

Click this button to create a SimEvents System object from a template.

Select one of these options.

- Basic

Starts MATLAB Editor and displays a template for a simple discrete-event System object using the fewest System object methods.

After you save the SimEvents System object, you can enter the name in the **System object name** text box.

Simulate using

Select a simulation mode.

Interpreted execution

Simulate model using all supported MATLAB functions. Choosing this option can slow simulation performance.

Code generation

On the first model run, simulate and generate code for this block using only MATLAB functions supported for code generation. If the structure of the block does not change, subsequent model runs do not regenerate the code.

Entity Gate

Gate entities

Library

Routing

Description

When the **Operating mode** parameter is set to `Enable gate`, this block represents a gate that is open whenever the control signal at the input port is positive, and closed whenever the signal is zero or negative. By definition, an open gate permits entity arrivals as long as the entities would be able to advance immediately to the next block, while a closed gate forbids entity arrivals. The input signal is a numerical signal of type `double`. Because the signal can remain positive for a time interval of arbitrary length, an enabled gate can remain open for a time interval of arbitrary length. The length can be zero or a positive number.

When the **Operating mode** parameter is set to `Release gate`, this block permits the arrival of one pending entity when a signal-based event or function call occurs; at all other times, the entity input port of the block is unavailable. By definition, the opening of the gate permits one pending entity to arrive if the entity is able to advance immediately to the next block.

When the **Operating mode** parameter is set to `Selection gate`, this block permits the arrival of pending entities whenever the signal at the control port matches the attributes of the pending entities, otherwise it prevents the arrival of pending entities.

No simulation time passes between the opening and subsequent closing of the gate. The gate opens and then closes in the same time instant. If no entity is already pending when the gate opens, then the gate closes without processing any entities.

The **Open gate at simulation start** parameter opens the gate at the start of simulation.

Parameters

Operating mode

Select the mode of operation of this gate. Select `Enable gate` to allow entity arrivals upon receiving a message with a positive value. Select `Release gate` to allow one pending entity arrival per message arrival. Select `Selection gate` to allow pending entity arrival with specified attribute .

Open gate at simulation start

Select this option to open the gate at the start of the simulation.

Entity Generator

Generate entities

Library

Basic

Description

This block generates entities.

Parameters

Generation method

Select the method of generation. Choose `Time-based` to generate entities using intergeneration times from an input signal or statistical distribution. Choose `Event-based` for an external event to determine the entity intergeneration time.

Time source

Select the source of the intergeneration time. Select `Dialog` to specify a fixed period between entity generations. Select `Signal port` to generate entities based on an input signal. Select `MATLAB action` to define a MATLAB script that defines the intergeneration time. This parameter is visible when **Generation method** is set to `Time-based`.

Period

Define the period between the generation of entities. This parameter is visible when **Generation method** is set to `Time-based`.

Generate entity at simulation start

Check this box to generate an entity at the start of the simulation.

Entity type

Choose the type of entity to generate. The `Anonymous` type has a data value associated with it. The `Structured` type includes attributes that you can set. The `Bus object` type lets you generate bus objects as entities.

Entity priority

Determines the priority of the generated entity. A lower value indicates higher priority.

Entity type name

Specify the name of the generated entity. This parameter is visible when **Entity type** is set to `Bus object` or `Structured`.

Data initial value

Specify the initial value of the data of an anonymous entity. This parameter is visible when you set **Entity type** to `Anonymous`. This value cannot be of type `int64`.

Define attributes

Define the attributes of the generated entity. This parameter is visible when **Entity type** is set to `Structured`.

Note When done, you can export the structured entity type as a bus object, with the name **Entity type name**, to the base workspace. You need to export this bus object when using the MATLAB Discrete-Event System and Discrete Event Chart blocks.

Event actions

Specify the behavior of the entity on certain events. Define the behavior in the **Event action** parameter. For example, the **Generate** action is called when an entity is generated.

Event action

Define the behavior for the event action specified in **Event actions**.

Number of entities departed, d

Outputs the number of entities that have departed the block.

Pending entity present in block, pe

Indicates whether there are pending entities that have yet to depart the block.

Average intergeneration time, w

Outputs the average time between generation of entities.

Entity Input Switch

Switch input entities

Library

Routing

Description

Note This page is the block reference page for the Input Switch block introduced in R2016a. To see the documentation on the previous Input Switch block, see [Input Switch \(Obsolete\)](#).

This block allows arrival of entities at its ports. The selected entity input port can change during the simulation.

Parameters

Number of input ports

Determines how many entity input ports the block has.

Active port selection

Select `All` to allow arrival of entities at all ports. Select `Switch` to allow arrival of an entity at only one port at a time.

Switching criterion

Select the criterion for switching between input ports. Select `Round robin` to select ports in a round robin fashion. Select `From control port` to let the control port

determine the selected port. Select `Equiprobable` to let the block randomly select any port with equal probability.

Initial port selection

Specify which port to allow arrival of entity from initially.

Seed

Specify the seed for the random number generator to determine the input port. This parameter is visible when **Switching criterion** is set to `Equiprobable`.

Entity Output Switch

Output entities

Library

Routing

Description

Note This page is the block reference page for the Output Switch block introduced in R2016a. To see the documentation for the previous Output Switch block, see [Output Switch \(Obsolete\)](#).

The block allows you to select an output port for departure of an entity.

Parameters

Number of output ports

Specify the number of output ports.

Switching criterion

Choose the criterion for switching between output ports. Select `First port that is not blocked` to output the entity to the first unblocked port. Select `Round robin` to output entities in a round robin fashion among the output ports. Select `From control port` to introduce a control port that specifies the output port for entity departure. Select `From attribute` to specify an attribute that determines the output port. Select `Equiprobable` to randomly select an output port for entity departure.

Initial port selection

Specify the output port at the start of the simulation. This parameter is visible when **Switching criterion** is set to `Round robin` or `From control port`.

Switch Attribute name

Specify the attribute that determines the output port. This parameter is visible when **Switching criterion** is set to `From attribute`.

Seed

Specify the seed for the random number generator to determine the output port. This parameter is visible when **Switching criterion** is set to `Equiprobable`.

Entity Queue

Enqueue entities

Library

Basic

Description

This block stores entities in a queue, based on order of arrival or priority. The entity at the head of the queue departs when the downstream block is ready to accept it.

Parameters

Capacity

Specify the capacity of the queue.

Queue type

Choose the type of queue. Select `FIFO` for a first-in-first-out queue. Select `LIFO` for a last-in-first-out queue. Select `Priority` to store the entities in order of their priority.

Entity arrival source

Choose the source of arrival for the entities. Select `Multicast` to receive entities broadcast from Entity Multicast blocks.

Multicast tag

Specify the tag when accepting entities broadcast via multicast sources. This parameter is visible when you set **Entity arrival source** to `Multicast`.

Priority source

Specify which attribute of the entity determines its priority. This parameter is visible when you set **Queue type** to `Priority`.

Sorting direction

Choose the direction of sorting entities based on priority. Specify 'ascending' if you want entities with smaller key values to appear in front of the queue. Specify 'descending' if you want entities with greater key values to appear in front of the queue.

Event actions

Specify the behavior of the entity in certain events. Define the behavior in the **Event action** parameter. For example, the **Generate** action is called after an entity is generated.

Event action

Define the behavior for the event action specified in **Event actions**.

Number of entities departed, d

Outputs the number of entities that have departed the block.

Number of entities in block, n

Outputs the number of entities present in the block, which have yet to depart.

Average wait, w

Outputs the average wait time for entities in the block.

Average queue length, l

Outputs the average length of the entity queue.

Entity Replicator

Replicate entities

Library

Routing

Description

This block duplicates entities. It outputs the duplicate entities and can also output the original entity. There is always an output port for the original entity.

Parameters

Replicas depart from

Choose how replicas depart. Select `Separate output ports` to output one entity from each output port. Select `Single output port` to output all replicas from a single output port.

Replication amount source

Choose the source to specify the number of replicas. Select `Dialog` to specify the number of replicas in the dialog box. Select `Attribute` to select an attribute that will specify the number of replicas. This parameter is visible when you set **Replicas depart from** to `Single output port`.

Number of replicas

Specify the number of replicas. This number depends on the selection of the **Replicas depart from** parameter. If you select `Single output port`, all replicas depart from this output port. If you select `Separate output ports`, each replica has its own port.

Replicate attribute name

Specify the attribute that determines the number of replicas. This parameter is visible when you set **Replicas depart from** to `Single` output port and **Replication amount source** is set to `Attribute`.

Hold original entity until all replicas depart

Select this check box to hold the original entity until all the replicas have departed.

Resource Acquirer

Acquire entity resources

Library

Resources

Description

This block acquires the use of resources for a passing entity. You can specify that the block acquire certain resource types.

Initialize the block with specified amount of available resources. Then:

- Use one or more Resource Acquirer blocks to reserve the use of those resources.
- Use a Resource Releaser block to return resources back to this block for future use.

Resources are visible to the current subsystem and its children. Resource are not visible to parent subsystems.

Parameters

Maximum number of waiting entities

Enter the maximum number of entities that can wait for a resource.

Event actions

Specify the behavior of the entity on certain events. Define the behavior in the **Event action** parameter. For example, the **Entry** action is called when an entity is generated.

Event actions

Define the behavior for the event action specified in **Event actions**.

Number of entities departed, d

Outputs the number of entities that have departed the block.

Number of entities in block, n

Outputs the number of entities present in the block.

Average wait, w

Outputs the average wait time for entities in the block.

Available Resources

Use the **Available Resources** controls to:

- Select the resources from the resources defined in all the Resource Pool blocks in the model.
- Add the resources to the Selected Resources table, where you can configure resource acquisition details.

The list displays all the available resources in the model. (If there are no resources, the **Available Attributes** list is empty.)

If the resource list is long, you can type the resource name in the text box to filter the list.

Use the buttons in the **Available Resources** section to help build the resources table. The buttons perform these actions.

Button	Action
	Refresh the Available Resources list. The list updates with any upstream model changes you make while the block dialog box is open.
	Add the selected resources to the Selected Resources table.

Button	Action
	Move the selected resource from the Selected Resources table to the Available Resources list.
	Note If the selected resource is one you added manually, this button appears dimmed.

The message area below the available resources list displays additional messages about the resources, as they apply.

Message	Meaning
> Resource already selected	You have already added the resource to the Selected Resources table. You cannot add the resource to the table again.

Selected Resources

Use the controls under **Selected Resources** to build and manage the list of resources to attach to the entity. Each resource appears as a row in a table.

Using these controls, you can:

- Add a resource manually.
- Modify a resource that you added to the table from the **Available Resources** list to attach to the entity.

The buttons under **Selected Resources** perform these actions:

Button	Action	Notes
	Add a template resource to the table.	Rename the resource and specify its properties.
	Add a copy of the selected resource to the table to use as the basis of a new resource.	Rename the copy. Two resources cannot have the same name.
	Remove the selected resource from the Selected Resources table.	When you delete a resource this way, no confirmation appears and you cannot undo the operation.

Button	Action	Notes
	Move the selected resource up in order in the Selected Resources table.	N/A
	Move the selected resource down in order in the Selected Resources table.	N/A

Note If you delete a row and apply the change, the deletion can affect signal output ports corresponding to other attributes. For example, if the block has a signal output port **A2** and you delete the attribute with a port marked **A1**, the block relabels **A2** as **A1**. Verify that any signal that connects to the relabeled port is still connected as you expect.

Property	Specify	Use
Name	The name of the resource. Each resource must have a unique name.	Double-click the existing name, and then type the new name.
Amount Source	Whether the resource amount, that an entity requests, comes from the dialog box or an attribute.	Select Dialog or Attribute . If you select Attribute , the source of the resource amount comes from the attribute of the entity. This option allows each entity to acquire varying amounts of resources. For more information, see “Set Resource Amount with Attributes”

Property	Specify	Use
Amount	The value to assign to the resource (when the resource comes from the dialog box).	Double-click the value, and then type the value you want to assign. This value is the number of resources acquired per entity. For example, if Amount is 3, each entity that arrives at the Release Acquire must wait to acquire 3 resources before departing the block.

Introduced in R2016a

Resource Pool

Pool entity resources

Library

Resources

Description

This block defines resources that entities can use during model simulation. Use the Resource Acquirer and Resource Releaser blocks to work with these resources.

Initialize the block with the specified amount of available resources. Then:

- Use one or more Resource Acquirer blocks to reserve the use of those resources.
- Use a Resource Releaser block to return resources back to this block for future use.

Resources are visible to the current subsystem and its children. Resource are not visible to parent subsystems.

Parameters

Resource name

Enter name of entity resource.

Resource granularity

Select granularity of resource use.

- `Discrete unit` — Use whole number increment.
- `Fractional amount` — Use fractional increment.

Reusable upon release

- Select this check box to allow this resource to return to the resource pool upon release. An example of such a resource is a table in a restaurant, which is available for reuse when a customer leaves.

Selecting this check box enables the **Resource amount source** check box.

- Clear this check box to prevent this resource from returning to the resource pool upon release. In this case, when the resource is released, it is no longer available in the resource pool. An example of such a resource is food in a restaurant, which is not reusable upon consumption.

Resource amount source

Select resource amount source.

- Dialog

Select this option to enable the `Resource amount` parameter. Selecting this parameter enables the **Resource amount** parameter.

- Message port

Select this option to enable an input message port. If you want a variable capacity resource, select this option. The payload of the arriving message increments the existing number of resources for the block. For example, if the resource pool has five resources, and a message with a payload of three arrives at the input port, the block has eight resources available. The number of resources cannot decrement. Selecting this parameter enables the **Initial resource amount** parameter.

Resource amount

Enter amount of resource.

Initial resource amount

Enter initial amount of resource.

Amount in use, u

Outputs the amount of resources that the block has acquired and has not yet released. For example, if the resource pool has ten resources, and the entity acquires all of them, this port shows 10. When the block releases the resources, this port shows 0.

Average utilization, util

Outputs the average resource utilization.

Amount available, avail

Outputs the amount of resources available.

Introduced in R2016a

Resource Releaser

Release entity resources

Library

Resources

Description

This block releases the use of resources for a passing entity. You can specify that the block release certain resource types or release all resources.

Parameters

Resource to release

Select the resources to release.

- All

Release the use of all resources for a passing entity.

- Selected

Release selected resources. Selecting this option enables the **Available Resources** table.

Available Resources

Use the **Available Resources** controls to:

- Select the resources from the resources defined in all the Resource Pool blocks in the model
- Add the resources to the Selected Resources table, where you can modify them.

The list displays all the resources in the model. (If there are no resources, the **Available Resources** list is empty).

If the resource list is long, you can type the resource name in the text box to filter the list.

Use the buttons in the **Available Resources** section to help build the resources table. The buttons perform these actions.

Button	Action
	Refresh the Available Resources list. The list updates with any upstream model changes you make while the block dialog box is open.
	Add the selected resources to the Selected Resources table.
	Move the selected resource from the Selected Resources table to the Available Resources list. Note: If the selected resource is one you added manually, this button appears dimmed.

The message area below the available resources list displays additional messages about the resources, as they apply.

Message	Meaning
> Resource already selected	You have already added the resource to the Selected Resources table. You cannot add the resource to the table again.

Selected Resources

Use the controls under **Selected Resources** to build and manage the list of resources to release. Each resource appears as a row in a table.

Using these controls, you can:

- Add a resource manually.
- Modify a resource that you added to the table from the **Available Resources** list to release.

The buttons under **Selected Resources** perform these actions.

Button	Action	Notes
	Add a template resource to the table.	Rename the resource and specify its properties.
	Add a copy of the selected resource to the table to use as the basis of a new resource.	Rename the copy. Two resources cannot have the same name.
	Remove the selected resource from the Selected Resources table.	When you delete a resource this way, no confirmation appears and you cannot undo the operation.
	Move the selected resource up in order in the Selected Resources table.	N/A
	Move the selected resource down in order in the Selected Resources table.	N/A

Note If you delete a row and apply the change, the deletion can affect signal output ports corresponding to other attributes. For example, if the block has a signal output port **A2** and you delete the attribute with a port marked **A1**, the block relabels **A2** as **A1**. Verify that any signal that connects to the relabeled port is still connected as you expect.

Property	Specify	Use
Name	The name of the resource to release.	Double-click the existing name, and then type the new name.

Entity Server

Serve entities

Library

Basic

Description

This block serves entities as they arrive. It can serve multiple entities simultaneously and output each entity through the output port, unless the port is blocked. When the block permits preemption, an entity in the server can depart early through a second port.

Parameters

Capacity

Specify the number of entities the block can serve simultaneously.

Service time source

Choose the source to specify the service time.

Service time attribute name

Specify the attribute used to determine the service time. This parameter is visible when **Service time source** is set to `Attribute`.

Service time value

Specify the value of the service time. This parameter is visible when **Service time source** is set to `Dialog`.

Service time action

Use MATLAB code to specify service time.

Event actions

Specify the behavior of the entity in certain events. Define the behavior in the **Event action** parameter. For example, the **Generate** action is called after an entity is generated.

Event action

Define the behavior for the event action specified in **Event actions**.

Permit preemption based on attribute

Select this check box if you want to allow preemption of entities. Selecting this check box enables these parameters:

- **Sorting attribute name**
- **Sorting direction**
- **Write residual time to attribute**
- **Number of pending entities, np**

Sorting attribute name

Specify the name of the attribute used to determine the priority.

Sorting direction

Choose the direction of sorting the entities. Specify 'ascending' if you want entities with smaller key values to appear in front of the queue. Specify 'descending' if you want entities with greater key values to appear in front of the queue.

Write residual time to attribute

Allow the block to save the residual service time from a preempted entity to an attribute.

This parameter is visible when the **Permit preemption based on attribute** parameter is selected. Selecting this parameter enables the **Residual time attribute name** parameter.

Residual time attribute name

Specify the name of the attribute to contain the residual service time of a preempted entity. This parameter is visible when the **Write residual time to attribute** parameter is selected.

Number of entities departed, d

Outputs the number of entities that have departed the block.

Number of entities in block, n

Outputs the number of entities present in the block.

Pending entity present in block, pe

Indicates whether there are entities present in the block that have yet to depart.

Number of pending entities, np

Outputs the number of pending entities in the block, which have yet to depart.

Average wait, w

Outputs the average wait time for entities in the block.

Utilization, util

Outputs the average number of entities being served.

Number of entities preempted, np

Outputs the number of preempted entities. This check box appears if the **Permit preemption based on attribute** check box is selected.

Message Receive

Extract data from received messages

Library

Other

Description

The Message Receive block extracts data from received messages and writes them to the output signal port. If there are no new messages when the block executes, the block uses the **Value source when queue is empty** value:

- Hold last value
Hold data read from the last message.
- Use initial value
Writes default data.

Data Type Support

The Message Receive block accepts inputs of any type that Simulink supports, including enumerated types. For more information, see “Data Types Supported by Simulink” (Simulink).

Parameters

Queue length

Specify message queue length.

Queue type

Specify message queue type. Selecting **Queue type** > **Priority** enables the **Priority** order parameter.

Choose from:

- FIFO
- LIFO
- Priority

Priority order

Specify message queue priority.

Choose from:

- Ascending
- Descending

Show queue status

Select to show queue status.

Initial value

Enter an initial value.

Value source when queue is empty

Specify the value to receive when received message queue is empty.

Choose from:

- Hold last value

Holds data read from the last message.

- Use initial value

Writes default data.

Sample time (-1 for inherited)

Specify the time interval between samples.

To inherit the sample time, set this parameter to -1.

See “Specify Sample Time” (Simulink) for more information.

SimEvents Examples

“SimEvents Common Design Patterns”

Introduced in R2016a

SimEvents Debugger

Debug SimEvents models

Library

Other

Description

The SimEvents Debugger block enables the debugger for your SimEvents model. You can:

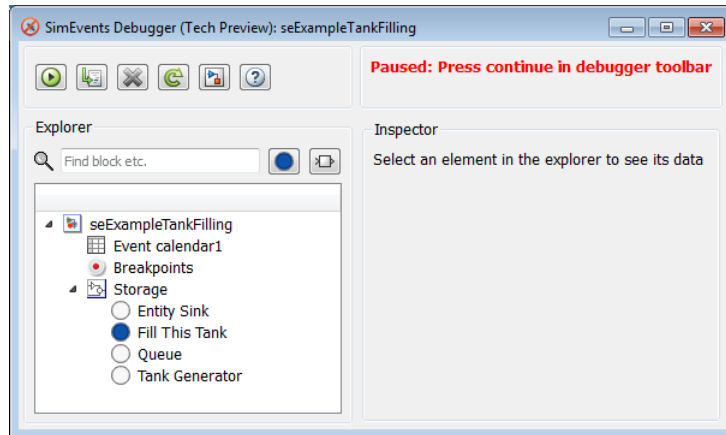

- Inspect entities and their attribute values in storage blocks
- Set breakpoints on blocks and events
- Watch entities

Note The SimEvents debugger is a preliminary version.

To start debugging your model:

- 1 From the SimEvents Library, drag the SimEvents Debugger block into your SimEvents model.
- 2 In the Simulink editor, click the **Step Forward** button.

The debugger interface appears.

- Click the **Continue simulation** button () to begin the simulation in the debugger. When the simulation completes, the debugger interface closes.
- To control the simulation of the model, click the buttons.
- To explore their data and behavior, the model tree displays in the left pane. Select the elements in the tree
- When done, on the Simulink editor, click the **Stop** button to stop the simulation.

Inspect Entities

To inspect entities in the debugger;

- To step to the next time step and inspect entities, in the Simulink editor, click the **Step Forward** button again. This action skips over all events at t_{now} .
- To step to the next event and inspect entities, in the debugger, click .
- To set a breakpoint:
 - At a particular time, use the Simulation Stepper to set breakpoints.
 - At an event on the event calendar, in the debugger, in the left pane, click an event calendar.

- At every event, in the debugger, in the left pane, select the event calendar. In the Event Calendar Events pane, select the **Break before event execution** check box.
- When an entity enters a block, in the debugger, select the block. At the bottom of the Inspector pane, select the **Break upon entry** check box.
- When an entity leaves a block, in the debugger, select the block. At the bottom of the Inspector pane, select the **Break prior to entity exit** check box.
- To go to a breakpoint:
 - In the debugger, click the **Continue** button ().

Note When you stop the debugger at a breakpoint, the Simulink editor and the MATLAB Command Window appear unresponsive. However, you can inspect entities, set new breakpoints, and continue the simulation from the debugger window.

- To watch entities:
 - In the left tree, click the block. In the Inspector pane, select the check box of the entity you want to watch.

Parameters

Enable debugger

Select this check box to enable the debugger for your model.

Introduced in R2016a

Entity Sink (Obsolete)

Accept or block entities

Library

SimEvents Sinks

Description

This block provides a way to terminate an entity path:

- If you select **Input port available for entity arrivals**, the block always accepts entity arrivals.
- If you do not select **Input port available for entity arrivals**, the block never accepts entity arrivals. The simulation issues an error message if an entity attempts to arrive at the block.

Ports

Entity Input Ports

Label	Description
IN	Port for entities that arrive or attempt to arrive.

Signal Output Ports

Label	Description	Time of Update When Statistic Is On
#a	Number of entities that the block has accepted. You see this port only if you select Input port available for entity arrivals , and then select the Report number of entities arrived, #a check box.	After entity arrival

The initial output value is 0. This value is in effect from the start of the simulation until the first update by the block.

Parameters

Input port available for entity arrivals

Determines whether the block accepts or blocks entities that attempt to arrive.

Report number of entities arrived, #a

Allows you to use the signal output port labeled #a. You see this field only if you select **Input port available for entity arrivals**.

Introduced before R2006a

Entity Splitter (Obsolete)

Divide composite entity into component entities

Library

Entity Management

Description

This block divides a composite entity into its components and outputs the component entities through each entity output port that is not blocked. A composite entity is an entity that the Entity Combiner (Obsolete) block creates using the **Retain structure in departing entity** option. In a typical pairing, the number of entity input ports of the Entity Combiner block equals the number of entity output ports of the Entity Splitter block.

Timeout events, if any, corresponding to the composite entity are canceled during the splitting operation.

Note If you want identical copies of an arriving entity to advance along multiple entity paths, use the Replicate (Obsolete) block instead of the Entity Splitter block. The Replicate block copies entities without regard to their structure.

Attributes and Timers

Attributes and timers from the original component entities (that combined to form the composite entity) are present in the component entities that depart from this block. The values of the attributes and timers might have changed between the combining and splitting operations.

If the composite entity acquired a new attribute or a new timer between the combining and splitting operations, then it is not present in the component entities that depart from this block.

Complete or Partial Splitting

The **Split entity when** parameter affects the circumstances under which the block accepts an entity to split. Choices are in the table.

Parameter Value	Description
All entity output ports are not blocked	The block accepts an entity to split only when all component entities would be able to depart immediately.
Any entity output port is not blocked	The block accepts an entity to split when at least one component entity would be able to depart immediately.

Departure of Component Entities

Each time the block splits an entity, the component entities depart in a sequence whose start is determined by the **Departure port precedence** parameter. Choices are in the next table.

Parameter Value	Description	Example
OUT1 port	Each time the block splits an entity, the component entities depart via entity output ports OUT1 , OUT2 , OUT3 ,..., in that sequence.	The sequence of departures is always OUT1 , OUT2 , OUT3 ,... throughout the simulation.

Parameter Value	Description	Example
Round robin	Each time the block splits an entity, the first component entity departs via the port after the one that received preference on the last such occasion. The remaining component entities depart via the subsequent ports in turn.	On a block with three entity output ports, the first time the block splits an entity, the component entities depart in the sequence OUT1, OUT2, OUT3 . The second time, the component entities depart in the sequence OUT2, OUT3, OUT1 . The third time, the component entities depart in the sequence OUT3, OUT1, OUT2 . The fourth time is analogous to the first time, and so on.
Equiprobable	Each time the block splits an entity, the first component entity departs via a randomly selected entity output port. All entity output ports are equally likely to be selected and the Initial seed parameter initializes the random number generation process. The remaining component entities depart via the subsequent ports in turn.	On a block with four entity output ports, if the random number is three, then the component entities depart in the sequence OUT3, OUT4, OUT1, OUT2 . If the random number is two on the next such occasion, then the component entities depart in the sequence OUT2, OUT3, OUT4, OUT1 .

An example in which the choice of **Departure port precedence** parameter is relevant is a model that sets an attribute on each component entity based on its departure port and then advances all component entities along a merged path to a **FIFO Queue** block. At each splitting occurrence during the simulation, the **Departure port precedence** parameter determines the sequence of the component entities in the queue.

In some cases, a departure through one entity output port causes another entity output port to become newly blocked. For example, this could happen if two entity output ports connect to a **Path Combiner** block, which in turn connects to a **Single Server** block whose service time is nonzero. Use the **If an output port becomes blocked during split** parameter to determine how the block responds. Choices are in the table below.

Parameter Value	Description
Discard entity	The block discards the component entity that is supposed to depart through the newly blocked entity output port.
Warn and discard entity	The block issues a warning message in the MATLAB Command Window, and discards the component entity that is supposed to depart through the newly blocked entity output port.
Error	The simulation halts with an error message.

Ports

Entity Input Ports

Label	Description
IN	Port for arriving entities, which must be composite entities created by the Entity Combiner block using the Retain structure in departing entity option.

Entity Output Ports

Label	Description
OUT1, OUT2, OUT3, and so on	Entity ports through which component entities depart. The entity that departs via the OUTn port corresponds to the entity that arrived at the INn entity input port of the corresponding Entity Combiner block. The Number of entity output ports parameter determines how many of these entity output ports the block has.

Signal Output Ports

Label	Description	Time of Update When Statistic Is On	Order of Update
#a	Number of entities that have arrived at this block since the start of the simulation.	After entity arrival	1
#d	Number of entities that have departed from this block since the start of the simulation.	After entity departure	2

The initial output value, which is in effect from the start of the simulation until the first update by the block, is 0 for all signals.

Parameters

Entity Splitter Tab

Number of entity output ports

Determines how many entity output ports the block has.

Split entity when

Determines whether the block is available to arriving entities whenever at least one entity output port is not blocked, or only when all entity output ports are not blocked.

Departure port precedence

Determines the start of the sequence in which the block outputs the component entities, each time the block splits an entity.

Initial seed

A nonnegative integer that initializes the random number generator used to determine the output sequence. You see this field only if you set **Departure port precedence** to `Equiprobable`.

If number of component entities does not match number of entity output ports

Determines whether the block issues a message when the number of component entities in the arriving composite entity does not equal the number of entity output ports of this block. “Continue” means that the block ignores any extra entity output ports and discards any extra component entities.

If an output port becomes blocked during split

Determines whether the block issues a message when a component entity is unable to depart because an output port becomes blocked during the splitting process. You see this field only if you set **Split entity when** to `All entity output ports are not blocked`.

Statistics Tab

Number of entities arrived

Allows you to use the signal output port labeled **#a**.

Number of entities departed

Allows you to use the signal output port labeled **#d**.

Examples

See “Manage Data in Composite Entities”.

Entity Combiner (Obsolete)

“Combine Entities”

Introduced in R2007a

Entity-Based Function-Call Event Generator (Obsolete)

Generate function call events corresponding to entities

Library

Generators / Event Generators

Description

Note The Entity-Based Function-Call Event Generator block will be removed in a future release. Use the Entity Departure Function-Call Generator (Obsolete) block instead.

This block generates a function call corresponding to each entity that arrives at the block. You can choose whether the block generates the function call before or after the departure. You can use the function call to invoke function-call subsystems, Stateflow blocks, or other blocks that accept function-call inputs.

This block is similar to the Entity Departure Function-Call Generator (Obsolete) block, which offers more flexibility.

Ports

Entity Input Ports

Label	Description
IN	Port for arriving entities.

Entity Output Ports

Label	Description
OUT	Port for departing entities.

Signal Output Ports

Label	Description	Time of Update When Port Is Present	Order of Update
f1	Function-call signal.	Before or after entity departure, depending on Generate function call parameter	1
#d	Number of entities that have departed from this block since the start of the simulation	After entity departure	3
#f1	Number of function calls the block has generated since the start of the simulation.	After entity departure	2

The initial output value for the numerical signals, which is in effect from the start of the simulation until the first update by the block, is 0.

Parameters

Function Call Tab

Generate function call

Determines whether the function call occurs before or after the entity departs from this block.

Statistics Tab

Number of entities departed

Allows you to use the signal output port labeled **#d**.

Number of f1 function calls

Allows you to use the signal output port labeled **#f1**.

See Also

Entity Departure Function-Call Generator (Obsolete), Signal-Based Function-Call Event Generator (Obsolete)

Introduced before R2006a

Event-Based Entity Generator (Obsolete)

Generate entity upon signal-based event or function call

Library

Generators / Entity Generators

Description

This block is designed to generate entities when events of a specified type occur.

When to Generate Entities	Generate entities upon Value
Each time the application updates (that is, recomputes and outputs) the value of a signal	Sample time hit from port <code>ts</code>
Each time an input signal has a trigger edge	Trigger from port <code>tr</code>
Each time an input signal changes its value	Change in signal from port <code>vc</code>
Each time an input signal carries a function call	Function call from port <code>fcn</code>

Note An exceptional case is when the block temporarily suspends its normal entity-generation behavior. See the description of the `Delay first pending entity` option in “Responding to Blockage at the Entity Output Port” on page 2-99.

Responding to Blockage at the Entity Output Port

You can choose how this block responds when the subsequent entity input port is not available to accept the newly generated entity. The responses and corresponding parameters values are in the table.

Response to Blockage	Parameter Values
Error message	Clear the Allow OUT port blocking check box.
The block stores the entity as a pending entity, and immediately discards it. The entity does not depart from the block.	Select Allow OUT port blocking and set Response during blockage period to Discard generated entities
The block stores the entity as a pending entity, and temporarily suspends the generation of additional entities. During this suspension, when the block executes <code>EntityGeneration</code> events, it does not produce new entities. When the subsequent entity input port becomes available, the pending entity departs and the block resumes normal operation.	Select Allow OUT port blocking and set Response during blockage period to Delay first pending entity

Ports

Signal Input Ports

Label	Description
ts	When this signal has an update, the block generates an entity. This signal must be an event-based signal. You see this port only if you set Generate entities upon to <code>Sample time hit</code> from port <code>ts</code> .
tr	When this signal satisfies the specified trigger criteria, the block generates an entity. This signal must be an event-based signal. You see this port only if you set Generate entities upon to <code>Trigger</code> from port <code>tr</code> .
vc	When this signal satisfies the specified value-change criteria, the block generates an entity. This signal must be an event-based signal. You see this port only if you set Generate entities upon to <code>Change in signal</code> from port <code>vc</code> .
fcn	When this signal carries a function call, the block generates an entity. This signal must be an event-based function call. You see this port only if you set Generate entities upon to <code>Function call</code> from port <code>fcn</code> .

Entity Output Ports

Label	Description
OUT	Port through which generated entities depart.

Signal Output Ports

Label	Description	Time of Update When Statistic Is On	Order of Update
#d	Number of entities that have departed from this block since the start of the simulation.	After entity departure	3
pe	A value of 1 indicates that the block stores an entity that has tried and failed to depart. In that case, the entity is a pending entity. A value of 0 indicates that the block does not store any pending entities.	Sample time hit of 1 occurs after the block stores an entity that has tried and failed to depart. Sample time hit of 0 occurs after the departure or discarding of the pending entity.	1
w	Average intergeneration time, in seconds, for all pairs of successive entities that have departed from this block. The signal value is 0 before the second entity departure.	After entity departure	2

The initial output value, which is in effect from the start of the simulation until the first update by the block, is 0 for all signals.

Parameters**Entity Generation Tab****Generate entities upon**

The type of event that indicates when the block can generate an entity.

Trigger type, Type of change in signal value

Trigger type determines whether rising, falling, or either type of trigger edge causes an entity generation. You see this field only if you set **Generate entities upon** to `Trigger` from port `tr`.

Type of change in signal value determines whether rising, falling, or either type of value change causes an entity generation. You see this field only if you set **Generate entities upon** to `Change in signal` from port `vc`.

Specify event priority for entity generation

Select this option to prioritize the entity-generation event explicitly, relative to other simultaneous events in the simulation. If you do not select this option, the event has priority `SYS1` on the event calendar.

Generation event priority

The priority of the entity-generation event, relative to other simultaneous events in the simulation. You see this field only if you select **Resolve simultaneous signal updates according to event priority**.

Allow entity generation upon sample time hit (or function call) at simulation start time

If you select **Allow entity generation upon sample time hit at simulation start time**, the block generates the first entity when the simulation begins. Otherwise, the block generates the first entity upon the first update of the `ts` signal at a nonzero value of time. You see this field only if you set **Generate entities** to `Sample time hit` from port `ts`.

If you select **Allow entity generation upon function call at simulation start time**, the block responds to function calls at the starting time of the simulation. Otherwise, the block responds only to function calls at subsequent times. You see this field only if you set **Generate entities upon** to `Function call` from port `fcn`.

Blocking Tab

Allow OUT port blocking

If you do not select this option and a generated entity cannot depart immediately, the simulation halts with an error message.

Response during blockage period

Determines how the block responds if a generated entity cannot depart immediately; see “Responding to Blockage at the Entity Output Port” on page 2-99. You see this field only if you select **Allow OUT port blocking**.

Entity Type Tab**Entity type**

The blank type includes no attributes. The standard type includes attributes called *Priority* and *Count* with default values of 10 and 0, respectively.

Statistics Tab**Number of entities departed**

Allows you to use the signal output port labeled **#d**.

Pending entity present in block

Allows you to use the signal output port labeled **pe**.

Average intergeneration time

Allows you to use the signal output port labeled **w**.

Entity Sink (Obsolete)

“Generate Entities When Events Occur”

Introduced before R2006a

Event-Based Random Number (Obsolete)

Generate random numbers from specified distribution, parameters, and initial seed

Library

Generators / Signal Generators

Description

This block generates random numbers in an event-based manner, inferring from a subsequent block when to generate a new random number. For example, when connected to the **t** input port of a Single Server block, the Event-Based Random Number block generates a new random number each time an entity arrives at the server.

You specify the distribution from which the block draws random numbers. The seed of the random number generator is reset to the value of the **Initial seed** parameter each time a simulation starts, which makes the random behavior repeatable.

Connecting to Other Blocks

This block has a restricted set of valid connections to other blocks because the Event-Based Random Number block infers from a subsequent block when to generate a new random number.

All indirect connections must be via blocks that have all of the following characteristics:

- Has exactly one input signal
- Has no function-call output signals

Tip For an indirect connection to the Atomic Subsystem block, the restrictions on input and output signals apply to the subsystem itself, not the blocks inside the subsystem.

Distribution Types

The **Distribution** parameter names the type of distribution the block uses to generate random numbers. When you set the **Distribution** parameter, the block changes its dialog box to show additional parameters that determine the probability density function (or probability mass function, for a discrete distribution). The available distributions and the additional parameters for each are described in the sections that follow.

Distribution	Additional Parameters
Exponential	Mean
Uniform	Minimum, Maximum
Bernoulli	Probability of 1
Binomial	Probability of success in a single trial, Number of trials
Triangular	Minimum, Maximum, Mode
Gamma	Threshold, Scale, Shape
Gaussian (normal)	Mean, Standard deviation
Geometric	Probability of success in a single trial
Poisson	Mean
Lognormal	Threshold, Mu, Sigma
Log-logistic	Threshold, Scale
Beta	Minimum, Maximum, Shape parameter a, Shape parameter b
Discrete uniform	Minimum, Maximum, Number of values
Weibull	Threshold, Scale, Shape
Arbitrary continuous	Value vector, Cumulative probability function vector
Arbitrary discrete	Value vector, Probability vector

For information about the definitions and properties of each distribution, see “References” on page 2-113 below.

Range of Output Values

Different distributions have different output ranges. Make sure the distribution and parameters you choose are suitable for your application. For example, when generating random service times, do not use a Gaussian distribution because it can produce negative numbers.

Ports

This block has one signal output port for the random numbers. The initial output value is 0. This value is in effect from the start of the simulation until the first update by the block.

The block has no entity ports, and no signal input port.

Parameters

Distribution

The distribution from which the block generates random numbers.

Mean

The mean value of an exponential, Gaussian, or Poisson distribution.

Minimum

The minimum value of a uniform, triangular, beta, or discrete uniform distribution.

Maximum

The maximum value of a uniform, triangular, beta, or discrete uniform distribution.

Probability for output to be 1

The probability of a one in a Bernoulli distribution.

Probability of success in a single trial

The probability of a successful outcome in each trial used to describe a binomial or geometric distribution.

Number of trials

The number of trials used to describe a binomial distribution.

Mode

The statistical mode of a triangular distribution. The triangular distribution also uses the **Minimum** and **Maximum** parameters to define its density function.

Threshold, Scale, Shape

Parameters that define the density function of a gamma, log-logistic, or Weibull distribution. The log-logistic distribution does not use a **Shape** parameter, however.

Threshold, Mu, Sigma

Parameters that define the density function of a lognormal distribution. The log of a lognormal random variable is normally distributed with mean **Mu** and standard deviation **Sigma**.

Standard deviation

The standard deviation of a Gaussian distribution, which also uses the **Mean** parameter to define its density function.

Shape parameter a, Shape parameter b

The first and second shape parameters, respectively, of a beta distribution. The beta distribution also uses the **Minimum** and **Maximum** parameters to define its density function.

Number of values

The number of possible outputs of a discrete uniform distribution, including the values of the **Minimum** and **Maximum** parameters. **Number of values** must exceed 1.

Value vector

A vector of values in ascending order, representing the possible random values in an arbitrary continuous or arbitrary discrete distribution.

Cumulative probability function vector

A vector of values in ascending order representing the cumulative probability function for an arbitrary continuous distribution. The first and last values of the vector must be 0 and 1, respectively. This parameter and the **Value vector** parameter must have the same vector length.

Probability vector

A vector of values representing the probability of each value in the **Value vector** function for an arbitrary discrete distribution. This vector must contain nonnegative values that sum to 1. This parameter and the **Value vector** parameter must have the same vector length.

Initial seed

A nonnegative integer that initializes the random number generator.

Algorithm

Below are the expressions for f , the probability density functions for the continuous distributions and probability mass functions for the discrete distributions that the block supports.

Exponential Distribution

$$f(x) = \begin{cases} \frac{1}{\mu} \exp\left(-\frac{x}{\mu}\right) & \text{for } x \geq 0 \\ 0 & \text{otherwise} \end{cases}$$

where μ is the **Mean** parameter, a positive number.

A similar function in the Statistics and Machine Learning Toolbox™ software is `exprnd`.

Uniform Distribution

$$f(x) = \begin{cases} \frac{1}{U - L} & \text{for } L \leq x \leq U \\ 0 & \text{otherwise} \end{cases}$$

where L is the **Minimum** parameter and U is the **Maximum** parameter.

Similar functions are `rand` in MATLAB software and `unifrnd` in the Statistics and Machine Learning Toolbox software.

Bernoulli Distribution

$$f(x) = \begin{cases} p^x(1-p)^{1-x} & \text{for } x = 0, 1 \\ 0 & \text{otherwise} \end{cases}$$

where p is the **Probability of 1** parameter. The value p must be between 0 and 1, inclusive. This is a discrete distribution.

This distribution is a special case of the binomial distribution in which the number of trials is 1.

Binomial Distribution

$$f(x) = \begin{cases} \frac{n!}{x!(n-x)!} p^x q^{(n-x)} & \text{for } x = 0, 1, 2, \dots, n \\ 0 & \text{otherwise} \end{cases}$$

where p is the **Probability of success in a single trial** parameter, $q = 1-p$, and n is the **Number of trials** parameter. The value p must be between 0 and 1, inclusive, while n must be positive. This is a discrete distribution.

A similar function in the Statistics and Machine Learning Toolbox software is `binornd`.

Triangular Distribution

$$f(x) = \begin{cases} \frac{2(x-L)}{(U-L)(m-L)} & \text{for } L \leq x \leq m \\ \frac{2(U-x)}{(U-L)(U-m)} & \text{for } m < x \leq U \\ 0 & \text{otherwise} \end{cases}$$

where L is the **Minimum** parameter, U is the **Maximum** parameter, and m is the **Mode** parameter. These parameters must satisfy $L < m < U$.

Gamma Distribution

$$f(x) = \begin{cases} \frac{\left(\frac{x-\theta}{b}\right)^{a-1} \exp\left(-\frac{x-\theta}{b}\right)}{b\Gamma(a)} & \text{for } x \geq \theta \\ 0 & \text{otherwise} \end{cases}$$

where θ is the **Threshold** parameter, b is the **Scale** parameter, and a is the **Shape** parameter. The **Scale** and **Shape** parameters must be positive. Also, Γ is the gamma function (gamma in MATLAB code).

A similar function in the Statistics and Machine Learning Toolbox software is `gamrnd`.

Gaussian (Normal) Distribution

$$f(x) = \frac{\exp\left(-\frac{(x-\mu)^2}{2\sigma^2}\right)}{\sigma\sqrt{2\pi}}$$

where μ is the **Mean** parameter and σ is the **Standard deviation** parameter. The standard deviation parameter must be nonnegative.

Similar functions are `randn` in MATLAB software and `normrnd` in the Statistics and Machine Learning Toolbox software.

Geometric Distribution

If the **Probability of success in a single trial** parameter is strictly between 0 and 1, then the probability mass function is defined by

$$f(x) = \begin{cases} pq^x & \text{for } x = 0, 1, 2, \dots \\ 0 & \text{otherwise} \end{cases}$$

where p is the **Probability of success in a single trial** parameter and $q = 1-p$.

In the special case where the **Probability of success in a single trial** parameter is 1, then

$$f(x) = \begin{cases} 1 & \text{for } x = 0 \\ 0 & \text{otherwise} \end{cases}$$

This is a discrete distribution.

A similar function in the Statistics and Machine Learning Toolbox software is `geornd`.

Poisson Distribution

$$f(x) = \begin{cases} \frac{e^{-\lambda}\lambda^x}{x!} & \text{for } x = 0, 1, 2, \dots \\ 0 & \text{otherwise} \end{cases}$$

where λ is the **Mean** parameter, a positive number. This is a discrete distribution.

A similar function in the Statistics and Machine Learning Toolbox software is `poissrnd`.

Lognormal Distribution

$$f(x) = \begin{cases} \frac{\exp\left[\frac{-(\ln(x-\theta)-\mu)^2}{2\sigma^2}\right]}{(x-\theta)\sigma\sqrt{2\pi}} & \text{for } x \geq \theta \\ 0 & \text{otherwise} \end{cases}$$

where θ is the **Threshold** parameter, μ is the **Mu** parameter, and σ is the **Sigma** parameter. The **Sigma** parameter must be positive.

A similar function in the Statistics and Machine Learning Toolbox software is `lognrnd`.

Log-Logistic Distribution

The log-logistic distribution is derived from the logistic distribution, as follows:

X = Random variable with logistic distribution

$Y = e^X$ = Random variable with log-logistic distribution

The probability density function for the logistic distribution is

$$f_{\text{logistic}}(x) = \frac{1}{b} \cdot \frac{e^{(x-\theta)/b}}{\left(1 + e^{(x-\theta)/b}\right)^2}$$

where θ is the **Threshold** parameter and b is the **Scale** parameter. The **Scale** parameter must be positive.

Beta Distribution

$$f(x) = \begin{cases} \frac{(x-L)^{a-1}(U-x)^{b-1}}{B(a,b)(U-L)^{a+b-1}} & \text{for } L \leq x \leq U \\ 0 & \text{otherwise} \end{cases}$$

where L is the **Minimum** parameter, M is the **Maximum** parameter, a is the **Shape parameter a** parameter, b is the **Shape parameter b** parameter, and $B(a,b)$ is the beta function defined by

$$B(a,b) = \int_0^1 t^{a-1}(1-t)^{b-1} dt$$

The two shape parameters must be positive.

A similar function in the Statistics and Machine Learning Toolbox software is `betarnd`.

Discrete Uniform Distribution

$$f(x) = \begin{cases} 1/K & \text{for } x = L + k \frac{(U-L)}{K-1}, k = 0, 1, 2, \dots, K-1 \\ 0 & \text{otherwise} \end{cases}$$

where L is the **Minimum** parameter, U is the **Maximum** parameter, and K is the **Number of values** parameter. This is a discrete distribution. If $(U-L)/(K-1)$ and L are both integers, then all outputs from this distribution are integers.

Similar functions are `randi` in MATLAB software and `unidrnd` in the Statistics and Machine Learning Toolbox software.

Weibull Distribution

$$f(x) = \begin{cases} \frac{\gamma}{\alpha} \left(\frac{x-\theta}{\alpha} \right)^{(\gamma-1)} \exp \left[- \left(\frac{x-\theta}{\alpha} \right)^\gamma \right] & \text{for } x \geq \theta \\ 0 & \text{otherwise} \end{cases}$$

where θ is the **Threshold** parameter, α is the **Scale** parameter, and γ is the **Shape** parameter. The **Scale** and **Shape** parameters must be positive.

A similar function in the Statistics and Machine Learning Toolbox software is `wblrnd`.

Event-Based Sequence (Obsolete)

Generate sequence of numbers from specified column vector

Library

Generators / Signal Generators

Description

This block generates an event-based signal using data you provide, inferring from a subsequent block when to output the next value from your data. You specify the data as a column vector using the **Vector of output values** parameter. The parameter value can be any MATLAB language expression that evaluates to a column vector, including the name of a column vector variable in the MATLAB base workspace. As an example of inferring timing from a subsequent block, if you connect this block to the **t** input port of a Single Server block, then the Event-Based Sequence block outputs a new value each time an entity arrives at the server.

Behavior After Data Runs Out

If the block needs more data than the vector contains, subsequent output values follow a rule you specify using the **Form output after final data value by** parameter. The table below lists possible values for this parameter.

Note In all cases, the choice of parameter value affects only the values, not the timing, of the output signal. The output signal is always an event-based signal whose sample time hits depend on notifications from a subsequent block.

Parameter Value	Description
Cyclic repetition	When the block needs a new output value after exhausting the data, it starts over at the beginning of the vector.
Holding final value	After exhausting the data, the block outputs the last data value for every sample time hit.
Setting to infinity	After exhausting the data, the block outputs the value <code>inf</code> for every sample time hit. For example, if the block outputs intergeneration times for an entity generator, then the generator produces up to a fixed number of entities.
Setting to zero	After exhausting the data, the block outputs zero for every sample time hit. For example, if the block outputs service times for a server, then the server delays up to a fixed number of entities.

Connecting to Other Blocks

This block has a restricted set of valid connections to other blocks because the Event-Based Sequence block infers from a subsequent block when to generate a new random number.

All indirect connections must be via blocks that have all of the following characteristics:

- Has exactly one input signal
- Has no function-call output signals

Tip For an indirect connection to the Atomic Subsystem block, the restrictions on input and output signals apply to the subsystem itself, not the blocks inside the subsystem.

Ports

This block has one signal output port for the numbers in the sequence. The initial output value is 0. This value is in effect from the start of the simulation until the first update by the block.

The block has no entity ports, and no signal input port.

Parameters

Vector of output values

A column vector whose entries become values of this block's output signal. To use a column vector variable in the MATLAB base workspace, enter the variable name.

Form output after final data value by

The method for generating output after the block exhausts the data referenced in the **Vector of output values** parameter.

Event-Based Random Number (Obsolete), Repeating Sequence Stair, From Workspace

Introduced in R2006b

Event Filter (Obsolete)

Conditionalize, suppress, or prioritize execution of Atomic Subsystem

Library

SimEvents Ports and Subsystems

Description

This block influences an Atomic Subsystem block by specifying the signal-based events upon which the subsystem executes. This block can also prioritize the execution of a subsystem with regard to other events occurring simultaneously by scheduling a subsystem execution on the event calendar. Consider an event-based signal that is an input to an Atomic Subsystem block. Without the Event Filter block, every sample time hit of the signal causes the subsystem to execute immediately. Inserting the Event Filter block on that signal line enables you to influence the subsystem behavior as follows:

- Specify the type of signal-based event that causes the subsystem to execute. Choices are:
 - Sample time hit
 - Change in signal value (rising, falling, or either)
 - Trigger (rising, falling, or either)

If the input signal of this block is a nonscalar array, the block detects one qualifying event if any of the positions in the array has a qualifying event. For example, a change in signal value from [1 2 3] to [1 5 6] represents one qualifying event, not two. If N distinct qualifying events occur at distinct sample time hits in the input signal of this block, the subsystem executes times and updates its output signals N times.

- Prevent the input signal of this block from causing the subsystem to execute. In this case, the signal passively provides data to the subsystem. The subsystem can still execute based on signal-based events of a different input signal.
- Prioritize the subsystem execution, relative to other simultaneous events in the simulation. Instead of occurring immediately upon a signal-based event, the execution becomes a scheduled event on the event calendar.

Connecting to Other Blocks

The output port of this block can connect to only one input port of an Atomic Subsystem block. The connection line cannot branch.

Behavior During Simulation

When the input signal of an Event Filter block has a sample time hit, it does the following:

- 1 Updates its output signal with the value of the input signal. This value is available to the Atomic Subsystem block to which the Event Filter block connects.
- 2 Determines whether to execute the Atomic Subsystem block, based on the settings in the block dialog box of the Event Filter block. If the Event Filter block is not supposed to execute the Atomic Subsystem block, the Event Filter does nothing further, until the next sample time hit of the input signal. Otherwise, processing continues to the next step.
- 3 Determines when to execute the Atomic Subsystem block.
 - If you did not select the **Resolve simultaneous signal updates according to event priority** option, the Event Filter block executes the Atomic Subsystem block immediately.
 - If you select the **Resolve simultaneous signal updates according to event priority** option, the Event Filter block schedules an event on the event calendar. The event time is the current simulation time. The event priority is the value of the **Event priority** parameter in the Event Filter block. When the event calendar executes this event, the Atomic Subsystem block performs its computation.
 - If you select both the **Resolve simultaneous signal updates according to event priority** option, and the configuration parameter **Prevent duplicate events on multiport blocks and branched signals**, the software uses the

Event priority parameter to help Simulink to sort blocks in the model. In this case, the software no longer schedules an event on the event calendar.

Ports

Signal Input Ports

Label	Description
None	Event-based signal. The signal can have any fixed dimension or complexity. It has data type double.

Signal Output Ports

Label	Description
None	Event-based signal whose value matches that of the input signal. This output signal connects to an input port of an Atomic Subsystem block. When the Event Filter block detects a qualifying signal-based event in its input signal, the subsystem executes immediately or the block schedules an execution event on the event calendar. (Block parameters determine the type of event that qualifies and the choice of immediate or scheduled execution.)

The initial output value is the same as that of the input signal. This value is in effect before the first sample time hit of the input signal.

Parameters

Execute atomic subsystem

Determines what constitutes a qualifying event in the input signal of this block. If the signal is complex, you must select `Upon sample time hit` or `Never`.

Trigger type

The type of trigger that further restricts the event type specified in **Execute atomic subsystem**. You see this field only if you set **Execute atomic subsystem** to `Upon trigger`.

Type of change in signal value

The type of change in the signal value that further restricts the event type specified in **Execute atomic subsystem**. You see this field only if you set **Execute atomic subsystem** to `Upon change in signal`.

Resolve simultaneous signal updates according to event priority

Select this option to control the sequencing of the subsystem execution in response to updates in the input signal of this block, relative to other simultaneous events in the simulation. If you do not select this option, the application executes the subsystem immediately upon detecting the signal-based event.

Event priority

The priority of the subsystem execution event (in response to updates in the input signal of this block), relative to other simultaneous events in the simulation.

Use of this parameter depends on the following:

- You see this field only if you select **Resolve simultaneous signal updates according to event priority**.
- If you also select the configuration parameter **Prevent duplicate events on multiport blocks and branched signals** in your model, the software uses the **Event priority** parameter to help Simulink to sort blocks in the model. In this case, the software does not schedule an event that you can view on the SimEvents event calendar.

Introduced in R2011b

Event to Timed Signal (Obsolete)

Convert event-based signal to time-based signal

Library

Gateways

Description

This block converts an event-based data signal into a time-based data signal. The output signal assumes exactly one value at any given time on the simulation clock. The output signal is almost identical to the input signal, except:

- The output signal omits zero-duration values, if any, from the input signal.
- The output signal has a sample time type of “fixed in minor step.” As a result, the output signal might have sample time hits at times unrelated to the input signal but related to other time-based signals in the model.
- The output signal is suitable for modeling time-based dynamics. The signal cannot be an input to a block that requires an event-based input signal. Blocks that can process either time-based or event-based signals might process them differently.
- The initial output value is the same as the initial input value. However, if the input signal is undefined at $T = 0$, as in the case of an atomic subsystem that has an event-based input signal, the output signal of this block has an initial output of 0.

Ports

Signal Input Ports

Label	Description
None	Event-based signal. The signal can have any fixed dimension, complexity, or data type.

Signal Output Ports

Label	Description
None	Time-based signal

Timed to Event Function-Call (Obsolete)

“Time-Based Signals and SimEvents Block Transitions”

Introduced in R2011b

FIFO Queue (Obsolete)

Store entities in sequence for undetermined length of time

Library

Queues

Description

This block stores up to N entities simultaneously, where N is the **Capacity** parameter value. The block attempts to output an entity through the **OUT** port, but retains the entity if the **OUT** port is blocked. If the block is storing multiple entities and no entity times out, then entities depart in a first-in, first-out (FIFO) fashion. If an entity in this block is scheduled to time out, then it might depart prematurely via the optional **TO** port. The length of time that an entity stays in this block cannot be determined in advance.

The **IN** port is unavailable whenever this block stores exactly N entities. In this case, the queue is said to be full.

Ports

Entity Input Ports

Label	Description
IN	Port for arriving entities, which are stored.

Entity Output Ports

Label	Description
OUT	Port for departing entities that do not time out while in this block.
TO	Port for entities that time out while in this block. You see this port only if you select Enable TO port for timed-out entities . This port must not be blocked when an entity attempts to depart here.

Signal Output Ports

Label	Description	Time of Update When Statistic Is On	Order of Update When Entity Departs
#d	Number of entities that have departed from this block via the OUT port since the start of the simulation.	After entity departure via the OUT port	3
#n	Number of entities currently in the queue.	After entity arrival and after entity departure	2
w	Sample mean of the waiting times in this block for all entities that have departed via any port.	After entity departure	1
len	Average number of entities in the queue over time, that is, the time average of the #n signal.	After entity arrival and after entity departure.	1
#to	Number of entities that have timed out from this block since the start of the simulation.	After entity departure via the TO port	3

Output signals having the same number in the Order of Update column in the table above are updated in an arbitrary sequence relative to each other; you should not rely on a specific sequence for your simulation results.

The initial output value, which is in effect from the start of the simulation until the first update by the block, is 0 for all signals.

Parameters

FIFO Queue Tab

Capacity

Determines how many entities the block can store at a time. The capacity must be a positive integer or `Inf`.

Timeout Tab

Enable TO port for timed-out entities

This option becomes relevant if an entity times out while in this block. Selecting this option provides a **TO** entity output port through which the timed-out entity departs. If you clear this option in a model that uses timeouts, see the **If entity has no destination when timeout occurs** parameter of the Schedule Timeout (Obsolete) block.

Statistics Tab

These parameters determine whether the block produces data at signal output ports or omits those ports. For descriptions of the data and ports, see the preceding table, “Signal Output Ports”.

Number of entities departed

Allows you to use the signal output port labeled **#d**.

Number of entities in queue

Allows you to use the signal output port labeled **#n**.

Average wait

Allows you to use the signal output port labeled **w**.

Average queue length

Allows you to use the signal output port labeled **len**.

Number of entities timed out

Allows you to use the signal output port labeled **#to**.

Introduced before R2006a

Get Attribute (Obsolete)

Output value of entity attribute

Library

Attributes

Description

This block outputs signals using data from entity attributes. For each arriving entity, the block updates the signal at the signal output ports using values from attributes named in the block dialog box. The block also outputs the entity unchanged.

Parameters

Get Attribute Tab

Use the **Available Attributes** controls to:

- Select the attributes from incoming entity paths that you want to access.
- Add the attributes to the **Get Attribute** table, where you can modify them.

The list displays all the attributes on all the incoming entities. (If the entity paths entering the Get Attribute block do not have any attributes, the **Available Attributes** list is empty).

If the attribute list is long, you can type the attribute name in the text box to filter the list.

Use the buttons in the **Available Attributes** section to help build the attributes table. The buttons perform these actions:

Button	Action
	Refresh the Available Attributes list. This action updates the list with any upstream model changes you make while the block dialog box is open.
	Add the selected attribute to the Get Attribute table.
	Move the selected attribute from the Get Attribute table to the Available Attributes list. Note: If the selected attribute is one you added manually, this button appears dimmed.

The message area below the available attributes list displays additional messages about the attributes, as they apply.

Message	Meaning
> Attribute already selected	You have already added the attribute to the Get Attribute table. You cannot add the attribute to the table again.
* Attribute may not be present	When multiple entity paths enter the block, all entities might not have the same attributes. Attributes that are not on all entering entities display an asterisk in the list, and this message appears. If you add such an attribute to the Get Attribute table, the behavior depends on how the If Missing field is set.

Use the controls under **Get Attribute** to build and manage the list of attributes to access on each incoming entity. Each attribute appears as a row in a table.

Using these controls, you can:

- Specify an attribute manually to access on the entity.
- Modify an attribute that you added to the table from the **Available Attributes** list to access on the entity.

The buttons under **Get Attribute** perform these actions:

Button	Action	Notes
	Add a template attribute to the table.	Rename the attribute and specify its properties.
	Add a copy of the selected attribute to the table to use as the basis of a new attribute.	Rename the copy. Two attributes cannot have the same name.
	Remove the selected attribute from the Get Attribute table.	When you delete an attribute this way, no confirmation appears and you cannot undo the operation.

Note If you delete a row and apply the change, the deletion can affect signal output ports corresponding to other attributes. For example, if the block has a signal output port **A2** and you delete the attribute with a port marked **A1**, the block relabels **A2** as **A1**. Verify that any signal that connects to the relabeled port is still connected as you expect.

The table displays the attributes you added from the **Available Attributes** list or added manually. Use it to set these four attribute properties:

Property	Specify	Use
Attribute Name	<p>The name of the attribute to access. Each attribute must have a unique name.</p> <p>If the attribute name does not match an attribute listed in Available Attributes, the block displays ?? next to the attribute name. This symbol denotes that the attribute is not present on incoming entity paths. The simulation behavior you see depends on the value of If Missing (see “Missing Attributes” on page 2-133).</p>	<p>Double-click the existing name, and then type the new name.</p>
If Missing	<p>The response of the block when the entity does not have an attribute named in the table.</p>	<p>Select a block response from the list.</p>
Default Value	<p>The value for the corresponding output signal if the entity does not have an attribute specified in the table. To learn about the kind of data you can use as a default value, see “Attribute Value Support”. You can set this field only if you set If Missing to <code>Default value or Warn</code>.</p>	<p>Double-click the field and type a value.</p>

Property	Specify	Use
Vector Is 1-D	Whether the block considers the default value as a vector of length N when Default Value evaluates to an N-element row or column vector. Otherwise, the block considers the default value as a multidimensional array. This option affects attributes whose If Missing parameter is set to <code>Default value</code> or <code>Warn</code> .	Select the check box to treat the attribute as a vector of length N. Clear it to treat the attribute as a multidimensional array.

Missing Attributes

You can specify the block behavior if the arriving entity does not have an attribute listed in the table of the block dialog box. Use the **If Missing** parameter for that attribute.

Parameter Value	Block Behavior in Case of Missing Attribute
Error	The block issues an error message and halts simulation. In this case, the Default Value and Treat Vector as 1-D parameters are disabled.
Default value	The block outputs a default value that you specify using the Default Value and Treat Vector as 1-D parameters. The simulation proceeds.
Warn	The block outputs a default value that you specify using the Default Value and Treat Vector as 1-D parameters. The block also issues a warning in the MATLAB Command Window. The simulation proceeds.

Statistics Tab

These parameters determine whether the block produces data at signal output ports or omits those ports. For descriptions of the data and ports, see Signal Output Ports.

Number of entities departed

Allows you to use the signal output port labeled **#d**.

Ports

Entity Input Ports

Label	Description
IN	Port for arriving entities

Entity Output Ports

Label	Description
OUT	Port for departing entities

Signal Output Ports

Label	Description	Time of Update When Statistic Is On
#d	Number of entities that have departed from this block since the start of the simulation.	After entity departure
<i>Attribute name</i>	Value of the attribute of the same name specified in the table. The default Name that corresponds to each row is Attributex , where x = 1, 2, 3, etc.	After entity departure

The initial output value, which is in effect from the start of the simulation until the first update by the block, is 0 for all signals.

Set Attribute (Obsolete)

“Manipulate Entity Attributes”

Introduced before R2006a

Infinite Server (Obsolete)

Delay any number of entities for period of time

Library

Servers

Description

This block serves any number of entities for a period of time, called the service time, and then attempts to output them through the **OUT** port. If the **OUT** port is blocked, then the block holds the entities until the port becomes unblocked. If an entity in this block is scheduled to time out, then it might depart prematurely via the optional **TO** port.

An infinite server is like an infinite set of single servers connected in parallel, followed by a path combiner; the path combiner notifies entities of an unblocked path in the sequence in which the entities completed their service time, until one entity departs.

You specify the service time, which is the duration of service, via a parameter, attribute, or signal, depending on the **Service time from** parameter value. The block determines the service time for an entity upon its arrival. Service times are assumed to be specified in seconds.

Note If you specify the service time via an event-based signal, be sure that its updates occur before the entity arrives.

The **IN** port of an infinite server is always available. You can interpret an infinite server as a mechanism for delaying entities. Some discussions of this block suggest this interpretation by using the word delay instead of serve.

Ports

Entity Input Ports

Label	Description
IN	Port for arriving entities, which will be served.

Signal Input Ports

Label	Description
t	Service time, in seconds, for a newly arrived entity. This signal must be an event-based signal. You see this port only if you set Service time from to Signal port t.

Entity Output Ports

Label	Description
OUT	Port for departing entities that have completed their service time and have not timed out while in this block.
TO	Port for entities that time out while in this block. You see this port only if you select Enable TO port for timed-out entities . This port must not be blocked when an entity attempts to depart here.

Signal Output Ports

Label	Description	Time of Update When Statistic Is On	Order of Update When Entity Departs
#d	Number of entities that have departed from this block via the OUT port since the start of the simulation.	After entity departure via the OUT port	5
#n	Number of entities in the block.	After entity arrival and after entity departure	4
pe	A value of 1 indicates that the block stores at least one entity that has tried and failed to depart. Such entities are pending entities. A value of 0 indicates that the block does not store any pending entities.	After the block stores an entity that has tried and failed to depart. In this case, the signal value is 1. After the departure of a pending entity. In this case, the signal value depends on whether any other pending entities remain in the block.	1
#pe	Number of pending entities in the block.	After the block stores an entity that has tried and failed to depart. After the departure of a pending entity.	3
w	Sample mean of the waiting times in this block for all entities that have departed via any port. An entity's waiting time might exceed its service time if the OUT port is blocked when the entity completes service.	After entity departure	2
#to	Number of entities that have timed out from this block since the start of the simulation.	After entity departure via the TO port	5

Output signals having the same number in the Order of Update column in the table above are updated in an arbitrary sequence relative to each other; you should not rely on a specific sequence for your simulation results.

The initial output value, which is in effect from the start of the simulation until the first update by the block, is 0 for all signals.

Parameters

Infinite Server Tab

Service time from

Determines whether the service time is computed from a parameter in this dialog box, a signal input port, or an attribute of the entity being served.

Service time

The service time, in seconds, for all entities. You see this field only if you set **Service time from** to *Dialog*.

Attribute name

The name of the attribute whose value the block uses as the service time for an entity. You see this field only if you set **Service time from** to *Attribute*.

Service completion event priority

The priority of the service completion event, relative to other simultaneous events in the simulation.

Timeout Tab

Enable TO port for timed-out entities

This option becomes relevant if an entity times out while in this block. Selecting this option provides a **TO** entity output port through which the timed-out entity departs. If you clear this option in a model that uses timeouts, see the **If entity has no destination when timeout occurs** parameter of the Schedule Timeout (Obsolete) block.

Statistics Tab

These parameters determine whether the block produces data at signal output ports or omits those ports.

Number of entities departed

Allows you to use the signal output port labeled **#d**.

Number of entities in block

Allows you to use the signal output port labeled **#n**.

Pending entity present in block

Allows you to use the signal output port labeled **pe**.

Number of pending entities

Allows you to use the signal output port labeled **#pe**.

Average wait

Allows you to use the signal output port labeled **w**.

Number of entities timed out

Allows you to use the signal output port labeled **#to**.

Single Server (Obsolete), N-Server (Obsolete)

“Write Events Actions”

Introduced before R2006a

Initial Value (Obsolete)

Output specified value until first sample time hit

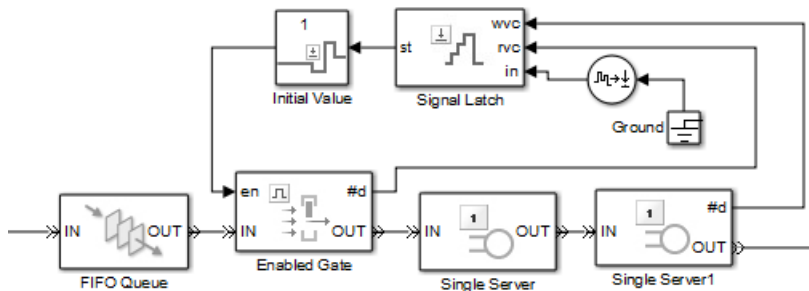

Library

Signal Management

Description

This block establishes an initial value for an event-based signal. Before the first sample time hit at the input port, the value of the output signal is the **Value until first sample time hit** parameter value. Starting from the first sample time hit, the output signal is identical to the input signal.

The following model fragment illustrates block usage in a feedback loop. When the simulation starts, the Initial Value block provides an initial value of 1 that opens the gate to permit the first entity to advance into the feedback loop. Without a nonzero initial value, no entity would arrive at the servers and the Signal Latch block would never experience any events.

Note The IC block in the Simulink library set operates in a time-based manner and is not suitable for event-based signals.

Ports

Signal Input Ports

Label	Description
None	The first sample time hit in this signal causes the block to stop using the initial value from the block dialog box. From then on, the output signal is identical to the input signal. This signal must be an event-based signal.

Signal Output Ports

Label	Description
None	The value is either the initial value in the block dialog box or the input signal value, depending on whether the input signal has had a sample time hit yet during the simulation.

The initial output value is the value of the **Value until first sample time hit** parameter. This value is in effect strictly before the first sample time hit of the input signal.

Parameters

Value until first sample time hit

The value to output before the first sample time hit of the input signal. The value of this parameter must have the same dimensions, data type, and complexity as the input signal.

Input Switch (Obsolete)

Accept entities from selected entity input port

Library

Routing

Description

Note This page is the block reference page for the Input Switch block introduced before R2016a. To see the documentation on the new Input Switch block, see Entity Input Switch.

This block selects exactly one entity input port for potential arrivals. The selected entity input port can change during the simulation. When one entity input port becomes selected, all others become unavailable.

The rules the block uses for selecting an entity input port are listed in the table.

Switching criterion Value	Description
Round robin	At the beginning of the simulation, IN1 is selected. After each departure, the block selects the entity input port next to the last selected port. After exhausting all entity input ports, the block returns to the first one, IN1 .
Equiprobable	At the beginning of the simulation and after each departure, the block randomly chooses which entity input port is selected for the next arrival. All entity input ports are equally likely. The Initial seed parameter initializes the random number generation process.

Switching criterion Value	Description
From signal port p	Selecting this option creates an additional signal input port, labeled p . The signal at this port must have integer values between 1 and the Number of entity input ports parameter value. The block detects changes in this integer value and selects the corresponding entity input port for future arriving entities.

Tip If multiple entity input ports of the Input Switch block are on entity paths that come from a single block having multiple entity output ports, include a storage block in each path.

For example, instead of connecting two entity output ports of an Entity Splitter block directly to two entity input ports of an Input Switch block, insert a storage block in each of the two paths.

Ports

Entity Input Ports

Label	Description
IN1, IN2, IN3, and so on	Ports for potential entity arrivals. At any given time, one input port is selected and the others are unavailable. The Number of entity input ports parameter determines how many of these entity input ports the block has.

Signal Input Ports

Label	Description
p	Index of the entity input port that is available. Values are 1, 2, 3,..., Number of entity input ports . This signal must be an event-based signal. You see this port only if you set Switching criterion to From signal port p.

Entity Output Ports

Label	Description
OUT	Port for departing entities.

Signal Output Ports

Label	Description	Time of Update When Statistic Is On	Order of Update
#d	Number of entities that have departed from this block since the start of the simulation	After entity departure	2
last	Index of the input port that was available the last time an entity departed. The initial value is 0. After an entity has departed, values are 1, 2, 3,..., Number of entity input ports .	After entity departure	1

The initial output value, which is in effect from the start of the simulation until the first update by the block, is 0 for all signals.

Parameters

Input Switch Tab

Number of entity input ports

Determines how many entity input ports the block has.

Switching criterion

The rule that determines which entity input port is selected for receiving entities.

Initial seed

A nonnegative integer that initializes the random number generator used to select an entity input port. You see this field only if you set **Switching criterion** to Equiprobable.

Resolve simultaneous signal updates according to event priority

Select this option to prioritize the port-selection event explicitly, relative to other simultaneous events in the simulation. If you do not select this option, the event has priority SYS1 on the event calendar. You see this field only if you set **Switching criterion** to From signal port p.

Event priority

The priority of the port-selection event, relative to other simultaneous events in the simulation. You see this field only if you set **Switching criterion** to `From signal port p` and select **Resolve simultaneous signal updates according to event priority**.

Statistics Tab

These parameters determine whether the block produces data at signal output ports or omits those ports. For descriptions of the data and ports, see the preceding table, “Signal Output Ports”.

Number of entities departed

Allows you to use the signal output port labeled **#d**.

Last entity arrival port

Allows you to use the signal output port labeled **last**.

Instantaneous Entity Counting Scope (Obsolete)

Plot entity count versus time

Library

SimEvents Sinks

Description

This block creates a plot by counting arriving entities at each arrival time. The block restarts the count from 1 when the time changes. As a result, the count is cumulative for a given time instant but not cumulative across the entire simulation.

Note If you want to plot the total number of arriving entities across the entire simulation, connect the **#d** signal of the Entity Departure Counter (Obsolete) block to the Signal Scope (Obsolete) block.

Use the **Enable entity OUT port** option to choose whether the entity advances to a subsequent block or whether the block absorbs the arriving entity.

Ports

Entity Input Ports

Label	Description
IN	Port for arriving entities, which the block counts.

Entity Output Ports

Label	Description
OUT	Port for departing entities. You see this port only if you select Enable entity OUT port .

Parameters

Plotting Tab

Enable entity OUT port

Causes the block to have an entity output port labeled **OUT**, through which the arriving entity departs. If you clear this box, the block absorbs arriving entities.

Open scope at start of simulation

Selecting this option causes the plot window to open when you start the simulation. If you clear this box, you can open the plot window by double-clicking the block icon.

Axes Tab

Initial X axis lower limit, Initial X axis upper limit

The interval shown on the X axis at the beginning of the simulation. The interval might change from this initial setting due to zooming, autoscaling, or the **If X value is beyond limit** setting.

If X value is beyond limit

Determines how the plot changes if one or more X values are not within the limits shown on the X axis.

Initial Y axis lower limit, Initial Y axis upper limit

The interval shown on the Y axis at the beginning of the simulation. The interval might change from this initial setting due to zooming, autoscaling, or the **If Y value is beyond limit** setting.

If Y value is beyond limit

Determines how the plot changes if one or more entity counts are not within the limits shown on the Y axis.

Show grid

Toggles the grid on and off.

Figure Tab

Title

Text that appears as the title of the plot, above the axes.

Y label

Text that appears to the left of the vertical axis.

X label

Text that appears below the horizontal axis.

Position

A four-element vector of the form `[left bottom width height]` specifying the position of the scope window. (0,0) is the lower left corner of the display.

Show number of entities

Displays the number of plotted points using an annotation in the plot window.

Data History Tab

Store data when scope is closed

Select `Unlimited` to have the block cache all data for future viewing, `Limited` to cache a portion of the most recent data, and `Disabled` to avoid caching undisplayed data.

Limit data points to

The number of data points the block caches, using the most recent data. You see this field only if you set **Store data when scope is closed** to `Limited`.

See Also

Entity Departure Counter (Obsolete), Instantaneous Event Counting Scope (Obsolete)

“Count Entities”

Introduced before R2006a

Instantaneous Event Counting Scope (Obsolete)

Plot event count versus time

Library

SimEvents Sinks

Description

This block creates a plot by counting events. The block restarts the count from 1 when the time changes. As a result, the count is cumulative for a given time instant but not cumulative across the entire simulation.

When the block has a **ts** input port and the input signal is an event-based signal, a stem with no marker represents the initial output of the signal.

Ports

Signal Input Ports

Label	Description
ts	When this signal has an update, the counter increments. This signal must be an event-based signal. You see this port only if you set Plot points upon to <code>Sample time hit</code> from port <code>ts</code> .
tr	When this signal satisfies the specified trigger criteria, the counter increments. This signal must be an event-based signal. You see this port only if you set Plot points upon to <code>Trigger</code> from port <code>tr</code> .
vc	When this signal satisfies the specified value-change criteria, the counter increments. This signal must be an event-based signal. You see this port only if you set Plot points upon to <code>Change in signal</code> from port <code>vc</code> .
fcn	When this signal carries a function call, the counter increments. This signal must be an event-based function call. You see this port only if you set Plot points upon to <code>Function call</code> from port <code>fcn</code> .

Parameters

Plotting Tab

Plot points upon

The type of event that indicates when the block increments its counter.

Trigger type, Type of change in signal value

Trigger type determines whether rising, falling, or either type of trigger edge causes the block to increment its counter. You see this field only if you set **Plot points upon** to `Trigger` from port `tr`.

Type of change in signal value determines whether rising, falling, or either type of value change causes the block to increment its counter. You see this field only if you set **Plot points upon** to `Change in signal` from port `vc`.

Open scope at start of simulation

Selecting this option causes the plot window to open when you start the simulation. If you clear this box, you can open the plot window by double-clicking the block icon.

Axes Tab

Initial X axis lower limit, Initial X axis upper limit

The interval shown on the X axis at the beginning of the simulation. The interval might change from this initial setting due to zooming, autoscaling, or the **If X value is beyond limit** setting.

If X value is beyond limit

Determines how the plot changes if one or more X values are not within the limits shown on the X axis.

Initial Y axis lower limit, Initial Y axis upper limit

The interval shown on the Y axis at the beginning of the simulation. The interval might change from this initial setting due to zooming, autoscaling, or the **If Y value is beyond limit** setting.

If Y value is beyond limit

Determines how the plot changes if one or more event counts are not within the limits shown on the Y axis.

Show grid

Toggles the grid on and off.

Figure Tab

Title

Text that appears as the title of the plot, above the axes.

Y label

Text that appears to the left of the vertical axis.

X label

Text that appears below the horizontal axis.

Position

A four-element vector of the form `[left bottom width height]` specifying the position of the scope window. (0,0) is the lower left corner of the display.

Show number of points

Displays the number of plotted points using an annotation in the plot window.

Data History Tab

Store data when scope is closed

Select `Unlimited` to have the block cache all data for future viewing, `Limited` to cache a portion of the most recent data, and `Disabled` to avoid caching undisplayed data.

Limit data points to

The number of data points the block caches, using the most recent data. You see this field only if you set **Store data when scope is closed** to `Limited`.

See Also

Signal Scope (Obsolete), Instantaneous Entity Counting Scope (Obsolete)

Introduced before R2006a

LIFO Queue (Obsolete)

Store entities in stack for undetermined length of time

Library

Queues

Description

This block stores up to N entities simultaneously, where N is the **Capacity** parameter value. The block attempts to output an entity through the **OUT** port but retains the entity if the **OUT** port is blocked. If the block is storing multiple entities and no entity times out, then entities depart in a last-in, first-out (LIFO) fashion. If an entity in this block is scheduled to time out, then it might depart prematurely via the optional **TO** port. The length of time that an entity stays in this block cannot be determined in advance.

The **IN** port is unavailable whenever this block stores exactly N entities. In this case, the queue is said to be full.

Ports

Entity Input Ports

Label	Description
IN	Port for arriving entities, which will be stored.

Entity Output Ports

Label	Description
OUT	Port for departing entities that do not time out while in this block.
TO	Port for entities that time out while in this block. You see this port only if you select Enable TO port for timed-out entities . This port must not be blocked when an entity attempts to depart here.

Signal Output Ports

Label	Description	Time of Update When Statistic Is On	Order of Update When Entity Departs
#d	Number of entities that have departed from this block via the OUT port since the start of the simulation.	After entity departure via the OUT port	3
#n	Number of entities currently in the queue.	After entity arrival and after entity departure	2
w	Sample mean of the waiting times in this block for all entities that have departed via any port.	After entity departure	1
len	Average number of entities in the queue over time, that is, the time average of the #n signal.	After entity arrival and after entity departure.	1
#to	Number of entities that have timed out from this block since the start of the simulation.	After entity departure via the TO port	3

Output signals having the same number in the Order of Update column in the table above are updated in an arbitrary sequence relative to each other; you should not rely on a specific sequence for your simulation results.

The initial output value, which is in effect from the start of the simulation until the first update by the block, is 0 for all signals.

Parameters

LIFO Queue Tab

Capacity

Determines how many entities the block can store at a time. The capacity must be a positive integer or `Inf`.

Timeout Tab

Enable **TO** port for timed-out entities

This option becomes relevant if an entity times out while in this block. Selecting this option provides a **TO** entity output port through which the timed-out entity departs. If you clear this option in a model that uses timeouts, see the **If entity has no destination when timeout occurs** parameter of the Schedule Timeout (Obsolete) block.

Statistics Tab

These parameters determine whether the block produces data at signal output ports or omits those ports. For descriptions of the data and ports, see the preceding table, “Signal Output Ports”.

Number of entities departed

Allows you to use the signal output port labeled **#d**.

Number of entities in queue

Allows you to use the signal output port labeled **#n**.

Average wait

Allows you to use the signal output port labeled **w**.

Average queue length

Allows you to use the signal output port labeled **len**.

Number of entities timed out

Allows you to use the signal output port labeled **#to**.

Sequence Viewer

Display message or events between blocks during simulation

Library

Stateflow, SimEvents, Simulink Test™

Description

The Sequence Viewer block displays messages or events between certain blocks during simulation. The blocks that you can display messages and events for are called lifeline blocks and include:

- Subsystems
- Stateflow charts
- Blocks that contain messages, for example, Stateflow charts.

Parameters

History

Specify maximum number of events to keep in viewer.

Default: 5000

See Also

Topics

“Work with Sequence Viewer” (Stateflow)

“Work with Sequence Viewer”

Introduced in R2015b

N-Server (Obsolete)

Serve up to N entities for period of time

Library

Servers

Description

This block stores up to N entities, serving each one independently for a period of time and then attempting to output the entity through the **OUT** port. If the **OUT** port is blocked, then the entity stays in this block until the port becomes unblocked. If an entity in this block is scheduled to time out, then it might depart prematurely via the optional **TO** port.

An N-server is like a set of N single servers connected in parallel, followed by a path combiner; the path combiner notifies entities of an unblocked path in the sequence in which the entities completed their service time, until one entity departs.

You specify the service time, which is the duration of service, via a parameter, attribute, or signal, depending on the **Service time from** parameter value. The block determines the service time for an entity upon its arrival. Service times are assumed to be specified in seconds.

Note If you specify the service time via an event-based signal, be sure that its updates occur before the entity arrives.

All entities that arrive do so via the **IN** port. The **IN** port is unavailable whenever this block contains N entities. In that case, the **IN** port becomes available when at least one of the N entities departs.

Ports

Entity Input Ports

Port Label	Description
IN	Port for arriving entities, which will be served.

Signal Input Ports

Port Label	Description
t	Service time, in seconds, for a newly arrived entity. This signal must be an event-based signal. You see this port only if you set Service time from to Signal port t.
pause	Port for input signal that disables all servers when the signal is positive. While the servers are disabled, any occupied servers retain their entities and the software pauses the remaining service time for each server. When the signal at the input port becomes nonpositive, each server resumes service. You see this port only if you select Allow service control and set Service change upon disabling to Pause.
complete	<p>Port for input signal that disables all servers when the signal is positive.</p> <p>When a positive signal enters the complete port, the software:</p> <ul style="list-style-type: none"> • Disables all servers. • Immediately completes service in all occupied servers. • Resets the remaining service time in all servers. <p>If no blockage exists at the entity output port of the N-Server block, entities immediately advance from occupied servers to downstream blocks. When the signal at the input port becomes nonpositive, normal behavior of the N-Server block resumes.</p> <p>You see this port only if you select Allow service control and set Service change upon disabling to Force complete.</p>

Entity Output Ports

Port Label	Description
OUT	Port for departing entities that have completed their service time and have not timed out while in this block.
TO	Port for entities that time out while in this block. You see this port only if you select Enable TO port for timed-out entities . This port must not be blocked when an entity attempts to depart here.

Signal Output Ports

Port Label	Description	Time of Update When Statistic Is On	Order of Update When Entity Departs
#d	Number of entities that have departed from this block via the OUT port since the start of the simulation.	After entity departure via the OUT port	5
#n	Number of entities currently in the block, between 0 and N.	After entity arrival and after entity departure	4
pe	<p>A value of 1 indicates that the block stores at least one entity that has tried and failed to depart. Such entities are pending entities.</p> <p>A value of 0 indicates that the block does not store any pending entities.</p>	<p>After the block stores an entity that has tried and failed to depart. In this case, the signal value is 1.</p> <p>After the departure of a pending entity. In this case, the signal value depends on whether any other pending entities remain in the block.</p>	1
#pe	Number of pending entities in the block.	<p>After the block stores an entity that has tried and failed to depart.</p> <p>After the departure of a pending entity.</p>	3
w	Sample mean of the waiting times in this block for all entities that have departed via any port. An entity's waiting time might exceed its service time if the OUT port is blocked when the entity completes service.	After entity departure	2

Port Label	Description	Time of Update When Statistic Is On	Order of Update When Entity Departs
util	Utilization of the N-server. If Number of servers is finite, util is the time average of the fraction of servers that are storing an entity. At time values when an entity arrives or departs, util equals 1/N times the time average of the #n signal. If Number of servers is infinite, then util is always zero.	Performance considerations cause the block to update the signal only after each arrival or departure of an entity.	2
#to	Number of entities that have timed out from this block since the start of the simulation.	After entity departure via the TO port	5
so	Occupancy status of each server in the N-Server block. The so port outputs a vector of values. If a server is unoccupied, the value of the corresponding vector element is 0 . If a server is occupied, the vector element has a value of 1 .	After entity arrival and after entity departure	6

Output signals having the same number in the Order of Update column in the table above are updated in an arbitrary sequence relative to each other; you should not rely on a specific sequence for your simulation results.

The initial output value, which is in effect from the start of the simulation until the first update by the block, is 0 for all signals.

A more precise definition of the utilization signal **util** at an update time $T > 0$ is

$$\frac{1}{T} \sum_k \left(\frac{(\#n)_k}{N} \right) \cdot \text{length}(I_k)$$

where I_k is the k th time interval between successive pairs of times that **util** is updated and $(\#n)_k$ is the number of entities the N-Server block is storing during the open interval I_k . If an update of **util** occurs at $T=0$, the value is $\#n/N$.

Parameters

N-Server Tab

Number of servers

The number of servers the block represents, N.

Service time from

Determines whether the service time is computed from a parameter in this dialog box, an input signal, or an attribute of the entity being served.

Service time

The service time, in seconds, for all entities. You see this field only if you set **Service time from** to `Dialog`.

Attribute name

The name of the attribute whose value the block uses as the service time for an entity. You see this field only if you set **Service time from** to `Attribute`.

Service completion event priority

The priority of the service completion event, relative to other simultaneous events in the simulation.

Service control Tab

Allow service control

Adds an input signal port to the block. When you input a positive signal to this added signal port, the software disables servers in the block and applies a service change. You specify the service change action using an option that becomes visible when you select **Allow service control**.

Service change upon disabling

Specifies the service change action that the software applies to disabled servers. You see this option only if you select **Allow service control**.

By default, **Service change upon disabling** is set to `Pause`. When `Pause` is selected, the signal input port added by **Allow service control** is labeled **pause**. When you input a positive signal to the **pause** port, the software disables all servers in the block. While this input signal remains positive, any occupied servers retain their entities and the software pauses the remaining service time for each server. When the signal at the input port becomes nonpositive, each server resumes service.

You can also set **Service change upon disabling** to `Force complete`. In this case, when you click **OK**, the label of the signal input port added by **Allow service control** changes to **complete**.

When a positive signal enters the **complete** port, the software:

- Disables all servers.
- Immediately completes service in all occupied servers.
- Resets the remaining service time in all servers.

If no blockage exists at the entity output port of the N-Server block, entities immediately advance from occupied servers to downstream blocks. When the signal at the input port becomes nonpositive, normal behavior of the N-Server block resumes.

For an example of using the **complete** port, see “Task Preemption in a Multitasking Processor”.

Block entity entry to disabled servers

Determines whether unoccupied servers can accept entities while the signal at the **pause** or **complete** port is positive.

Control event priority

The priority of the service control event, relative to other simultaneous events in the simulation.

Timeout Tab

Enable TO port for timed-out entities

This option becomes relevant if an entity times out while in this block. Selecting this option provides a **TO** entity output port through which the timed-out entity departs.

If you clear this option in a model that uses timeouts, see the **If entity has no destination when timeout occurs** parameter of the Schedule Timeout (Obsolete) block.

Statistics Tab

These parameters determine whether the block produces data at signal output ports or omits those ports. For descriptions of the data and ports, see the preceding table, “Signal Output Ports”.

Number of entities departed

Allows you to use the signal output port labeled **#d**.

Number of entities in block

Allows you to use the signal output port labeled **#n**.

Pending entity present in block

Allows you to use the signal output port labeled **pe**.

Number of pending entities

Allows you to use the signal output port labeled **#pe**.

Average wait

Allows you to use the signal output port labeled **w**.

Utilization

Allows you to use the signal output port labeled **util**.

Number of entities timed out

Allows you to use the signal output port labeled **#to**.

Server occupancy, so

Allows you to use the signal output port labeled **so**.

Output Switch (Obsolete)

Select entity output port for departure

Library

Routing

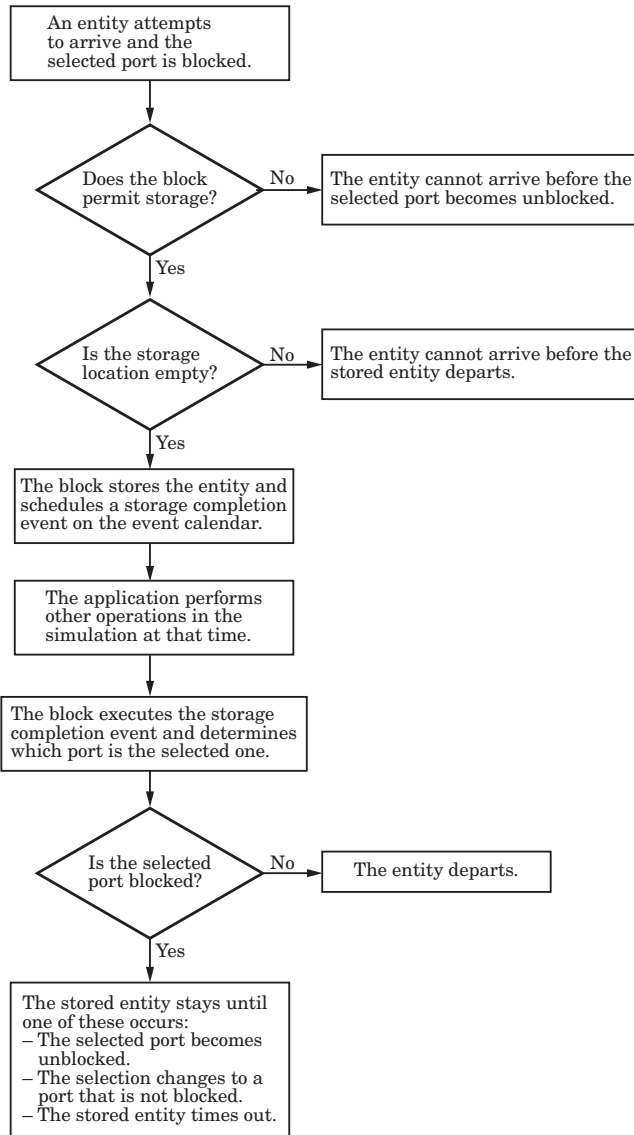

Description

Note This page is the block reference page for the Output Switch block introduced before R2016a. To see the documentation for the new Output Switch block, see Entity Output Switch.

This block receives entities, which depart through one of multiple entity output ports. The selected port can change during the simulation.

Managing Arrivals and Departures

When the selected port is not blocked, an arriving entity departs through that port. When an entity attempts to arrive and the selected port is blocked, the block's behavior depends on the block's configuration and state, as illustrated in the figure.

Note This block permits storage only if you set **Switching criterion** to From signal port *p*, and then select **Store entity before switching**.

Entities that time out depart via the block's **TO** port.

Switching Criteria

The **Switching criterion** parameter indicates how the block determines which entity output port is selected for departure at any given time. The values of the **Switching criterion** parameter are described in the table below.

Switching criterion Value	Description
Round robin	The first arriving entity in the simulation departs via the OUT1 port. Upon each subsequent arrival, the block selects the entity output port next to the last selected port. After exhausting all entity output ports, the block returns to the first one, OUT1 .
Equiprobable	At the beginning of the simulation and upon each departure, the block randomly chooses the entity output port through which the next arriving entity departs. All entity output ports are equally likely to be selected. The Initial seed parameter initializes the random number generation process.
First port that is not blocked	When an entity attempts to arrive, the block attempts to output the entity through OUT1 . If that port is blocked, then the block attempts to output the entity through OUT2 , and so on. If all entity output ports are blocked, then this block's IN port is unavailable and the entity cannot arrive.
From signal port p	Selecting this option creates an additional signal input port, labeled p . The signal at this port uses integer values between 1 and the Number of entity output ports parameter value to refer to entity output ports. The block monitors the p signal's value throughout the simulation and reacts to changes by selecting the corresponding entity output port.

Switching criterion Value	Description
From attribute	An arriving entity departs through the entity output port that corresponds to the value of an attribute of your choice. Name the attribute using the Attribute name parameter. The attribute value must be an integer between 1 and the Number of entity output ports parameter value. If the indicated entity output port is blocked, then this block does not accept the entity for arrival until the entity output port becomes unblocked.

Note If you set **Switching criterion** to From signal port *p*, then the block offers several options to help you ensure that the signal is up to date and valid when the block uses it to determine how to process the arriving entity. Be especially careful when the signal is in a feedback loop, or when the signal can change at the same time an entity arrives. For details, see “Use Messages To Route Entities”.

Ports

Entity Input Ports

Label	Description
IN	Port for arriving entities.

Signal Input Ports

Label	Description
<i>p</i>	Index of the entity output port through which an arriving entity departs. Values must be integers between 1 and Number of entity output ports . This signal must be an event-based signal. You see this port only if you set Switching criterion to From signal port <i>p</i> .

Entity Output Ports

Label	Description
OUT1 , OUT2 , OUT3 , and so on	Entity ports through which an arriving entity departs, where the Switching criterion parameter determines which of multiple ports the entity departs through. The Number of entity output ports parameter determines how many of these entity output ports the block has.
TO	Port for entities that time out while in this block. You see this port only if you set Switching criterion to From signal port p, select Store entity before switching , and select Enable TO port for timed-out entities . This port must not be blocked when an entity attempts to depart here.

Signal Output Ports

Label	Description	Time of Update When Statistic Is On	Order of Update
#d	Number of entities that have departed from this block without timing out, since the start of the simulation.	After entity departure via a port other than TO	3
#to	Number of entities that have timed out from this block since the start of the simulation.	After entity departure via the TO port	2
pe	A value of 1 indicates that the block stores an entity that has tried and failed to depart. In that case, the entity is a pending entity. A value of 0 indicates that the block does not store any pending entities.	Sample time hit of 1 occurs after the block stores an entity that has tried and failed to depart. Sample time hit of 0 occurs after the departure of the pending entity via any port.	1
last	Index of the output port through which the last entity departed, excluding timed-out entities. Aside from the initial output, values of this signal are 1, 2, 3,..., Number of entity output ports .	After entity departure via a port other than TO	2

The initial output value, which is in effect from the start of the simulation until the first update by the block, is 0 for all signals.

Parameters

Output Switch Tab

Number of entity output ports

Determines how many entity output ports the block has.

Switching criterion

The rule that determines which entity output port an arriving entity departs through.

Initial seed

A nonnegative integer that initializes the random number generator used to select an entity output port. You see this field only if you set **Switching criterion** to Equiprobable.

Specify initial port selection

Select this option to indicate the initially selected entity output port. For details, see “Specify an Initial Port Selection”. You see this field only if you set **Switching criterion** to From signal port *p*.

Initial port selection

The entity output port that the block selects when the simulation begins. The value must be an integer between 1 and **Number of entity output ports**. The block uses **Initial port selection** instead of the *p* signal's value until the signal has its first sample time hit. You see this field only if you set **Switching criterion** to From signal port *p* and select **Specify initial port selection**.

Store entity before switching

If you select this option, the block can store one entity at a time. Furthermore, the block decouples its arrival and departure processing to give other blocks in the simulation an opportunity to update the *p* signal if appropriate. If you do not select this option, the block processes an arrival and departure as an atomic operation and assumes that the *p* signal is already up to date at the given time. You see this field only if you set **Switching criterion** to From signal port *p*.

Resolve simultaneous signal updates according to event priority

Select this option to prioritize the port-selection event explicitly, relative to other simultaneous events in the simulation. If you do not select this option, the event has priority `SYS1` on the event calendar. You see this field only if you set **Switching criterion** to `From signal port p` and do not select **Store entity before switching**.

Event priority

The priority of the port-selection event, relative to other simultaneous events in the simulation. **Switching criterion** to `From signal port p`, do not select **Store entity before switching**, and select **Resolve simultaneous signal updates according to event priority**.

Attribute name

The name of an attribute used to select an entity output port. You see this field only if you set **Switching criterion** to `From attribute`.

Timeout Tab

Enable TO port for timed-out entities

This option is available only if you set **Switching criterion** to `From signal port p`, and then select **Store entity before switching** on the **Output Switch** tab of the dialog box. This option becomes relevant if an entity times out while in this block. Selecting this option provides a **TO** entity output port through which the timed-out entity departs. If you clear this option in a model that uses timeouts, see the description of the **If entity has no destination when timeout occurs** parameter on the Schedule Timeout (Obsolete) block reference page.

Statistics Tab

These parameters determine whether the block produces data at signal output ports or omits those ports. For descriptions of the data and ports, see the preceding table, “Signal Output Ports”.

Number of entities departed

Allows you to use the signal output port labeled **#d**.

Number of entities timed out

Allows you to use the signal output port labeled **#to**.

Pending entity present in block, pe

Allows you to use the signal output port labeled **pe**. You can select this check box only if you set **Switching criterion** to `From signal port p`, and then select **Store entity before switching** on the **Output Switch** tab of the dialog box.

Last entity departure port

Allows you to use the signal output port labeled **last**.

See Also

Input Switch (Obsolete)

“Use Messages To Route Entities”

Introduced before R2006a

Path Combiner (Obsolete)

Merge entity paths

Library

Routing

Description

This block accepts entities through any entity input port and outputs them through a single entity output port. You specify the number of entity input ports using the **Number of entity input ports** parameter.

If multiple entities arrive at the Path Combiner block simultaneously while the entity output port is not blocked, then the sequence in which the entities depart depends on the sequence of departure events from blocks that precede the Path Combiner block. Even if the departure time is the same for multiple entities, the sequence might affect the system's behavior. For example, if the entities advance to a queue, the departure sequence determines their positions in the queue.

Multiple instances of entities of the same type, but with different attributes, can arrive at the Path Combiner block. In these situations, the compiled entity type displays the union type.

Input Port Precedence

The **Input port precedence** parameter indicates how the block determines which entity input port to notify first, whenever the entity output port changes its status from blocked to unblocked. The first notified port is the first port to become available to an arriving entity. Choices for the **Input port precedence** parameter are described in the following table.

Input Port Precedence	Action when Entity Output Port Becomes Unblocked	Example for Block with Four Entity Input Ports
IN1 port	Notify entity input ports IN1, IN2, IN3 ,... until either an entity arrives or all ports are notified.	Throughout the simulation, the sequence of notifications is always IN1, IN2, IN3, IN4 .
Equiprobable	Notify a random entity input port. All are equally likely and the Initial seed parameter initializes the random number generator. If this does not result in an entity arrival, notify the subsequent ports in turn until either an entity arrives or all ports are notified.	If the random number is three, notify the ports in the sequence IN3, IN4, IN1, IN2 . If the random number is two on the next such occasion, notify the ports in the sequence IN2, IN3, IN4, IN1 .
Round robin	Notify the port next to the one through which the last departing entity arrived. The IN1 port is considered “next to” the last entity input port on the block. If this does not result in an entity arrival, notify the subsequent ports in turn until either an entity arrives or all ports are notified.	An entity arrives through the IN2 port and advances to a Single Server block. Meanwhile, entities attempt to arrive at the Path Combiner block. When the server becomes available, the Path Combiner block notifies the ports in the sequence IN3, IN4, IN1, IN2 . The sequence starts with IN3 because it is next to IN2 , which is the port through which the last departing entity arrived.
From signal port p	Notify the port whose index is the value of the p input signal. If this does not result in an entity arrival, notify the subsequent ports in turn until either an entity arrives or all ports are notified.	If the value of the p signal is three, notify the ports in the sequence IN3, IN4, IN1, IN2 . If p is two on the next such occasion, notify the ports in the sequence IN2, IN3, IN4, IN1 .

Ports

Entity Input Ports

Label	Description
IN1, IN2, IN3 , and so on	Port for arriving entities. The Number of entity input ports parameter determines how many of these entity input ports the block has.

Signal Input Ports

Label	Description
p	Index of the entity input port that the block makes available first, upon an event that changes the entity output port from blocked to unblocked. Values are 1, 2, 3,..., Number of entity input ports . This signal must be an event-based signal. You see this port only if you set Input port precedence to From signal port p.

Entity Output Ports

Label	Description
OUT	Port for departing entities.

Signal Output Ports

Label	Description	Time of Update When Statistic Is On	Order of Update
#d	Number of entities that have departed from this block since the start of the simulation.	After entity departure	2
last	Index of the input port through which the last entity arrived. The initial value is 0. After an entity has arrived and departed, values are 1, 2, 3,..., Number of entity input ports .	After entity departure	1

The initial output value, which is in effect from the start of the simulation until the first update by the block, is 0 for all signals.

Parameters

Path Combiner Tab

Number of entity input ports

Determines how many entity input ports the block has.

Status Notification Tab

Input port precedence

Determines which entity input port the block makes available first, upon an event that changes the entity output port from blocked to unblocked.

Initial seed

A nonnegative integer that initializes the random number generator used to select an entity input port for first notification about status changes. You see this field only if you set **Input port precedence** to Equiprobable.

Resolve simultaneous signal updates according to event priority

Select this option to prioritize the event that updates the port precedence explicitly, relative to other simultaneous events in the simulation. If you do not select this option, the event has priority `SYS1` on the event calendar. You see this field only if you set **Switching criterion** to From signal port `p`.

Event priority

The priority of the event that updates the port precedence, relative to other simultaneous events in the simulation. **Switching criterion** to From signal port `p` and select **Resolve simultaneous signal updates according to event priority**.

Statistics Tab

These parameters determine whether the block produces data at signal output ports or omits those ports. For descriptions of the data and ports, see the preceding table, “Signal Output Ports”.

Number of entities departed

Allows you to use the signal output port labeled **#d**.

Last entity arrival port

Allows you to use the signal output port labeled **last**.

Input Switch (Obsolete), Output Switch (Obsolete)

Introduced before R2006a

Priority Queue (Obsolete)

Store entities in sorted sequence for undetermined length of time

Library

Queues

Description

This block stores up to N entities simultaneously in a sorted sequence, where N is the **Capacity** parameter value. The queue sorts entities according to the values of an attribute, in either ascending or descending order. Use the **Sorting attribute name** and **Sorting direction** parameters to determine the sorting behavior. The block accepts real numbers, Inf , and $-Inf$ as valid values of the sorting attribute.

The block attempts to output an entity through the **OUT** port but retains the entity if the **OUT** port is blocked. If an entity in this block is scheduled to time out, then it might depart prematurely via the optional **TO** port. The length of time that an entity stays in this block cannot be determined in advance. The **IN** port is unavailable whenever this block stores exactly N entities. In this case, the queue is said to be full.

While you can view the value of the sorting attribute as an entity priority, this value has nothing to do with event priorities or block priorities.

Ports

Entity Input Ports

Label	Description
IN	Port for arriving entities, which will be stored.

Entity Output Ports

Label	Description
OUT	Port for departing entities that do not time out while in this block.
TO	Port for entities that time out while in this block. You see this port only if you select Enable TO port for timed-out entities . This port must not be blocked when an entity attempts to depart here.

Signal Output Ports

Label	Description	Time of Update When Statistic Is On	Order of Update When Entity Departs
#d	Number of entities that have departed from this block via the OUT port since the start of the simulation.	After entity departure via the OUT port	3
#n	Number of entities currently in the queue.	After entity arrival and after entity departure	2
w	Sample mean of the waiting times in this block for all entities that have departed via any port.	After entity departure	1
len	Average number of entities in the queue over time, that is, the time average of the #n signal.	After entity arrival and after entity departure.	1
#to	Number of entities that have timed out from this block since the start of the simulation.	After entity departure via the TO port	3

Output signals having the same number in the Order of Update column in the table above are updated in an arbitrary sequence relative to each other; you should not rely on a specific sequence for your simulation results.

The initial output value, which is in effect from the start of the simulation until the first update by the block, is 0 for all signals.

Parameters

Priority Queue Tab

Capacity

Determines how many entities the block can store at a time. The capacity must be a positive integer or *Inf*.

Sorting attribute name

The block uses this attribute to sort entities in the queue.

Sorting direction

Determines whether the entity at the head of the queue is the one with the smallest (*Ascending*) or largest (*Descending*) value of the attribute named above. Entities sharing the same attribute value are sorted in FIFO sequence.

Timeout Tab

Enable TO port for timed-out entities

This option becomes relevant if an entity times out while in this block. Selecting this option provides a **TO** entity output port through which the timed-out entity departs. If you clear this option in a model that uses timeouts, see the **If entity has no destination when timeout occurs** parameter of the Schedule Timeout (Obsolete) block.

Statistics Tab

These parameters determine whether certain ports produce data throughout the simulation, produce data only when you stop or pause the simulation, or are omitted from the block. For descriptions of the affected ports, see the preceding table, “Signal Output Ports”.

Number of entities departed

Allows you to use the signal output port labeled **#d**.

Number of entities in queue

Allows you to use the signal output port labeled **#n**.

Average wait

Allows you to use the signal output port labeled **w**.

Average queue length

Allows you to use the signal output port labeled **len**.

Number of entities timed out

Allows you to use the signal output port labeled **#to**.

Examples

- “Serve Preferred Customers First”

Introduced before R2006a

Read Timer (Obsolete)

Report statistical data about named timer associated with arriving entities

Library

Timing

Description

This block reads the value of a timer that the Start Timer (Obsolete) block previously associated with the arriving entity. Using the **Report elapsed time** and **Report average elapsed time** parameters, you can configure the block to report the following statistics via the **et** and **w** signal output ports, respectively:

- The instantaneous value from the named timer associated with the arriving entity
- The average of **et** values among all entities that have arrived at this block during the simulation and possessed a timer of the specified name

Note If the arriving entity does not possess a timer of that name, then you can configure the block to either produce an error or ignore the timer's absence. In the latter case, the output signals maintain their previous values.

The timer continues timing after the entity departs from this block, which is relevant if the same entity arrives at another Read Timer block later in the simulation.

Ports

Entity Input Ports

Label	Description
IN	Port for arriving entities.

Entity Output Ports

Label	Description
OUT	Port for departing entities.

Signal Output Ports

Label	Description	Time of Update When Statistic Is On	Order of Update
#d	Number of entities that have departed from this block since the start of the simulation.	After entity departure	3
#t	Total number of entities that have departed from this block and possessed a timer of the specified name.	After entity departure	2
et	Instantaneous elapsed time for the arriving entity, if it possesses a timer of the specified name.	After entity departure	2
w	Average among the et values for all entities that have arrived at this block and possessed a timer of the specified name.	After entity departure	1

Output signals having the same number in the Order of Update column in the table above are updated in an arbitrary sequence relative to each other; you should not rely on a specific sequence for your simulation results.

The initial output value, which is in effect from the start of the simulation until the first update by the block, is 0 for all signals.

Parameters

Read Timer Tab

Timer tag

Name of the timer to read. This timer tag corresponds to the **Timer tag** parameter of a Start Timer block in the model.

If entity does not have tagged timer

Behavior of the block if an arriving entity does not possess a timer with the specified timer tag.

Statistics Tab

These parameters determine whether the block produces data at signal output ports or omits those ports.

Number of entities departed

Allows you to use the signal output port labeled **#d**.

Number of entities departed with specified tag

Allows you to use the signal output port labeled **#t**. If you set **If entity does not have tagged timer** to `Ignore`, then the **#t** value might be less than the **#d** value.

Elapsed time

Allows you to use the signal output port labeled **et**.

Average elapsed time

Allows you to use the signal output port labeled **w**.

See Also

Start Timer (Obsolete)

Introduced before R2006a

Release Gate (Obsolete)

Allow one pending entity to arrive when event occurs

Library

Gates

Description

This block permits the arrival of one pending entity when a signal-based event or function call occurs; at all other times, the entity input port of the block is unavailable. By definition, the opening of the gate permits one pending entity to arrive if the entity is able to advance immediately to the next block.

No simulation time passes between the opening and subsequent closing of the gate. The gate opens and then closes in the same time instant. If no entity is already pending when the gate opens, then the gate closes without processing any entities.

The **Open gate upon** parameter determines the type of event that opens the gate:

- Sample time hits of a signal
- Edges in a trigger signal
- Changes in the numerical value of a signal
- Function calls

Ports

Entity Input Ports

Label	Description
IN	Port for arriving entities.

Signal Input Ports

Label	Description
ts	When this signal has an update, the gate opens. This signal must be an event-based signal. You see this port only if you set Open gate upon to Sample time hit from port ts.
tr	When this signal satisfies the specified trigger criteria, the gate opens. This signal must be an event-based signal. You see this port only if you set Open gate upon to Trigger from port tr.
vc	When this signal satisfies the specified value-change criteria, the gate opens. This signal must be an event-based signal. You see this port only if you set Open gate upon to Change in signal from port vc.
fcn	When this signal carries a function call, the gate opens. This signal must be an event-based function call. You see this port only if you set Open gate upon to Function call from port fcn.

Entity Output Ports

Label	Description
OUT	Port for departing entities.

Signal Output Ports

Label	Description	Time of Update When Statistic Is On
#d	Number of entities that have departed from this block since the start of the simulation.	After entity departure

The initial output value is 0. This value is in effect from the start of the simulation until the first update by the block.

Parameters

Release Gate Tab

Open gate upon

Determines the type of event that causes the gate to open instantaneously.

Trigger type, Type of change in signal value

Trigger type determines whether rising, falling, or either type of trigger edge causes the gate to open. You see this field only if you set **Open gate upon** to `Trigger from port tr`.

Type of change in signal value determines whether rising, falling, or either type of value change causes the gate to open. You see this field only if you set **Open gate upon** to `Change in signal from port vc`.

Resolve simultaneous signal updates according to event priority

Select this option to prioritize the gate-opening event explicitly, relative to other simultaneous events in the simulation. If you do not select this option, the event has priority `SYS1` on the event calendar.

Event priority

The priority of the gate-opening event, relative to other simultaneous events in the simulation. You see this field only if you select **Resolve simultaneous signal updates according to event priority**.

Statistics Tab

These parameters determine whether the block produces data at signal output ports or omits those ports.

Number of entities departed

Allows you to use the signal output port labeled **#d**.

See Also

Enabled Gate (Obsolete)

Introduced before R2006a

Replicate (Obsolete)

Output copies of entity

Library

Routing

Description

This block outputs a copy of the arriving entity through each entity output port that is not blocked. You specify the number of copies that the block makes, using the **Number of entity output ports** parameter.

When the block replicates an entity that is subject to a timeout, all departing entities share the same expiration time; that is, the timeout events corresponding to all departing entities share the same scheduled event time. Logistically, the block cancels the timeout event of the arriving entity and schedules new timeout events for the departing entities.

Complete or Partial Replication

The **Replicate entity when** parameter affects the circumstances under which the block accepts an entity to replicate. Choices are in the table below.

Parameter Value	Description
All entity output ports are not blocked	The block accepts an entity to replicate only when all entity output ports are connected to available ports of subsequent blocks.

Parameter Value	Description
Any entity output port is not blocked	The block accepts an entity to replicate when at least one entity output port is connected to an available port of a subsequent block.

If you connect multiple copies of this block, you can implement logical combinations of the parameter values in the table.

Departure of Copies

Each time the block replicates an entity, the copies depart in a sequence whose start is determined by the **Departure port precedence** parameter. Choices are in the table below.

Parameter Value	Description	Example
OUT1 port	Each time the block replicates an entity, the copies depart via entity output ports OUT1 , OUT2 , OUT3 ,..., in that sequence.	The sequence of departures is always OUT1 , OUT2 , OUT3 ,... throughout the simulation.
Round robin	Each time the block replicates an entity, the first copy departs via the port after the one that received preference on the last such occasion. The remaining copies depart via the subsequent ports in turn.	On a block with three entity output ports, the first time the block replicates an entity, the copies depart in the sequence OUT1 , OUT2 , OUT3 . The second time, the copies depart in the sequence OUT2 , OUT3 , OUT1 . The third time, the copies depart in the sequence OUT3 , OUT1 , OUT2 . The fourth time is analogous to the first time, and so on.

Parameter Value	Description	Example
Equiprobable	Each time the block replicates an entity, the first copy departs via a randomly selected entity output port. All entity output ports are equally likely to be selected and the Initial seed parameter initializes the random number generation process. The remaining copies depart via the subsequent ports in turn.	On a block with four entity output ports, if the random number is three, then the copies depart in the sequence OUT3, OUT4, OUT1, OUT2 . If the random number is two on the next such occasion, then the copies depart in the sequence OUT2, OUT3, OUT4, OUT1 .

An example in which the choice of **Departure port precedence** parameter is relevant is a model that sets an attribute on each replicated entity based on its departure port and then advances all replicated entities along a merged path to a FIFO Queue block. At each replication occurrence during the simulation, the **Departure port precedence** parameter determines the sequence of the replicated entities in the queue.

In some cases, a departure through one entity output port causes another entity output port to become newly blocked. For example, this could happen if two entity output ports connect to a Path Combiner block, which in turn connects to a Single Server block whose service time is nonzero. Use the **If an output port becomes blocked during replication** parameter to determine how the block responds. Choices are in the table below.

Parameter Value	Description
Discard entity	The block discards the entity that is supposed to depart through the newly blocked entity output port.
Warn and discard entity	The block issues a warning message in the MATLAB Command Window, and discards the entity that is supposed to depart through the newly blocked entity output port.
Error	The simulation halts with an error message.

Ports

Entity Input Ports

Label	Description
IN	Port for arriving entities.

Entity Output Ports

Label	Description
OUT1, OUT2, OUT3, and so on	Port for departing entities, which are copies of the arriving entity. The Number of entity output ports parameter determines how many of these entity input ports the block has.

Signal Output Ports

Label	Description	Time of Update When Statistic Is On	Order of Update
#a	Number of entities that have arrived at this block since the start of the simulation.	After entity arrival	1
#d	Number of entities that have departed from this block since the start of the simulation.	After each entity departure	2

The initial output value, which is in effect from the start of the simulation until the first update by the block, is 0 for all signals.

Parameters

Replicate Tab

Number of entity output ports

Determines how many entity output ports the block has; that is, the maximum number of copies the block makes for each arriving entity.

Replicate entity when

Determines whether the block is available to arriving entities whenever at least one entity output port is not blocked, or only when all entity output ports are not blocked.

Departure port precedence

Determines the start of the sequence in which the block outputs the copies, each time the block replicates an entity.

Initial seed

A nonnegative integer that initializes the random number generator used to determine the output sequence. You see this field only if you set **Departure port precedence** to Equiprobable.

If an output port becomes blocked during replication

Determines whether the block issues a message when a replicated entity is unable to depart because an output port becomes blocked during the replication process. You see this field only if you set **Replicate entity when** to All entity output ports are not blocked.

Statistics Tab

These parameters determine whether the block produces data at signal output ports or omits those ports. For descriptions of the data and ports, see the preceding table, “Signal Output Ports”.

Number of entities arrived

Allows you to use the signal output port labeled **#a**.

Number of entities departed

Allows you to use the signal output port labeled **#d**.

Event-Based Entity Generator (Obsolete), Path Combiner (Obsolete)

“Replicate Entities on Multiple Paths”

Introduced before R2006a

Resource Acquire (Obsolete)

Acquire resource

Library

Entity Management

Description

This block accepts an entity that requests the use of resources, assigns resources to it, and then outputs it.

You can specify the resource types and amounts for the entity. The block stores the assigned resource with the entity, where each resource has a name and a value.

You can optionally specify a timeout that limits the maximum duration an entity waits for resources. You can also prioritize how resources are granted.

Ports

Entity Input Ports

Label	Description
IN	Port for arriving entities.

Entity Output Ports

Label	Description
OUT	Port for departing entities that have acquired resources.

Signal Output Ports

Label	Description	Time of Update When Statistic Is On	Order of Update When Entity Departs
#d	Number of entities that have departed from this block since the start of the simulation or since the last reset.	After entity departure	3
#n	Number of entities currently in the block, between 0 and <i>N</i> .	After entity arrival and after entity departure	2
w	Sample mean of the waiting times in this block for all entities that have departed via any port. If the OUT port is blocked when the entity completes service, an entity waiting time exceeds its service time.	After entity departure	1
#to	Number of entities that have timed out from this block since the start of the simulation.	After entity departure via the TO port	3

Parameters

Main Tab

Maximum number of waiting entities

Enter maximum number of entities that can wait for a resource.

Acquisition priority

Enter priority number for resource acquisition. This number prioritizes the Resource Acquire block that has higher priority in a model that has multiple Resource Acquire blocks. A smaller numeric value indicates higher priority.

Use the **Available Resources** controls to.

- Select the resources from the resources defined in all the Resource Pool blocks in the model.
- Add the resources to the Selected Resources table, where you can configure resource acquisition details.

The list displays all the available resources in the model. (If there are no resources, the **Available Attributes** list is empty.)

If the resource list is long, you can type the resource name in the text box to filter the list.

Use the buttons in the **Available Resources** section to help build the resources table. The buttons perform these actions:

Button	Action
	Refresh the Available Resources list. The list updates with any upstream model changes you make while the block dialog box is open.
	Add the selected resources to the Selected Resources table.
	Move the selected resource from the Selected Resources table to the Available Resources list. Note: If the selected resource is one you added manually, this button appears dimmed.

The message area below the available resources list displays additional messages about the resources, as they apply.

Message	Meaning
> Resource already selected	You have already added the resource to the Selected Resources table. You cannot add the resource to the table again.

Use the controls under **Selected Resources** to build and manage the list of resources to attach to the entity. Each resource appears as a row in a table.

Using these controls, you can:

- Add a resource manually.
- Modify a resource that you added to the table from the **Available Resources** list to attach to the entity.

The buttons under **Selected Resources** perform these actions:

Button	Action	Notes
	Add a template resource to the table.	Rename the resource and specify its properties.
	Add a copy of the selected resource to the table to use as the basis of a new resource.	Rename the copy. Two resources cannot have the same name.
	Remove the selected resource from the Selected Resources table.	When you delete a resource this way, no confirmation appears and you cannot undo the operation.
	Move the selected resource up in order in the Selected Resources table.	NA
	Move the selected resource down in order in the Selected Resources table.	NA

Note If you delete a row and apply the change, the deletion can affect signal output ports corresponding to other attributes. For example, if the block has a signal output port **A2** and you delete the attribute with a port marked **A1**, the block relabels **A2** as **A1**. Verify that any signal that connects to the relabeled port is still connected as you expect.

Property	Specify	Use
Name	The name of the resource. Each resource must have a unique name.	Double-click the existing name, and then type the new name.

Property	Specify	Use
Amount Source	Whether the resource amount, that an entity requests, comes from the dialog box or an attribute.	Select Dialog or Attribute . If you select Attribute , the source of the resource amount comes from the attribute of the entity. This option allows each entity to acquire varying amounts of resources. For more information, see “Set Resource Amount with Attributes”
Amount	The value to assign to the resource (when the resource comes from the dialog box).	Double-click the value, and then type the value you want to assign. This value is the number of resources acquired per entity. For example, if Amount is 3, each entity that arrives at the Release Acquire must wait to acquire 3 resources before departing the block.

Timeout Tab

Enable TO port for timed-out entities

Select to use the signal output port labeled **TO**.

Statistics Tab

Number of entities departed, #d

Select to use the signal output port labeled **#d**.

Number of entities in block, #n

Select to use the signal output port labeled **#n**.

Average wait, w

Select to use the signal output port labeled **w**.

Number of entities timed out, #to

Select to use the signal output port labeled **#to**.

Introduced in R2015a

Resource Pool (Obsolete)

Define resource

Library

Entity Management

Description

This block defines resources that entities can use during model simulation. Use the Resource Acquire and Resource Release blocks to work with these resources.

Initialize the block with specified amount of available resources. Then:

- Use one or more Resource Acquire blocks to reserve the use of those resources.
- Use a Resource Release block to return resources back to this block for future use.

Resources are visible to the current subsystem and its children. Resource are not visible to parent subsystems.

Ports

Resource Input Ports

Label	Description
amount	Port for arriving signals to specify the amount of the resource. You see this port only if you set Resource amount source to Signal port.

Signal Output Ports

Label	Description	Time of Update When Statistic is On
#u	Port to display the number of resources in use. You see this port only if you set Resource amount source to Signal port.	1
util	Port to display the average use of the resources. You see this port only if you select the Average utilization, util check box.	2

Parameters

Main Tab

Resource name

Enter name of entity resource.

Resource granularity

Select granularity of resource use.

- Discrete unit — Use whole number increment.
- Fractional amount — Use fractional increment.

Reusable upon release

- Select this check box to allow this resource to return to the resource pool upon release. An example of such a resource is a table in a restaurant, which is available for reuse when a customer leaves.

Selecting this check box enables the **Resource amount source** check box.

- Clear this check box to prevent this resource from returning to the resource pool upon release. An example of such a resource is food in a restaurant, which is not reusable upon consumption.

Resource amount source

Select resource amount source.

- Dialog

Selecting this option enables the `Resource amount` parameter.

- Signal port

The block derives the resource amount from the signal port.

Resource amount

Enter amount of resource.

Statistics Tab

Amount in use, #u

Select to use the signal output port labeled **#u**.

Average utilization, util

Select to use the signal output port labeled **util**.

Resource Release (Obsolete)

Release resources that entities do not need

Library

Entity Management

Description

This block releases the use of resources for a passing entity. You can specify that the block release certain resource types or release all resources.

Ports

Entity Input Ports

Label	Description
IN	Port for arriving entities.

Entity Output Ports

Label	Description
OUT	Port for departing entities that have released use of their resources.

Signal Output Ports

Label	Description	Time of Update When Statistic Is On
#d	Number of entities that have departed from this block since the start of the simulation or since the last reset.	After entity departure

Parameters

Main Tab

Resource to Release

Select the resources to release.

- All

Release the use of all resources for a passing entity.

- Selected

Release selected resources. Selecting this option enables the **Available Resources** table.

Use the **Available Resources** controls to:

- Select the resources from the resources defined in all the Resource Pool blocks in the model
- Add the resources to the Selected Resources table, where you can modify them.

The list displays all the resources in the model. (If there are no resources, the **Available Resources** list is empty).

If the resource list is long, you can type the resource name in the text box to filter the list.

Use the buttons in the **Available Resources** section to help build the resources table. The buttons perform these actions:

Button	Action
	Refresh the Available Resources list. The list updates with any upstream model changes you make while the block dialog box is open.
	Add the selected resources to the Selected Resources table.

Button	Action
	<p>Move the selected resource from the Selected Resources table to the Available Resources list.</p> <p>Note: If the selected resource is one you added manually, this button appears dimmed.</p>

The message area below the available resources list displays additional messages about the resources, as they apply.

Message	Meaning
> Resource already selected	You have already added the resource to the Selected Resources table. You cannot add the resource to the table again.

Use the controls under **Selected Resources** to build and manage the list of resources to release. Each resource appears as a row in a table.

Using these controls, you can:

- Add a resource manually.
- Modify a resource that you added to the table from the **Available Resources** list to release.

The buttons under **Selected Resources** perform these actions:

Button	Action	Notes
	Add a template resource to the table.	Rename the resource and specify its properties.
	Add a copy of the selected resource to the table to use as the basis of a new resource.	Rename the copy. Two resources cannot have the same name.
	Remove the selected resource from the Selected Resources table.	When you delete a resource this way, no confirmation appears and you cannot undo the operation.

Button	Action	Notes
	Move the selected resource up in order in the Selected Resources table.	N/A
	Move the selected resource down in order in the Selected Resources table.	N/A

Note If you delete a row and apply the change, the deletion can affect signal output ports corresponding to other attributes. For example, if the block has a signal output port **A2** and you delete the attribute with a port marked **A1**, the block relabels **A2** as **A1**. Verify that any signal that connects to the relabeled port is still connected as you expect.

Property	Specify	Use
Name	The name of the resource to release.	Double-click the existing name, and then type the new name.

Statistics Tab

Number of entities departed, #d

Select to use the signal output port labeled #d.

Resource Acquire (Obsolete), Resource Pool (Obsolete)

“Model with Resources”

Introduced in R2015a

Schedule Timeout (Obsolete)

Schedule timeout event for each entity

Library

Timing

Description

This block schedules a timeout event for each arriving entity. Timeout events enable you to limit the time that an entity spends on designated entity paths during the simulation. Topologically, this block designates a beginning of an entity path that is relevant to the time limit.

Characteristics of Timeout Event

The timeout event is on the event calendar and has these characteristics:

- Event time equal to the entity's arrival time plus a timeout interval. You specify the timeout interval via a parameter, attribute, or signal, depending on the **Timeout interval from** parameter value. The block determines the absolute event time of an entity's timeout event upon the entity's arrival.

Note If you specify the timeout interval via an event-based signal, be sure that its updates occur before the entity arrives.

For example, if an entity arrives at $T=5$ and the timeout interval is 3 (seconds), then the block schedules the timeout event to occur at $T=5+3=8$.

- A name that you specify via the **Timeout tag** parameter. The event calendar can contain multiple independent timeout events for the same entity, as long as they have distinct timeout tags. This block does not affect timeout events having other timeout tags.
- Event priority that you specify via the **Timeout event priority** parameter. Note that if timeout events for two entities have distinct event priorities and are scheduled for the same value, or sufficiently close values, of the simulation clock, then the priority values determine which entity times out first.

Occurrence of Timeout Event

If the timeout event occurs for a specific entity, then that entity attempts to depart from a **TO** entity output port of the storage block in which it resides. To configure a block so that it has a **TO** port, select the **Enable TO port for timed-out entities** parameter in the block's dialog box. If the timeout event occurs while the entity is in a block that has no **TO** port, then the Schedule Timeout block's **If entity has no destination when timeout occurs** parameter indicates whether the simulation halts with an error message, or discards the entity while issuing a warning.

To cancel a timeout event before it occurs, use the Cancel Timeout (Obsolete) block. You cannot directly change the scheduled time or priority of a timeout event that is already on the event calendar. You can, however, cancel a timeout event and subsequently schedule a new one having the same timeout tag.

Ports

Entity Input Ports

Label	Description
IN	Port for arriving entities.

Signal Input Ports

Label	Description
ti	Timeout interval for a newly arrived entity. This signal must be an event-based signal. You see this port only if you set Timeout interval from to Signal port ti.

Entity Output Ports

Label	Description
OUT	Port for entities whose timeout event the block has just scheduled.

Signal Output Ports

Label	Description	Time of Update When Statistic Is On
#d	Number of entities that have departed from this block since the start of the simulation.	After entity departure

The initial output value is 0. This value is in effect from the start of the simulation until the first update by the block.

Parameters

Schedule Timeout

Timeout tag

Name of the timeout to associate with each entity. Enter a new timeout tag, or reschedule a previous timeout by choosing it in the drop-down list.

Timeout interval from

Determines whether the timeout interval is computed from a parameter in this dialog box, an input signal, or an attribute of the arriving entity.

Timeout interval

The length of time between an entity's arrival time and the scheduled timeout event for that entity. You see this field only if you set **Timeout interval from** to `Dialog`.

Attribute name

The name of the attribute whose value the block uses as the timeout interval for an entity. You see this field only if you set **Timeout interval from** to `Attribute`.

Timeout event priority

The priority of the timeout event, relative to other simultaneous events in the simulation.

If timeout is already scheduled

Behavior of the block if a timeout event with the specified timeout tag is already scheduled for the arriving entity.

If entity has no destination when timeout occurs

Behavior of the block if a timeout event occurs for an entity that resides in a block that has no visible **TO** entity output port.

Statistics Tab

These parameters determine whether the block produces data at signal output ports or omits those ports.

Number of entities departed

Allows you to use the signal output port labeled **#d**.

See Also

Cancel Timeout (Obsolete)

Introduced in R2007a

Set Attribute (Obsolete)

Assign data to entity

Library

Attributes

Description

This block accepts an entity, assigns data to it, and then outputs it. Assigned data is stored in entity attributes. Each attribute has a name and a value that you specify. You can specify up to 32 attributes in the block. To learn about the kind of data an attribute can store, see “Attribute Value Support”.

Parameters

Set Attribute Tab

Use the **Available Attributes** controls to:

- Select the attributes from incoming entity paths that you want to access on the departing entity.
- Add the attributes to the **Set Attribute** table, where you can modify them.

The list displays all the attributes on all the incoming entities. (If the entity paths entering the Set Attribute block do not have any attributes, the **Available Attributes** list is empty).

If the attribute list is long, you can type the attribute name in the text box to filter the list.

Use the buttons in the **Available Attributes** section to help build the attributes table. The buttons perform these actions:

Button	Action
	Refresh the Available Attributes list. This action updates the list with any upstream model changes you make while the block dialog box is open.
	Add the selected attribute to the Set Attribute table.
	Move the selected attribute from the Set Attribute table to the Available Attributes list. Note: If the selected attribute is one you added manually, this button appears dimmed.

The message area below the available attributes list displays additional messages about the attributes, as they apply.

Message	Meaning
> Attribute already selected	You have already added the attribute to the Set Attribute table. You cannot add the attribute to the table again.
* Attribute may not be present	When multiple entity paths enter the block, all entities might not have the same attributes. Attributes that are not on all entering entities display an asterisk in the list, and this message appears. If you add such an attribute to the Set Attribute table, the behavior depends on how the Create attribute if not present check box is set.

Create attribute if not present

Check box that enables the block to define new attributes when an attribute in the table is not present in the current entity. If the check box is deselected, the simulation issues an error if an attribute named in the table does not already exist.

Select the check box if you want to:

- Set an attribute on each departing entity that previously existed on only certain incoming entity paths.
- Set a new attribute that you manually defined in the table on each departing entity.

Clear the check box if you want to:

- Protect against scenarios in which you add an attribute to the table from the **Available Attributes** list and later rename the attribute. When the check box is not selected, the renamed attribute causes an error because it no longer matches one present in the current entity.

Use the controls under **Set Attribute** to build and manage the list of attributes to attach to each departing entity. Each attribute appears as a row in a table.

Using these controls, you can:

- Add an attribute manually to attach to the entity.
- Modify an attribute that you added to the table from the **Available Attributes** list to attach to the entity.

The buttons under **Set Attribute** perform these actions:

Button	Action	Notes
	Add a template attribute to the table.	Rename the attribute and specify its properties.
	Add a copy of the selected attribute to the table to use as the basis of a new attribute.	Rename the copy. Two attributes cannot have the same name.
	Remove the selected attribute from the Set Attribute table.	When you delete an attribute this way, no confirmation appears and you cannot undo the operation.

Note If you delete a row and apply the change, the deletion can affect signal output ports corresponding to other attributes. For example, if the block has a signal output port **A2**

and you delete the attribute with a port marked **A1**, the block relabels **A2** as **A1**. Verify that any signal that connects to the relabeled port is still connected as you expect.

The table displays the attributes you added from the **Available Attributes** list or added manually. Use it to set these four attribute properties:

Property	Specify	Use
Attribute Name	The name of the attribute. Each attribute must have a unique name.	Double-click the existing name, and then type the new name.
Value From	Whether the data for the attribute value comes from the dialog box or a signal.	Select Dialog or Signal port . If you select Signal port , an input port with the name specified is added to the block after you apply your changes. When you connect a signal to the input port, the block assigns the value of the signal to the attribute during simulation.
Value	The value to assign to the attribute (when the attribute comes from the dialog box).	Double-click the value, and then type the value you want to assign.
Vector Is 1-D	Whether the block assigns the attribute as a vector of length N or as a multidimensional array when the Value evaluates to an N-element row or column vector. This property applies only to values that come from the dialog box when the value evaluates to an N-element row or column vector.	Select the check box to assign the attribute as a vector of length N. Clear it to assign the attribute as a multidimensional array.

Statistics Tab

These parameters determine whether the block produces data at signal output ports or omits those ports. For descriptions of the data and ports, see Signal Output Ports.

Number of entities departed

Allows you to use the signal output port labeled **#d**.

Ports

Entity Input Ports

Label	Description
IN	Port for arriving entities

Signal Input Ports

Label	Description
<i>Attribute name</i>	Data to assign to the attribute specified in each row of the table. The signal must be a fixed-size, event-based signal. You see this port only if you set Value From to Signal port. The default Name that corresponds to each row is Attributex , where x = 1, 2, 3, etc.

Entity Output Ports

Label	Description
OUT	Port for departing entities, with data assigned to them.

Signal Output Ports

Label	Description	Time of Update When Statistic Is On
#d	Number of entities that have departed from this block since the start of the simulation.	After entity departure

The initial output value is 0. This value is in effect from the start of the simulation until the first update by the block.

Signal Latch (Obsolete)

Write input signal value to memory and read memory to output signal upon events

Library

Signal Management

Description

The Signal Latch block is a versatile block for manipulating event-based signals. You can use it to delay or resample signals based on events, not time. This block stores and outputs the values of the **in** input signal based on events:

- The block writes the value of the **in** signal to an internal memory location when a “write to memory” event occurs. The **Write to memory upon** parameter indicates the type of signal-based event or function call that causes a write event.
- The block reads the memory value and updates the signal at the **out** port, if present, when a “read from memory” event occurs. The **Read from memory upon** parameter indicates the type of internal or external event that causes a read event:
 - If you set **Read from memory upon** to **Write to memory event**, then every write event causes a read event. The **out** signal is like a resampled version of the **in** signal.
 - Otherwise, the **Read from memory upon** parameter indicates the type of signal-based event or function call that causes a read event. In this case, write and read events occur independently and are not required to alternate. The **out** signal is like a delayed resampled version of the **in** signal.

This block is useful for modeling feedback loops in discrete-event systems in which an output from one component is an input to another component. Because the two components work separately in such a system, the updates of the input and output

signals are independent in both causality and timing. This block lets you control the causality and timing associated with storing the output from one component and updating the value received by the other component.

Ports

Signal Input Ports

Label	Description
wts	Signal whose updates cause write events. This signal must be an event-based signal. You see this port only if you set Write to memory upon to <code>Sample time hit</code> from port <code>wts</code> .
wtr	Trigger signal whose edges cause write events. This signal must be an event-based signal. You see this port only if you set Write to memory upon to <code>Trigger</code> from port <code>wtr</code> .
wvc	Signal whose numerical changes in value cause write events. This signal must be an event-based signal. You see this port only if you set Write to memory upon to <code>Change in signal</code> from port <code>wvc</code> .
wfcn	Function-call signal that causes write events. This signal must be an event-based function call. You see this port only if you set Write to memory upon to <code>Function call</code> from port <code>wfcn</code> .
rts	Signal whose updates cause read events. This signal must be an event-based signal. You see this port only if you set Read from memory upon to <code>Sample time hit</code> from port <code>rts</code> .
rtr	Trigger signal whose edges cause read events. This signal must be an event-based signal. You see this port only if you set Read from memory upon to <code>Trigger</code> from port <code>rtr</code> .
rvc	Signal whose numerical changes in value cause read events. This signal must be an event-based signal. You see this port only if you set Read from memory upon to <code>Change in signal</code> from port <code>rvc</code> .
rfcn	Function-call signal that causes read events. This signal must be an event-based function call. You see this port only if you set Read from memory upon to <code>Function call</code> from port <code>rfcn</code> .
in	Signal to be resampled and/or delayed. This signal must be an event-based signal.

Signal Output Ports

Label	Description	Time of Update When Statistic Is On	Order of Update	Initial Value
st	0 or 1, depending on whether the block more recently processed a read or write event.	Upon write events and upon read events	1	0
mem	The value of the block's internal memory when a write event occurs.	Upon write events	1	Value of Initial memory value parameter
out	The value of the block's internal memory when a read event occurs.	Upon read events	1	

Output signals having the same number in the Order of Update column in the table above are updated in an arbitrary sequence relative to each other; you should not rely on a specific sequence for your simulation results.

The initial value is in effect from the start of the simulation until the first update by the block.

Parameters

Write Tab

Initial memory value

The value in the block's internal memory before the first write event occurs.

Write to memory upon

The type of signal-based event or function call that causes a write event.

Trigger type, Type of change in signal value

Trigger type determines whether rising, falling, or either type of trigger edge causes a write event. You see this field only if you set **Write to memory upon** to `Trigger from port wtr`.

Type of change in signal value determines whether rising, falling, or either type of value change causes a write event. You see this field only if you set **Write to memory upon** to `Change in signal from port wvc`.

Resolve simultaneous signal updates according to event priority

Select this option to control the sequencing of the write event, relative to other simultaneous events in the simulation. If you do not select this option, the application executes the write event immediately upon detecting the signal-based event that causes it.

Event priority for writing to memory

The priority of the write event, relative to other simultaneous events in the simulation.

Use of this parameter depends on the following:

- You see this field only if you select **Resolve simultaneous signal updates according to event priority** on this tab.
- If you select **Resolve simultaneous signal updates according to event priority** on both the write tab and the read tab, the software ignores **Event priority for reading from memory**. Instead, the simulation resolves simultaneous signal updates based on only the **Event priority for writing to memory** parameter. In this case, the software executes the write event before the read event.
- If you select the configuration parameter **Prevent duplicate events on multiport blocks and branched signals** in your model, the software uses the **Event priority for writing to memory** parameter to help Simulink to sort blocks in the model. In this case, the software no longer schedules an event that you can view on the SimEvents event calendar.

Read Tab

Read from memory upon

The type of signal-based event, function call, or internal write event that causes a read event.

Trigger type, Type of change in signal value

Trigger type determines whether rising, falling, or either type of trigger edge causes a read event. You see this field only if you set **Read from memory upon** to `Trigger from port rtr`.

Type of change in signal value determines whether rising, falling, or either type of value change causes a read event. You see this field only if you set **Read from memory upon** to Change in signal from port rvc.

Resolve simultaneous signal updates according to event priority

Select this option to control the sequencing of the read event, relative to other simultaneous events in the simulation. If you do not select this option, the application executes the read event immediately upon detecting the signal-based event that causes it. You see this field only if you set **Read from memory upon** to an option other than Write to memory event.

Event priority for reading from memory

The priority of the read event, relative to other simultaneous events in the simulation.

Use of this parameter depends on the following:

- You see this field only if you select **Resolve simultaneous signal updates according to event priority** on this tab.
- If you select **Resolve simultaneous signal updates according to event priority** on both the write tab and the read tab, the software ignores **Event priority for reading from memory**. Instead, the simulation resolves simultaneous signal updates based on only the **Event priority for writing to memory** parameter. In this case, the software executes the write event before the read event.
- If you select the configuration parameter **Prevent duplicate events on multiport blocks and branched signals** in your model, the software uses the **Event priority for writing to memory** parameter to help Simulink to sort blocks in the model. In this case, the software no longer schedules an event that you can view on the SimEvents event calendar.

Status Tab

Report state of the block

Allows you to use the signal output port labeled **st**.

Report memory value upon write event

Allows you to use the signal output port labeled **mem**.

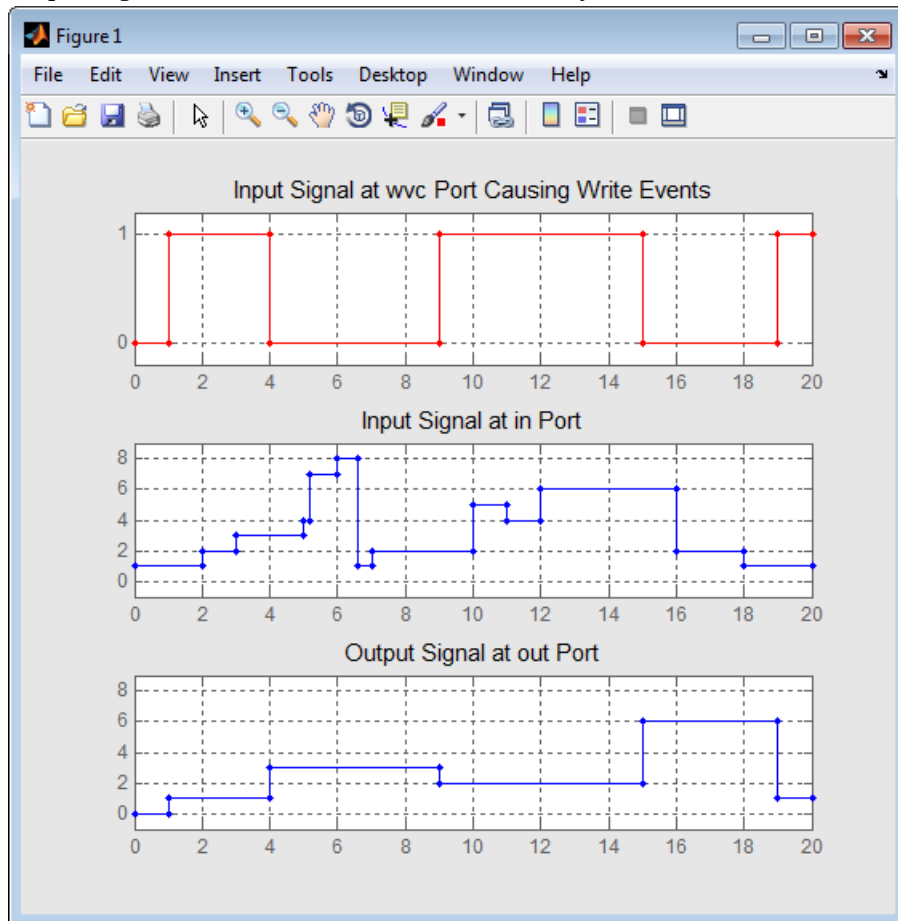

Report memory value upon read event

Allows you to use the signal output port labeled **out**.

Examples

Example 2.1. Reading from Memory Upon Each Write Event

In the plot below, the output signal reflects values of the input signal upon each rising or falling value of the **wvc** signal. Between successive write events, the output signal maintains the value from the most recent write event. Before the first write event, the output signal is 0 because of the initial memory value.

Example 2.2. Independent Read and Write Events

In the plot below, the **mem** signal reflects values of the input signal upon each rising or falling value of the **wvc** signal, while the **out** signal reflects values of the **mem** signal upon each rising or falling value of the **rvc** signal.

Data Store Memory, Data Store Read, Data Store Write

Introduced before R2006a

Signal Scope (Obsolete)

Plot data from signal

Library

SimEvents Sinks

Description

This block creates a plot using data from an event-based signal. The data for the vertical axis comes from the signal connected to the block's signal input port labeled **in**.

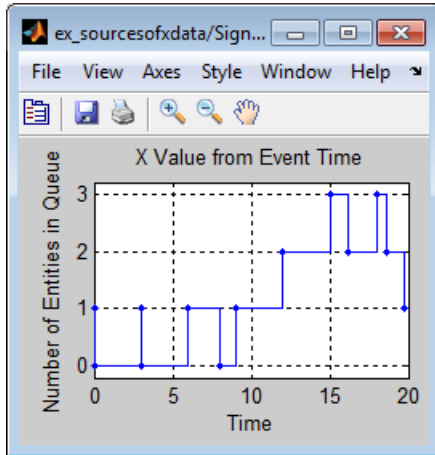

The **Plot type** parameter on the **Plotting** tab determines whether and how the block connects the points that it plots.

Selecting Data for the Horizontal Axis

Use the **X value from** parameter to select the type of data for the horizontal axis. The table below describes the choices.

Source of X Data	Description of Plot
Event time	Plot of the in signal versus simulation time. For example, you might use this option to see how the length of a queue changes over time.
Index	Plot of the in signal's successive values against a horizontal axis that represents the index of the values. The signal's first value during the simulation has an index of 1, the signal's second value has an index of 2, and so on. For example, you might use this option for a signal that has zero-duration values, to help determine the exact sequence among values that the signal assumes simultaneously.

The figures below illustrate the different sources of data for the horizontal axis. The plots look similar, except that the second plot has uniform horizontal spacing rather than time-based spacing between successive points.

Ports

Signal Input Ports

Label	Description
in	Signal containing data for the Y axis. This signal must be an event-based signal.

Signal Output Ports

Label	Description
#c	Number of points the block has plotted.

The initial output value is 0. This value is in effect from the start of the simulation until the first update by the block.

Parameters

Plotting Tab

Plot type

The presentation format for the data.

X value from

Source of data for the plot's horizontal axis. See “Selecting Data for the Horizontal Axis” on page 2-229 for details.

Open scope at start of simulation

Selecting this option causes the plot window to open when you start the simulation. If you clear this box, you can open the plot window by double-clicking the block icon.

Axes Tab

Initial X axis lower limit, Initial X axis upper limit

The interval shown on the X axis at the beginning of the simulation. The interval might change from this initial setting due to zooming, autoscaling, or the **If X value is beyond limit** setting.

If X value is beyond limit

Determines how the plot changes if one or more X values are not within the limits shown on the X axis.

Initial Y axis lower limit, Initial Y axis upper limit

The interval shown on the Y axis at the beginning of the simulation. The interval might change from this initial setting due to zooming, autoscaling, or the **If Y value is beyond limit** setting.

If Y value is beyond limit

Determines how the plot changes if one or more values of the **in** signal are not within the limits shown on the Y axis.

Show grid

Toggles the grid on and off.

Figure Tab

Title

Text that appears as the title of the plot, above the axes.

Y label

Text that appears to the left of the vertical axis.

X label

Text that appears below the horizontal axis.

Position

A four-element vector of the form [left bottom width height] specifying the position of the scope window. (0,0) is the lower left corner of the display.

Show number of points

Displays the number of plotted points using an annotation in the plot window.

Data History Tab

Store data when scope is closed

Select `Unlimited` to have the block cache all data for future viewing, `Limited` to cache a portion of the most recent data, and `Disabled` to avoid caching undisplayed data.

Limit data points to

The number of data points the block caches, using the most recent data. You see this field only if you set **Store data when scope is closed** to `Limited`.

Statistics Tab

These parameters determine whether the block produces data at signal output ports or omits those ports. For descriptions of the data and ports, see the preceding table, “Signal Output Ports”.

Number of points plotted

Allows you to use the signal output port labeled **#c**.

X-Y Signal Scope (Obsolete), Attribute Scope (Obsolete)

Introduced before R2006a

Signal-Based Function-Call Generator (Obsolete)

Convert signal-based events into function calls

Library

Generators/Function-Call Generators

Description

This block converts a signal-based event or a function-call input into one or two function calls that you can use to invoke function-call subsystems, Stateflow blocks, or other blocks that accept function-call inputs. You specify the type of event the block translates and whether the block suppresses its output under certain conditions. You can also delay the output function calls by an amount of time that you specify via a parameter or an input signal.

Criteria for Generating Function Calls

The primary criterion, based on the **Generate function call only upon** parameter, is a signal-based event or a function call. By default, the block generates a function call upon each event of the type you specify.

To generate up to two function calls upon each event, select **Generate optional f2 function call**. If the block generates function calls at both the **f1** and **f2** output ports, then it generates the **f1** call first and generates the **f2** call as a subsequent part of the same operation.

To make the **f1** or **f2** output function call contingent upon a secondary criterion, select **Suppress function call f1 if enable signal e1 is not positive** or **Suppress function call f2 if enable signal e2 is not positive**. The block acquires an additional signal input port, labeled **e1** or **e2**, to which you connect a control signal. If the control signal is

zero or negative when the block is about to generate the function call, then the block suppresses the function call. The **e1** and **e2** ports operate independently of each other as secondary criteria for their respective function-call output ports.

Ports

Signal Input Ports

Label	Description
t	The delay, in seconds, between the input event and the output function call. A positive value schedules the function call in the future, while a value of zero schedules the function call at the current simulation time. This signal must be an event-based signal. You see this port only if you select Resolve simultaneous signal updates according to event priority , and then set Function-call delay from to Signal port <code>t</code> .
ts	When this signal has an update, the primary criterion is satisfied. This signal must be an event-based signal. You see this port only if you set Generate function call only upon to Sample time hit from port <code>ts</code> .
tr	When this signal has a rising or falling edge, depending on the Trigger type parameter, the primary criterion is satisfied. This signal must be an event-based signal. You see this port only if you set Generate function call only upon to Trigger from port <code>tr</code> .
vc	When this signal increases or decreases, depending on the Type of change in signal value parameter, the primary criterion is satisfied. This signal must be an event-based signal. You see this port only if you set Generate function call only upon to Change in signal from port <code>vc</code> .
fcn	When this signal carries a function call, the primary criterion is satisfied. This signal must be an event-based function call. You see this port only if you set Generate function call only upon to Function call from port <code>fcn</code> . Do not connect this port to an output port from the same instance of this block.
e1	When this signal is 0 or negative, the block does not generate a function call at the f1 output port. This signal must be an event-based signal. You see this input port only if you select Suppress function call f1 if enable signal e1 is not positive .
e2	When this signal is 0 or negative, the block does not generate a function call at the f2 output port. This signal must be an event-based signal. You see this input port only if you select Suppress function call f2 if enable signal e2 is not positive .

Signal Output Ports

Label	Description	Order of Update
f1	Function call, possibly contingent on e1 input signal	1
f2	Function call, possibly contingent on e2 input signal	2
#f1	Number of function calls the block has generated at the f1 port during the simulation	3
#f2	Number of function calls the block has generated at the f2 port during the simulation	3

Output signals having the same number in the Order of Update column in the table above are updated in an arbitrary sequence relative to each other; you should not rely on a specific sequence for your simulation results.

The initial output value for the numerical signals, which is in effect from the start of the simulation until the first update by the block, is 0.

Parameters

Function Call Tab

Generate function call only upon

The primary criterion for determining when the block generates a function call. Optional secondary criteria are established by the **Suppress function call...** parameters below.

Trigger type, Type of change in signal value

Trigger type determines whether rising, falling, or either type of trigger edge causes the block to generate a function call. You see this field only if you set **Generate function call only upon** to `Trigger` from port `tr`.

Type of change in signal value determines whether rising, falling, or either type of value change causes the block to generate a function call. You see this field only if you set **Generate function call only upon** to `Change in signal` from port `vc`.

Suppress function call f1 if enable signal e1 is not positive

Selecting this option causes **f1** function calls to be contingent upon a positive value at the **e1** signal input port.

Generate optional f2 function call

Selecting this option causes the block to generate a function call at the optional **f2** output port when appropriate criteria are satisfied.

Suppress function call f2 if enable signal e2 is not positive

Selecting this option causes **f2** function calls to be contingent upon a positive value at the **e2** signal input port. You see this field only if you select **Generate optional f2 function call**.

Timing Tab

Resolve simultaneous signal updates according to event priority

Select this option to control the sequencing of the function-call event, relative to other simultaneous events in the simulation. If you do not select this option, the application issues the function call immediately upon detecting the signal-based event that causes it.

Note If this block has both a function-call input and a signal input, you might need to select this option to prevent latency in the signal.

Event priority

The priority of the function-call event, relative to other simultaneous events in the simulation.

Use of this parameter depends on the following:

- You see this field only if you select **Resolve simultaneous signal updates according to event priority**.
- If you select the configuration parameter **Prevent duplicate events on multiport blocks and branched signals** in your model, the software uses the **Event priority** parameter to sort blocks in the model. In this case, the software does not schedule an event that you can view on the event calendar.

Function-call delay from

Determines whether the delay between the input event and the output function call is computed from a parameter in this dialog box or from an input signal. You see this field only if you select **Resolve simultaneous signal updates according to event priority**.

Function-call time delay

The delay, in seconds, between the input event and the output function call. A positive value schedules the function call in the future, while a value of zero schedules the function call at the current simulation time. You see this field only if you select **Resolve simultaneous signal updates according to event priority**, and then set **Function-call delay from** to `Dialog`.

Statistics Tab

Number of f1 function calls

Allows you to use the signal output port labeled **#f1**.

Number of f2 function calls

Allows you to use the signal output port labeled **#f2**. This field is active only if you select **Generate optional f2 function call** on the **Function Call** tab of this dialog box.

Entity Departure Function-Call Generator (Obsolete)

Introduced in R2011b

Signal-Based Function-Call Event Generator (Obsolete)

Generate function-call events in response to signal-based events

Library

Generators / EventGenerators

Description

Note The Signal-Based Function-Call Event Generator block will be removed in a future release. Use the Signal-Based Function-Call Generator (Obsolete) block instead.

This block generates an output function call corresponding to each signal-based event or input function call. You specify the type of event the block responds to. You can use the function call to invoke function-call subsystems, Stateflow blocks, or other blocks that accept function-call inputs.

This block is similar to the Signal-Based Function-Call Generator (Obsolete) block, which offers more flexibility.

Ports

Signal Input Ports

Label	Description
ts	When this signal has an update, the block generates a function call. This signal must be an event-based signal. You see this port only if you set Generate function call only upon to Sample time hit from port ts .
tr	When this signal satisfies the specified trigger criteria, the block generates a function call. This signal must be an event-based signal. You see this port only if you set Generate function call only upon to Trigger from port tr .
vc	When this signal satisfies the specified value-change criteria, the block generates a function call. This signal must be an event-based signal. You see this port only if you set Generate function call only upon to Change in signal from port vc .
fcn	When this signal carries a function call, the block generates a function call. This signal must be an event-based function call. You see this port only if you set Generate function call only upon to Function call from port fcn . Do not connect this port to an output port from the same instance of this block.

Signal Output Ports

Label	Description	Order of Update
f1	Function-call signal.	1
#f1	Number of function calls the block has generated during the simulation.	2

The initial output value for the numerical signals, which is in effect from the start of the simulation until the first update by the block, is 0.

Parameters

Function Call Tab

Generate function call only upon

The primary criterion for determining when the block generates a function call. Optional secondary criteria are established by the **Suppress function call...** parameters below.

Trigger type

Determines whether rising, falling, or either type of trigger edge causes the block to generate a function call. You see this field only if you set **Generate function call only upon** to `Trigger` from port `tr`.

Type of change in signal value

Determines whether rising, falling, or either type of value change causes the block to generate a function call. You see this field only if you set **Generate function call only upon** to `Change in signal` from port `vc`.

Resolve simultaneous signal updates according to event priority

Select this option to control the sequencing of the function-call event, relative to other simultaneous events in the simulation. If you do not select this option, the application issues the function call immediately upon detecting the signal-based event that causes it.

Event priority

The priority of the function-call event, relative to other simultaneous events in the simulation. You see this field only if you select **Resolve simultaneous signal updates according to event priority**.

Statistics Tab

Number of f1 function calls

Allows you to use the signal output port labeled **#f1**.

Signal-Based Function-Call Generator (Obsolete)

Introduced before R2006a

Single Server (Obsolete)

Serve one entity for period of time

Library

Servers

Description

This block serves one entity for a period of time, and then attempts to output the entity through the **OUT** port. If the **OUT** port is blocked, then the entity stays in this block until the port becomes unblocked. If an entity in this block is scheduled to time out, then it might depart prematurely via the optional **TO** port.

You specify the service time, which is the duration of service, via a parameter, attribute, or signal, depending on the **Service time from** parameter value. The block determines the service time for an entity upon its arrival. Service times are assumed to be specified in seconds.

Note If you specify the service time via an event-based signal, be sure that its updates occur before the entity arrives.

The block permits preemption if you select **Permit preemption based on attribute**. In this case, an entity in the server can depart early via the **P** port. Preemption occurs only if attributes of the current entity and the entity attempting to arrive satisfy specified criteria.

When the block does not permit preemption, the **IN** port is unavailable whenever this block stores an entity. In this case, the **IN** port becomes available when the entity departs.

Ports

Entity Input Ports

Label	Description
IN	Port for arriving entities, which will be served.

Signal Input Ports

Label	Description
t	Service time, in seconds, for a newly arrived entity. This signal must be an event-based signal. You see this port only if you set Service time from to Signal port t.

Entity Output Ports

Label	Description
OUT	Port for departing entities that have completed their service time, have not timed out while in this block, and have not been preempted.
P	Port for entities that have been preempted by an arriving entity. This port must not be blocked at the time of preemption.
TO	Port for entities that time out while in this block. You see this port only if you select Enable TO port for timed-out entities . This port must not be blocked when an entity attempts to depart here.

Signal Output Ports

Label	Description	Time of Update When Statistic Is On	Order of Update When Entity Departs
#d	Number of entities that have departed from this block via the OUT port since the start of the simulation.	After entity departure via the OUT port	4
#n	Number of entities currently in the block, either 0 or 1.	After entity arrival and after entity departure via the OUT or TO port	3
#p	Number of entities that have been preempted from this block since the start of the simulation.	After entity departure via the P port	4
pe	A value of 1 indicates that the block stores at least one entity that has tried and failed to depart. In that case, the entity is a pending entity. A value of 0 indicates that the block does not store any pending entities.	Sample time hit of 1 occurs after the block stores an entity that has tried and failed to depart. Sample time hit of 0 occurs after the departure of the pending entity via any port.	1
w	Sample mean of the waiting times in this block for all entities that have departed from the OUT or TO port. An entity's waiting time might exceed its service time if the OUT port is blocked when the entity completes service.	After entity departure via the OUT or TO port	2

Label	Description	Time of Update When Statistic Is On	Order of Update When Entity Departs
util	Utilization of the server, which is the fraction of simulation time spent storing an entity. At $T=0$, the utilization is 0 or 1 depending on whether the server contains an entity.	Performance considerations cause the block to suppress signal updates until specific occurrences cause updates. In On mode, updates occur after an entity departure via the OUT or TO port, and after an entity arrival. In Upon stop or pause mode, updates occur when the simulation stops or pauses.	2
#to	Number of entities that have timed out from this block since the start of the simulation.	After entity departure via the TO port	4

Output signals having the same number in the Order of Update column in the table above are updated in an arbitrary sequence relative to each other; you should not rely on a specific sequence for your simulation results.

The initial output value, which is in effect from the start of the simulation until the first update by the block, is 0 for all signals.

Parameters

Single Server Tab

Service time from

Determines whether the service time is computed from a parameter in this dialog box, an input signal, or an attribute of the entity being served.

Service time

The service time, in seconds, for all entities. You see this field only if you set **Service time from** to `Dialog`.

Attribute name

The name of the attribute whose value the block uses as the service time for an entity. You see this field only if you set **Service time from** to `Attribute`.

Service completion event priority

The priority of the service completion event, relative to other simultaneous events in the simulation.

Preemption Tab**Permit preemption based on attribute**

If you select this option, the block can replace an entity by a higher priority entity. Otherwise, the block never permits new arrivals when it is storing an entity. Selecting this option also clears the **Average wait, w** check box on the **Statistics** tab and makes that parameter unavailable.

Sorting attribute name

The block uses this attribute to determine whether a new entity can preempt the one in the server. You see this field only if you select **Permit preemption based on attribute**.

Sorting direction

Preemption occurs when the arriving entity has a strictly smaller (`Ascending`) or strictly larger (`Descending`) value of the attribute named above, compared to the attribute value of the entity in the server. You see this field only if you select **Permit preemption based on attribute**.

Write residual service time to attribute

If you select this option, a preemption event causes the block to set an attribute in the preempted entity. The attribute value is the remaining service time the entity would have required if it had not been preempted. You see this field only if you select **Permit preemption based on attribute**.

Residual service time attribute name

The name of the attribute the block uses when recording the residual service time of entities. You see this field only if you select **Write residual service time to attribute**.

Create attribute if not present

Selecting this option enables the block to define a new attribute for the residual service time. Otherwise, the block issues an error if the attribute named above does

not already exist. You see this field only if you select **Write residual service time to attribute**.

Timeout Tab

Enable TO port for timed-out entities

This option becomes relevant if an entity times out while in this block. Selecting this option provides a **TO** entity output port through which the timed-out entity departs. If you clear this option in a model that uses timeouts, see the **If entity has no destination when timeout occurs** parameter of the Schedule Timeout (Obsolete) block.

Statistics Tab

These parameters determine whether certain ports produce data throughout the simulation, produce data only when you stop or pause the simulation, or are omitted from the block. For descriptions of the affected ports, see the preceding table, “Signal Output Ports”.

Number of entities departed

Allows you to use the signal output port labeled **#d**.

Number of entities in block

Allows you to use the signal output port labeled **#n**.

Number of entities preempted

Allows you to use the signal output port labeled **#p**. This field is available only if you select the **Permit preemption based on attribute** option on the **Preemption** tab.

Pending entity present in block

Allows you to use the signal output port labeled **pe**.

Average wait

Allows you to use the signal output port labeled **w**. This field is available only if you clear the **Permit preemption based on attribute** option on the **Preemption** tab.

Utilization

Allows you to use the signal output port labeled **util**.

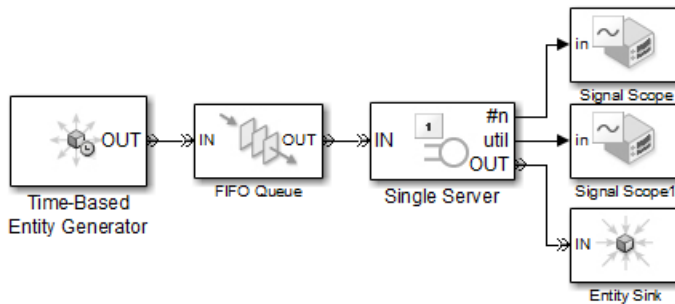

Number of entities timed out

Allows you to use the signal output port labeled **#to**.

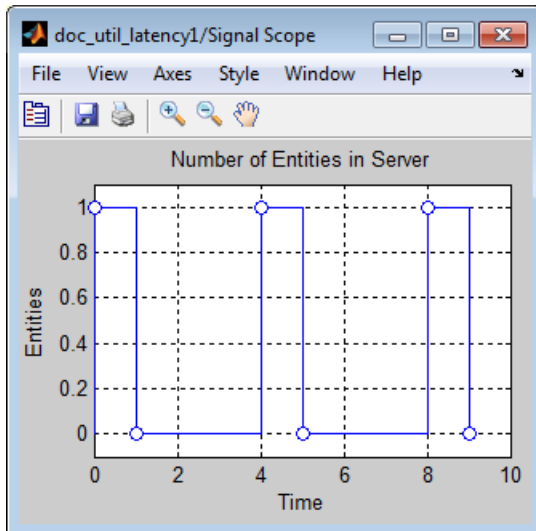

Examples

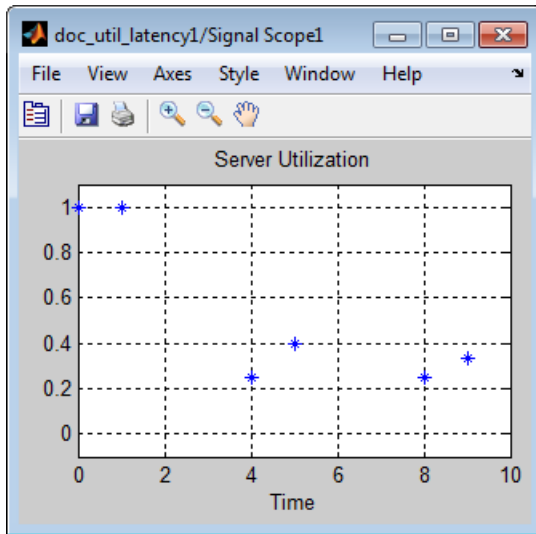

- “Build a Discrete-Event Model”
- “Constructs Involving Queues and Servers”

The following example illustrates the timing of updates of the **util** signal, as described in Signal Output Ports.

The server has idle periods that reduce its utilization. However, the server block recomputes the **util** signal only when the number of entities in the server changes. While the definition of utilization says that the utilization is less than 1 at time 3, the **util** signal remains at its previous value of 1 until the next entity arrives at time 4.

In a longer simulation, the differences in the value of **util** compared to its theoretical definition become less pronounced.

“Write Events Actions”

Introduced before R2006a

Start Timer (Obsolete)

Associate named timer to each arriving entity independently and start timing

Library

Timing

Description

This block associates a named timer to each arriving entity independently and starts the timer. If the entity was previously associated with a timer of the same name, then the block either continues or restarts that timer, depending on your setting for the **If timer has already started** parameter; the `Warn` and `continue` option can be helpful for debugging or preventing modeling errors. Other timers, if any, associated with the arriving entity are unaffected.

This block works with the Read Timer (Obsolete) block. To read the value of the timer named in this block, reference the timer name in the Read Timer block.

Ports

Entity Input Ports

Label	Description
IN	Port for arriving entities.

Entity Output Ports

Label	Description
OUT	Port for departing entities, which have named timers attached to them.

Signal Output Ports

Label	Description	Time of Update When Statistic Is On
#d	Number of entities that have departed from this block since the start of the simulation.	After entity departure

The initial output value is 0. This value is in effect from the start of the simulation until the first update by the block.

Parameters

Start Timer Tab

Timer tag

Name of the timer to associate with each entity. Enter a new timer tag, or restart a previous timer by choosing it in the drop-down list.

If timer has already started

Behavior of the block if an arriving entity already has a timer with the specified timer tag.

Statistics Tab

These parameters determine whether the block produces data at signal output ports or omits those ports.

Number of entities departed

Allows you to use the signal output port labeled #d.

See Also

Read Timer (Obsolete)

Introduced before R2006a

Time-Based Entity Generator (Obsolete)

Generate entities using intergeneration times from signal or statistical distribution

Library

Generators / Entity Generators

Description

This block is designed to generate entities using intergeneration times that satisfy criteria that you specify. The intergeneration time is the time interval between two successive generation events.

Intergeneration Times	Value of Generate entities upon Parameter
Distributed according to various parameters in the block dialog box	Intergeneration time from dialog
Specified using an input signal that the block reads at the start of the simulation and each time it generates an entity	Intergeneration time from port t

Responding to Blockage at the Entity Output Port

You can choose how this block responds when it generates an entity that the subsequent entity input port is not available to accept:

- If you set **Response when blocked** to `Error`, the simulation halts with an error message.
- If you set **Response when blocked** to `Pause generation`, this block holds the entity, which becomes a pending entity. The block does not schedule another entity generation event yet. The **Response when unblocked** parameter determines what the block does next:

- If you set **Response when unblocked** to `Immediate restart`, after this block learns that the subsequent port is available, the pending entity departs. After the pending entity departs, this block schedules the generation of the next entity.
- If you set **Response when unblocked** to `Delayed restart`, upon learning that the subsequent port is available, this block schedules an event of type `DelayedRestart`. The event time is the current time plus the same intergeneration time the block used when generating the pending entity. When the block executes the event, the pending entity attempts to depart.

Use the `Delayed restart` option if you want to:

- Keep the arrival process memoryless, when **Distribution** is `Exponential`.
- Prevent correlation among multiple instances of this block if they become unblocked simultaneously.

For an example, see “Example: Responding to Blockage” on page 2-258.

Ports

Signal Input Ports

Label	Description
t	Time interval between generation events of the current entity and the next entity. The block reads the value after the current entity departs and the block updates its output signals, if any. If you do not select Generate entity at simulation start , then the block also reads the value of this signal at the start of the simulation. This signal must be an event-based signal. You see this port only if you set Generate entities upon to <code>Intergeneration time from port t</code> .

Entity Output Ports

Label	Description
OUT	Port through which generated entities depart.

Signal Output Ports

Label	Description	Time of Update When Statistic Is On	Order of Update
#d	Number of entities that have departed from this block since the start of the simulation.	After entity departure	3
pe	A value of 1 indicates that the block stores an entity that has tried and failed to depart. In that case, the entity is a pending entity. A value of 0 indicates that the block does not store any pending entities.	Sample time hit of 1 occurs after the block stores an entity that has tried and failed to depart. Sample time hit of 0 occurs after the departure of the pending entity.	1
w	Average interdeparture time, in seconds, for all pairs of successive entities that have departed from this block. The signal value is 0 before the second entity departure.	After entity departure	2

The initial output value, which is in effect from the start of the simulation until the first update by the block, is 0 for all signals.

Parameters

Entity Generation Tab

Generate entities upon

Determines where the block gets instructions about when to generate entities.

Distribution

The statistical distribution of intergeneration times. You see this field only if you set **Generate entities upon** to Intergeneration time from dialog.

Period

The time interval between entity generations, in seconds. You see this field only if you set **Generate entities upon** to Intergeneration time from dialog and set **Distribution** to Constant.

Initial seed

A nonnegative integer that initializes the random number generator. You see this field only if you set **Generate entities upon** to Intergeneration time from dialog and set **Distribution** to Uniform or Exponential.

Minimum

The lower endpoint, in seconds, of the interval over which the distribution is uniform. This field appears only if you set **Generate entities upon** to Intergeneration time from dialog and set **Distribution** to Uniform.

Maximum

The upper endpoint, in seconds, of the interval over which the distribution is uniform. This field appears only if you set **Generate entities upon** to Intergeneration time from dialog and set **Distribution** to Uniform.

Mean

The expected value of the exponential distribution. You see this field only if you set **Generate entities upon** to Intergeneration time from dialog and set **Distribution** to Exponential.

Generation event priority

The priority of the entity-generation event, relative to other simultaneous events in the simulation.

Generate entity at simulation start

If you select this option, the block generates the first entity when the simulation begins and the second entity at the first intergeneration time. Otherwise, the block generates the first entity at the first intergeneration time.

Blocking Tab**Response when blocked**

Determines how the block responds if a generated entity cannot depart immediately because the entity input port of the subsequent block is unavailable; see “Responding to Blockage at the Entity Output Port” on page 2-254.

Response when unblocked

Determines entity generation behavior if the entity input port of the subsequent block is available again after a prior blockage; see “Responding to Blockage at the Entity Output Port” on page 2-254.

Entity Type Tab

Entity type

The blank type includes no attributes. The standard type includes attributes called *Priority* and *Count*, with default values of 10 and 0, respectively.

Statistics Tab

These parameters determine whether the block produces data at signal output ports or omits those ports.

Number of entities departed

Allows you to use the signal output port labeled **#d**.

Pending entity present in block

Allows you to use the signal output port labeled **pe**.

Average intergeneration time

Allows you to use the signal output port labeled **w**.

Examples

- “Build a Discrete-Event Model”

Example: Responding to Blockage

To illustrate the blockage options, consider a Time-Based Entity Generator block followed by a Single Server block, then followed by an Entity Sink block.

Suppose the block configurations have these characteristics:

- The entity generator has **Response when blocked** set to `Pause` generation.
- The entity generator generates the first entity at $T=1$ and uses an intergeneration time of 1 s.
- The service times for the first three entities in the server are 1.5, 2.2, and 1.8.

The following tables indicate how the **Response when unblocked** values affect the behavior in the simulation.

Immediate Restart

Time (s)	Behavior
1	Entity generator generates and outputs the first entity to the server. The entity input port of the server becomes unavailable. The first entity is in service until $T=1+1.5=2.5$.
2	Entity generator generates the second entity and holds it because the OUT port is blocked.
2.5	First entity departs from the server. The entity input port of the server becomes available and the second entity advances from the entity generator to the server. The entity input port of the server then becomes unavailable. The second entity is in service until $T=2.5+2.2=4.7$. The entity generator schedules the next generation for $T=2.5+1=3.5$.
3.5	Entity generator generates the third entity, and holds it because the OUT port is blocked.
4.7	Second entity departs from the server. The entity input port of the server becomes available and the third entity advances from the entity generator to the server. The entity input port of the server then becomes unavailable. The third entity is in service until $T=4.7+1.8=6.5$. The entity generator schedules the next generation for $T=4.7+1=5.7$.

Delayed Restart

Time (s)	Behavior
1	Entity generator generates the first entity. The entity advances to the server. The entity input port of the server becomes unavailable. The entity is in service until $T=1+1.5=2.5$.
2	Entity generator generates the second entity. The entity becomes a pending entity because the OUT port is blocked.
2.5	First entity departs from the server. The entity input port of the server becomes available. The entity generator schedules a delayed restart event for the second entity at $T=2.5+1=3.5$.
3.5	The second entity advances from the entity generator to the server. The entity input port of the server then becomes unavailable. The second entity is in service until $T=3.5+2.2=5.7$. The entity generator schedules the next generation for $T=3.5+1=4.5$.
4.5	Entity generator generates the third entity. The entity becomes a pending entity because the OUT port is blocked.
5.7	Second entity departs from the server. The entity input port of the server becomes available. The entity generator schedules a delayed restart event for the third entity at $T=5.7+1=6.7$.
6.7	The third entity advances from the entity generator to the server. The entity input port of the server then becomes unavailable. The third entity is in service until $T=6.7+1.8=8.5$. The entity generator schedules the next generation for $T=6.7+1=7.7$.

Event-Based Entity Generator (Obsolete), Entity Sink (Obsolete)

Introduced before R2006a

Time-Based Function-Call Generator (Obsolete)

Generate function-call events in a time-based manner.

Library

Generators/Function-Call Generators

Description

This block generates function-call events, either once at the start of simulation, using an intergeneration period that you specify in the block dialog box, or using a signal connected to the input port. The intergeneration period is the time interval between two successive generation events.

You can set the **Event generation mode** parameter of the block to one of three values. The block determines the intergeneration period differently for each value of the **Event generation mode** parameter that you choose.

Value of Event generation mode Parameter	Intergeneration Period
Only at simulation start	None, because only one event is generated
Period from dialog	Specified in the Period parameter of the block dialog box
Period from port	Specified using an input signal t that the block reads at the start of the simulation and each time it generates an entity

If you select the configuration parameter **Prevent duplicate events on multiport blocks and branched signals** in your model, the Time-Based Function-Call Generator block is compatible with all other blocks from SimEvents version 4.0 (R2011b), or later.

Ports

Signal Input Ports

Label	Description
t	Time interval between generation of the current function-call event and the next function-call event. You see this port only if you set the Event generation mode parameter to <code>Period from port</code> in the block dialog box. At the start of the simulation and each time the block updates its output signals, the block reads the value at the input port, or if the preceding block is an Event-Based Random Number or Event-Based Sequence block, actively requests an updated input value. The signal connected to the input port must be an event-based signal.

Signal Output Ports

Label	Description
f	Port through which generated function-call signals depart.
#f	Number of function-call events that have been executed by the block. You only see this port if you select the Report number of events executed, #f check box in the block dialog box.

The initial output value — in effect from the start of the simulation until the first update by the block— is 0, for all signals.

Parameters

Event generation mode

Determines the mode that the block uses to generate function-call events.

Period

The time interval between generation of successive function-call events, in seconds. You see this field only if you set the **Event generation mode** parameter to `Period from dialog` in the block dialog box.

Number of simultaneous event repetitions per period

The number of simultaneous function-call events that the block generates in each period. Use this parameter to generate a function-call with multiple iterations.

Report number of events executed, #f

Determines if the number of function-call events that have executed by the block is made available via a signal output port on the block.

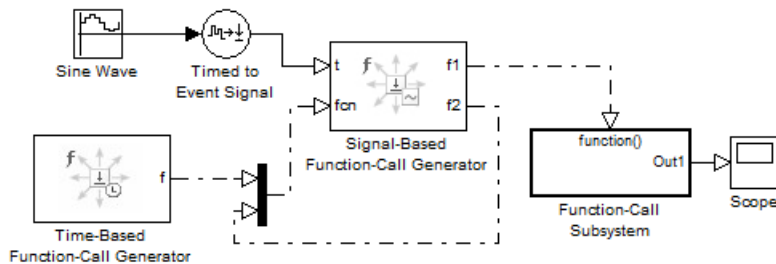

Event priority

The priority of the function-call event relative to other simultaneous events in the simulation.

Examples

Seed Event Generation

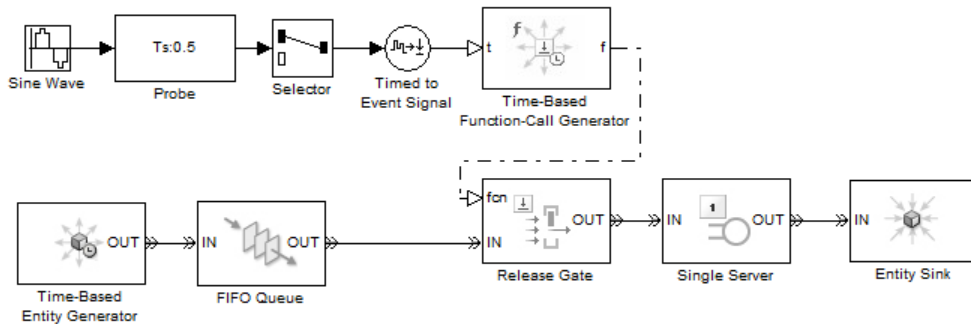

To generate a seed event in your model at simulation time $T=0$, you can use the Time-Based Function-Call Generator block. A seed event is an initial impulse that models with certain block configurations require to update the outputs of their blocks and to start generating events.

In this example, the **Event generation mode** parameter of the Time-Based Function-Call Generator block is set to `Only at simulation start`. At simulation time $T=0$, the Time-Based Function-Call Generator block produces an initial function-call event — or seed event — to the Signal-Based Function-Call Generator block. This seed event causes the Signal-Based Function-Call Generator block to update its outputs. After simulation time $T=0$, the simulation continues to update the outputs of the Signal-Based Function-Call Generator block. The model is now self-sustaining.

Time Synchronization

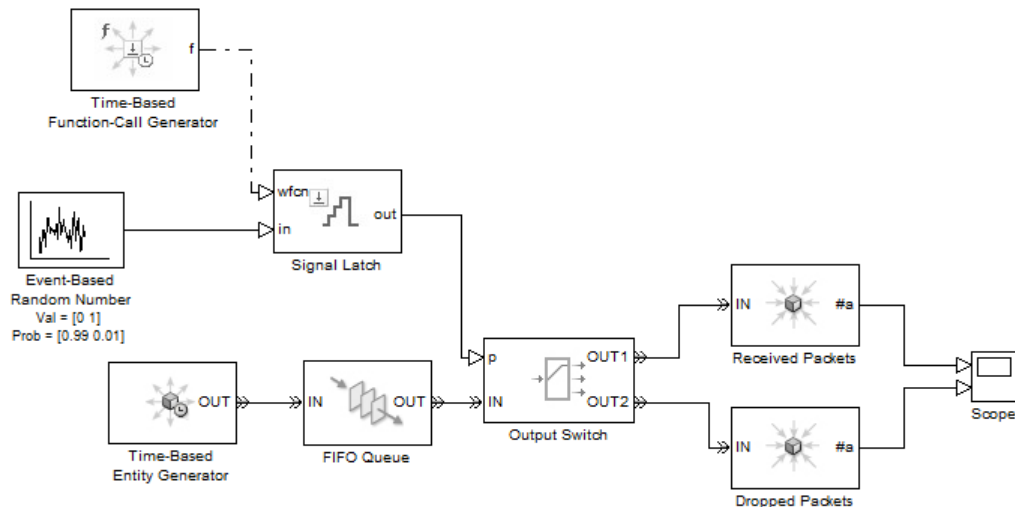

When you want to synchronize events with a time-based process outside the SimEvents domain, use the Time-Based Function-Call Generator block.

In this model, the **Event generation mode** parameter of the Time-Based Function-Call Generator block is set to `Period` from `port`. The Probe block detects the sample time of a sine wave signal and connects it to the input port `t` of the Time-Based Function-Call Generator block. The value at the input port `t` determines the period — or time delay — between successive function-call events generated by the block and is used to control entity advancement through the Release Gate block.

Discrete-Event Model with Statistical Distribution

You can use the Time-Based Function-Call Generator block to model a discrete-event system that is driven by a time-based process drawn from a statistical distribution.

In this model, using a statistical distribution, the Event-Based Random Number block generates random values. The Time-Based Generator block periodically produces a function-call event to store the current output value of the Event-Based Random Number block in the Signal Latch block. This value is used, in turn, to select the output port of the Output Switch block. Based on the statistical distribution specified in this model, the value that is output by the Signal Latch block has a 99% probability of being **1**. When this situation is the case, the *first* output port of the Output Switch block is selected, and an entity advances as a received packet. Conversely, 1% of entities advance as dropped packets.

Introduced in R2012a

Timed to Event Function-Call (Obsolete)

Convert time-based function call to event-based function call

Library

Gateways

Description

This block converts a scalar time-based function call into an event-based function call. The output signal is almost identical to the input signal, except that the output can be an input to a block that requires an event-based function-call input signal.

Ports

Signal Input Ports

Label	Description
None	Time-based function-call signal.

Signal Output Ports

Label	Description
None	Event-based function-call signal.

See Also

Event to Timed Function-Call (Obsolete)

“Time-Based Signals and SimEvents Block Transitions”

Introduced in R2011b

Timed to Event Signal (Obsolete)

Convert time-based signal to event-based signal

Library

Gateways

Description

This block converts a time-based data signal into an event-based data signal. The value of the output signal is identical to that of the input signal. The output signal can be an input to a block that requires an event-based input signal.

Ports

Signal Input Ports

Label	Description
None	Time-based signal. The signal can have any fixed dimension, complexity, or data type.

Signal Output Ports

Label	Description
None	Event-based signal

The initial output value is the same as the initial input value.

“Time-Based Signals and SimEvents Block Transitions”

Introduced in R2011b

X-Y Attribute Scope (Obsolete)

Plot data from two attributes of arriving entities

Library

SimEvents Sinks

Description

This block plots a curve using data from two real scalar-valued attributes of arriving entities. Use the **Y attribute name** and **X attribute name** parameters to specify which attributes to plot.

Use the **Enable entity OUT port** option to choose whether the entity advances to a subsequent block or whether the block absorbs the arriving entity.

The **Plot type** parameter on the **Plotting** tab determines whether and how the block connects the points that it plots.

Ports

Entity Input Ports

Label	Description
IN	Port for arriving entities, whose attributes contain the data to plot.

Entity Output Ports

Label	Description
OUT	Port for departing entities. You see this port only if you select Enable entity OUT port .

Signal Output Ports

Label	Description
#a	Number of entities that have arrived at the block since the start of the simulation.

The initial output value is 0. This value is in effect from the start of the simulation until the first update by the block.

Parameters

To open the block dialog box, click the Parameters toolbar button in the plot window.

Plotting Tab

Plot type

The presentation format for the data.

Y attribute name

Name of the attribute to plot along the vertical axis.

X attribute name

Name of the attribute to plot along the horizontal axis.

Enable entity OUT port

Causes the block to have an entity output port labeled **OUT**, through which the arriving entity departs. If you clear this box, the block absorbs arriving entities.

Open scope at start of simulation

Selecting this option causes the plot window to open when you start the simulation. If you clear this box, you can open the plot window by double-clicking the block icon.

Axes Tab

Initial X axis lower limit, Initial X axis upper limit

The interval shown on the X axis at the beginning of the simulation. The interval might change from this initial setting due to zooming, autoscaling, or the **If X value is beyond limit** setting.

If X value is beyond limit

Determines how the plot changes if one or more X values are not within the limits shown on the X axis.

Initial Y axis lower limit, Initial Y axis upper limit

The interval shown on the Y axis at the beginning of the simulation. The interval might change from this initial setting due to zooming, autoscaling, or the **If Y value is beyond limit** setting.

If Y value is beyond limit

Determines how the plot changes if one or more Y values are not within the limits shown on the Y axis.

Show grid

Toggles the grid on and off.

Figure Tab

Title

Text that appears as the title of the plot, above the axes.

Y label

Text that appears to the left of the vertical axis.

X label

Text that appears below the horizontal axis.

Figure Position

A four-element vector of the form `[left bottom width height]` specifying the position of the scope window. (0,0) is the lower left corner of the display.

Show number of entities

Displays the number of plotted points using an annotation in the plot window.

Data History Tab

Store data when scope is closed

Select `Unlimited` to have the block cache all data for future viewing, `Limited` to cache a portion of the most recent data, and `Disabled` to avoid caching undisplayed data.

Limit data points to

The number of data points the block caches, using the most recent data. You see this field only if you set **Store data when scope is closed** to *Limited*.

Statistics Tab

Number of points plotted

Allows you to use the signal output port labeled **#a**.

Examples

This section is not available for prerelease.

X-Y Signal Scope (Obsolete)

Plot data from two signals

Library

SimEvents Sinks

Description

The **Plot type** parameter on the **Plotting** tab determines whether and how the block connects the points that it plots.

Ports

Signal Input Ports

Label	Description
in	Signal containing data for Y axis. This signal must be an event-based signal.
x	Signal containing data for X axis. This signal must be an event-based signal.

Signal Output Ports

Label	Description
#c	Number of points the block has plotted.

The initial output value is 0. This value is in effect from the start of the simulation until the first update by the block.

Parameters

Plotting Tab

Plot type

The presentation format for the data.

Open scope at start of simulation

Selecting this option causes the plot window to open when you start the simulation. If you clear this box, you can open the plot window by double-clicking the block icon.

Axes Tab

Initial X axis lower limit, Initial X axis upper limit

The interval shown on the X axis at the beginning of the simulation. The interval might change from this initial setting due to zooming, autoscaling, or the **If X value is beyond limit** setting.

If X value is beyond limit

Determines how the plot changes if one or more X values are not within the limits shown on the X axis.

Initial Y axis lower limit, Initial Y axis upper limit

The interval shown on the Y axis at the beginning of the simulation. The interval might change from this initial setting due to zooming, autoscaling, or the **If Y value is beyond limit** setting.

If Y value is beyond limit

Determines how the plot changes if one or more Y values are not within the limits shown on the Y axis.

Show grid

Toggles the grid on and off.

Figure Tab

Title

Text that appears as the title of the plot, above the axes.

Y label

Text that appears to the left of the vertical axis.

X label

Text that appears below the horizontal axis.

Figure Position

A four-element vector of the form `[left bottom width height]` specifying the position of the scope window. (0,0) is the lower left corner of the display.

Show number of points

Displays the number of plotted points using an annotation in the plot window.

Data History Tab

Store data when scope is closed

Select `Unlimited` to have the block cache all data for future viewing, `Limited` to cache a portion of the most recent data, and `Disabled` to avoid caching undisplayed data.

Limit data points to

The number of data points the block caches, using the most recent data. You see this field only if you set **Store data when scope is closed** to `Limited`.

Statistics Tab

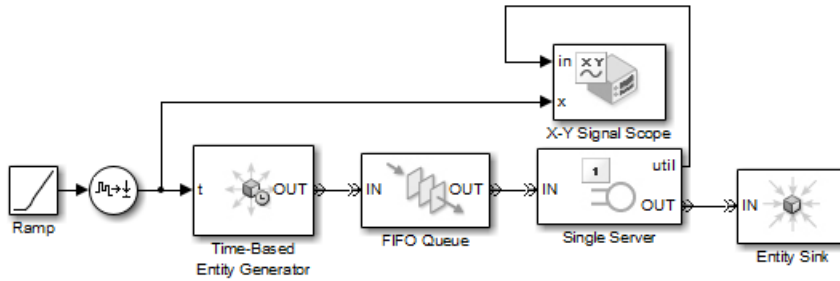

These parameters determine whether the block produces data at signal output ports or omits those ports. For descriptions of the data and ports, see the preceding table, “Signal Output Ports”.

Number of points plotted, #c

Allows you to use the signal output port labeled **#c**.

Examples

The model below shows the relationship between the utilization of a server and the interarrival time of entities.

Signal Scope (Obsolete), X-Y Attribute Scope (Obsolete)

Introduced before R2006a

Conveyor System

Transport entities

Library: Other

Description

The Conveyor System block transports entities across a surface. Use this block to model transportation applications.

When using the **Conveyor length**, **Conveyor speed**, **Minimum distance between entities**, and **Entity length value** parameters, ensure that the values are consistent with each other. For example, if you want an entity length of 10 cm using a conveyor system of length 100 m, use these values:

- **Conveyor length** to 100
- **Entity length** to 0.1

Ports

Input

port_1 — Incoming entity

scalar

Input entity port for entities entering the queue.

Data Types: bus

Output

port_1 — Exiting entity

scalar

Output entity port for entities leaving the queue

Data Types: `bus`

d — Number of exited entities

off (default) | on

Selecting this check box outputs the number of entities that have exited the block.

Dependencies

To enable this port, select the **Statistics > Number of entities departed, d** check box.

Data Types: `double`

n — Entities in block

off (default) | on

Selecting this check box outputs the number of entities in the block.

Dependencies

To enable this block, select the **Statistics > Number of entities in block, n** check box.

Data Types: `double`

pe — Pending entity in block

off (default) | on

Selecting this check box outputs the number of pending entities in the conveyor system.

Dependencies

To enable this port, select the **Statistics > Pending entity in block, pe**.

Data Types: `double`

Parameters

Conveyor length — Length of surface

100 (default) | numeric

Length of surface that entities travel on.

Conveyor speed — Speed of surface

1000 (default) | numeric

Speed of surface that entities travel on.

Minimum distance between entities — Minimum physical separation

0 (default) | numeric

Minimum physical separation entities maintain while moving across the conveyor system.

Entity length source — Entity length source

Dialog (default) | Attribute

Provide entity length, selected from the drop-down list.

Dependencies

- Dialog — Selecting this option enables the **Entity length value** parameter.
- Attribute — Selecting this option enables the **Entity length attribute name** parameter.

Entity length value — Length of entities

0.1 (default) | numeric

Length of entities, specified as a numeric value.

Dependencies

To enable this parameter, select **Entity length value**Dialog.

Entity length attribute name — Name of entity length attribute

Length (default) | character vector

Name of entity length attribute, specified as a character vector.

Blocked output behavior — Behavior when the output is blocked

Accumulate (default) | Pause Error

Behavior when output is blocked, selected from drop-down list:

- Accumulate — Accumulate entities.

- `Pause` — Pause conveyor system.
- `Error` — Return an error.

Error if conveyor full — Conveyor behavior when the maximum number of entities is reached

`on` (default) | `off`

Conveyor behavior when system is full.

`on`

Return an error if the conveyor system is full.

`off`

Do not return an error if the conveyor system is full.

Simulate using — Simulate using specified mode

Interpreted execution (default) | code generation

Select the simulation mode.

Code generation

On the first model run, simulate and generate code for using only MATLAB functions supported for code generation. If the structure of the block does not change, subsequent model runs do not regenerate the code.

Interpreted execution

Simulate model using all supported MATLAB functions. Choosing this option can slow simulation performance.

Number of entities departed, `d` — Number of entities departed

`off` (default) | `on`

Number of entities that have departed the block.

Number of entities in block, `n` — Number of existing entities

`off` (default) | `on`

Outputs the number of entities present in the block.

Pending entity in block, `pe` — Pending entities

`off` (default) | `on`

Indicates whether there are entities present in the block that have yet to depart.

Configuration Parameters

- “SimEvents Pane” on page 3-2
- “SimEvents Diagnostics Pane” on page 3-8

SimEvents Pane

Note These configuration parameters are obsolete. They are available only for SimEvents releases prior to R2016a.

In this section...

“SimEvents Pane Overview” on page 3-2

“Execution order” on page 3-3

“Seed for event randomization” on page 3-4

“Maximum events per block” on page 3-5

“Maximum events per model” on page 3-5

“Prevent duplicate events on multiport blocks and branched signals” on page 3-6

SimEvents Pane Overview

Note These configuration parameters are obsolete. They are available only for SimEvents releases prior to R2016a.

Configure modelwide parameters related to discrete-event simulation and the logging of events and entities.

Configuration

This pane appears only if your model contains a SimEvents block.

Execution order

Note These configuration parameters are obsolete. They are available only for SimEvents releases prior to R2016a.

Select an algorithm for determining the sequence for processing simultaneous events having equal priorities.

Settings

Default: Arbitrary

Arbitrary

Causes the simulation to use an internal algorithm to determine the sequence for processing simultaneous events having equal priorities.

Randomized

Causes the simulation to assign equal probability to all possible execution sequences of simultaneous events having equal numerical priorities.

Tip

The processing sequence might be different from the sequence in which the events were scheduled on the event calendar.

Dependency

Selecting Randomized enables **Seed for event randomization**.

Command-Line Information

Parameter: propIdentEvents

Type: double

Value: 0 | 1

Default: 0

Seed for event randomization

Note These configuration parameters are obsolete. They are available only for SimEvents releases prior to R2016a.

Initialize the random number generator for event processing.

Settings

Default: 123456789

Minimum: 0

Maximum: $2^{31}-1$

This is a number that initializes the random number generator used to determine the sequence for processing simultaneous events having equal priorities.

Tips

- For a given value of this parameter, the output of the random number generator is repeatable.
- To avoid unexpected correlations, make the value of this parameter distinct from all other seed parameters in the model (for example, the **Initial seed** parameter in the Event-Based Random Number block).

Dependency

This parameter is enabled by **Execution order**.

Command-Line Information

Parameter: propIdentEventSeed

Type: string

Value:

Default: '123456789'

Maximum events per block

Note These configuration parameters are obsolete. They are available only for SimEvents releases prior to R2016a.

Limit the number of entity generation, service completion, subsystem execution, and function-call events that each SimEvents block performs at each fixed time instant.

Settings

Default: 1000

Minimum: 2

Maximum: $2^{31}-1$

Command-Line Information

Parameter: propMaxDesBlkSimulEvents

Type: string

Value:

Default: '1000'

Maximum events per model

Note These configuration parameters are obsolete. They are available only for SimEvents releases prior to R2016a.

Limit the total number of events scheduled via the event calendar at each fixed time instant. This is the maximum number of events per discrete-event system in a model.

Settings

Default: 100000

Minimum: 2

Maximum: $2^{31}-1$

Command-Line Information

Parameter: propMaxDesMdlSimulEvents

Type: string

Value:

Default: '100000'

Prevent duplicate events on multiport blocks and branched signals

Note These configuration parameters are obsolete. They are available only for SimEvents releases prior to R2016a.

Prevent multifiring behavior on multiport blocks or branched signals that results in duplication of events. Multifiring behavior, an implicit result of the way that the software executes particular block configurations, occurs when the software executes a block more than once in response to a single, discrete event in the simulation.

Settings

Default: On

On

Enable **Prevent duplicate events on multiport blocks and branched signals** parameter to prevent multifiring behavior.

Off

Allow multifiring behavior on multiport blocks or branched signals.

Command-Line Information

Parameter: propPreventDuplicateEvents

Type: integer or boolean

Value:

Default: '1' for integer, 'True' for boolean

More About

- “SimEvents Diagnostics Pane” on page 3-8

SimEvents Diagnostics Pane

Note These configuration parameters are obsolete. They are available only for SimEvents releases prior to R2016a.

In this section...

“Diagnostics Pane Overview” on page 3-8

“Attribute output delayed relative to entities” on page 3-9

“Response to function call delayed relative to entities” on page 3-10

“Statistical output delayed relative to entities” on page 3-12

“Modification of attribute values used for decision making” on page 3-13

“Identical seeds for random number generators” on page 3-15

Diagnostics Pane Overview

Note These configuration parameters are obsolete. They are available only for SimEvents releases prior to R2016a.

Specify what diagnostic action the application should take, if any, when it detects situations that might cause problems or unexpected results in the simulation.

Configuration

This pane appears only if your model contains a SimEvents block.

Tips

- The options are typically to do nothing or to display a warning or an error message.
- A warning does not terminate a simulation, but an error does.

Attribute output delayed relative to entities

Note These configuration parameters are obsolete. They are available only for SimEvents releases prior to R2016a.

Select the diagnostic action to take if the application detects a situation in which a Get Attribute block updates a signal during entity advancement, but a subsequent block responds to the signal update after the entity has arrived. The application's processing sequence might cause the latter block to process the entity using outdated signal values.

Settings

Default: error

none

The application does not check for this situation.

warning

When the application detects this situation, it displays a warning.

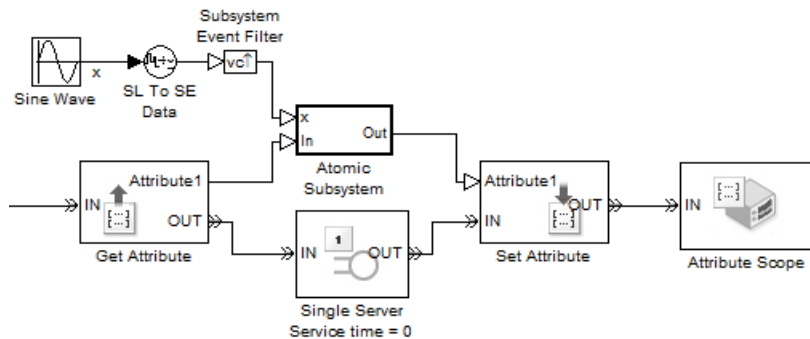

error

When the application detects this situation, it terminates the simulation and displays an error message.

Tip

A Single Server block whose **Service time** parameter is 0 can address the problem by storing the entity while the latter block responds to the signal update.

Example 3.1. Example of Solution

Alternatively, you might be able to address the problem by using an attribute directly instead of by using the signal output of a Get Attribute block.

Command-Line Information

Parameter: propDiagAttribOutput

Type: double

Value: 0 | 1 | 2

Default: 2

Recommended Settings

Application	Setting
Debugging	warning or error
Efficiency	none

Response to function call delayed relative to entities

Note These configuration parameters are obsolete. They are available only for SimEvents releases prior to R2016a.

Select the diagnostic action to take if the application detects a situation in which a block issues a function call during entity advancement, but subsequent blocks respond to the function call and its consequences after the entity has arrived. The application's processing sequence might cause subsequent blocks to process the entity using outdated values of a signal whose update is a consequence of the function call.

Settings

Default: error

none

The application does not check for this situation.

warning

When the application detects this situation, it displays a warning.

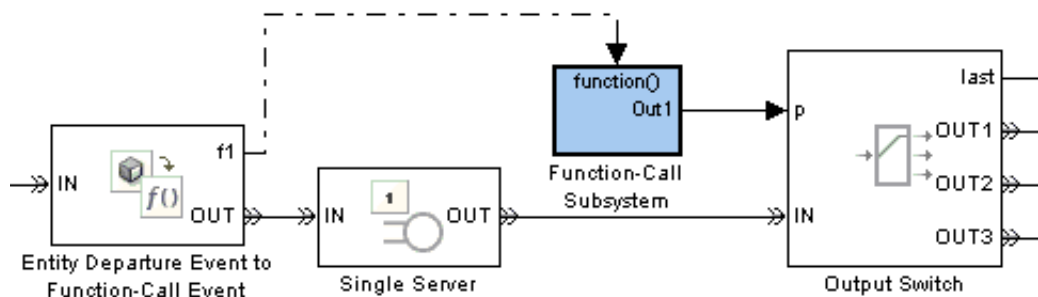

error

When the application detects this situation, it terminates the simulation and displays an error message.

Tip

A Single Server block whose **Service time** parameter is 0 can address the problem by storing the entity while subsequent blocks respond to the function call and its consequences.

Example 3.2. Example of Solution

Command-Line Information

Parameter: propDiagFcnCallOutput

Type: double

Value: 0 | 1 | 2

Default: 2

Recommended Settings

Application	Setting
Debugging	warning or error
Efficiency	none

Statistical output delayed relative to entities

Note These configuration parameters are obsolete. They are available only for SimEvents releases prior to R2016a.

Select the diagnostic action to take if the application detects a situation in which a block updates a statistical output signal during entity advancement, but a subsequent block responds to the signal update after the entity has arrived. The application's processing sequence might cause the latter block to process the entity using outdated signal values.

Settings

Default: error

none

The application does not check for this situation.

warning

When the application detects this situation, it displays a warning.

error

When the application detects this situation, it terminates the simulation and displays an error message.

Tip

A Single Server block whose **Service time** parameter is 0 can address the problem by storing the entity while the latter block responds to the signal update.

Example 3.3. Example of Solution

Command-Line Information

Parameter: propDiagStatOutput

Type: double

Value: 0 | 1 | 2

Default: 1

Recommended Settings

Application	Setting
Debugging	warning or error
Efficiency	none

Modification of attribute values used for decision making

Note These configuration parameters are obsolete. They are available only for SimEvents releases prior to R2016a.

Select the diagnostic action to take if the application detects certain situations in which a block modifies an attribute that a subsequent block uses to determine its availability. In some of these cases, internal queries among blocks might result in a decision based on information that changes when the entity actually advances.

Settings

Default: error

none

The application does not check for this situation.

warning

When the application detects this situation, it displays a warning.

error

When the application detects this situation, it terminates the simulation and displays an error message.

Tip

A Single Server block whose **Service time** parameter is 0 can address the problem by storing the entity while the latter block responds to the signal update.

Example 3.4. Example of Solution

Command-Line Information

Parameter: propDiagChangeAttrib

Type: double

Value: 0 | 1 | 2

Default: 2

Recommended Settings

Application	Setting
Debugging	warning or error
Efficiency	none

Identical seeds for random number generators

Note These configuration parameters are obsolete. They are available only for SimEvents releases prior to R2016a.

Select the diagnostic action to take if the application detects that multiple random number generators use the same seed value, which might cause correlations among random processes.

Settings

Default: warning

none

The application does not check for this situation.

warning

When the application detects this situation, it displays a warning.

error

When the application detects this situation, it terminates the simulation and displays an error message.

Tips

- If you set the parameter to `warning`, the warning message contains hyperlinks labeled “Randomize” and “Randomize All” that can help you address the problem.
- The `se_randomizeseeds` function provides a programmatic way to address the problem.
- Set the parameter to `none` if duplicate seeds are intentional in your model.

Command-Line Information

Parameter: `propRNGIdenticalSeeds`

Type: double

Value: 0 | 1 | 2

Default: 1

Recommended Settings

Application	Setting
Debugging	warning or error
Efficiency	none

Upgrade Advisor Checks

SimEvents Upgrade Advisor Checks

Note These checks are obsolete. They are available only for SimEvents releases prior to R2016a.

In this section...
“Checks Overview” on page 4-2
“Check for implicit event duplication caused by SimEvents blocks” on page 4-2

Checks Overview

Note These checks are obsolete. They are available only for SimEvents releases prior to R2016a.

Use SimEvents Upgrade Advisor checks to identify backward-compatibility issues in your model.

Check for implicit event duplication caused by SimEvents blocks

Note These checks are obsolete. They are available only for SimEvents releases prior to R2016a.

Check configuration parameters of model for status of **Prevent duplicate events on multiport blocks and branched signals** option.

Description

This Upgrade Advisor check verifies if you have selected the **Prevent duplicate events on multiport blocks and branched signals** check box in the Configuration Parameters dialog box of your model.

When you run a model created in a version of SimEvents prior to R2012a, the model might exhibit a behavior called multifiring that leads to duplication of events in the simulation. This event duplication behavior is implicit in models with certain

configurations and results from the way the software executes the blocks of such configurations. Implicit event duplication is resolved in R2012a with the addition of the configuration parameter **Prevent duplicate events on multiport blocks and branched signals**.

Available with SimEvents.

Results and Recommended Actions

Condition	Recommended Action
SimEvents > Prevent duplicate events on multiport blocks and branched signals check box is not selected.	In the Configuration Parameters dialog box of your model, select the SimEvents > Prevent duplicate events on multiport blocks and branched signals check box.

An alternative to the recommended action in the preceding table is to use the **Modify Settings** button in the **Action** section of the Upgrade Advisor results pane. If you click **Modify Settings**, the software directly enables **Prevent duplicate events on multiport blocks and branched signals**.

Note The configuration parameter **Prevent duplicate events on multiport blocks and branched signals** is not compatible with blocks from versions of SimEvents prior to 4.0 (R2011b). The Upgrade Advisor provides the recommended action (if any) for the check, “Check for implicit event duplication caused by SimEvents blocks” on page 4-2.

More About

- “Consult the Upgrade Advisor” (Simulink)

SimEvents Terminology

advance	To depart from one block and arrive immediately at another block. An entity advances from block to block during a simulation.
arrival	Entrance of an entity to a block via an entity input port. Arrival is the opposite of departure.
attribute	Data associated with an entity. For example, an entity might be associated with a size, weight, speed, or part number.
available	The state of an entity input port that permits entities to arrive at the block. For example, when a Entity Server block is empty, its entity input port is available. When the block is busy serving, its entity input port is unavailable.
blocked	The state of an entity output port when an entity is trying to depart via the port and the port connects to an unavailable entity input port of another block. For example, consider a Entity Queue block whose entity output port is connected to the Entity Server block's entity input port. Suppose the queue contains one entity. The queue's entity output port is blocked if the server's entity input port is unavailable, and not blocked if the server's entity input port is available. If the queue is empty, then its entity output port is not blocked because no entity is trying to depart.
component entity	An entity that forms part of a composite entity.
composite entity	An entity that comprises one or more entities as subordinate parts. The parts are called component entities.
departure	Exit of an entity from a block via an entity output port. Departure is the opposite of arrival.

discrete-event system

A system in which state transitions depend on asynchronous discrete incidents called events. You typically construct a discrete-event system by adding a variety of blocks, such as generators, queues, and servers, from the SimEvents block library.

One or more discrete-event systems can coexist with time-based systems in a Simulink model. SimEvents software automatically handles signals transitioning from time-based components/systems to and from discrete-event components/systems and labels these signal lines with a capital **E**.

entity

An abstract representation of an item of interest in a discrete-event simulation. The specific interpretation of an entity depends on what you are modeling. Entities can carry data, known as attributes.

For example, an entity could represent a packet in a communication network, a person using a bank of elevators, or a part on a conveyor belt.

entity input port

An input port at which an entity can potentially arrive. An entity input port can be available or unavailable; this state, which can change during the simulation, helps determine whether the port actually accepts the arrivals of new entities.

entity output port

An output port from which an entity can potentially depart. An entity output port can have a state of blocked or not blocked; this state, which can change during the simulation, determines whether the port's attempt to output an entity is successful.

entity path

A connection from an entity output port to an entity input port, depicted as a line connecting the entity ports of two blocks. An entity path represents the equivalence between an entity's departure from the first block and arrival at the second block. The connection line depicts a relationship between the two blocks.

	<p>An entity path is in active use by an entity only at zero or more discrete times during the simulation. By contrast, a connection line between signal ports represents a signal that has a well-defined value at all times during the simulation.</p>
entity port	<p>An entity input port or an entity output port.</p>
entity priority	<p>A positive number associated with an entity, used to sequence its departure with regard to other simultaneous departures. A lower number indicates a higher priority.</p>
event	<p>An observation of an instantaneous incident that may change a state variable, an output, and/or the occurrence of other events. Examples of events are the generation of a new data packet in communications, the exit of a person from an elevator, and the placement of a new part on a conveyor belt.</p>
event calendar	<p>The internal list of events that are scheduled for the current time or future times.</p> <p>For example, when a server begins its service time on a specific entity, the application inserts an entry into the event calendar for the completion of service on that entity at a future time. In a system representing elevator passengers, this event calendar entry might represent the event whereby a specific person in an elevator reaches the desired floor.</p>
event-based simulation	<p>A simulation that permits the system's state transitions to depend on asynchronous discrete incidents called events.</p>
intergeneration time	<p>The time interval between successive generations.</p>
pending entity	<p>An entity that has tried and failed to depart from the block in which the entity resides. The failure occurs because the entity output port through which the entity would depart is connected to an unavailable entity input port of another block.</p>

preemption	The replacement of an entity in a server block by an entity that satisfies certain criteria.
signal port	An input or output port that represents a numerical quantity that changes over time and that is defined for all times during the simulation. Unlike an entity port, a signal port has no state and does not have entity arrivals or entity departures.
simultaneous events	<p>Events that occur at the same value, or sufficiently close values, of the simulation clock. Events scheduled on the event calendar for times T and $T+\Delta t$ are considered simultaneous if $0 \leq \Delta t \leq 128 * \text{eps} * T$, where eps is the floating-point relative accuracy in MATLAB software and T is the simulation time.</p> <p>For example, in a D/D/1 queuing system where the arrival rate equals the service rate, an entity generation event and a service completion event are simultaneous. Parameters in the model determine which of these events occurs first, though the clock has the same value in both cases.</p>
time-based signal	A signal that can change only in response to the simulation clock.
time-based simulation	<p>A simulation in which state transitions depend on time.</p> <p>For example, a simulation based solely on differential equations in which time is an independent variable is a time-based simulation.</p>
unavailable	<p>The state of an entity input port that prevents entities from arriving at the block.</p> <p>For example, when an Entity Server block is empty, its entity input port is available. When the block is busy serving, its entity input port is unavailable.</p>
zero-duration value	A value that an event-based signal assumes at an instant in time but that does not persist for a positive duration.

For example, when a full N-server advances one entity to the next block, the statistical signal representing the number of entities in the block assumes the value N-1. However, if the departure causes another entity to arrive at the block at the same time instant, then the statistical signal assumes the value N. The value of N-1, which does not persist for a positive duration, is a zero-duration value.. This phenomenon occurs in many situations.
