Blocks — Alphabetical List

Abs

Output absolute value of input

Library

Math Operations

Description

The Abs block outputs the absolute value of the input.

For signed-integer data types, the absolute value of the most negative value is not representable by the data type. In this case, the **Saturate on integer overflow** check box controls the behavior of the block:

If you...	The block...	And...
Select this check box	Saturates to the most positive value of the integer data type	<ul style="list-style-type: none"> For 8-bit signed integers, -128 maps to 127. For 16-bit signed integers, -32768 maps to 32767. For 32-bit signed integers, -2147483648 maps to 2147483647.
Do not select this check box	Wraps to the most negative value of the integer data type	<ul style="list-style-type: none"> For 8-bit signed integers, -128 remains -128. For 16-bit signed integers, -32768 remains -32768. For 32-bit signed integers, -2147483648 remains -2147483648.

The Abs block supports zero-crossing detection. However, when you select **Enable zero-crossing detection** on the dialog box, the block does not report the simulation

minimum or maximum in the Fixed-Point Tool. If you want to use the Fixed-Point Tool to analyze a model, disable zero-crossing detection for all Abs blocks in the model first.

Data Type Support

The Abs block accepts real signals of the following data types:

- Floating point
- Built-in integer
- Fixed point

The block also accepts complex floating-point inputs. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Enable zero-crossing detection

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1 . To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Output minimum

Specify the minimum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Output maximum

Specify the maximum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Output data type

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” in *Simulink User's Guide* for more information.

Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer). in the Fixed-Point Designer™ documentation.

Saturate on integer overflow

Action	Reason for Taking This Action	What Happens	Example
Select this check box.	Your model has possible overflow and you want explicit saturation protection in the generated code.	Overflows saturate to the maximum value that the data type can represent.	The number 130 does not fit in a signed 8-bit integer and saturates to 127.
Do not select this check box.	You want to optimize efficiency of your generated code.	Overflows wrap to the appropriate value that is representable by the data type.	The number 130 does not fit in a signed 8-bit integer and wraps to -126.

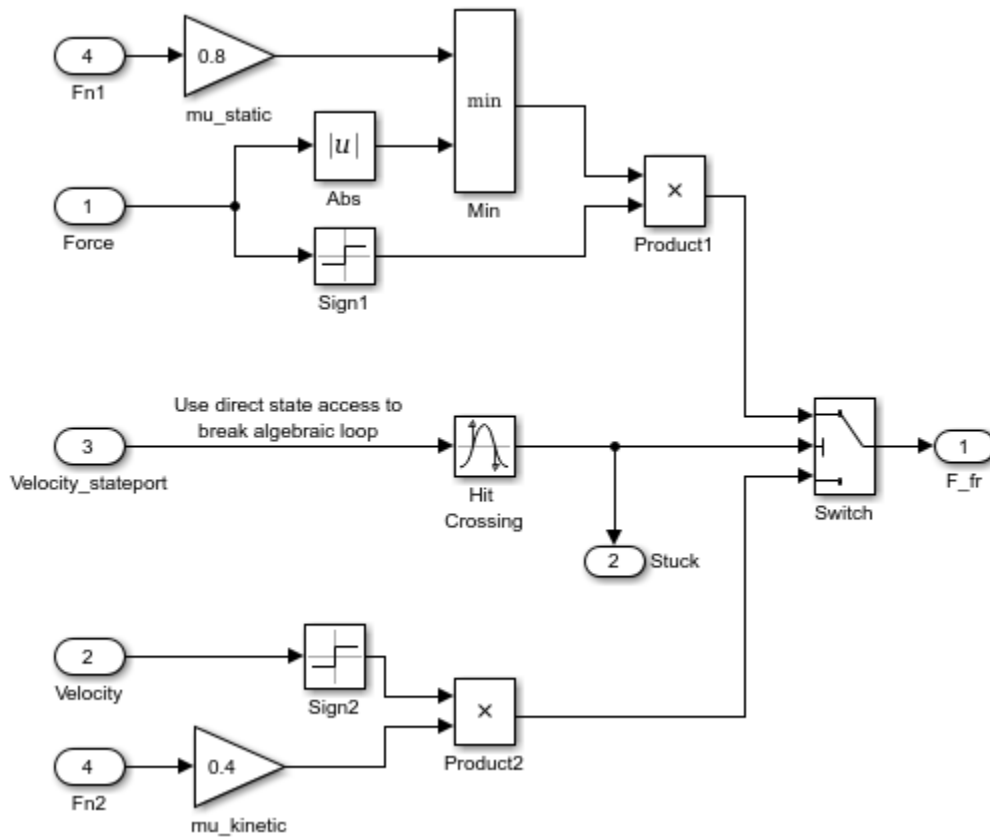

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Examples

Usage as an Input to a MinMax Block

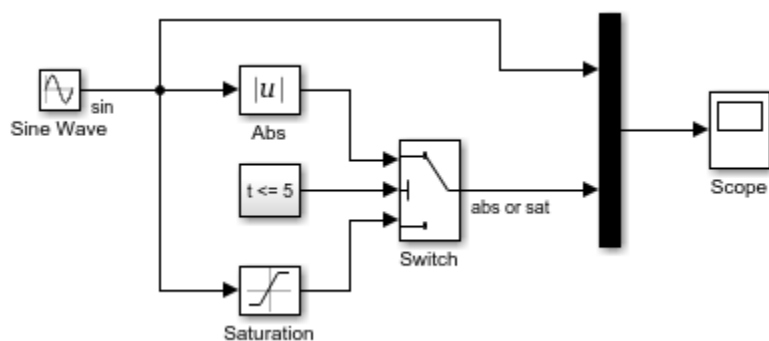

The `sldemo_hardstop` model shows how you can use the Abs block as an input to the MinMax block.

In the `sldemo_hardstop` model, the Abs block is in the Friction Model subsystem.

Usage as an Input to a Switch Block

The `sldemo_zeroring` model shows how you can use the `Abs` block as an input to the `Switch` block.

Characteristics

Data Types	Double Single Base Integer Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	Yes, if enabled
Code Generation	Yes

Introduced before R2006a

Action Port

Implement Action subsystems used in `if` and `switch` control flow statements

Library

Ports & Subsystems

Description

Action Port blocks implement action subsystems used in `if` and `switch` control flow statements. The If Action Subsystem and the Switch Case Action Subsystem blocks each contain an Action Port block.

Data Type Support

Action Port blocks do not have data inputs or outputs.

Parameters

- “States when execution is resumed” on page 1-8
- “Propagate sizes of variable-size signals” on page 1-10

States when execution is resumed

Specify how to handle internal states when a subsystem with an Action Port block reenables.

Default: held

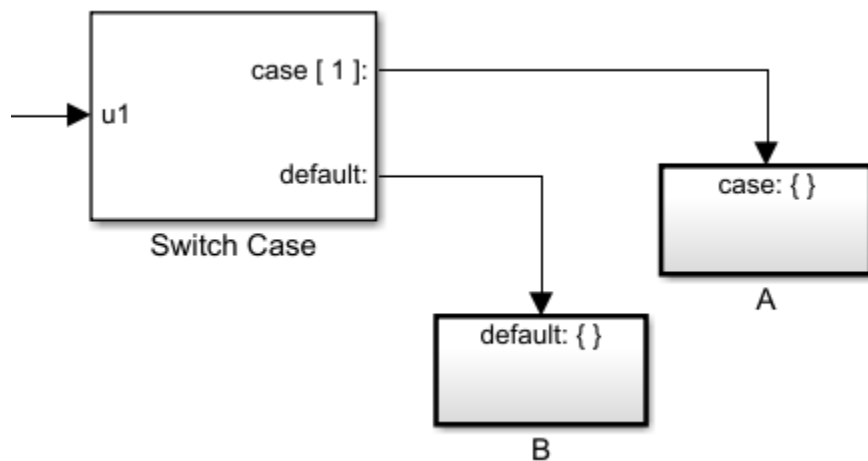

held

When the subsystem reenables, retains the states of the Action subsystem with their previous values. Retains the previous values of states between calls even if calling other member Action subsystems of an if-else or switch control flow statement.

reset

Reinitializes the states of the Action subsystem to initial values when the subsystem reenables.

Reenablement of a subsystem occurs when called and the condition of the call is true after having been previously false. In the following example, the Action Port blocks for both Action subsystems A and B have the **States when execution is resumed** parameter set to reset.

If case[1] is true, call Action subsystem A. This result implies that the default condition is false. When later calling B for the default condition, its states are reset. In the same way, Action subsystem A states are reset when calling A right after calling Action subsystem B.

Repeated calls to the Action subsystem of a case does not reset its states. If calling A again right after a previous call to A, this action does not reset the states of A. This behavior is because the condition of case[1] was not previously false. The same applies to B.

Parameter: InitializeStates

Type: character vector

Value: 'held' | 'reset' |

Default: 'held'

Propagate sizes of variable-size signals

Specify when to propagate a variable-size signal.

Default: Only when execution is resumed

Only when execution is resumed

Propagates variable-size signals only when reenabling the subsystem containing the Action Port block.

During execution

Propagates variable-size signals at each time step.

Parameter: PropagateVarSize

Type: character vector

Value: 'Only when execution is resumed' | 'During execution'

Default: 'Only when execution is resumed'

Characteristics

Sample Time	Inherited from driving If or Switch Case block
-------------	--

Algebraic Constraint

Constrain input signal

Library: Simulink / Math Operations

Description

The Algebraic Constraint block constrains the input signal $f(z)$ to z or 0 and outputs an algebraic state z . The block outputs a value that produces 0 or z at the input. The output must affect the input through a direct feedback path. In other words, the feedback path only contains blocks with direct feedthrough. For example, you can specify algebraic equations for index 1 differential-algebraic systems (DAEs).

Ports

Input

$f(z)$ — Input signal

real scalar or vector

Signal is subjected to the constraint $f(z) = 0$ or $f(z) = z$ to solve the algebraic loop.

Data Types: double

Output

z — Output state

real scalar or vector

Solution to the algebraic loop when the input signal $f(z)$ is subjected to the constraint $f(z) = 0$ or $f(z) = z$.

Data Types: double

Parameters

Constraint — Constraint on input signal

$f(z) = 0$ (default) | $f(z) = z$

Type of constraint for which to solve. You can Choice to solve for $f(z) = 0$ or $f(z) = z$

Solver — Algebraic Loop Solver

auto (default) | Trust Region | Line Search

Choice between the Trust Region [1], [2] or Line Search [3] algorithms to solve the algebraic loop. By default this value is set to `auto`, which selects the solver based on the model configuration

Tolerance — Solver Tolerance

auto (default) | positive scalar

This option is visible when you explicitly specify a solver to be used (Trust region or Line Search) in the **Solver** dropdown menu. Specify a smaller value for higher accuracy or a larger value for faster execution. By default it is set to `auto`.

Initial Guess — Initial guess of solution value

0 (default) | scalar

Initial guess for the algebraic state z that is close to the expected solution value to improve the efficiency of the algebraic loop solver. By default, this value is set to 0

Model Examples

Block Characteristics

Data Types	double
Multidimensional Signals	No
Variable-Size Signals	No

Argument Inport

Argument input port for Simulink Function block

Description

This block is an input argument port for a function that you define in the Simulink Function block.

Data Type Support

The Argument Inport block accepts complex or real signals of any data type that Simulink supports, including fixed-point and enumerated data types. The Argument Inport block also accepts a bus object as a data type.

The numeric and data types of the block output are the same as those of its input. You can specify the signal type and data type of an input argument to an Argument Inport block using the **Signal type** and **Data type** parameters. For more information, see “Data Types Supported by Simulink”.

Parameters

- “Port number” on page 1-15
- “Argument Name” on page 1-15
- “Minimum” on page 1-16
- “Maximum” on page 1-16

- “Data type” on page 1-17
- “Show data type assistant” on page 1-18
- “Mode” on page 1-18
- “Data type override” on page 1-20
- “Signedness” on page 1-20
- “Word length” on page 1-21
- “Scaling” on page 1-21
- “Fraction length” on page 1-22
- “Slope” on page 1-22
- “Bias” on page 1-23
- “Output as nonvirtual bus” on page 1-23
- “Lock data type settings against changes by the fixed-point tools” on page 1-24
- “Port dimensions” on page 1-24
- “Signal type” on page 1-24

Port number

Specify the port number of the block.

Default: 1

This parameter controls the order in which the port that corresponds to the block appears in the parent subsystem or model block.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Argument Name

Default: u

This parameter provides the name of the input argument in the function prototype of the Simulink Function block.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Minimum

Specify the minimum value for the block to output.

Default: [] (unspecified)

This number must be a finite real double scalar value.

Note If you specify a bus object as the data type for this block, do not set the minimum value for bus data on the block. Simulink ignores this setting. Instead, set the minimum values for bus elements of the bus object specified as the data type. For information on the Minimum property of a bus element, see `Simulink.BusElement`.

Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Maximum

Specify the maximum value for the block to output.

Default: [] (unspecified)

This number must be a finite real double scalar value.

Note If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For information on the Maximum property of a bus element, see `Simulink.BusElement`.

Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Data type

Specify the output data type of the argument input.

Default: double

double

Data type is double.

single

Data type is single.

int8

Data type is int8.

uint8

Data type is uint8.

int16

Data type is int16.

uint16

Data type is uint16.

int32

Data type is int32.

uint32

Data type is uint32.

boolean

Data type is boolean.

`fixdt(1,16,0)`

Data type is fixed point `fixdt(1,16,0)`.

`fixdt(1,16,2^0,0)`

Data type is fixed point `fixdt(1,16,2^0,0)`.

Enum: `<class name>`

Data type is enumerated, for example, Enum: `Basic Colors`.

Bus: `<object name>`

Data type is a bus object.

`<data type expression>`

The name of a data type object, for example `Simulink.NumericType`

Do not specify a bus object as the expression.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Show data type assistant

Display the **Data Type Assistant**.

The **Data Type Assistant** helps you set the **Output data type** parameter.

For more information, see “Control Signal Data Types”.

Mode

Select the category of data to specify.

Default: `Built in`

`Built in`

Built-in data types. Selecting `Built in` enables a second text box to the right. Select one of the following:

- `double` (default)

- single
- int8
- uint8
- int16
- uint16
- int32
- uint32
- boolean

Fixed point

Fixed-point data types.

Enumerated

Enumerated data types. Selecting `Enumerated` enables a second menu/text box to the right, where you can enter the class name.

Bus object

Bus object. Selecting `Bus` enables a **Bus object** parameter to the right, where you enter the name of a bus object that you want to use to define the structure of the bus. If you need to create or change a bus object, click **Edit** to the right of the **Bus object** field to open the Simulink Bus Editor. For details, see “Create Bus Objects with the Bus Editor”.

Expression

Expressions that evaluate to data types. Selecting `Expression` enables a second menu/text box to the right, where you can enter the expression.

Do not specify a bus object as the expression.

Clicking the **Show data type assistant** button enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

For more information, see “Specify Data Types Using Data Type Assistant”.

Data type override

Specify data type override mode for this signal.

Default: `Inherit`

`Inherit`

Inherits the data type override setting from its context, that is, from the block, `Simulink.Signal` object or Stateflow® chart in Simulink that is using the signal.

`Off`

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

This parameter appears only when the **Mode** is `Built in` or `Fixed point`.

Signedness

Specify whether you want the fixed-point data as signed or unsigned.

Default: `Signed`

`Signed`

Specify the fixed-point data as signed.

`Unsigned`

Specify the fixed-point data as unsigned.

Selecting **Mode** > `Fixed point` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Word length

Specify the bit size of the word that holds the quantized integer.

Default: 16

Minimum: 0

Maximum: 32

Selecting **Mode** > Fixed point enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

Default: Best precision

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

Best precision

Specify best-precision values.

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting `Slope` and `bias` enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

For more information, see “Specifying a Fixed-Point Data Type”.

Fraction length

Specify fraction length for fixed-point data type.

Default: 0

Binary points can be positive or negative integers.

Selecting **Scaling** > `Binary point` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Slope

Specify slope for the fixed-point data type.

Default: 2^0

Specify any positive real number.

Selecting **Scaling** > `Slope` and `bias` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Bias

Specify bias for the fixed-point data type.

Default: 0

Specify any real number.

Selecting **Scaling** > Slope and bias enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Output as nonvirtual bus

Output a nonvirtual bus.

Default: Off

On

Output a nonvirtual bus.

Off

Output a virtual bus.

- Select this option if you want code generated from this model to use a C structure to define the structure of the bus signal output by this block.
- All signals in a nonvirtual bus must have the same sample time, even if the elements of the associated bus object specify inherited sample times. Any bus operation that would result in a nonvirtual bus that violates this requirement generates an error. Therefore, if you select this option all signals in the bus must have the same sample time. You can use a Rate Transition block to change the sample time of an individual signal, or of all signals in a bus, to allow the signal or bus to be included in a nonvirtual bus.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Lock data type settings against changes by the fixed-point tools

Select to lock data type settings of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

Default: Off

On

Locks all data type settings for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change data type settings for this block.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Port dimensions

Specify the dimensions of the input signal to the block.

Default: 1

Valid values are:

n	Vector signal of width n accepted
[m n]	Matrix signal having m rows and n columns accepted

Signal type

Specify the numeric type of the argument input.

Default: real

real

Specify the numeric type as a real number.

complex

Specify the numeric type as a complex number.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Characteristics

Dimensionalized	Yes
Multidimensionalized	Yes
Zero-Crossing Detection	No

Argument Output

Simulink Function

Introduced in R2014b

Argument Output

Argument output port for Simulink Function block

Description

This block is an output argument port for a function that you define in the Simulink Function block.

Data Type Support

The Argument Output block accepts real or complex signals of any data type that Simulink supports. An Argument Output block can also accept fixed-point and enumerated data types when the block is not a root-level output port. The complexity and data type of the block output are the same as those of its input. The Argument Output block also accepts a bus object as a data type.

For more information, see “Data Types Supported by Simulink”.

Parameters

- “Port number” on page 1-27
- “Argument Name” on page 1-27
- “Minimum” on page 1-28
- “Maximum” on page 1-28
- “Data type” on page 1-29

- “Show data type assistant” on page 1-30
- “Mode” on page 1-30
- “Data type override” on page 1-32
- “Signedness” on page 1-32
- “Word length” on page 1-33
- “Scaling” on page 1-33
- “Fraction length” on page 1-34
- “Slope” on page 1-34
- “Bias” on page 1-35
- “Lock output data type setting against changes by the fixed-point tools” on page 1-35
- “Output as nonvirtual bus” on page 1-35
- “Port dimensions” on page 1-36
- “Signal type” on page 1-37

Port number

Specify the port number of the block.

Default: 1

This parameter controls the order in which the port that corresponds to the block appears on the parent subsystem or model block.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Argument Name

Specify the name of the output argument.

Default: y

This parameter provides the name of the output argument in the function prototype of the Simulink Function block.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Minimum

Specify the minimum value for the block to output.

Default: [] (unspecified)

This number must be a finite real double scalar value.

Note If you specify a bus object as the data type for this block, do not set the minimum value for bus data on the block. Simulink ignores this setting. Instead, set the minimum values for bus elements of the bus object specified as the data type. For information on the Minimum property of a bus element, see `Simulink.BusElement`.

Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Maximum

Specify the maximum value for the block to output.

Default: [] (unspecified)

This number must be a finite real double scalar value.

Note If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For information on the Maximum property of a bus element, see `Simulink.BusElement`.

Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Data type

Specify the output data type of the external input.

Default: double

double

Data type is double.

single

Data type is single.

int8

Data type is int8.

uint8

Data type is uint8.

int16

Data type is int16.

uint16

Data type is uint16.

int32

Data type is int32.

uint32

Data type is uint32.

boolean

Data type is boolean.

`fixdt(1,16,0)`

Data type is fixed point `fixdt(1,16,0)`.

`fixdt(1,16,2^0,0)`

Data type is fixed point `fixdt(1,16,2^0,0)`.

Enum: `<class name>`

Data type is enumerated, for example, Enum: `BasicColors`.

Bus: `<object name>`

Data type is a bus object.

`<data type expression>`

The name of a data type object, for example `Simulink.NumericType`

Do not specify a bus object as the expression.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Show data type assistant

Display the **Data Type Assistant**.

The **Data Type Assistant** helps you set the **Output data type** parameter.

For more information, see “Control Signal Data Types”.

Mode

Select the category of data to specify.

Default: `Built in`

`Built in`

Built-in data types. Selecting `Built in` enables a second menu/text box to the right. Select one of the following:

- `double` (default)

- single
- int8
- uint8
- int16
- uint16
- int32
- uint32
- boolean

Fixed point

Fixed-point data types.

Enumerated

Enumerated data types. Selecting `Enumerated` enables a second menu/text box to the right, where you can enter the class name.

Bus object

Bus object. Selecting `Bus` enables a **Bus object** parameter to the right, where you enter the name of a bus object that you want to use to define the structure of the bus. If you need to create or change a bus object, click **Edit** to the right of the **Bus object** field to open the Simulink Bus Editor. For details, see “Create Bus Objects with the Bus Editor”.

Expression

Expressions that evaluate to data types. Selecting `Expression` enables a second menu/text box to the right, where you can enter the expression.

Do not specify a bus object as the expression.

Clicking the **Show data type assistant** button enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specify Data Types Using Data Type Assistant”.

Data type override

Specify data type override mode for this signal.

Default: `Inherit`

`Inherit`

Inherits the data type override setting from its context, that is, from the block, `Simulink.Signal` object or Stateflow chart in Simulink that is using the signal.

`Off`

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

This parameter appears only when the **Mode** is `Built in` or `Fixed point`.

Signedness

Specify whether you want the fixed-point data as signed or unsigned.

Default: `Signed`

`Signed`

Specify the fixed-point data as signed.

`Unsigned`

Specify the fixed-point data as unsigned.

Selecting **Mode** > `Fixed point` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Word length

Specify the bit size of the word that holds the quantized integer.

Default: 16

Minimum: 0

Maximum: 32

Selecting **Mode** > Fixed point enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

Default: Best precision

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

Best precision

Specify best-precision values.

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting `Slope` and `bias` enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

For more information, see “Specifying a Fixed-Point Data Type”.

Fraction length

Specify fraction length for fixed-point data type.

Default: 0

Binary points can be positive or negative integers.

Selecting **Scaling** > `Binary point` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Slope

Specify slope for the fixed-point data type.

Default: 2^0

Specify any positive real number.

Selecting **Scaling** > `Slope` and `bias` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Bias

Specify bias for the fixed-point data type.

Default: 0

Specify any real number.

Selecting **Scaling** > `Slope` and `bias` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

Default: Off

On

Locks the output data type setting for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change the output data type setting for this block.

Parameter: `LockScale`

Type: character vector

Value: 'off' | 'on'

Default: 'off'

For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Output as nonvirtual bus

Output a nonvirtual bus.

Default: Off

On

Output a nonvirtual bus.

Off

Output a virtual bus.

- Select this option if you want code generated from this model to use a C structure to define the structure of the bus signal output by this block.
- All signals in a nonvirtual bus must have the same sample time, even if the elements of the associated bus object specify inherited sample times. Any bus operation that would result in a nonvirtual bus that violates this requirement generates an error. Therefore, if you select this option all signals in the bus must have the same sample time. You can use a Rate Transition block to change the sample time of an individual signal, or of all signals in a bus, to allow the signal or bus to be included in a nonvirtual bus.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Port dimensions

Specify the dimensions that a signal must have to connect to this Outport block.

Default: 1

Valid values are:

N	The signal connected to this port must be a vector of size N.
[R C]	The signal connected to this port must be a matrix having R rows and C columns.

Clearing **via bus object** enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Signal type

Specify the numeric type of the signal output by this block.

Default: `real`

`real`

Output a real-valued signal. The signal connected to this block must be real. If it is not, Simulink software displays an error if you try to update the diagram or simulate the model that contains this block.

`complex`

Output a complex signal. The signal connected to this block must be complex. If it is not, Simulink software displays an error if you try to update the diagram or simulate the model that contains this block.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Characteristics

Dimensionalized	Yes
Multidimensionalized	Yes
Zero-Crossing Detection	No

Introduced in R2014b

Assertion

Check whether signal is zero

Library

Model Verification

Description

The Assertion block checks whether any of the elements of the input signal is zero. If all elements are nonzero, the block does nothing. If any element is zero, the block halts the simulation, by default, and displays an error message. Use the block parameter dialog box to:

- Specify that the block should display an error message when the assertion fails but allow the simulation to continue.
- Specify a MATLAB® expression to evaluate when the assertion fails.
- Enable or disable the assertion.

You can also use the **Model Verification block enabling** setting in the Configuration Parameters dialog box to enable or disable all Assertion blocks in a model.

The Assertion block and its companion blocks in the Model Verification library are intended to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to physically remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

The Assertion block works in normal, accelerator and rapid accelerator simulation modes.

Note For information about how Simulink Coder™ generated code handles Model Verification blocks, see “Debug” (Simulink Coder).

Data Type Support

The Assertion block accepts input signals of any dimensions and any numeric data type that Simulink supports, including fixed-point data types.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Enable assertion

Clearing this check box disables the Assertion block, that is, causes the model to behave as if the Assertion block did not exist. The **Model Verification block enabling** setting in the Configuration Parameters dialog box lets you enable or disable all Assertion blocks in a model regardless of the setting of this option.

Simulation callback when assertion fails

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Stop simulation when assertion fails

Selecting this check box causes the Simulink software to terminate the simulation when the block input is zero. After terminating the simulation, the software displays an error. Clearing this check box causes the Simulink software to continue the simulation and display a warning when the block input is zero.

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	No
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Assignment

Assign values to specified elements of signal

Library

Math Operations

Description

The Assignment block assigns values to specified elements of the signal. You can specify the indices of the elements to be assigned values either by entering the indices in the block dialog box or by connecting an external indices source or sources to the block. The signal at the block data port, labeled U, specifies values to be assigned to Y. The block replaces the specified elements of Y with elements from the data signal.

Based on the value you enter for the **Number of output dimensions** parameter, a table of index options is displayed. Each row of the table corresponds to one of the output dimensions in **Number of output dimensions**. For each dimension, you can define the elements of the signal to work with. Specify a vector signal as a 1-D signal and a matrix signal as a 2-D signal. When you configure the Assignment block for multidimensional signal operations, the block icon changes.

For example, assume a 5-D signal with a one-based index mode. The table in the Assignment block dialog changes to include one row for each dimension. If you define each dimension with the following entries:

- 1

Index Option, select Assign all

- 2

Index Option, select Index vector (dialog)

Index, enter [1 3 5]

- 3

Index Option, select Starting index (dialog)

Index, enter 4

- 4

Index Option, select Starting index (port)

- 5

Index Option, select Index vector (port)

The assigned values will be $Y(1:end, [1\ 3\ 5], 4:3+size(U, 3), Idx4:Idx4+size(U, 4)-1, Idx5)=U$, where $Idx4$ and $Idx5$ are the input ports for dimensions 4 and 5.

The Assignment block's data port is labeled U. The rest of this section refers to the data port as U to simplify the explanation of the block's usage.

When using the Assignment block in Normal mode, Simulink initializes block outputs to zero even if the model does not explicitly initialize them. In Accelerator mode, Simulink converts the model into an S-Function. This involves code generation. The code generated may not do implicit initialization of block outputs. In such cases, you must explicitly initialize the model outputs.

You can use the block to assign values to vector, matrix, or multidimensional signals.

You can use an array of buses as an input signal to an Assignment block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

Iterated Assignment

You can use the Assignment block to assign values computed in a For or While Iterator loop to successive elements of a vector, matrix, or multidimensional signal in a single time step. For example, the following model uses a For Iterator block to create a vector signal each of whose elements equals $3*i$ where i is the index of the element.

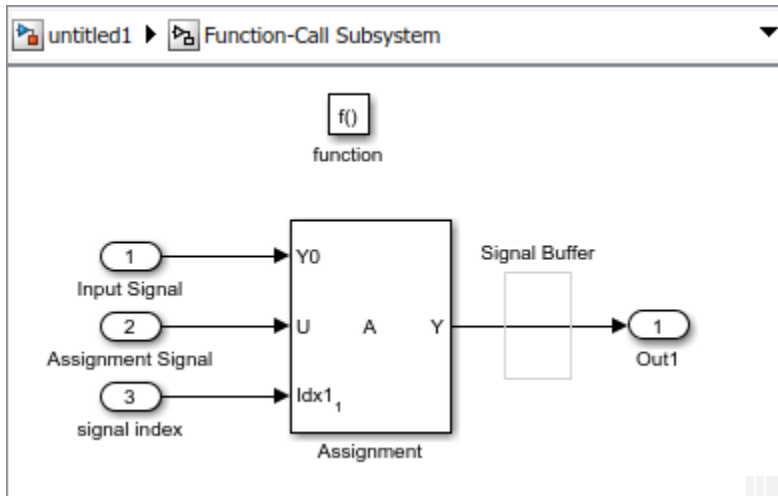

Iterated assignment uses an iterator (For or While) block to generate indices for the Assignment block. On the first iteration of an iterated assignment, the Assignment block copies the first input (Y0) to the output (Y) and assigns the second input (U) to the output Y(E₁). On successive iterations, the Assignment block assigns the current value of U to Y(E_i), that is, without first copying Y0 to Y. These actions occur in a single time step.

Assignment Block in Conditional Subsystem

If you place an Assignment block in a conditional subsystem block, a signal buffer can be inserted in many cases, and merging of signals from Assignment blocks with partial writes can cause an error.

However, if you select the **Ensure output is virtual** check box for the conditional subsystem Output block, such cases are supported and partial writes to arrays using Assignment blocks are possible.

Data Type Support

The data and initialization ports of the Assignment block accept signals of any data type that Simulink supports, including fixed-point, enumerated, and nonvirtual bus data types. The external indices port accepts any built-in data type, except Boolean data types.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Number of output dimensions

Enter the number of dimensions of the output signal.

Index mode

Select the indexing mode: **One-based** or **Zero-based**. If **One-based** is selected, an index of 1 specifies the first element of the input vector, 2, the second element, and so on. If **Zero-based** is selected, an index of 0 specifies the first element of the input vector, 1, the second element, and so on.

Index Option

Define, by dimension, how the elements of the signal are to be indexed. From the list, select:

- Assign all

This is the default. All elements are assigned.

- Index vector (dialog)

Enables the **Index** column. Enter the indices of elements.

- Index vector (port)

Disables the **Index** column. The index port defines the indices of elements.

- Starting index (dialog)

Enables the **Index** column. Enter the starting index of the range of elements to be assigned values.

- Starting index (port)

Disables the **Index** column. The index port defines the starting index of the range of elements to be assigned values.

If you choose `Index vector (port)` or `Starting index (port)` for any dimension in the table, you can specify the value for the **Initialize output (Y)** parameter to be one of the following:

- Initialize using input port <Y0>
- Specify size for each dimension in table

Otherwise, Y0 always initializes output port Y.

The **Index** and **Output Size** columns are displayed as relevant.

Index

If the **Index Option** is `Index vector (dialog)`, enter the index of each element you are interested in.

If the **Index Option** is `Starting index (dialog)`, enter the starting index of the range of elements to be selected. The number of elements from the starting point is determined by the size of this dimension at U.

Output Size

Enter the width of the block output signal. If you select `Specify size for each dimension in table` for the **Initialize output (Y)** parameter, this column is enabled.

Initialize output (Y)

Specify how to initialize the output signal. The **Initialize output** parameter appears when you set **Index Option** to `Index vector (port)` or `Starting index (port)`.

- Initialize using input port <Y0>

The signal at the input port Y0 initializes the output.

- Specify size for each dimension in table

The block requires you to specify the width of the block's output signal in the **Output Size** parameter. If the output has unassigned elements, the value of those elements is undefined.

Action if any output element is not assigned

Specify whether to produce a warning or error if you have not assigned all output elements. Options include:

- `Error` — Simulink software terminates the simulation and displays an error.
- `Warning` — Simulink software displays a warning and continues the simulation.
- `None` — Simulink software takes no action.

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Characteristics

Code Generation	Yes

Introduced before R2006a

Backlash

Model behavior of system with play

Library

Discontinuities

Description

The Backlash block implements a system in which a change in input causes an equal change in output. However, when the input changes direction, an initial change in input has no effect on the output. The amount of side-to-side play in the system is referred to as the *deadband*. The deadband is centered about the output. This figure shows the block's initial state, with the default deadband width of 1 and initial output of 0.

A system with play can be in one of three modes:

- Disengaged — In this mode, the input does not drive the output and the output remains constant.
- Engaged in a positive direction — In this mode, the input is increasing (has a positive slope) and the output is equal to the input *minus* half the deadband width.
- Engaged in a negative direction — In this mode, the input is decreasing (has a negative slope) and the output is equal to the input *plus* half the deadband width.

If the initial input is outside the deadband, the **Initial output** parameter value determines whether the block is engaged in a positive or negative direction, and the output at the start of the simulation is the input plus or minus half the deadband width.

For example, the Backlash block can be used to model the meshing of two gears. The input and output are both shafts with a gear on one end, and the output shaft is driven by the input shaft. Extra space between the gear teeth introduces *play*. The width of this spacing is the **Deadband width** parameter. If the system is disengaged initially, the output (the position of the driven gear) is defined by the **Initial output** parameter.

The following figures illustrate the block's operation when the initial input is within the deadband. The first figure shows the relationship between the input and the output while the system is in disengaged mode (and the default parameter values are not changed).

The next figure shows the state of the block when the input has reached the end of the deadband and engaged the output. The output remains at its previous value.

The final figure shows how a change in input affects the output while they are engaged.

If the input reverses its direction, it disengages from the output. The output remains constant until the input either reaches the opposite end of the deadband or reverses its direction again and engages at the same end of the deadband. Now, as before, movement in the input causes equal movement in the output.

For example, if the deadband width is 2 and the initial output is 5, the output, y , at the start of the simulation is as follows:

- 5 if the input, u , is between 4 and 6
- $u + 1$ if $u < 4$
- $u - 1$ if $u > 6$

Data Type Support

The Backlash block accepts and outputs real values of `single`, `double`, and built-in integer data types.

Parameters

Deadband width

Specify the width of the deadband. The default is 1.

Initial output

Specify the initial output value. The default value is 0. This parameter is tunable. Simulink does not allow the initial output of this block to be `inf` or `NaN`.

Input processing

Specify whether the block performs sample- or frame-based processing. You can select one of the following options:

- `Elements as channels (sample based)` — Treat each element of the input as a separate channel (sample-based processing).
- `Columns as channels (frame based)` — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox™ license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

- `Inherited` — Inherit the processing mode from the input signal and delay the input accordingly. You can identify whether the input signal is sample or frame based by looking at the signal line. Simulink represents sample-based signals with a single line and frame-based signals with a double line.

Note When you choose the `Inherited` option for the **Input processing** parameter, and the input signal is frame-based, Simulink will generate a warning or error in future releases.

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input `u`. All other input signals must be sample based.

Input Signal <code>u</code>	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

Enable zero-crossing detection

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Examples

The following model shows the effect of a sine wave passing through a Backlash block.

The Backlash block uses default parameter values: the deadband width is 1 and the initial output is 0. The following plot shows that the Backlash block output is zero until the input reaches the end of the deadband (at 0.5). Now the input and output are engaged and the output moves as the input does until the input changes direction (at 1.0). When the input reaches 0, it again engages the output at the opposite end of the deadband.

A Input engages in positive direction. Change in input causes equal change in output.

B Input disengages. Change in input does not affect output.

C Input engages in negative direction. Change in input causes equal change in output.

D Input disengages. Change in input does not affect output.

Characteristics

Data Types	Double Single Base Integer
Sample Time	Inherited from driving block

Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	Yes, if enabled
Code Generation	Yes

Introduced before R2006a

Unresolved Link

Indicate unresolved reference to library block

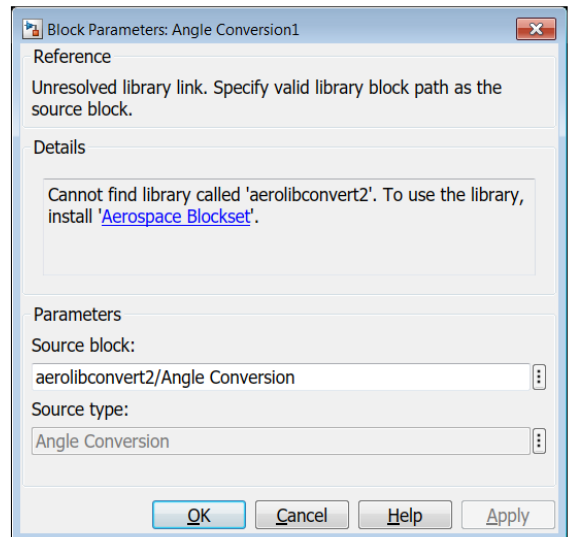

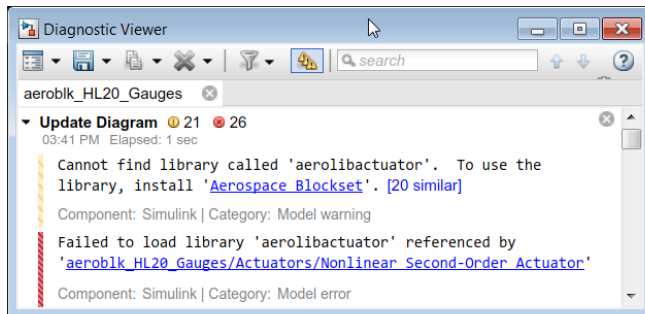

Description

This block indicates an unresolved reference to a library block (see “Linked Blocks”). You can use this block's parameter dialog box to fix the reference to point to the actual location of the library block.

Parameters

Details

The **Details** field contains a description of the cause of the unresolved link. Simulink tries to help you find and install missing products that a model needs to run. For missing products, the block description provides a link. Click the link to open Add-On Explorer and install the missing products.

You can customize the Unresolved Link block description for your library to include URLs as follows:

```
set_param(library1,'libraryinfo','https://www.mathworks.com');
```

Here, `library1` is the name of the library for which you want to change the description, and `libraryinfo` is the property that provides the description of the unresolved link.

Source block

Path of the library block that this link represents. To fix a bad link, either click the link in the description to open Add-On Explorer and install a missing product, or edit the **Source block** field to the correct path of the library block. Then select Apply or OK to apply the fix and close the dialog box.

Alternatively, to fix an unresolved link, you can:

- Delete the unresolved block and copy the library block back into your model.
- Add the folder that contains the required library to the MATLAB path and select either **Simulation > Update Diagram** or **Diagram > Refresh Blocks**.

Source type

Type of library block that this link represents.

Introduced in R2014a

Band-Limited White Noise

Introduce white noise into continuous system

Library

Sources

Description

Simulation of White Noise

The Band-Limited White Noise block generates normally distributed random numbers that are suitable for use in continuous or hybrid systems.

Theoretically, continuous white noise has a correlation time of 0, a flat power spectral density (PSD), and a total energy of infinity. In practice, physical systems are never disturbed by white noise, although white noise is a useful theoretical approximation when the noise disturbance has a correlation time that is very small relative to the natural bandwidth of the system.

In Simulink software, you can simulate the effect of white noise by using a random sequence with a correlation time much smaller than the shortest time constant of the system. The Band-Limited White Noise block produces such a sequence. The correlation time of the noise is the sample rate of the block. For accurate simulations, use a correlation time much smaller than the fastest dynamics of the system. You can get good results by specifying

$$tc \approx \frac{1}{100} \frac{2\pi}{f_{max}},$$

where f_{max} is the bandwidth of the system in rad/sec.

Comparison with the Random Number Block

The primary difference between this block and the Random Number block is that the Band-Limited White Noise block produces output at a specific sample rate. This rate is related to the correlation time of the noise.

Usage with the Averaging Power Spectral Density Block

The Band-Limited White Noise block specifies a two-sided spectrum, where the units are Hz. The Averaging Power Spectral Density block specifies a one-sided spectrum, where the units are the square of the magnitude per unit radial frequency: $\text{Mag}^2/(\text{rad}/\text{sec})$. When you feed the output of a Band-Limited White Noise block into an Averaging Power Spectral Density block, the average PSD value is π times smaller than the **Noise power** of the Band-Limited White Noise block. This difference is the result of converting the units of one block to the units of the other: $1/(1/2)(2\pi) = 1/\pi$, where:

- $1/2$ is the factor for converting from a two-sided to one-sided spectrum
- 2π is the factor for converting from Hz to rad/sec

Algorithm

To produce the correct intensity of this noise, the covariance of the noise is scaled to reflect the implicit conversion from a continuous PSD to a discrete noise covariance. The appropriate scale factor is $1/tc$, where tc is the correlation time of the noise. This scaling ensures that the response of a continuous system to the approximate white noise has the same covariance as the system would have to true white noise. Because of this scaling, the covariance of the signal from the Band-Limited White Noise block is not the same as the **Noise power** (intensity) parameter. This parameter is actually the height of the PSD of the white noise. This block approximates the covariance of white noise as the **Noise power** divided by tc .

Data Type Support

The Band-Limited White Noise block outputs real values of type `double`.

Parameters

Noise power

Specify the height of the PSD of the white noise. The default value is 0.1.

Sample time

Specify the correlation time of the noise. The default value is 0.1. For more information, see “Specify Sample Time” in the Simulink documentation.

Seed

Specify the starting seed for the random number generator. The default value is 23341.

Interpret vector parameters as 1-D

Select to output a 1-D array when the block parameters are vectors. Otherwise, output a 2-D array one of whose dimensions is 1. See “Determining the Output Dimensions of Source Blocks” in the Simulink documentation.

Examples

The following Simulink examples show how to use the Band-Limited White Noise block:

- `slexAircraftExample`
- `sldemo_radar_eml`

Characteristics

Data Types	Double
Sample Time	Specified in the Sample time parameter

Bias

Add bias to input

Library

Math Operations

Description

The Bias block adds a bias, or offset, to the input signal according to

$$Y = U + bias,$$

where U is the block input and Y is the output.

Data Type Support

The Bias block accepts and outputs real or complex values of the following data types:

- Floating point
- Built-in integer
- Fixed point

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Bias

Specify the value of the offset to add to the input signal.

Saturate on integer overflow

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Do not select this check box.	<p>You want to optimize efficiency of your generated code.</p> <p>You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.</p>	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Characteristics

Data Types	Double Single Base Integer Fixed-Point
Sample Time	Inherited from driving block

Bit Clear

Set specified bit of stored integer to zero

Library

Logic and Bit Operations

Description

The Bit Clear block sets the specified bit, given by its index, of the stored integer to zero. Scaling is ignored.

You can specify the bit to be set to zero with the **Index of bit** parameter, where bit zero is the least significant bit.

Data Type Support

The Bit Clear block supports Simulink integer, fixed-point, and Boolean data types. The block does not support true floating-point data types or enumerated data types.

Parameters

Index of bit

Index of bit where bit 0 is the least significant bit.

Examples

If the Bit Clear block is turned on for bit 2, bit 2 is set to 0. A vector of constants $2.^{[0\ 1\ 2\ 3\ 4]}$ is represented in binary as [00001 00010 00100 01000 10000]. With bit 2 set to 0, the result is [00001 00010 00000 01000 10000], which is represented in decimal as [1 2 0 8 16].

Characteristics

Data Types	Boolean Base Integer Fixed-Point
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Code Generation	Yes

Bit Set

Introduced before R2006a

Bit Concat

Concatenates up to 128 input words into single output

Library

HDL Coder / HDL Operations

Description

The Bit Concat block concatenates up to 128 input words into a single output. The input port labeled **L** designates the lowest-order input word. The port labeled **H** designates the highest-order input word. The right-to-left ordering of words in the output follows the low-to-high ordering of input signals.

How the block operates depends on the number and dimensions of the inputs, as follows:

- Single input: The input is a scalar or a vector. When the input is a vector, the coder concatenates the individual vector elements.
- Two inputs: Inputs are any combination of scalar and vector. When one input is scalar and the other is a vector, the coder performs scalar expansion. Each vector element is concatenated with the scalar, and the output has the same dimension as the vector. When both inputs are vectors, they must have the same size.
- Three or more inputs (up to a maximum of 128 inputs): Inputs are uniformly scalar or vector. All vector inputs must have the same size.

Parameters

Number of Inputs: Enter an integer specifying the number of input signals. The number of block input ports updates when you change **Number of Inputs**.

- Default: 2
- Minimum: 1
- Maximum: 128

Caution Make sure that the **Number of Inputs** is equal to the number of signals you connect to the block. If the block has unconnected inputs, an error occurs at code generation time.

Ports

The block has up to 128 input ports, with H representing the highest-order input word, and L representing the lowest-order input word. The maximum concatenated output word size is 128 bits.

Supported Data Types

- Input: Fixed-point, integer (signed or unsigned), Boolean
- Output: Unsigned fixed-point or integer

Introduced in R2014a

Bit Reduce

AND, OR, or XOR bit reduction on all input signal bits to single bit

Library

HDL Coder / HDL Operations

Description

The Bit Reduce block performs a selected bit-reduction operation (AND, OR, or XOR) on all the bits of the input signal, for a single-bit result.

Parameters

Reduction Mode

Specifies the reduction operation:

- AND (default): Perform a bitwise AND reduction of the input signal.
- OR: Perform a bitwise OR reduction of the input signal.
- XOR: Perform a bitwise XOR reduction of the input signal.

Ports

The block has the following ports:

Input

- Supported data types: Fixed-point, integer (signed or unsigned), Boolean
- Minimum bit width: 2
- Maximum bit width: 128

Output

Supported data type: `ufix1`

Bit Rotate

Rotate input signal by bit positions

Library

HDL Coder / HDL Operations

Description

The Bit Rotate block rotates the input signal left or right by the specified number of bit positions.

Parameters

Rotate Mode: Specifies direction of rotation, left or right. The default is `Rotate Left`.

Rotate Length: Specifies the number of bits to rotate. Specify a value greater than or equal to zero. The default is 0.

Ports

The block has the following ports:

Input

- Supported data types: Fixed-point, integer (signed or unsigned), Boolean
- Minimum bit width: 2
- Maximum bit width: 128

Output

Has the same data type as the input signal.

Bit Set

Set specified bit of stored integer to one

Library

Logic and Bit Operations

Description

The Bit Set block sets the specified bit of the stored integer to one. Scaling is ignored.

You can specify the bit to be set to one with the **Index of bit** parameter, where bit zero is the least significant bit.

Data Type Support

The Bit Set block supports Simulink integer, fixed-point, and Boolean data types. The block does not support true floating-point data types or enumerated data types.

Parameters

Index of bit

Index of bit where bit 0 is the least significant bit.

Examples

If the Bit Set block is turned on for bit 2, bit 2 is set to 1. A vector of constants $2.^{[0\ 1\ 2\ 3\ 4]}$ is represented in binary as [00001 00010 00100 01000 10000]. With bit 2 set to 1, the result is [00101 00110 00100 01100 10100], which is represented in decimal as [5 6 4 12 20].

Characteristics

Data Types	Boolean Base Integer Fixed-Point

Bit Clear

Introduced before R2006a

Bit Shift

Logical or arithmetic shift of input signal

Library

HDL Coder / HDL Operations

Description

The Bit Shift block performs a logical or arithmetic shift on the input signal.

Parameters

Shift Mode

Default: Shift Left Logical

Specifies the type and direction of shift:

- Shift Left Logical (default)
- Shift Right Logical
- Shift Right Arithmetic

Shift Length

Specifies the number of bits to be shifted. Specify a value greater than or equal to zero. The default is 0.

Ports

The block has the following ports:

Input

- Supported data types: Fixed-point, integer (signed or unsigned), Boolean
- Minimum bit width: 2
- Maximum bit width: 128

Output

Has the same data type and bit width as the input signal.

Introduced in R2014a

Bit Slice

Return field of consecutive bits from input signal

Library

HDL Coder / HDL Operations

Description

The Bit Slice block returns a field of consecutive bits from the input signal. Specify the lower and upper boundaries of the bit field by using zero-based indices in the **LSB Position** and **MSB Position** parameters.

Parameters

MSB Position

Specifies the bit position (zero-based) of the most significant bit (MSB) of the field to extract. The default is 7.

For an input word size *WS*, **LSB Position** and **MSB Position** must satisfy the following constraints:

```
WS > MSB Position >= LSB Position >= 0;
```

The word length of the output is computed as $(\text{MSB Position} - \text{LSB Position}) + 1$.

LSB Position

Specifies the bit position (zero-based) of the least significant bit (LSB) of the field to extract. The default is 0.

Ports

The block has the following ports:

Input

- Supported data types: Fixed-point, integer (signed or unsigned), Boolean
- Maximum bit width: 128

Output

Supported data types: unsigned fixed-point or unsigned integer.

Bitwise Operator

Specified bitwise operation on inputs

Library

Logic and Bit Operations

Description

Bitwise Operations

The Bitwise Operator block performs the bitwise operation that you specify on one or more operands. Unlike logic operations of the Logical Operator block, bitwise operations treat the operands as a vector of bits rather than a single value.

You can select one of the following bitwise operations:

Bitwise Operation	Description
AND	TRUE if the corresponding bits are all TRUE
OR	TRUE if at least one of the corresponding bits is TRUE
NAND	TRUE if at least one of the corresponding bits is FALSE
NOR	TRUE if no corresponding bits are TRUE
XOR	TRUE if an odd number of corresponding bits are TRUE
NOT	TRUE if the input is FALSE (available only for single input)

Restrictions on Block Operations

The Bitwise Operator block does not support shift operations. For shift operations, use the Shift Arithmetic block.

When configured as a multi-input XOR gate, this block performs modulo-2 addition according to the IEEE® Standard for Logic Elements.

Behavior of Inputs and Outputs

The output data type, which the block inherits from the driving block, must represent zero exactly. Data types that satisfy this condition include signed and unsigned integer data types.

The size of the block output depends on the number of inputs, the vector size, and the operator you select:

- The NOT operator accepts only one input, which can be a scalar or a vector. If the input is a vector, the output is a vector of the same size containing the bitwise logical complements of the input vector elements.
- For a single vector input, the block applies the operation (except the NOT operator) to all elements of the vector.
 - If you do not specify a bit mask, the output is a scalar.
 - If you do specify a bit mask, the output is a vector.
- For two or more inputs, the block performs the operation between all of the inputs. If the inputs are vectors, the block performs the operation between corresponding elements of the vectors to produce a vector output.

Bit Mask Behavior

Block behavior changes depending on whether you use a bit mask.

If the Use bit mask check box is...	The block accepts...	And you specify...	By using...
Selected	One input	Bit Mask	Any valid MATLAB expression, such as $2^5+2^2+2^0$ for the bit mask 00100101
Not selected	Multiple inputs, all having the same base data type	Number of input ports	Any positive integer greater than 1

Tip You can also use character vectors to specify a hexadecimal bit mask such as {'FE73', '12AC'}.

Bit Set and Bit Clear Operations

You can use the bit mask to set or clear a bit on the input.

To perform a...	Set the Operator parameter to...	And create a bit mask with...
Bit set	OR	A 1 for each corresponding input bit that you want to set to 1
Bit clear	AND	A 0 for each corresponding input bit that you want to set to 0

Suppose you want to set the fourth bit of an 8-bit input vector. The bit mask would be 00010000, which you can specify as 2^4 for the **Bit Mask** parameter. To clear the bit, the bit mask would be 11101111, which you can specify as $2^7+2^6+2^5+2^3+2^2+2^1+2^0$ for the **Bit Mask** parameter.

Data Type Support

The Bitwise Operator block supports the following data types:

- Built-in integer
- Fixed point
- Boolean

The block does not support floating-point data types or enumerated data types. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Operator

Specify the bitwise logical operator for the block operands.

Use bit mask

Select to use the bit mask. Clearing this check box enables **Number of input ports** and disables **Bit Mask** and **Treat mask as**.

Number of input ports

Specify the number of inputs. The default value is 1.

Bit Mask

Specify the bit mask to associate with a single input. This parameter is available only when you select **Use bit mask**.

Tip Do not use a mask greater than 53 bits. Otherwise, an error message appears during simulation.

Treat mask as

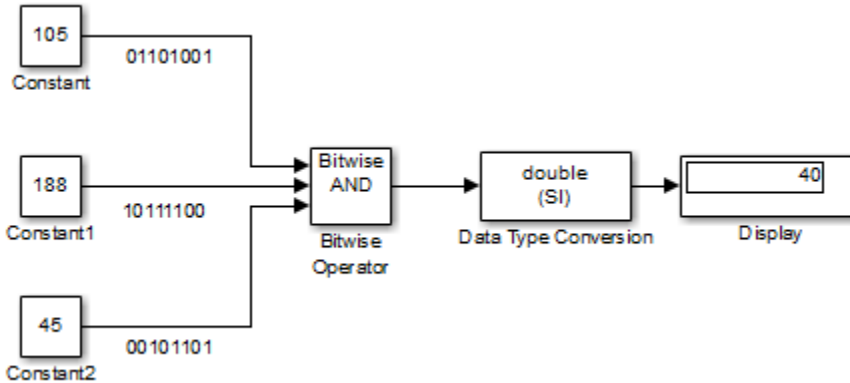

Specify whether to treat the mask as a real-world value or a stored integer. This parameter is available only when you select **Use bit mask**.

The encoding scheme is $V = SQ + B$, as described in “Scaling” (Fixed-Point Designer) in the Fixed-Point Designer documentation. **Real World Value** treats the mask as V . **Stored Integer** treats the mask as Q .

Examples

Unsigned Inputs for the Bitwise Operator Block

The following model shows how the Bitwise Operator block works for unsigned inputs.

Each Constant block outputs an 8-bit unsigned integer (`uint8`). To determine the binary value of each Constant block output, use the `dec2bin` function. The results for all logic operations appear in the next table.

Operation	Binary Value	Decimal Value
AND	00101000	40
OR	11111101	253
NAND	11010111	215
NOR	00000010	2
XOR	11111000	248
NOT	N/A	N/A

Signed Inputs for the Bitwise Operator Block

The following model shows how the Bitwise Operator block works for signed inputs.

Each Constant block outputs an 8-bit signed integer (`int8`). To determine the binary value of each Constant block output, use the `dec2bin` function. The results for all logic operations appear in the next table.

Operation	Binary Value	Decimal Value
AND	01000000	64
OR	11111011	-5
NAND	10111111	-65
NOR	00000100	4
XOR	11000010	-62
NOT	N/A	N/A

Characteristics

Data Types	Boolean Base Integer Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No

Code Generation	Yes

Bus Assignment

Replace specified bus elements

Library: Simulink / Signal Routing

Description

The Bus Assignment block assigns the values of a signal to bus elements. Use a Bus Assignment block to change bus element values without adding Bus Selector and Bus Creator blocks that select bus elements and reassemble them into a bus.

Connect the bus signal to the first input port. To other input ports, connect one or more signals whose values you want to assign to a bus element. Use the Block Parameters dialog box to specify the bus elements to be replaced. The block displays an assignment input port for each such element. For an example of a model that uses a Bus Assignment block, see “Assign Signal Values to a Bus”.

By default, Simulink repairs broken selections in the Bus Assignment Block Parameters dialog boxes that are due to upstream bus hierarchy changes. Simulink generates a warning to highlight that it modified the model. To prevent Simulink from making these repairs automatically, in the **Model Configuration Parameters > Diagnostics > Connectivity** pane, set the “Repair bus selections” diagnostic to `Error without repair`.

Limitations

When using arrays of buses with a Bus Assignment block, these limitations apply:

- You can assign or replace a subbus that is an array of buses. However, the nested bus cannot be nested inside an array of buses.

- To replace a signal in an array of buses, use a Selector block to select the index for the bus element that you want to use with the Bus Assignment block. Then, use that selected bus element with the Bus Assignment block.

Ports

Input

Bus — Accept bus signal for bus element value assignment

real or complex values of any data type supported by Simulink

Input bus signals can have real or complex values of any data type supported by Simulink, including bus objects, arrays of buses, fixed-point, and enumerated data types. For details about data types, see Simulink, “Data Types Supported by Simulink”.

The signal connected to the assignment port must have the same structure, data type, and sample time as the bus element to which it corresponds. You can use a Rate Transition block to change the sample time of an individual signal or signals in a bus, to include the signal or bus in a nonvirtual bus. See “Virtual and Nonvirtual Buses” for more information.

:= — Accept signals whose value are assigned to bus elements

real or complex values of any data type supported by Simulink

Assignment input ports can accept signals can have real or complex values of any data type supported by Simulink, including bus objects, arrays of buses, fixed-point, and enumerated data types. You cannot use the Bus Assignment block to replace a bus that is nested within an array of buses. For details about data types, see Simulink, “Data Types Supported by Simulink”.

The Bus Assignment block assigns signals connected to its assignment input ports to specified elements of the bus connected to its bus input port. The block replaces the signals previously assigned to those elements. The change does not affect the composition of the bus; it affects only the values of the signals themselves. Signals not replaced are unaffected by the replacement of other signals.

Output

Bus — Output bus signal

virtual or nonvirtual bus

Bus that includes the assigned bus element values and the values of the bus elements of the input bus that you did not assign values to.

Parameters

Signals in the bus — Bus element signals of input bus

list of signal names

List of the bus element signals of the input bus signal. An arrow next to a signal name indicates that the input signal is a bus. To display the signals in an input bus, click the arrow.

Click any item in the list to select it. To find the source of the selected signal, click **Find**. Simulink opens and highlights the system containing the signal source. To move the currently selected signal into the adjacent list of signals to be assigned values (see **Signals that are being assigned** below), click **Select>>**. To refresh the display to reflect modifications to the bus connected to the block, click **Refresh**.

Filter by name — Filter set of displayed signals

text

Specify a search term to use for filtering a long list of input signals. Do not enclose the search term in quotation marks. The filter does a partial string search. To access filtering options, including using a regular expression for specifying the search term, click the  button on the right of the **Filter by name** edit box.

Enable regular expression — Filter set of displayed input signals

off (default) | on

Enable the use of MATLAB regular expressions for filtering signal names. For example, entering `t$` in the **Filter by name** edit box displays all signals whose names end with a lowercase `t` (and their immediate parents). For details, see “Regular Expressions” (MATLAB).

Dependencies

To access this parameter, click the  button on the right of the **Filter by name** edit box.

Show filtered results as a flat list — Filter set of displayed input signals
off (default) | on

By default, the list displays as a tree list of filtered signals, based on the search text in the **Filter by name** edit box. To use a flat list format that uses dot notation to reflect the hierarchy of bus signals, select this parameter.

Dependencies

To access this parameter, click the  button on the right of the **Filter by name** edit box

Signals that are being assigned — Bus element signals to be assigned
list of signal names

Names of bus elements to be assigned values. This block displays an assignment input port for each bus element in this list. The label of the corresponding input port contains the name of the element. You can order the signals by using the **Up**, **Down**, or **Remove**. Port connectivity is maintained when you change the signal order.

If an input bus no longer contains a bus element, three question marks (???) appear before the name of that bus element. The reason for this event is that the bus has changed since the last time you refreshed the Bus Assignment block input and bus element assignment lists. To address this issue, either modify the bus to include a signal of the specified name or remove the name from the list of bus elements designated to be assigned values.

Programmatic Use

Block Parameter:OutputSignals

Type:character vector

Values: 'signal1' | 'signal2'

Default:none

Model Examples

Block Characteristics

Data Types	double single Boolean base integer fixed point enumerated bus
Multidimensional Signals	Yes
Variable-Size Signals	Yes

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual data type or capability support depends on block implementation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

Fixed-Point Conversion

Design and simulate fixed-point algorithms using Fixed-Point Designer™.

Actual data type or capability support depends on block implementation.

Bus Creator

Create bus signal from input signals

Library: Simulink / Commonly Used Blocks
Simulink / Signal Routing

Description

The Bus Creator block combines a set of signals into a bus. To bundle a group of signals with a Bus Creator block, set the block parameter **Number of inputs** to the number of signals in the group. The block displays the number of inport ports that you specify. Connect to the resulting input ports the signals that you want to group.

You can connect any type of signal to the inputs, including other bus signals. To access individual signals in a bus signal, connect the output port of the block to a Bus Selector block port.

The signals in the bus are ordered from the top input port to the bottom input port. See “Port Location After Rotating or Flipping” for a description of the port order for various block orientations. To rearrange the signals in the output bus signal, use buttons such as **Up** or **Down** buttons.

Simulink hides the name of a Bus Creator block when you copy it from the Simulink library to a model.

Tip For models that include bus signals composed of many bus elements that feed subsystems, consider using the In Bus Element and Out Bus Element blocks. You can use these bus element port blocks instead of Inport with Bus Selector blocks for inputs, and Outport with Bus Creator blocks for outputs. These bus element port blocks:

- Reduce signal line complexity and clutter in a block diagram.
- Make it easier to change the interface incrementally.

- Allow access to a bus element closer to the point of usage, avoiding the use of a Bus Selector and Goto block configuration.
-

Ports

Input

Port_1 — Accept signal to include in bus

real or complex values of any data type supported by Simulink

Input signals can have real or complex values of any data type supported by Simulink, including bus objects, arrays of buses, fixed-point, and enumerated data types. For details about data types, see Simulink, “Data Types Supported by Simulink”.

Output

Port_1 — Output bus signal

virtual or nonvirtual bus

Bus that combines the input signals.

Parameters

Number of inputs — Number of input ports

2 (default) | integer

Number of inputs, not fewer than two. Increasing the number of connected ports adds empty ports below the connected ports. Before you simulate the model, make sure an input signal is connected to each input port.

Tip As you draw a new signal line close to input side of a virtual Bus Creator block, if all input ports are already connected, the :

- Adds another input port to the Bus Creator block
- Updates the **Number of inputs** parameter

- Add to the list of bus signals a signal name for the new signal
-

Programmatic Use

Block Parameter:Inputs

Type:character vector

Values:integer greater than or equal to 2

Default:' 2 '

Signals in the bus — Input signals

list of signal names

List of input signals to combine into a bus signal. An arrow next to a signal name indicates that the input signal is a bus. To display the signals in an input bus, click the arrow. For information about working with the signals in the list, see “Bus Creation Using Bus Creator Blocks” .

Filter by name — Filter set of displayed input signals

text

Specify a search term to filter a long list of input signals. Do not enclose the search term in quotation marks. The filter does a partial string search. To access filtering options, including using a regular expression to specify the search term, click the  button on the right side of the **Filter by name** edit box.

Enable regular expression — Filter set of displayed input signals

off (default) | on

Enable the use of MATLAB regular expressions for filtering signal names. For example, entering `t$` in the **Filter by name** edit box displays all signals whose names end with a lowercase `t` (and their immediate parents). For details, see “Regular Expressions” (MATLAB).

Dependencies

To access this parameter, click the  button on the right side of the **Filter by name** edit box.

Show filtered results as a flat list — Filter set of displayed input signals

off (default) | on

By default, a tree list displays the filtered signals, based on the search text in the **Filter by name** edit box. To use a flat list format that uses dot notation to reflect the hierarchy of bus signals, select this parameter.

Dependencies

To access this parameter, click the  button on the right-hand side of the **Filter by name** edit box

Output data type — Data type of output signal

`{'Inherit: auto'} (default) | 'Bus: <object name>' | <datatype expression>`

Data type of the output bus signal.

Determine whether you want the Bus Creator block to output a virtual or nonvirtual bus.

- For a virtual bus, use the **Output data type** parameter default (`Inherit: auto`) or set the parameter to specify a bus object using `Bus: <object name>`.
- For a nonvirtual bus, set the **Output data type** parameter to specify a bus object using `Bus: <object name>` and click **Output as nonvirtual bus**.

If you select `'Bus: <object name>'`, specify a bus object in the edit box. The bus object must be in the base workspace when you perform an update diagram or simulate the model. To define a bus object using the Bus Editor, click **Show data type assistant** and then click **Edit**. For details, see “Create Bus Objects with the Bus Editor”.

If you select `'<data type expression>'`, specify an expression that evaluates to a data type. Do not specify a bus object as the expression.

Programmatic Use

Block Parameter:`OutDataTypeStr`

Type:character vector

Values:`{'Inherit: auto'} | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'boolean' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | 'Enum: <class name>' | 'Bus: <object name>'`

Default:`'inherit: auto'`

Require input signal names to match signals above — Require input signal names to match names listed in dialog box

`off (default) | on`

To check that the input signal names match the signal names in the Bus Creator Block Parameters dialog box, enable this parameter (the default setting).

Tip The **Require input signal names to match signals above** parameter might be removed in a future release. To enforce strong data typing, consider using the **Override bus signal names from inputs** parameter. If you select **Override bus signal names from inputs**, the **Require input signal names to match signals above** setting is ignored.

Programmatic Use

Block Parameter: OutDataTypeStr

Type: character vector

Values: 'on' | 'off'

Default: 'on'

Rename selected signal — Change name of currently selected signal

' ' (default) | character vector

Specify a name for the currently selected input signal. See “Signal Names and Labels” for guidelines for signal names.

Dependencies

The **Require input signal names to match signals above** parameter must be enabled.

Override bus signal names from inputs — Override bus signal names from input signals

off (default) | on

By default, the Bus Creator block overrides bus signal names from inputs. To inherit bus signal names from a bus object, clear this parameter. Clearing the parameter:

- Enforces strong data typing.
- Avoids having to enter a signal name multiple times: in the bus object and in the model. Entering the name multiple times can accidentally create signal name mismatches.
- Supports the array of buses requirement to have consistent signal names across array elements.

Alternatively, you can enforce strong data typing and also check that input signal names match the bus object element names.

- Select the **Override bus signal names from inputs** check box.
- Set the **Element name mismatch** parameter to `error`.

Dependencies

To display this parameter, the **Output data type** parameter must be set to a bus object.

Programmatic Use

Block Parameter:`InheritFromInputs`

Type:character vector

Values:'on' | 'off'

Default:'on'

Output as nonvirtual bus — Output nonvirtual bus

on (default) | off

Output a nonvirtual bus from the Bus Creator block. All signals in a nonvirtual bus must have the same sample time, even if the elements of the associated bus object specify inherited sample times. Any bus operation resulting in a nonvirtual bus that violates this requirement generates an error. To include in a nonvirtual bus a signal or bus that has a different sample time than the other input signals, use a Rate Transition block to change the sample time that signal. For details, see “Specify Bus Signal Sample Times”.

Enable this parameter to generate code that uses a C structure to define the structure of the bus signal output by this block.

Dependencies

The **Output data type** parameter must be set to a bus object.

Programmatic Use

Block Parameter:`NonVirtualBus`

Type:character vector

Values:'on' | 'off'

Default:'on'

Model Examples

Buses in Simulink

Bus Selector

Select signals from incoming bus

Library: Simulink / Commonly Used Blocks
Simulink / Signal Routing

Description

The Bus Selector block outputs a specified subset of the elements of the bus at its input. The block can output the specified elements as separate signals or as a new bus.

By default, Simulink implicitly converts a nonbus signal to a bus signal to support connecting the signal to a Bus Selector block. To prevent Simulink from performing that conversion, set the “Non-bus signals treated as bus signals” diagnostic to warning or error.

When the block outputs multiple elements, it outputs each element from a separate port from top to bottom of the block. See “Port Location After Rotating or Flipping” for a description of the port order for various block orientations.

In the Simulink Editor, as you draw a new signal line close to output side of a Bus Selector block and all output ports are already connected, Simulink Editor:

- Adds a port
- Prompts you to specify the signal to be selected

You cannot use this automatic port addition approach in either of these cases if:

- There is no bus input signal connected to the Bus Selector block.
- You do not specify a signal in response to the prompt that appears when you draw a signal line close to the Bus Selector block icon.
- You select the **Output as bus** parameter.

Tip For models that include bus signals composed of many bus elements that feed subsystems, consider using the In Bus Element and Out Bus Element blocks. You can use these bus element port blocks instead of Inport with Bus Selector blocks for inputs, and Outport with Bus Creator blocks for outputs. These bus element port blocks:

- Reduce signal line complexity and clutter in a block diagram.
 - Make it easier to change the interface incrementally.
 - Allow access to a bus element closer to the point of usage, avoiding the use of a Bus Selector and Goto block configuration.
-

Ports

Input

Port_1 — Accept bus signal to select signals from

real or complex values of any data type supported by Simulink except for arrays of buses

Input bus signals can have real or complex values of any data type supported by Simulink except for arrays of buses. To work with an array of buses signal, select with a Selector block the index for the bus element that you want to use with the Bus Selector block. Then use that selected bus element with the Bus Selector block.

Output

Port_1 — Output selected bus elements of input bus

nonbus signal (default) | virtual bus

Output selected bus element signals of an input bus signal.

When the block outputs separate elements, it outputs each element from a separate port from top to bottom of the block. See “Port Location After Rotating or Flipping” for a description of the port order for various block orientations.

If you select the **Output as bus** parameter, the output bus is virtual. To produce nonvirtual bus output, insert a Signal Conversion block after the Bus Selector block. Set the Signal Conversion block **Output** parameter to `Nonvirtual bus` and use a `Simulink.Bus` bus object for the **Data type** parameter. For an example, see the Signal Conversion documentation.

Parameters

Signals in the bus — Element signals in input bus

list of signal names

List of bus element signals of the input bus, from which to select signals to output. To select a signal to output, click the signal in the list and then click **Select>>**.

To refresh the display to reflect modifications to the bus connected to the block, click **Refresh**.

To find the source of a signal entering the block, select the signal in the list and click **Find**. The Simulink software highlights the signal source in the block diagram.

Programmatic Use

Block Parameter:InputSignals

Type:matrix

Values:signal name

Default:{ ' [] ' }

Filter by name — Filter set of displayed input signals

text

Specify a search term to use for filtering a long list of input signals. Do not enclose the search term in quotation marks. The filter does a partial string search. To access filtering options, including using a regular expression to specify the search term, click the  button on the right side of the **Filter by name** edit box.

Enable regular expression — Filter set of displayed input signals

off (default) | on

Enable the use of MATLAB regular expressions for filtering signal names. For example, entering `t$` in the **Filter by name** edit box displays all signals whose names end with a lowercase `t` (and their immediate parents). For details, see “Regular Expressions” (MATLAB).

Dependencies

To access this parameter, click the  button on the right side of the **Filter by name** edit box.

Show filtered results as a flat list — Filter set of displayed input signals

off (default) | on

By default, a tree displays the filtered signals, based on the search text in the **Filter by name** edit box. Select this parameter to use a flat list format that uses dot notation to reflect the hierarchy of bus signals.

Dependencies

To access this parameter, click the  button on the right side of the **Filter by name** edit box

Selected signals — Selected bus elements signals

list of signal names

If an output signal listed in the **Selected signals** list box is not an input to the Bus Selector block, the signal name starts with three question marks (???).

You can change the list by using the **Up**, **Down**, and **Remove** buttons. To save your changes, click **Apply**. You can select multiple contiguous signals to move or remove. You cannot rearrange leaf signals within a bus. For example, you can move bus signal `Bus1` up or down in the list, but you cannot reorder any of the bus elements of `Bus1`. Port connectivity is maintained when you change the signal order.

Programmatic Use

Block Parameter: `OutputSignals`

Type: character vector

Values: character vector in the form of `'signal1', signal2'`

Default: none

Output as bus — Output selected elements as bus

on (default) | off

By default, the block outputs the selected elements as standalone signals, each from an output port that is labeled with the corresponding bus element name. To output the selected bus element signals as a bus, select this parameter.

The output bus is virtual. To produce nonvirtual bus output, insert a Signal Conversion block after the Bus Selector block. Set the Signal Conversion block **Output** parameter to `Nonvirtual bus` and use a `Simulink.Bus` bus object for the **Data type** parameter. For an example, see the Signal Conversion documentation.

When the **Selected signals** list includes only one signal and you enable **Output as bus**, then if the selected signal is:

- A nonbus signal, it is treated as a nonbus signal (it is not wrapped in a bus).
- A bus signal, then the output is that bus signal.

Programmatic Use

Block Parameter:OutputAsBus

Type:character vector

Values:'on' | 'off'

Default:'off'

Bus to Vector

Convert virtual bus to vector

Library: Simulink / Signal Attributes

Description

The Bus to Vector block converts a virtual bus signal to a vector signal. The input bus signal must consist of scalar, 1-D, or either row or column vectors having the same data type, signal type, and sampling mode. If the input bus contains row or column vectors, this block outputs a row or column vector, respectively; otherwise, it outputs a 1-D array.

Use the block only to replace an implicit bus-to-vector conversion with an equivalent explicit conversion. To identify and correct buses used as vectors without manually inserting Bus to Vector blocks, you can use the Simulink Model Advisor “**Check bus signals treated as vectors**” on page 8-29 check. Alternatively, you can use the `Simulink.BlockDiagram.addBusToVector` function, which automatically inserts Bus to Vector blocks wherever needed.

Note If you use **Save As** for a model in a version of the Simulink product before R2007a, Simulink replaces each Bus to Vector block with a null subsystem that outputs nothing. Before you can use the model, reconnect or otherwise correct each signal that used to contain a Bus to Vector block but now is interrupted by a null subsystem.

Ports

Input

Port_1 — Accept signal to convert to vector
virtual bus | nonbus signal

An input virtual bus signal must consist of scalar, 1-D, or either row or column vectors having the same data type, signal type, and sampling mode. If the input is a nonbus signal, the block does no conversion.

Output

Port_1 — Output vector signal

vector | 1-D array

Output a vector signal, based on input bus signal. If the input bus contains row or column vectors, the block outputs a row or column vector, respectively. Otherwise, it outputs a 1-D array.

Parameters

This block has no user-accessible parameters.

Model Examples

Block Characteristics

Data Types	double single Boolean base integer fixed point enumerated bus

Callback Button

Execute MATLAB code based on user input

Library: Simulink / Dashboard

A rectangular button with rounded corners and a light gray border, containing the text "Callback Button" in a sans-serif font.

Description

The Callback Button block executes MATLAB code based on user input. The Callback Button block reacts to clicks and presses from the user. You can specify separate code to execute for each action. The Callback Button block repeats the code specified for the press action at a specified rate as long as you continue to press the button.

The Callback Button block registers a click when you release the left mouse button with the cursor on the Callback Button. The code for a press executes when you click the Callback Button and hold for the specified **Press Delay**.

Double-clicking the Callback Button block does not open its dialog box during simulation and when the block is selected. To edit the block's parameters, you can use the **Property Inspector**, or you can right-click the block and select **Block Parameters** from the context menu.

Parameters

Button Text — Text on button

'Callback Button' (default) | character array

Text that appears on the button.

Mouse Action — Mouse action to run code

'ClickFcn' (default) | 'PressFcn'

Mouse action that causes the MATLAB code to execute.

- Select `ClickFcn` to view and edit the code that executes when the Callback Button block is clicked.

- Select `PressFcn` to view and edit the code that executes when the button is pressed.

MATLAB Code — Code to execute based on user input

empty (default) | MATLAB Code

MATLAB code that executes based on user input.

Dependency

The MATLAB code displayed depends on the Mouse Action parameter selection.

- Select `ClickFcn` to view and edit the code that executes when the Callback Button block is clicked.
- Select `PressFcn` to view and edit the code that executes when the button is pressed.

Press Delay (ms) — Time to hold button for press

500 (default) | scalar

Amount of time required to cause the `PressFcn` code to execute.

Dependency

Press Delay (ms) is only visible when `PressFcn` is selected as the Mouse Action.

Repeat Interval (ms) — Time interval to repeat PressFcn code

0 (default) | scalar

Time interval after which the `PressFcn` code executes again if the Callback Button block is still pressed.

Dependency

Repeat Interval (ms) is only visible when `PressFcn` is selected as the Mouse Action.

“Tune and Visualize Your Model with Dashboard Blocks”

“Decide How to Visualize Simulation Data”

Introduced in R2017b

Check Box

Select parameter or variable value

Library: Simulink / Dashboard

Description

The Check Box block allows you to set the value of a parameter or variable during simulation by checking or clearing the box. Use the Check Box block with other Dashboard blocks to create an interactive dashboard for your model.

Double-clicking the Check Box block does not open its dialog box during simulation and when the block is selected. To edit the block's parameters, you can use the **Property Inspector**, or you can right-click the block and select **Block Parameters** from the context menu.

Connection

Dashboard block controls connect to variables and block parameters. To connect a Dashboard block to a variable or parameter, use the **Connection** table in the block's parameters.

- 1 Double-click the block.
- 2 Populate the **Connection** table by selecting blocks of interest in your model.
- 3 Mark the option button next to the parameter or variable you want to adjust during simulation.
- 4 Click **Apply**.

Limitations

- You cannot save the block connections or properties in model files that use the MDL format.

To save connections and properties, save the model file in the SLX format.

- Dashboard blocks can only connect to real scalar signals.
- Dashboard blocks cannot connect to blocks that are commented out.
- Dashboard blocks cannot connect to signals inside reference models.
- Parameters specified by indexing a variable array do not appear in the **Connection** table. For example, a block parameter defined using the variable `engine(1)` does not appear in the table.

To access the parameter in the **Connection** table, assign the indexed value to a scalar variable, such as `engine_1`. Then, use the scalar variable to define the block parameter.

Parameters

Connection — Select a block parameter to connect

signal connection options

Select the block parameter to control using the **Connection** table. To open the dialog box, double-click the block. Then, populate the **Connection** table by selecting a block in your model. Select the variable parameter you want to control, and click **Apply**.

Note To see workspace variables in the connection table, update the model diagram with **Ctrl+D**.

States

Value (Unchecked) — Value when unchecked

0 (default) | scalar

Value assigned to the connected parameter when the Check Box block is not checked.

Value (Checked) — Value when checked

0 (default) | scalar

Value assigned to the connected parameter when the Check Box block is checked.

Label — Block label position

'Top' (default) | 'Bottom' | 'Hide'

Position of the block label. When the block is connected to a signal, the label is the name of the connected signal. When the block is not connected, the label is the instructional text.

Check Discrete Gradient

Check that absolute value of difference between successive samples of discrete signal is less than upper bound

Library

Model Verification

Description

The Check Discrete Gradient block checks each signal element at its input to determine whether the absolute value of the difference between successive samples of the element is less than an upper bound. Use the block parameter dialog box to specify the value of the upper bound (1 by default). If the verification condition is true, the block does nothing. Otherwise, the block halts the simulation, by default, and displays an error in the Diagnostic Viewer.

The **Model Verification block enabling** setting in the Configuration Parameters dialog box lets you enable or disable all model verification blocks, including Check Discrete Gradient blocks, in a model.

The Check Discrete Gradient block and its companion blocks in the Model Verification library are intended to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to physically remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

Note For information about how Simulink Coder generated code handles Model Verification blocks, see “Debug” (Simulink Coder).

Data Type Support

The Check Discrete Gradient block accepts `single`, `double`, `int8`, `int16`, and `int32` input signals of any dimensions. This block also supports fixed-point data types.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Maximum gradient

Specify the upper bound on the gradient of the discrete input signal.

Enable assertion

Clearing this check box disables the Check Discrete Gradient block, that is, causes the model to behave as if the block did not exist. The **Model Verification block enabling** setting in the Configuration Parameters dialog box allows you to enable or disable all model verification blocks in a model, including Check Discrete Gradient blocks, regardless of the setting of this option.

Simulation callback when assertion fails

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Stop simulation when assertion fails

Selecting this check box causes the Check Discrete Gradient block to halt the simulation when the block's output is zero and the Simulink software displays an error. Otherwise, the Simulink software displays a warning and continues the simulation.

Output assertion signal

Selecting this check box causes the Check Discrete Gradient block to output a Boolean signal that is true (1) at each time step if the assertion succeeds and false (0) if the assertion fails. The data type of the output signal is `Boolean` if you have selected the **Implement logic signals as Boolean data** check box on the Configuration Parameters dialog box. Otherwise the data type of the output signal is `double`.

Select icon type

Specify the type of icon used to display this block in a block diagram: either `graphic` or `text`. The `graphic` option displays a graphical representation of the assertion condition on the icon. The `text` option displays a mathematical expression that represents the assertion condition. If the icon is too small to display the expression, the text icon displays an exclamation point. To see the expression, enlarge the block.

Characteristics

Data Types	Double Single Base Integer Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	No
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Check Dynamic Gap

Check that gap of possibly varying width occurs in range of signal's amplitudes

Library

Model Verification

Description

The Check Dynamic Gap block checks that a gap of possibly varying width occurs in the range of a signal's amplitudes. The test signal is the signal connected to the input labeled *sig*. The inputs labeled *min* and *max* specify the lower and upper bounds of the dynamic gap, respectively. If the verification condition is true, the block does nothing. If not, the block halts the simulation, by default, and displays an error message.

The Check Dynamic Gap block and its companion blocks in the Model Verification library are intended to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to physically remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

Note For information about how Simulink Coder generated code handles Model Verification blocks, see “Debug” (Simulink Coder).

Data Type Support

The Check Dynamic Gap block accepts input signals of any dimensions and of any numeric data type that Simulink supports. All three input signals must have the same

dimension and data type. If the inputs are nonscalar, the block checks each element of the input test signal to the corresponding elements of the reference signals.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Enable assertion

Clearing this check box disables the Check Dynamic Gap block, that is, causes the model to behave as if the block did not exist. The **Model Verification block enabling** setting in the Configuration Parameters dialog box allows you to enable or disable all model verification blocks in a model, including Check Dynamic Gap blocks, regardless of the setting of this option.

Simulation callback when assertion fails

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Stop simulation when assertion fails

Selecting this check box causes the Check Dynamic Gap block to halt the simulation when the block's output is zero and the Simulink software displays an error. Otherwise, the Simulink software displays a warning and continues the simulation.

Output assertion signal

Selecting this check box causes the Check Dynamic Gap block to output a Boolean signal that is true (1) at each time step if the assertion succeeds and false (0) if the assertion fails. The data type of the output signal is `Boolean` if you have selected the **Implement logic signals as Boolean data** check box on the Configuration Parameters dialog box. Otherwise the data type of the output signal is `double`.

Select icon type

Specify the type of icon used to display this block in a block diagram: either `graphic` or `text`. The `graphic` option displays a graphical representation of the assertion condition on the icon. The `text` option displays a mathematical expression that represents the assertion condition. If the icon is too small to display the expression, the text icon displays an exclamation point. To see the expression, enlarge the block.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated
Sample Time	Inherited from driving block
Direct Feedthrough	No
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Check Dynamic Lower Bound

Check that one signal is always less than another signal

Library

Model Verification

Description

The Check Dynamic Lower Bound block checks that the amplitude of a reference signal is less than the amplitude of a test signal at the current time step. The test signal is the signal connected to the input labeled *sig*. If the verification condition is true, the block does nothing. If not, the block halts the simulation, by default, and displays an error message.

The Check Dynamic Lower Bound block and its companion blocks in the Model Verification library are intended to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to physically remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

Note For information about how Simulink Coder generated code handles Model Verification blocks, see “Debug” (Simulink Coder).

Data Type Support

The Check Dynamic Lower Bound block accepts input signals of any numeric data type that Simulink supports. The test and the reference signals must have the same

dimensions and data type. If the inputs are nonscalar, the block checks each element of the input test signal to the corresponding elements of the reference signal.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Enable assertion

Clearing this check box disables the Check Dynamic Lower Bound block, that is, causes the model to behave as if the block did not exist. The **Model Verification block enabling** setting in the Configuration Parameters dialog box allows you to enable or disable all model verification blocks, including Check Dynamic Lower Bound blocks, in a model regardless of the setting of this option.

Simulation callback when assertion fails

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Stop simulation when assertion fails

Selecting this check box causes the Check Dynamic Lower Bound block to halt the simulation when the block's output is zero and the Simulink software displays an error. Otherwise, the Simulink software displays a warning and continues the simulation.

Output assertion signal

Selecting this check box causes the Check Dynamic Lower Bound block to output a Boolean signal that is true (1) at each time step if the assertion succeeds and false (0) if the assertion fails. The data type of the output signal is `Boolean` if you have selected the **Implement logic signals as Boolean data** check box on the Configuration Parameters dialog box. Otherwise the data type of the output signal is `double`.

Select icon type

Specify the type of icon used to display this block in a block diagram: either `graphic` or `text`. The `graphic` option displays a graphical representation of the assertion condition on the icon. The `text` option displays a mathematical expression that represents the assertion condition. If the icon is too small to display the expression, the text icon displays an exclamation point. To see the expression, enlarge the block.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated
Sample Time	Inherited from driving block
Direct Feedthrough	No
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Check Dynamic Range

Check that signal falls inside range of amplitudes that varies from time step to time step

Library

Model Verification

Description

The Check Dynamic Range block checks that a test signal falls inside a range of amplitudes at each time step. The width of the range can vary from time step to time step. The input labeled *sig* is the test signal. The inputs labeled *min* and *max* are the lower and upper bounds of the valid range at the current time step. If the verification condition is true, the block does nothing. If not, the block halts the simulation, by default, and displays an error message.

The Check Dynamic Range block and its companion blocks in the Model Verification library are intended to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to physically remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

Note For information about how Simulink Coder generated code handles Model Verification blocks, see “Debug” (Simulink Coder).

Data Type Support

The Check Dynamic Range block accepts input signals of any dimensions and of any numeric data type that Simulink supports. All three input signals must have the same dimension and data type. If the inputs are nonscalar, the block checks each element of the input test signal to the corresponding elements of the reference signals.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Enable assertion

Clearing this check box disables the Check Dynamic Range block, that is, causes the model to behave as if the block did not exist. The **Model Verification block enabling** setting in the Configuration Parameters dialog box allows you to enable or disable all model verification blocks in a model, including Check Dynamic Range blocks, regardless of the setting of this option.

Simulation callback when assertion fails

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Stop simulation when assertion fails

Selecting this check box causes the Check Dynamic Range block to halt the simulation when the block's output is zero and the Simulink software display an error. Otherwise, the Simulink software displays a warning and continues the simulation.

Output assertion signal

Selecting this check box causes the Check Dynamic Range block to output a Boolean signal that is true (1) at each time step if the assertion succeeds and false (0) if the assertion fails. The data type of the output signal is `Boolean` if you selected the **Implement logic signals as Boolean data** check box on the Configuration Parameters dialog box. Otherwise the data type of the output signal is `double`.

Select icon type

Specify the type of icon used to display this block in a block diagram: either `graphic` or `text`. The `graphic` option displays a graphical representation of the assertion

condition on the icon. The `text` option displays a mathematical expression that represents the assertion condition. If the icon is too small to display the expression, the text icon displays an exclamation point. To see the expression, enlarge the block.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated
Sample Time	Inherited from driving block
Direct Feedthrough	No
Multidimensional Signals	Yes
Variable-Size Signals	No

Check Dynamic Upper Bound

Check that one signal is always greater than another signal

Library

Model Verification

Description

The Check Dynamic Upper Bound block checks that the amplitude of a reference signal is greater than the amplitude of a test signal at the current time step. The test signal is the signal connected to the input labeled *sig*. If the verification condition is true, the block does nothing. If not, the block halts the simulation, by default, and displays an error message.

The Check Dynamic Upper Bound block and its companion blocks in the Model Verification library are intended to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error-checking off by disabling the verification blocks. You do not have to physically remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

Note For information about how Simulink Coder generated code handles Model Verification blocks, see “Debug” (Simulink Coder).

Data Type Support

The Check Dynamic Upper Bound block accepts input signals of any dimensions and of any numeric data type that Simulink supports. The test and the reference signals must

have the same dimensions and data type. If the inputs are nonscalar, the block compares each element of the input test signal to the corresponding elements of the reference signal.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Enable assertion

Clearing this check box disables the Check Dynamic Upper Bound block, that is, causes the model to behave as if the block did not exist. The **Model Verification block enabling** setting in the Configuration Parameters dialog box allows you to enable or disable all model verification blocks, including Check Dynamic Upper Bound blocks, in a model regardless of the setting of this option.

Simulation callback when assertion fails

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Stop simulation when assertion fails

Selecting this check box causes the Check Dynamic Upper Bound block to halt the simulation when the block's output is zero and the Simulink software displays an error. Otherwise, the Simulink software displays a warning and continues the simulation.

Output assertion signal

Selecting this check box causes the Check Dynamic Upper Bound block to output a Boolean signal that is true (1) at each time step if the assertion succeeds and false (0) if the assertion fails. The data type of the output signal is `Boolean` if you have selected the **Implement logic signals as Boolean data** check box on the Configuration Parameters dialog box. Otherwise the data type of the output signal is `double`.

Select icon type

Specify the type of icon used to display this block in a block diagram: either `graphic` or `text`. The `graphic` option displays a graphical representation of the assertion condition on the icon. The `text` option displays a mathematical expression that

represents the assertion condition. If the icon is too small to display the expression, the text icon displays an exclamation point. To see the expression, enlarge the block.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated
Sample Time	Inherited from driving block
Direct Feedthrough	No
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Check Input Resolution

Check that input signal has specified resolution

Library

Model Verification

Description

The Check Input Resolution block checks whether the input signal has a specified scalar or vector resolution (see **Resolution** in “Parameters” on page 1-132). If the resolution is a scalar, the input signal must be a multiple of the resolution within a $10e-3$ tolerance. If the resolution is a vector, the input signal must equal an element of the resolution vector. If the verification condition is true, the block does nothing. If not, the block halts the simulation, by default, and displays an error message.

The Check Input Resolution block and its companion blocks in the Model Verification library are intended to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to physically remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

Note For information about how Simulink Coder generated code handles Model Verification blocks, see “Debug” (Simulink Coder).

Data Type Support

The Check Input Resolution block accepts input signals of data type `double` and of any dimension. If the input signal is nonscalar, the block checks the resolution of each element of the input test signal.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Resolution

Specify the resolution that the input signal must have.

Enable assertion

Clearing this check box disables the Check Input Resolution block, that is, causes the model to behave as if the block did not exist. The **Model Verification block enabling** setting in the Configuration Parameters dialog box allows you to enable or disable all model verification blocks in a model, including Check Input Resolution blocks, regardless of the setting of this option.

Simulation callback when assertion fails

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Stop simulation when assertion fails

Selecting this check box causes the Check Input Resolution block to halt the simulation when the block's output is zero and the Simulink software displays an error. Otherwise, the Simulink software displays a warning and continues the simulation.

Output assertion signal

Selecting this check box causes the Check Input Resolution block to output a Boolean signal that is true (1) at each time step if the assertion succeeds and false (0) if the assertion fails. The data type of the output signal is `Boolean` if you have selected the **Implement logic signals as Boolean data** check box on the Configuration Parameters dialog box. Otherwise the data type of the output signal is `double`.

Characteristics

Data Types	Double
Sample Time	Inherited from driving block
Direct Feedthrough	No
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Check Static Gap

Check that gap exists in signal's range of amplitudes

Library

Model Verification

Description

The Check Static Gap block checks that each element of the input signal is less than (or optionally equal to) a static lower bound or greater than (or optionally equal to) a static upper bound at the current time step. If the verification condition is true, the block does nothing. If not, the block halts the simulation, by default, and displays an error message.

The Check Static Gap block and its companion blocks in the Model Verification library are intended to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to physically remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

Note For information about how Simulink Coder generated code handles Model Verification blocks, see “Debug” (Simulink Coder).

Data Type Support

The Check Static Gap block accepts input signals of any dimensions and of any numeric data type that Simulink supports.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Upper bound

Specify the upper bound of the gap in the input signal's range of amplitudes.

Inclusive upper bound

Selecting this check box specifies that the gap includes the upper bound.

Lower bound

Specify the lower bound of the gap in the input signal's range of amplitudes.

Inclusive lower bound

Selecting this check box specifies that the gap includes the lower bound.

Enable assertion

Clearing this check box disables the Check Static Gap block, that is, causes the model to behave as if the block did not exist. The **Model Verification block enabling** setting in the Configuration Parameters dialog box allows you to enable or disable all model verification blocks in a model, including Check Static Gap blocks, regardless of the setting of this option.

Simulation callback when assertion fails

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Stop simulation when assertion fails

Selecting this check box causes the Check Static Gap block to halt the simulation when the block's output is zero and the Simulink software displays an error. Otherwise, the Simulink software displays a warning and continues the simulation.

Output assertion signal

Selecting this check box causes the Check Static Gap block to output a Boolean signal that is true (1) at each time step if the assertion succeeds and false (0) if the assertion fails. The data type of the output signal is `Boolean` if you have selected the **Implement logic signals as Boolean data** check box on the **Optimization** pane of the Configuration Parameters dialog box. Otherwise the data type of the output signal is `double`.

Select icon type

Specify the type of icon used to display this block in a block diagram: either `graphic` or `text`. The `graphic` option displays a graphical representation of the assertion condition on the icon. The `text` option displays a mathematical expression that represents the assertion condition. If the icon is too small to display the expression, the text icon displays an exclamation point. To see the expression, enlarge the block.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated
Sample Time	Inherited from driving block
Direct Feedthrough	No
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Check Static Lower Bound

Check that signal is greater than (or optionally equal to) static lower bound

Library

Model Verification

Description

The Check Static Lower Bound block checks that each element of the input signal is greater than (or optionally equal to) a specified lower bound at the current time step. Use the block parameter dialog box to specify the value of the lower bound and whether the lower bound is inclusive. If the verification condition is true, the block does nothing. If not, the block halts the simulation, by default, and displays an error message.

The Check Static Lower Bound block and its companion blocks in the Model Verification library are intended to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to physically remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

Note For information about how Simulink Coder generated code handles Model Verification blocks, see “Debug” (Simulink Coder).

Data Type Support

The Check Static Lower Bound block accepts input signals of any dimensions and of any numeric data type that Simulink supports.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Lower bound

Specify the lower bound on the range of amplitudes that the input signal can have.

Inclusive boundary

Selecting this check box makes the range of valid input amplitudes include the lower bound.

Enable assertion

Clearing this check box disables the Check Static Lower Bound block, that is, causes the model to behave as if the block did not exist. The **Model Verification block enabling** setting in the Configuration Parameters dialog box allows you to enable or disable all model verification blocks in a model, including Check Static Lower Bound blocks, regardless of the setting of this option.

Simulation callback when assertion fails

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Stop simulation when assertion fails

Selecting this check box causes the Check Static Lower Bound block to halt the simulation when the block's output is zero and the Simulink software displays an error. Otherwise, the Simulink software displays a warning and continues the simulation.

Output assertion signal

Selecting this check box causes the Check Static Lower Bound block to output a Boolean signal that is true (1) at each time step if the assertion succeeds and false (0) if the assertion fails. The data type of the output signal is `Boolean` if you have selected the **Implement logic signals as Boolean data** check box on the Configuration Parameters dialog box. Otherwise the data type of the output signal is `double`.

Select icon type

Specify the type of icon used to display this block in a block diagram: either `graphic` or `text`. The `graphic` option displays a graphical representation of the assertion

condition on the icon. The `text` option displays a mathematical expression that represents the assertion condition. If the icon is too small to display the expression, the text icon displays an exclamation point. To see the expression, enlarge the block.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated
Sample Time	Inherited from driving block
Direct Feedthrough	No
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Check Static Range

Check that signal falls inside fixed range of amplitudes

Library

Model Verification

Description

The Check Static Range block checks that each element of the input signal falls inside the same range of amplitudes at each time step. Use the block parameter dialog box to specify the upper and lower bounds of the valid amplitude range and whether the range includes the bounds. If the verification condition is true, the block does nothing. If not, the block halts the simulation, by default, and displays an error message.

The Check Static Range block and its companion blocks in the Model Verification library are intended to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to physically remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

Note For information about how Simulink Coder generated code handles Model Verification blocks, see “Debug” (Simulink Coder).

Data Type Support

The Check Static Range block accepts input signals of any dimensions and of any numeric data type that Simulink supports.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Upper bound

Specify the upper bound of the range of valid input signal amplitudes.

Inclusive upper bound

Selecting this check box specifies that the valid signal range includes the upper bound.

Lower bound

Specify the lower bound of the range of valid input signal amplitudes.

Inclusive lower bound

Selecting this check box specifies that the valid signal range includes the lower bound.

Enable assertion

Clearing this check box disables the Check Static Range block, that is, causes the model to behave as if the block did not exist. The **Model Verification block enabling** setting in the Configuration Parameters dialog box allows you to enable or disable all model verification blocks in a model, including Check Static Range blocks, regardless of the setting of this option.

Simulation callback when assertion fails

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Stop simulation when assertion fails

Selecting this check box causes the Check Static Range block to halt the simulation when the block's output is zero and the Simulink software display an error. Otherwise, the Simulink software displays a warning and continues the simulation.

Output assertion signal

Selecting this check box causes the Check Static Range block to output a Boolean signal that is true (1) at each time step if the assertion succeeds and false (0) if the assertion fails. The data type of the output signal is `Boolean` if you have selected the

Implement logic signals as Boolean data check box in the Configuration Parameters dialog box. Otherwise the data type of the output signal is double.

Select icon type

Specify the type of icon used to display this block in a block diagram: either `graphic` or `text`. The `graphic` option displays a graphical representation of the assertion condition on the icon. The `text` option displays a mathematical expression that represents the assertion condition. If the icon is too small to display the expression, the text icon displays an exclamation point. To see the expression, enlarge the block.

Examples

The `sldemo_fuelsys` model shows how you can use the Check Static Range block to verify that the sample time is consistent throughout the model.

The Check Static Range block appears in the `sldemo_fuelsys/fuel_rate_control/validate_sample_time` subsystem.

Verify sample time: aspects of the design assume a 0.01 second sample time.

Characteristics

Introduced before R2006a

Check Static Upper Bound

Check that signal is less than (or optionally equal to) static upper bound

Library

Model Verification

Description

The Check Static Upper Bound block checks that each element of the input signal is less than (or optionally equal to) a specified upper bound at the current time step. Use the block parameter dialog box to specify the value of the upper bound and whether the bound is inclusive. If the verification condition is true, the block does nothing. If not, the block halts the simulation, by default, and displays an error message.

The Check Static Upper Bound block and its companion blocks in the Model Verification library are intended to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to physically remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

Note For information about how Simulink Coder generated code handles Model Verification blocks, see “Debug” (Simulink Coder).

Data Type Support

The Check Static Upper Bound block accepts input signals of any dimensions and of any numeric data type that Simulink supports.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Upper bound

Specify the upper bound on the range of amplitudes that the input signal can have.

Inclusive boundary

Selecting this check box makes the range of valid input amplitudes include the upper bound.

Enable assertion

Clearing this check box disables the Check Static Upper Bound block, that is, causes the model to behave as if the block did not exist. The **Model Verification block enabling** setting in the Configuration Parameters dialog box allows you to enable or disable all model verification blocks in a model, including Check Static Upper Bound blocks, regardless of the setting of this option.

Simulation callback when assertion fails

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Stop simulation when assertion fails

Selecting this check box causes the Check Static Upper Bound block to halt the simulation when the block's output is zero and the Simulink software displays an error. Otherwise, the Simulink software displays a warning and continues the simulation.

Output assertion signal

Selecting this check box causes the Check Static Upper Bound block to output a Boolean signal that is true (1) at each time step if the assertion succeeds and false (0) if the assertion fails. The data type of the output signal is `Boolean` if you have selected the **Implement logic signals as Boolean data** check box in the Configuration Parameters dialog box. Otherwise the data type of the output signal is `double`.

Select icon type

Specify the type of icon used to display this block in a block diagram: either `graphic` or `text`. The `graphic` option displays a graphical representation of the assertion

condition on the icon. The `text` option displays a mathematical expression that represents the assertion condition. If the icon is too small to display the expression, the text icon displays an exclamation point. To see the expression, enlarge the block.

Chirp Signal

Generate sine wave with increasing frequency

Library

Sources

Description

The Chirp Signal block generates a sine wave whose frequency increases at a linear rate with time. You can use this block for spectral analysis of nonlinear systems. The block generates a scalar or vector output.

The parameters, **Initial frequency**, **Target time**, and **Frequency at target time**, determine the block's output. You can specify any or all of these variables as scalars or arrays. All the parameters specified as arrays must have the same dimensions. The block expands scalar parameters to have the same dimensions as the array parameters. The block output has the same dimensions as the parameters unless you select the **Interpret vector parameters as 1-D** check box. If you select this check box and the parameters are row or column vectors, the block outputs a vector (1-D array) signal.

The following limitations apply to the Chirp Signal block:

- The start time of the simulation must be 0. To confirm this value, go to the **Solver** pane in the Configuration Parameters dialog box and view the **Start time** field.
- Suppose that you use a Chirp Signal block in an enabled subsystem. Whenever the subsystem is enabled, the block output matches what would appear if the subsystem were enabled throughout the simulation.

Data Type Support

The Chirp Signal block outputs a real-valued signal of type `double`.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Initial frequency

The initial frequency of the signal, specified as a scalar or matrix value. The default is 0.1 Hz.

Target time

The time at which the frequency reaches the **Frequency at target time** parameter value, a scalar or matrix value. The frequency continues to change at the same rate after this time. The default is 100 seconds.

Frequency at target time

The frequency of the signal at the target time, a scalar or matrix value. The default is 1 Hz.

Interpret vector parameters as 1-D

If selected, column or row matrix values for the **Initial frequency**, **Target time**, and **Frequency at target time** parameters result in a vector output whose elements are the elements of the row or column. For more information, see “Determining the Output Dimensions of Source Blocks” in the Simulink documentation.

Characteristics

Data Types	Double
Sample Time	Continuous
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No

Code Generation	Yes
-----------------	-----

Introduced before R2006a

Clock

Display and provide simulation time

Library

Sources

Description

The Clock block outputs the current simulation time at each simulation step. This block is useful for other blocks that need the simulation time.

When you need the current time within a discrete system, use the Digital Clock block.

Data Type Support

The Clock block outputs a real-valued signal of type `double`.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Display time

Select this check box to display the current simulation time inside the Clock block icon.

Decimation

Specify a positive integer for the interval at which Simulink updates the Clock icon when you select **Display time**.

Suppose that the decimation is 1000. For a fixed integration step of 1 millisecond, the Clock icon updates at 1 second, 2 seconds, and so on.

Examples

The following Simulink examples show how to use the Clock block:

- `sldemo_tonegen_fixpt`
- `penddemo`

Characteristics

Data Types	Double
Sample Time	Continuous
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Digital Clock

Introduced before R2006a

Combinatorial Logic

Implement truth table

Library

Logic and Bit Operations

Description

The Combinatorial Logic block implements a standard truth table for modeling programmable logic arrays (PLAs), logic circuits, decision tables, and other Boolean expressions. You can use this block in conjunction with Memory blocks to implement finite-state machines or flip-flops.

You specify a matrix that defines all possible block outputs as the **Truth table** parameter. Each row of the matrix contains the output for a different combination of input elements. You must specify outputs for every combination of inputs. The number of columns is the number of block outputs.

The relationship between the number of inputs and the number of rows is:

$$\text{number of rows} = 2^{\text{(number of inputs)}}$$

Simulink returns a row of the matrix by computing the row's index from the input vector elements. Simulink computes the index by building a binary number where input vector elements having zero values are 0 and elements having nonzero values are 1, then adding 1 to the result. For an input vector, u , of m elements:

$$\text{row index} = 1 + u(m) * 2^0 + u(m-1) * 2^1 + \dots + u(1) * 2^{m-1}$$

Two-Input AND Logic

This example builds a two-input AND function, which returns 1 when both input elements are 1, and 0 otherwise. To implement this function, specify the **Truth table** parameter value as [0; 0; 0; 1]. The portion of the model that provides the inputs to and the output from the Combinatorial Logic block might look like this:

The following table indicates the combination of inputs that generate each output. The input signal labeled “Input 1” corresponds to the column in the table labeled Input 1. Similarly, the input signal “Input 2” corresponds to the column with the same name. The combination of these values determines the row of the Output column of the table that is passed as block output.

For example, if the input vector is [1 0], the input references the third row:

$$(2^{1*1} + 1)$$

The output value is 0.

Row	Input 1	Input 2	Output
1	0	0	0
2	0	1	0
3	1	0	0
4	1	1	1

Circuit Logic

This sample circuit has three inputs: the two bits (**a** and **b**) to be summed and a carry-in bit (**c**). It has two outputs: the carry-out bit (**c'**) and the sum bit (**s**).

The truth table and corresponding outputs for each combination of input values for this circuit appear in the following table.

Inputs			Outputs	
a	b	c	c'	s
0	0	0	0	0
0	0	1	0	1
0	1	0	0	1
0	1	1	1	0
1	0	0	0	1
1	0	1	1	0
1	1	0	1	0
1	1	1	1	1

To implement this adder with the Combinatorial Logic block, you enter the 8-by-2 matrix formed by columns **c'** and **s** as the **Truth table** parameter.

You can also implement sequential circuits (that is, circuits with states) with the Combinatorial Logic block by including an additional input for the state of the block and feeding the output of the block back into this state input.

Data Type Support

The type of signals accepted by a Combinatorial Logic block depends on whether you selected the Boolean logic signals option (see “Implement logic signals as Boolean data (vs. double)”). If this option is enabled, the block accepts real signals of type `Boolean` or `double`. The **Truth table** parameter can have Boolean values (0 or 1) of any data type,

including fixed-point data types. If the table contains non-Boolean values, the data type of the table must be `double`.

The type of the output is the same as that of the input except that the block outputs `double` if the input is `Boolean` and the truth table contains non-Boolean values.

If Boolean compatibility mode is disabled, the Combinatorial Logic block accepts only signals of type `Boolean`. The block outputs `double` if the truth table contains non-Boolean values of type `double`. Otherwise, the output is `Boolean`.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Truth table

Specify the matrix of outputs. Each column corresponds to an element of the output vector and each row corresponds to a row of the truth table.

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Examples

Usage with the Memory Block to Implement a Finite-State Machine

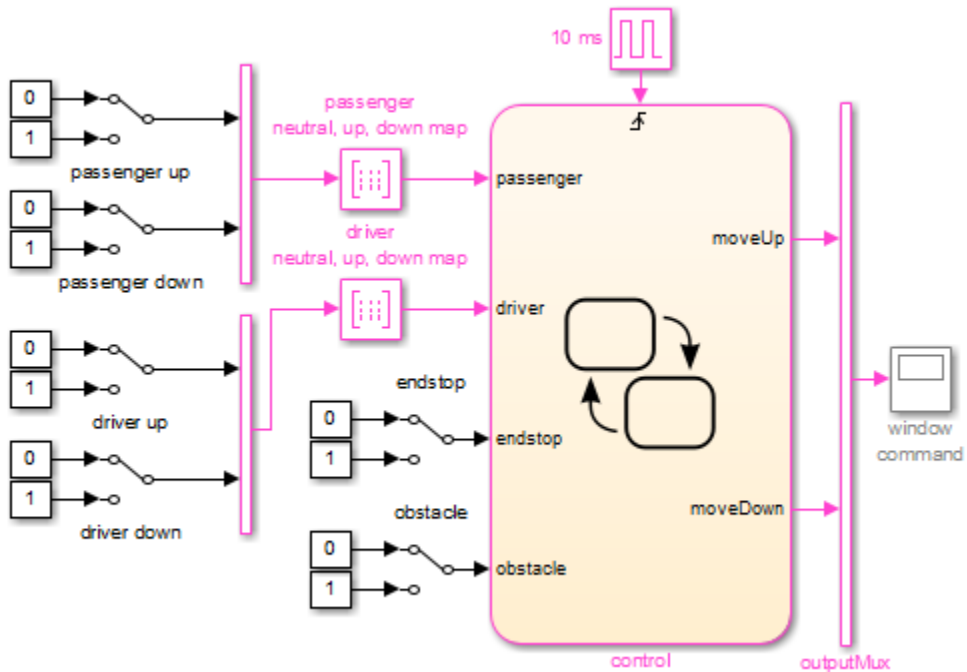

The `sldemo_clutch` model shows how you can use the Combinatorial Logic block with the Memory block to implement a finite-state machine.

The finite-state machine appears in the `Friction Mode Logic/Lockup FSM` subsystem.

Usage with a Stateflow Chart to Implement a Finite-State Machine

The powerwindow model shows how you can use two Combinatorial Logic blocks as inputs to a Stateflow chart to implement a finite-state machine.

Characteristics

Data Types	Double Boolean
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Combo Box

Select parameter value from drop-down menu

Library: Simulink / Dashboard

Description

The Combo Box block lets you set the value of a parameter to one of several values. You can define each selectable value and its label through the Combo Box block parameters. Use the Combo Box block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model.

Double-clicking the Combo Box block does not open its dialog box during simulation and when the block is selected. To edit the block's parameters, you can use the **Property Inspector**, or you can right-click the block and select **Block Parameters** from the context menu.

Connection

Dashboard block controls connect to variables and block parameters. To connect a Dashboard block to a variable or parameter, use the **Connection** table in the block's parameters.

- 1 Double-click the block.
- 2 Populate the **Connection** table by selecting blocks of interest in your model.
- 3 Mark the option button next to the parameter or variable you want to adjust during simulation.
- 4 Click **Apply**.

Limitations

- You cannot save the block connections or properties in model files that use the MDL format.

To save connections and properties, save the model file in the SLX format.

- Dashboard blocks can only connect to real scalar signals.
- Dashboard blocks cannot connect to blocks that are commented out.
- Dashboard blocks cannot connect to signals inside reference models.
- Parameters specified by indexing a variable array do not appear in the **Connection** table. For example, a block parameter defined using the variable `engine(1)` does not appear in the table.

To access the parameter in the **Connection** table, assign the indexed value to a scalar variable, such as `engine_1`. Then, use the scalar variable to define the block parameter.

Parameters

Connection — Select a block parameter to connect

signal connection options

Select the block parameter to control using the **Connection** table. To open the dialog box, double-click the block. Then, populate the **Connection** table by selecting a block in your model. Select the variable parameter you want to control, and click **Apply**.

Note To see workspace variables in the connection table, update the model diagram with **Ctrl+D**.

States

value — Values for selected option

0/1/2 (default) | scalar

Values assigned to the connected parameter when you select the option with the corresponding **Label**. Click the **+** button to add options.

Label — Option labels

'Label1'/'Label2'/'Label3' (default) | character vector

Label for each option. You can use the **Label** to display the value the connected parameter takes when the switch is positioned at the bottom, or you can enter a text label.

Example: `Gain = 1`

Label — Block label position

'Top' (default) | 'Bottom' | 'Hide'

Position of the block label. When the block is connected to a signal, the label is the name of the connected signal. When the block is not connected, the label is the instructional text.

Compare To Constant

Determine how signal compares to specified constant

Library

Logic and Bit Operations

Description

The Compare To Constant block compares an input signal to a constant. Specify the constant in the **Constant value** parameter. Specify how the input is compared to the constant value with the **Operator** parameter. The **Operator** parameter can have the following values:

- == — Determine whether the input is equal to the specified constant.
- ~= — Determine whether the input is not equal to the specified constant.
- < — Determine whether the input is less than the specified constant.
- <= — Determine whether the input is less than or equal to the specified constant.
- > — Determine whether the input is greater than the specified constant.
- >= — Determine whether the input is greater than or equal to the specified constant.

The output is 0 if the comparison is false, and 1 if it is true.

Data Type Support

The Compare To Constant block accepts inputs of any data type that Simulink supports, including fixed-point and enumerated data types. The block first converts its **Constant**

value parameter to the input data type, and then performs the specified operation. The block output is `uint8` or `boolean` as specified by the **Output data type** parameter.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Operator

Specify how the input is compared to the constant value, as discussed in Description on page 1-161.

Constant value

Specify the constant value to which the input is compared.

Output data type

Specify the data type of the output, `boolean` or `uint8`.

Enable zero-crossing detection

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	Yes, if enabled
Code Generation	Yes

See Also

Compare To Zero

Introduced before R2006a

Compare To Zero

Determine how signal compares to zero

Library

Logic and Bit Operations

Description

The Compare To Zero block compares an input signal to zero. Specify how the input is compared to zero with the **Operator** parameter. The **Operator** parameter can have the following values:

- == — Determine whether the input is equal to zero.
- ~= — Determine whether the input is not equal to zero.
- < — Determine whether the input is less than zero.
- <= — Determine whether the input is less than or equal to zero.
- > — Determine whether the input is greater than zero.
- >= — Determine whether the input is greater than or equal to zero.

The output is 0 if the comparison is false, and 1 if it is true.

Data Type Support

The Compare To Zero block accepts inputs of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean

The block output is `uint8` or `boolean`, depending on your selection for the **Output data type** parameter. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Tip If the input data type cannot represent zero, parameter overflow occurs. To detect this overflow, go to the **Diagnostics > Data Validity** pane of the Configuration Parameters dialog box and set **Parameters > Detect overflow** to `warning` or `error`.

In this case, the block compares the input signal to the *ground value* of the input data type. For example, if you have an input signal of type `fixdt(0, 8, 2^0, 10)`, the input data type can represent unsigned 8-bit integers from 10 to 265 due to a bias of 10. The ground value is 10, instead of 0.

Parameters

Operator

Specify how the input is compared to zero, as discussed in Description on page 1-164.

Output data type

Specify the data type of the output, `boolean` or `uint8`.

Enable zero-crossing detection

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point
Direct Feedthrough	Yes
Multidimensional Signals	Yes

Variable-Size Signals	Yes
Zero-Crossing Detection	Yes, if enabled
Code Generation	Yes

Complex to Magnitude-Angle

Compute magnitude and/or phase angle of complex signal

Library

Math Operations

Description

The Complex to Magnitude-Angle block accepts a complex-valued signal of type `double` or `single`. It outputs the magnitude and/or phase angle of the input signal, depending on the setting of the **Output** parameter. The outputs are real values of the same data type as the block input. The input can be an array of complex signals, in which case the output signals are also arrays. The magnitude signal array contains the magnitudes of the corresponding complex input elements. The angle output similarly contains the angles of the input elements.

Data Type Support

See the preceding description.

Parameters

Output

Determines the output of this block. Choose from the following values: `Magnitude and angle` (outputs the input signal's magnitude and phase angle in radians),

Magnitude (outputs the input's magnitude), Angle (outputs the input's phase angle in radians).

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Characteristics

Data Types	Double Single
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Complex to Real-Imag

Output real and imaginary parts of complex input signal

Library

Math Operations

Description

The Complex to Real-Imag block accepts a complex-valued signal of any data type that Simulink supports, including fixed-point data types. It outputs the real and/or imaginary part of the input signal, depending on the setting of the **Output** parameter. The real outputs are of the same data type as the complex input. The input can be an array (vector or matrix) of complex signals, in which case the output signals are arrays of the same dimensions. The real array contains the real parts of the corresponding complex input elements. The imaginary output similarly contains the imaginary parts of the input elements.

Data Type Support

See the preceding description. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Output

Determines the output of this block. Choose from the following values: `Real` and `imag` (outputs the input signal's real and imaginary parts), `Real` (outputs the input's real part), `Imag` (outputs the input's imaginary part).

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Configurable Subsystem

Represent any block selected from user-specified library of blocks

Library

Ports & Subsystems

Description

The Configurable Subsystem block represents one of a set of blocks contained in a specified library of blocks. The block's context menu lets you choose which block the configurable subsystem represents.

Configurable Subsystem blocks simplify creation of models that represent families of designs. For example, suppose that you want to model an automobile that offers a choice of engines. To model such a design, you would first create a library of models of the engine types available with the car. You would then use a Configurable Subsystem block in your car model to represent the choice of engines. To model a particular variant of the basic car design, a user need only choose the engine type, using the configurable engine block's dialog.

To create a configurable subsystem in a model, you must first create a library containing a master configurable subsystem and the blocks that it represents. You can then create configurable instances of the master subsystem by dragging copies of the master subsystem from the library and dropping them into models.

You can add any type of block to a master configurable subsystem library. Simulink derives the port names for the configurable subsystem by making a unique list from the port names of all the choices. However, Simulink uses default port names for non-subsystem block choices.

Note that you cannot break library links in a configurable subsystem because Simulink uses those links to reconfigure the subsystem when you choose a new configuration. Breaking links would be useful only if you do not intend to reconfigure the subsystem. In this case, you can replace the configurable subsystem with a nonconfigurable subsystem that implements the permanent configuration.

Creating a Master Configurable Subsystem

To create a master configurable subsystem:

- 1 Create a library of blocks representing the various configurations of the configurable subsystem.
- 2 Save the library.
- 3 Create an instance of the Configurable Subsystem block in the library.

To do this, drag a copy of the Configurable Subsystem block from the Simulink Ports & Subsystems library into the library you created in the previous step.

- 4 Display the Configurable Subsystem block dialog by double-clicking it. The dialog displays a list of the other blocks in the library.
- 5 Under **List of block choices** in the dialog box, select the blocks that represent the various configurations of the configurable subsystems you are creating.
- 6 Click the **OK** button to apply the changes and close the dialog box.
- 7 Select **Block Choice** from the Configurable Subsystem block's context menu.

The context menu displays a submenu listing the blocks that the subsystem can represent.

- 8 Select the block that you want the subsystem to represent by default.
- 9 Save the library.

Note If you add or remove blocks from a library, you must recreate any Configurable Subsystem blocks that use the library.

If you modify a library block that is the default block choice for a configurable subsystem, the change does not immediately propagate to the configurable subsystem. To propagate this change, do one of the following:

- Change the default block choice to another block in the subsystem, then change the default block choice back to the original block.

- Recreate the configurable subsystem block, including the selection of the updated block as the default block choice.

If a configurable subsystem in your model contains a broken link to a library block, editing the link and saving the model does not fix the broken link the next time you open the model. To fix a broken library link in your configurable subsystem, use one of the following approaches.

- Convert the configurable subsystem to a variant subsystem. Right-click the configurable subsystem, and select **Subsystem and Model Reference > Convert Subsystem to > Variant Subsystem**.
- Remove the library block from the master configurable subsystem library, add the library block back to the master configurable subsystem library, and then resave the master configurable subsystem library.

Creating an Instance of a Configurable Subsystem

To create an instance of a configurable subsystem in a model:

- 1 Open the library containing the master configurable subsystem.
- 2 Drag a copy of the master into the model.
- 3 Select **Block Choice** from the copy's context menu.
- 4 Select the block that you want the configurable subsystem to represent.

The instance of the configurable system displays the icon and parameter dialog box of the block that it represents.

Setting Instance Block Parameters

As with other blocks, you can use the parameter dialog box of a configurable subsystem instance to set the instance's parameters interactively and the `set_param` command to set the parameters from the MATLAB command line or in a MATLAB file. If you use `set_param`, you must specify the full path name of the configurable subsystem's current block choice as the first argument of `set_param`, for example:

```
curr_choice = get_param('mymod/myconfigsys', 'BlockChoice');  
curr_choice = ['mymod/myconfigsys/' curr_choice];  
set_param(curr_choice, 'MaskValues', ...);
```

Mapping I/O Ports

A configurable subsystem displays a set of input and output ports corresponding to input and output ports in the selected library. Simulink uses the following rules to map library ports to Configurable Subsystem block ports:

- Map each uniquely named input/output port in the library to a separate input/output port of the same name on the Configurable Subsystem block.
- Map all identically named input/output ports in the library to the same input/output ports on the Configurable Subsystem block.
- Terminate any input/output port not used by the currently selected library block with a Terminator/Ground block.

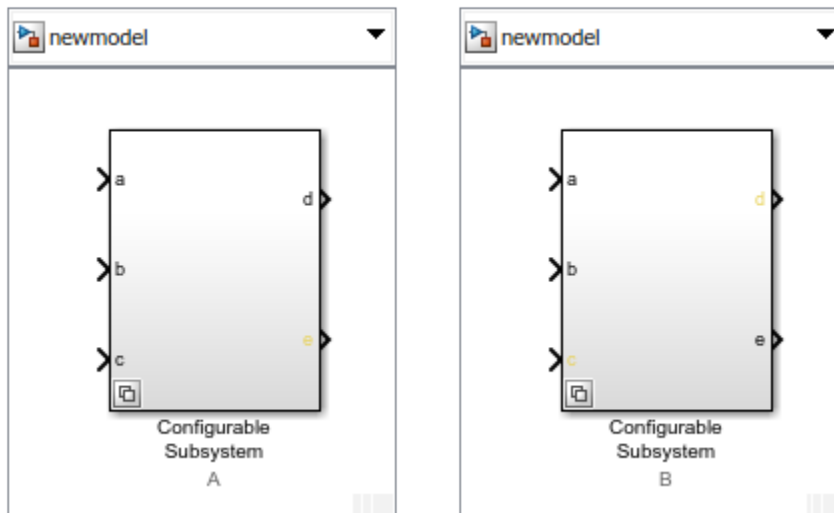

This mapping allows a user to change the library block represented by a Configurable Subsystem block without having to rewire connections to the Configurable Subsystem block.

For example, suppose that a library contains two blocks A and B and that block A has input ports labeled a, b, and c and an output port labeled d and that block B has input ports labeled a and b and an output port labeled e.

A Configurable Subsystem block based on this library would have three input ports labeled a, b, and c, respectively, and two output ports labeled d and e.

In this example, port a on the Configurable Subsystem block connects to port a of the selected library block no matter which block is selected. On the other hand, port c on the Configurable Subsystem block functions only if library block A is selected. Otherwise, it simply terminates.

Note A Configurable Subsystem block does not provide ports that correspond to non-I/O ports, such as the trigger and enable ports on triggered and enabled subsystems. Thus, you cannot use a Configurable Subsystem block directly to represent blocks that have such ports. You can do so indirectly, however, by wrapping such blocks in subsystem blocks that have input or output ports connected to the non-I/O ports.

Convert to Variant Subsystem

Right-click a configurable subsystem and select **Subsystems and Model Reference > Convert Subsystem To > Variant Subsystem**.

During conversion, Simulink performs the following operations:

- Replaces the Subsystem block with a Variant Subsystem block, preserving ports and connections.
- Adds the original subsystem as a variant choice in the Variant Subsystem block.
- Overrides the Variant Subsystem block to use the subsystem that was originally the active choice.
- Preserves links to libraries. For linked subsystems, Simulink adds the linked subsystem as a variant choice.

Simulink also preserves the subsystem block masks, and it copies the masks to the variant choice.

See Variant Subsystem for more information on variant choices.

Data Type Support

The Configurable Subsystem block accepts and outputs signals of the same types that are accepted or output by the block that it currently represents. The data types can be any that Simulink supports, including fixed-point data types.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

List of block choices

Select the blocks you want to include as members of the configurable subsystem. You can include user-defined subsystems as blocks.

Port names

Lists of input and output ports of member blocks. In the case of multiports, you can rearrange selected port positions by clicking the **Up** and **Down** buttons.

Characteristics

A Configurable Subsystem block has the characteristics of the block that it currently represents. Double-clicking the block opens the dialog box for the block that it currently represents.

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated Bus
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Code Generation	Yes

Introduced before R2006a

Constant

Generate constant value

Library

Sources

Description

The Constant block generates a real or complex constant value.

The block generates scalar, vector, or matrix output, depending on:

- The dimensionality of the **Constant value** parameter
- The setting of the **Interpret vector parameters as 1-D** parameter

The output of the block has the same dimensions and elements as the **Constant value** parameter. If you specify for this parameter a vector that you want the block to interpret as a vector, select the **Interpret vector parameters as 1-D** parameter. Otherwise, if you specify a vector for the **Constant value** parameter, the block treats that vector as a matrix.

Data Type Support

By default, the Constant block outputs a signal whose data type and complexity are the same as those of the **Constant value** parameter. However, you can specify the output to be any data type that Simulink supports, including fixed-point and enumerated data types. The Enumerated Constant block can be more convenient than the Constant block

for outputting a constant enumerated value. You can also use a bus object as the output data type, which can help to simplify a model (see “Bus Support” on page 1-189 for details).

Note If you specify a bus object as the data type for this block, do not set the minimum and maximum values for bus data on the block. Simulink ignores these settings. Instead, set the minimum and maximum values for bus elements of the bus object specified as the data type. The values should be finite real double scalar.

For information on the Minimum and Maximum properties of a bus element, see `Simulink.BusElement`.

For more information about data type support, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Constant value

Specify the constant value output of the block.

Default: 1

Minimum: value from the **Output minimum** parameter

Maximum: value from the **Output maximum** parameter

- You can enter any expression that MATLAB evaluates as a matrix, including the Boolean keywords `true` and `false`.
- If you set the **Output data type** to be a bus object, you can specify either:
 - A full MATLAB structure corresponding to the bus object
 - 0 to indicate a structure corresponding to the ground value of the bus object

For details, see “Bus Support” on page 1-189.

- For non-bus data types, Simulink converts this parameter from its value data type to the specified output data type offline, using round toward nearest and saturation.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Interpret vector parameters as 1-D

Select this check box to output a vector of length N if the **Constant value** parameter evaluates to an N -element row or column vector.

Default: On

On

Outputs a vector of length N if the **Constant value** parameter evaluates to an N -element row or column vector. For example, the block outputs a matrix of dimension 1-by- N or N -by-1.

Off

Does not output a vector of length N if the **Constant value** parameter evaluates to an N -element row or column vector.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Sample time

Specify the interval between times that the Constant block output can change during simulation (for example, due to tuning the **Constant value** parameter).

Default: `inf`

This setting indicates that the block output can never change. This setting speeds simulation and generated code by avoiding the need to recompute the block output.

See “Specify Sample Time” in the online documentation for more information.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Output minimum

Lower value of the output range that Simulink checks.

Default: [] (unspecified)

Specify this number as a finite, real, double, scalar value.

Note If you specify a bus object as the data type for this block, do not set the minimum value for bus data on the block. Simulink ignores this setting. Instead, set the minimum values for bus elements of the bus object specified as the data type. For information on the Minimum parameter for a bus element, see `Simulink.BusElement`.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Parameter: OutMin

Type: character vector

Value: ' [] '

Default: ' [] '

Output maximum

Upper value of the output range that Simulink checks.

Default: [] (unspecified)

Specify this number as a finite, real, double, scalar value.

Note If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For information on the Maximum parameter for a bus element, see `Simulink.BusElement`.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Note **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Parameter: OutMax

Type: character vector

Value: ' [] '

Default: ' [] '

Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

Default: Best precision

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

Best precision

Specify best-precision values.

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting Slope and bias enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

For more information, see “Specifying a Fixed-Point Data Type”.

Output data type

Specify the output data type.

Default: Inherit: Inherit from 'Constant value'

Inherit: Inherit from 'Constant value'

Use data type of **Constant value**.

Inherit: Inherit via back propagation

Use data type of the driving block.

double

Output data type is double.

single

Output data type is single.

int8

Output data type is int8.

uint8

Output data type is uint8.

int16

Output data type is int16.

uint16

Output data type is uint16.

int32

Output data type is int32.

uint32

Output data type is uint32.

boolean

Output data type is boolean.

fixdt(1,16)

Output data type is fixed point fixdt(1,16).

fixdt(1,16,0)

Output data type is fixed point fixdt(1,16,0).

fixdt(1,16,2^0,0)

Output data type is fixed point fixdt(1,16,2^0,0).

Enum: <class name>

Use an enumerated data type, for example, Enum: BasicColors.

Bus: <object name>

Data type is a bus object.

<data type expression>

Data type is data type object, for example Simulink.NumericType.

Do not specify a bus object as the expression.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Control Signal Data Types” for more information.

Show data type assistant

Display the **Data Type Assistant**.

The **Data Type Assistant** helps you set the **Output data type** parameter.

For more information, see “Control Signal Data Types”.

Mode

Select the category of data to specify.

Default: `Inherit`

`Inherit`

Inheritance rules for data types. Selecting `Inherit` enables a second menu/text box to the right. Select one of the following choices:

- `Inherit from 'Constant value' (default)`
- `Inherit via back propagation`

`Built in`

Built-in data types. Selecting `Built in` enables a second menu/text box to the right. Select one of the following choices:

- `double (default)`
- `single`
- `int8`
- `uint8`
- `int16`

- uint16
- int32
- uint32
- boolean

Fixed point

Fixed-point data types.

Enumerated

Enumerated data types. Selecting `Enumerated` enables a second menu/text box to the right, where you can enter the class name.

Bus object

Bus object. Selecting `Bus` enables a **Bus object** parameter to the right, where you enter the name of a bus object that you want to use to define the structure of the bus. If you need to create or change a bus object, click **Edit** to the right of the **Bus object** field to open the Simulink Bus Editor. For details, see “Create Bus Objects with the Bus Editor”.

Expression

Expressions that evaluate to data types. Selecting `Expression` enables a second menu/text box to the right, where you can enter the expression.

Do not specify a bus object as the expression.

Data type override

Specify data type override mode for this signal.

Default: `Inherit`

`Inherit`

Inherits the data type override setting from its context, that is, from the block, `Simulink.Signal` object or Stateflow chart in Simulink that is using the signal.

`Off`

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

This parameter appears only when the **Mode** is `Built in` or `Fixed point`.

Signedness

Specify whether you want the fixed-point data as signed or unsigned.

Default: `Signed`

`Signed`

Specify the fixed-point data as signed.

`Unsigned`

Specify the fixed-point data as unsigned.

Selecting **Mode** > `Fixed point` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Word length

Specify the bit size of the word that holds the quantized integer.

Default: `16`

Minimum: `0`

Maximum: `32`

Selecting **Mode** > `Fixed point` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Fraction length

Specify fraction length for fixed-point data type.

Default: 0

Binary points can be positive or negative integers.

Selecting **Scaling** > `Binary point` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Slope

Specify slope for the fixed-point data type.

Default: 2^0

Specify any positive real number.

Selecting **Scaling** > `Slope and bias` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Bias

Specify bias for the fixed-point data type.

Default: 0

Specify any real number.

Selecting **Scaling** > `Slope` and `bias` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

Default: Off

On

Locks the output data type setting for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change the output data type setting for this block.

Parameter: `LockScale`

Type: character vector

Value: 'off' | 'on'

Default: 'off'

For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Bus Support

Using Bus Objects as the Output Data Type

The Constant block supports nonvirtual buses as the output data type. If you use a bus object as the data type, set **Constant value** to 0 or a MATLAB structure that matches the bus object.

Using Structures for the Constant Value

The structure you specify must contain a value for every element of the bus represented by the bus object. The block output is a nonvirtual bus signal.

You can use the `Simulink.Bus.createMATLABStruct` to create a full structure that corresponds to a bus.

You can use `Simulink.Bus.createObject` to create a bus object from a MATLAB structure.

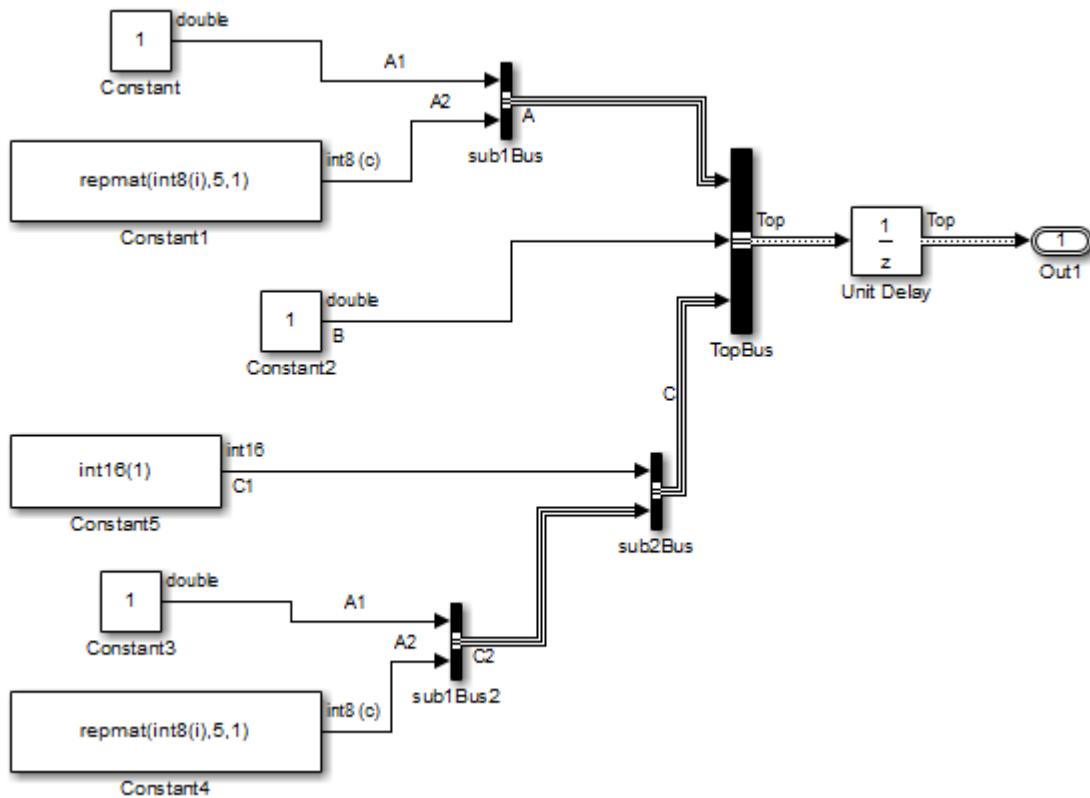

If the signal elements in the output bus use numeric data types other than `double`, you can specify the structure fields by using typed expressions such as `uint16(37)` or untyped expressions such as `37`. To control the field data types, you can use the bus object as the data type of a `Simulink.Parameter` object. To decide whether to use typed or untyped expressions, see “Control Data Types of Initial Condition Structure Fields”.

Example of Using a Bus Object for a Constant Block

The following example illustrates how using a bus object as an output data type for a Constant block can help to simplify a model.

- 1 Open the `ex_busic` model and update it.

This model uses six Constant blocks. For details about the model, see “Create Partial Structures for Initialization”.

- Open the `ex_constantbus` model and update it. This model uses one Constant block that replaces the six Constant blocks in the `ex_basic` model.

- Simulate the `ex_constantbus` model. To verify that the output from the Constant block reflects the values from `constant_value_struct`, perform the next two steps.

- 4 At the MATLAB command line, examine the `constant_value_struct` structure that the Constant block uses for its **Constant value** parameter.

```
constant_value_struct

constant_value_struct =

    A: [1x1 struct]
    B: 5
    C: [1x1 struct]
```

- 5 Examine the logged data in the `logouts` variable, focusing on the B element of the A1 bus signal. The `constant_value_struct` structure sets the B element to 5.

```
logouts.get('A1').Values.B.Data
```

Group Constant Signals into an Array of Buses

You can use a Constant block to compactly represent multiple constant-valued signals as an array of buses. You can use this technique to reduce the number of signal lines in a model and the number of variables that the model uses, especially when the model repeats an algorithm with different parameter values.

To generate a constant-valued array of bus signals, use an array of MATLAB structures in a Constant block. The block output is an array of buses, and each field in the array of structures provides the simulation value for the corresponding signal element.

You can also use an array of structures to specify the `Value` property of a `Simulink.Parameter` object, and use the parameter object in a Constant block.

- 1 Open the example model `ex_constantbus_array`.

The variables `ParamBus` and `const_param_struct` appear in the base workspace. The variable `const_param_struct` contains a structure whose field names match the elements of the bus type that `ParamBus` defines.

- 2 Update the diagram to view the signal line widths.

The output of the Constant block is a single scalar bus of type `ParamBus`. The structure variable `const_param_struct` specifies the constant value in the block.

- 3 At the command prompt, create an array of two structures by copying the structure `const_param_struct`. Customize the field values by indexing into the individual structures in the array.

```

const_struct_array = ...
  [const_param_struct const_param_struct];

const_struct_array(2).Offset = 158;
const_struct_array(2).Gain = 3.83;
const_struct_array(2).Threshold = 1039.77

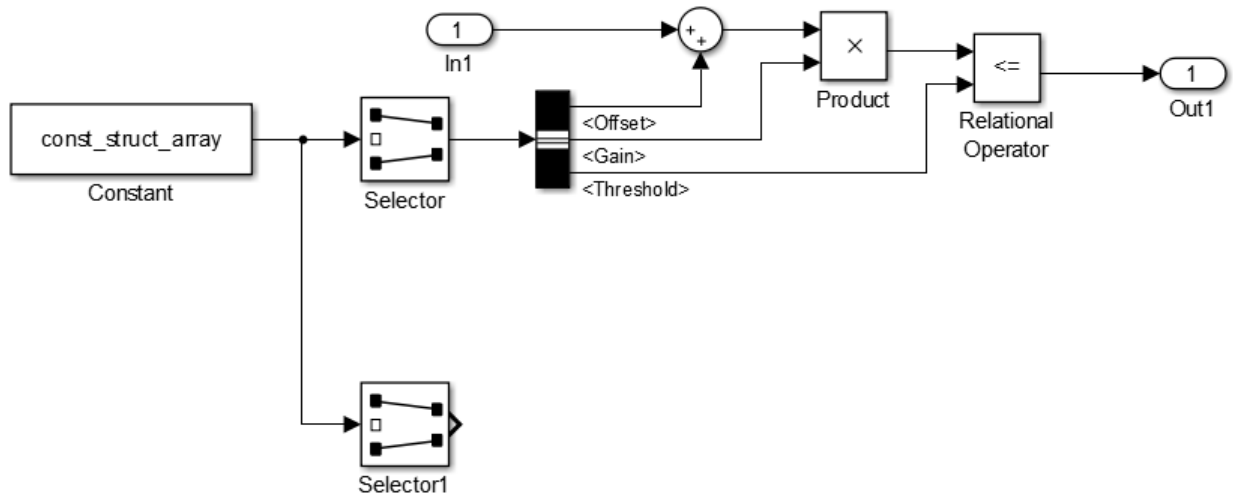

const_struct_array =

1x2 struct array with fields:

    Offset
    Gain
    Threshold

```

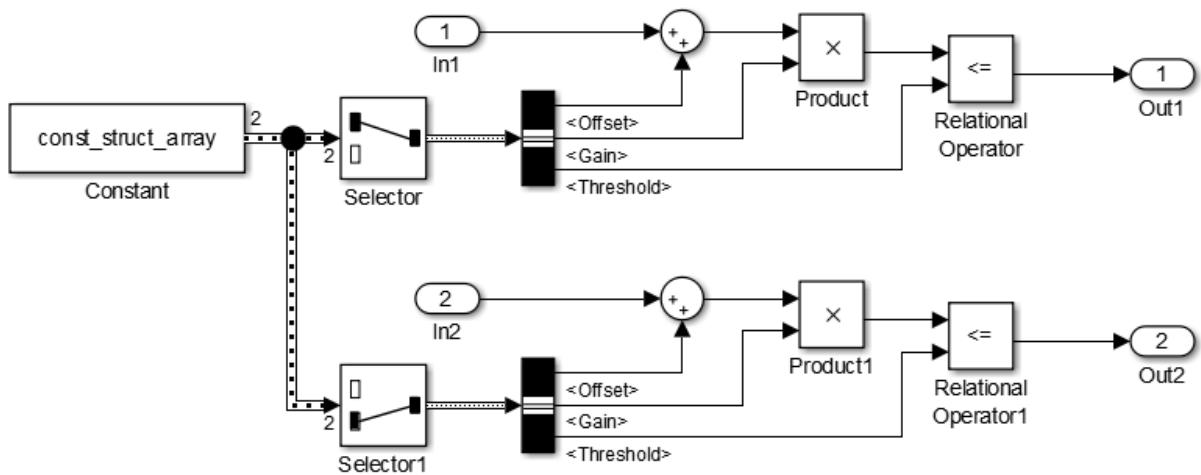

- 4 In the Constant block dialog box, set **Constant value** to `const_struct_array`.
- 5 Add two Selector blocks to the model, and connect the Constant block as shown.

- 6 In the Selector block dialog box, set **Index** to 1 and **Input port size** to 2.
- 7 In the Selector1 block dialog box, set **Index** to 2 and **Input port size** to 2.
- 8 Copy the block algorithm in the model, and connect the blocks as shown.

- 9 Update the diagram. The signal line width and style indicate that the output of the Constant block is an array of buses. The Selector blocks each extract one of the buses in the array.

Each copy of the algorithm uses the constant values provided by the corresponding structure in the variable `const_struct_array`.

To create an array of structures for a bus that uses a large hierarchy of signal elements, consider using the function `Simulink.Bus.createMATLABStruct`. You can also use this technique to create an array of structures if you do not have a scalar structure that you can copy.

Setting Configuration Parameters to Support Using a Bus Object Data Type

To enable the use of a bus object as an output data type, before you start a simulation, set **Configuration Parameters > Diagnostics > Data Validity > Advanced parameters > Underspecified initialization detection** to `Simplified`. For more information, see “Underspecified initialization detection”.

Examples

The following Simulink examples show how to use the Constant block:

- `sldemo_auto_climatecontrol`
- `sldemo_boiler`
- `sldemo_bounce`

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated Bus

Cosine HDL Optimized

Implement fixed-point cosine wave optimized for HDL code generation

Library

HDL Coder™ / Lookup Tables

Description

The Cosine HDL Optimized block implements a fixed-point cosine wave by using a lookup table method that exploits quarter-wave symmetry.

You define the number of lookup table points in the **Number of data points** parameter. The block implementation is most efficient for HDL code generation when you specify the lookup table data points to be (2^n) , where n is an integer. For information about the behavior of this block in HDL Coder, see Cosine HDL Optimized.

Depending on your selection of the **Output formula** parameter, the blocks can output these functions of the input signal:

- $\sin(2\pi u)$
- $\cos(2\pi u)$
- $\exp(i2\pi u)$
- $\sin(2\pi u)$ and $\cos(2\pi u)$

Use the **Table data type** parameter to specify the word length of the fixed-point output data type. The fraction length of the output is the output word length minus 2.

Data Type Support

The Cosine HDL Optimized block accepts signals of these data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean

The output of the block is a fixed-point data type.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Output formula

Select the signal(s) to output.

Number of data points

Specify the number of data points to retrieve from the lookup table. The implementation is most efficient when you specify the lookup table data points to be (2^n) , where n is an integer.

Table data type

Specify the table data type. You can specify an expression that evaluates to a data type, for example, `fixdt(1,16,0)`.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the table data type.

Show data type assistant

Select the mode of data type specification. If you select *Expression*, enter an expression that evaluates to a data type, for example, `fixdt(1,16,0)`.

If you select *Fixed point*, you can use the options in the **Data Type Assistant** to specify the fixed-point data type. In the *Fixed point* mode, you can choose binary

point scaling, and specify the signedness, word length, fraction length, and the data type override setting.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Coulomb and Viscous Friction

Model discontinuity at zero, with linear gain elsewhere

Library

Discontinuities

Description

The Coulomb and Viscous Friction block models Coulomb (static) and viscous (dynamic) friction. The block models a discontinuity at zero and a linear gain otherwise.

The block output matches the MATLAB result for:

$$y = \text{sign}(x) .* (\text{Gain} .* \text{abs}(x) + \text{Offset})$$

where y is the output, x is the input, Gain is the signal gain for nonzero input values, and Offset is the Coulomb friction.

The block accepts one input and generates one output. The input can be a scalar, vector, or matrix with real and complex elements.

- For a scalar input, Gain and Offset can have dimensions that differ from the input. The output is a scalar, vector, or matrix depending on the dimensions of Gain and Offset .
- For a vector or matrix input, Gain and Offset must be scalar or have the same dimensions as the input. The output is a vector or matrix of the same dimensions as the input.

Data Type Support

The Coulomb and Viscous Friction block supports real inputs of the following data types:

- Floating point
- Built-in integer
- Fixed point

The block supports complex inputs only for floating-point data types, `double` and `single`. The output uses the same data type as the input.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Coulomb friction value

Specify the offset that applies to all input values.

Coefficient of viscous friction

Specify the signal gain for nonzero input values.

Examples

Scalar Input

Suppose that you have the following model:

In this model, the block input x (-5) and Gain (2) are scalar values, but Offset is the vector [1 3 2 0]. Therefore, the block uses element-wise scalar expansion to compute the output.

For example, for the first offset, 1, the output is calculated using the formula $y = \text{sign}(x) .* (\text{Gain} .* \text{abs}(x) + \text{Offset})$ as follows:

$$y = - * (2 * 5) + 1$$

$$y = -11$$

Vector Input

Suppose that you have the following model:

In this model, vector dimensions for block input x and Offset are the same.

Matrix Input

Suppose that you have the following model:

In this model, matrix dimensions for block input x and Offset are the same.

Characteristics

Data Types	Double Single Base Integer Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	Yes
Code Generation	Yes

Introduced before R2006a

Counter Free-Running

Count up and overflow back to zero after reaching maximum value for specified number of bits

Library

Sources

Description

The Counter Free-Running block counts up until reaching the maximum value, $2^{Nbits} - 1$, where $Nbits$ is the number of bits. Then the counter overflows to zero and begins counting up again.

After overflow, the counter always initializes to zero. However, if you select the global doubles override, the Counter Free-Running block does not wrap back to zero.

This block does not report wrap on overflow warnings during simulation. To report these warnings, see the `Simulink.restoreDiagnostic` reference page. The block does report errors due to wrap on overflow.

Data Type Support

The Counter Free-Running block outputs an unsigned integer.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Number of Bits

Specify the number of bits.

When you use...	Such as...	The block counts up to...	Which is...
A positive integer	8	$2^8 - 1$	255
An unsigned integer expression	<code>uint8(8)</code>	<code>uint8(2^{uint8(8)} - 1)</code>	254

Sample time

Specify the time interval between samples. To inherit the sample time, set this parameter to -1. See “Specify Sample Time” in the Simulink documentation.

Examples

Bit Specification Using a Positive Integer

Suppose that you have the following model:

The block parameters are:

Parameter	Setting
Number of Bits	8
Sample time	-1

The solver options for the model are:

Parameter	Setting
Stop time	255
Type	Fixed-step

Parameter	Setting
Solver	discrete (no continuous states)
Fixed-step size	1

At $t = 255$, the counter reaches the maximum value:

$$2^8 - 1$$

If you change the stop time of the simulation to 256, the counter wraps to zero.

Bit Specification Using an Unsigned Integer Expression

Suppose that you have the following model:

The block parameters are:

Parameter	Setting
Number of Bits	uint8(8)
Sample time	-1

The solver options for the model are:

Parameter	Setting
Stop time	254
Type	Fixed-step
Solver	discrete (no continuous states)
Fixed-step size	1

At $t = 254$, the counter reaches the maximum value:

$$\text{uint8}(2^{\text{uint8}(8)} - 1)$$

If you change the stop time of the simulation to 255, the counter wraps to zero.

Characteristics

Data Types	Base Integer Fixed-Point
Sample Time	Specified in the Sample time parameter
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Counter LimitedMATLAB Function

Introduced before R2006a

Counter Limited

Count up and wrap back to zero after outputting specified upper limit

Library

Sources

Description

The Counter Limited block counts up until the specified upper limit is reached. Then the counter wraps back to zero, and restarts counting up. The counter always initializes to zero.

You can specify the upper limit with the **Upper limit** parameter.

You can specify the sample time with the **Sample time** parameter. A **Sample time** of `-1` means that the sample time is inherited.

The output is an unsigned integer of 8, 16, or 32 bits, with the smallest number of bits needed to represent the upper limit.

This block does not report wrap on overflow warnings during simulation. To report these warnings, see the `Simulink.restoreDiagnostic` reference page. The block does report errors due to wrap on overflow.

Data Type Support

The Counter Limited block outputs an unsigned integer.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Upper limit

Specify the upper limit.

Sample time

Specify the time interval between samples. To inherit the sample time, set this parameter to -1. See “Specify Sample Time” in the Simulink documentation.

Examples

The following Simulink examples show how to use the Counter Limited block:

- `sldemo_tonegen_fixpt`

Characteristics

Data Types	Boolean Base Integer Fixed-Point
Sample Time	Specified in the Sample time parameter
Multidimensional Signals	No
Variable-Size Signals	No
Code Generation	Yes

See Also

Counter Free-Running

Introduced before R2006a

Dashboard Scope

Trace signals during simulation

Library: Simulink / Dashboard

Description

The Dashboard Scope block shows connected signals during simulation on a scope display. You can use the Dashboard Scope block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model. The Dashboard Scope block provides a complete picture of a signal's behavior over the course of the simulation. Use the Dashboard Scope block to display real (not complex) signals of any data type that Simulink supports, including enumerated data types.

Connection

Dashboard blocks do not use ports to connect to signals. To connect a signal to a Dashboard block, use the **Connection** table in the block's parameters.

- 1 Double-click the block.
- 2 Populate the **Connection** table by selecting signals of interest in your model.
- 3 Mark the option button next to the signal you want to display.
- 4 Click **Apply**.

Data Cursors

You can add data cursors to the Dashboard Scope to inspect the displayed signals. To add data cursors, right-click the Dashboard Scope block. Under the **Data Cursors** menu, select the number of cursors you want to add.

Zoom and Pan

You can also zoom and pan to inspect your signals. To change zoom and pan modes, right-click the Dashboard Scope block, and select the zoom or pan mode you want.

Limitations

- You cannot save the block connections or properties in model files that use the MDL format.
To save connections and properties, save the model file in the SLX format.
- Dashboard blocks can only connect to real scalar signals.
- Dashboard blocks cannot connect to blocks that are commented out.
- Dashboard blocks cannot connect to signals inside reference models.
- If you turn off logging for a signal connected to a Dashboard block, the model stops sending data from that signal to the block. To view the signal again, reconnect the signal.
- External mode simulation does not support visualization Dashboard blocks.

Parameters

Connection — Select a signal to connect and display

signal connection options

Signal connection options. Populate the **Connection** table by selecting signals of interest in your model. Mark the check box next to the signal you want to display. Click **Apply** to connect the signal.

Time Span — Set horizontal axis span

auto (default) | scalar

A finite, real double, scalar value that sets the time span of the block's scope display.

When Time Span is specified as `auto`, the block sets its time span to the model's simulation stop time.

Min — Set y-axis minimum

-3 (default) | scalar

A finite, real, double, scalar value that sets the minimum of the vertical axis on the block's scope display.

The **Min** value must be less than the **Max** value.

Max — Set y-axis maximum

3 (default) | scalar

A finite, real, double, scalar value that sets the maximum of the vertical axis on the block's scope display.

The **Max** value must be greater than the **Min** value.

Legend — Set position of legend

'Top' (default) | 'Right' | 'Hide'

Options from the drop-down menu specify the position of the legend in the block's scope display. The legend shows the color chosen for each connected signal next to the signal's name.

Scale axes limits at stop — Autoscale axes limits when simulation finishes

on (default) | off

When on, performs a fit-to-view operation on the data displayed in the scope when the simulation stops.

Show "Double-click to connect" message — Show or hide message

on (default) | off

When on, shows instructional text if the block is not connected. When the block is not connected, you can turn this parameter off to hide the text.

Data Store Memory

Define data store

Library

Signal Routing

Description

The Data Store Memory block defines and initializes a named shared data store, which is a memory region usable by Data Store Read and Data Store Write blocks that specify the same data store name.

The location of the Data Store Memory block that defines a data store determines which Data Store Read and Data Store Write blocks can access the data store:

- If the Data Store Memory block is in the *top-level system*, Data Store Read and Data Store Write blocks anywhere in the model can access the data store.
- If the Data Store Memory block is in a *subsystem*, Data Store Read and Data Store Write blocks in the same subsystem or in any subsystem below it in the model hierarchy can access the data store.

Data Store Read or Data Store Write blocks cannot access a Data Store Memory block that is either in a model that contains a Model block or in a referenced model.

Do not include a Data Store Memory block in a subsystem that a For Each Subsystem block represents.

Obtaining correct results from data stores requires ensuring that data store reads and writes occur in the expected order. For details, see:

- “Order Data Store Access”
- “Data Store Diagnostics”
- “Log Data Stores”

You can use `Simulink.Signal` objects in addition to, or instead of, Data Store Memory blocks to define data stores. A data store defined in the *base* workspace with a signal object is a *global* data store. Global data stores are accessible to every model, including all referenced models. See “Data Stores” for more information.

Data Type Support

The Data Store Memory block stores real or complex signals of these data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean
- Enumerated
- Bus

The block does not support variable-size signals.

Note If you specify a bus object as the data type for this block, do not set the minimum and maximum values for bus data on the block. Simulink ignores these settings. Instead, set the minimum and maximum values for bus elements of the bus object specified as the data type. The values should be finite real double scalar.

For information on the Minimum and Maximum properties of a bus element, see `Simulink.BusElement`.

For more information, see “Data Types Supported by Simulink”.

You can use arrays of buses with a Data Store Memory block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

Parameters

Data store name

Specify a name for the data store you are defining with this block. Data Store Read and Data Store Write blocks with the same name can read from, and write to, the data store initialized by this block. The name can represent a Data Store Memory block or a sign object defined to be a data store.

Rename All

Rename the data store everywhere the Data Store Read and Data Store Write blocks use it in a model.

You cannot use **Rename All** to rename a data store if you:

- Use a `Simulink.Signal` object in a workspace to control the code generated for the data store
- Use a `Simulink.Signal` object instead of a Data Store Memory block to define the data store

You must instead rename the corresponding `Simulink.Signal` object from Model Explorer. For an example, see “Rename Data Store Defined by Signal Object”.

Corresponding Data Store Read/Write blocks

List all the Data Store Read and Data Store Write blocks that have the same data store name as the current block, and that are in the current system or in any subsystem below it in the model hierarchy. Double-click a block in this list to highlight the block and bring it to the foreground.

Initial value

Specify the initial value or values of the data store. The **Minimum** parameter specifies the minimum value for this parameter, and the **Maximum** parameter specifies the maximum value.

If you specify a nonscalar value and set **Dimensions** to -1 (the default), the data store has the same dimensions as the array. Data that you write to the data store (by using Data Store Write blocks) must have these dimensions.

If you set the **Dimensions** parameter to a value other than -1 , the initial value dimensions must match the dimensions that you specify, unless the initial value is a scalar or a MATLAB structure. If you specify a scalar, each element of the data store

uses the scalar as the initial value. Use this technique to apply the same initial value (the scalar that you specify) to each element without manually matching the dimensions of the initial value with the dimensions of the data store.

To use this block to initialize a nonvirtual bus signal, specify the initial value as a MATLAB structure and set the model configuration parameter “Underspecified initialization detection” to `Simplified`. For more information about initializing nonvirtual bus signals using structures, see “Specify Initial Conditions for Bus Signals”.

Minimum

Specify the minimum value that the block should output. The default value is [] (unspecified). This number must be a finite real double scalar value.

Note If you specify a bus object as the data type for this block, do not set the minimum value for bus data on the block. Simulink ignores this setting. Instead, set the minimum values for bus elements of the bus object specified as the data type. For information on the `Minimum` property of a bus element, see `Simulink.BusElement`.

Simulink uses the minimum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Maximum

Specify the maximum value that the block should output. The default value is [] (unspecified). This number must be a finite real double scalar value.

Note If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For

information on the Maximum property of a bus element, see `Simulink.BusElement`.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Data type

Specify the output data type. You can set it to:

- A rule that inherits a data type (for example, `Inherit: auto`)
- The name of a built-in data type (for example, `single`)
- The name of a data type object (for example, a `Simulink.NumericType` object)
- An expression that evaluates to a data type (for example, `fixdt(1,16,0)`). Do not specify a bus object as the data type in an expression; use `Bus: <object name>` to specify a bus data type.
- `Bus: <object name>`; enter the name of a bus object that you want to use to define the structure of the bus. The bus must be a nonvirtual bus. If you need to create or change a bus object, click the **Show data type assistant** button and then click the **Edit** button to the right of the **Bus object** field to open the Simulink Bus Editor. For details, see “Create Bus Objects with the Bus Editor”.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Data type** parameter.

See “Control Signal Data Types”.

Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Signal type

Specify the numeric type, real or complex, of the values in the data store.

Dimensions (-1 to infer from Initial value)

Dimensions of the data store. The default value, -1, enables you to set the dimensions of the data store by using the **Initial value** parameter. However, in this case, you cannot use scalar expansion with the initial value. You must specify the initial value by using an array that has the dimensions that you want.

If you use a value other than -1, specify the same dimensions as the dimensions of the **Initial value** parameter, unless you specify the initial value as a scalar (for scalar expansion) or a MATLAB structure. If the data store represents an array of buses, and if you use a MATLAB structure for the initial value, you can specify dimensions to initialize the array of buses with this structure.

Interpret vector parameters as 1-D

Specify that the data store interpret vector initial values as one-dimensional.

By default, MATLAB represents vector data as matrices, which have two dimensions. For example, MATLAB represents the vector [1 2 3] as a 1-by-3 matrix.

When you select this parameter, the data store represents vector data by using only one dimension instead of two. For example, if you specify an initial value of [1 2 3], the data store stores a one-dimensional vector with three elements.

For more information, see “Determining the Output Dimensions of Source Blocks”.

Data store name must resolve to Simulink signal object

Specify that Simulink software, when compiling the model, searches the model and base workspace for a `Simulink.Signal` object having the same name, as described in “Symbol Resolution”. If Simulink does not find such an object, the compilation stops, with an error. Otherwise, Simulink compares the attributes of the signal object to the corresponding attributes of the Data Store Memory block. If the block and the object attributes are inconsistent, Simulink halts model compilation and displays an error.

Share across model instances

In a single model reference hierarchy, when you use multiple Model blocks to refer to a model that contains a Data Store Memory block, by default, each instance of the referenced model (each Model block) reads from and writes to a separate copy of the data store. When you select **Share across model instances**, instead of interacting with a separate copy, all of the instances read from and write to the same data store.

When you set the model configuration parameter **Code interface packaging** to `Reusable function` to generate reentrant code from a model (Simulink Coder), a data store with **Share across model instances** selected appears in the code as a global symbol that the generated entry-point functions access directly. For example, a global symbol is a global variable or a field of a global structure variable. Therefore, each call that your code makes to the entry-point functions (each instance of the model) shares the data.

For an example, see “Share Data Between Instances of a Reusable Algorithm”.

Signal object class

Choose a custom storage class package by selecting a signal object class that the target package defines. For example, to apply custom storage classes from the built-in package `mpt`, select `mpt.Signal`. Unless you use an ERT-based code generation target with Embedded Coder® software, custom storage classes do not affect the generated code.

For information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

To programmatically set this parameter, use `StateSignalObject`. See “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder).

Storage class

Applies the storage class or custom storage class that you select from the list. For information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than `Simulink`.

To programmatically set this parameter, use `StateStorageClass` or `StateSignalObject`. See “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder).

TypeQualifier

Specify a storage type qualifier such as `const` or `volatile`.

Setting **Storage class** to `ExportedGlobal`, `ImportedExtern`, `ImportedExternPointer`, or `SimulinkGlobal` enables this parameter. This parameter is hidden unless you previously set its value.

Note **TypeQualifier** will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder software, custom storage classes and memory sections do not affect the generated code.

See “Discrete Block State Naming in Generated Code” (Simulink Coder) for more information.

Detect read before write

Select the diagnostic action to take if the model attempts to read data from a data store to which it has not written data in this time step. See also the “Detect read before write” diagnostic in the **Data Store Memory block** section of the **Model Configuration Parameters > Diagnostics > Data Validity** pane.

Default: `warning`

`none`

Simulink software takes no action.

`warning`

Simulink software displays a warning and continues the simulation.

`error`

Simulink software terminates the simulation and displays an error.

Detect write after read

Select the diagnostic action to take if the model attempts to write data to the data store after previously reading data from it in the current time step. See also the “Detect write after read” diagnostic in the **Data Store Memory block** section of the **Model Configuration Parameters > Diagnostics > Data Validity** pane.

Default: warning

none

Simulink software takes no action.

warning

Simulink software displays a warning and continues the simulation.

error

Simulink software terminates the simulation and displays an error.

Detect write after write

Select the diagnostic action to take if the model attempts to write data to the data store twice in succession in the current time step. See also the “Detect write after write” diagnostic in the **Data Store Memory block** section of the **Model Configuration Parameters > Diagnostics > Data Validity** pane.

Default: warning

none

Simulink software takes no action.

warning

Simulink software displays a warning and continues the simulation.

error

Simulink software terminates the simulation and displays an error.

Log signal data

Select this option to save the values of this signal to the MATLAB workspace during simulation. See “Signal Logging” for details.

Logging name

Use this pair of controls, consisting of a list box and an edit field, to specify the name associated with logged signal data.

Simulink uses the signal name as its logging name by default. To specify a custom logging name, select **Custom** from the list box and enter the custom name in the adjacent edit field.

Limit data points to last

Discard all but the last N data points, where N is the number that you enter in the adjacent edit field. For more information, see “Log Data Stores”.

Decimation

Log every N th data point, where N is the number that you enter in the adjacent edit field. For example, suppose that your model uses a fixed-step solver with a step size of 0.1 s. If you select this option and accept the default decimation value (2), Simulink records data points for this signal at times 0.0, 0.2, 0.4, and so on. For more information, see “Log Data Stores”.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated Bus
Multidimensional Signals	Yes
Variable-Size Signals	No
Code Generation	Yes

Introduced before R2006a

Data Store Read

Read data from data store

Library

Signal Routing

Description

The Data Store Read block copies data from the named data store to its output. More than one Data Store Read block can read from the same data store.

The data store from which the data is read is determined by the location of the Data Store Memory block or signal object that defines the data store. For more information, see “Data Stores” and Data Store Memory.

Obtaining correct results from data stores requires ensuring that data store reads and writes occur in the expected order. See “Order Data Store Access” and “Data Store Diagnostics” for details.

Data Type Support

The Data Store Read block can output a real or complex signal of these data types:

- Floating point
- Built-in integer
- Fixed point

- Boolean
- Enumerated
- Bus

The block does not support variable-size signals.

For more information, see “Data Types Supported by Simulink”.

You can use arrays of buses with a Data Store Read block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

Parameters

Data store name

Specifies the name of the data store from which this block reads data. The adjacent pull-down list lists the names of Data Store Memory blocks that exist at the same level in the model as the Data Store Read block or at higher levels. The pulldown list also includes all `Simulink.Signal` objects in the base and model workspaces. To change the name, select a name from the pull-down list or enter the name directly in the edit field.

When Simulink software compiles the model containing this block, Simulink software searches the model upwards from this block's level for a Data Store Memory block having the specified data store name. If Simulink software does not find such a block, it searches the model workspace and the MATLAB workspace for a `Simulink.Signal` object having the same name. See “Symbol Resolution” for more information about the search path.

If Simulink software finds the signal object, it creates a hidden Data Store Memory block at the model's root level having the properties specified by the signal object and an initial value of 0. If Simulink software finds neither the Data Store Memory block nor the signal object, it halts the compilation and displays an error.

Data store memory block

This field lists the Data Store Memory block that initialized the store from which this block reads.

Data store write blocks

This parameter lists all the Data Store Write blocks with the same data store name as this block that are in the same (sub)system or in any subsystem below it in the

model hierarchy. Double-click any entry on this list to highlight the block and bring it to the foreground.

Sample time

The sample time, which controls when the block reads from the data store. A value of -1 indicates that the sample time is inherited. See “Specify Sample Time” for more information.

Use the **Element Selection** pane to select a subset of the bus or matrix elements defined for the associated data store. The Data Store Read block icon reflects the elements that you specify. For details, see “Accessing Specific Bus and Matrix Elements”.

Elements in the array or Signals in the bus (Prompt is specific to the type of data.)

For bus signals, lists the elements in the associated data store. The list displays the maximum dimensions for each element, in parentheses.

For data stores with a bus data type, you can expand the tree to view the bus elements. For data stores with arrays, you can read the whole data store, or you can specify one or more elements of the whole data store.

You can select an element and then use one of the following approaches:

- Click **Select>>** to display that element (and all its subelements) in the **Selected element(s)** list.
- Use the **Specify element(s) to select** edit box to specify the bus or matrix elements that you want to select for reading. Then click **Select>>**.

To refresh the display to reflect modifications to the bus or matrix used in the data store, click **Refresh**.

Specify element(s) to select

Enter a MATLAB expression to define the specific element that you want to read. For example, for a data store named `DSM` that has maximum dimensions of `[3, 5]`, you could enter expressions such as `DSM(2, 4)` or `DSM([1 3], 2)` in the edit box and then click **Select>>**.

To apply the element selection, click **OK**.

Selected Element(s)

Displays the elements that you select. The Data Store Read block icon displays a port for each element that you specify.

To change the order of bus or matrix elements in the list, select the element in the list and click **Up** or **Down**. Changing the order of the elements in the list changes the order of the ports. To remove an element, click **Remove**.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated Bus

Introduced before R2006a

Data Store Write

Write data to data store

Library

Signal Routing

Description

The Data Store Write block copies the value at its input to the named data store. Each write operation performed by a Data Store Write block writes over the data store, replacing the previous contents.

The data store to which this block writes is determined by the location of the Data Store Memory block or signal object that defines the data store. For more information, see “Data Stores” and Data Store Memory. The size of the data store is set by the signal object or the Data Store Memory block that defines and initializes the data store. Each Data Store Write block that writes to that data store must write the same amount of data.

More than one Data Store Write block can write to the same data store. However, if two Data Store Write blocks attempt to write to the same data store during the same simulation step, results are unpredictable.

Obtaining correct results from data stores requires ensuring that data store reads and writes occur in the expected order. For details, see “Order Data Store Access” and “Data Store Diagnostics”.

You can log the values of a local or global data store data variable for all the steps in a simulation. For details, see “Log Data Stores”.

Data Type Support

The Data Store Write block accepts a real or complex signal of these data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean
- Enumerated
- Bus

The block does not support variable-size signals.

For more information, see “Data Types Supported by Simulink”.

You can use an array of buses with a Data Store Write block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

Parameters

Data store name

Specifies the name of the data store to which this block writes data. The adjacent pull-down list lists the names of Data Store Memory blocks that exist at the same level in the model as the Data Store Write block or at higher levels. The pulldown list also includes all `Simulink.Signal` objects in the base and model workspaces. To change the name, select a name from the pull-down list or enter the name directly in the edit field.

When Simulink software compiles the model containing this block, Simulink software searches the model upwards from this block's level for a Data Store Memory block having the specified data store name. If Simulink does not find such a block, it searches the model workspace and the MATLAB workspace for a `Simulink.Signal` object having the same name. If Simulink software finds neither the Data Store Memory block nor the signal object, it halts the compilation and displays an error. See “Symbol Resolution” for more information about the search path.

If Simulink finds a signal object, it creates a hidden Data Store Memory block at the model's root level having the properties specified by the signal object and an initial

value set to a matrix of zeros. The dimensions of that matrix are inherited from the `Dimensions` property of the signal object.

Data store memory block

This field lists the Data Store Memory block that initialized the store to which this block writes.

Data store read blocks

This parameter lists all the Data Store Read blocks with the same data store name as this block that are in the same (sub)system or in any subsystem below it in the model hierarchy. Double-click any entry on this list to highlight the block and bring it to the foreground.

Sample time

Specify the sample time that controls when the block writes to the data store. A value of `-1` indicates that the sample time is inherited. See “Specify Sample Time” for more information.

Use the **Element Assignment** pane to assign a subset of the bus or matrix elements defined for writing to the associated data store. The Data Store Write block icon reflects the elements that you specify. For details, see “Accessing Specific Bus and Matrix Elements”.

Elements in the array or Signals in the bus (Prompt is specific to the type of data.)

For bus signals, lists the elements in the associated data store. The list displays the maximum dimensions for each element, in parentheses.

For data stores with a bus data type, you can expand the tree to view the bus elements. For data stores with arrays, you can write the whole data store, or you can assign one or more elements to the whole data store.

You can select an element and then use one of the following approaches:

- Click **Select>>** to display that element (and all its subelements) in the **Assigned element(s)** list.
- Use the **Specify element(s) to assign** edit box to specify the bus or matrix elements that you want to select for reading. Then click **Select>>**.

To refresh the display to reflect modifications to the bus or matrix used in the data store, click **Refresh**.

Specify element(s) to assign

Enter a MATLAB expression to define the specific element that you want to write. For example, for a data store named DSM that has maximum dimensions of [3, 5], you could enter expressions such as `DSM(2, 4)` or `DSM([1 3], 2)` in the edit box. Then click **Select>>**.

To apply the element selection, click **OK**.

Assigned Element(s)

Displays the elements that you selected for assignment. The Data Store Write block icon displays a port for each element that you specify.

To change the order of bus or matrix elements in the list, select the element in the list and click **Up** or **Down**. Changing the order of the elements in the list changes the order of the ports. To remove an element, click **Remove**.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated Bus

Data Type Conversion

Convert input signal to specified data type

Library

Signal Attributes

Description

The Data Type Conversion block converts an input signal of any Simulink data type to the data type that you specify.

The input can be any real- or complex-valued signal. If the input is real, the output is real. If the input is complex, the output is complex.

Note To control the output data type by specifying block parameters, or to inherit a data type from a downstream block, use the Data Type Conversion block. To inherit a data type from a different signal in the model, use the Data Type Conversion Inherited block.

Convert Fixed-Point Signals

When you convert between fixed-point data types, the **Input and output to have equal** parameter controls block behavior. If neither input nor output use fixed-point scaling, because they are not of a fixed-point data type or have trivial fixed-point scaling, this parameter does not change the behavior of the block. For more information about fixed-point numbers, see “Fixed-Point Numbers in Simulink” (Fixed-Point Designer).

To convert a signal from one data type to another by attempting to preserve the real-world value of the input signal, select **Real World Value (RWV)**, the default setting. The block accounts for the scaling of the input and output and, within the limits of the specified data types, attempts to generate an output of equal real-world value.

To change the real-world value of the input signal by performing a scaling reinterpretation of the stored integer value, select `Stored Integer (SI)`. Within the limits of the specified data types, the block attempts to preserve the stored integer value of the signal during conversion. A best practice is to specify input and output data types using the same word length and signedness so that the block changes only the scaling of the signal. Specifying a different signedness or word length for the input and output could produce unexpected results such as range loss or unexpected sign extensions. For an example, see “Reinterpret Signal Using a Fixed-Point Data Type” on page 1-249.

If you select `Stored Integer (SI)`, the block does not perform a lower-level bit reinterpretation of a floating-point input signal. For example, if the input is of the data type `single` and has value 5, the bits that store the input in memory are given in hexadecimal by the following command.

```
num2hex(single(5))  
40a00000
```

However, the Data Type Conversion block does not treat the stored integer value as 40a00000, but instead as the real-world value, 5. After conversion, the stored integer value of the output is 5.

Cast Enumerated Signals

Use a Data Type Conversion block to cast enumerated signals as follows:

- 1 To cast a signal of enumerated type to a signal of any numeric type.

The underlying integers of all enumerated values input to the Data Type Conversion block must be within the range of the numeric type. Otherwise, an error occurs during simulation.

- 2 To cast a signal of any integer type to a signal of enumerated type.

The value input to the Data Type Conversion block must match the underlying value of an enumerated value. Otherwise, an error occurs during simulation.

You can enable the block’s **Saturate on integer overflow** parameter so that Simulink uses the default value of the enumerated type when the value input to the block does not match the underlying value of an enumerated value. See “Type Casting for Enumerations” (Simulink Coder).

You cannot use a Data Type Conversion block in the following cases:

- To cast a non-integer numeric signal to an enumerated signal.
- To cast a complex signal to an enumerated signal, regardless of the data types of the complex signal's real and imaginary parts.

See “Simulink Enumerations” for information on working with enumerated types.

Data Type Support

The Data Type Conversion block handles any data type that Simulink supports, including fixed-point and enumerated data types.

For more information, see “Data Types Supported by Simulink”.

Parameters

Show data type assistant

Display the **Data Type Assistant**.

The **Data Type Assistant** helps you set the **Output data type** parameter.

For more information, see “Control Signal Data Types”.

Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

Default: Off

On

Locks the output data type setting for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change the output data type setting for this block.

Parameter: LockScale

Type: character vector

Value: 'off' | 'on'

Default: 'off'

For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Input and output to have equal

Specify which type of input and output must be equal, in the context of fixed point data representation.

Default: Real World Value (RWV)

Real World Value (RWV)

Specifies the goal of making the Real World Value (RWV) of the input equal to the Real World Value (RWV) of the output.

Stored Integer (SI)

Specifies the goal of making the Stored Integer (SI) value of the input equal to the Stored Integer (SI) value of the output.

For the command-line information, see “Block-Specific Parameters” on page 6-128.

Integer rounding mode

Specify the rounding mode for fixed-point operations.

Default: Floor

Ceiling

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

Floor

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

Simplest

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

Parameter: `RndMeth`

Type: character vector

Value: `'Ceiling'` | `'Convergent'` | `'Floor'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Default: `'Floor'`

For more information, see “Rounding” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

Saturate on integer overflow

Specify whether overflows saturate.

Default: Off On

Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

 Off

Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Parameter: SaturateOnIntegerOverflow

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Output minimum

Lower value of the output range that Simulink checks.

Default: [] (unspecified)

Specify this number as a finite, real, double, scalar value.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Parameter: OutMin

Type: character vector

Value: ' [] '

Default: ' [] '

Output maximum

Upper value of the output range that Simulink checks.

Default: [] (unspecified)

Specify this number as a finite, real, double, scalar value.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Note **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Parameter: OutMax

Type: character vector

Value: ' [] '

Default: ' [] '

Output data type

Specify the output data type.

Default: Inherit: Inherit via back propagation

Inherit: Inherit via back propagation

Use data type of the driving block.

double

Output data type is double.

single

Output data type is single.

int8

Output data type is int8.

uint8

Output data type is uint8.

`int16`

Output data type is `int16`.

`uint16`

Output data type is `uint16`.

`int32`

Output data type is `int32`.

`uint32`

Output data type is `uint32`.

`boolean`

Output data type is `boolean`. The Data Type Conversion block converts real, nonzero numeric values (including NaN and Inf) to `boolean true` (1).

`fixdt(1,16,0)`

Output data type is fixed point `fixdt(1,16,0)`.

`fixdt(1,16,2^0,0)`

Output data type is fixed point `fixdt(1,16,2^0,0)`.

Enum: `<class name>`

Use an enumerated data type, for example, `Enum: BasicColors`.

`<data type expression>`

Use a data type object, for example, `Simulink.NumericType`.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

For more information, see “Control Signal Data Types”.

Mode

Select the category of data to specify.

Default: `Inherit`

Inherit

Inheritance rules for data types. Selecting `Inherit` enables `Inherit` via back propagation.

Built in

Built-in data types. Selecting `Built in` enables a second menu/text box to the right. Select one of the following choices:

- `double (default)`
- `single`
- `int8`
- `uint8`
- `int16`
- `uint16`
- `int32`
- `uint32`
- `boolean`

Fixed point

Fixed-point data types.

Enumerated

Enumerated data types. Selecting `Enumerated` enables a second menu/text box to the right, where you can enter the class name.

Expression

Expressions that evaluate to data types. Selecting `Expression` enables a second menu/text box to the right, where you can enter the expression.

Clicking the **Show data type assistant** button enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specify Data Types Using Data Type Assistant”.

Data type override

Specify data type override mode for this signal.

Default: `Inherit`

`Inherit`

Inherits the data type override setting from its context, that is, from the block, `Simulink.Signal` object or Stateflow chart in Simulink that is using the signal.

`Off`

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

This parameter appears only when the **Mode** is `Built in` or `Fixed point`.

Signedness

Specify whether you want the fixed-point data as signed or unsigned.

Default: `Signed`

`Signed`

Specify the fixed-point data as signed.

`Unsigned`

Specify the fixed-point data as unsigned.

Selecting **Mode** > `Fixed point` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Word length

Specify the bit size of the word that holds the quantized integer.

Default: 16

Minimum: 0

Maximum: 32

Selecting **Mode** > Fixed point enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

Default: Best precision

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

Best precision

Specify best-precision values.

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting `Slope` and `bias` enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

For more information, see “Specifying a Fixed-Point Data Type”.

Fraction length

Specify fraction length for fixed-point data type.

Default: 0

Binary points can be positive or negative integers.

Selecting **Scaling** > `Binary point` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Slope

Specify slope for the fixed-point data type.

Default: 2^0

Specify any positive real number.

Selecting **Scaling** > `Slope` and `bias` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Bias

Specify bias for the fixed-point data type.

Default: 0

Specify any real number.

Selecting **Scaling** > `Slope` and `bias` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Examples

Real-World Values and Stored Integers

The example model `ex_data_type_conversion_rvw_si` uses Data Type Conversion blocks to show the meaning of the real-world value and the stored integer of a signal. For basic information about fixed-point scaling, see “Scaling” (Fixed-Point Designer).

The Fixed-Point Constant block represents the real-world value 15 by using a fixed-point data type with binary-point scaling 2^{-5} . Due to the scaling, the output signal uses a stored integer value of 480.

The model uses Data Type Conversion blocks to convert the signal to a fixed-point data type with binary-point scaling 2^{-2} .

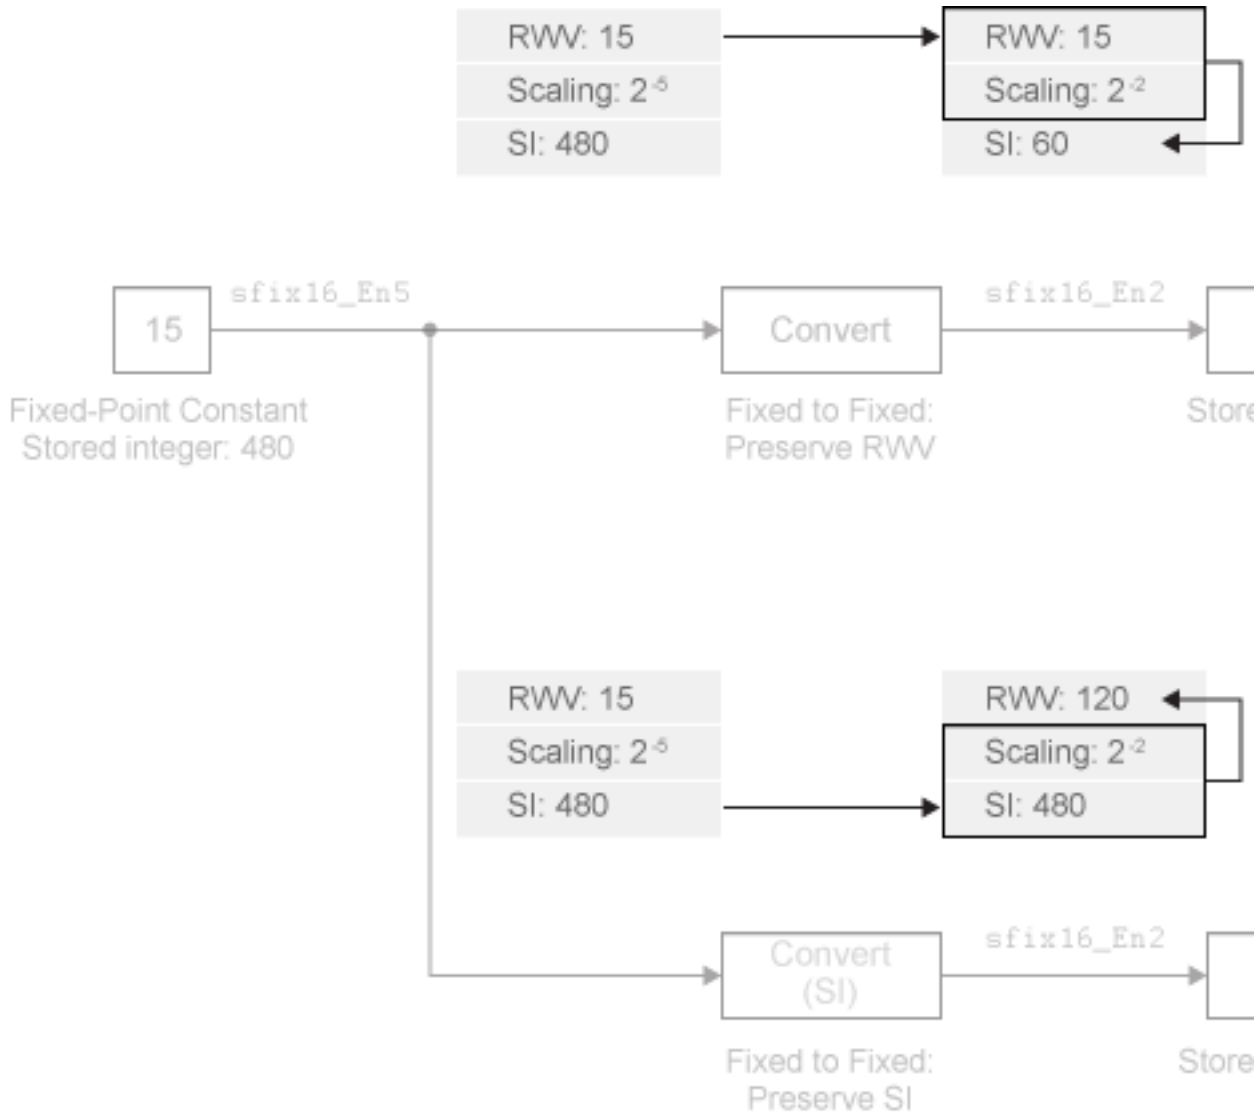

- The Fixed to Fixed: Preserve RWV block converts the input signal by preserving the real-world value, 15. The parameter **Input and output to have equal** is set to Real World Value (RWV).

The output signal has the same real-world value as the input, that is, 15. Due to the fixed-point scaling, the output uses a stored integer value of 60.

- The Fixed to Fixed: Preserve SI block converts the input signal by preserving the stored integer value, 480. The parameter **Input and output to have equal** is set to Stored Integer (SI).

The output signal uses the same stored integer value as the input, that is, 480. Due to the fixed-point scaling, the output has a real-world value of 120.

The figure shows the conversion mechanism for the two blocks.

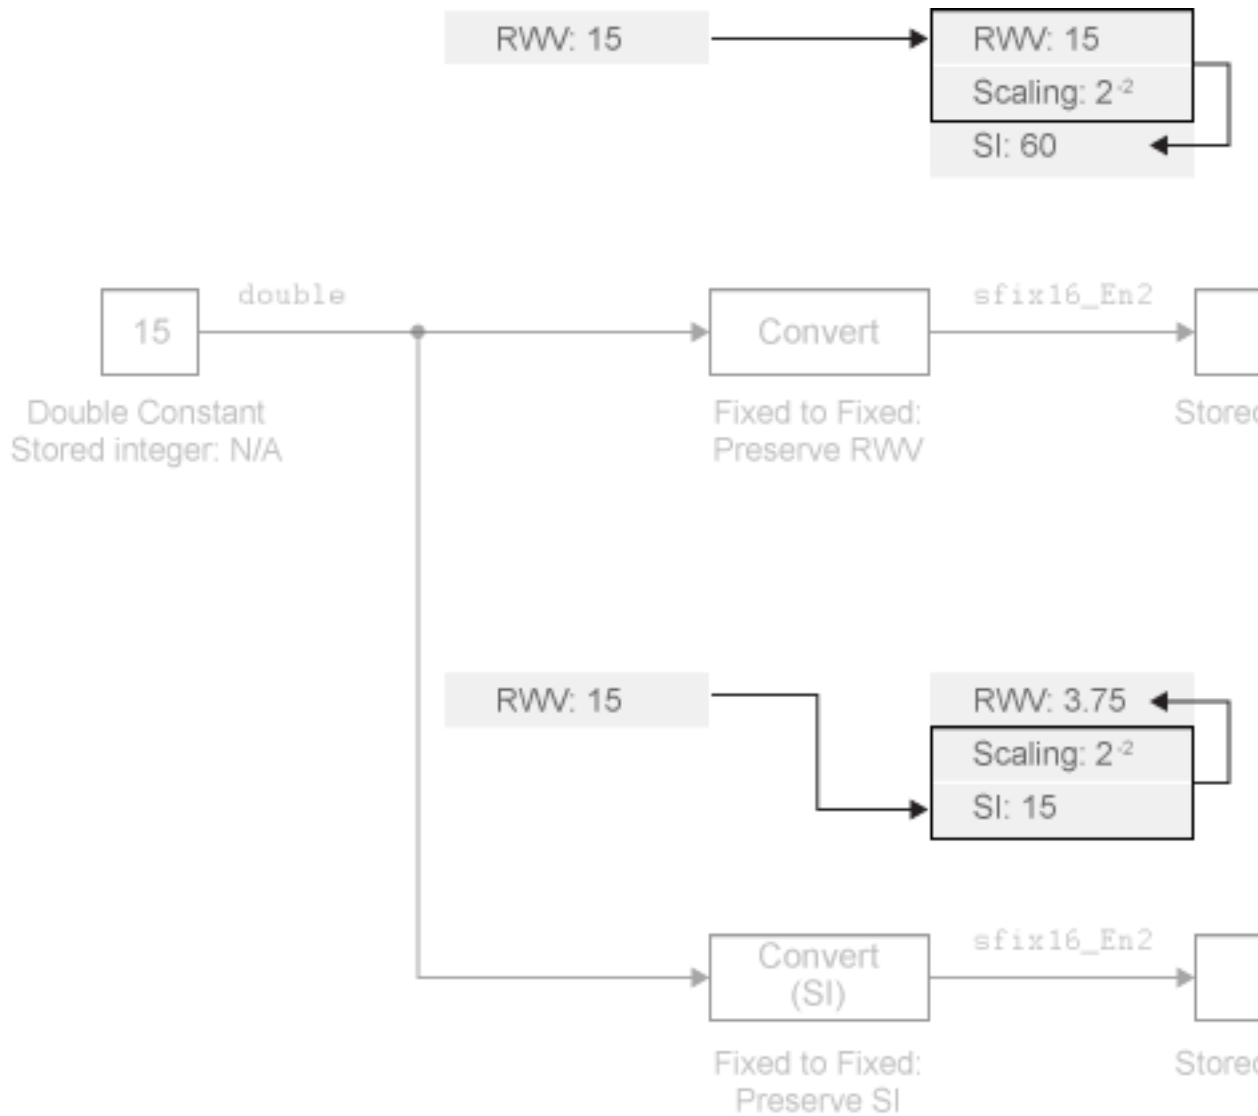

The Double Constant block represents the real-world value 15 by using the floating-point data type `double`. The output signal does not use fixed-point scaling.

The model uses Data Type Conversion blocks to convert the `double` signal to a fixed-point data type with binary-point scaling 2^{-2} .

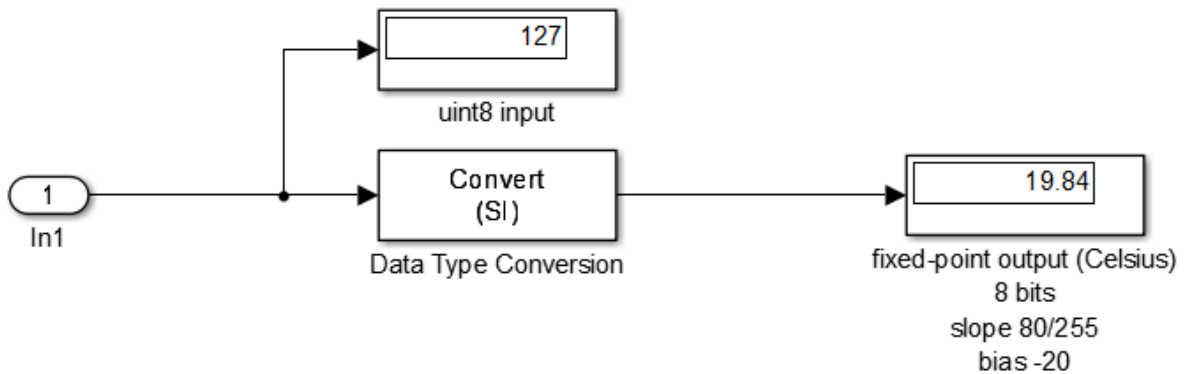

- The Float to Fixed: Preserve RWV block converts the input signal by preserving the real-world value, 15. The output signal has the same real-world value. Due to the fixed-point scaling, the output uses a stored integer value of 60.
- The Float to Fixed: Preserve SI block converts the input signal by attempting to preserve the stored integer value. However, the block does not use the underlying bits that store the floating-point signal in memory. Instead, the block uses the real-world value of the input, 15, as the stored integer of the output signal. Due to the fixed-point scaling, the real-world value of the output is 3.75.

The figure shows the conversion mechanism for the two blocks. The blocks also use these mechanisms if the input uses the floating-point data type `single`.

Reinterpret Signal Using a Fixed-Point Data Type

Suppose your hardware uses the data type `uint8` to store data from a temperature sensor. Also suppose that the minimum stored integer value 0 represents -20 degrees Celsius while the maximum 255 represents 60 degrees. The following model uses a Data Type Conversion block to convert the stored integer value of the sensor data to degrees Celsius.

The Data Type Conversion block parameter **Input and output to have equal** is set to *Stored Integer (SI)*. The block output signal is of a fixed-point data type with word length 8, slope $80/255$, and bias -20 .

The Data Type Conversion block reinterprets the integer input, 127, as a Celsius output, 19.84 degrees. The block output uses the specified slope and bias to scale the stored integer of the input.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated

Introduced before R2006a

Data Type Conversion Inherited

Convert from one data type to another using inherited data type and scaling

Library

Signal Attributes

Description

The Data Type Conversion Inherited block forces dissimilar data types to be the same. The first input is used as the reference signal and the second input is converted to the reference type by inheriting the data type and scaling information. (See “Port Location After Rotating or Flipping” for a description of the port order for various block orientations.) Either input undergoes scalar expansion such that the output has the same width as the widest input.

Inheriting the data type and scaling provides these advantages:

- It makes reusing existing models easier.
- It allows you to create new fixed-point models with less effort since you can avoid the detail of specifying the associated parameters.

Data Type Support

The Data Type Conversion Inherited block accepts signals of the following data types:

- Floating point
- Built-in integer

- Fixed point
- Boolean
- Enumerated

For more information, see “Data Types Supported by Simulink”.

Parameters

Input and Output to have equal

Specify whether the `Real World Value (RWV)` or the `Stored Integer (SI)` of the input and output should be the same. Refer to `Description` on page 1-232 in the `Data Type Conversion` block reference page for more information about these choices.

Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer), in the `Fixed-Point Designer` documentation.

Saturate to max or min when overflows occur

Select to have overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated

Data Type Duplicate

Force all inputs to same data type

Library

Signal Attributes

Description

The Data Type Duplicate block forces all inputs to have exactly the same data type. Other attributes of input signals, such as dimension, complexity, and sample time, are completely independent.

You can use the Data Type Duplicate block to check for consistency of data types among blocks. If all signals do not have the same data type, the block returns an error message.

The Data Type Duplicate block is typically used such that one signal to the block controls the data type for all other blocks. The other blocks are set to inherit their data types via back propagation.

The block is also used in a user created library. These library blocks can be placed in any model, and the data type for all library blocks are configured according to the usage in the model. To create a library block with more complex data type rules than duplication, use the Data Type Propagation block.

Data Type Support

The Data Type Duplicate block accepts signals of the following data types:

- Floating point

- Built-in integer
- Fixed point
- Boolean
- Enumerated

For more information, see “Data Types Supported by Simulink”.

Parameters

Number of input ports

Specify the number of inputs to this block.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated Bus

Data Type Propagation

Set data type and scaling of propagated signal based on information from reference signals

Library

Signal Attributes

Description

The Data Type Propagation block allows you to control the data type and scaling of signals in your model. You can use this block in conjunction with fixed-point blocks that have their **Output data type** parameter configured to `Inherit: Inherit via back propagation`.

The block has three inputs: Ref1 and Ref2 are the reference inputs, while the Prop input back propagates the data type and scaling information gathered from the reference inputs. This information is then passed on to other fixed-point blocks.

The block provides you with many choices for propagating data type and scaling information. For example, you can:

- Use the number of bits from the Ref1 reference signal, or use the number of bits from widest reference signal.
- Use the range from the Ref2 reference signal, or use the range of the reference signal with the greatest range.
- Use a bias of zero, regardless of the biases used by the reference signals.
- Use the precision of the reference signal with the least precision.

You specify how data type information is propagated with the **Propagated data type** parameter list. If the parameter list is configured as `Specify` via dialog, then you manually specify the data type via the **Propagated data type** edit field. If the parameter list is configured as `Inherit` via propagation rule, then you must use the parameters described in “Parameters” on page 1-258.

You specify how scaling information is propagated with the **Propagated scaling** parameter list. If the parameter list is configured as `Specify` via dialog, then you manually specify the scaling via the **Propagated scaling** edit field. If the parameter list is configured as `Inherit` via propagation rule, then you must use the parameters described in “Parameters” on page 1-258.

After you use the information from the reference signals, you can apply a second level of adjustments to the data type and scaling by using individual multiplicative and additive adjustments. This flexibility has a variety of uses. For example, if you are targeting a DSP, then you can configure the block so that the number of bits associated with a MAC (multiply and accumulate) operation is twice as wide as the input signal, and has a certain number of guard bits added to it.

The Data Type Propagation block also provides a mechanism to force the computed number of bits to a useful value. For example, if you are targeting a 16-bit micro, then the target C compiler is likely to support sizes of only 8 bits, 16 bits, and 32 bits. The block will force these three choices to be used. For example, suppose the block computes a data type size of 24 bits. Since 24 bits is not directly usable by the target chip, the signal is forced up to 32 bits, which is natively supported.

There is also a method for dealing with floating-point reference signals. This makes it easier to create designs that are easily retargeted from fixed-point chips to floating-point chips or vice versa.

The Data Type Propagation block allows you to set up libraries of useful subsystems that will be properly configured based on the connected signals. Without this data type propagation process, a subsystem that you use from a library will almost certainly not work as desired with most integer or fixed-point signals, and manual intervention to configure the data type and scaling would be required. This block can eliminate the manual intervention in many situations.

Precedence Rules

The precedence of the dialog box parameters decreases from top to bottom. Additionally:

- Double-precision reference inputs have precedence over all other data types.
- Single-precision reference inputs have precedence over integer and fixed-point data types.
- Multiplicative adjustments are carried out before additive adjustments.
- The number of bits is determined before the precision or positive range is inherited from the reference inputs.

Data Type Support

The Data Type Propagation block accepts signals of the following data types:

- Floating-point
- Built-in integer
- Fixed-point
- Boolean

For more information, see “Data Types Supported by Simulink”.

Parameters

Propagated data type

Use the parameter list to propagate the data type via the dialog box, or inherit the data type from the reference signals. Use the edit field to specify the data type via the dialog box.

If any reference input is double, output is

Specify *single* or *double*. This parameter makes it easier to create designs that are easily retargeted from fixed-point chips to floating-point chips or vice versa.

This parameter is visible only when you set **Propagated data type** to *Inherit via propagation rule*.

If any reference input is single, output is

Specify *single* or *double*. This parameter makes it easier to create designs that are easily retargeted from fixed-point chips to floating-point chips or visa versa.

This parameter is visible only when you set **Propagated data type** to `Inherit` via propagation rule.

Is-Signed

Specify the sign of Prop as one of the following values:

Parameter Value	Description
<code>IsSigned1</code>	Prop is a signed data type if Ref1 is a signed data type.
<code>IsSigned2</code>	Prop is a signed data type if Ref2 is a signed data type.
<code>IsSigned1</code> or <code>IsSigned2</code>	Prop is a signed data type if either Ref1 or Ref2 are signed data types.
<code>TRUE</code>	Ref1 and Ref2 are ignored, and Prop is always a signed data type.
<code>FALSE</code>	Ref1 and Ref2 are ignored, and Prop is always an unsigned data type.

For example, if the Ref1 signal is `ufix(16)`, the Ref2 signal is `sfix(16)`, and the **Is-Signed** parameter is `IsSigned1` or `IsSigned2`, then Prop is forced to be a signed data type.

This parameter is visible only when you set **Propagated data type** to `Inherit` via propagation rule.

Number-of-bits: Base

Specify the number of bits used by Prop for the base data type as one of the following values:

Parameter Value	Description
<code>NumBits1</code>	The number of bits for Prop is given by the number of bits for Ref1.
<code>NumBits2</code>	The number of bits for Prop is given by the number of bits for Ref2.
<code>max([NumBits1 NumBits2])</code>	The number of bits for Prop is given by the reference signal with largest number of bits.
<code>min([NumBits1 NumBits2])</code>	The number of bits for Prop is given by the reference signal with smallest number of bits.
<code>NumBits1+NumBits2</code>	The number of bits for Prop is given by the sum of the reference signal bits.

For more information about the base data type, refer to Targeting an Embedded Processor (Fixed-Point Designer).

This parameter is visible only when you set **Propagated data type** to `Inherit` via propagation rule.

Number-of-bits: Multiplicative adjustment

Specify the number of bits used by Prop by including a multiplicative adjustment that uses a data type of `double`. For example, suppose you want to guarantee that the number of bits associated with a multiply and accumulate (MAC) operation is twice as wide as the input signal. To do this, you configure this parameter to the value 2.

This parameter is visible only when you set **Propagated data type** to `Inherit` via propagation rule.

Number-of-bits: Additive adjustment

Specify the number of bits used by Prop by including an additive adjustment that uses a data type of `double`. For example, if you are performing multiple additions during a MAC operation, the result might overflow. To prevent overflow, you can associate guard bits with the propagated data type. To associate four guard bits, you specify the value 4.

This parameter is visible only when you set **Propagated data type** to `Inherit` via propagation rule.

Number-of-bits: Allowable final values

Force the computed number of bits used by Prop to a useful value. For example, if you are targeting a processor that supports only 8, 16, and 32 bits, then you configure this parameter to `[8, 16, 32]`. The block always propagates the smallest specified value that fits. If you want to allow all fixed-point data types, you would specify the value `1:128`.

This parameter is visible only when you set **Propagated data type** to `Inherit` via propagation rule.

Propagated scaling

Use the parameter list to propagate the scaling via the dialog box, inherit the scaling from the reference signals, or calculate the scaling to obtain best precision.

Propagated scaling (Slope or [Slope Bias])

Specify the scaling as either a slope or a slope and bias.

This parameter is visible only when you set **Propagated scaling** to *Specify* via dialog.

Values used to determine best precision scaling

Specify any values to be used to constrain the precision, such as the upper and lower limits on the propagated input. Based on the data type, the scaling will automatically be selected such that these values can be represented with no overflow error and minimum quantization error.

This parameter is visible only when you set **Propagated scaling** to *Obtain* via best precision.

Slope: Base

Specify the slope used by Prop for the base data type as one of the following values:

Parameter Value	Description
Slope1	The slope of Prop is given by the slope of Ref1.
Slope2	The slope of Prop is given by the slope of Ref2.
max([Slope1 Slope2])	The slope of Prop is given by the maximum slope of the reference signals.
min([Slope1 Slope2])	The slope of Prop is given by the minimum slope of the reference signals.
Slope1*Slope2	The slope of Prop is given by the product of the reference signal slopes.
Slope1/Slope2	The slope of Prop is given by the ratio of the Ref1 slope to the Ref2 slope.
PosRange1	The range of Prop is given by the range of Ref1.
PosRange2	The range of Prop is given by the range of Ref2.
max([PosRange1 PosRange2])	The range of Prop is given by the maximum range of the reference signals.
min([PosRange1 PosRange2])	The range of Prop is given by the minimum range of the reference signals.
PosRange1*PosRange2	The range of Prop is given by the product of the reference signal ranges.
PosRange1/PosRange2	The range of Prop is given by the ratio of the Ref1 range to the Ref2 range.

You control the precision of Prop with Slope1 and Slope2, and you control the range of Prop with PosRange1 and PosRange2. Additionally, PosRange1 and PosRange2 are one bit higher than the maximum positive range of the associated reference signal.

This parameter is visible only when you set **Propagated scaling** to `Inherit` via propagation rule.

Slope: Multiplicative adjustment

Specify the slope used by Prop by including a multiplicative adjustment that uses a data type of `double`. For example, if you want 3 bits of additional precision (with a corresponding decrease in range), the multiplicative adjustment is 2^{-3} .

This parameter is visible only when you set **Propagated scaling** to `Inherit` via propagation rule.

Slope: Additive adjustment

Specify the slope used by Prop by including an additive adjustment that uses a data type of `double`. An additive slope adjustment is often not needed. The most likely use is to set the multiplicative adjustment to 0, and set the additive adjustment to force the final slope to a specified value.

This parameter is visible only when you set **Propagated scaling** to `Inherit` via propagation rule.

Bias: Base

Specify the bias used by Prop for the base data type. The parameter values are described as follows:

Parameter Value	Description
Bias1	The bias of Prop is given by the bias of Ref1.
Bias2	The bias of Prop is given by the bias of Ref2.
max([Bias1 Bias2])	The bias of Prop is given by the maximum bias of the reference signals.
min([Bias1 Bias2])	The bias of Prop is given by the minimum bias of the reference signals.
Bias1*Bias2	The bias of Prop is given by the product of the reference signal biases.

Parameter Value	Description
Bias1/Bias2	The bias of Prop is given by the ratio of the Ref1 bias to the Ref2 bias.
Bias1+Bias2	The bias of Prop is given by the sum of the reference biases.
Bias1-Bias2	The bias of Prop is given by the difference of the reference biases.

This parameter is visible only when you set **Propagated scaling** to `Inherit` via propagation rule.

Bias: Multiplicative adjustment

Specify the bias used by Prop by including a multiplicative adjustment that uses a data type of `double`.

This parameter is visible only when you set **Propagated scaling** to `Inherit` via propagation rule.

Bias: Additive adjustment

Specify the bias used by Prop by including an additive adjustment that uses a data type of `double`.

If you want to guarantee that the bias associated with Prop is zero, you should configure both the multiplicative adjustment and the additive adjustment to 0.

This parameter is visible only when you set **Propagated scaling** to `Inherit` via propagation rule.

Characteristics

Introduced before R2006a

Data Type Scaling Strip

Remove scaling and map to built in integer

Library

Signal Attributes

Description

The Scaling Strip block strips the scaling off a fixed point signal. It maps the input data type to the smallest built in data type that has enough data bits to hold the input. The stored integer value of the input is the value of the output. The output always has nominal scaling (slope = 1.0 and bias = 0.0), so the output does not make a distinction between real world value and stored integer value.

Data Type Support

The Data Type Scaling Strip block accepts signals of any numeric data type that Simulink supports, including fixed-point data types.

For more information, see “Data Types Supported by Simulink”.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point
------------	--

Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Dead Zone

Provide region of zero output

Library

Discontinuities

Description

The Dead Zone block generates zero output within a specified region, called its dead zone. You specify the lower limit (LL) and upper limit (UL) of the dead zone as the **Start of dead zone** and **End of dead zone** parameters, respectively. The block output depends on the input (U) and the values for the lower and upper limits:

Input	Output
$U \geq LL$ and $U \leq UL$	Zero
$U > UL$	$U - UL$
$U < LL$	$U - LL$

Data Type Support

The Dead Zone block accepts and outputs real signals of the following data types:

- Floating point
- Built-in integer
- Fixed point

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Start of dead zone

Specify the lower limit of the dead zone. The default is -0.5 .

End of dead zone

Specify the upper limit of the dead zone. The default is 0.5 .

Saturate on integer overflow

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Do not select this check box.	<p>You want to optimize efficiency of your generated code.</p> <p>You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.</p>	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Treat as gain when linearizing

The linearization commands in Simulink software treat this block as a gain in state space. Select this check box to cause the commands to treat the gain as 1; otherwise, the commands treat the gain as 0.

Enable zero-crossing detection

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Examples

The following model uses lower and upper limits of -0.5 and 0.5 , with a sine wave as input.

This plot shows the effect of the Dead Zone block on the sine wave. When the input sine wave is between -0.5 and 0.5 , the output is zero.

Characteristics

Data Types	Double Single Base Integer Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	Yes, if enabled
Code Generation	Yes

Dead Zone Dynamic

Introduced before R2006a

Dead Zone Dynamic

Set inputs within bounds to zero

Library

Discontinuities

Description

The Dead Zone Dynamic block dynamically bounds the range of the input signal, providing a region of zero output. The bounds change according to the upper and lower limit input signals where

- The input within the bounds is set to zero.
- The input below the lower limit is shifted down by the lower limit.
- The input above the upper limit is shifted down by the upper limit.

The input for the upper limit is the `up` port, and the input for the lower limit is the `lo` port.

Data Type Support

The Dead Zone Dynamic block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Characteristics

Data Types	Double Single Base Integer Fixed-Point
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Code Generation	Yes

Decrement Real World

Decrease real world value of signal by one

Library

Additional Math & Discrete / Additional Math: Increment - Decrement

Description

The Decrement Real World block decreases the real world value of the signal by one. Overflows always wrap.

Data Type Support

The Decrement Real World block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Characteristics

Data Types	Double Single Base Integer Fixed-Point

Decrement Stored Integer

Decrease stored integer value of signal by one

Library

Additional Math & Discrete / Additional Math: Increment - Decrement

Description

The Decrement Stored Integer block decreases the stored integer value of a signal by one.

Floating-point signals also decrease by one, and overflows always wrap.

Data Type Support

The Decrement Stored Integer block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Characteristics

Data Types	Double Single Base Integer Fixed-Point
------------	--

Decrement Time To Zero

Decrease real-world value of signal by sample time, but only to zero

Library

Additional Math & Discrete / Additional Math: Increment - Decrement

Description

The Decrement Time To Zero block decreases the real-world value of the signal by the sample time, T_s . The output never goes below zero. This block works only with fixed sample rates and does not work inside a triggered subsystem.

Data Type Support

The Decrement Time To Zero block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Characteristics

Data Types	Double Single Base Integer Fixed-Point
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Delay

Delay input signal by fixed or variable sample periods

Library

Discrete

Description

The Delay block outputs the input of the block after a delay. The block determines the delay time based on the value of the **Delay length** parameter. The block supports:

- Variable delay length
- Specification of the initial condition from an input port
- State storage
- Using a circular buffer instead of an array buffer for state storage
- Resetting the state to the initial condition with an external reset signal
- Controlling execution of the block at every time step with an external enable signal

The initial block output depends on a number of factors such as the **Initial condition** parameter and the simulation start time. For more information, see “Initial Block Output” on page 1-282. The **External reset** parameter determines if the block output resets to the initial condition on triggering. The **Show enable port** parameter determines if the block execution is controlled in every time step by an external enable signal.

Initial Block Output

The output of the Delay block in the first few time steps of the simulation depends on the block sample time, the delay length, and the simulation start time. The block supports

specifying or inheriting discrete sample times to determine the time interval between samples. For more information, see “Specify Sample Time”.

Suppose that the block inherits a discrete sample time as $[T_{\text{sampling}}, T_{\text{offset}}]$, where T_{sampling} is the sampling period and T_{offset} is the initial time offset. n is the value of the block’s **Delay length** parameter and T_{start} is the simulation start time for the model.

The table shows the Delay block output for the first few time steps.

Simulation Time Range	Block Output
(T_{start}) to $(T_{\text{start}} + T_{\text{offset}})$	Zero
$(T_{\text{start}} + T_{\text{offset}})$ to $(T_{\text{start}} + T_{\text{offset}} + n * T_{\text{sampling}})$	Initial condition parameter
After $(T_{\text{start}} + T_{\text{offset}} + n * T_{\text{sampling}})$	Input signal

Data Type Support

The block’s parameters have these dimensional requirements:

- **Delay length** and **External reset** must be scalar.
- **Initial condition** can be scalar or nonscalar.
- For frame-based processing, signal dimensions of the data input port u cannot be larger than two.

The block supports input signals with these data types.

Input Signal	Supported Data Types
Data input port u	<ul style="list-style-type: none"> • Floating point • Built-in integer • Fixed point • Boolean • Enumerated

Input Signal	Supported Data Types
Delay length d	<ul style="list-style-type: none"> Floating point Fixed-point integer Built-in integer
Enable port 	<ul style="list-style-type: none"> Floating point Built-in integer Fixed point Integer (only <code>ufix1</code>) Boolean
External reset port 	<ul style="list-style-type: none"> Floating point Built-in integer Fixed point Integer (only <code>ufix1</code>) Boolean
Initial condition $x0$	<ul style="list-style-type: none"> Floating point Built-in integer Fixed point Boolean Enumerated

When u is Boolean, $x0$ must be Boolean. When u uses an enumerated type, $x0$ must use the same enumerated type. Otherwise, $x0$ can use a floating-point, built-in integer, or fixed-point data type that fits in the data type of u . For example, when u uses `int32`, $x0$ can use `int8` but not `double`.

The data type of the output signal is the same as the input signal u .

For more information, see “Data Types Supported by Simulink”.

Variable-Size Support

The Delay block provides the following support for variable-size signals:

- The data input port u accepts variable-size signals. The other input ports do not accept variable-size signals.

- The output port has the same signal dimensions as the data input port u for variable-size inputs.

The rules that apply to variable-size signals depend on the input processing mode of the Delay block.

Input Processing Mode	Rules for Variable-Size Signal Support
Elements as channels (sample based)	<ul style="list-style-type: none"> • The signal dimensions change only during state reset when the block is enabled. • The initial condition must be scalar.
Columns as channels (frame based)	<ul style="list-style-type: none"> • No support
Inherited (where input is a sample-based signal)	<ul style="list-style-type: none"> • The signal dimensions change only during state reset when the block is enabled. • The initial condition must be scalar.
Inherited (where input is a frame-based signal)	<ul style="list-style-type: none"> • The channel size changes only during state reset when the block is enabled. • The initial condition must be scalar. • The frame size must be constant.

Bus Support

The Delay block provides the following support for bus signals:

- The data input port u accepts virtual and nonvirtual bus signals. The other input ports do not accept bus signals.
- The output port has the same bus type as the data input port u for bus inputs.
- Buses work with:
 - Sample-based and frame-based processing
 - Fixed and variable delay length
 - Array and circular buffers

To use a bus signal as the input to a Delay block, you should specify the initial condition on the dialog box. In other words, the initial condition cannot come from the input port

×0. Support for virtual and nonvirtual buses depends on the initial condition that you specify and whether the **State name** parameter is empty or not.

Initial Condition	State Name	
	Empty	Not Empty
Zero	Virtual and nonvirtual bus support	Nonvirtual bus support only
Nonzero scalar	Virtual and nonvirtual bus support	No bus support
Nonscalar	No bus support	No bus support
Structure	Virtual and nonvirtual bus support	Nonvirtual bus support only
Partial structure	Virtual and nonvirtual bus support	Nonvirtual bus support only

Parameters

Delay length

Specify whether to enter the delay length directly on the dialog box (fixed delay) or to inherit the delay from an input port (variable delay).

- If you set **Source** to `Dialog`, enter the delay length in the edit field under **Value**.
- If you set **Source** to `Input port`, verify that an upstream signal supplies a delay length for the d input port. You can also specify its maximum value by specifying the parameter **Upper limit**.

Specify the scalar delay length as a real, non-negative integer. An out-of-range or non-integer value in the dialog box (fixed delay) returns an error. An out-of-range value from an input port (variable delay) casts it into the range. A non-integer value from an input port (variable delay) truncates it to the integer.

This parameter is not tunable for simulation or code generation.

Initial condition

Specify whether to enter the initial condition directly on the dialog box or to inherit the initial condition from an input port.

- If you set **Source** to `Dialog`, enter the initial condition in the edit field under **Value**.
- If you set **Source** to `Input port`, verify that an upstream signal supplies an initial condition for the `x0` input port.

Simulink converts offline the data type of **Initial condition** to the data type of the input signal `u` using a round-to-nearest operation and saturation.

Note When **State name must resolve to Simulink signal object** is selected on the **State Attributes** pane, the block copies the initial value of the signal object to the **Initial condition** parameter. However, when the source for **Initial condition** is `Input port`, the block ignores the initial value of the signal object.

Input processing

Specify whether the block performs sample- or frame-based processing. You can select one of the following options:

- `Elements as channels (sample based)` — Treat each element of the input as a separate channel (sample-based processing).
- `Columns as channels (frame based)` — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

- `Inherited` — Inherit the processing mode from the input signal and delay the input accordingly. You can identify whether the input signal is sample or frame based by looking at the signal line. Simulink represents sample-based signals with a single line and frame-based signals with a double line.

Note When you choose the `Inherited` option for the **Input processing** parameter, and the input signal is frame-based, Simulink will generate a warning or error in future releases.

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input u . All other input signals must be sample based.

Input Signal u	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

Use circular buffer for state

Select to use a circular buffer for storing the state in simulation and code generation. Otherwise, an array buffer stores the state.

Using a circular buffer can improve execution speed when the delay length is large. For an array buffer, the number of copy operations increases as the delay length goes up. For a circular buffer, the number of copy operations is constant for increasing delay length.

If one of the following conditions is true, an array buffer always stores the state because a circular buffer does not improve execution speed:

- For sample-based signals, the delay length is 1.
- For frame-based signals, the delay length is no larger than the frame size.

Prevent direct feedthrough

Select to increase the delay length from zero to the lower limit for the **Input processing** mode:

- For sample-based signals, increase the minimum delay length to 1.
- For frame-based signals, increase the minimum delay length to the frame length.

Selecting this check box prevents direct feedthrough from the input port, u , to the output port. However, this check box cannot prevent direct feedthrough from the initial condition port, $x0$, to the output port.

This check box is available when you set **Delay length: Source** to `Input port`.

Remove delay length check in generated code

Select to remove code that checks for out-of-range delay length.

Check Box	Result	When to Use
Selected	Generated code does not include conditional statements to check for out-of-range delay length.	For code efficiency
Cleared	Generated code includes conditional statements to check for out-of-range delay length.	For safety-critical applications

This check box is available when you set **Delay length: Source** to `Input port`.

Diagnostic for delay length

Specify whether to produce a warning or error when the input `d` is less than the lower limit or greater than the **Delay length: Upper limit**. The lower limit depends on the setting for **Prevent direct feedthrough**.

- If the check box is cleared, the lower limit is zero.
- If the check box is selected, the lower limit is 1 for sample-based signals and frame length for frame-based signals.

Options for the diagnostic include:

- `None` — Simulink software takes no action.
- `Warning` — Simulink software displays a warning and continues the simulation.
- `Error` — Simulink software terminates the simulation and displays an error.

This parameter is available when you set **Delay length: Source** to `Input port`.

Show enable port

Select to show an enable port for this block. This port can control execution of the block. The block is considered enabled when the input to this port is nonzero, and is disabled when the input is 0. The value of the input is checked at the same time step as the block execution.

External reset

Specify the trigger event to use to reset the states to the initial conditions.

Reset Mode	Behavior
None	No reset.
Rising	Reset on a rising edge.
Falling	Reset on a falling edge.
Either	Reset on either a rising or falling edge.
Level	Reset in either of these cases: <ul style="list-style-type: none"> • when the reset signal is nonzero at the current time step • when the reset signal value changes from nonzero at the previous time step to zero at the current time step
Level hold	Reset when the reset signal is nonzero at the current time step

The reset signal must be a scalar of type `single`, `double`, `boolean`, or `integer`. Fixed point data types, except for `ufix1`, are not supported.

Sample time (-1 for inherited)

Specify the time interval between samples. To inherit the sample time, set this parameter to `-1`. This block supports discrete sample time, but not continuous sample time.

State name

Use this parameter to assign a unique name to the block state. The default is `' '`. When this field is blank, no name is assigned. When using this parameter, remember these considerations:

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

This parameter enables **State name must resolve to Simulink signal object** when you click **Apply**.

For more information, see “Discrete Block State Naming in Generated Code” (Simulink Coder).

State name must resolve to Simulink signal object

Select this check box to require that the state name resolve to a Simulink signal object. This check box is cleared by default.

State name enables this parameter. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than `None`.

Selecting this check box disables **Code generation storage class**.

Signal object class

Choose a custom storage class package by selecting a signal object class that the target package defines. For example, to apply custom storage classes from the built-in package `mpt`, select `mpt.Signal`. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes do not affect the generated code.

If the class that you want does not appear in the list, select `Customize class lists`. For instructions, see “Apply Custom Storage Classes Directly to Signal Lines, Block States, and Output Blocks” (Embedded Coder).

To programmatically set this parameter, use `StateSignalObject`.

For information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

Code generation storage class

Select state storage class for code generation.

Default: `Auto`

`Auto`

`Auto` is the appropriate storage class for states that you do not need to interface to external code.

StorageClass

Applies the storage class or custom storage class that you select from the list. For information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than `Simulink`.

State name enables this parameter.

To programmatically set this parameter, use `StateStorageClass` or `StateSignalObject`. See “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder).

TypeQualifier

Note **TypeQualifier** will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

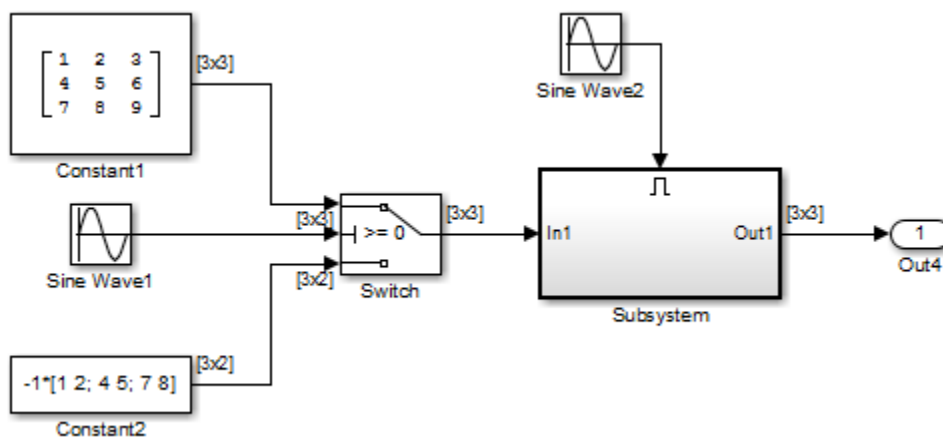

Specify a storage type qualifier such as `const` or `volatile`.

Setting **Code generation storage class** to `ExportedGlobal`, `ImportedExtern`, `ImportedExternPointer`, or `SimulinkGlobal` enables this parameter. This parameter is hidden unless you previously set its value.

Examples

Variable-Size Signals for Sample-Based Processing

This model shows how the Delay block supports variable-size signals for sample-based processing.

The Switch block controls whether the input signal to the enabled subsystem is a 3-by-3 or 3-by-2 matrix. The Delay block appears inside the enabled subsystem.

The model follows the rules for variable-size signals when the Delay block uses sample-based processing.

Rule	How the Model Follows the Rule
The signal dimensions change only during state reset when the block is enabled.	The Enable block sets Propagate sizes of variable-size signals to Only when enabling.
The initial condition must be scalar.	The Delay block sets Initial condition to 0.0, a scalar value.

Bus Signals for Frame-Based Processing

This model shows how the Delay block supports bus signals for frame-based processing.

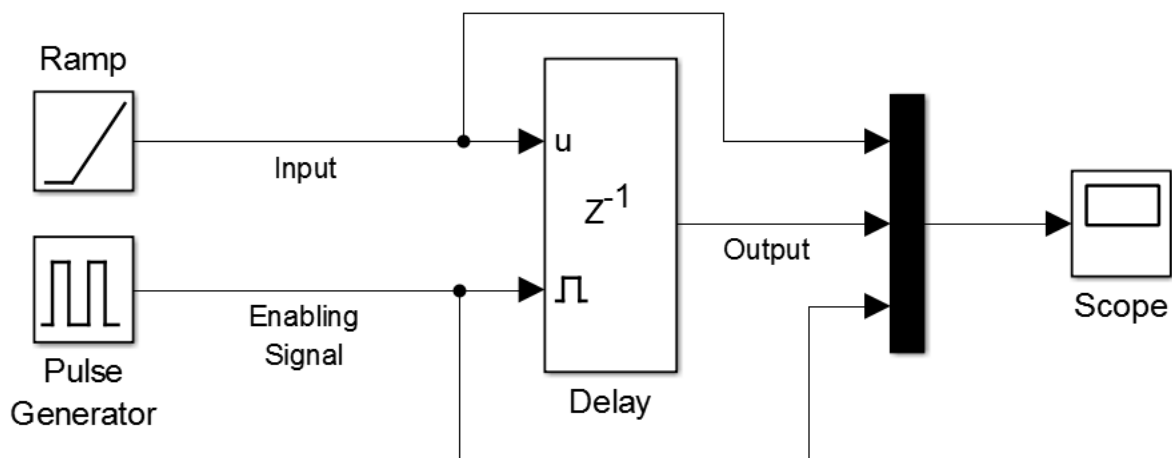

Each Constant block supplies an input signal to the Bus Creator block, which outputs a two-dimensional bus signal. After the Delay block delays the bus signal by three sample periods, the Bus Selector block separates the bus back into the two original signals.

The model follows the rules for bus signals when the Delay block uses frame-based processing.

Rule	How the Model Follows the Rule
For the initial condition, set the value on the dialog box.	The Delay block sets Initial condition to 0, a scalar value.
For frame-based processing, signal dimensions of the data input port u cannot be larger than two. (This rule applies to all inputs for the port u , not just bus signals.)	The bus input to the Delay block has two dimensions.

Enable or Disable Execution of the Delay Block

This example shows how you can enable or disable the execution of the Delay block using the enable port of the block. Consider this model. A ramp input signal feeds into a Delay block whose execution is controlled by an enabling signal. A Pulse Generator block generates this enabling signal.

The Scope block displays the output of the Delay block along with the enabling signal and the ramp input. Simulating the model and viewing the scope output shows the following graph.

The magenta marks show that the Delay block outputs the input signal delayed by one time step only while the enabling signal is 1. At $t=5$ sec, the enabling signal becomes 0 and the Delay block does not execute. Hence, the output is held constant until the next time the enabling signal becomes 1.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated Bus
Sample Time	Specified in the Sample time parameter
Direct Feedthrough	Yes, when you clear Prevent direct feedthrough

Multidimensional Signals	Yes

Demux

Extract and output elements of virtual vector signal

Library: Simulink / Commonly Used Blocks
Simulink / Signal Routing

Description

The Demux block extracts the components of an input vector signal and outputs separate signals. The output signal ports are ordered from top to bottom. See “Mux Signals” for information about creating and decomposing vectors.

Ports

Input

Port_1 — Accept nonbus vector signal to extract and output signals from real or complex values of any nonbus data type supported by Simulink

Output

Port_1 — Output signals extracted from input vector signal nonbus signal with real or complex values of any data type supported by Simulink

Output signals extracted from the input vector. The output signal ports are ordered from top to bottom. See “Port Location After Rotating or Flipping” for a description of the port order for various block orientations.

Parameters

Number of outputs — Number of outputs

2 (default) | scalar | vector

Specify the number and, optionally, the dimensionality of each output port. If you do not specify the dimensionality of the outputs, the block determines the dimensionality of the outputs.

The value can be a scalar specifying the number of outputs or a vector whose elements specify the widths of the block output ports. The block determines the size of its outputs from the size of the input signal and the value of the **Number of outputs** parameter.

If you specify a scalar for the **Number of outputs** parameter and all of the output ports are connected, as you draw a new signal line close to output side of a Demux block, Simulink adds a port and updates the **Number of outputs** parameter.

For an input vector of width n , here is what the block outputs.

Parameter Value	Block outputs...	Examples and Comments
$p = n$	p scalar signals	If the input is a three-element vector and you specify three outputs, the block outputs three scalar signals.
$p > n$	Error	This value is not supported.
$p < n$ $n \bmod p = 0$	p vector signals each having n/p elements	If the input is a six-element vector and you specify three outputs, the block outputs three two-element vectors.
$p < n$ $n \bmod p = m$	m vector signals each having $(n/p) + 1$ elements and $p - m$ signals having n/p elements	If the input is a five-element vector and you specify three outputs, the block outputs two two-element vector signals and one scalar signal.

Parameter Value	Block outputs...	Examples and Comments
$[p_1 \ p_2 \ \dots \ p_m]$ $p_1+p_2+\dots+p_m=n$ $p_i > 0$	m vector signals having widths p_1, p_2, \dots, p_m	If the input is a five-element vector and you specify $[3, 2]$ as the output, the block outputs three of the input elements on one port and the other two elements on the other port.
An array that has one or more of m elements with a value of -1 , which specifies that Simulink infers the size for the element. For example, suppose that you have a four-element array with a total width of 14 and you specify the parameter to be $[p_1 \ p_2 \ -1 \ p_4]$. The value for the third element (the -1 element) is $14 - (p_1 + p_2 + p_4)$	m vector signals	If p_i is greater than zero, the corresponding output has width p_i . If p_i is -1 , the width of the corresponding output is computed dynamically.
$[p_1 \ p_2 \ \dots \ p_m]$ $p_1+p_2+\dots+p_m \neq n$ $p_i = > 0$	Error	This value is not supported

If you specify the number of outputs that is smaller than the number of input elements, the block distributes the elements as evenly as possible over the outputs. For example, this model, model distributes the seven input signals as evenly as possible.

You can use -1 in a vector expression to indicate that the block dynamically sizes the corresponding port. For example, the expression $[-1, 3 -1]$ causes the block to output three signals where the second signal always has three elements. The sizes of the first and third signals depend on the size of the input signal.

If a vector expression comprises positive values and -1 values, the block assigns as many elements as needed to the ports with positive values. The block distributes the remaining elements as evenly as possible over the ports with -1 values. For example, suppose that the block input is seven elements wide and you specify the output as $[-1, 3 -1]$. In this model, the block outputs two elements on the first port, three elements on the second, and two elements on the third.

Programmatic Use

Block Parameter:Outputs

Type:scalar or vector

Values:character vector

Default:{ '2' } or vector

Display option — Displayed block icon

bar (default) | none

By default, the block icon is a solid bar of the block foreground color. To display the icon as a box containing the block type name, select none.

Programmatic Use

Block Parameter:Display option

Derivative

Output time derivative of input

Library

Continuous

Description

The Derivative block approximates the derivative of the input signal u with respect to the simulation time t . You obtain the approximation of

$$\frac{du}{dt},$$

by computing a numerical difference $\Delta u/\Delta t$, where Δu is the change in input value and Δt is the change in time since the previous simulation (major) time step.

This block accepts one input and generates one output. The initial output for the block is zero.

The precise relationship between the input and output of this block is:

$$y(t) = \frac{\Delta u}{\Delta t} = \frac{u(t) - u(T_{previous})}{t - T_{previous}} \Big|_{t > T_{previous}},$$

where t is the current simulation time and $T_{previous}$ is the time of the last output time of the simulation. The latter is the same as the time of the last major time step.

The Derivative block output might be very sensitive to the dynamics of the entire model. The accuracy of the output signal depends on the size of the time steps taken in the

simulation. Smaller steps allow a smoother and more accurate output curve from this block. However, unlike with blocks that have continuous states, the solver does not take smaller steps when the input to this block changes rapidly. Depending on the dynamics of the driving signal and model, the output signal of this block might contain unexpected fluctuations. These fluctuations are primarily due to the driving signal output and solver step size.

Because of these sensitivities, structure your models to use integrators (such as Integrator blocks) instead of Derivative blocks. Integrator blocks have states that allow solvers to adjust step size and improve accuracy of the simulation. See “Circuit Model” for an example of choosing the best-form mathematical model to avoid using Derivative blocks in your models,

If you must use the Derivative block with a variable step solver, set the solver maximum step size settings to a value such that the Derivative block can generate answers with adequate accuracy. To determine this value, you might need to repeatedly run the simulation using different solver settings.

When the input to this block is a discrete signal, the continuous derivative of the input exhibits an impulse when the value of the input changes. Otherwise, it is 0. Alternatively, you can define the discrete derivative of a discrete signal using the difference of the last two values of the signal, as follows:

$$y(k) = \frac{1}{\Delta t}(u(k) - u(k - 1))$$

Taking the z -transform of this equation results in:

$$\frac{Y(z)}{u(z)} = \frac{1 - z^{-1}}{\Delta t} = \frac{z - 1}{\Delta t \cdot z}$$

The Discrete Derivative block models this behavior. Use this block instead of the Derivative block to approximate the discrete-time derivative of a discrete signal.

Improved Linearization with Transfer Fcn Blocks

The Laplace domain transfer function for the operation of differentiation is:

$$\frac{Y(s)}{X(s)} = s$$

This equation is not a proper transfer function, nor does it have a state-space representation. As such, the Simulink software linearizes this block as an effective gain

of 0 unless you explicitly specify that a proper first-order transfer function should be used to approximate the linear behavior of this block (see “Coefficient c in the transfer function approximation $s/(c*s + 1)$ used for linearization” on page 1-306).

To improve linearization, you can also try to incorporate the derivative term in other blocks. For example, if you have a Derivative block in series with a Transfer Fcn block, try using a single Transfer Fcn block of the form

$$\frac{s}{s+a}$$

For example, you can replace the first set of blocks in this figure with the blocks below them.

Data Type Support

The Derivative block accepts and outputs a real signal of type `double`. For more information, see “Data Types Supported by Simulink”.

Parameters

Coefficient c in the transfer function approximation $s/(c*s + 1)$ used for linearization

Specify the time constant c to approximate the linearization of your system.

Default: `inf`

- The exact linearization of the Derivative block is difficult, because the dynamic equation for the block is $y = \dot{u}$, which you cannot represent as a state-space system. However, you can approximate the linearization by adding a pole to the Derivative to create a transfer function $s / (c * s + 1)$. The addition of a pole filters the signal before differentiating it, which removes the effect of noise.
- The default value `inf` corresponds to a linearization of 0.
- A best practice is to change the value of c to $\frac{1}{f_b}$, where f_b is the break frequency for the filter.
- **Coefficient c in the transfer function approximation $s/(c*s+1)$ used for linearization** must be a finite positive value. This value must be nonzero.

Parameter: `CoefficientInTFapproximation`

Type: character vector

Value: `'inf'`

Default: `'inf'`

Characteristics

Data Types	Double
Sample Time	Continuous
Direct Feedthrough	Yes

Deserializer1D

Convert scalar stream or smaller vectors to vector signal

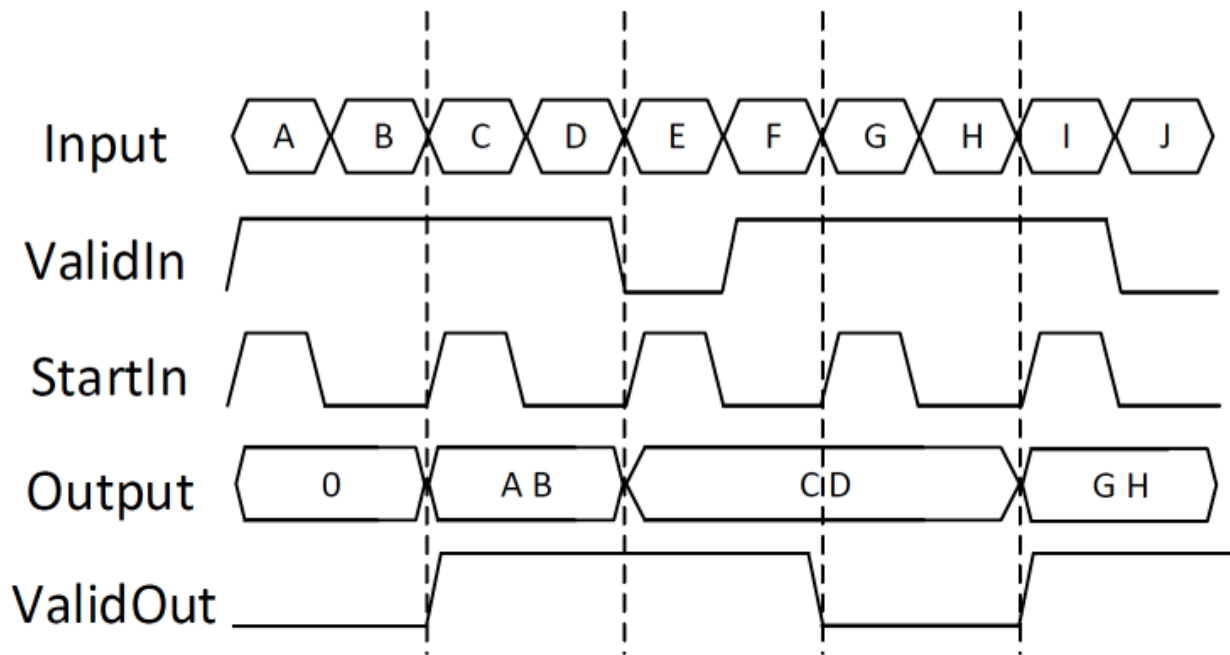

Library

HDL Coder / HDL Operations

Description

The Deserializer1D block buffers a faster, scalar stream or vector signals into a larger, slower vector signal. The faster input signal is converted to a slower signal based on the **Ratio** and **Idle Cycle** values, the conversion changes sample time. Also, the output signal is delayed one slow signal cycle because the serialized data needs to be collected before it can be output as a vector. See the examples below for more details.

You can configure the deserialization to depend on a valid input signal ValidIn and a start signal StartIn. If the **ValidIn** and **StartIn** block parameters are both selected, data collection starts only if both ValidIn and StartIn signals are true. Consider this example:

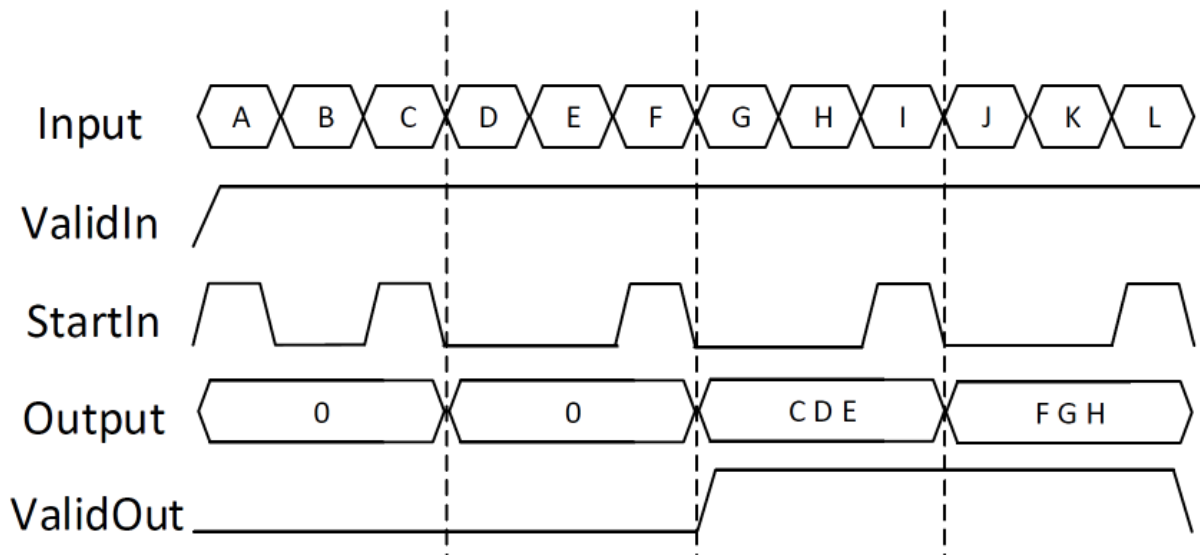

- **Ratio** is 2 and **Idle Cycles** is 0, so each output cycle is two input signals long with all data points considered.
- **ValidIn** and **StartIn** are selected, so data collection can begin only when both **StartIn** and **ValidIn** signals are true.
- **ValidOut** is selected.

In the first cycle, **ValidIn** and **StartIn** are true, so data collection begins for A and B. The block outputs the deserialized vector in the next valid cycle, so the AB vector is output in the next cycle. This is also true in the second cycle for C and D.

In the third cycle, starting at E, **StartIn** is true, but **ValidIn** is not. E is dropped. At F, **ValidIn** is true, but **StartIn** is not, so F is also dropped. Since it cannot collect data for E or F, **Deserializer1D** outputs the previous cycle vector, CD, but **ValidOut** changes to false.

Another scenario to consider is when the **StartIn** signal arrives too early. If the length between two **StartIn** signals is not long enough to collect a full ratio cycle, the insufficient signal data is dropped. Consider this example:

- **Ratio** is 3, so each cycle is two sections long.
- **Idle Cycles** is 0, so all data inputs are considered.
- **ValidIn** and **StartIn** are selected, so data collection can begin only when both StartIn and ValidIn signals are true.
- **ValidOut** is selected.

In the first cycle, ValidIn and StartIn are true, so data collection can begin for A and B. However, at C another StartIn signal arrives before three signals can be collected. Because the StartIn arrived early, A and B are dropped and no valid vector is collected during the first cycle. Therefore, the output of the second cycle is still zero. Deserialization begins at the StartIn at C, for C, D, and E. This vector is output at the next valid cycle, which is cycle 3. Similarly, deserialization starts again at the StartIn at F, and outputs the FGH vector in the fourth cycle.

You specify the block output for the first sampling period with the value of the **Initial condition** parameter.

Parameters

Ratio

Enter the deserialization ratio. Default is 1.

The ratio is the output vector size, divided by the input vector size. The ratio must be divisible by the input vector size.

Idle Cycles

Enter the number of idle cycles added to the end of each serialized input. Default is 0.

The value of **Idle Cycles** affects the deserialized output rate. For example, if **Ratio** is 2 and the input signal is A, B, B, C, D, D, . . . , without idle cycles the output would be AB, BC, DD. . . . However for the same input and ratio with **Idle Cycles** set to 1, the output is AB, CD. . . . The idle cycles, B and D, are dropped.

The Deserializer1D behavior changes if **Idle Cycles** is not zero, and **ValidIn** or **StartIn** are on. The idle cycles value affects only the output rate, while **ValidIn** and **StartIn** control what input data is deserialized.

Initial condition

Specify the initial output of the simulation. Default is 0.

StartIn

Select to activate the StartIn port. Default is off.

ValidIn

Select to activate the ValidIn port. Default is off.

ValidOut

Select to activate ValidOut port. Default is off.

Input data port dimensions (-1 for inherited)

Enter the size of the input data signal. The input size must be divisible by the ratio plus the number of idle cycles. By default, the block inherits size based on context within the model.

Input sample time (-1 for inherited)

Enter the time interval between sample time hits or specify another appropriate sample time such as continuous. By default, the block inherits its sample time based on context within the model. For more information, see “Sample Time”.

Input signal type

Specify the input signal type of the block as `auto`, `real`, or `complex`.

Ports

S

Input signal to deserialize. Bus data types are not supported.

ValidIn

Indicates valid input signal. Use with the Serializer1D block. This port is available when you select the **ValidIn** check box.

Data type: Boolean

StartOut

Indicates where to start deserialization. Use with the Serializer1D block. This port is available when you select the **StartOut** check box.

Data type: Boolean

P

Deserialized output signal. Bus data types are not supported.

ValidOut

Indicates valid output signal. This port is available when you select the **ValidOut** check box.

Data type: Boolean

Detect Change

Detect change in signal value

Library

Logic and Bit Operations

Description

The Detect Change block determines if an input does not equal its previous value.

- The output is true (equal to 1) when the input signal does not equal its previous value.
- The output is false (equal to 0) when the input signal equals its previous value.

Data Type Support

The Detect Change block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean
- Enumerated

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Initial condition

Set the initial condition for the previous input U/z .

Input processing

Specify whether the block performs sample- or frame-based processing. You can select one of the following options:

- **Elements as channels (sample based)** — Treat each element of the input as a separate channel (sample-based processing).
- **Columns as channels (frame based)** — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

- **Inherited** — Inherit the processing mode from the input signal and delay the input accordingly. You can identify whether the input signal is sample or frame based by looking at the signal line. Simulink represents sample-based signals with a single line and frame-based signals with a double line.

Note When you choose the **Inherited** option for the **Input processing** parameter, and the input signal is frame-based, Simulink will generate a warning or error in future releases.

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input u . All other input signals must be sample based.

Input Signal u	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes

Input Signal u	Input Processing Mode	Block Works?
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

Output data type

Set the output data type to `boolean` or `uint8`.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated
Direct Feedthrough	Yes
Multidimensional Signals	No

Detect Decrease

Detect decrease in signal value

Library

Logic and Bit Operations

Description

The Detect Decrease block determines if an input is strictly less than its previous value.

- The output is true (equal to 1) when the input signal is less than its previous value.
- The output is false (equal to 0) when the input signal is greater than or equal to its previous value.

Data Type Support

The Detect Decrease block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean
- Enumerated

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Initial condition

Set the initial condition for the previous input U/z .

Input processing

Specify whether the block performs sample- or frame-based processing. You can select one of the following options:

- `Elements as channels (sample based)` — Treat each element of the input as a separate channel (sample-based processing).
- `Columns as channels (frame based)` — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

- `Inherited` — Inherit the processing mode from the input signal and delay the input accordingly. You can identify whether the input signal is sample or frame based by looking at the signal line. Simulink represents sample-based signals with a single line and frame-based signals with a double line.

Note When you choose the `Inherited` option for the **Input processing** parameter, and the input signal is frame-based, Simulink will generate a warning or error in future releases.

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input u . All other input signals must be sample based.

Input Signal u	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes

Input Signal u	Input Processing Mode	Block Works?
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

Output data type

Set the output data type to `boolean` or `uint8`.

Characteristics

Detect Fall Negative

Detect falling edge when signal value decreases to strictly negative value, and its previous value was nonnegative

Library

Logic and Bit Operations

Description

The Detect Fall Negative block determines if the input is less than zero, and its previous value was greater than or equal to zero.

- The output is true (equal to 1) when the input signal is less than zero, and its previous value was greater than or equal to zero.
- The output is false (equal to 0) when the input signal is greater than or equal to zero, or if the input signal is negative, its previous value was also negative.

Data Type Support

The Detect Fall Negative block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Initial condition

Set the initial condition of the Boolean expression $U/z < 0$.

Input processing

Specify whether the block performs sample- or frame-based processing. You can select one of the following options:

- `Elements as channels (sample based)` — Treat each element of the input as a separate channel (sample-based processing).
- `Columns as channels (frame based)` — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

- `Inherited` — Inherit the processing mode from the input signal and delay the input accordingly. You can identify whether the input signal is sample or frame based by looking at the signal line. Simulink represents sample-based signals with a single line and frame-based signals with a double line.

Note When you choose the `Inherited` option for the **Input processing** parameter, and the input signal is frame-based, Simulink will generate a warning or error in future releases.

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input u . All other input signals must be sample based.

Input Signal u	Input Processing Mode	Block Works?

Detect Fall Nonpositive

Detect falling edge when signal value decreases to nonpositive value, and its previous value was strictly positive

Library

Logic and Bit Operations

Description

The Detect Fall Nonpositive block determines if the input is less than or equal to zero, and its previous value was greater than zero.

- The output is true (equal to 1) when the input signal is less than or equal to zero, and its previous value was greater than zero.
- The output is false (equal to 0) when the input signal is greater than zero, or if it is nonpositive, its previous value was also nonpositive.

Data Type Support

The Detect Fall Nonpositive block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Initial condition

Set the initial condition of the Boolean expression $U/z \leq 0$.

Input processing

Specify whether the block performs sample- or frame-based processing. You can select one of the following options:

- `Elements as channels (sample based)` — Treat each element of the input as a separate channel (sample-based processing).
- `Columns as channels (frame based)` — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

- `Inherited` — Inherit the processing mode from the input signal and delay the input accordingly. You can identify whether the input signal is sample or frame based by looking at the signal line. Detect Increase

Detect increase in signal value

Library

Logic and Bit Operations

Description

The Detect Increase block determines if an input is strictly greater than its previous value.

- The output is true (equal to 1) when the input signal is greater than its previous value.
- The output is false (equal to 0) when the input signal is less than or equal to its previous value.

Data Type Support

The Detect Increase block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean
- Enumerated

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Initial condition

Set the initial condition for the previous input U/z .

Input processing

Specify whether the block performs sample- or frame-based processing. You can select one of the following options:

- `Elements as channels (sample based)` — Treat each element of the input as a separate channel (sample-based processing).
- `Columns as channels (frame based)` — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

- `Inherited` — Inherit the processing mode from the input signal and delay the input accordingly. You can identify whether the input signal is sample or frame based by looking at the signal line. Simulink represents sample-based signals with a single line and frame-based signals with a double line.

Note When you choose the `Inherited` option for the **Input processing** parameter, and the input signal is frame-based, Simulink will generate a warning or error in future releases.

Introduced before R2006a

Detect Rise Nonnegative

Detect rising edge when signal value increases to nonnegative value, and its previous value was strictly negative

Library

Logic and Bit Operations

Description

The Detect Rise Nonnegative block determines if the input is greater than or equal to zero, and its previous value was less than zero.

- The output is true (equal to 1) when the input signal is greater than or equal to zero, and its previous value was less than zero.
- The output is false (equal to 0) when the input signal is less than zero, or if the input signal is nonnegative, its previous value was also nonnegative.

Data Type Support

The Detect Rise Nonnegative block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Initial condition

Set the initial condition of the Boolean expression $U/z \geq 0$.

Input processing

Specify whether the block performs sample- or frame-based processing. You can select one of the following options:

- `Elements as channels (sample based)` — Treat each element of the input as a separate channel (sample-based processing).
- `Columns as channels (frame based)` — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

- `Inherited` — Inherit the processing mode from the input signal and delay the input accordingly. You can identify whether the input signal is sample or frame based by looking at the signal line. Simulink represents sample-based signals with a single line and frame-based signals with a double line.

Note When you choose the `Inherited` option for the **Input processing** parameter, and the input signal is frame-based, Simulink will generate a warning or error in future releases.

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input `u`. All other input signals must be sample based.

Input Signal <code>u</code>	Input Processing Mode	Block Works?
Sample based	Sample based	Yes

Input Signal u	Input Processing Mode	Block Works?
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

Output data type

Set the output data type to `boolean` or `uint8`.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	Yes
Code Generation	Yes

See Also

Detect Change, Detect Decrease, Detect Fall Negative, Detect Fall Nonpositive, Detect Increase, Detect Rise Positive

Introduced before R2006a

Detect Rise Positive

Detect rising edge when signal value increases to strictly positive value, and its previous value was nonpositive

Library

Logic and Bit Operations

Description

The Detect Rise Positive block determines if the input is strictly positive, and its previous value was nonpositive.

- The output is true (equal to 1) when the input signal is greater than zero, and the previous value was less than or equal to zero.
- The output is false (equal to 0) when the input is negative or zero, or if the input is positive, the previous value was also positive.

Data Type Support

The Detect Rise Positive block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Initial condition

Set the initial condition of the Boolean expression $U/z > 0$.

Input processing

Specify whether the block performs sample- or frame-based processing. You can select one of the following options:

- `Elements as channels (sample based)` — Treat each element of the input as a separate channel (sample-based processing).
- `Columns as channels (frame based)` — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

- `Inherited` — Inherit the processing mode from the input signal and delay the input accordingly. You can identify whether the input signal is sample or frame based by looking at the signal line. Simulink represents sample-based signals with a single line and frame-based signals with a double line.

Note When you choose the `Inherited` option for the **Input processing** parameter, and the input signal is frame-based, Simulink will generate a warning or error in future releases.

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input `u`. All other input signals must be sample based.

Input Signal <code>u</code>	Input Processing Mode	Block Works?
Sample based	Sample based	Yes

Input Signal u	Input Processing Mode	Block Works?
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

Output data type

Set the output data type to `boolean` or `uint8`.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	Yes
Code Generation	Yes

See Also

Detect Change, Detect Decrease, Detect Fall Negative, Detect Fall Nonpositive, Detect Increase, Detect Rise Nonnegative

Introduced before R2006a

Difference

Calculate change in signal over one time step

Library

Discrete

Description

The Difference block outputs the current input value minus the previous input value.

Data Type Support

The Difference block accepts signals of any numeric data type that Simulink supports, including fixed-point data types. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Initial condition for previous input

Set the initial condition for the previous input.

Input processing

Specify whether the block performs sample- or frame-based processing. You can select one of the following options:

- **Elements as channels (sample based)** — Treat each element of the input as a separate channel (sample-based processing).
- **Columns as channels (frame based)** — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

- **Inherited** — Inherit the processing mode from the input signal and delay the input accordingly. You can identify whether the input signal is sample or frame based by looking at the signal line. Simulink represents sample-based signals with a single line and frame-based signals with a double line.

Note When you choose the **Inherited** option for the **Input processing** parameter, and the input signal is frame-based, Simulink will generate a warning or error in future releases.

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input *u*. All other input signals must be sample based.

Input Signal <i>u</i>	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

Output minimum

Specify the minimum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Output maximum

Specify the maximum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Output data type

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” in the *Simulink User's Guide* for more information.

Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

Saturate to max or min when overflows occur

Select to have overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	Yes
Code Generation	Yes

Introduced before R2006a

Digital Clock

Output simulation time at specified sampling interval

Library

Sources

Description

The Digital Clock block outputs the simulation time only at the specified sampling interval. At other times, the block holds the output at the previous value. To control the precision of this block, set the **Sample time** parameter in the block dialog box.

Use this block rather than the Clock block (which outputs continuous time) when you need the current simulation time within a discrete system.

Data Type Support

The Digital Clock block outputs a real signal of type `double`. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Sample time

Specify the sampling interval. The default value is 1 second. For more information, see [Specifying Sample Time](#) in the Simulink documentation.

Do not specify a continuous sample time, either 0 or $[0, 0]$. Also, avoid specifying -1 (inheriting the sample time) because this block is a source.

Examples

In the following model, the Scope block shows the output of a Digital Clock block with a **Sample time** of 0.2.

The Digital Clock block outputs the simulation time every 0.2 seconds. Otherwise, the block holds the output at the previous value.

Characteristics

Data Types	Double
Sample Time	Specified in the Sample time parameter
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Clock

Introduced before R2006a

Direct Lookup Table (n-D)

Index into N-dimensional table to retrieve element, column, or 2-D matrix

Library

Lookup Tables

Description

Block Inputs and Outputs

The Direct Lookup Table (n-D) block uses inputs as zero-based indices into an n -dimensional table. The number of inputs varies with the shape of the output: an element, column, or 2-D matrix.

You define a set of output values as the **Table data** parameter. The first input specifies the zero-based index to the table dimension that is *one higher* than the output dimensionality. The next input specifies the zero-based index to the next table dimension, and so on.

Output Shape	Output Dimensionality	Table Dimension That Maps to the First Input
Element	0	1
Column	1	2
Matrix	2	3

Suppose that you want to select a column of values from a 4-D table:

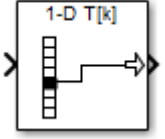

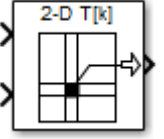

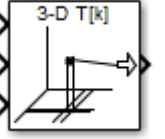

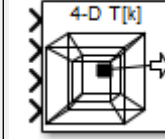

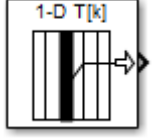

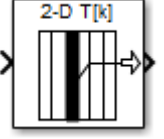

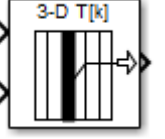

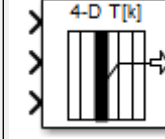

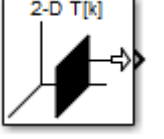

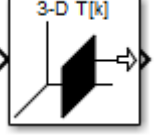

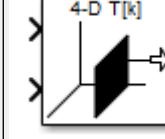

The following mapping of block input port to table dimension applies:

This input port...	Is the index for this table dimension...
1	2
2	3
3	4

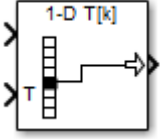

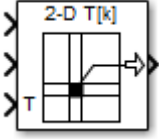

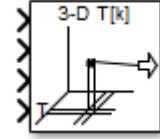

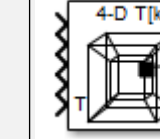

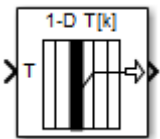

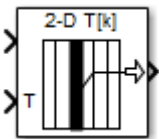

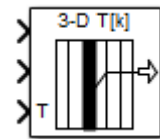

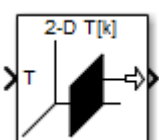

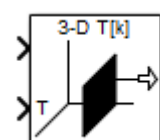

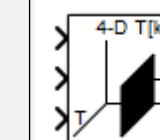

Changes in Block Icon Appearance

Depending on parameters you set, the block icon changes appearance. For table dimensions higher than 4, the icon matches the 4-D version but shows the exact number of dimensions in the top text.

When you use the **Table data** parameter, you see the following icons:

Object That Inputs Select from the Table	Number of Table Dimensions			
	1	2	3	4
Element				
Column				
2-D Matrix	Not applicable			

When you use the table input port, you see the following icons:

Object That Inputs Select from the Table	Number of Table Dimensions			
	1	2	3	4
Element				
Column				
2-D Matrix	Not applicable			

Data Type Support

The Direct Lookup Table (n-D) block accepts input signals of different data types.

Type of Input Port	Data Types Supported
Index port	<ul style="list-style-type: none"> • Floating point • Built-in integer • Boolean • Enumerated data types

Type of Input Port	Data Types Supported
Table port (with the label T)	<ul style="list-style-type: none"> • Floating point • Built-in integer • Fixed point • Boolean • Enumerated data types

The output data type is the same as the table data type. Inputs for indexing must be real, but table data can be complex.

When the table data is...	The block inherits the output type from...
Not an input	The Table data type parameter
An input	The table input port

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

- “Main tab” on page 1-345
- “Table Attributes tab” on page 1-347

Main tab

Number of table dimensions

Specify the number of dimensions that the **Table data** parameter must have. This value determines the number of independent variables for the table and the number of inputs to the block.

To specify...	Do this...
1, 2, 3, or 4	Select the value from the drop-down list.
A higher number of table dimensions	Enter a positive integer directly in the field. The maximum number of table dimensions that this block supports is 30.

Inputs select this object from table

Specify whether the output data is a single element, a column, or a 2-D matrix. The number of input ports for indexing depends on your selection.

Selection	Number of Input Ports for Indexing
Element	Number of table dimensions
Column	Number of table dimensions – 1
2-D Matrix	Number of table dimensions – 2

This numbering matches MATLAB indexing. For example, if you have a 4-D table of data, follow these guidelines:

To access...	Specify...	As in...
An element	Four indices	<code>array(1,2,3,4)</code>
A column	Three indices	<code>array(:,2,3,4)</code>
A 2-D matrix	Two indices	<code>array(:, :, 3, 4)</code>

Make table an input

Select this check box to force the Direct Lookup Table (n-D) block to ignore the **Table data** parameter. Instead, a new input port appears with **T** next to it. Use this port to input table data.

Table data

Specify the table of output values. The matrix size must match the dimensions of the **Number of table dimensions** parameter. The **Table data** field is available only if you clear the **Make table an input** check box.

Tip During block diagram editing, you can leave the **Table data** field empty. But for simulation, you must match the number of dimensions in **Table data** to the **Number of table dimensions**. For details on how to construct multidimensional MATLAB arrays, see “Multidimensional Arrays” (MATLAB) in the MATLAB documentation.

Click **Edit** to open the Lookup Table Editor. For more information, see “Edit Lookup Tables” in the Simulink documentation.

Diagnostic for out-of-range input

Specify whether to show a warning or error when an index is out of range with respect to the table dimension. Options include:

- `None` — Simulink software takes no action.
- `Warning` — Simulink software displays a warning and continues the simulation.
- `Error` — Simulink software terminates the simulation and displays an error.

When you select `None` or `Warning`, the block clamps out-of-range indices to fit table dimensions. For example, if the specified index is 5.3 and the maximum index for that table dimension is 4, the block clamps the index to 4.

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Table Attributes tab

Note The parameters in the **Table Attributes** pane are not available if you select **Make table an input**. In this case, the block inherits all table attributes from the input port with the label `T`.

Table minimum

Specify the minimum value for table data. The default value is `[]` (unspecified).

Table maximum

Specify the maximum value for table data. The default value is `[]` (unspecified).

Table data type

Specify the table data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit from 'Table data'`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Table data type** parameter.

Lock data type settings against changes by the fixed-point tools

Select to lock all data type settings of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Examples

When Table Data Is Not an Input

Suppose that you have the following model:

The Direct Lookup Table (n-D) block parameters are:

Block Parameter	Value
Number of table dimensions	4
Inputs select this object from table	Column
Make table an input	off
Table data	a
Diagnostic for out-of-range input	Warning
Sample time	-1
Table minimum	[]

Block Parameter	Value
Table maximum	[]
Table data type	int16
Lock data type settings against changes by the fixed-point tools	off

In this example, `a` is a 4-D array of linearly increasing values that you define with the following model preload function:

```
a = reshape(1:2800, [4 5 20 7]);
```

When you run the model, you get the following results:

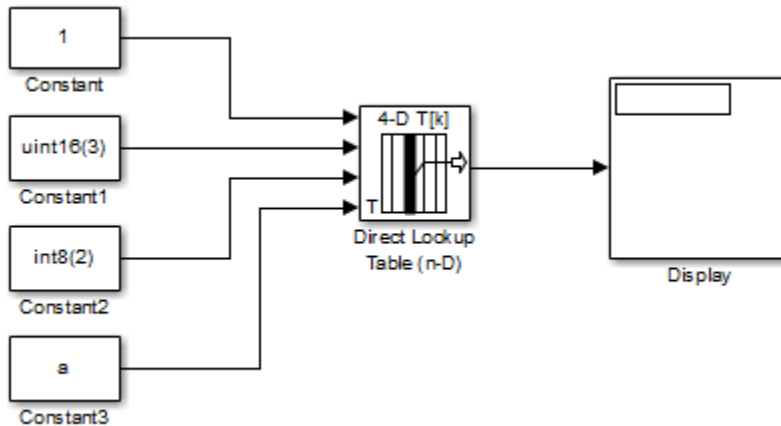

Because the Direct Lookup Table (n-D) block uses zero-based indexing, the output is:

```
a(:,2,4,3)
```

The output has the same data type as the table: `int16`.

When Table Data Is an Input

Suppose that you have the following model:

The Direct Lookup Table (n-D) block parameters are:

Block Parameter	Value
Number of table dimensions	4
Inputs select this object from table	Column
Make table an input	on
Diagnostic for out-of-range input	Warning
Sample time	-1

The key parameters of the Constant3 block are:

Block Parameter	Value
Constant value	a
Output data type	fixdt(1,16,2)

In this example, a is a 4-D array of linearly increasing values that you define with the following model preload function:

```
a = reshape(1:2800, [4 5 20 7]);
```

When you run the model, you get the following results:

The Constant3 block feeds the 4-D array to the Direct Lookup Table (n-D) block, using the fixed-point data type `fixdt(1, 16, 2)`. Because the Direct Lookup Table (n-D) block uses zero-based indexing, the output is:

```
a(:, 2, 4, 3)
```

The output has the same data type as the table: `fixdt(1, 16, 2)`.

Characteristics

Data Types	Double Single Boolean Base Integer Enumerated
Sample Time	Inherited from driving block

Discrete Derivative

Compute discrete-time derivative

Library

Discrete

Description

The Discrete Derivative block computes an optionally scaled discrete time derivative as follows

$$y(t_n) = \frac{Ku(t_n)}{T_s} - \frac{Ku(t_{n-1})}{T_s}$$

where

- $u(t_n)$ and $y(t_n)$ are the block's input and output at the current time step, respectively.
- $u(t_{n-1})$ is the block's input at the previous time step.
- K is a scaling factor.
- T_s is the simulation's discrete step size, which must be fixed.

Note Do not use this block in subsystems with a non-periodic trigger (for example, non-periodic function-call subsystems). This configuration will produce inaccurate results.

Data Type Support

The Discrete Derivative block supports all numeric Simulink data types, including fixed-point data types.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Gain value

Scaling factor used to weight the block's input at the current time step.

Initial condition for previous weighted input $K*u/Ts$

Set the initial condition for the previous scaled input.

Input processing

Specify whether the block performs sample- or frame-based processing. You can select one of the following options:

- **Elements as channels (sample based)** — Treat each element of the input as a separate channel (sample-based processing).
- **Columns as channels (frame based)** — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

- **Inherited** — Inherit the processing mode from the input signal and delay the input accordingly. You can identify whether the input signal is sample or frame based by looking at the signal line. Simulink represents sample-based signals with a single line and frame-based signals with a double line.

Note When you choose the **Inherited** option for the **Input processing** parameter, and the input signal is frame-based, Simulink will generate a warning or error in future releases.

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input u . All other input signals must be sample based.

Input Signal u	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

Output minimum

Specify the minimum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Output maximum

Specify the maximum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Output data type

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” in *Simulink User's Guide* for more information.

Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer). in the Fixed-Point Designer documentation.

Saturate to max or min when overflows occur

Select to have overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Characteristics

Data Types	Double Single Base Integer Fixed-Point
Direct Feedthrough	Yes
Multidimensional Signals	No

Variable-Size Signals	Yes
Code Generation	Yes

Derivative

Introduced before R2006a

Discrete Filter

Model Infinite Impulse Response (IIR) filters

Library

Discrete

Description

The Discrete Filter block independently filters each channel of the input signal with the specified digital IIR filter. You can specify the filter structure as one of | Direct form I | Direct form I transposed | Direct form II | Direct form II transposed. The block implements static filters with fixed coefficients. You can tune the coefficients of these static filters.

This block filters each channel of the input signal independently over time. The **Input processing** parameter allows you to specify how the block treats each element of the input. You can specify treating input elements as an independent channel (sample-based processing), or treating each column of the input as an independent channel (frame-based processing). To perform frame-based processing, you must have a DSP System Toolbox license.

The output dimensions equal those of the input, except when you specify a matrix of filter taps for the **Numerator coefficients** parameter. When you do so, the output dimensions depend on the number of different sets of filter taps you specify.

Use the **Numerator coefficients** parameter to specify the coefficients of the discrete filter numerator polynomial. Use the **Denominator coefficients** parameter to specify the coefficients of the denominator polynomial of the function. The **Denominator coefficients** parameter must be a vector of coefficients.

Specify the coefficients of the numerator and denominator polynomials in ascending powers of z^{-1} . The Discrete Filter block lets you use polynomials in z^{-1} (the delay operator) to represent a discrete system. This method is the one that signal processing engineers typically use. Conversely, the Discrete Transfer Fcn block lets you use polynomials in z to represent a discrete system. This method is the one that control engineers typically use. When the numerator and denominator polynomials have the same length, the two methods are identical.

Specifying Initial States

In **Dialog parameters** and **Input port(s)** modes, the block initializes the internal filter states to zero by default, which is equivalent to assuming past inputs and outputs are zero. You can optionally use the **Initial states** parameter to specify nonzero initial states for the filter delays.

To determine the number of initial state values you must specify, and how to specify them, see the following table on Valid Initial States and Number of Delay Elements (Filter States). The **Initial states** parameter can take one of four forms as described in the following table.

Valid Initial States

Initial state	Examples	Description
Scalar	5 Each delay element for each channel is set to 5.	The block initializes all delay elements in the filter to the scalar value.
Vector (for applying the same delay elements to each channel)	For a filter with two delay elements: $[d_1 \ d_2]$ The delay elements for all channels are d_1 and d_2 .	Each vector element specifies a unique initial condition for a corresponding delay element. The block applies the same vector of initial conditions to each channel of the input signal. The vector length must equal the number of delay elements in the filter (specified in the table Number of Delay Elements (Filter States)).
Vector or matrix (for applying different delay elements to each channel)	For a 3-channel input signal and a filter with two delay elements: $[d_1 \ d_2 \ D_1 \ D_2 \ d_1 \ d_2]$ or $\begin{bmatrix} d_1 & D_1 & d_1 \\ d_2 & D_2 & d_2 \end{bmatrix}$ <ul style="list-style-type: none"> The delay elements for channel 1 are d_1 and d_2. The delay elements for channel 2 are D_1 and D_2. The delay elements for channel 3 are d_1 and d_2. 	Each vector or matrix element specifies a unique initial condition for a corresponding delay element in a corresponding channel: <ul style="list-style-type: none"> The vector length must be equal to the product of the number of input channels and the number of delay elements in the filter (specified in the table Number of Delay Elements (Filter States)). The matrix must have the same number of rows as the number of delay elements in the filter (specified in the table Number of Delay Elements (Filter States)), and must have one column for each channel of the input signal.
Empty matrix	$[\]$ Each delay element for each channel is set to 0.	The empty matrix, $[\]$, is equivalent to setting the Initial conditions parameter to the scalar value 0.

The number of delay elements (filter states) per input channel depends on the filter structure, as indicated in the following table.

Number of Delay Elements (Filter States)

Filter Structure	Number of Delay Elements per Channel
Direct form I Direct form I transposed	<ul style="list-style-type: none"> • number of zeros - 1 • number of poles - 1
Direct form II Direct form II transposed	$\max(\text{number of zeros, number of poles}) - 1$

The following tables describe the valid initial states for different sizes of input and different number of channels. These tables provide this information according to whether you set the **Input processing** parameter to frame based or sample based.

Frame-Based Processing

Input	Number of Channels	Valid Initial States (Dialog Box)	Valid Initial States (Input Port)
<ul style="list-style-type: none"> • Column vector (K-by-1) • Unoriented vector (K) 	1	<ul style="list-style-type: none"> • Scalar • Column vector (M-by-1) • Row vector (1-by-M) 	<ul style="list-style-type: none"> • Scalar • Column vector (M-by-1)
<ul style="list-style-type: none"> • Row vector (1-by-N) • Matrix (K-by-N) 	N	<ul style="list-style-type: none"> • Scalar • Column vector (M-by-1) • Row vector (1-by-M) • Matrix (M-by-N) 	<ul style="list-style-type: none"> • Scalar • Matrix (M-by-N)

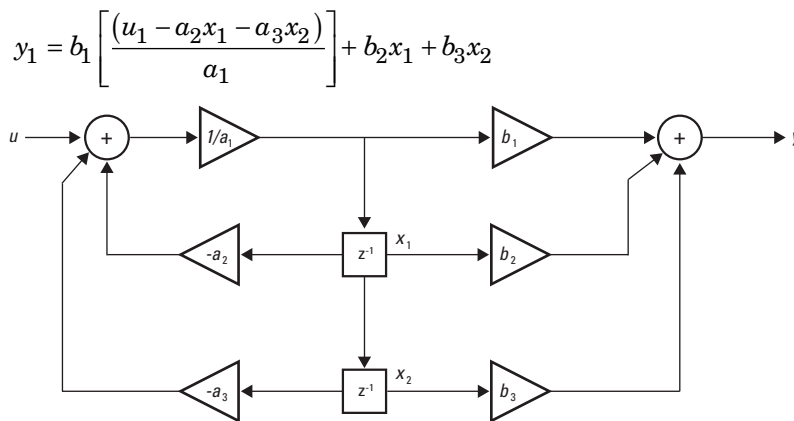

Sample-Based Processing

Input	Number of Channels	Valid Initial States (Dialog Box)	Valid Initial States (Input Port)
<ul style="list-style-type: none"> • Scalar 	1	<ul style="list-style-type: none"> • Scalar • Column vector (M-by-1) • Row vector (1-by-M) 	<ul style="list-style-type: none"> • Scalar • Column vector (M-by-1) • Row vector (1-by-M)
<ul style="list-style-type: none"> • Row vector (1-by-N) • Column vector (N-by-1) • Unoriented vector (N) 	N	<ul style="list-style-type: none"> • Scalar • Column vector (M-by-1) • Row vector (1-by-M) • Matrix (M-by-N) 	<ul style="list-style-type: none"> • Scalar
<ul style="list-style-type: none"> • Matrix (K-by-N) 	$K \times N$	<ul style="list-style-type: none"> • Scalar • Column vector (M-by-1) • Row vector (1-by-M) • Matrix (M-by-$(K \times N)$) 	<ul style="list-style-type: none"> • Scalar

When the **Initial states** is a scalar, the block initializes all filter states to the same scalar value. Enter 0 to initialize all states to zero. When the **Initial states** is a vector or a matrix, each vector or matrix element specifies a unique initial state. This unique state corresponds to a delay element in a corresponding channel:

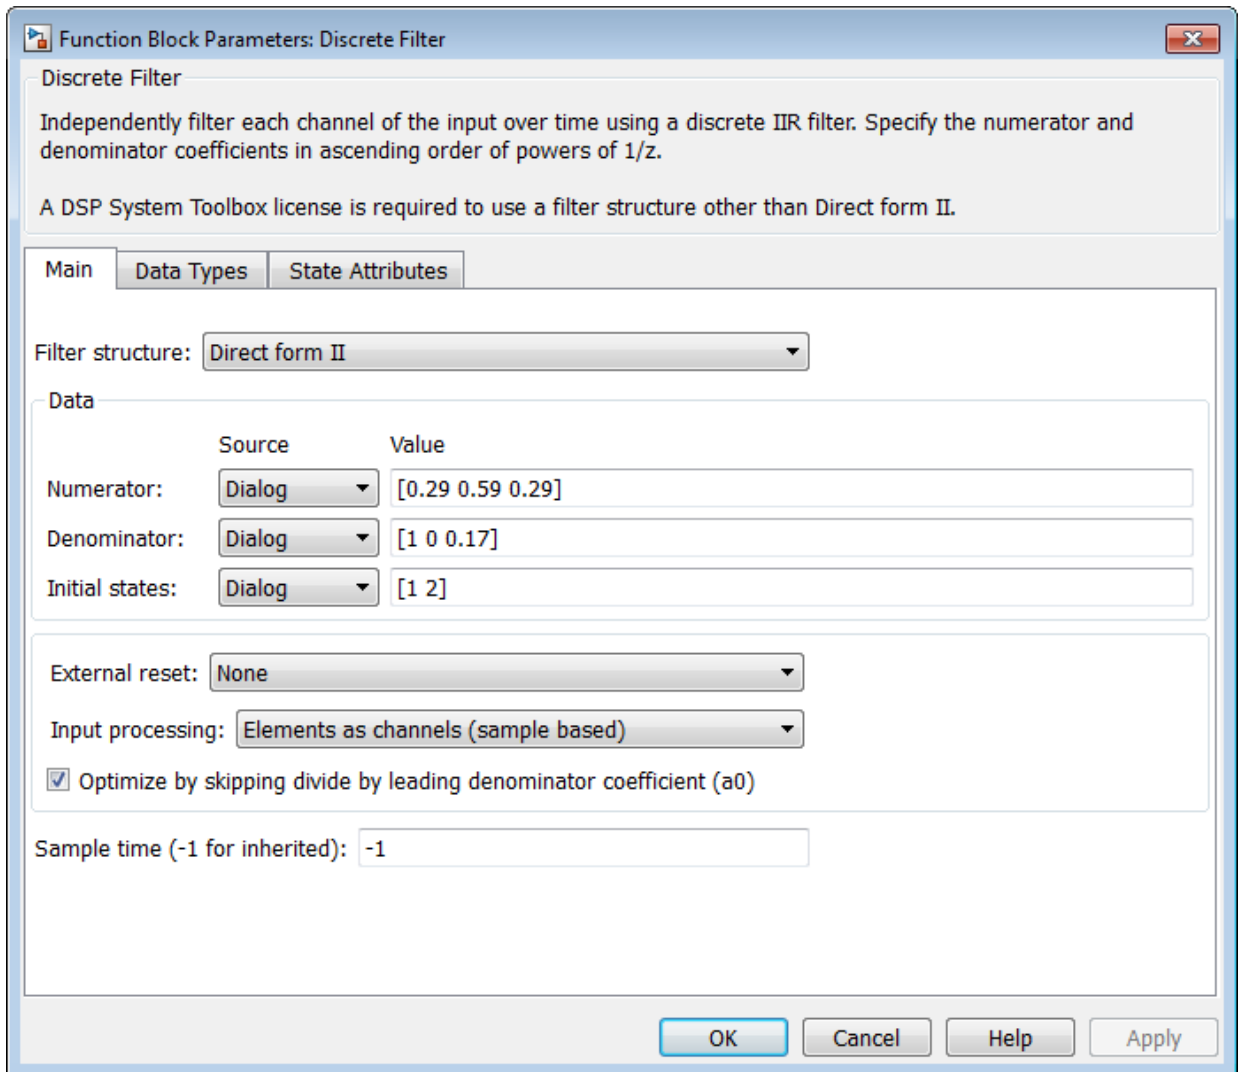

- The vector length must equal the number of delay elements in the filter, $M = \max(\text{number of zeros}, \text{number of poles})$.
- The matrix must have the same number of rows as the number of delay elements in the filter, $M = \max(\text{number of zeros}, \text{number of poles})$. The matrix must also have one column for each channel of the input signal.

The following example shows the relationship between the initial filter output and the initial input and state. Given an initial input u_1 , the first output y_1 is related to the initial state $[x_1, x_2]$ and initial input by:

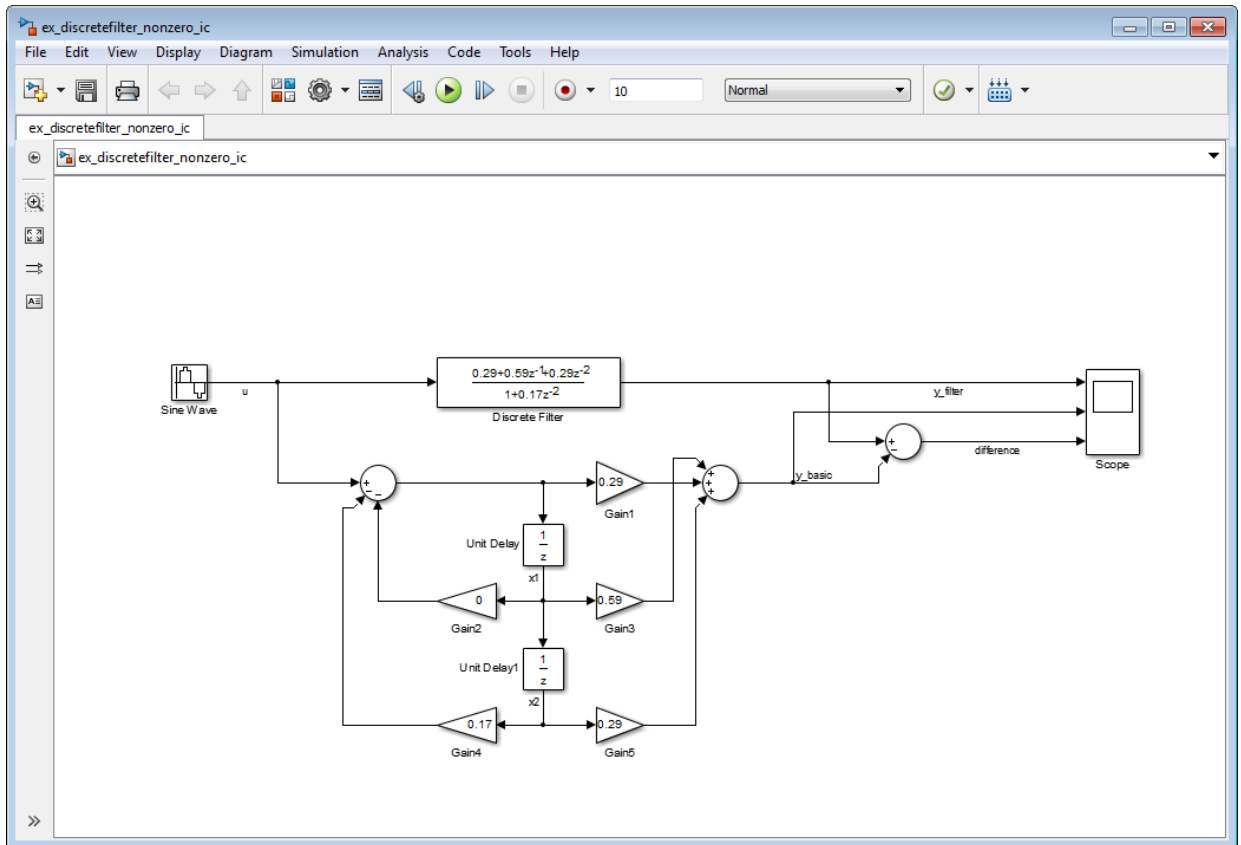

To see an example of how to set initial conditions as a vector:

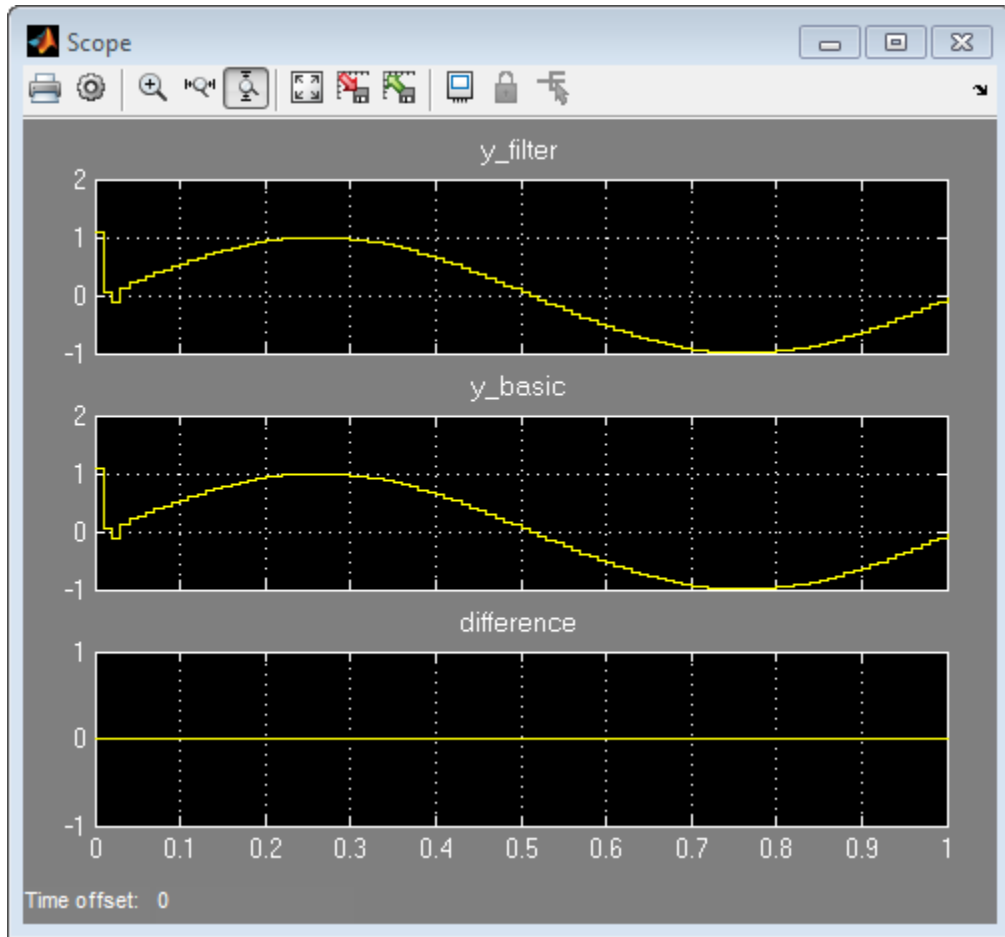

- Click on the model `ex_discretefilter_nonzero_ic`, or type it at the MATLAB command prompt.
- Double-click on the Discrete Filter block, and set the parameters. The following shows how to set the initial conditions of the Discrete Filter block to `[1 2]`.

- Simulate the model, by left-clicking the green simulation icon.

- Double-click the scope. You can see that the difference between the signal filtered by the Discrete Filter block, and the signal from the filter's building blocks, is zero.

This demonstrates that you can enter the initial conditions of the Discrete Filter block as a vector of $[1 \ 2]$. You can also set the initial condition of the first Unit Delay to 1 and the second Unit Delay to 2. The resulting outputs are the same.

Data Type Support

The Discrete Filter block accepts and outputs real and complex signals of any signed numeric data type that Simulink supports. The block supports the same types for the numerator and denominator coefficients.

Numerator and denominator coefficients must have the same complexity. They can have different word lengths and fraction lengths.

The following diagrams show the filter structure and the data types used within the Discrete Filter block for fixed-point signals.

The block omits the dashed divide when you select the **Optimize by skipping divide by leading denominator coefficient (a0)** parameter.

Parameters

Numerator

Numerator coefficients of the discrete filter. To specify the coefficients, set the **Source** to `Dialog`. Then, enter the coefficients in **Value** as descending powers of z . Use a row vector to specify the coefficients for a single numerator polynomial.

Denominator

Denominator coefficients of the discrete filter. To specify the coefficients, set the **Source** to `Dialog`. Then, enter the coefficients in **Value** as descending powers of z . Use a row vector to specify the coefficients for a single denominator polynomial.

Initial states

If the **Source** is `Dialog`, then, in **Value**, specify the initial states of the filter states. To learn how to specify initial states, see “Specifying Initial States” on page 1-359.

If the **Source** is `Input port`, then you do not need to specify **Value**.

External reset

Specify the trigger event to use to reset the states to the initial conditions.

Reset Mode	Behavior
None	No reset.
Rising	Reset on a rising edge.
Falling	Reset on a falling edge.
Either	Reset on either a rising or falling edge.
Level	Reset in either of these cases: <ul style="list-style-type: none"> • when the reset signal is nonzero at the current time step • when the reset signal value changes from nonzero at the previous time step to zero at the current time step
Level hold	Reset when the reset signal is nonzero at the current time step

The reset signal must be a scalar of type single, double, boolean, or integer. Fixed point data types, except for `ufix1`, are not supported.

Input processing

Specify whether the block performs sample- or frame-based processing.

- Elements as channels (sample based) — Process each element of the input as an independent channel.
- Columns as channels (frame based) — Process each column of the input as an independent channel.

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

Optimize by skipping divide by leading denominator coefficient (a0)

Select when the leading denominator coefficient, a_0 , equals 1. This parameter optimizes your code.

When you select this check box, the block does not perform a divide-by- a_0 either in simulation or in the generated code. An error occurs if a_0 is not equal to one.

When you clear this check box, the block is fully tunable during simulation. It performs a divide-by- a_0 in both simulation and code generation.

Sample time

Specify the time interval between samples. To inherit the sample time, set this parameter to `-1`. See “Specify Sample Time” in “How Simulink Works” in the *Simulink User's Guide*.

State

Specify the state data type. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- A built-in integer, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **State** parameter.

See “Specify Data Types Using Data Type Assistant” for more information.

Numerator coefficients

Specify the numerator coefficient data type. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in integer, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Numerator coefficients** parameter.

See “Specify Data Types Using Data Type Assistant” for more information.

Numerator coefficient minimum

Specify the minimum value that a numerator coefficient can have. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Numerator coefficient maximum

Specify the maximum value that a numerator coefficient can have. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Numerator product output

Specify the product output data type for the numerator coefficients. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Numerator product output** parameter.

See “Specify Data Types Using Data Type Assistant” for more information.

Numerator accumulator

Specify the accumulator data type for the numerator coefficients. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Numerator accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” for more information.

Denominator coefficients

Specify the denominator coefficient data type. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in integer, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Denominator coefficients** parameter.

See “Specify Data Types Using Data Type Assistant” for more information.

Denominator coefficient minimum

Specify the minimum value that a denominator coefficient can have. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Denominator coefficient maximum

Specify the maximum value that a denominator coefficient can have. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Denominator product output

Specify the product output data type for the denominator coefficients. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Denominator product output** parameter.

See “Specify Data Types Using Data Type Assistant” for more information.

Denominator accumulator

Specify the accumulator data type for the denominator coefficients. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Denominator accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” for more information.

Output

Specify the output data type. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Signal Data Types” for more information.

Output minimum

Specify the minimum value that the block can output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Output maximum

Specify the maximum value that the block can output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select to lock all data type settings of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer). in the Fixed-Point Designer documentation.

Saturate on integer overflow

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box.	<p>You want to optimize efficiency of your generated code.</p> <p>You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.</p>	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. Usually, the code generation process can detect

when overflow is not possible. In this case, the code generator does not produce saturation code.

State name

Use this parameter to assign a unique name to the block state. The default is ' '. When this field is blank, no name is assigned. When using this parameter, remember these considerations:

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

This parameter enables **State name must resolve to Simulink signal object** when you click **Apply**.

For more information, see “Discrete Block State Naming in Generated Code” (Simulink Coder).

State name must resolve to Simulink signal object

Select this check box to require that the state name resolve to a Simulink signal object. This check box is cleared by default.

State name enables this parameter. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than `None`.

Selecting this check box disables **Code generation storage class**.

Signal object class

Choose a custom storage class package by selecting a signal object class that the target package defines. For example, to apply custom storage classes from the built-in package `mpt`, select `mpt.Signal`. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes do not affect the generated code.

If the class that you want does not appear in the list, select `Customize class lists`. For instructions, see “Apply Custom Storage Classes Directly to Signal Lines, Block States, and Output Blocks” (Embedded Coder).

To programmatically set this parameter, use `StateSignalObject`.

For information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage

classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

Code generation storage class

Select state storage class for code generation.

Default: `Auto`

`Auto`

`Auto` is the appropriate storage class for states that you do not need to interface to external code.

StorageClass

Applies the storage class or custom storage class that you select from the list. For information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than `Simulink`.

State name enables this parameter.

To programmatically set this parameter, use `StateStorageClass` or `StateSignalObject`. See “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder).

TypeQualifier

Note **TypeQualifier** will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

Specify a storage type qualifier such as `const` or `volatile`.

Setting **Code generation storage class** to `ExportedGlobal`, `ImportedExtern`, `ImportedExternPointer`, or `SimulinkGlobal` enables this parameter. This parameter is hidden unless you previously set its value.

During simulation, the block uses the following values:

- The initial value of the signal object to which the state name resolves
- Minimum and maximum values of the signal object

For more information, see “Discrete Block State Naming in Generated Code” (Simulink Coder) in the Simulink Coder documentation.

Characteristics

Data Types	Double Single Base Integer Fixed-Point
Sample Time	Specified in the Sample time parameter
Direct Feedthrough	Only when the leading numerator coefficient does not equal zero
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Filter Structure Diagrams

The diagrams in the following sections show the filter structures supported by the Digital Filter block. They also show the data types used in the filter structures for fixed-point signals. You can set the coefficient, output, accumulator, product output, and state data types shown in these diagrams in the block dialog.

- “IIR direct form I” on page 1-379
- “IIR direct form I transposed” on page 1-381
- “IIR direct form II” on page 1-384
- “IIR direct form II transposed” on page 1-386

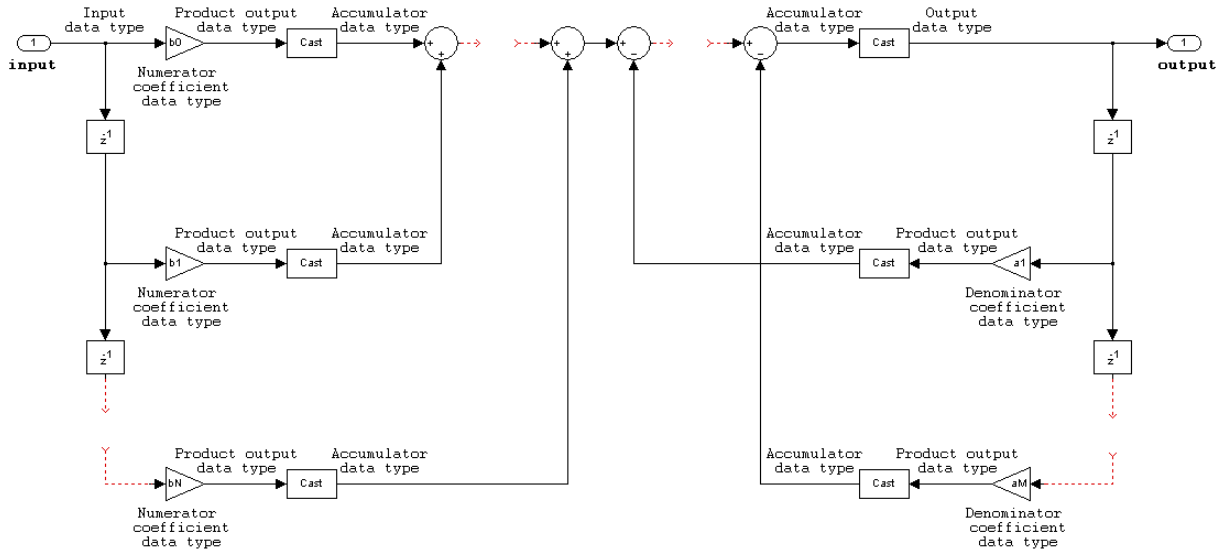

IIR direct form I

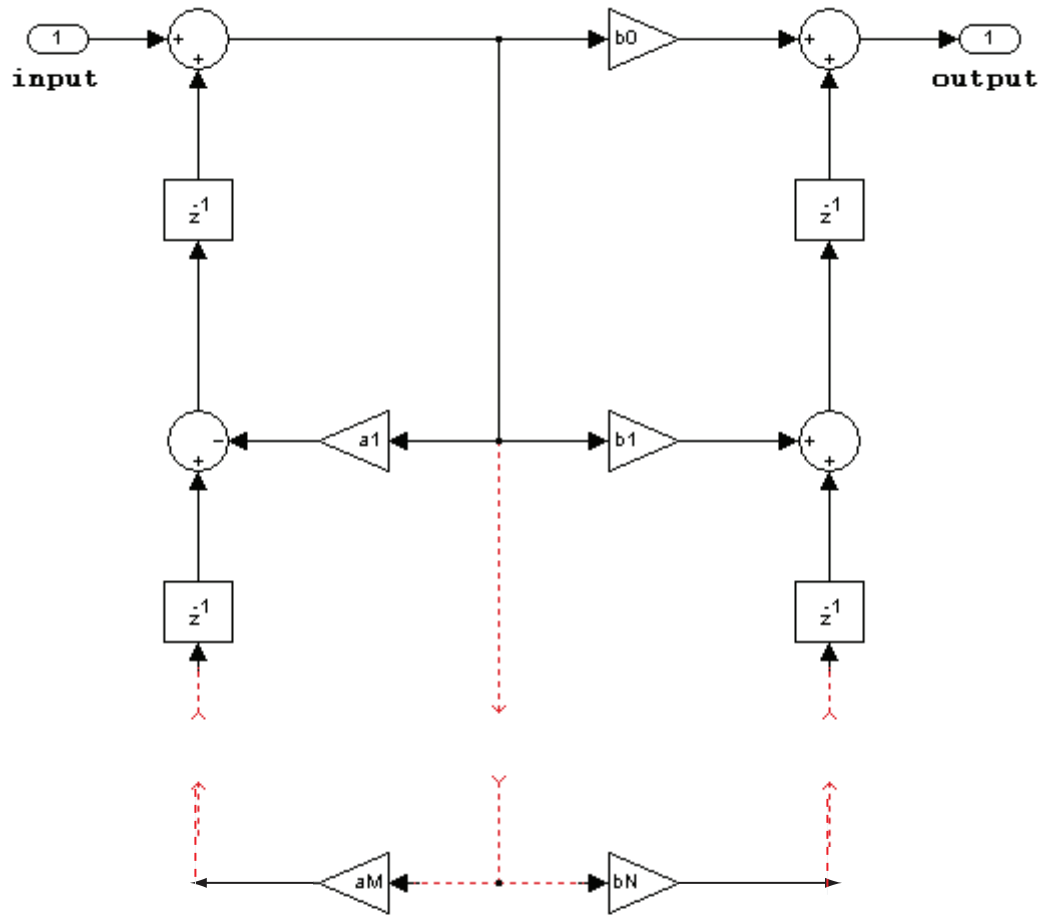

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Numerator and denominator coefficients must have the same complexity characteristics.
 - When the numerator and denominator coefficients are specified using input ports and have different complexities from each other, you get an error.
 - When the numerator and denominator coefficients are specified in the dialog box and have different complexities from each other, the block does not error. Instead, it processes the filter as if two sets of complex coefficients are provided. The real-valued coefficient set is treated as if it is a complex vector with zero-valued imaginary parts.

- Numerator and denominator coefficients must have the same word length. They can have different fraction lengths.
- The State data type cannot be specified on the block mask for this structure. Doing so is not possible because the input and output states have the same data types as the input and output buffers.

IIR direct form I transposed

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs can be real or complex.

- Numerator and denominator coefficients can be real or complex.
- Numerator and denominator coefficients must have the same complexity characteristics.
 - When the numerator and denominator coefficients are specified using input ports and have different complexities from each other, you get an error.
 - When the numerator and denominator coefficients are specified in the dialog box and have different complexities from each other, the block does not error. Instead, it processes the filter as if two sets of complex coefficients are provided. The real-valued coefficient set is treated as if it is a complex vector with zero-valued imaginary parts.
- States are complex when either the input or the coefficients are complex.
- Numerator and denominator coefficients must have the same word length. They can have different fraction lengths.

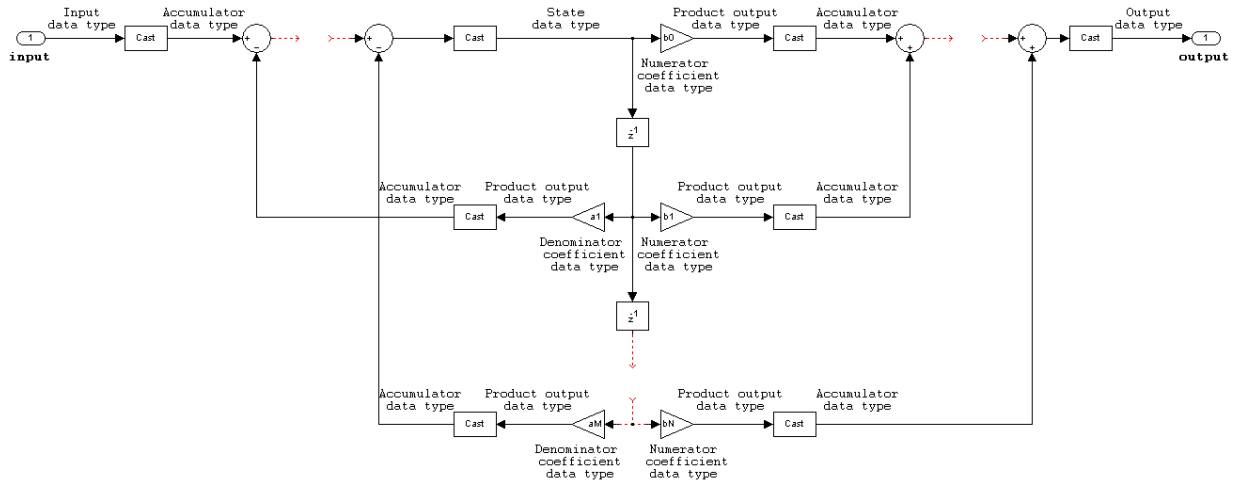

IIR direct form II

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Numerator and denominator coefficients must have the same complexity characteristics.
 - When the numerator and denominator coefficients are specified using input ports and have different complexities from each other, you get an error.
 - When the numerator and denominator coefficients are specified in the dialog box and have different complexities from each other, the block does not error. Instead, it processes the filter as if two sets of complex coefficients are provided. The real-valued coefficient set is treated as if it is a complex vector with zero-valued imaginary parts.
- States are complex when either the inputs or the coefficients are complex.

- Numerator and denominator coefficients must have the same word length. They can have different fraction lengths.

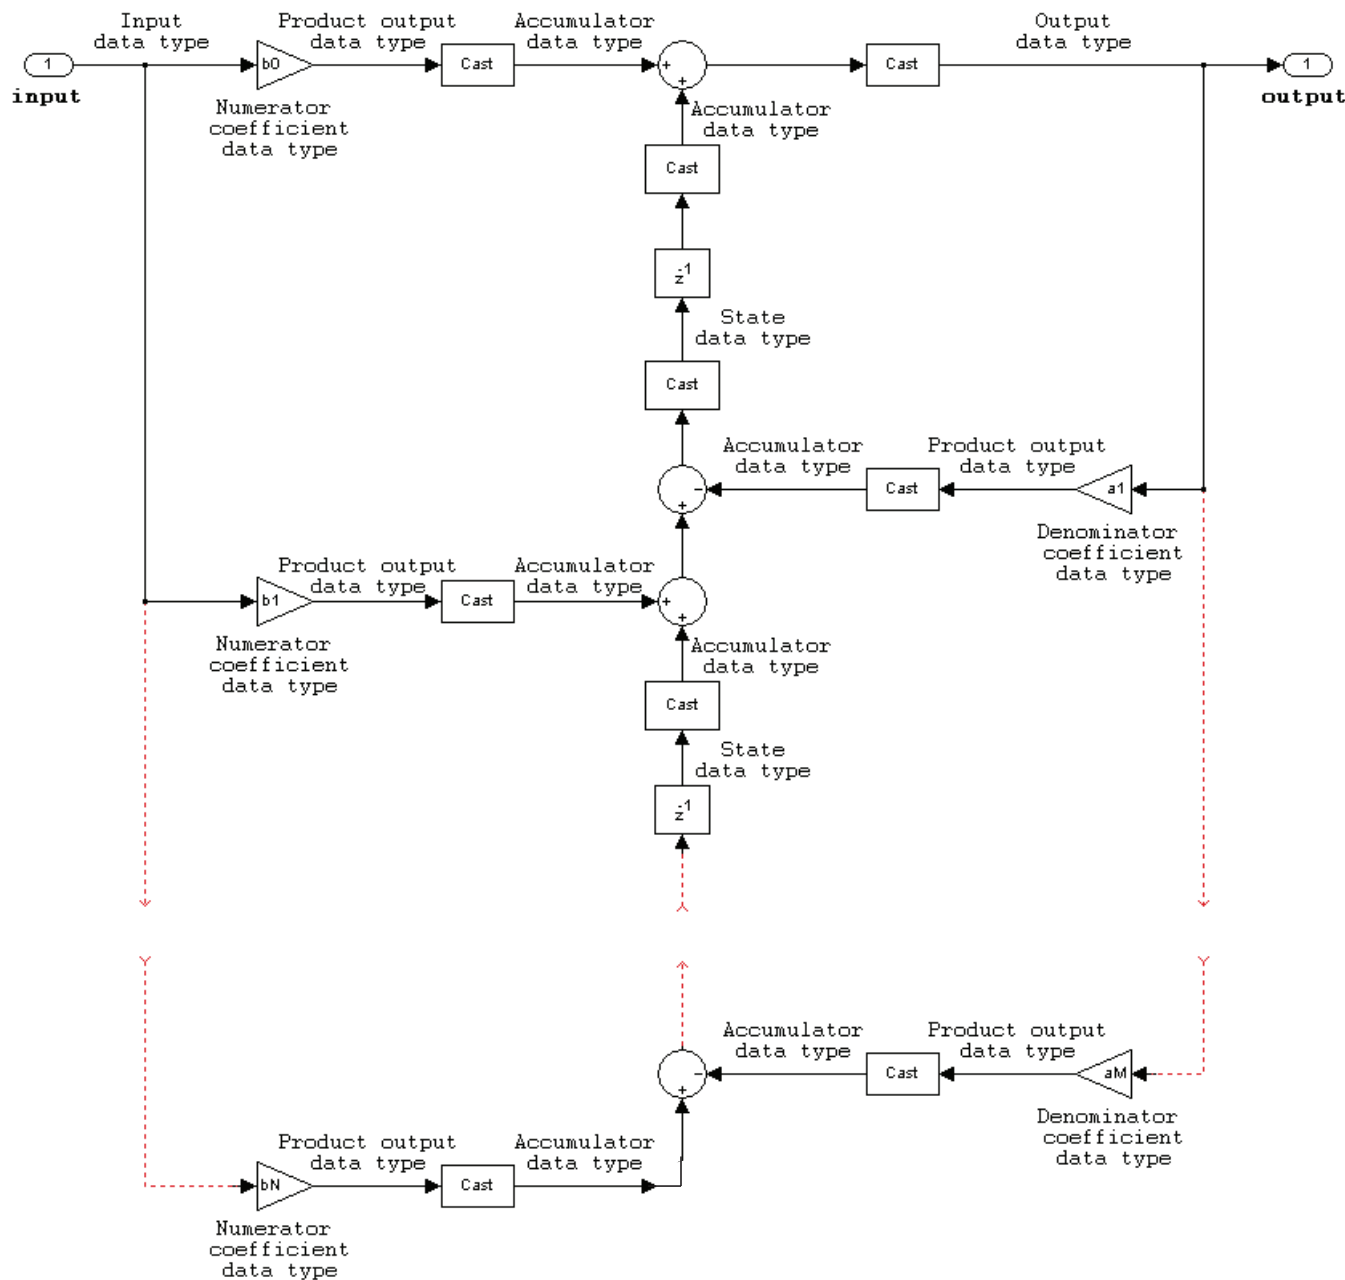

IIR direct form II transposed

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Numerator and denominator coefficients must have the same complexity characteristics.

- When the numerator and denominator coefficients are specified using input ports and have different complexities from each other, you get an error.
- When the numerator and denominator coefficients are specified in the dialog box and have different complexities from each other, the block does not error. Instead, it processes the filter as if two sets of complex coefficients are provided. The real-valued coefficient set is treated as if it is a complex vector with zero-valued imaginary parts.
- States are complex when either the inputs or the coefficients are complex.
- Numerator and denominator coefficients must have the same word length. They can have different fraction lengths.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed only)
- 8-, 16-, and 32-bit signed integers

Discrete FIR Filter

Model FIR filters

Library

Discrete

Description

The Discrete FIR Filter block independently filters each channel of the input signal with the specified digital FIR filter. The block can implement static filters with fixed coefficients, as well as time-varying filters with coefficients that change over time. You can tune the coefficients of a static filter during simulation.

This block filters each channel of the input signal independently over time. The **Input processing** parameter allows you to specify whether the block treats each element of the input as an independent channel (sample-based processing), or each column of the input as an independent channel (frame-based processing). To perform frame-based processing, you must have a DSP System Toolbox license.

The output dimensions equal those of the input, except when you specify a matrix of filter taps for the **Coefficients** parameter. When you do so, the output dimensions depend on the number of different sets of filter taps you specify.

The outputs of this block numerically match the outputs of the DSP System Toolbox Digital Filter Design block.

This block supports the Simulink state logging feature. See “States”.

Filter Structure Support

You can change the filter structure implemented with the Discrete FIR Filter block by selecting one of the following from the **Filter structure** parameter:

- Direct form
- Direct form symmetric
- Direct form antisymmetric
- Direct form transposed
- Lattice MA

You must have an available DSP System Toolbox license to run a model with any of these filter structures other than `Direct form`.

Specifying Initial States

The Discrete FIR Filter block initializes the internal filter states to zero by default, which has the same effect as assuming that past inputs and outputs are zero. You can optionally use the **Initial states** parameter to specify nonzero initial conditions for the filter delays.

To determine the number of initial states you must specify and how to specify them, see the table on valid initial states. The **Initial states** parameter can take one of the forms described in the next table.

Valid Initial States

Initial Condition	Description
Scalar	The block initializes all delay elements in the filter to the scalar value.
Vector or matrix (for applying different delay elements to each channel)	<p>Each vector or matrix element specifies a unique initial condition for a corresponding delay element in a corresponding channel:</p> <ul style="list-style-type: none"> • The vector length equal the product of the number of input channels and the number of delay elements in the filter, <code>#_of_filter_coeffs-1</code> (or <code>#_of_reflection_coeffs</code> for Lattice MA). • The matrix must have the same number of rows as the number of delay elements in the filter, <code>#_of_filter_coeffs-1</code> (<code>#_of_reflection_coeffs</code> for Lattice MA), and must have one column for each channel of the input signal.

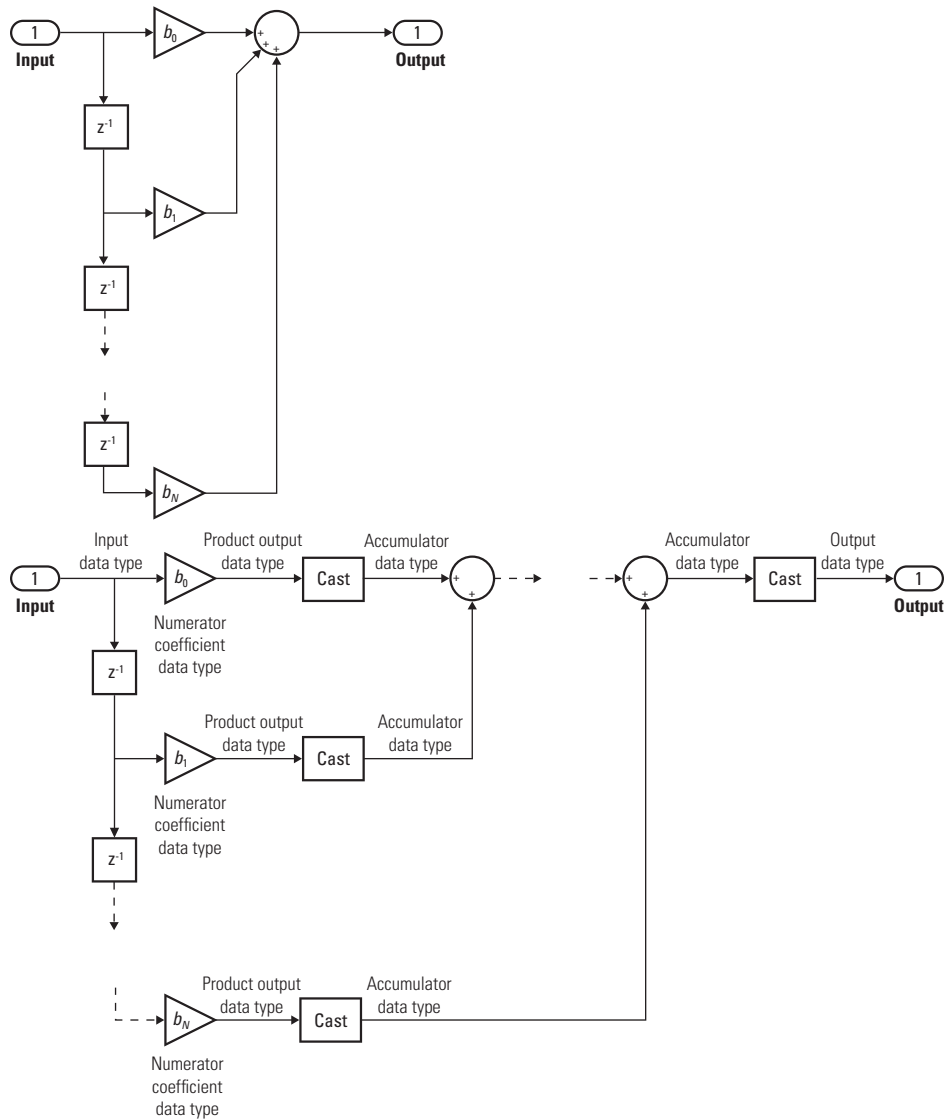

Data Type Support

The Discrete FIR Filter block accepts and outputs real and complex signals of any numeric data type supported by Simulink. The block supports the same types for the coefficients.

The following diagrams show the filter structure and the data types used within the Discrete FIR Filter block for fixed-point signals.

Direct Form

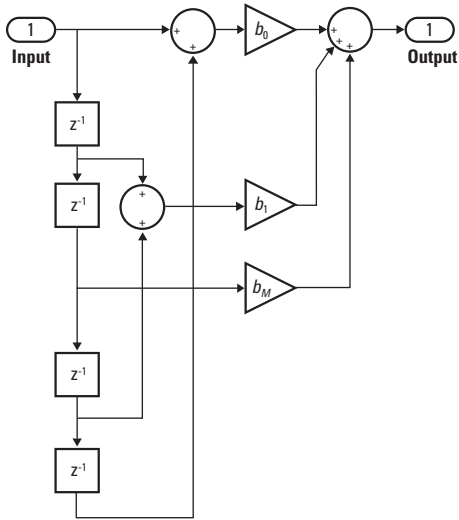

You cannot specify the state data type on the block mask for this structure because the input states have the same data types as the input.

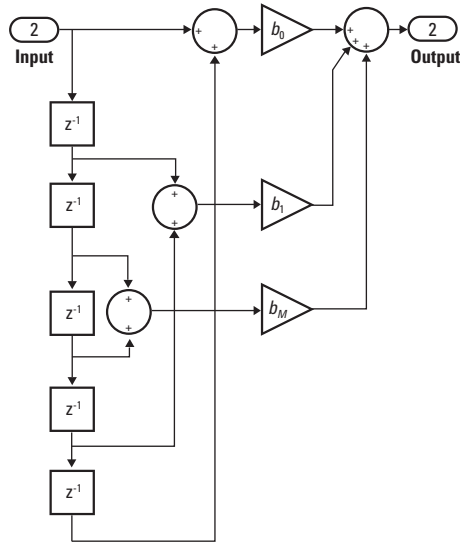

Direct Form Symmetric

You cannot specify the state data type on the block mask for this structure because the input states have the same data types as the input.

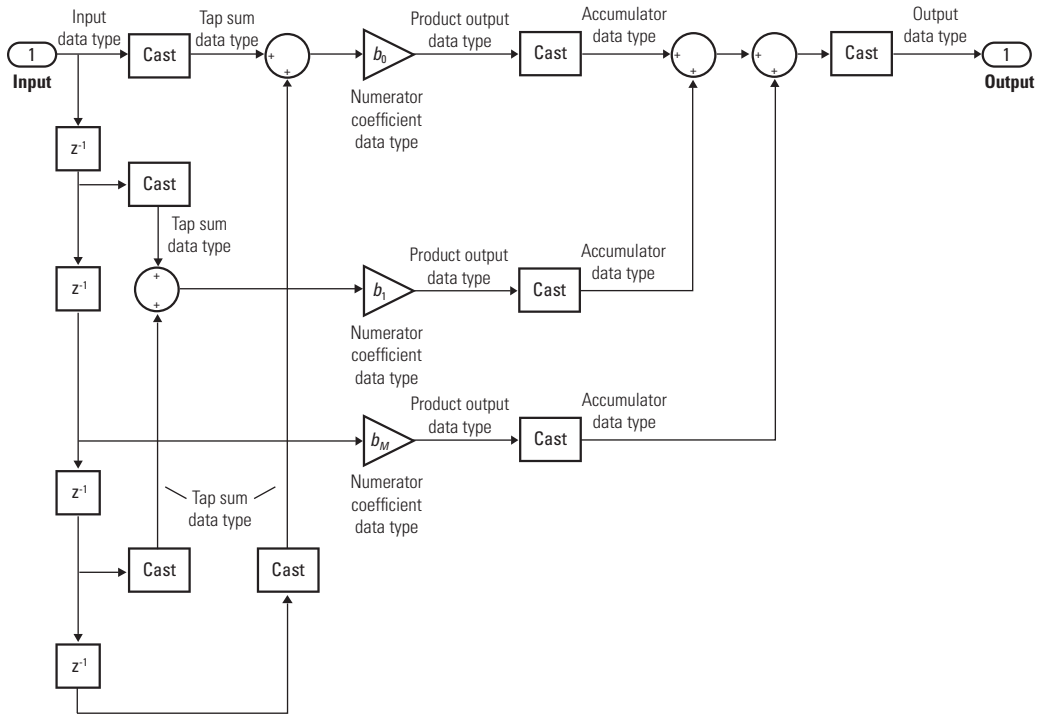

It is assumed that the filter coefficients are symmetric. The block only uses the first half of the coefficients for filtering.

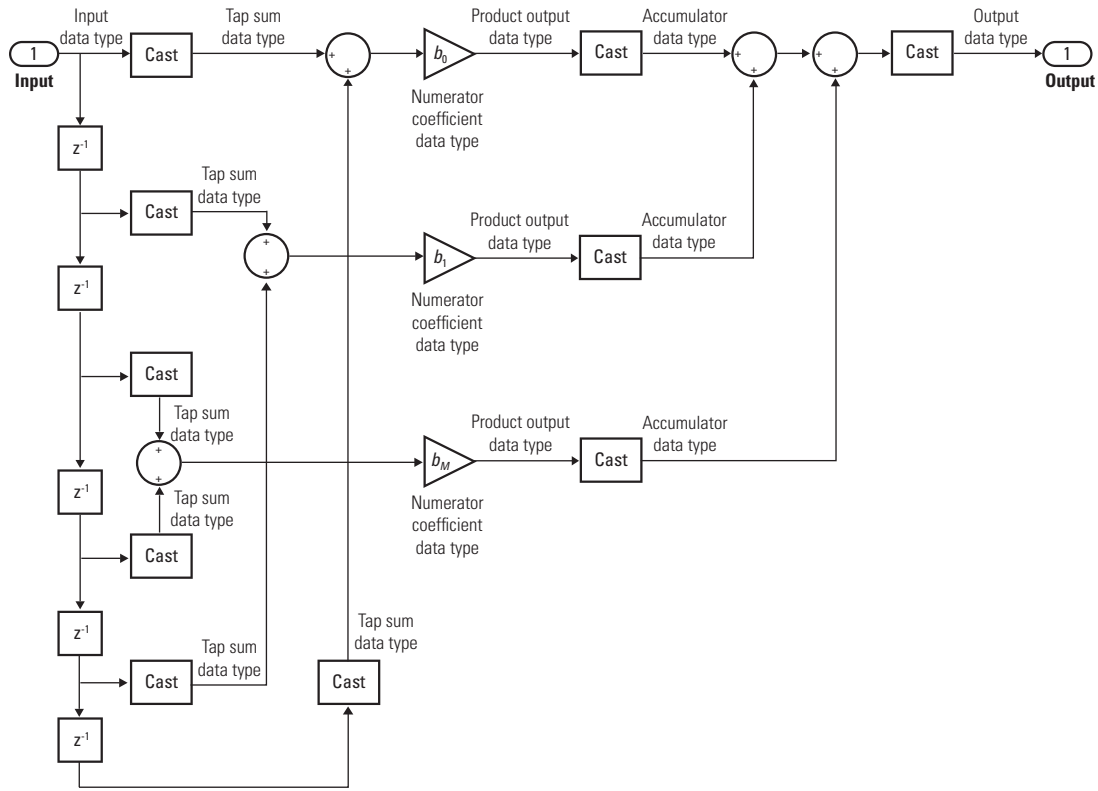

Even Order - Type I

Odd Order - Type II

Even Order - Type I

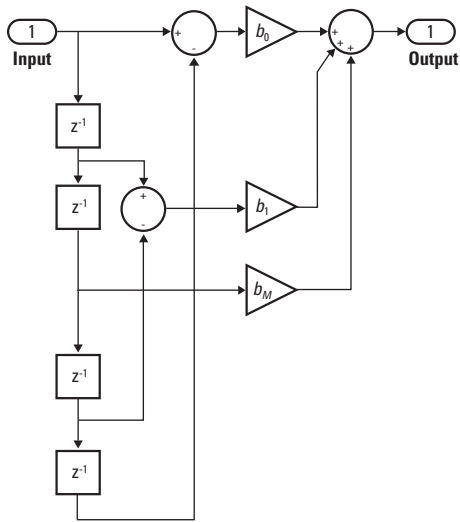

Odd Order - Type II

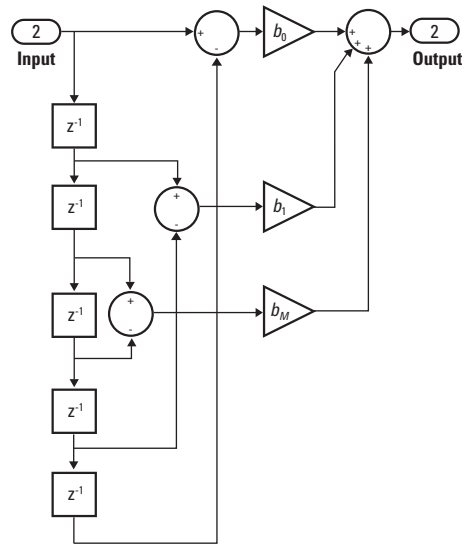

Direct Form Antisymmetric

You cannot specify the state data type on the block mask for this structure because the input states have the same data types as the input.

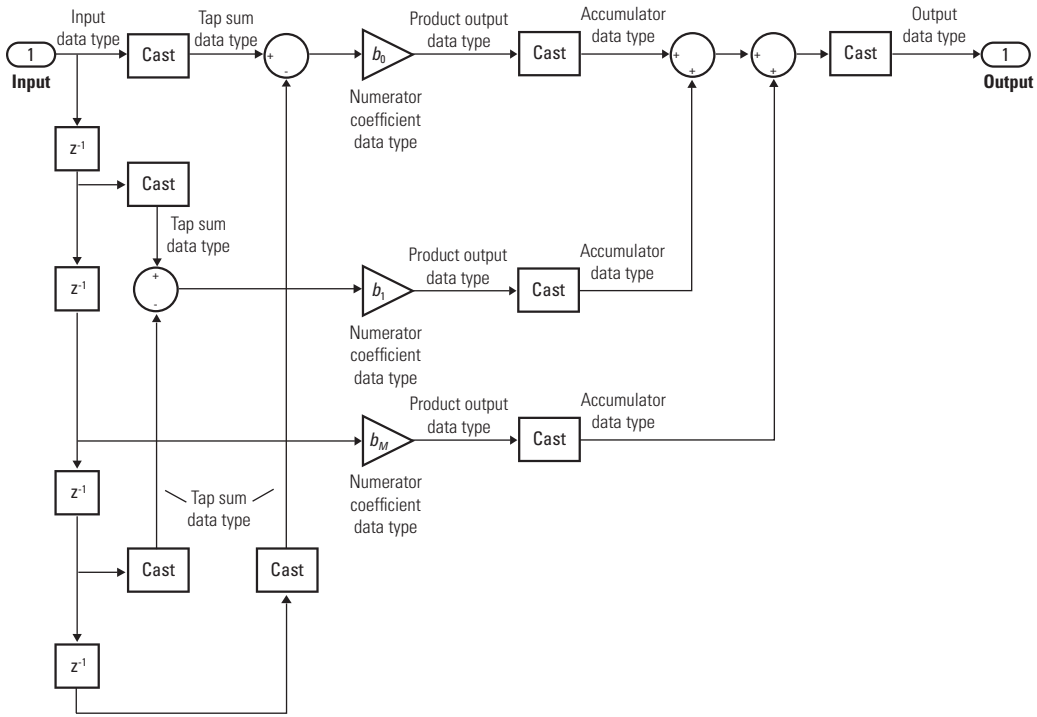

It is assumed that the filter coefficients are antisymmetric. The block only uses the first half of the coefficients for filtering.

Even Order - Type III

Odd Order - Type IV

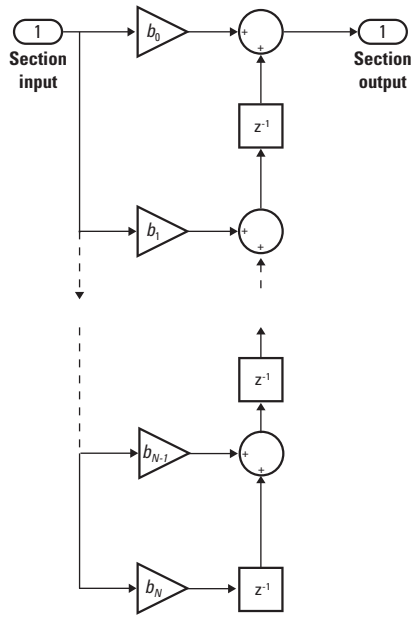

Even Order - Type III

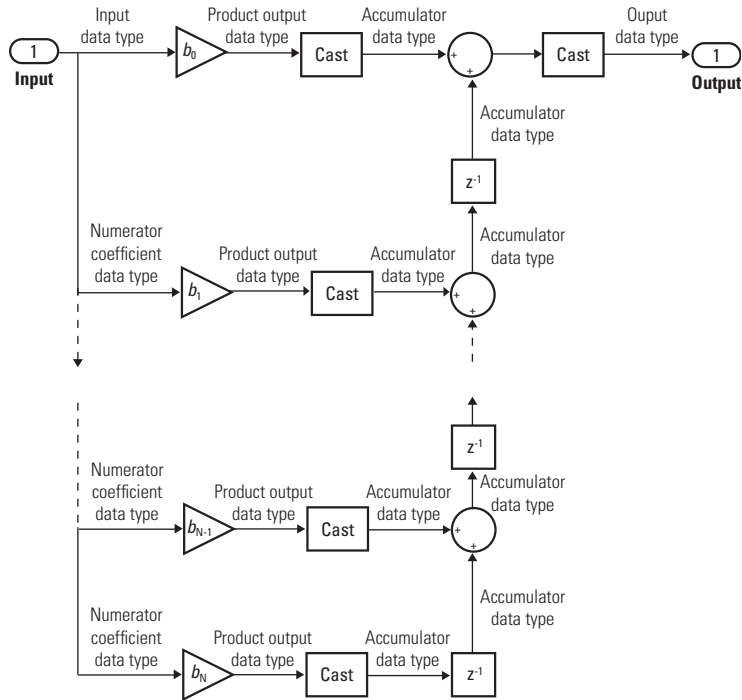

Odd Order - Type IV

Direct Form Transposed

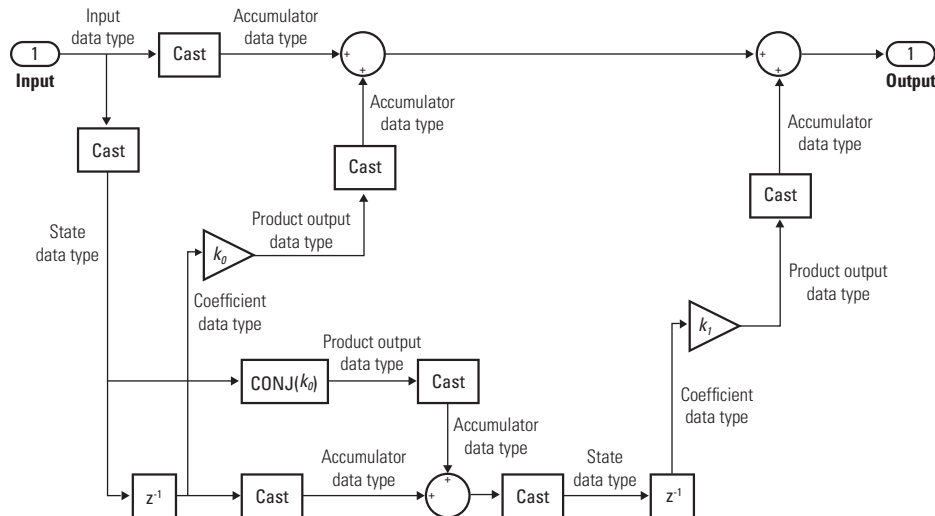

States are complex when either the inputs or the coefficients are complex.

Lattice MA

Parameters

Coefficient source

Select whether you want to specify the filter coefficients on the block mask or through an input port.

Filter structure

Select the filter structure you want the block to implement. You must have an available DSP System Toolbox license to run a model with a Discrete FIR Filter block that implements any filter structure other than direct form.

Coefficients

Specify the vector coefficients of the filter's transfer function. Filter coefficients must be specified as a row vector. When you specify a row vector of filter taps, the block applies a single filter to the input. To apply multiple filters to the same input, specify a matrix of coefficients, where each row represents a different set of filter taps. This parameter is visible only when **Coefficient source** is set to `Dialog parameters`. For multiple filter, **Filter structure** must be `Direct form`, and the input must be a scalar.

Input processing

Specify whether the block performs sample- or frame-based processing. You can select one of the following options:

- Elements as channels (sample based) — Treat each element of the input as an independent channel (sample-based processing).
- Columns as channels (frame based) — Treat each column of the input as an independent channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

Initial states

Specify the initial conditions of the filter states. To learn how to specify initial states, see “Specifying Initial States” on page 1-391.

Show enable port

Select to show an enable port for this block. This port can control execution of the block. The block is considered enabled when the input to this port is nonzero, and is disabled when the input is 0. The value of the input is checked at the same time step as the block execution.

External reset

Specify the trigger event to use to reset the states to the initial conditions.

Reset Mode	Behavior
None	No reset.
Rising	Reset on a rising edge.
Falling	Reset on a falling edge.
Either	Reset on either a rising or falling edge.
Level	Reset in either of these cases: <ul style="list-style-type: none"> • when the reset signal is nonzero at the current time step • when the reset signal value changes from nonzero at the previous time step to zero at the current time step
Level hold	Reset when the reset signal is nonzero at the current time step

The reset signal must be a scalar of type `single`, `double`, `boolean`, or `integer`. Fixed point data types, except for `ufix1`, are not supported.

Sample time (-1 for inherited)

Specify the time interval between samples. To inherit the sample time, set this parameter to `-1`. See “Specify Sample Time” in “How Simulink Works” in the *Simulink User's Guide*.

Tap sum

Specify the tap sum data type of a direct form symmetric or direct form antisymmetric filter, which is the data type the filter uses when it sums the inputs prior to multiplication by the coefficients. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in integer, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

This parameter is only visible when the selected filter structure is either `Direct form symmetric` or `Direct form antisymmetric`.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Tap sum** parameter.

See “Specify Data Types Using Data Type Assistant” for more information.

Coefficients

Specify the coefficient data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- A built-in integer, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Coefficients** parameter.

See “Specify Data Types Using Data Type Assistant” for more information.

Coefficients minimum

Specify the minimum value that a filter coefficient should have. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Coefficients maximum

Specify the maximum value that a filter coefficient should have. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Product output

Specify the product output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output** parameter.

See “Specify Data Types Using Data Type Assistant” for more information.

Accumulator

Specify the accumulator data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in data type, for example, `int8`

- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” for more information.

State

Specify the state data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- A built-in integer, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

This parameter is only visible when the selected filter structure is `Lattice MA`.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **State** parameter.

See “Specify Data Types Using Data Type Assistant” for more information.

Output

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Signal Data Types” in the *Simulink User's Guide* for more information.

Output minimum

Specify the minimum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Output maximum

Specify the maximum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Lock data type settings against changes by the fixed-point tools

Select to lock all data type settings of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer). in the Fixed-Point Designer documentation.

Saturate on integer overflow

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box.	<p>You want to optimize efficiency of your generated code.</p> <p>You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.</p>	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. Usually, the code generation process can detect

when overflow is not possible. In this case, the code generator does not produce saturation code.

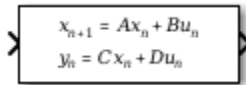

Characteristics

Data Types	Double Single Base Integer Fixed-Point
Sample Time	Specified in the Sample time parameter
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Introduced in R2008a

Discrete State-Space

Implement discrete state-space system

$$\begin{aligned} x_{n+1} &= Ax_n + Bu_n \\ y_n &= Cx_n + Du_n \end{aligned}$$

Library

Discrete

Description

Block Behavior for Non-Empty Matrices

The Discrete State-Space block implements the system described by

$$\begin{aligned} x(n+1) &= Ax(n) + Bu(n) \\ y(n) &= Cx(n) + Du(n), \end{aligned}$$

where u is the input, x is the state, and y is the output. The matrix coefficients must have these characteristics, as illustrated in the following diagram:

- **A** must be an n-by-n matrix, where n is the number of states.
- **B** must be an n-by-m matrix, where m is the number of inputs.
- **C** must be an r-by-n matrix, where r is the number of outputs.
- **D** must be an r-by-m matrix.

The block accepts one input and generates one output. The width of the input vector is the number of columns in the **B** and **D** matrices. The width of the output vector is the

number of rows in the **C** and **D** matrices. To define the initial state vector, use the **Initial conditions** parameter.

To specify a vector or matrix of zeros for **A**, **B**, **C**, **D**, or **Initial conditions**, use the `zeros` function.

Block Behavior for Empty Matrices

When the matrices **A**, **B**, and **C** are empty (for example, `[]`), the functionality of the block becomes $y(n) = Du(n)$. If the **Initial conditions** vector is also empty, the block uses an initial state vector of zeros.

Data Type Support

The Discrete State Space block accepts and outputs a real signal of type `single` or `double`. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

A, B, C, D

Specify the matrix coefficients, as defined in the Description section.

Initial conditions

Specify the initial state vector. The default value is 0. Simulink does not allow the initial states of this block to be `inf` or `NaN`.

Sample time (-1 for inherited)

Specify the time interval between samples. See “Specify Sample Time”.

State name

Use this parameter to assign a unique name to the block state. The default is `' '`. When this field is blank, no name is assigned. When using this parameter, remember these considerations:

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.

- The state name applies only to the selected block.

This parameter enables **State name must resolve to Simulink signal object** when you click **Apply**.

For more information, see “Discrete Block State Naming in Generated Code” (Simulink Coder).

State name must resolve to Simulink signal object

Select this check box to require that the state name resolve to a Simulink signal object. This check box is cleared by default.

State name enables this parameter. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than `None`.

Selecting this check box disables **Code generation storage class**.

Signal object class

Choose a custom storage class package by selecting a signal object class that the target package defines. For example, to apply custom storage classes from the built-in package `mpt`, select `mpt.Signal`. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes do not affect the generated code.

If the class that you want does not appear in the list, select `Customize class lists`. For instructions, see “Apply Custom Storage Classes Directly to Signal Lines, Block States, and Output Blocks” (Embedded Coder).

To programmatically set this parameter, use `StateSignalObject`.

For information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

Code generation storage class

Select state storage class for code generation.

Default: `Auto`

`Auto`

`Auto` is the appropriate storage class for states that you do not need to interface to external code.

StorageClass

Applies the storage class or custom storage class that you select from the list. For information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than Simulink.

State name enables this parameter.

To programmatically set this parameter, use `StateStorageClass` or `StateSignalObject`. See “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder).

TypeQualifier

Note **TypeQualifier** will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

Specify a storage type qualifier such as `const` or `volatile`.

Setting **Code generation storage class** to `ExportedGlobal`, `ImportedExtern`, `ImportedExternPointer`, or `SimulinkGlobal` enables this parameter. This parameter is hidden unless you previously set its value.

During simulation, the block uses the following values:

- The initial value of the signal object to which the state name is resolved
- Min and Max values of the signal object

For more information, see “Discrete Block State Naming in Generated Code” (Simulink Coder) in the Simulink Coder documentation.

Characteristics

Data Types	Double Single
Sample Time	Specified in the Sample time parameter
Direct Feedthrough	Only if $D \neq 0$
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Discrete-Time Integrator

Perform discrete-time integration or accumulation of signal

Library

Discrete

Description

Capabilities of the Discrete-Time Integrator Block

You can use the Discrete-Time Integrator block in place of the Integrator block to create a purely discrete system. With the Discrete-Time Integrator block, you can:

- Define initial conditions on the block dialog box or as input to the block.
- Define an input gain (K) value.
- Output the block state.
- Define upper and lower limits on the integral.
- Reset the state depending on an additional reset input.

Output Equations

The block starts from the first time step, $n = 0$, with either initial output $y(0) = IC$ or initial state $x(0) = IC$, depending on the **Initial condition setting** parameter value.

For a given step $n > 0$ with simulation time $t(n)$, Simulink updates output $y(n)$ as follows:

- Forward Euler method:

$$y(n) = y(n-1) + K * [t(n) - t(n-1)] * u(n-1)$$

- Backward Euler method:

$$y(n) = y(n-1) + K * [t(n) - t(n-1)] * u(n)$$

- Trapezoidal method:

$$y(n) = y(n-1) + K * [t(n) - t(n-1)] * [u(n) + u(n-1)] / 2$$

Simulink automatically selects a state-space realization of these output equations depending on the block sample time, which can be explicit or triggered. When using explicit sample time, $t(n) - t(n-1)$ reduces to the sample time T for all $n > 0$. For more information on these methods, see “Integration and Accumulation Methods” on page 1-416.

Integration and Accumulation Methods

The block can integrate or accumulate using the forward Euler, backward Euler, and trapezoidal methods. Assume that u is the input, y is the output, and x is the state. For a given step n , Simulink updates $y(n)$ and $x(n+1)$. In integration mode, T is the block sample time (delta T in the case of triggered sample time). In accumulation mode, $T = 1$. The block sample time determines when the output is computed but not the output value. K is the gain value. Values clip according to upper or lower limits.

- Forward Euler method (default), also known as forward rectangular, or left-hand approximation

For this method, the software approximates $1/s$ as $T / (z-1)$. The expressions for the output of the block at step n are:

$$\begin{aligned} x(n+1) &= x(n) + K * T * u(n) \\ y(n) &= x(n) \end{aligned}$$

The block uses the following steps to compute the output:

$$\begin{aligned} \text{Step 0:} \quad & y(0) = IC \text{ (clip if necessary)} \\ & x(1) = y(0) + K * T * u(0) \end{aligned}$$

$$\begin{aligned} \text{Step 1:} \quad & y(1) = x(1) \\ & x(2) = x(1) + K * T * u(1) \end{aligned}$$

$$\begin{aligned} \text{Step } n: \quad & y(n) = x(n) \\ & x(n+1) = x(n) + K \cdot T \cdot u(n) \quad (\text{clip if necessary}) \end{aligned}$$

Using this method, input port 1 does not have direct feedthrough.

- Backward Euler method, also known as backward rectangular or right-hand approximation

For this method, the software approximates $1/s$ as $T \cdot z / (z-1)$. The resulting expression for the output of the block at step n is

$$y(n) = y(n-1) + K \cdot T \cdot u(n).$$

Let $x(n) = y(n-1)$. The block uses these steps to compute the output.

If the parameter **Initial condition setting** is set to Output:

$$\begin{aligned} \text{Step } 0: \quad & y(0) = \text{IC (clipped if necessary)} \\ & x(1) = y(0) \end{aligned}$$

If the parameter **Initial condition setting** is set to State (most efficient):

$$\begin{aligned} \text{Step } 0: \quad & x(0) = \text{IC (clipped if necessary)} \\ & x(1) = y(0) = x(0) + K \cdot T \cdot u(0) \end{aligned}$$

$$\begin{aligned} \text{Step } 1: \quad & y(1) = x(1) + K \cdot T \cdot u(1) \\ & x(2) = y(1) \end{aligned}$$

$$\begin{aligned} \text{Step } n: \quad & y(n) = x(n) + K \cdot T \cdot u(n) \\ & x(n+1) = y(n) \end{aligned}$$

Using this method, input port 1 has direct feedthrough.

- Trapezoidal method

For this method, the software approximates $1/s$ as $T/2 \cdot (z+1) / (z-1)$.

When T is fixed (equal to the sampling period), the expressions to compute the output are:

$$\begin{aligned} x(n) &= y(n-1) + K \cdot T / 2 \cdot u(n-1) \\ y(n) &= x(n) + K \cdot T / 2 \cdot u(n) \end{aligned}$$

If the **Initial condition setting** parameter is set to Output:

Step 0: $y(0) = \text{IC (clipped if necessary)}$
 $x(1) = y(0) + K \cdot T / 2 \cdot u(0)$

If the **Initial condition setting** parameter is set to State (most efficient):

Step 0: $x(0) = \text{IC (clipped if necessary)}$
 $y(0) = x(0) + K \cdot T / 2 \cdot u(0)$
 $x(1) = y(0) + K \cdot T / 2 \cdot u(0)$

Step 1: $y(1) = x(1) + K \cdot T / 2 \cdot u(1)$
 $x(2) = y(1) + K \cdot T / 2 \cdot u(1)$

Step n: $y(n) = x(n) + K \cdot T / 2 \cdot u(n)$
 $x(n+1) = y(n) + K \cdot T / 2 \cdot u(n)$

Here, $x(n+1)$ is the best estimate of the next output. It is not the same as the state, in that $x(n)$ is not equal to $y(n)$.

If T is variable (for example, obtained from the triggering times), the block uses these steps to compute the output.

If the **Initial condition setting** parameter is set to Output:

Step 0: $y(0) = \text{IC (clipped if necessary)}$
 $x(1) = y(0)$

If the **Initial condition setting** parameter is set to State (most efficient):

Step 0: $x(0) = \text{IC (clipped if necessary)}$
 $x(1) = y(0) = x(0) + K \cdot T / 2 \cdot u(0)$

Step 1: $y(1) = x(1) + T / 2 \cdot (u(1) + u(0))$
 $x(2) = y(1)$

Step n: $y(n) = x(n) + T / 2 \cdot (u(n) + u(n-1))$
 $x(n+1) = y(n)$

Using this method, input port 1 has direct feedthrough.

Define Initial Conditions

You can define the initial conditions as a parameter on the block dialog box or input them from an external signal:

- To define the initial conditions as a block parameter, set the **Initial condition source** parameter to `internal` and enter the value in the **Initial condition** text box.
- To provide the initial conditions from an external source, set the **Initial condition source** parameter to `external`. An additional input port appears on the block.

When to Use the State Port

Use the state port instead of the output port:

- When the output of the block is fed back into the block through the reset port or the initial condition port, causing an algebraic loop. For an example, see the `sldemo_bounce_two_integrators` model.
- When you want to pass the state from one conditionally executed subsystem to another, which can cause timing problems. For an example, see the `sldemo_clutch` model.

You can work around these problems by passing the state through the state port rather than the output port. Simulink generates the state at a slightly different time from the output, which protects your model from these problems. To output the block state, select the **Show state port** check box. The state port appears on the top of the block

Limit the Integral

To keep the output within certain levels, select the **Limit output** check box and enter the limits in the corresponding text box. Doing so causes the block to function as a

limited integrator. When the output reaches the limits, the integral action turns off to prevent integral windup. During a simulation, you can change the limits but you cannot change whether the output is limited. The table shows how the block determines output.

Integral	Output
Less than or equal to the Lower saturation limit and the input is negative	Held at the Lower saturation limit
Between the Lower saturation limit and the Upper saturation limit	The integral
Greater than or equal to the Upper saturation limit and the input is positive	Held at the Upper saturation limit

To generate a signal that indicates when the state is being limited, select the **Show saturation port** check box. A new saturation port appears below the block output port:

The signal has one of three values:

- 1 indicates that the upper limit is being applied.
- 0 indicates that the integral is not limited.
- -1 indicates that the lower limit is being applied.

Reset the State

The block can reset its state to the initial condition you specify, based on an external signal. To cause the block to reset its state, select one of the **External reset** parameter options. A reset port appears that indicates the reset trigger type:

The reset port has direct feedthrough. If the block output feeds back into this port, either directly or through a series of blocks with direct feedthrough, an algebraic loop results.

To resolve this loop, feed the output of the block state port into the reset port instead. To access the block state, select the **Show state port** check box.

Reset Trigger Types

The **External reset** parameter lets you determine the attribute of the reset signal that triggers the reset. The trigger options include:

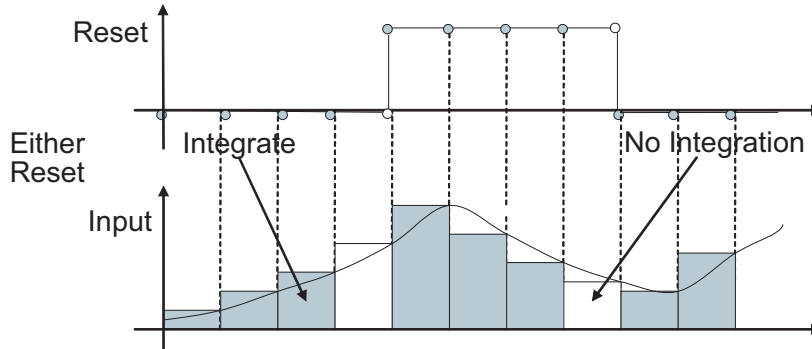

- `rising` – Resets the state when the reset signal has a rising edge. For example, this figure shows the effect that a rising reset trigger has on backward Euler integration.

- `falling` – Resets the state when the reset signal has a falling edge. For example, this figure shows the effect that a falling reset trigger has on backward Euler integration.

- `either` – Resets the state when the reset signal rises or falls. For example, the following figure shows the effect that an either reset trigger has on backward Euler integration.

- `level` – Resets and holds the output to the initial condition while the reset signal is nonzero. For example, this figure shows the effect that a level reset trigger has on backward Euler integration.

- `sampled level` – Resets the output to the initial condition when the reset signal is nonzero. For example, this figure shows the effect that a sampled level reset trigger has on backward Euler integration.

The sampled level reset option requires fewer computations, making it more efficient than the level reset option. However, the sampled level reset option can introduce a discontinuity when integration resumes.

Note For the discrete-time integrator block, all trigger detections are based on signals with positive values. For example, a signal changing from -1 to 0 is not considered a rising edge, but a signal changing from 0 to 1 is.

Behavior in Simplified Initialization Mode

Simplified initialization mode is enabled when you set **Underspecified initialization detection** to **Simplified** on the **Configuration Parameters** dialog box. If you use simplified initialization mode, the behavior of the Discrete-Time Integrator block differs from classic initialization mode. The new initialization behavior is more robust and provides more consistent behavior in these cases:

- In algebraic loops
- On enable and disable
- When comparing results using triggered sample time against explicit sample time, where the block is triggered at the same rate as the explicit sample time

Simplified initialization mode enables easier conversion from Continuous-Time Integrator blocks to Discrete-Time Integrator blocks, because the initial conditions have the same meaning for both blocks.

For more information on classic and simplified initialization modes, see “Underspecified initialization detection”.

When you use simplified initialization mode with **Initial condition setting** set to Output, the enable and disable behavior of the block is simplified as follows:

At disable time t_d :

$$y(t_d) = y(t_d-1)$$

At enable time t_e :

- If the parent subsystem control port has **States when enabling** set to reset:

$$y(t_e) = IC.$$

- If the parent subsystem control port has **States when enabling** set to held:

$$y(t_e) = y(t_d).$$

The following figure shows this condition.

When using simplified initialization mode, you cannot place the Discrete-Time Integrator block in an Iterator Subsystem.

In simplified initialization mode, Iterator subsystems do not maintain elapsed time. Thus, if a Discrete-Time Integrator block, which needs elapsed time, is placed inside an Iterator Subsystem block, Simulink reports an error.

Simulink does not support model simulation when all the following conditions are true:

- A Discrete-Time Integrator block is placed within a triggered subsystem or a function-call subsystem.
- The block's **Initial condition setting** parameter is set to `State` (most efficient).
- Simplified initialization mode is enabled.

Behavior in an Enabled Subsystem Inside a Function-Call Subsystem

Suppose that you have a function-call subsystem that contains an enabled subsystem, which contains a Discrete-Time Integrator block. The following behavior applies.

Integrator Method	Sample Time Type of Function-Call Trigger Port	Value of <code>delta T</code> When Function-Call Subsystem Executes for the First Time After Enabled	Reason for Behavior
Forward Euler	Triggered	$t - t_{\text{start}}$	When the function-call subsystem executes for the first time, the integrator algorithm uses t_{start} as the previous simulation time.
Backward Euler and Trapezoidal	Triggered	$t - t_{\text{previous}}$	When the function-call subsystem executes for the first time, the integrator algorithm uses t_{previous} as the previous simulation time.
Forward Euler, Backward Euler, and Trapezoidal	Periodic	Sample time of the function-call generator	In periodic mode, the Discrete-Time Integrator block uses sample time of the function-call generator for <code>delta T</code> .

Data Type Support

The Discrete-Time Integrator block accepts real signals of the following data types:

- Floating point
- Built-in integer
- Fixed point

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

During simulation, the block uses the following values:

- The initial value of the signal object to which the state name is resolved
- Min and Max values of the signal object

For more information, see “Discrete Block State Naming in Generated Code” (Simulink Coder) in the Simulink Coder documentation.

Show data type assistant

Display the **Data Type Assistant**.

The **Data Type Assistant** helps you set the **Output data type** parameter.

For more information, see “Control Signal Data Types”.

Integrator method

Specify the integration or accumulation method.

Default: Integration: Forward Euler

Integration: Forward Euler

Integrator method is Forward Euler.

Integration: Backward Euler

Integrator method is Backward Euler.

Integration: Trapezoidal

Integrator method is Trapezoidal.

Accumulation: Forward Euler

Accumulation method is Forward Euler.

Accumulation: Backward Euler

Accumulation method is Backward Euler.

Accumulation: Trapezoidal

Accumulation method is Trapezoidal.

Parameter: IntegratorMethod

Type: character vector

Value: 'Integration: Forward Euler' | 'Integration: Backward Euler' |
'Integration: Trapezoidal' | 'Accumulation: Forward Euler' |
'Accumulation: Backward Euler' | 'Accumulation: Trapezoidal'

Default: 'Integration: Forward Euler'

Gain value

Specify a scalar, vector, or matrix by which to multiply the integrator input. Each element of the gain must be a positive real number.

Default: 1.0

- Specifying a value other than 1.0 (the default) is semantically equivalent to connecting a Gain block to the input of the integrator.
- Valid entries include:
 - `double(1.0)`
 - `single(1.0)`
 - `[1.1 2.2 3.3 4.4]`
 - `[1.1 2.2; 3.3 4.4]`
- Using this parameter to specify the input gain eliminates a multiplication operation in the generated code. However, this parameter must be nontunable to realize this

benefit. If you want to tune the input gain, set this parameter to 1.0 and use an external Gain block to specify the input gain.

Parameter: gainval

Type: character vector

Value: '1.0'

Default: '1.0'

External reset

Reset the states to their initial conditions when a trigger event occurs in the reset signal.

Default: none

none

Do not reset the state to initial conditions.

rising

Reset the state when the reset signal has a rising edge.

falling

Reset the state when the reset signal has a falling edge.

either

Reset the state when the reset signal rises or falls.

level

Reset and holds the output to the initial condition while the reset signal is nonzero.

sampled level

Reset the output to the initial condition when the reset signal is nonzero.

Parameter: ExternalReset

Type: character vector

Value: 'none' | 'rising' | 'falling' | 'either' | 'level' | 'sampled level'

Default: 'none'

Initial condition source

Get the initial conditions of the states.

Default: `internal`

`internal`

Get the initial conditions of the states from the **Initial condition** parameter.

`external`

Get the initial conditions of the states from an external block.

Simulink software does not allow the initial condition of this block to be `inf` or `NaN`.

Selecting `internal` enables the **Initial condition** parameter.

Selecting `external` disables the **Initial condition** parameter.

Parameter: `InitialConditionSource`

Type: character vector

Value: `'internal' | 'external'`

Default: `'internal'`

Initial condition

Specify the states' initial conditions.

Default: 0

Minimum: value of **Output minimum** parameter

Maximum: value of **Output maximum** parameter

Simulink software does not allow the initial condition of this block to be `inf` or `NaN`.

Setting **Initial condition source** to `internal` enables this parameter.

Setting **Initial condition source** to `external` disables this parameter.

Parameter: InitialCondition

Type: scalar or vector

Value: '0'

Default: '0'

Initial condition setting

Specify whether to apply the **Initial condition** parameter to the block state or output. This initial condition is also used as the reset value. This parameter was named **Use initial condition as initial and reset value for** in Simulink before R2014a.

Default: State (most efficient)

State (most efficient)

Use this option in all situations except when the block is in a triggered subsystem or a function-call subsystem and **Integrator method** is set to an integration method.

Set the following initial conditions:

$$x(0) = IC$$

At reset:

$$x(n) = IC$$

Output

Use this option when the block is in a triggered subsystem or a function-call subsystem and **Integrator method** is set to an integration method.

Set the following initial conditions:

$$y(0) = IC$$

At reset:

$$y(n) = IC$$

Compatibility

This option is present to provide backward compatibility. You cannot select this option for Discrete-Time Integrator blocks in Simulink models but you can select it

for Discrete-Time Integrator blocks in a library. Use this option to maintain compatibility with Simulink models created before R2014a.

Prior to R2014a, the option `State` (most efficient) was known as `State only` (most efficient). The option `Output` was known as `State and output`. The behavior of the block with the option `Compatibility` is as follows.

- If **Underspecified initialization detection** is set to `Classic`, the **Initial condition setting** parameter behaves as `State (most efficient)`.
- If **Underspecified initialization detection** is set to `Simplified`, the **Initial condition setting** parameter behaves as `Output`.

Parameter: `InitialConditionSetting`

Type: character vector

Value: `'State (most efficient)'` | `'Output'` | `'Compatibility'`

Default: `'Output'`

Sample time (-1 for inherited)

Enter the discrete interval between sample time hits.

Default: 1

By default, the block uses a discrete sample time of 1. To set a different sample time, enter another discrete value, such as 0.1.

See also “Specify Sample Time” in the online documentation for more information.

- Do not specify a sample time of 0. This value specifies a continuous sample time, which the Discrete-Time Integrator block does not support.
- Do not specify a sample time of `inf` or `NaN` because these values are not discrete.
- If you specify -1 to inherit the sample time from an upstream block, verify that the upstream block uses a discrete sample time. For example, the Discrete-Time Integrator block cannot inherit a sample time of 0.

Parameter: `SampleTime`

Type: character vector

Value: '1'
Default: '1'

Limit output

Limit the block's output to a value between the **Lower saturation limit** and **Upper saturation limit** parameters.

Default: Off

On

Limit the block's output to a value between the **Lower saturation limit** and **Upper saturation limit** parameters.

Off

Do not limit the block's output to a value between the **Lower saturation limit** and **Upper saturation limit** parameters.

This parameter enables **Upper saturation limit**.

This parameter enables **Lower saturation limit**.

Parameter: LimitOutput
Type: character vector
Value: 'off' | 'on'
Default: 'off'

Upper saturation limit

Specify the upper limit for the integral.

Default: `inf`

Minimum: value of **Output minimum** parameter

Maximum: value of **Output maximum** parameter

Limit output enables this parameter.

Parameter: UpperSaturationLimit

Type: scalar or vector

Value: 'inf'

Default: 'inf'

Lower saturation limit

Specify the lower limit for the integral.

Default: -inf

Minimum: value of **Output minimum** parameter

Maximum: value of **Output maximum** parameter

Limit output enables this parameter.

Parameter: LowerSaturationLimit

Type: scalar or vector

Value: '-inf'

Default: '-inf'

Show saturation port

Add a saturation output port to the block.

Default: Off

On

Add a saturation output port to the block.

Off

Do not add a saturation output port to the block.

Parameter: ShowSaturationPort

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Show state port

Add an output port to the block for the block's state.

Default: Off

On

Add an output port to the block for the block's state.

Off

Do not add an output port to the block for the block's state.

Parameter: ShowStatePort

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Ignore limit and reset when linearizing

Cause Simulink linearization commands to treat this block as not resettable and as having no limits on its output, regardless of the settings of the block reset and output limitation options.

Default: Off

On

Cause Simulink linearization commands to treat this block as not resettable and as having no limits on its output, regardless of the settings of the block reset and output limitation options.

Off

Do not cause Simulink linearization commands to treat this block as not resettable and as having no limits on its output, regardless of the settings of the block reset and output limitation options.

Ignoring the limit and resetting allows you to linearize a model around an operating point. This point may cause the integrator to reset or saturate.

Parameter: IgnoreLimit

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

Default: Off

On

Locks the output data type setting for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change the output data type setting for this block.

Parameter: LockScale

Type: character vector

Value: 'off' | 'on'

Default: 'off'

For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Integer rounding mode

Specify the rounding mode for fixed-point operations.

Default: `Floor`

`Ceiling`

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

`Convergent`

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

`Floor`

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

`Nearest`

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

`Round`

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

`Simplest`

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

`Zero`

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

Parameter: `RndMeth`

Type: character vector

Value: `'Ceiling'` | `'Convergent'` | `'Floor'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Default: `'Floor'`

For more information, see “Rounding” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

Saturate on integer overflow

Specify whether overflows saturate.

Default: Off

On

Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Off

Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Parameter: SaturateOnIntegerOverflow

Type: character vector

Value: 'off' | 'on'

Default: 'off'

State name

Use this parameter to assign a unique name to each state.

Default: ' '

- If left blank, no name is assigned.
- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

This parameter enables **State name must resolve to Simulink signal object** when you click the **Apply** button.

For more information, see “Discrete Block State Naming in Generated Code” (Simulink Coder).

Parameter: StateName

Type: character vector

Value: ' '

Default: ' '

State name must resolve to Simulink signal object

Require that state name resolve to Simulink signal object.

Default: Off

On

Require that state name resolve to Simulink signal object.

Off

Do not require that state name resolve to Simulink signal object.

State name enables this parameter. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than `None`.

Selecting this check box disables **Code generation storage class**.

Parameter: `StateMustResolveToSignalObject`

Type: character vector

Value: `'off' | 'on'`

Default: `'off'`

Signal object class

Choose a custom storage class package by selecting a signal object class that the target package defines. For example, to apply custom storage classes from the built-in package `mpt`, select `mpt.Signal`. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes do not affect the generated code.

To programmatically set this parameter, use `StateSignalObject`.

For examples and more information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

`Simulink.Signal`

Use custom storage classes from the built-in package `Simulink`.

Package.Class

Use custom storage classes from the package that defines the class that you select.

If the class that you want does not appear in the list, select `Customize class lists`. For instructions, see “Apply Custom Storage Classes Directly to Signal Lines, Block States, and Output Blocks” (Embedded Coder).

Code generation storage class

Select state storage class for code generation.

Default: Auto

Auto

Auto is the appropriate storage class for states that you do not need to interface to external code.

StorageClass

Applies the storage class or custom storage class that you select from the list. For information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than Simulink.

State name enables this parameter.

Command-Line Information

Parameter: StateStorageClass

Type: character vector

Value: 'Auto' | 'ExportedGlobal' | 'ImportedExtern' | 'ImportedExternPointer' | 'SimulinkGlobal' | 'Custom'

Default: 'Auto'

Code generation storage class

Select state storage class for code generation.

Default: Auto

Auto

Auto is the appropriate storage class for states that you do not need to interface to external code.

StorageClass

Applies the storage class or custom storage class that you select from the list. For information about storage classes, see “Control Signals and States in Code by

Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than `Simulink`.

State name enables this parameter.

TypeQualifier

Note **TypeQualifier** will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

Specify a storage type qualifier such as `const` or `volatile`.

- **Default:** `' '` (empty character vector)
- `const`
- `volatile`

Setting **Code generation storage class** to `ExportedGlobal`, `ImportedExtern`, `ImportedExternPointer`, or `SimulinkGlobal` enables this parameter. This parameter is hidden unless you previously set its value.

Parameter Name: `RTWStateStorageTypeQualifier`

Value Type: character vector

Default: `' '` (empty character vector)

Output minimum

Lower value of the output range that Simulink checks.

Default: `[]` (unspecified)

Specify this number as a finite, real, double, scalar value.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Parameter: OutMin

Type: character vector

Value: ' [] '

Default: ' [] '

Output maximum

Upper value of the output range that Simulink checks.

Default: [] (unspecified)

Specify this number as a finite, real, double, scalar value.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).

- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Note **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Parameter: OutMax

Type: character vector

Value: ' [] '

Default: ' [] '

Output data type

Specify the output data type.

Default: `Inherit: Inherit via internal rule`

`Inherit: Inherit via internal rule`

Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
- To specify your own inheritance rule, use `Inherit: Inherit via back propagation` and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.

Inherit: Inherit via back propagation

Use data type of the driving block.

double

Output data type is double.

single

Output data type is single.

int8

Output data type is int8.

uint8

Output data type is uint8.

int16

Output data type is int16.

uint16

Output data type is uint16.

int32

Output data type is int32.

uint32

Output data type is uint32.

fixdt(1,16,0)

Output data type is fixed point fixdt(1,16,0).

fixdt(1,16,2^0,0)

Output data type is fixed point fixdt(1,16,2^0,0).

<data type expression>

Use a data type object, for example, Simulink.NumericType.

Parameter: OutDataTypeStr

Type: character vector

Value: 'Inherit: Inherit via internal rule' | 'Inherit: Inherit via back propagation' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)'

Default: 'Inherit: Inherit via internal rule'

For more information, see “Control Signal Data Types”.

Mode

Select the category of data to specify.

Default: `Inherit`

`Inherit`

Inheritance rules for data types. Selecting `Inherit` enables a second menu/text box to the right. Select one of the following choices:

- `Inherit via internal rule (default)`
- `Inherit via back propagation`

`Built in`

Built-in data types. Selecting `Built in` enables a second menu/text box to the right. Select one of the following choices:

- `double (default)`
- `single`
- `int8`
- `uint8`
- `int16`
- `uint16`
- `int32`
- `uint32`

`Fixed point`

Fixed-point data types.

`Expression`

Expressions that evaluate to data types. Selecting `Expression` enables a second menu/text box to the right, where you can enter the expression.

Clicking the **Show data type assistant** button enables this parameter.

Parameter: OutDataTypeStr

Type: character vector

Value: 'Inherit: Inherit via internal rule' | 'Inherit: Inherit via back propagation' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)'

Default: 'Inherit: Inherit via internal rule'

See “Specify Data Types Using Data Type Assistant”.

Data type override

Specify data type override mode for this signal.

Default: Inherit

Inherit

Inherits the data type override setting from its context, that is, from the block, Simulink.Signal object or Stateflow chart in Simulink that is using the signal.

Off

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

This parameter appears only when the **Mode** is Built in or Fixed point.

Signedness

Specify whether you want the fixed-point data as signed or unsigned.

Default: Signed

Signed

Specify the fixed-point data as signed.

Unsigned

Specify the fixed-point data as unsigned.

Selecting **Mode** > Fixed point enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Word length

Specify the bit size of the word that holds the quantized integer.

Default: 16

Minimum: 0

Maximum: 32

Selecting **Mode** > Fixed point enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

Default: Best precision

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

Best precision

Specify best-precision values.

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting Slope and bias enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

For more information, see “Specifying a Fixed-Point Data Type”.

Fraction length

Specify fraction length for fixed-point data type.

Default: 0

Binary points can be positive or negative integers.

Selecting **Scaling** > Binary point enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Slope

Specify slope for the fixed-point data type.

Default: 2^0

Specify any positive real number.

Selecting **Scaling** > `Slope` and `bias` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Bias

Specify bias for the fixed-point data type.

Default: 0

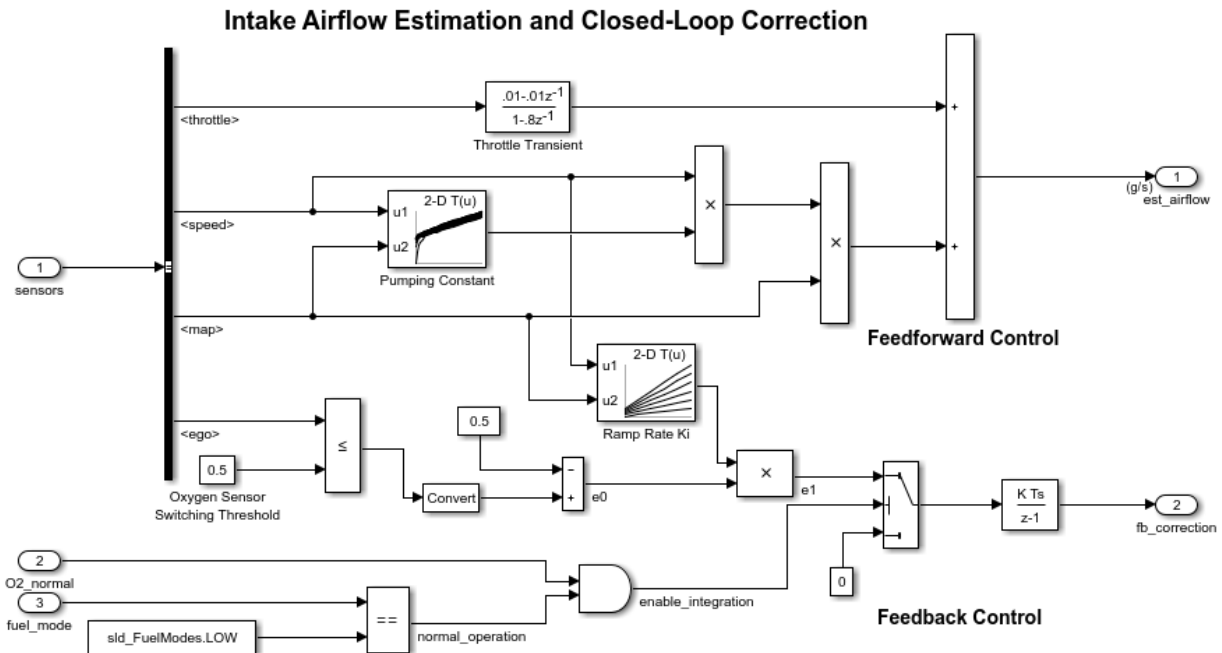

Specify any real number.

Selecting **Scaling** > `Slope` and `bias` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Examples

The `sldemo_fuelsys` model uses a Discrete-Time Integrator block in the `fuel_rate_control/airflow_calc` subsystem. This block uses the Forward Euler integration method.

When the Switch block feeds a nonzero value into the Discrete-Time Integrator block, integration occurs. Otherwise, integration does not occur.

Characteristics

Data Types	Double Single Base Integer Fixed-Point
Sample Time	Specified in the Sample time parameter
Direct Feedthrough	Yes, of the reset and external initial condition source ports. The input has direct feedthrough for every integration method except Forward Euler and accumulation Forward Euler.
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Discrete Transfer Fcn

Implement discrete transfer function

Library

Discrete

Description

The Discrete Transfer Fcn block implements the z -transform transfer function:

$$H(z) = \frac{num(z)}{den(z)} = \frac{num_0 z^m + num_1 z^{m-1} + \dots + num_m}{den_0 z^n + den_1 z^{n-1} + \dots + den_n}$$

where $m+1$ and $n+1$ are the number of numerator and denominator coefficients, respectively. num and den contain the coefficients of the numerator and denominator in descending powers of z . num can be a vector or matrix, den must be a vector, and you specify both as parameters on the block dialog box. The order of the denominator must be greater than or equal to the order of the numerator.

Specify the coefficients of the numerator and denominator polynomials in descending powers of z . This block lets you use polynomials in z to represent a discrete system, a method that control engineers typically use. Conversely, the Discrete Filter block lets you use polynomials in z^{-1} (the delay operator) to represent a discrete system, a method that signal processing engineers typically use. The two methods are identical when the numerator and denominator polynomials have the same length.

The Discrete Transfer Fcn block applies the z -transform transfer function to each independent channel of the input. The **Input processing** parameter allows you to specify whether the block treats each element of the input as an individual channel (sample-based processing), or each column of the input as an individual channel (frame-based processing). To perform frame-based processing, you must have a DSP System Toolbox license.

Specifying Initial States

Use the **Initial states** parameter to specify initial filter states. To determine the number of initial states you must specify and how to specify them, see the following tables.

Frame-Based Processing

Input	Number of Channels	Valid Initial States (Dialog Box)	Valid Initial States (Input Port)
<ul style="list-style-type: none"> • Column vector (K-by-1) • Unoriented vector (K) 	1	<ul style="list-style-type: none"> • Scalar • Column vector (M-by-1) • Row vector (1-by-M) 	<ul style="list-style-type: none"> • Scalar • Column vector (M-by-1)
<ul style="list-style-type: none"> • Row vector (1-by-N) • Matrix (K-by-N) 	N	<ul style="list-style-type: none"> • Scalar • Column vector (M-by-1) • Row vector (1-by-M) • Matrix (M-by-N) 	<ul style="list-style-type: none"> • Scalar • Matrix (M-by-N)

Sample-Based Processing

Input	Number of Channels	Valid Initial States (Dialog Box)	Valid Initial States (Input Port)
<ul style="list-style-type: none"> • Scalar 	1	<ul style="list-style-type: none"> • Scalar • Column vector (M-by-1) • Row vector (1-by-M) 	<ul style="list-style-type: none"> • Scalar • Column vector (M-by-1) • Row vector (1-by-M)
<ul style="list-style-type: none"> • Row vector (1-by-N) • Column vector (N-by-1) • Unoriented vector (N) 	N	<ul style="list-style-type: none"> • Scalar • Column vector (M-by-1) • Row vector (1-by-M) • Matrix (M-by-N) 	<ul style="list-style-type: none"> • Scalar
<ul style="list-style-type: none"> • Matrix (K-by-N) 	$K \times N$	<ul style="list-style-type: none"> • Scalar • Column vector (M-by-1) • Row vector (1-by-M) • Matrix (M-by-$(K \times N)$) 	<ul style="list-style-type: none"> • Scalar

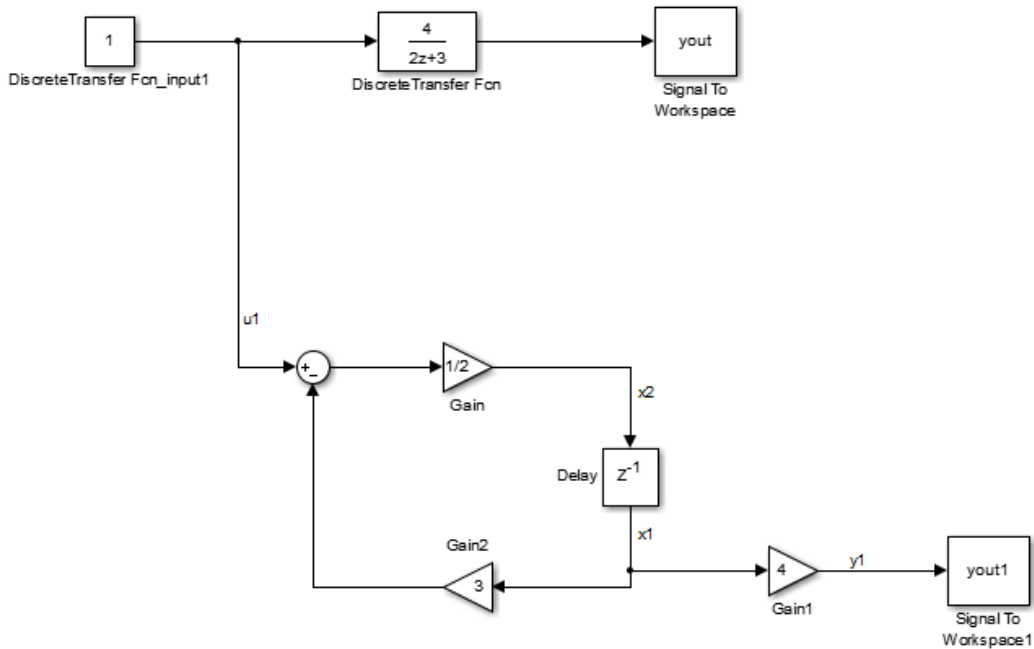

When the **Initial states** is a scalar, the block initializes all filter states to the same scalar value. Enter 0 to initialize all states to zero. When the **Initial states** is a vector or a matrix, each vector or matrix element specifies a unique initial state for a corresponding delay element in a corresponding channel:

- The vector length must equal the number of delay elements in the filter, $M = \max(\text{number of zeros}, \text{number of poles})$.
- The matrix must have the same number of rows as the number of delay elements in the filter, $M = \max(\text{number of zeros}, \text{number of poles})$. The matrix must also have one column for each channel of the input signal.

The following example shows the relationship between the initial filter output and the initial input and state. Given an initial input u_1 , the first output y_1 is related to the initial state $[x_1, x_2]$ and initial input by:

$$y_1 = 4x_1$$

$$x_2 = 1/2(u_1 - 3x_1)$$

Data Type Support

The Discrete Transfer Function block accepts and outputs real and complex signals of any signed numeric data type that Simulink supports. The block supports the same types for the numerator and denominator coefficients.

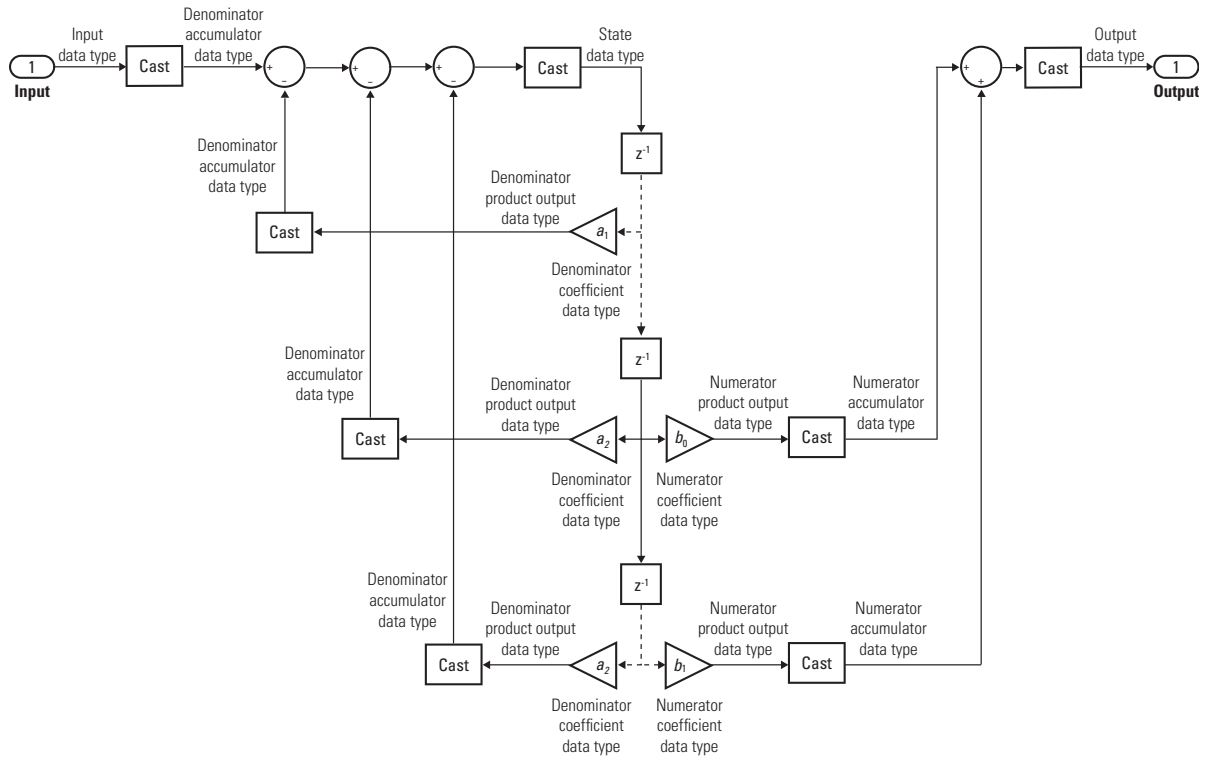

Numerator and denominator coefficients must have the same complexity. They can have different word lengths and fraction lengths.

States are complex when either the input or the coefficients are complex.

The following diagrams show the filter structure and the data types that the block uses for floating-point and fixed-point signals.

The block omits the dashed divide when you select the **Optimize by skipping divide by leading denominator coefficient (a0)** parameter.

Parameters

Numerator

Numerator coefficients of the discrete transfer function. To specify the coefficients, set the **Source** to `Dialog`. Then enter the coefficients in **Value** as descending powers of z . Use a row vector to specify the coefficients for a single numerator polynomial. Use a matrix to specify coefficients for multiple filters to be applied to the same input. Each matrix row represents a set of filter taps.

Denominator

Denominator coefficients of the discrete transfer function. To specify the coefficients, set the **Source** to `Dialog`. Then, enter the coefficients in **Value** as descending powers of z . Use a row vector to specify the coefficients for a single denominator

polynomial. Use a matrix to specify coefficients for multiple filters to be applied to the same input. Each matrix row represents a set of filter taps.

Initial states

If the **Source** is `Dialog`, then, in **Value**, specify the initial states of the filter states. To learn how to specify initial states, see “Specifying Initial States” on page 1-454.

If the **Source** is `Input port`, then there is nothing to be specified for **Value**.

External reset

Specify the trigger event to use to reset the states to the initial conditions.

Reset Mode	Behavior
None	No reset.
Rising	Reset on a rising edge.
Falling	Reset on a falling edge.
Either	Reset on either a rising or falling edge.
Level	Reset in either of these cases: <ul style="list-style-type: none"> • when the reset signal is nonzero at the current time step • when the reset signal value changes from nonzero at the previous time step to zero at the current time step
Level hold	Reset when the reset signal is nonzero at the current time step

The reset signal must be a scalar of type `single`, `double`, `boolean`, or `integer`. Fixed point data types, except for `ufix1`, are not supported.

Input processing

Specify whether the block performs sample- or frame-based processing.

- `Elements as channels (sample based)` — Process each element of the input as an independent channel.
- `Columns as channels (frame based)` — Process each column of the input as an independent channel.

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

Optimize by skipping divide by leading denominator coefficient (a0)

Select when the leading denominator coefficient, a_0 , equals one. This parameter optimizes your code.

When you select this check box, the block does not perform a divide-by- a_0 either in simulation or in the generated code. An error occurs if a_0 is not equal to one.

When you clear this check box, the block is fully tunable during simulation, and performs a divide-by- a_0 in both simulation and code generation.

Sample time

Specify the time interval between samples. To inherit the sample time, set this parameter to `-1`. See “Specify Sample Time” in “How Simulink Works” in the *Simulink User's Guide*.

State

Specify the state data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- A built-in integer, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **State** parameter.

See “Specify Data Types Using Data Type Assistant” in the *Simulink User's Guide* for more information.

Numerator coefficients

Specify the numerator coefficient data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in integer, for example, `int8`

- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Numerator coefficients** parameter.

See “Specify Data Types Using Data Type Assistant” in the *Simulink User’s Guide* for more information.

Numerator coefficient minimum

Specify the minimum value that a numerator coefficient can have. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Numerator coefficient maximum

Specify the maximum value that a numerator coefficient can have. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Numerator product output

Specify the product output data type for the numerator coefficients. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Numerator product output** parameter.

See “Specify Data Types Using Data Type Assistant” in the *Simulink User's Guide* for more information.

Numerator accumulator

Specify the accumulator data type for the numerator coefficients. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Numerator accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” in the *Simulink User's Guide* for more information.

Denominator coefficients

Specify the denominator coefficient data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in integer, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Denominator coefficients** parameter.

See “Specify Data Types Using Data Type Assistant” in the *Simulink User's Guide* for more information.

Denominator coefficient minimum

Specify the minimum value that a denominator coefficient can have. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)

- Automatic scaling of fixed-point data types

Denominator coefficient maximum

Specify the maximum value that a denominator coefficient can have. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Denominator product output

Specify the product output data type for the denominator coefficients. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Denominator product output** parameter.

See “Specify Data Types Using Data Type Assistant” in the *Simulink User's Guide* for more information.

Denominator accumulator

Specify the accumulator data type for the denominator coefficients. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Denominator accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” in the *Simulink User's Guide* for more information.

Output

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Signal Data Types” in the *Simulink User's Guide* for more information.

Output minimum

Specify the minimum value that the block can output. The default value is `[]` (unspecified). Simulink uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Output maximum

Specify the maximum value that the block can output. The default value is `[]` (unspecified). Simulink uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select to lock all data type settings of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer). in the Fixed-Point Designer documentation.

Saturate on integer overflow

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box.	<p>You want to optimize efficiency of your generated code.</p> <p>You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.</p>	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. Usually, the code generation process can detect

when overflow is not possible. In this case, the code generator does not produce saturation code.

State name

Use this parameter to assign a unique name to the block state. The default is ' '. When this field is blank, no name is assigned. When using this parameter, remember these considerations:

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

This parameter enables **State name must resolve to Simulink signal object** when you click **Apply**.

For more information, see “Discrete Block State Naming in Generated Code” (Simulink Coder).

State name must resolve to Simulink signal object

Select this check box to require that the state name resolve to a Simulink signal object. This check box is cleared by default.

State name enables this parameter. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than `None`.

Selecting this check box disables **Code generation storage class**.

Signal object class

Choose a custom storage class package by selecting a signal object class that the target package defines. For example, to apply custom storage classes from the built-in package `mpt`, select `mpt.Signal`. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes do not affect the generated code.

If the class that you want does not appear in the list, select `Customize class lists`. For instructions, see “Apply Custom Storage Classes Directly to Signal Lines, Block States, and Outport Blocks” (Embedded Coder).

To programmatically set this parameter, use `StateSignalObject`.

For information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage

classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

Code generation storage class

Select state storage class for code generation.

Default: `Auto`

`Auto`

`Auto` is the appropriate storage class for states that you do not need to interface to external code.

StorageClass

Applies the storage class or custom storage class that you select from the list. For information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than `Simulink`.

State name enables this parameter.

To programmatically set this parameter, use `StateStorageClass` or `StateSignalObject`. See “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder).

TypeQualifier

Note **TypeQualifier** will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

Specify a storage type qualifier such as `const` or `volatile`.

Setting **Code generation storage class** to `ExportedGlobal`, `ImportedExtern`, `ImportedExternPointer`, or `SimulinkGlobal` enables this parameter. This parameter is hidden unless you previously set its value.

During simulation, the block uses the following values:

- The initial value of the signal object to which the state name resolves
- Minimum and maximum values of the signal object

For more information, see “Discrete Block State Naming in Generated Code” (Simulink Coder) in the Simulink Coder documentation.

Characteristics

Data Types	Double Single Base Integer Fixed-Point
Sample Time	Specified in the Sample time parameter
Direct Feedthrough	Only when the leading numerator coefficient is not equal to zero and the numerator order equals the denominator order
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Discrete Zero-Pole

Model system defined by zeros and poles of discrete transfer function

Library

Discrete

Description

The Discrete Zero-Pole block models a discrete system defined by the zeros, poles, and gain of a z -domain transfer function. This block assumes that the transfer function has the following form:

$$H(z) = K \frac{Z(z)}{P(z)} = K \frac{(z - Z_1)(z - Z_2) \dots (z - Z_m)}{(z - P_1)(z - P_2) \dots (z - P_n)},$$

where Z represents the zeros vector, P the poles vector, and K the gain. The number of poles must be greater than or equal to the number of zeros ($n \geq m$). If the poles and zeros are complex, they must be complex conjugate pairs.

The block displays the transfer function depending on how the parameters are specified. See Zero-Pole for more information.

Data Type Support

The Discrete Zero-Pole block accepts and outputs real signals of type `double` and `single`. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Zeros

Specify the matrix of zeros. The default is $[1]$.

Poles

Specify the vector of poles. The default is $[0 \ 0.5]$.

Gain

Specify the gain. The default is 1.

Sample time

Specify the time interval between samples. See [Specifying Sample Time](#) in the “How Simulink Works” chapter of the Simulink documentation.

State name

Use this parameter to assign a unique name to the block state. The default is ' '. When this field is blank, no name is assigned. When using this parameter, remember these considerations:

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

This parameter enables **State name must resolve to Simulink signal object** when you click **Apply**.

For more information, see “Discrete Block State Naming in Generated Code” (Simulink Coder).

State name must resolve to Simulink signal object

Select this check box to require that the state name resolve to a Simulink signal object. This check box is cleared by default.

State name enables this parameter. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than `None`.

Selecting this check box disables **Code generation storage class**.

Signal object class

Choose a custom storage class package by selecting a signal object class that the target package defines. For example, to apply custom storage classes from the built-

in package `mpt`, select `mpt.Signal`. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes do not affect the generated code.

If the class that you want does not appear in the list, select `Customize class lists`. For instructions, see “Apply Custom Storage Classes Directly to Signal Lines, Block States, and Output Blocks” (Embedded Coder).

To programmatically set this parameter, use `StateSignalObject`.

For information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

Code generation storage class

Select state storage class for code generation.

Default: `Auto`

`Auto`

`Auto` is the appropriate storage class for states that you do not need to interface to external code.

StorageClass

Applies the storage class or custom storage class that you select from the list. For information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than `Simulink`.

State name enables this parameter.

To programmatically set this parameter, use `StateStorageClass` or `StateSignalObject`. See “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder).

TypeQualifier

Note **TypeQualifier** will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use

an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

Specify a storage type qualifier such as `const` or `volatile`.

Setting **Code generation storage class** to `ExportedGlobal`, `ImportedExtern`, `ImportedExternPointer`, or `SimulinkGlobal` enables this parameter. This parameter is hidden unless you previously set its value.

During simulation, the block uses the following values:

- The initial value of the signal object to which the state name is resolved
- Min and Max values of the signal object

For more information, see “Discrete Block State Naming in Generated Code” (Simulink Coder) in the Simulink Coder documentation.

Characteristics

Data Types	Double Single
Sample Time	Specified in the Sample time parameter
Direct Feedthrough	Yes, if the number of zeros and poles are equal
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Display

Display signal value during simulation

Library: Simulink / Dashboard

42

Description

The Display block connects to a signal in your model and displays its value during simulation. You can edit the parameters of the Display block while a simulation runs. Use the Display block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model.

Connection

Dashboard blocks do not use ports to connect to signals. To connect a signal to a Dashboard block, use the **Connection** table in the block's parameters.

- 1 Double-click the block.
- 2 Populate the **Connection** table by selecting signals of interest in your model.
- 3 Mark the option button next to the signal you want to display.
- 4 Click **Apply**.

Limitations

- You cannot save the block connections or properties in model files that use the MDL format.

To save connections and properties, save the model file in the SLX format.

- Dashboard blocks can only connect to real scalar signals.
- Dashboard blocks cannot connect to blocks that are commented out.
- Dashboard blocks cannot connect to signals inside reference models.

- Parameters specified by indexing a variable array do not appear in the **Connection** table. For example, a block parameter defined using the variable `engine(1)` does not appear in the table.

To access the parameter in the **Connection** table, assign the indexed value to a scalar variable, such as `engine_1`. Then, use the scalar variable to define the block parameter.

Parameters

Connection — Select a signal to connect and display

signal connection options

Signal connection options. Populate the **Connection** table by selecting signals of interest in your model. Mark the check box next to the signal you want to display. Click **Apply** to connect the signal.

Format — Format for displaying numerical values

`long` (default) | `long_e`

Format for displaying numerical values.

- When you select `long`, the block displays numeric signal values using up to 15 digits with a fixed decimal point that displays up to four decimal places.
- When you select `long_e`, the block displays numeric signal values in scientific notation using up to 16 digits with a floating decimal point.

Alignment — Text alignment in block

'Center' (default) | 'Left' | 'Right'

Text alignment in Display block.

Label — Block label position

'Top' (default) | 'Bottom' | 'Hide'

Position of the block label. When the block is connected to a signal, the label is the name of the connected signal. When the block is not connected, the label is the instructional text.

Introduced in R2017b

Display

Show value of input

Library

Sinks

Description

Format Options

You control the display format using the **Format** parameter:

If you select...	The block displays...
short	A 5-digit scaled value with fixed decimal point
long	A 15-digit scaled value with fixed decimal point
short_e	A 5-digit value with a floating decimal point
long_e	A 16-digit value with a floating decimal point
bank	A value in fixed dollars and cents format (but with no \$ or commas)
hex (Stored Integer)	The stored integer value of a fixed-point input in hexadecimal format

If you select...	The block displays...
binary (Stored Integer)	The stored integer value of a fixed-point input in binary format
decimal (Stored Integer)	The stored integer value of a fixed-point input in decimal format
octal (Stored Integer)	The stored integer value of a fixed-point input in octal format

If the input to a Display block has an enumerated data type (see “Simulink Enumerations” and “Define Simulink Enumerations”):

- The block displays enumerated values, not the values of underlying integers.
- Setting **Format** to any of the `Stored Integer` settings causes an error.

Display Abbreviations

The following abbreviations appear on the Display block to help you identify the format of the value.

When you see...	The value that appears is...
(SI)	The stored integer value
	Note (SI) does not appear when the signal is of an integer data type.
hex	In hexadecimal format
bin	In binary format
oct	In octal format

Frequency of Data Display

The amount of data that appears and the time steps at which the data appears depend on the **Decimation** block parameter and the `SampleTime` property:

- The **Decimation** parameter enables you to display data at every n th sample, where n is the decimation factor. The default decimation, 1, displays data at every time step.

Note The Display block updates its display at the initial time, even when the **Decimation** value is greater than one.

- The `SampleTime` property, which you can set with `set_param`, enables you to specify a sampling interval at which to display points. This property is useful when you are using a variable-step solver where the interval between time steps is not the same. The default sample time, `-1`, causes the block to ignore the sampling interval when determining the points to display.

Note If the block inherits a sample time of `Inf`, the **Decimation** parameter is ignored.

Resizing Options

If the block input is an array, you can resize the block to show more than just the first element. You can resize the block vertically or horizontally. If the block input is a vector, the block sequentially adds display fields from left to right and top to bottom. The block displays as many values as possible. A black triangle indicates that the block is not displaying all input array elements.

The Display block shows the first 200 elements of a vector signal and the first 20 rows and 10 columns of a matrix signal.

Floating Display

To use the block as a floating display, select the **Floating display** check box. The block input port disappears and the block displays the value of the signal on a selected line.

If you select **Floating display**:

- Turn off signal storage reuse for your model. See “Signal storage reuse” in the Simulink documentation for more information.
- Do not connect a multidimensional signal to a floating display. Otherwise, you get a simulation error because the block does not support multidimensional signals.

Data Type Support

The Display block accepts real or complex signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean
- Enumerated

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Format

Specify the format of the data that appears, as discussed in “Format Options” on page 1-476. The default is `short`.

Decimation

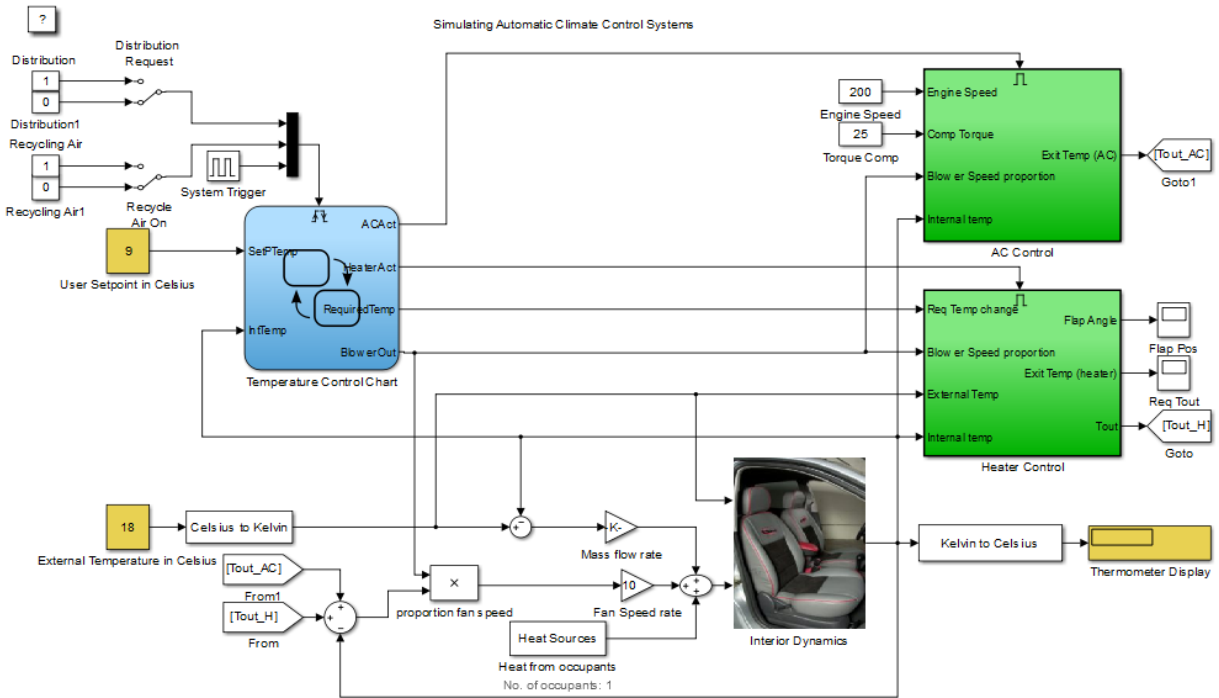

Specify how often to display data, as discussed in “Frequency of Data Display” on page 1-477. The default is 1.

Floating display

Select to use the block as a floating display, as discussed in “Floating Display” on page 1-478.

Examples

The `sldemo_auto_climatecontrol` model shows how you can use the Display block.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated
Sample Time	Use <code>set_param</code> to specify the <code>SampleTime</code> property
Multidimensional Signals	No
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	No

Scope

Introduced before R2006a

Divide

Divide one input by another

Library

Math Operations

Description

The Product and Product of Elements blocks are variants of the Divide block.

- For information on the Product block, see Product.
- For information on the Product of Elements block, see Product of Elements.

Supported Block Operations

The Divide block outputs the result of dividing its first input by its second. The inputs can be scalars, a scalar and a nonscalar, or two nonscalars that have the same dimensions. The Divide block is functionally a Product block that has two block parameter values preset:

- **Multiplication:** `Element-wise(.*)`
- **Number of Inputs:** `*/`

Setting non-default values for either of those parameters can change a Divide block to be functionally equivalent to a Product block or a Product of Elements block. See the documentation of those two blocks for more information.

Expected Differences Between Simulation and Code Generation

If any of the Divide block inputs contains a NaN or `inf` value, or if the block generates NaN or `inf` during execution, you might see different results when you compare the block simulation results with the generated code. This difference is due to the nonfinite NaN or `inf` values. In such cases, inspect your model configuration and eliminate the conditions that produce NaN or `inf`.

Code Optimizations

The Simulink Coder build process provides efficient code for matrix inverse and division operations. The following summary describes the benefits and when each benefit is available:

Benefit	Small matrices (2-by-2 to 5-by-5)	Medium matrices (6-by-6 to 20-by-20)	Large matrices (larger than 20-by-20)
Faster code execution time, compared to R2011a and earlier releases	Yes	No	Yes
Reduced ROM and RAM usage, compared to R2011a and earlier releases	Yes, for real values	Yes, for real values	Yes, for real values
Reuse of variables	Yes	Yes	Yes
Dead code elimination	Yes	Yes	Yes
Constant folding	Yes	Yes	Yes
Expression folding	Yes	Yes	Yes
Consistency with MATLAB Coder results	Yes	Yes	Yes

For blocks that have three or more inputs of different dimensions, the code might include an extra buffer to store temporary variables for intermediate results.

Parameters

Show data type assistant

Display the **Data Type Assistant**.

The **Data Type Assistant** helps you set the **Output data type** parameter.

For more information, see “Control Signal Data Types”.

Number of inputs

Control two properties of the block:

- The number of input ports on the block
- Whether each input is multiplied or divided into the output

Default: * /

- **1 or * or /**

Has one input. In element-wise mode, processes the input as described for the Product of Elements block. In matrix mode, if the parameter value is 1 or *, the block outputs the input value. If the value is /, the input must be a square matrix (including a scalar as a degenerate case) and the block outputs the matrix inverse. See “Element-wise Mode” on page 1-1176 and “Matrix Mode” on page 1-1177 for more information.

- **Integer value > 1**

Has the number of inputs given by the integer value. The inputs are multiplied together in element-wise mode or matrix mode, as specified by the **Multiplication** parameter. See “Element-wise Mode” on page 1-1176 and “Matrix Mode” on page 1-1177 for more information.

- **Unquoted string of two or more * and / characters**

Has the number of inputs given by the length of the character vector. Each input that corresponds to a * character is multiplied into the output. Each input that corresponds to a / character is divided into the output. The operations occur in

element-wise mode or matrix mode, as specified by the **Multiplication** parameter. See “Element-wise Mode” on page 1-1176 and “Matrix Mode” on page 1-1177 for more information.

Setting **Number of inputs** to * and selecting `Element-wise(.*)` for **Multiplication** enables the parameter **Multiply over**.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Multiplication

Specify whether the Product block operates in Element-wise mode or Matrix mode.

Default: `Element-wise(.*)`

`Element-wise(.*)`

Operate in Element-wise mode.

`Matrix(*)`

Operate in Matrix mode.

Selecting `Element-wise(.*)` and setting **Number of inputs** to * enable the following parameter:

- **Multiply over**

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Multiply over

Affect multiplication on matrix input.

Default: All dimensions

All dimensions

Output a scalar that is product of all elements of the matrix, or the product of their inverses, depending on the value of **Number of inputs**.

Specified dimension

Output a vector, the composition of which depends on the value of the **Dimension** parameter.

- Enable this parameter by selecting `Element-wise (.*)` for **Multiplication** and setting **Number of inputs** to `*` or `1` or `/`.
- Setting this parameter to `Specified dimension` enables the **Dimension** parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Dimension

Affect multiplication on matrix input.

Default: 1

Minimum: 1

Maximum: 2

1

Output a vector that contains an element for each column of the input matrix.

2

Output a vector that contains an element for each row of the input matrix.

Each element of the output vector contains the product of all elements in the corresponding column or row of the input matrix, or the product of the inverses of those elements, depending on the value of **Number of inputs**:

- 1 or *

Multiply the values of the column or row elements

- /

Multiply the inverses of the column or row elements

Enable this parameter by selecting `Specified` dimension for **Multiply over**.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Require all inputs to have the same data type

Require that all inputs have the same data type.

Default: Off

On

Require that all inputs have the same data type.

Off

Do not require that all inputs have the same data type.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

Default: Off

On

Locks the output data type setting for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change the output data type setting for this block.

Parameter: LockScale

Type: character vector

Value: 'off' | 'on'

Default: 'off'

For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Integer rounding mode

Specify the rounding mode for fixed-point operations.

Default: Floor

Ceiling

Rounds positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

Floor

Rounds positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

Simplest

Chooses between rounding toward floor and rounding toward zero to generate rounding code that is as efficient as possible.

Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

For more information, see “Rounding” (Fixed-Point Designer).

Saturate on integer overflow

Specify whether overflows saturate.

Default: Off

On

Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Off

Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.

- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Parameter: SaturateOnIntegerOverflow

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Output minimum

Lower value of the output range that Simulink checks.

Default: [] (unspecified)

Specify this number as a finite, real, double, scalar value.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Parameter: OutMin
Type: character vector
Value: ' [] '
Default: ' [] '

Output maximum

Upper value of the output range that Simulink checks.

Default: [] (unspecified)

Specify this number as a finite, real, double, scalar value.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Note **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Parameter: OutMax
Type: character vector
Value: ' [] '
Default: ' [] '

Output data type

Specify the output data type.

Default: `Inherit: Inherit via internal rule`

`Inherit: Inherit via internal rule`

Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use the simple choice of `Inherit: Same as first input`.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
- To specify your own inheritance rule, use `Inherit: Inherit via back propagation` and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.

`Inherit: Inherit via back propagation`

Use data type of the driving block.

`Inherit: Same as first input`

Use data type of the first input signal.

`double`

Output data type is double.

`single`

Output data type is single.

`int8`

Output data type is int8.

`uint8`

Output data type is uint8.

`int16`

Output data type is `int16`.

`uint16`

Output data type is `uint16`.

`int32`

Output data type is `int32`.

`uint32`

Output data type is `uint32`.

`fixdt(1,16,0)`

Output data type is fixed point `fixdt(1,16,0)`.

`fixdt(1,16,2^0,0)`

Output data type is fixed point `fixdt(1,16,2^0,0)`.

<data type expression>

Use a data type object, for example, `Simulink.NumericType`.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

For more information, see “Control Signal Data Types”.

Mode

Select the category of data to specify.

Default: `Inherit`

`Inherit`

Inheritance rules for data types. Selecting `Inherit` enables a second menu/text box to the right. Select one of the following choices:

- `Inherit` via internal rule (default)
- `Inherit` via back propagation
- Same as first input

Built in

Built-in data types. Selecting `Built in` enables a second menu/text box to the right. Select one of the following choices:

- `double` (default)
- `single`
- `int8`
- `uint8`
- `int16`
- `uint16`
- `int32`
- `uint32`

Fixed point

Fixed-point data types.

Expression

Expressions that evaluate to data types. Selecting `Expression` enables a second menu/text box to the right, where you can enter the expression.

Clicking the **Show data type assistant** button enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specify Data Types Using Data Type Assistant”.

Data type override

Specify data type override mode for this signal.

Default: `Inherit`

`Inherit`

Inherits the data type override setting from its context, that is, from the block, `Simulink.Signal` object or Stateflow chart in Simulink that is using the signal.

Off

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

This parameter appears only when the **Mode** is `Built in` or `Fixed point`.

Signedness

Specify whether you want the fixed-point data as signed or unsigned.

Default: Signed

Signed

Specify the fixed-point data as signed.

Unsigned

Specify the fixed-point data as unsigned.

Selecting **Mode** > `Fixed point` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Word length

Specify the bit size of the word that holds the quantized integer.

Default: 16

Minimum: 0

Maximum: 32

Selecting **Mode** > `Fixed point` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

Default: `Best precision`

`Binary point`

Specify binary point location.

`Slope and bias`

Enter slope and bias.

`Best precision`

Specify best-precision values.

Selecting **Mode** > `Fixed point` enables this parameter.

Selecting `Binary point` enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting `Slope and bias` enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

For more information, see “Specifying a Fixed-Point Data Type”.

Fraction length

Specify fraction length for fixed-point data type.

Default: 0

Binary points can be positive or negative integers.

Selecting **Scaling** > `Binary point` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Slope

Specify slope for the fixed-point data type.

Default: 2^0

Specify any positive real number.

Selecting **Scaling** > `Slope and bias` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Bias

Specify bias for the fixed-point data type.

Default: 0

Specify any real number.

Selecting **Scaling** > `Slope and bias` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Examples

The following examples show the output of the Divide block for some typical inputs using default block parameter values.

Introduced before R2006a

DocBlock

Create text that documents model and save text with model

Library

Model-Wide Utilities

Description

The DocBlock allows you to create and edit text that documents a model, and save that text with the model. Double-clicking an instance of the block creates a temporary file containing the text associated with this block and opens the file in an editor. Use the editor to modify the text and save the file. Simulink software stores the contents of the saved file in the model file.

The DocBlock supports HTML, Rich Text Format (RTF), and ASCII text document types. The default editors for these different document types are

- HTML — Microsoft® Word (if available). Otherwise, the DocBlock opens HTML documents using the editor specified on the **Editor/Debugger Preferences** pane of the Preferences dialog box.
- RTF — Microsoft Word (if available). Otherwise, the DocBlock opens RTF documents using the editor specified on the **Editor/Debugger Preferences** pane of the Preferences dialog box.
- Text — The DocBlock opens text documents using the editor specified on the **Editor/Debugger Preferences** pane of the Preferences dialog box.

Use the `docblock` command to change the default editors.

Data Type Support

Not applicable.

Parameters

Code generation template symbol (Embedded Coder license required)

Enter a template symbol name in this field. Embedded Coder software uses this symbol to add comments to the code generated from the model. For more information, see “Add Global Comments” (Embedded Coder).

Document type

Select the type of document associated with the DocBlock. The options are:

- Text (the default)
- RTF
- HTML

Note If you are using a DocBlock to add comments to your code during code generation, ensure that you set the **Document Type** as Text. If you set the **Document Type** as RTF or HTML, your comments will not appear in the code.

Characteristics

Data Types	Not applicable
Multidimensional Signals	No
Variable-Size Signals	No
Code Generation	Yes

Introduced before R2006a

Dot Product

Generate dot product of two vectors

Library

Math Operations

Description

The Dot Product block generates the dot product of the vectors at its inputs. The scalar output, y , is equal to the MATLAB operation

$$y = \text{sum}(\text{conj}(u1) .* u2)$$

where $u1$ and $u2$ represent the vectors at the block's top and bottom inputs, respectively. (See “Port Location After Rotating or Flipping” in the Simulink documentation for a description of the port order for various block orientations.) The inputs can be vectors, column vectors (single-column matrices), or scalars. If both inputs are vectors or column vectors, they must be the same length. If $u1$ and $u2$ are both column vectors, the block outputs the equivalent of the MATLAB expression $u1' * u2$.

The elements of the input vectors can be real- or complex-valued signals. The signal type (complex or real) of the output depends on the signal types of the inputs.

Input 1	Input 2	Output
real	real	real
real	complex	complex
complex	real	complex

Input 1	Input 2	Output
complex	complex	complex

To perform element-by-element multiplication without summing, use the Product block.

Data Type Support

The Dot Product block accepts and outputs signals of any numeric data type that Simulink supports, including fixed-point data types.

For more information, see “Data Types Supported by Simulink”.

Parameters

Require all inputs to have same data type

Select to require all inputs to have the same data type.

Output minimum

Specify the minimum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Output maximum

Specify the maximum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as

SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Output data type

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” for more information.

Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer). in the Fixed-Point Designer documentation.

Saturate on integer overflow

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box.	<p>You want to optimize efficiency of your generated code.</p> <p>You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.</p>	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. Usually, the code generation process can detect

when overflow is not possible. In this case, the code generator does not produce saturation code.

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Product

Introduced before R2006a

Dual Port RAM

Dual port RAM with two output ports

Library

HDL Coder / HDL Operations

Description

The Dual Port RAM block models a RAM that supports simultaneous read and write operations, and has both a read data output port and write data output port. You can use this block to generate HDL code that maps to RAM in most FPGAs.

If you do not need to use the write output data, `wr_dout`, you can achieve better RAM inference with synthesis tools by using the Simple Dual Port RAM block.

Read-During-Write Behavior

During a write, new data appears at the output of the write port (`wr_dout`) of the Dual Port RAM block. If a read operation occurs simultaneously at the same address as a write operation, old data appears at the read output port (`rd_dout`).

Parameters

Address port width

Address bit width. Minimum bit width is 2, and maximum bit width is 29. The default is 8.

Ports

The block has the following ports:

`wr_din`

Write data input. The data can be any width. It inherits the width and data type from the input signal.

Data type: scalar fixed point, integer, or complex

`wr_addr`

Write address.

Data type: scalar unsigned integer (`uintN`) or unsigned fixed point (`ufixN`) with a fraction length of 0

`wr_en`

Write enable.

Data type: Boolean

`rd_addr`

Read address.

Data type: scalar unsigned integer (`uintN`) or unsigned fixed point (`ufixN`) with a fraction length of 0

`wr_dout`

Output data from write address, `wr_addr`.

`rd_dout`

Output data from read address, `rd_addr`.

Dual Rate Dual Port RAM | Simple Dual Port RAM | Single Port RAM

Introduced in R2014a

Dual Rate Dual Port RAM

Dual Port RAM that supports two rates

Library

HDL Coder / HDL Operations

Description

The Dual Rate Dual Port RAM block models a RAM that supports simultaneous read and write operations to different addresses at two clock rates. Port A of the RAM can run at one rate, and port B can run at a different rate.

In high-performance hardware applications, you can use this block to access the RAM twice per clock cycle. If you generate HDL code, this block maps to a dual-clock dual-port RAM in most FPGAs.

Simultaneous Access

You can access different addresses from ports A and B simultaneously. You can also read the same address from ports A and B simultaneously.

However, do not access an address from one RAM port while it is being written from the other RAM port. During simulation, if you access an address from one RAM port at the same time as you write that address from the other RAM port, the software reports an error.

Read-During-Write Behavior

The RAM has write-first behavior. When you write to the RAM, the new write data is immediately available at the output port.

HDL Code Generation

For simulation results that match the generated HDL code, in the Solver pane of the Configuration Parameters dialog box, clear the checkbox for **Treat each discrete rate as a separate task**. When the checkbox is cleared, single-tasking mode is enabled.

If you simulate this block with **Treat each discrete rate as a separate task** selected, multitasking mode is enabled. The output data can update in the same cycle but in the generated HDL code, the output data is updated one cycle later.

Parameters

Address port width

Address bit width. Minimum bit width is 2, and maximum bit width is 28. The default value is 8.

Ports

The block has the following ports:

`din_A`

Write data input for RAM port A. The data can be any width. It inherits the width and data type from the input signal.

Data type: scalar fixed point, integer, or complex

`addr_A`

Write address for RAM port A.

Data type: scalar unsigned integer (`uintN`) or unsigned fixed point (`ufixN`) with a fraction length of 0

`we_A`

Write enable for RAM port A. Set `we_A` to `true` for a write operation, or `false` for a read operation.

Data type: Boolean

`din_B`

Write data input for RAM port B. The data can be of any width, and inherits the width and data type from the input signal.

Data type: scalar fixed point, integer, or complex

`addr_B`

Write address for RAM port B.

Data type: scalar unsigned integer (`uintN`) or unsigned fixed point (`ufixN`) with a fraction length of 0

`we_B`

Write enable for RAM port B. Set `we_B` to `true` for a write operation, or `false` for a read operation.

Data type: Boolean

`dout_A`

Output data from RAM port A address, `addr_A`.

`dout_B`

Output data from RAM port B address, `addr_B`.

Dual Port RAM | HDL FIFO | Simple Dual Port RAM | Single Port RAM

Introduced in R2014a

Dual Port RAM System, Simple Dual Port RAM System, Single Port RAM System

RAM blocks based on the `hdl.RAM` system object with ability to provide initial value

Library: HDL Coder / HDL RAMs / Dual Port RAM System
 HDL Coder / HDL RAMs / Simple Dual Port RAM System
 HDL Coder / HDL RAMs / Single Port RAM System

Description

The blocks are MATLAB System blocks that use the `hdl.RAM System` object™. You can specify the RAM type as `Dual port`, `Simple dual port`, or `Single port`. In terms of simulation behavior, the Dual Port RAM System block behaves similar to the Dual Port RAM, the Single Port RAM System behaves similar to the Single Port RAM, and so on. With the MATLAB System blocks, you can:

- Specify an initial value for the RAM. In the Block Parameters dialog box, enter a value for **Specify the RAM initial value**.
- Obtain faster simulation results when you use these blocks in your Simulink model.

Ports

Input

din — Write data input
 Scalar (default) | Vector

Data that you write into the RAM memory location when `wrEn` is true. This value can be double, single, integer, or a fixed-point (`fi`) object, and can be real or complex.

Data Types: `single` | `double` | `int8` | `int16` | `uint8` | `uint16` | `fixed point`

addr — Write or Read address

Scalar (default) | Vector

Address that you write the data into when `wrEn` is true. The RAM reads the value in memory location **addr** when `wrEn` is false. This value can be either fixed-point (`fi`) or integer, and must be real and unsigned.

Dependencies

To enable this port, set the **Specify the type of RAM** parameter to `Single port`.

Data Types: `uint8` | `uint16` | `fixed point`

wr_addr — Write address

Scalar (default) | Vector

RAM address that you write the data into. This value can be either fixed-point (`fi`) or integer, and must be real and unsigned.

Dependencies

To enable this port, set the **Specify the type of RAM** parameter to `Simple dual port` or `Dual port`.

Data Types: `uint8` | `uint16` | `fixed point`

wr_en — Write enable

Scalar (default) | Vector

When `wrEn` is true, the RAM writes the data into the memory location that you specify. If you set the **Specify the type of RAM** to `Single port`, the RAM reads the value in the memory location **addr** when `wrEn` is false.

Data Types: `Boolean`

rd_addr — Read address

Scalar (default) | Vector

Address that you read the data from the RAM. This value can be either `fixed-point` (`fi`) or `integer`, and must be real and unsigned.

Dependencies

To enable this port, set the **Specify the type of RAM** parameter to `Simple dual port` or `Dual port`.

Data Types: `uint8` | `uint16` | `fixed point`

Output

`dout` — Output data

`Scalar` (default) | `Vector`

Output data that the RAM reads from the memory location `addr` when `wrEn` is false.

Dependencies

To enable this port, set the **Specify the type of RAM** parameter to `Single port`.

`rd_dout` — Read data

`Scalar` (default) | `Vector`

Old output data that the RAM reads from the memory location `rd_addr`.

Dependencies

To enable this port, set the **Specify the type of RAM** parameter to `Simple dual port` or `Dual port`.

`wr_dout` — Write data output

`Scalar` (default) | `Vector`

New or old output data that the RAM reads from the memory location `wr_addr`.

Dependencies

To enable this port, set the **Specify the type of RAM** parameter to `Dual port`.

Parameters

Specify the type of RAM — RAM type

Dual port (default) | Simple dual port | Single port

Type of RAM, specified as either:

- `Single port` — Create a single port RAM with Write data, Address, and Write enable as inputs and Read data as the output.
- `Simple dual port` — Create a simple dual port RAM with Write data, Write address, Write enable, and Read address as inputs and data from read address as the output.
- `Dual port` — Create a dual port RAM with Write data, Write address, Write enable, and Read address as inputs and data from read address and write address as the outputs.

The code generator dynamically configures the input and output ports of the block based on the RAM type that you specify.

Specify the output data for a write operation — Write output behavior

New data (default) | Old data

Behavior for Write output, specified as either:

- `'New data'` — Send out new data at the address to the output.
- `'Old data'` — Send out old data at the address to the output.

Specify the RAM initial value — Initial simulation output of RAM

'0.0' (default) | Scalar | Vector

Initial simulation output of the System object, specified as either:

- A scalar value.
- A vector with one-to-one mapping between the initial value and the RAM words.

Block Characteristics

Data Types	double single base integer fixed point bus
Sample Time	Inherit
Direct Feedthrough	Yes
Multidimensional Signals	Scalar
Variable-Size Signals	Yes
Zero-Crossing Detection	No

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

If have HDL Coder installed, you can generate HDL code for the blocks. For more information, see Dual Port RAM System, Simple Dual Port RAM System, and Single Port RAM System.

Fixed-Point Conversion

Design and simulate fixed-point algorithms using Fixed-Point Designer™.

Edit

Enter new value for parameter

Library: Simulink / Dashboard

Description

The Edit block allows you to type in new values for block parameters during simulation. Use the Edit block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model.

Double-clicking the Edit block does not open its dialog box during simulation and when the block is selected. To edit the block's parameters, you can use the **Property Inspector**, or you can right-click the block and select **Block Parameters** from the context menu.

Connection

Dashboard block controls connect to variables and block parameters. To connect a Dashboard block to a variable or parameter, use the **Connection** table in the block's parameters.

- 1 Double-click the block.
- 2 Populate the **Connection** table by selecting blocks of interest in your model.
- 3 Mark the option button next to the parameter or variable you want to adjust during simulation.
- 4 Click **Apply**.

Limitations

- You cannot save the block connections or properties in model files that use the MDL format.

To save connections and properties, save the model file in the SLX format.

- Dashboard blocks can only connect to real scalar signals.
- Dashboard blocks cannot connect to blocks that are commented out.
- Dashboard blocks cannot connect to signals inside reference models.
- Parameters specified by indexing a variable array do not appear in the **Connection** table. For example, a block parameter defined using the variable `engine(1)` does not appear in the table.

To access the parameter in the **Connection** table, assign the indexed value to a scalar variable, such as `engine_1`. Then, use the scalar variable to define the block parameter.

Parameters

Connection — Select a block parameter to connect

signal connection options

Select the block parameter to control using the **Connection** table. To open the dialog box, double-click the block. Then, populate the **Connection** table by selecting a block in your model. Select the variable parameter you want to control, and click **Apply**.

Note To see workspace variables in the connection table, update the model diagram with **Ctrl+D**.

Align — Text alignment

'Center' (default) | 'Left' | 'Right'

Alignment of the text in the Edit block.

Label — Block label position

'Top' (default) | 'Bottom' | 'Hide'

Position of the block label. When the block is connected to a signal, the label is the name of the connected signal. When the block is not connected, the label is the instructional text.

Enable

Add enable port to subsystem or model

Library: Ports & Subsystems

Description

The Enable block allows an external signal to control execution of a subsystem or a model. To enable this functionality, add the block to a Subsystem block or at the root level of a model that is referenced in a Model block.

If you use an enable port at the root-level of a model:

- For multi-rate models, set the solver to single-tasking.
- For models with a fixed-step size, at least one block in the model must run at the specified fixed-step size rate.

Ports

Output

Enable signal — External enable signal for a subsystem or model

scalar

Enable signal attached externally to the outside of an Enable Subsystem block and passed to the inside of the subsystem. An enable signal port is added to an Enable block when you select the **Show output port** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `expression`

Parameters

States when enabling — Select block states when subsystem or model is disabled

held (default) | reset

When a Subsystem block or Model block is disabled, select what happens to block states for the blocks within the subsystem or model.

held

Hold block states at their previous values.

reset

Reset block states to their initial conditions (zero if not defined).

Programmatic Use

Block parameter: StatesWhenEnabling

Type: character vector

Value: 'held' | 'reset'

Default: 'held'

Propagate sizes of variable-size signals — Select when to propagate a variable-size signal

Only when enabling (default) | During execution

Select when to propagate a variable-size signal.

Only when enabling

Propagate a variable-size signal when reenabling a Subsystem block or Model block containing an Enable port block. When you select this option, sample time must be periodic.

During execution

Propagate variable-size signals at each time step.

Programmatic Use

Block parameter: PropagateVarSize

Type: character vector

Value: 'Only when enabling' | 'During execution'

Default: 'Only when enabling'

Show output port — Control display of output port for enable signal

off (default) | on

The output port passes the enable signal attached externally to the outside of an Enable Subsystem block or enabled Model block to the inside.

off

Remove the output port on the Enable port block.

on

Display an output port on the Enable port block. Selecting this option allows the subsystem or model to process the enable signal.

Programmatic Use

Block parameter: ShowOutputPort

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Enable zero-crossing detection — Control zero-crossing detection

on (default) | off

Control zero-crossing detection for a model.

on

Detect zero crossings.

off

Do not detect zero crossings.

Programmatic Use

Block parameter: ZeroCross

Type: character vector

Value: 'on' | 'off'

Default: 'on'

Port dimensions — Specify dimensions for the enable signal

1 (default) | [n] | [m n]

Specify dimensions for the enable signal attached externally to a Model block and passed to the inside of the block.

1

Scalar signal.

[n]

Vector signal of width n.

[m n]

Matrix signal having m rows and n columns.

Programmatic Use

Block parameter: PortDimensions

Type: character vector

Value: '1' | '[n]' | '[m n]'

Default: '1'

Sample time — Specify time interval

-1 (default) | Ts | [Ts, To]

Specify time interval between block method execution. See “Specify Sample Time”.

-1

Sample time inherited from the model.

Ts

Scalar where Ts is the time interval.

[Ts, To]

Vector where Ts is the time interval and To is the initial time offset.

Programmatic Use

Block parameter: SampleTime

Type: character vector

Value: '-1' | 'Ts' | '[Ts, To]'

Default: '-1'

Minimum — Specify minimum output value for the enable signal

[] (default) | real scalar

Specify minimum value for the enable signal attached externally to a Model block and passed to the inside of the block.

Simulink uses this value to perform:

- Simulation range checking. See “Signal Ranges”.
- Automatic scaling of fixed-point data types.
- Optimization of generated code. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. See “Optimize using the specified minimum and maximum values”.

[]

Unspecified minimum value.

real scalar

Real double scalar value.

Programmatic Use

Block parameter: OutMin

Type: character vector

Value: '[]' | '<real scalar>'

Default: '[]'

Maximum — Specify maximum output value for the enable signal

[] (default) | real scalar

Specify maximum value for the enable signal attached externally to a Model block and passed to the inside of the block.

Simulink uses this value to perform:

- Simulation range checking. See “Signal Ranges”.
- Automatic scaling of fixed-point data types.
- Optimization of generated code. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. See “Optimize using the specified minimum and maximum values”.

[]

Unspecified maximum value.

real scalar

Real double scalar value.

Programmatic Use

Block parameter: OutMax

Type: character vector

Value: '[]' | '<real scalar>'

Default: '[]'

Data type — Specify output data type for the enable signal

double (default) | single | int8 | uint8 | int16 | uint16 | int32 | uint32 |
boolean | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^,0) | <data type
expression>

Specify data type for the enable signal attached externally to a Model block and passed to the inside of the block.

double

Double-precision floating point.

single

Single-precision floating point.

int8

Signed 8-bit integer.

uint8

Unsigned 8-bit integer.

int16

Signed 16-bit integer.

uint16

Unsigned 16-bit integer.

int32

Signed 32-bit integer.

uint32

Unsigned 32-bit integer.

boolean

Boolean with a value of true or false.

fixdt(1,16)

Signed 16-bit fixed point number with binary point undefined.

fixdt(1,16,0)

Signed 16-bit fixed point number with binary point set to zero.

```
fixdt(1,16,2^0)
```

Signed 16-bit fixed point number with slope set to 2^0 and bias set to 0.

```
<data type expression>
```

Data type object, for example `Simulink.NumericType`. Do not specify a bus object as the expression.

Programmatic Use

b

Block parameter: `OutDataTypeStr`

Type: character vector

Value: `'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'boolean' | '<fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'`

Default: `'double'`

Mode — Select data type category

```
Build in (default) | Fixed point | Expression
```

Select data type category and display drop-down lists to help you define the data type.

Build in

Display drop-down lists for data type and Data type override.

Fixed point

Display drop-down lists for Signedness, Scaling, and Data type override.

Expression

Display text box for entering an expression.

Dependency

To enable this parameter, select the Show data type assistant button.

Programmatic Use

No equivalent command-line parameter.

Interpolate data — Specify value of missing workspace data

```
on (default) | off
```

Specify value of missing workspace data when loading data from the workspace.

on

Linearly Interpolate output at time steps for which no corresponding workspace data exists.

off

Do not interpolate output at time steps. The current output equals the output at the most recent time step for which data exists.

Programmatic Use

Block parameter: Interpolate

Type: character vector

Value: 'on' | 'off'

Default: 'on'

Introduced before R2006a

Enabled and Triggered Subsystem

Subsystem whose execution is enabled and triggered by external input

Library: Ports & Subsystems

Description

The Enabled and Triggered Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem that executes when both of these conditions occur:

- Enable control signal has a positive value.
- Trigger control signal has a trigger event.

Use Enabled and Triggered Subsystem blocks to model:

- Optional functionality that runs with the detection of an event.
- Alternative functionality that runs with the detection of an event.

Ports

Input

In — Signal input to a subsystem block

scalar | vector | matrix

Placing an Inport block in a subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Enable — Control signal input to a subsystem block

scalar

Placing an Enable block in a subsystem block adds an external input port to the block.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Trigger — Control signal input to a subsystem block

scalar

Placing a Trigger block in a subsystem block adds an external input port to the block.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

out — Signal output from a subsystem

scalar | vector | matrix

Placing an Outport block in a subsystem block adds an output port from the block. The port label on the subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Enable — Control signal input to a subsystem block

scalar | vector | matrix

Placing an Enable block in a subsystem block adds an external input port to the block and changes the block to an Enable Subsystem block.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

Output

Out — Signal output from a subsystem

scalar | vector | matrix

Placing an Outport block in a subsystem block adds an output port from the block. The port label on the subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated | bus

Enabled Synchronous Subsystem

Represent enabled subsystem that has synchronous reset and enable behavior

Library

HDL Coder / HDL Subsystems

Description

An Enabled Synchronous Subsystem is an Enabled Subsystem that uses the Synchronous mode of the State Control block. If an **S** symbol appears in the subsystem, then it is synchronous.

To create an Enabled Synchronous Subsystem block, add the block to your Simulink model from the HDL Subsystems block library. You can also add a State Control block with **State control** set to *Synchronous* inside an Enabled subsystem.

For more information, see State Control and “Enabled Subsystems”.

Data Type Support

See Inport for information on the data types accepted by a subsystem's input ports. See Outport for information on the data types output by a subsystem's output ports.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Show port labels

Cause Simulink software to display labels for the subsystem's ports on the subsystem's icon.

Default: `FromPortIcon`

`none`

Does not display port labels on the subsystem block.

`FromPortIcon`

If the corresponding port icon displays a signal name, display the signal name on the subsystem block. Otherwise, display the port block's name.

`FromPortBlockName`

Display the name of the corresponding port block on the subsystem block.

`SignalName`

If a name exists, display the name of the signal connected to the port on the subsystem block; otherwise, the name of the corresponding port block.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Read/Write permissions

Control user access to the contents of the subsystem.

Default: `ReadWrite`

`ReadWrite`

Enables opening and modification of subsystem contents.

`ReadOnly`

Enables opening but not modification of the subsystem. If the subsystem resides in a block library, you can create and open links to the subsystem and can make and

modify local copies of the subsystem but cannot change the permissions or modify the contents of the original library instance.

`NoReadOrWrite`

Disables opening or modification of subsystem. If the subsystem resides in a library, you can create links to the subsystem in a model but cannot open, modify, change permissions, or create local copies of the subsystem.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Name of error callback function

Enter name of a function to be called if an error occurs while Simulink software is executing the subsystem.

Default: ' '

Simulink software passes two arguments to the function: the handle of the subsystem and a character vector that specifies the error type. If no function is specified, Simulink software displays a generic error message if executing the subsystem causes an error.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Permit hierarchical resolution

Specify whether to resolve names of workspace variables referenced by this subsystem.

Default: All

All

Resolve all names of workspace variables used by this subsystem, including those used to specify block parameter values and Simulink data objects (for example, `Simulink.Signal` objects).

`ExplicitOnly`

Resolve only names of workspace variables used to specify block parameter values, data store memory (where no block exists), signals, and states marked as “must resolve”.

None

Do not resolve any workspace variable names.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Treat as atomic unit

Causes Simulink software to treat the subsystem as a unit when determining the execution order of block methods.

Default: Off

On

Cause Simulink software to treat the subsystem as a unit when determining the execution order of block methods. For example, when it needs to compute the output of the subsystem, Simulink software invokes the output methods of all the blocks in the subsystem before invoking the output methods of other blocks at the same level as the subsystem block.

Off

Cause Simulink software to treat all blocks in the subsystem as being at the same level in the model hierarchy as the subsystem when determining block method execution order. This can cause execution of methods of blocks in the subsystem to be interleaved with execution of methods of blocks outside the subsystem.

This parameter enables:

- “Minimize algebraic loop occurrences” on page 1-0 .
- “Sample time” on page 1-0
- “Function packaging” on page 1-0 (requires a Simulink Coder license)

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Treat as grouped when propagating variant conditions

Causes Simulink software to treat the subsystem as a unit when propagating variant conditions from Variant Source blocks or to Variant Sink blocks.

Default: On

On

Simulink treats the subsystem as a unit when propagating variant conditions from Variant Source blocks or to Variant Sink blocks. For example, when Simulink computes the variant condition of the subsystem, it propagates that condition to all the blocks in the subsystem.

Off

Simulink treats all blocks in the subsystem as being at the same level in the model hierarchy as the subsystem itself when determining their variant condition.

“Treat as grouped when propagating variant conditions” on page 1-0 enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Function packaging

Specify the code format to be generated for an atomic (nonvirtual) subsystem.

Default: Auto

Auto

Simulink Coder software chooses the optimal format for you based on the type and number of instances of the subsystem that exist in the model.

Inline

Simulink Coder software inlines the subsystem unconditionally.

Nonreusable function

Simulink Coder software explicitly generates a separate function in a separate file. Subsystems with this setting generate functions that might have arguments

depending on the “Function interface” on page 1-0 parameter setting. You can name the generated function and file using parameters “Function name” on page 1-0 and “File name (no extension)” on page 1-0 . These functions are not reentrant.

Reusable function

Simulink Coder software generates a function with arguments that allows reuse of subsystem code when a model includes multiple instances of the subsystem.

This option also generates a function with arguments that allows subsystem code to be reused in the generated code of a model reference hierarchy that includes multiple instances of a subsystem across referenced models. In this case, the subsystem must be in a library.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated Bus

Introduced in R2016a

Enumerated Constant

Generate enumerated constant value

Library

Sources

Description

The Enumerated Constant block outputs a scalar, array, or matrix of enumerated values. You can also use the Constant block to output enumerated values, but it provides block parameters that do not apply to enumerated types, such as **Output minimum** and **Output maximum**. When you need a block that outputs only constant enumerated values, preferably use Enumerated Constant rather than Constant. For more information, see “Simulink Enumerations”.

Data Type Support

The Enumerated Constant block supports only enumerated data types. Use the Constant block to output constant data of other types. For more information, see “Data Types Supported by Simulink”.

Parameters

Output data type

The **Output data type** field specifies the enumerated type from which you want the block to output one or more values. The initial value, Enum: SlDemoSign, is a dummy

enumerated type that prevents a newly cloned block from causing an error. To specify the desired enumerated type, select it from the pulldown or enter `Enum: ClassName` in the **Output data type** field, where *ClassName* is the name of the MATLAB class that defines the type.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Value

The **Value** field specifies the value(s) that the block outputs. The output of the block has the same dimensions and elements as the **Value** parameter. The initial value, `SlDemoSign.Positive`, is a dummy enumerated value that prevents a newly cloned block from causing an error.

To specify the desired enumerated value(s), select from the pulldown or enter any MATLAB expression that evaluates to the desired result, including an expression that uses tunable parameters. All values specified must be of the type indicated by the **Output data type**. To specify an array that includes every value in the enumerated type, use the `enumeration` function.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Sample time

Specify the interval between times that the Constant block output can change during simulation (for example, due to tuning the **Constant value** parameter).

Default: `inf`

This setting indicates that the block output can never change. This setting speeds simulation and generated code by avoiding the need to recompute the block output. See “Specify Sample Time” for more information.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Characteristics

Data Types	Enumerated
Sample Time	Specified in the Sample time parameter
Direct Feedthrough	Not applicable
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

“Simulink Enumerations”

Introduced in R2009b

Environment Controller

Create branches of block diagram that apply only to simulation or only to code generation

Library

Signal Routing

Description

This block outputs the signal at its Sim port only if the model that contains it is being simulated. It outputs the signal at its Coder port only if code is being generated from the model. This option enables you to create branches of a block diagram that apply only to simulation or code generation. The table below describes various scenarios where either the Sim or Coder port applies.

Scenario	Output
Normal mode simulation	Sim
Accelerator mode simulation	Sim
Rapid Accelerator mode simulation	Sim
Simulation of a referenced model (Normal or Accelerator modes)	Sim
Simulation of a referenced model (Processor-in-the-loop (PIL) mode)	Coder (uses the same code generated for a referenced model)
External mode simulation	Coder
Standard code generation	Coder
Code generation of a referenced model	Coder

Simulink Coder software does not generate code for blocks connected to the Sim port if these conditions hold:

- On the **Optimization > Signals and Parameters** pane of the Configuration Parameters dialog box, you set **Default parameter behavior** to `Inlined`.
- The blocks connected to the Sim port do not have external signals.
- The Sim port input path does not contain an S-function or an Interpreted MATLAB Function block.

If you enable block reduction optimization, Simulink eliminates blocks in the branch connected to the Coder port when compiling the model for simulation. For information about block reduction, see “Block reduction” in the online Simulink documentation.

Note Simulink Coder code generation eliminates the blocks connected to the Sim branch only if the Sim branch has the same signal dimensions as the Coder branch. Regardless of whether it eliminates the Sim branch, Simulink Coder uses the sample times on the Sim branch as well as the Coder branch to determine the fundamental sample time of the generated code and might, in some cases, generate sample-time handling code that applies only to sample times specified on the Sim branch.

Data Type Support

The Environment Controller block accepts signals of any data type that Simulink supports. The output uses the same data type as the input.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated Bus
Multidimensional Signals	Yes
Variable-Size Signals	No
Code Generation	Yes

Introduced before R2006a

Event Listener

Add event port to a subsystem block

Library: Ports & Subsystems

Description

Add event port to a Subsystem block.

Parameters

Event type — Select event type for subsystem

`Initialize` (default) | `Terminate` | `Reset`

Select event type for subsystem to execute initialize, reset, or terminate algorithms.

`Initialize`

Select to trigger the execution of an Initialize Function block with an initialize event.

`Terminate`

Select to trigger the execution of a Terminate Function block with a terminate event.

`Reset`

Select to trigger the execution of an Initialize Function block reconfigured as a Reset Function block with a reset event.

Programmatic Use

Parameter: `EventType`

Type: character vector

Value: `'Initialize'` | `'Terminate'` | `'Reset'`

Default: `'Initialize'`

Event name — Specify event name

`Reset` (default) | event name

Specify event name for Reset Function block

Reset

Default name on the face of the Reset Function block.

event name

User entered name displayed on the face of the Reset Function block, and the name of the reset event port on the Model block containing the Reset Function block.

When typing the name for a reset function, the auto-completion list provides some suggestions. The list is not complete.

Dependency

To enable this parameter, set the **Event** parameter to `Reset`.

Programmatic Use

Parameter: `EventName`

Type: character vector

Value: `'reset' | '<event name>'`

Default: `'reset'`

Enable variant condition — Control activating the variant control (condition)

`off` (default) | `on`

Control activating the variant control (condition) defined with the **Variant Control** parameter.

off

Deactivate variant control of subsystem.

on

Activate variant control of subsystem.

Dependency

Selecting this parameter, enables the **Variant control** and **Generate preprocessor conditionals** parameters.

Programmatic Use

Parameter: `Variant`

Type: character vector

Value: `'off' | 'on'`

Default: 'off'

Variant control — Specify variant control (condition) expression

Variant (default) | logical expression

Specify variant control (condition) expression that executes a variant Initialize function, Reset function, or Terminate function block when the expression evaluates to true.

Variant

Default name for a logical (Boolean) expression.

logical expression

A logical (Boolean) expression or a Simulink.Variant object representing a boolean expression.

If you want to generate code for your model, define the variables in the expression as Simulink.Parameter objects.

Dependency

To enable this parameter, select the **Enable variant condition** parameter.

Programmatic Use

Parameter: VariantControl

Type: character vector

Value: 'Variant' | '<logical expression>'

Default: 'Variant'

Generate preprocessor conditionals — Select if variant choices are enclosed within C preprocessor conditional statements

off (default) | on

Select if variant choices are enclosed within C preprocessor conditional statements.

off

Does not enclose variant choices within C preprocessor conditional statements.

on

When generating code for an ERT target, encloses variant choices within C preprocessor conditional statements (#if).

Dependency

To enable this parameter, select the **Enable variant condition** parameter.

Programmatic Use

Parameter: `GeneratePreprocessorConditionals`

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Extract Bits

Output selection of contiguous bits from input signal

Library

Logic and Bit Operations

Description

The Extract Bits block allows you to output a contiguous selection of bits from the stored integer value of the input signal. Use the **Bits to extract** parameter to define the method for selecting the output bits.

- Select `Upper half` to output the half of the input bits that contain the most significant bit. If there is an odd number of bits in the input signal, the number of output bits is given by the equation

$$\text{number of output bits} = \text{ceil}(\text{number of input bits}/2)$$

- Select `Lower half` to output the half of the input bits that contain the least significant bit. If there is an odd number of bits in the input signal, the number of output bits is given by the equation

$$\text{number of output bits} = \text{ceil}(\text{number of input bits}/2)$$

- Select `Range starting with most significant bit` to output a certain number of the most significant bits of the input signal. Specify the number of most significant bits to output in the **Number of bits** parameter.
- Select `Range ending with least significant bit` to output a certain number of the least significant bits of the input signal. Specify the number of least significant bits to output in the **Number of bits** parameter.

- Select `Range of bits` to indicate a series of contiguous bits of the input to output in the **Bit indices** parameter. You indicate the range in `[start end]` format, and the indices of the input bits are labeled contiguously starting at 0 for the least significant bit.

This block does not report wrap on overflow warnings during simulation. To report these warnings, see the `Simulink.restoreDiagnostic` reference page. The block does report errors due to wrap on overflow.

Data Type Support

The Extract Bits block accepts inputs of any numeric data type that Simulink supports, including fixed-point data types. Floating-point inputs are passed through the block unchanged. Boolean inputs are treated as `uint8` signals.

Note Performing bit operations on a signed integer is difficult. You can avoid difficulty by converting the data type of your input signals to unsigned integer types.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Bits to extract

Select the method for extracting bits from the input signal.

Number of bits

(Not shown on dialog above.) Select the number of bits to output from the input signal. Signed integer data types can have no less than two bits in them. Unsigned data integer types can be as short as a single bit.

This parameter is only visible if you select `Range starting with most significant bit` or `Range ending with least significant bit` for the **Bits to extract** parameter.

Bit indices

(Not shown on dialog above.) Specify a contiguous range of bits of the input signal to output. Specify the range in `[start end]` format. The indices are assigned to the input bits starting with 0 at the least significant bit.

This parameter is only visible if you select `Range of bits` for the **Bits to extract** parameter.

Output scaling mode

Select the scaling mode to use on the output bits selection:

- When you select `Preserve fixed-point scaling`, the fixed-point scaling of the input is used to determine the output scaling during the data type conversion.
- When you select `Treat bit field as an integer`, the fixed-point scaling of the input is ignored, and only the stored integer is used to compute the output data type.

Example

Consider an input signal that is represented in binary by 110111001:

- If you select `Upper half` for the **Bits to extract** parameter, the output is 11011 in binary.
- If you select `Lower half` for the **Bits to extract** parameter, the output is 11001 in binary.
- If you select `Range starting with most significant bit` for the **Bits to extract** parameter, and specify 3 for the **Number of bits** parameter, the output is 110 in binary.
- If you select `Range ending with least significant bit` for the **Bits to extract** parameter, and specify 8 for the **Number of bits** parameter, the output is 10111001 in binary.
- If you select `Range of bits` for the **Bits to extract** parameter, and specify `[4 7]` for the **Bit indices** parameter, the output is 1011 in binary.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point
Sample Time	Inherited
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Fcn

Apply specified expression to input

Library

User-Defined Functions

Description

The Fcn block applies the specified mathematical expression to its input. The expression can include one or more of these components:

- u — The input to the block. If u is a vector, $u(i)$ represents the i th element of the vector; $u(1)$ or u alone represents the first element.
- Numeric constants.
- Arithmetic operators (+ - * / ^).
- Relational operators (== != > < >= <=) — The expression returns 1 if the relation is true; otherwise, it returns 0.
- Logical operators (&& || !) — The expression returns 1 if the relation is true; otherwise, it returns 0.
- Parentheses.
- Mathematical functions — `abs`, `acos`, `asin`, `atan`, `atan2`, `ceil`, `cos`, `cosh`, `exp`, `floor`, `hypot`, `log`, `log10`, `power`, `rem`, `sgn` (equivalent to `sign` in MATLAB), `sin`, `sinh`, `sqrt`, `tan`, and `tanh`.

Note The Fcn block does not support `round` and `fix`. Use the Rounding Function block to apply these rounding modes.

- **Workspace variables** — Variable names that are not recognized in the preceding list of items are passed to MATLAB for evaluation. Matrix or vector elements must be specifically referenced (e.g., `A(1,1)` instead of `A` for the first element in the matrix).

The Fcn block observes the following rules of operator precedence:

- 1 ()
- 2 ^
- 3 + - (unary)
- 4 !
- 5 * /
- 6 + -
- 7 > < <= >=
- 8 == !=
- 9 &&
- 10 ||

The expression differs from a MATLAB expression in that the expression cannot perform matrix computations. Also, this block does not support the colon operator (:).

Block input can be a scalar or vector. The output is always a scalar. For vector output, consider using the Math Function block. If a block input is a vector and the function operates on input elements individually (for example, the `sin` function), the block operates on only the first vector element.

Limitations

The Fcn block has the following limitations:

- You cannot tune the expression during simulation in Normal or Accelerator mode (see “How Acceleration Modes Work”), or in generated code. To implement tunable expressions, tune the expression outside the Fcn block. For example, use the Relational Operator block to evaluate the expression outside.
- The Fcn block does not support custom storage classes. See “Custom Storage Classes” (Embedded Coder) in the Embedded Coder documentation.

Data Type Support

The Fcn block accepts and outputs signals of type `single` or `double`.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Expression

Specify the mathematical expression to apply to the input. Expression components are listed above. The expression must be mathematically well-formed (uses matched parentheses, proper number of function arguments, and so on). The expression has restrictions on tunability (see “Limitations” on page 1-555)

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Examples

The following example models show how to use the Fcn block:

- `sldemo_absbrake`
- `sldemo_enginewc` (Throttle & Manifold/Throttle subsystem)

Characteristics

Data Types	Double Single
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	No

Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Find

Find nonzero elements in array

Library

Math Operations

Description

The Find block locates all nonzero elements of the input signal and returns the linear indices of those elements. If the input is a multidimensional signal, the Find block can also return the subscripts of the nonzero input elements. In both cases, you can show an output port with the nonzero input values.

Data Type Support

The Find block accepts and outputs real values of any numeric data type that Simulink supports.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

- “Index output format” on page 1-559
- “Number of input dimensions” on page 1-559
- “Index mode” on page 1-560
- “Show output port for nonzero input values” on page 1-560

- “Sample time” on page 1-561
- “Output data type” on page 1-561
- “Mode” on page 1-562
- “Data type override” on page 1-563
- “Signedness” on page 1-564
- “Word length” on page 1-564
- “Scaling” on page 1-565

Index output format

Select the output format for the indices of the nonzero input values.

Default: Linear indices

Linear indices

Provides the element indices of any dimension signal in a vector form. For one dimension (vector) signals, indices correspond to the position of nonzero values within the vector. For signals with more than one dimension, the conversion of subscripts to indices is along the first dimension. You do not need to know the signal dimension of the input signal.

Subscripts

Provides the element indices of a two-dimension or larger signal in a subscript form. Because the block shows an output port for each dimension, this option requires you to know the number of dimensions for the input signal.

Selecting `Subscripts` from the **Index output format** list enables the **Number of input dimensions** parameter.

Parameter: `IndexOutputFormat`

Type: character vector

Value: `Linear indices` | `Subscripts`

Default: `Linear indices`

Number of input dimensions

Specify the number of dimensions for the input signal.

Default: 1

Minimum: 1

Maximum: 32

Selecting Subscripts from the **Index output format** list enables this parameter.

Parameter: NumberOfInputDimensions

Type: int

Value: positive integer value

Default: 1

Index mode

Specify the indexing mode.

Default: Zero-based

Zero-based

An index of 0 specifies the first element of the input vector. An index of 1 specifies the second element, and so on.

One-based

An index of 1 specifies the first element of the input vector. An index of 2, specifies the second element, and so on.

Parameter: IndexMode

Type: character vector

Value: Zero-based | One-based

Default: Zero-based

Show output port for nonzero input values

Show or hide the output port for nonzero input values.

Default: Off

On

Display the output port for nonzero input values. The additional output port provides the values of the nonzero input elements.

Off

Hide the output port for nonzero input values.

Parameter: ShowOutputPortForNonzeroInputValues

Type: character vector

Value: 'on' | 'off'

Default: 'off'

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Output data type

Specify the output data type.

Default: Inherit: Inherit via internal rule

Inherit: Inherit via internal rule

Output data type is defined by the target.

int8

Output data type is int8.

uint8

Output data type is uint8.

int16

Output data type is int16.

uint16

Output data type is uint16.

`int32`

Output data type is `int32`.

`uint32`

Output data type is `uint32`.

`fixdt(1,16)`

Output data type is fixed point, `fixdt(1,16)`.

`<data type expression>`

Use a data type object, for example, `Simulink.NumericType`.

Click the **Show data type assistant** button  to display additional parameters for the **Output data type** parameter.

Parameter: `OutDataTypeStr`

Type: character vector

Value: `'Inherit: Inherit via internal rule' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'fixdt(1,16)' | '<data type expression>'`

Default: `'Inherit: Inherit via internal rule'`

“Control Signal Data Types”, “Specify Data Types Using Data Type Assistant”

Mode

Select the category of data to specify.

Default: `Inherit`

`Inherit`

Inheritance rules for data types. Selecting `Inherit` enables a second list of the possible values:

- `Inherit via internal rule` (Discrete-Time Integrator, Gain, Product, Sum, Switch block default)

`Built in`

Built-in data types. Selecting `Built in` enables a second list of the possible values:

- int8
- uint8
- int16
- uint16
- int32
- uint32

Fixed point

Fixed-point data types.

Expression

Expressions that evaluate to data types. Selecting `Expression` enables a second text box, where you can enter the expression.

Clicking the **Show data type assistant** button enables this parameter.

Selecting `Fixed point` from the **Mode** list enables the following parameters:

- **Signed**
- **Scaling**
- **Word length**

“Specify Data Types Using Data Type Assistant”

Data type override

Specify data type override mode for this signal.

Default: `Inherit`

`Inherit`

Inherits the data type override setting from its context, that is, from the block, `Simulink.Signal` object or Stateflow chart in Simulink that is using the signal.

`Off`

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

This parameter appears only when the **Mode** is `Built in` or `Fixed point`.

Signedness

Specify whether the fixed-point data is signed or unsigned.

Default: Signed

Signed

Specifies the fixed-point data as signed.

Unsigned

Specifies the fixed-point data as unsigned.

Selecting `Fixed point` from the **Mode** list enables this parameter.

Word length

Specify the bit size of the word that holds the quantized integer.

Default: 16

Minimum: 0

Maximum: 32

Large word sizes represent large values with greater precision than small word sizes.

Selecting `Fixed point` from the **Mode** list enables this parameter.

Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

Default: Integer

Integer

Specifies a binary point location for fixed-point data and sets the fraction length to 0.

The **Scaling** list has only one item for you to select.

Selecting `Fixed point` from the **Mode** list enables this parameter.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Introduced in R2010a

First-Order Hold

Implement first-order sample-and-hold

Library

Discrete

Description

The First-Order Hold block implements a first-order sample-and-hold that operates at the specified sampling interval. This block has little value in practical applications and is included primarily for academic purposes.

This figure compares the output from a Sine Wave block and a First-Order Hold block.

Data Type Support

The First-Order Hold block accepts and outputs signals of type `double`. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Sample time

The time interval between samples. See “Specify Sample Time” in the online documentation for more information.

Characteristics

Data Types	Double
Sample Time	Specified in the Sample time parameter
Direct Feedthrough	No
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

See Also

Zero-Order Hold

Introduced before R2006a

Fixed-Point State-Space

Implement discrete-time state space

$$\left. \begin{array}{l} y(n) = Cx(n) + Du(n) \\ x(n+1) = Ax(n) + Bu(n) \end{array} \right\}$$

Library

Additional Math & Discrete / Additional Discrete

Description

The Fixed-Point State-Space block implements the system described by

$$y(n) = Cx(n) + Du(n)$$

$$x(n+1) = Ax(n) + Bu(n)$$

where u is the input, x is the state, and y is the output. Both equations have the same data type.

The matrices A , B , C and D have the following characteristics:

- A must be an n -by- n matrix, where n is the number of states.
- B must be an n -by- m matrix, where m is the number of inputs.
- C must be an r -by- n matrix, where r is the number of outputs.
- D must be an r -by- m matrix.

In addition:

- The state x must be an n -by-1 vector.
- The input u must be an m -by-1 vector.

- The output y must be an r -by-1 vector.

The block accepts one input and generates one output. The block determines the input vector width by the number of columns in the B and D matrices. Similarly, the block determines the output vector width by the number of rows in the C and D matrices.

Data Type Support

The Fixed-Point State-Space block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

State Matrix A

Specify the matrix of states.

Input Matrix B

Specify the column vector of inputs.

Output Matrix C

Specify the column vector of outputs.

Direct Feedthrough Matrix D

Specify the matrix for direct feedthrough.

Initial condition for state

Specify the initial condition for the state.

Data type for internal calculations

Specify the data type for internal calculations.

Scaling for State Equation $AX+BU$

Specify the scaling for state equations.

Scaling for Output Equation CX+DU

Specify the scaling for output equations.

Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer). in the Fixed-Point Designer documentation.

Saturate to max or min when overflows occur

Select to have overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point

Floating Scope and Scope Viewer

Display signals generated during simulation

Library

Sinks

Description

The Simulink Floating Scope block and Scope Viewer display time domain signals with respect to simulation time.

Input signal characteristics:

- **Signal** — Continuous (sample-based) or discrete (sample-based and frame-based).
- **Signal data type** — Any data type that Simulink supports including real, complex, fixed-point, and enumerated data types. See “Data Types Supported by Simulink”.
- **Signal dimension** — Scalar, one-dimensional (vector), two dimensional (matrix), or multidimensional. Display multiple channels within a signal depending on its dimension. See “Signal Dimensions” and “Determine Output Signal Dimensions”.

Floating Scope block characteristics:

- **Multiple y-axes (displays)** — Display multiple *y*-axes with multiple input ports. All of the *y*-axes have a common time range on the *x*-axis.
- **Multiple signals** — Show multiple signals on the same *y*-axis (display) from one or more input ports.
- **Modify parameters** — Modify scope parameter values before and during a simulation.

- **Display data after simulation** — If a Floating Scope is closed at the start of a simulation, scope data is still written to the scope during a simulation. As a result, if you open the Floating Scope after a simulation, the scope displays simulation results for input signals.

Note A Floating Scope block and Scope Viewer have the same functionality as a Scope block, but they are not connected to signal lines. Use the Signal Selector to add and display signals on a Floating Scope.

Note If you step back the simulation after adding or removing a signal, the Floating Scope clears the existing data. New data does not appear until the simulation steps forward again.

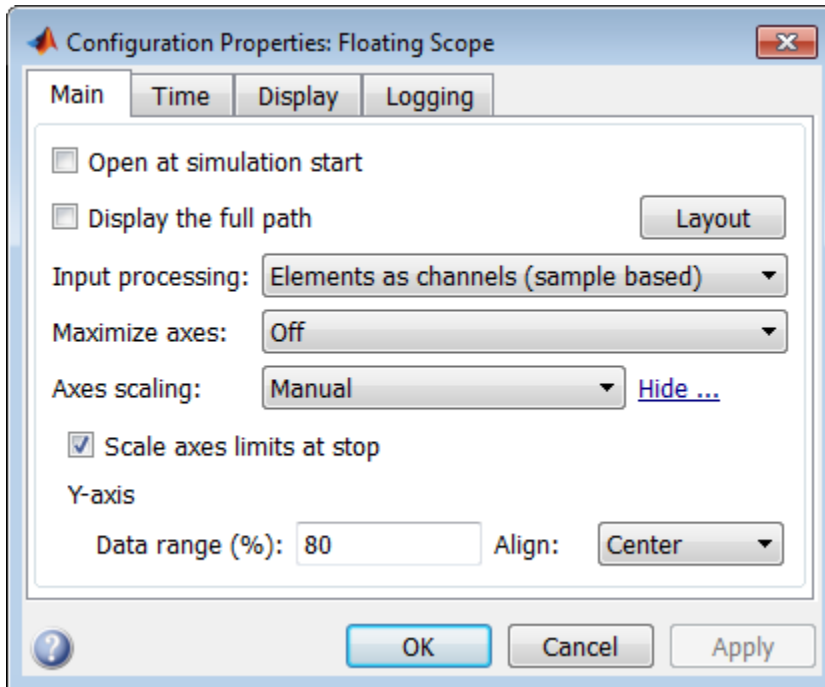

Note Scope Viewer may plot a single point when connected to a constant signal.

Note Simulink messages are not supported for Floating Scope block and Scope Viewer.

Note For information on controlling a Floating Scope programmatically, see “Control Scopes Programmatically” in the Simulink documentation.

When you use model configuration parameters such as **Signal storage reuse** and **Block reduction** for a faster simulation and optimized generated code, Simulink eliminates storage for some signals during simulation. You are unable to apply a Floating Scope to these eliminated signals. To work around this issue, configure an eliminated signal as a test point. You can then apply a Floating Scope to the signal regardless of optimization settings. To configure test points, see “Test Points”.

Configuration Properties

Open at simulation start

Specify when a Scope window opens.

Default: Clear for Scope block. Select for Time Scope block.

- Select
Open Scope window when simulation starts.
- Clear
Do not open a closed Scope at the start of a simulation.

Display the full path

Display full block path on Scope title bar.

Default: Clear

Select

Display block path and name.

Clear

Display block name.

Scope Configuration property: No corresponding property.

Number of input ports

Specify number of input ports on a Scope block, specified by a positive integer character vector. Maximum number of input ports is 96. This property does not apply to floating scopes and scope viewers.

Default: 1

Scope Configuration property: NumInputPorts.

Layout button

Specify number and arrangement of displays. The maximum layout is 16 rows by 16 columns.

To expand the layout grid beyond 4 by 4, click within the dialog box and drag. Maximum of 16 rows by 16 columns.

- If the number of displays are equal to the number of ports, signals from each port appear on separate displays.
- If the number of displays are less than the number of ports, signals from additional ports appear on the last display.
- For layouts with multiple columns and rows, ports are mapped down then across.

Default: 1 display

Scope Configuration property: `LayoutDimensions`.

Sample time

Specify time interval between Scope block updates during a simulation, specified as a positive real character vector. This property does not apply to floating scopes and scope viewers.

Default: -1 for inherited

Scope Configuration property: `SampleTime`.

Input processing

Specify sample-based or frame-based processing of signals.

Default: Elements as channels (sample based) for Scope block. Columns as channels (frame based) for Time Scope block.

Elements as channels (sample based)

Process signal values in a channel at each time interval.

Columns as channels (frame based)

Process signal values in a channel as a group of values from multiple time intervals.

Frame-based processing is available only with discrete input signals.

Scope Configuration property: `FrameBasedProcessing`.

Maximize axes

Maximize size of signal plots. Each of the plots expands to fit the full display.

Maximizing the size of signal plots removes the background area around the plots.

Default: `Off` for Scope block. `Auto` for Time Scope block.

`Auto`

If **Title** and **Y-label** properties are not specified, maximize all plots.

`On`

Maximize all plots. Values in **Title** and **Y-label** are hidden

`Off`

Do not maximize plots.

Scope Configuration property: `MaximizeAxes`.

Axes scaling

Specify when to scale *y*-axis to include all signal values.

Default: `Manual`

`Manual`

Manually scale *y*-axis range with **Scale Y-axis Limits** toolbar button.

Auto

Scale *y*-axis range during and after simulation. Selecting this option displays the **Do not allow Y-axis limits to shrink** check box.

If you want the *y*-axis range to increase and decrease with the maximum value of a signal, set **Axes scaling** to `Auto` and clear the **Do not allow Y-axis limits to shrink** check box.

After N Updates

Scale *y*-axis after the number of time steps specified in the Number of updates text box. Scaling occurs once during each run.

Do not allow Y-axis limits to shrink

Specify when *y*-axis range limits can change.

Default: Select

Select

Allow *y*-axis range limits to increase but not decrease during a simulation.

Clear

Allow *y*-axis range limits to increase and decrease.

Click the **Configure** link to the right of the **Axes scaling** property and set the **Axes scaling** property to `Auto` to display this property.

Number of updates

Specify the number of updates that occur during a simulation before a Scope scales the *y*-axes, specified as a positive integer character vector.

Default: 10

Display and activate this property by clicking the **Configure** link to the right of the **Axes scaling** property and set the **Axes scaling** property to `After N Updates`.

Scope Configuration property: `AxesScalingNumUpdates`.

Scale axes limits at stop

Specify when to scale axes.

Default: Select

- Select
Scale axes when simulation stops.
- Clear
Always scale axes.

Click the **Configure** link to the right of the **Axes scaling** property to display this property.

The *y*-axes limits are always scaled. The *x*-axis limits are scaled only if you also select the **Autoscale X-axis limits** check box.

Y-axis Data range (%)

Specify percentage of *y*-axis range for plotting data. For example, if you set this property to 100, plotted data uses the entire *y*-axis range.

Default: 80

Values are 1 through 100.

Click the **Configure** link to the right of the **Axes scaling** property to display this property.

Y-axis Align

Specify where to align plotted data along the *y*-axis data range when **Y-axis Data range** is set to less than 100 percent.

Default: Center

Top

Align signals with maximum values at top of y -axis range.

Center

Align signals with maximum and minimum values centered.

Bottom

Align signals with minimum values at bottom of y -axis range.

Click the **Configure** link to the right of the **Axes scaling** property to display this property.

Autoscale X-axis limits

Scale x -axis range limits when scaling axes.

Default: Clear

Select

Scale x -axis range to fit all signal values. If **Axes scaling** is set to `Auto`, scales the data currently within the axes, not the entire signal in the data buffer.

Clear

Do not scale x -axis range.

Click the **Configure** link to the right of the **Axes scaling** property to display this property.

X-axis Data range (%)

Specify percentage of x -axis range for plotting data. For example, if you set this property to 100, plotted data uses the entire x -axis range.

Default: 100

Values are 1 through 100.

Click the **Configure** link to the right of the **Axes scaling** property to display this property.

X-axis Align

Specify where to align plotted data along the x -axis when **X-axis Data range** is set to less than 100 percent.

Default: Center

Top

Align signals with maximum values at top of x -axis range.

Center

Align signals with maximum and minimum values centered.

Bottom

Align signals with minimum values at bottom of x -axis range.

Click the **Configure** link to the right of the **Axes scaling** property to display this property.

Time span

Specify length of x -axis range to display.

The block calculates the beginning and end times of the time range using the **Time display offset** and **Time span** properties. For example, if you set the **Time display offset** to 10 and the **Time span** to 20, the scope sets the time range from 10 to 30.

Default: Auto

Auto

Difference between the simulation start and stop times.

User defined

Value less than the total simulation time.

Scope Configuration property: `TimeSpan`.

Time span overrun action

Specify how to display data beyond the visible *x*-axis range.

You can see the effects of this option only when plotting is slow with large models or small step sizes.

Default: `Wrap`

`Wrap`

Draw a full screen of data from left to right, clear the screen, and then restart drawing of data.

`Scroll`

Move data to the left as new data is drawn on the right. This mode is graphically intensive and can affect run-time performance.

Scope Configuration property: `TimeSpanOverrunAction`.

Time units

Display units for the *x*-axis.

Default: `None` for Scope block. `Metric` for Time Scope block.

`Metric`

Display time units based on the length of **Time span**.

`Seconds`

Display Time (seconds).

`None`

Do not display time units.

Scope Configuration property: `TimeUnits`.

Time display offset

Offset the x -axis by a specified time value, specified as a real number or vector of real numbers.

For input signals with multiple channels, you can enter a scaler or vector.

- Scaler — Offset all channels of an input signal by the same time value.
- Vector — Independently offset the channels.

Default: 0

Scope Configuration property: `TimeDisplayOffset`.

Time-axis labels

Specify how x -axis (time) labels display

Default: `Bottom Displays Only` for Scope block. `All` for Time Scope block.

All

Display x -axis labels on all y -axes.

None

Do not display labels. Selecting `None` also clears the **Show time-axis label** check box.

Bottom Displays Only

Display x -axis label on the bottom y -axis.

Set **Active display** before setting this property. Activate this property by selecting **Show time-axis label** and setting **Maximize axes** to off.

Scope Configuration property: `TimeAxisLabels`.

Show time-axis label

Display or hide *x*-axis (time) labels.

Default: Clear for Scope block. Select for Time Scope block.

- Select
Display *x*-axis label for the active display
- Clear
Hide *x*-axis labels.

Set **Active display** before setting this property. If you select this property and set the **Time-axis labels** is set to `None`, this property is deactivated.

Scope Configuration property: `ShowTimeAxisLabel`.

Active display

Display for setting display-specific properties, specified as a positive integer. The number of a display corresponds to its column-wise placement index.

Default: 1

Setting this property selects the display for setting the properties **Show Grid**, **Show legend**, **Title**, **Plot signals as magnitude and phase**, **Y-label**, and **Y-Limits**.

Scope Configuration property: `ActiveDisplay`.

Title

Specify a title for display, specified as a character vector. The default value `%<SignalLabel>` uses the input signal name for the title.

Default: `%<SignalLabel>`

Set **Active display** before setting this property.

Scope Configuration property: `Title`.

Show legend

Show signal legend. The names listed in the legend are the signal names from the model. For signals with multiple channels, a channel index is appended after the signal name. See the Scope block reference for an example.

The legend lets you modify what signals are shown. To show only one signal, click the signal name. To toggle a signal on/off, right-click the signal name.

Default: Clear

Select

Display signal legend. Continuous signals have straight lines before their names and discrete signals have step-shaped lines.

Clear

Hide signal legend.

Set **Active Display** before setting this property.

Scope Configuration property: `ShowLegend`.

Connect a Sine Wave block to a Scope. Set the **Amplitude** parameter for the Sine Wave to [1 2]. Select the **Legends** check box for the Scope. Set the **Signal name** property for the signal to `MySignal`.

After simulating this model, the Scope window displays a sine wave for the two signal channels in `MySignal`, `MySignal:1`, and `MySignal:2`.

Edit the name of any channel in the legend by double-clicking the current name and entering a new channel name.

See also “Signal Dimensions” and “Determine Output Signal Dimensions”.

Show grid

Show vertical and horizontal grid lines.

Default: Select

Select
Display grid lines.

Clear
Hide grid lines.

Set **Active Display** before setting this property.

Scope Configuration property: ShowGrid.

Plot signals as magnitude and phase

Split display into magnitude and phase plots.

Default: Clear

Select

Display magnitude and phase plots. If the signal is real, plots the absolute value of the signal for the magnitude. The phase is 0 degrees for positive values and 180 degrees for negative values.

Clear

Display signal plot. If the signal is complex, plots the real and imaginary parts on the same y -axis.

Set **Active Display** before setting this property.

Scope Configuration property: PlotAsMagnitudePhase.

Y-limits (Minimum)

Specify minimum value of y -axis.

Default: -10

Set **Active display** before setting this property. Selecting **Plot signals as magnitude and phase** applies this property value to the magnitude plot. The y -axis limits of the phase plot are always [-180 180].

Scope Configuration property: YLimits.

Y-limits (Maximum)

Specify maximum value of y -axis, specified as real number.

Default: +10

Set **Active display** before setting this property. Selecting **Plot signals as magnitude and phase** applies this property value to the magnitude plot. The y -axis limits of the phase plot are always $[-180 \ 180]$.

Scope Configuration property: `YLimits`.

Y-label

Specify y -axis label, specified as a character vector.

Default: No label for Scope block. `Amplitude` for Time Scope block.

Set **Active display** before setting this property. Selecting **Plot signals as magnitude and phase** hides this property and plots are labeled `Magnitude` and `Phase`.

Scope Configuration property: `YLabel`.

Limit data points to last

Specify to limit buffered data values before plotting and saving signals.

Default: Clear, 5000

Select

Save specified number of data values for each signal. If the signal is frame-based, the number of buffered data values is the specified number of data values multiplied by the frame size.

For simulations with **Stop time** set to `inf`, consider selecting **Limit data points to last**.

In some cases, for example where the sample time is small, selecting this parameter can have the effect of plotting signals for less than the entire time range of a simulation. If a scope plots a portion of your signals, consider increasing the number of data values to save.

Clear

Save and plot all data values. Clearing **Limit data points to last** can cause an out-of-memory error for simulations that generate a large amount of data or for systems without enough available memory.

If this property is selected, also specify the number of data points by entering a positive integer in the text box. This property limits the data values a scope plots and the data values saved in the MATLAB variable specified in **Variable name**. Data values are from the end of a simulation.

Scope Configuration properties: `DataLoggingLimitDataPoints` and `DataLoggingMaxPoints`.

Decimation

Reduce the amount of scope data to display and save.

Default: Clear, 2

Select

Plot and Log (save) scope data every Nth data point, where N is the decimation factor entered in the text box.

Clear

Save all scope data values.

If this property is selected, also specify the decimation factor by entering a positive integer in the text box. The scope buffers every Nth data point, where N is the decimation factor you specify. A value of 1 buffers all data values. This property limits the data values a scope plots and the data values saved in the MATLAB variable specified in **Variable name**.

Log/Unlog Viewed Signals to Workspace

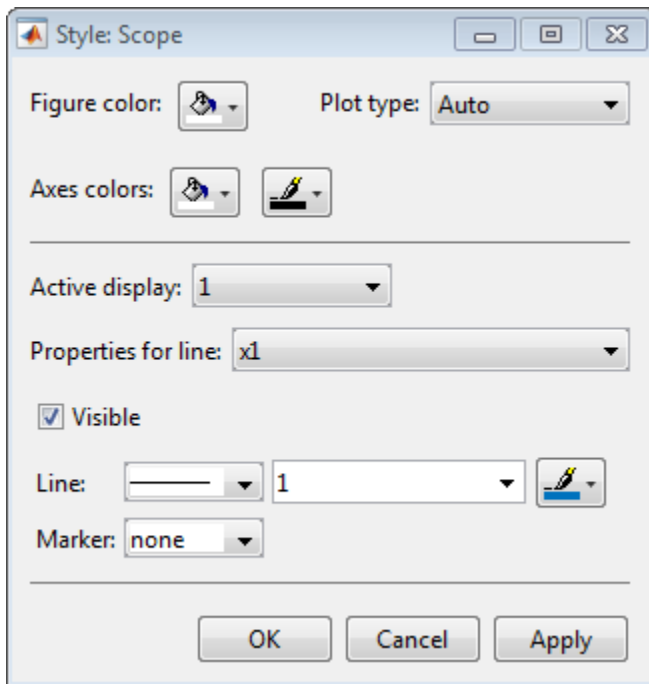

For signals selected with the Signal Selector, clicking this button selects the **Log signal data** check boxes in the Signals Properties dialog boxes.

Clicking the button a second time clears the **Log signal data** check boxes.

Style Properties

Open the Style dialog box:

- From the menu, select **View > Style**.
- From the Configuration Properties button arrow, select the Style button .

Select background color for display.

Specify how to plot a signal.

Default: Auto for Scope block. Line for Time Scope block.

- Line — Line graph.

- `Stairs` — Stair-step graph.
- `Auto` — Line graph if it is a continuous signal or a stair-step graph if it is a discrete signal.

Select active display for setting style properties.

Default: 1

Select the background color for axes (displays) with the first color pallet. Select the grid and label color with the second color pallet.

Select active line for setting line style properties.

Plot signal on active display.

Default: Select

Select
Plot signal.

Clear
Hide signal.

Select line style, width, and color.

Select marker style.

Default: None

Characteristics

Float Typecast

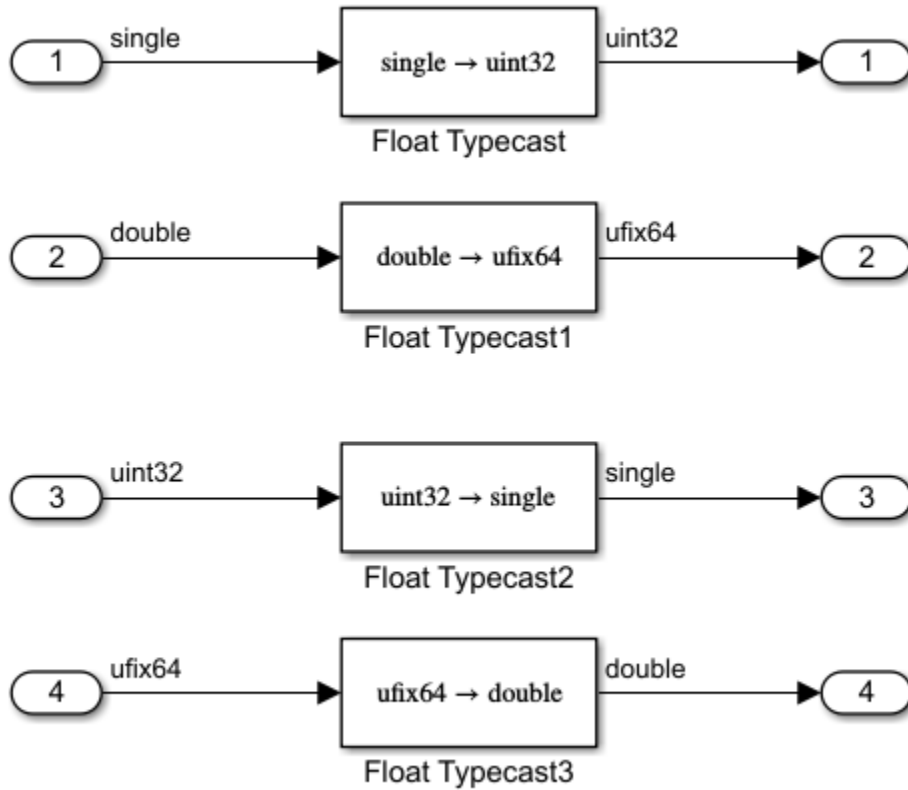

Typecast a floating-point type to an unsigned integer or vice versa

Library: HDL Coder / HDL Floating Point Operations / Float Typecast

Description

The block casts the underlying bits of the input to the corresponding fixed-point or floating point representation. The input and output of the block contain the same number of bits. This figure shows how the block mask, behavior, and output data type changes dynamically depending on the input data type that you specify.

Ports

Input

Port_1(u) — Input signal

scalar | vector

Port to provide input to the block.

Data Types: `single` | `double` | `uint32` | `fixed point`

Output

port_1(y) — Output signal

`scalar` | `vector`

Port to obtain calculated output from the block.

Data Types: `single` | `double` | `uint32` | `fixed point`

Model Examples

Block Characteristics

Data Types	<code>double</code> <code>single</code> <code>base integer</code> <code>fixed point</code> <code>bus</code>
Sample Time	<code>Inherit</code>
Direct Feedthrough	<code>Yes</code>
Multidimensional Signals	<code>Scalar</code>
Variable-Size Signals	<code>Yes</code>
Zero-Crossing Detection	<code>No</code>

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

If have HDL Coder installed, you can generate HDL code for the block in the `Native Floating Point` mode. For more information, see `Float Typecast`.

Fixed-Point Conversion

Design and simulate fixed-point algorithms using Fixed-Point Designer™.

For Each

Process elements or subarrays of a mask parameter or input signal independently

Library: Ports & Subsystems

Description

The For Each block serves as a control block for the For Each Subsystem block. Specifically, the For Each block enables the blocks inside the For Each Subsystem to process the elements of input signals or mask parameters independently. Each block inside this subsystem that has states maintains a separate set of states for each element or subarray that it processes. As the set of blocks in the subsystem processes the elements or subarrays, the subsystem concatenates the results to form output signals.

You can use a For Each subsystem to iteratively compute output after changing inputs or mask parameters. To do so, you configure the partitioning of input signals or mask parameters in the For Each block dialog box.

Partition Input Signals to the Subsystem

In a For Each subsystem, you can specify which input signals to partition for each iteration using the **Input Partition** tab in the dialog box of the For Each block. When specifying a signal to be partitioned, you also have to specify the **Partition Dimension**, **Partition Width**, and **Partition Offset** parameters.

Partition Parameters in the For Each block

You can partition the mask parameters of a For Each Subsystem block. Partitioning is useful for systems that have identical structures in each iteration but different parameter values. In this case, changing the model to partition extra input signals for each parameter is cumbersome. Instead, add a mask parameter to a For Each subsystem. For more information, see “Create a Simple Mask”. To select the mask parameter for

partitioning, use the Parameter Partition tab on the For Each block dialog box. For more information, see “Select Partition Parameters” on page 1-597

Concatenate Output

You define the dimension along which to concatenate the results by specifying the **Concatenation Dimension** in the Output Concatenation tab.

The results generated by the block for each subarray stack along the concatenation dimension, d_1 (y -axis). Whereas, if you specify d_2 by setting the concatenation dimension to 2, the results concatenate along the d_2 direction (x -axis). Thus if the process generates row vectors, then the concatenated result is a row vector.

Select Partition Parameters

When selecting an input signal or subsystem mask parameter for partitioning, you need to specify how to decompose it into elements or subarrays for each iteration. Do this by setting integer values for the **Partition Dimension**, **Partition Width**, and **Partition Offset** parameters.

As an illustration, consider an input signal matrix A of the form:

The labels d_1 and d_2 , respectively, define dimensions 1 and 2. If you retain the default setting of 1 for both the partition dimension and the partition width, and 0 for the partition offset, then Simulink slices perpendicular to partition dimension d_1 at a width equal to the partition width, that is one element.

Matrix A decomposes into these three row vectors.

If instead you specify d_2 as the partition dimension by entering the value 2, Simulink slices perpendicular to d_2 to form three column vectors.

In addition to setting the **Partition Dimension** to 2, if you set the **Partition Width** to 2 and the **Partition Offset** to -1, Simulink uses two overlapping 3x2 partitions for processing.

For an example using the **Partition Offset** parameter, open the Simulink model `.slexForEachOverlapExample`

Note Only signals are considered one-dimensional in Simulink. Mask parameters are row or column vectors, according to their orientation. To partition a row vector, specify the partition dimension as 2 (along the columns). To partition a column vector, specify the partition dimension as 1 (along the rows).

Examples

The following model demonstrates the partitioning of an input signal by a For Each block. Each row of this 2-by-3 input array contains three integers that represent the (x, y, z) -coordinates of a point. The goal is to translate each of these points based on a new origin at $(-20, -10, -5)$ and to display the results.

By placing the process of summing an input signal and the new origin inside of a For Each Subsystem block, you can operate on each set of coordinates by partitioning the input signal into two row vectors. To accomplish such partitioning, use the default settings of 1 for both the partition dimension and the partition width. If you also use the default concatenation dimension of 1, each new set of coordinates stacks in the d_1 direction, making your display a 2-by-3 array.

Alternatively, if you specify a concatenation dimension of 2, then you get a single row vector because each set of results stacks in the d_2 direction.

This example shows how to partition an input signal. To learn how the For Each block and subsystem handle a model with states, see the For Each Subsystem documentation.

Ports

Input

In — Signal input to a subsystem block

scalar | vector | matrix

Placing an Inport block in a subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated | bus

Output

Out — Signal output from a subsystem

scalar | vector | matrix

Placing an Outport block in a subsystem block adds an output port from the block. The port label on the subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated | bus

Parameters

Input Partition Tab

Select each input signal you want to partition and to specify the corresponding **Partition Dimension** and **Partition Width** parameters. See the Inport block reference page for more information.

Port — List of input ports

no default (default) | input port name

List of input ports connected to the For Each Subsystem block.

Partition — Select input port signals to partition

off (default) | on

Select input ports signals connected to the For Each Subsystem block to partition into subarrays or elements.

off

Clear input port signals.

on

Select input port signals to partition.

Dependency

Selecting this parameter enables the **Partition Dimension** and **Partition Width** parameters for the selected input port signal.

Programmatic Use

Parameter: InputPartition

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Partition Dimension — Specify dimension

1 (default) | integer

Specify the dimension through which to slice the input signal array. The resulting slices are perpendicular to the dimension that you specify. The slices also partition the array into subarrays or elements, as appropriate.

1

Specify a dimension of 1.

integer

Specify dimension. Minimum value 1.

Programmatic Use

Parameter: InputPartitionDimension

Type: character vector

Value: '1' | '<integer>'

Default: '1'

Partition Width — Specify width

1 (default) | integer

Specify the width of each partition slice of the input signal.

1

Width of one element.

integer

Specify width. Minimum value 1.

Programmatic Use

Parameter: InputPartitionWidth

Type: character vector

Value: '1' | '<integer>'

Default: '1'

Partition Offset — Specify partition offset

0 (default) | integer

Specify the offset for each partition slice of the input signal.

0

No offset between partition slices.

integer

Specify partition offset where the sum of the partition width and the partition offset is a positive integer.

For example, a **Partition Width** of 3 and a **Partition Offset** of -2 indicates that each 3 element slice overlaps its neighboring slices by 2 elements.

Programmatic Use

Parameter: SubsysMaskParameterOffset

Type: character vector

Value: '0' | '<integer>'

Default: '0'

Output Concatenation Tab

For each output port, specify the dimension along which to stack (concatenate) the For Each Subsystem block results. See the Outport block reference page for more information.

Port — List of output ports

none (default) | output port name

List of output ports connected to the For Each Subsystem block.

Concatenation Dimension — Specify dimension

1 (default) | integer

Specify the dimension along which to stack the results of the For Each Subsystem block.

1

The results stack in the d_1 direction. If the block generates column vectors, the concatenation process results in a single column vector.

integer

The results stack in the d_2 direction. If the block generates row vectors, the concatenation process results in a single row vector. Minimum value 1

Programmatic Use

Parameter: OutputConcatenationDimension

Type: character vector

Value: '1' | '<integer>'

Default: '1'

Parameter Partition Tab

Select each mask parameter to partition and to specify the corresponding **Partition Dimension** and **Partition Width** parameters. Parameters appear in the list only if you have added an editable parameter to the mask of the parent For Each subsystem.

Parameter — List of mask parameters

parameter name

List of mask parameters for the For Each Subsystem block.

Partition — Select mask parameters to partition

off (default) | on

Select mask parameters for the For Each Subsystem block to partition into subarrays or elements.

off

Clear mask parameters.

on

Select mask parameters to partition.

Dependency

Selecting this parameter enables the **Partition Dimension** and **Partition Width** parameters for the selected mask parameter.

Programmatic Use

Parameter: SubsysMaskParameterPartition

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Partition Dimension — Specify dimension

1 (default) | integer

Specify the dimension through which to slice the input signal array. The resulting slices are perpendicular to the dimension that you specify. The slices also partition the array into subarrays or elements, as appropriate.

Default: 1

1

Dimension of 1.

integer

Specify dimension. Minimum value 1

Programmatic Use

Parameter: SubsysMaskParameterPartitionDimension

Type: character vector

Value: '1' | '<integer>'

Default: '1'

Partition width — Specify partition width

1 (default) | integer

Specify the width of each partition slice of the input signal.

1

Width of one element.

For Each Subsystem

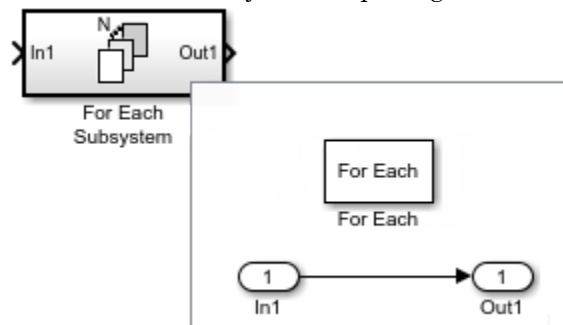

Subsystem that repeats execution on each element or subarray of input signal and concatenates results

Library: Ports & Subsystems

Description

The For Each Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem that repeats execution during a simulation time step on each element or subarray of an input signal.

The set of blocks within the subsystem represents the algorithm applied to a single element or subarray of the original signal. The For Each block inside the subsystem allows you to configure the decomposition of the subsystem inputs into elements or subarrays, and to configure the concatenation of the individual results into output signals.

Inside this subsystem, each block that has states maintains separate sets of states for each element or subarray that it processes. Consequently, the operation of this subsystem is similar in behavior to copying the contents of the subsystem for each

element in the original input signal and then processing each element using its respective copy of the subsystem.

An additional benefit of the For Each Subsystem block is that, for certain models, it improves the code reuse in SimulinkCoder generated code. Consider a model containing two reusable Atomic Subsystem blocks with the same scalar algorithm applied to each element of the signal. If the input signal dimensions of these subsystems are different, Simulink Coder generated code includes two distinct functions. You can replace these two subsystems with two identical For Each Subsystem blocks that are configured to process each element of their respective inputs using the same algorithm. For this case, Simulink Coder generated code consists of a single function parameterized by the number of input signal elements. This function is invoked twice — once for each unique instance of the For Each Subsystem block in the model. For each of these cases, the input signal elements have different values.

S-Function Support

The For Each Subsystem block supports both C-MEX S-functions and Level-2 MATLAB S-functions, provided that the S-function supports multiple execution instances using one of the following techniques:

- A C-MEX S-function must declare `ssSupportsMultipleExecInstances(S, true)` in the `mdlSetWorkWidths` method.
- A Level-2 MATLAB S-function must declare `block.SupportsMultipleExecInstances = true` in the setup method.

If you use the above specifications:

- Do not cache run-time data, such as `DWork` and Block I/O, using global or persistent variables or within the userdata of the S-function.
- Every S-function execution method from `mdlStart` up to `mdlTerminate` is called once for each element processed by the S-function, when it is in a For Each Subsystem block. Consequently, you need to be careful not to free the same memory on repeated calls to `mdlTerminate`. For example, consider a C-MEX S-function that allocates memory for a run-time parameter within `mdlSetWorkWidths`. The memory only needs to be freed once in `mdlTerminate`. As a solution, set the pointer to be empty after the first call to `mdlTerminate`.

Limitations

The For Each Subsystem block has these limitations, and these are the workarounds.

Limitation	Workaround
<p>You cannot log bus or an array of bus signals directly in the For Each subsystem.</p>	<p>Use one of these approaches:</p> <ul style="list-style-type: none"> • Use a Bus Selector block to select the signals you want to log and mark those signals for signal logging. • Attach the signal to an Outport block and log the signal outside the For Each subsystem.
<p>You cannot log a signal inside a referenced model that is inside a For Each subsystem if either of these conditions exists:</p> <ul style="list-style-type: none"> • The For Each subsystem is in a model simulating in Rapid Accelerator mode. • The For Each subsystem itself is in a model referenced by a Model block in Accelerator mode. 	<p>For the first condition, use Accelerator mode.</p> <p>For the second condition, use Normal or Rapid Accelerator mode.</p>
<p>You cannot log the states of the blocks in a For Each subsystem .</p>	<p>Save and restore the simulation state.</p>
<p>You cannot use Normal mode to simulate a Model block inside a For Each subsystem.</p>	<p>Use Accelerator or Rapid Accelerator mode.</p>
<p>Reusable code is generated for two For Each Subsystems with identical contents if their input and output signals are vectors (1-D or 2-D row or column vector). For n-D input and output signals, reusable code is generated only when the dimension along which the signal is partitioned is the highest dimension.</p>	<p>Permute the signal dimensions to transform the partition dimension and the concatenation dimension to the highest nonsingleton dimension for n-D signals.</p>

The For Each Subsystem block does not support these features:

- You cannot include these blocks or S-functions inside a For Each Subsystem:

- Data Store Memory, Data Store Read, or Data Store Write blocks inside the subsystem
- The From Workspace block if the input is a `Structure` with `Time` that has an empty time field
- The To Workspace and To File data saving blocks
- Goto and From blocks that cross the subsystem boundary
- Model Reference block with simulation mode set to Normal
- Shadow Inports
- ERT S-functions

For a complete list of the blocks that support the For Each Subsystem, type `showblockdatatypetable` at the MATLAB command line.

- You cannot use these types of signals:
 - Test-pointed signals or signals with an external storage class inside the system
 - Frame signals on subsystem input and output boundaries
 - Variable-size signals
 - Function-call signals crossing the boundaries of the subsystem
- Creation of a linearization point inside the subsystem
- Propagating the Jacobian flag for the blocks inside the subsystem. You can check this condition in MATLAB using `J.Mi.BlockAnalyticFlags.jacobian`, where `J` is the Jacobian object. To verify the correctness of the Jacobian of the For Each Subsystem block, perform these steps:
 - Look at the tag of the For Each Subsystem Jacobian. If it is `"not_supported"`, then the Jacobian is incorrect.
 - Move each block out of the For Each Subsystem and calculate its Jacobian. If any block is `"not_supported"` or has a warning tag, the For Each Subsystem Jacobian is incorrect.
- You cannot perform these types of code generation:
 - Generation of a Simulink Coder S-function target
 - Simulink Coder code generation under both of the following conditions:
 - A Stateflow or MATLAB Function block resides in the subsystem.

- This block tries to access global data outside the subsystem, such as Data Store Memory blocks or Simulink.Signal objects of ExportedGlobal storage class.
- PLC code generation

Ports

Input

in — Signal input to a subsystem block

scalar | vector | matrix

Placing an Inport block in a subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Output

out — Signal output from a subsystem

scalar | vector | matrix

Placing an Outport block in a subsystem block adds an output port from the block. The port label on the subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

For Iterator

Repeatedly execute contents of subsystem at current time step until iteration variable exceeds specified iteration limit

Library

Ports & Subsystems

Description

The For Iterator block, when placed in a subsystem, repeatedly executes the contents of the subsystem at the current time step until an iteration variable exceeds a specified iteration limit. You can use this block to implement the block diagram equivalent of a `for` loop in the C programming language.

The output of a For Iterator subsystem cannot be a function-call signal. Simulink software will display an error message if the simulation is run or the diagram updated.

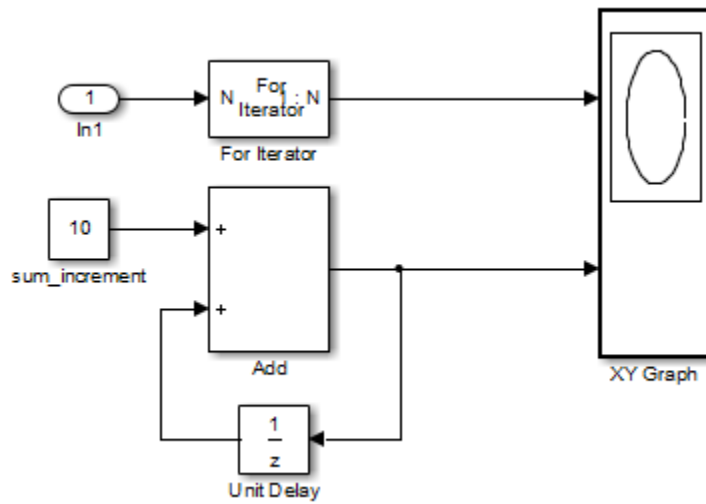

The block's parameter dialog allows you to specify the maximum value of the iteration variable or an external source for the maximum value and an optional external source for the next value of the iteration variable. If you do not specify an external source for the next value of the iteration variable, the next value is determined by incrementing the current value:

$$i_{n+1} = i_n + 1$$

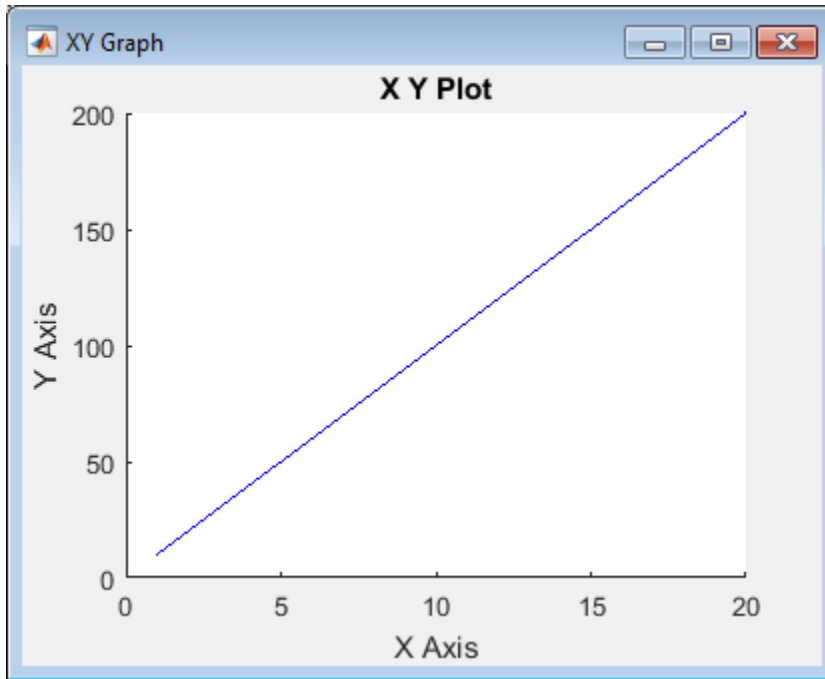

Suppose that you have the following model:

For 20 iterations, the For Iterator block increments a value by 10 at each time step:

The following figure shows the result.

The For Iterator subsystem in this example is equivalent to the following C code.

```
sum = 0;
iterations = 20;
sum_increment = 10;
for (i = 0; i < iterations; i++) {
    sum = sum + sum_increment;
}
```

Note Placing a For Iterator block in a subsystem makes it an atomic subsystem if it is not already an atomic subsystem.

Data Type Support

The following rules apply to the data type of the number of iterations (N) input port:

- The input port accepts data of mixed numeric types.
- If the input port value is noninteger, it is first truncated to an integer.
- Internally, the input value is cast to an integer of the type specified for the iteration variable output port.
- If no output port is specified, the input port value is cast to type `int32`.
- If the input port value exceeds the maximum value of the output port's type, it is truncated to that maximum value.

Data output for the iterator value can be selected as `double`, `int32`, `int16`, or `int8` in the block parameters dialog box.

The following rules apply to the iteration variable input port:

- It can appear only if the iteration variable output port is enabled.
- The data type of the iteration variable input port is the same as the data type of the iteration variable output port.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

States when starting

Set this field to `reset` if you want the states of the For subsystem to be reinitialized before the first iteration at each time step. Otherwise, set this field to `held` (the default) to make sure that these subsystem states retain their values from the last iteration at the previous time step.

Iteration limit source

If you set this field to `internal`, the value of the **Iteration limit** field determines the number of iterations. If you set this field to `external`, the signal at the For Iterator block's `N` port determines the number of iterations. The iteration limit source must reside outside the For Iterator subsystem.

Iteration limit

Set the number of iterations by specifying a number or a named constant. This field appears only if you selected `internal` for the **Iteration limit source** field. This parameter supports storage classes. You can define the named constant in the base

workspace of the Model Explorer as a `Simulink.Parameter` object of the built-in storage class `Define (custom)` type. For more information, see “Apply a Custom Storage Class from the Simulink Package Using Data Objects” (Embedded Coder) in the Embedded Coder documentation.

Set next i (iteration variable) externally

This option can be selected only if you select the **Show iteration variable** option. If you select this option, the For Iterator block displays an additional input for connecting an external iteration variable source. The value of the input at the current iteration is used as the value of the iteration variable at the next iteration.

Show iteration variable

If you select this check box, the For Iterator block outputs its iteration value.

Index mode

If you set this field to `Zero-based`, the iteration number starts at zero. If you set this field to `One-based`, the iteration number starts at one.

Iteration variable data type

Set the type for the iteration value output from the iteration number port to `double`, `int32`, `int16`, or `int8`.

Characteristics

Direct Feedthrough	No
Sample Time	Inherited from driving blocks
Scalar Expansion	No
Dimensionalized	No
Zero Crossing	No

For Iterator Subsystem

Subsystem that repeats execution during a simulation time step

Library: Ports & Subsystems

Description

The For Iterator Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem that repeats execution during a simulation time step while a logical (Boolean) condition is true.

When using simplified initialization mode, if you place a block that needs elapsed time (such as a Discrete-Time Integrator block) in a While Iterator Subsystem block, Simulink displays an error.

Ports

Input

In — Signal input to a subsystem block

scalar | vector | matrix

Placing an Inport block in a Subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Output

Out — Signal output from a subsystem

scalar | vector | matrix

Placing an Outport block in a Subsystem block adds an output port from the block. The port label on the Subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

From

Accept input from Goto block

Library

Signal Routing

Description

The From block accepts a signal from a corresponding Goto block, then passes it as output. The data type of the output is the same as that of the input from the Goto block. From and Goto blocks allow you to pass a signal from one block to another without actually connecting them. To associate a Goto block with a From block, enter the Goto block's tag in the **Goto Tag** parameter.

A From block can receive its signal from only one Goto block, although a Goto block can pass its signal to more than one From block.

This figure shows that using a Goto block and a From block is equivalent to connecting the blocks to which those blocks are connected. In the model at the left, Block1 passes a signal to Block2. That model is equivalent to the model at the right, which connects Block1 to the Goto block, passes that signal to the From block, then on to Block2.

The visibility of a Goto block tag determines the From blocks that can receive its signal. For more information, see [Goto and Goto Tag Visibility](#). The block indicates the visibility of the Goto block tag:

- A local tag name is enclosed in brackets ([]).
- A scoped tag name is enclosed in braces ({}).
- A global tag name appears without additional characters.

The From block supports signal label propagation.

Data Type Support

The From block outputs real or complex signals of any data type that Simulink supports, including fixed-point and enumerated data types.

For more information, see “Data Types Supported by Simulink”.

Parameters

Goto Tag

The tag of the Goto block that forwards its signal to this From block.

To change the tag, select a new tag from this control's drop-down list. The drop-down list displays the Goto tags that the From block can currently see. An item labeled `<More Tags . . . >` appears at the end of the list the first time you display the list in a Simulink session. Selecting this item causes the block to update the tags list to include the tags of Goto blocks residing in library subsystems referenced by the model containing this From block. Simulink software displays a progress bar while building the list of library tags. Simulink software saves the updated tags list for the duration of the Simulink session or until the next time you select the adjacent **Update Tags** button. You need to update the tags list again in the current session only if the libraries referenced by the model have changed since the last time you updated the list.

If you use multiple From and Goto Tag Visibility blocks to refer to the same Goto tag, you can simultaneously rename the tag in all of the blocks. Use the **Rename All** button in the Goto block dialog box. To find the Goto block, use the **Goto Source** hyperlink.

Update Tags

Updates the list of tags visible to this From block, including tags residing in libraries referenced by the model containing this From block.

Goto Source

Path of the Goto block connected to this From block. Clicking the path displays and highlights the Goto block.

Icon Display

Specifies the text to display on the From block's icon. The options are the block's tag, the name of the signal that the block represents, or both the tag and the signal name.

Examples

The following models show how to use the From block:

- `sldemo_auto_climatecontrol`
- `sldemo_hardstop`

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated Bus
Sample Time	Inherited from the block driving the Goto block

Goto

Introduced before R2006a

From File

Load data from MAT-file

Library

Sources

Description

The From File block loads data from a MAT-file to a model and outputs the data as a signal. The data is a sequence of samples. Each sample consists of a time stamp and an associated data value. The data can be in array format or MATLAB `timeseries` format.

The From File block icon shows the name of the MAT-file that supplies the data to the block.

You can have multiple From File blocks that load from the same MAT-file.

The supported MAT-file versions are Version 7.0 or earlier and Version 7.3. The From File block incrementally loads data from Version 7.3 files.

You can specify how the data is loaded, including:

- Sample time
- How to handle data for missing data points
- Whether to use zero-crossing detection

For more information, see “Load Data Using the From File Block”.

Code Generation Requirements

For a From File block, generating code that builds ERT or GRT targets or uses SIL or PIL simulation modes requires that:

- The MAT-file contains a nonempty, finite, real matrix with at least two rows.
 - Use a data type of `double` for the matrix.
 - Do not include any NaN, Inf, or -Inf elements in the matrix.
- In the From File block parameters dialog box:
 - Set the **Data extrapolation before first data point** and **Data extrapolation after last data point** parameters to `Linear extrapolation`.
 - Set the **Data interpolation within time range** parameter to `Linear interpolation`.
 - Clear the **Enable zero-crossing detection** parameter.

Data Type Support

For MATLAB `timeseries` data, the From File block loads real or complex signal data of any data type that Simulink supports. Fixed-point data cannot have a word length that exceeds 32 bits. The From File block supports loading nonvirtual bus signals in `timeseries` format.

For array data, the From File block loads only double signal data.

For more information, see “Create Data for a From File Block”.

Parameters

File name

The path or file name of the MAT-file that contains the input data. Specify a path or file name in one of these ways:

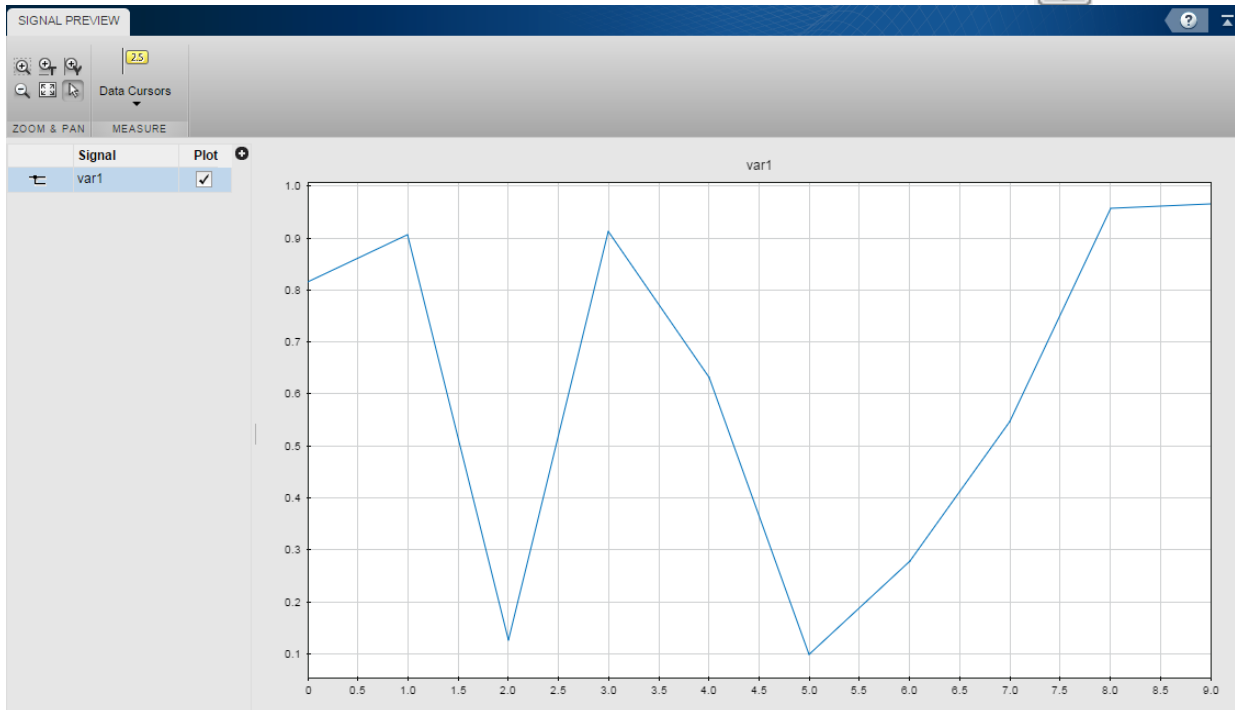

- Browse to a folder that contains a valid MAT-file.

On UNIX® systems, the path name can start with a tilde (~) character, which means your home folder.

- Enter the path for the file in the text box.

The default file name is `untitled.mat`. If you specify a file name without path information, Simulink loads the file in the current folder or on the MATLAB path. (To determine the current folder, at the MATLAB command prompt enter `pwd`.)

To preview the data in the Signal Preview window, click the view button .

Use the Signal Preview window to plot and inspect data.

- 1 To plot the signal, select the check box next to the signal. If the format is a bus, click the expander  to see and select the elements of the bus.
- 2 Explore the plots by using the **Measure** and **Zoom & Pan** sections of the toolbar.
 - In the **Measure** section, use the **Data Cursors** button to display one or two cursors for the plot. These cursors display the T and Y values of a data point in the plot. To view a data point, click a point on the line.
 - In the **Zoom & Pan** section, select how you want to zoom and pan the signal plots. Zooming is only for the selected axis.

Zoom Action	Button
Zoom in along the time and data value axes.	
Zoom in along the time axis. Click the button. On the graph, drag the cursor to select an area to enlarge.	
Zoom in along the data value axis. Click the button. On the graph, drag the cursor to select an area to enlarge.	
Zoom out from the graph.	
Fit the plot to the graph. Click the button. Click the graph to enlarge the plot to fill the graph.	
Pan the graph up, down, left, or right. Click the button. On the graph, drag the cursor to the area of the graph that you want to view.	

Parameter: FileName

Type: character vector

Default: 'untitled.mat'

Output data type

The data type for the data that the From File block outputs. For nonbus types, you can use `Inherit: auto` to skip any data type verification. If you specify an output data type, then the From File block verifies that the data in the file matches the specified data type. For more information, see “Control Signal Data Types”.

- `Inherit: auto` — Default
- `double`
- `single`
- `int8`
- `uint8`

- `int16`
- `uint16`
- `int32`
- `uint32`
- `boolean`
- `fixdt(1,16,0)` — Data type is fixed point (1,16,0).
- `fixdt(1,16,2^0,0)` — Data type is fixed point (1,16,2^0,0).
- Enum: `<class_name>` — Data type is enumerated.
- Bus: `<bus_object>` — Data type is a bus object. For details, see the “Using Bus Data” section.
- `<data type expression>` — The name of a data type object, for example `Simulink.NumericType`. Do not specify a bus object as the expression.

If you set **Output data type** as a bus object, the bus object must be available when you compile the model. For each signal in bus data, the From File block verifies that data type, dimension, and complexity are the same for the data and for the bus object.

>> (Show data type assistant)

Displays the **Data Type Assistant**, to help you to set the **Output data type** parameter.

Mode

The category of data to specify. For more information, see “Control Signal Data Types”.

- `Inherit` — Inheritance rule for data types. Selecting `Inherit` enables a second menu and text box. (Default)
- `Built in` — Built-in data types. Selecting `Built in` enables a second menu and text box. Select one of the following choices:
 - `double` — Default
 - `single`
 - `int8`
 - `uint8`

- `int16`
- `uint16`
- `int32`
- `uint32`
- `boolean`
- `Fixed point` — Fixed-point data types
- `Enumerated` — Enumerated data types. Selecting `Enumerated` enables a second menu/text box to the right, where you can enter the class name.
- `Bus` — Bus object. Enables a **Bus object** parameter, where you enter bus object name for defining the structure of the bus. If you create or change a bus object, open the Simulink Bus Editor by clicking **Edit**. For details, see “Create Bus Objects with the Bus Editor”.
- `Expression` — Expression that evaluates to a data type. Selecting `Expression` enables a second menu and text box to the right, where you enter the expression. Do not specify a bus object as the expression.

Sample time

The sample period and offset.

The From File block loads data from a MAT-file, using a sample time that either:

- You specify for the From File block.
- The From File block inherits from the blocks into which the From File block feeds data.

The default sample time is 0, which specifies a continuous sample time. The MAT-file is loaded at the base (fastest) rate of the model. For details, see “Specify Sample Time”.

Parameter: `SampleTime`

Type: character vector

Default: `'0'`

Data extrapolation before first data point

Extrapolation method for a simulation time hit that occurs before the initial time stamp in the MAT-file. Choose one of the following extrapolation methods.

Method	Description
Linear extrapolation	<p>(Default)</p> <p>If the MAT-file contains only one sample, then the From File block outputs the corresponding data value.</p> <p>If the MAT-file contains more than one sample, then the From File block linearly extrapolates using the first two samples:</p> <ul style="list-style-type: none"> • For double data, linearly extrapolates the value using the first two samples • For Boolean data, outputs the first data value • For a built-in data type other than double or Boolean, the From File block: <ul style="list-style-type: none"> • Upcasts the data to double • Performs linear extrapolation (as described for double data) • Downcasts the extrapolated data value to the original data type <p>You cannot use the Linear extrapolation option with enumerated (enum) data. All signals in a bus use the same extrapolation setting. If any signal in a bus uses enum data, then you cannot use the Linear extrapolation option.</p>
Hold first value	Uses the first data value in the file
Ground value	<p>Uses a value that depends on the data type of MAT-file sample data values:</p> <ul style="list-style-type: none"> • Fixed-point data types — uses the ground value • Numeric types other than fixed point — uses 0 • Boolean — uses false • Enumerated data types — uses default value

Parameter: ExtrapolationBeforeFirstDataPoint

Type: character vector

Value: 'Linear extrapolation' | 'Hold first value' | 'Ground value'
Default: 'Linear extrapolation'

Data interpolation within time range

The interpolation method that Simulink uses for a simulation time hit between two time stamps in the MAT-file. Choose one of the following interpolation methods.

Method	Description
Linear interpolation	<p>(Default)</p> <p>The From File block interpolates using the two corresponding MAT-file samples:</p> <ul style="list-style-type: none"> • For <code>double</code> data, linearly interpolates the value using the two corresponding samples • For <code>Boolean</code> data, uses <code>false</code> for the first half of the sample and <code>true</code> for the second half. • For a built-in data type other than <code>double</code> or <code>Boolean</code>, the From File block: <ul style="list-style-type: none"> • Upcasts the data to <code>double</code> • Performs linear interpolation, as described for <code>double</code> data • Downcasts the interpolated value to the original data type <p>You cannot use the <code>Linear interpolation</code> option with enumerated (<code>enum</code>) data. All signals in a bus use the same interpolation setting. If any signal in a bus uses <code>enum</code> data, then you cannot use the <code>Linear interpolation</code> option.</p>
Zero order hold	Uses the data from the first of the two samples

Parameter: `InterpolationWithinTimeRange`

Type: character vector

'Linear interpolation' | 'Zero order hold'

Default: 'Linear interpolation'

Data extrapolation after last data point

The extrapolation method for a simulation time hit that occurs after the last time stamp in the MAT-file. Choose one of the following extrapolation methods.

Method	Description
Linear extrapolation	<p>(Default)</p> <p>If the MAT-file contains only one sample, then the From File block outputs the corresponding data value.</p> <p>If the MAT-file contains more than one sample, then the From File block linearly extrapolates using data values of the last two samples:</p> <ul style="list-style-type: none"> • For <code>double</code> data, extrapolates the value using the last two samples. • For <code>Boolean</code> data, outputs the first data value. • For built-in data types other than <code>double</code> or <code>Boolean</code>: <ul style="list-style-type: none"> • Upcasts the data to <code>double</code> • Performs linear extrapolation, as described for <code>double</code> data • Downcasts the extrapolated value to the original data type <p>You cannot use the <code>Linear extrapolation</code> option with enumerated (<code>enum</code>) data. All signals in a bus use the same extrapolation setting. If any signal in a bus uses <code>enum</code> data, then you cannot use the <code>Linear extrapolation</code> option.</p>
Hold last value	Uses the last data value in the file

Method	Description
Ground value	<p>Uses a value that depends on the data type of MAT-file sample data values:</p> <ul style="list-style-type: none"> • Fixed-point data types — uses the ground value • Numeric types other than fixed point — uses 0 • Boolean — uses false • Enumerated data types — uses default value

Parameter: ExtrapolationAfterLastDataPoint

Type: character vector

'Linear extrapolation' | 'Hold last value' | 'Ground value'

Default: 'Linear extrapolation'

Enable zero-crossing detection

Enables zero-crossing detection.

The “Zero-Crossing Detection” parameter applies only if the **Sample time** parameter is set to 0 (continuous).

Simulink uses a technique known as zero-crossing detection to locate a discontinuity in time stamps, without resorting to excessively small time steps. “Zero-crossing” represents a discontinuity.

For the From File block, zero-crossing detection occurs only at time stamps in the file. Simulink examines only the time stamps, not the data values.

For bus signals, Simulink detects zero-crossings across all leaf bus elements.

If the input array contains duplicate time stamps (more than one entry with the same time stamp), Simulink detects a zero crossing at those time stamps. For example, suppose that the input array has this data:

```
time:      0 1 2 2 3
signal:    2 3 4 5 6
```

At time 2, there is a zero crossing from the input signal discontinuity.

For nonduplicate time stamps, zero-crossing detection depends on the settings of the following parameters:

- **Data extrapolation before first data point**
- **Data interpolation within time range**
- **Data extrapolation after last data point**

The From File block determination of when zero-crossing occurs depends on the time stamp.

Time Stamp	Setting
First	Data extrapolation before first data point is set to Ground value.
Between first and last	Data interpolation within time range is set to Zero-order hold.
Last	One or both of these settings occur: <ul style="list-style-type: none"> • Data extrapolation after last data point is set to Ground value. • Data interpolation within time range is set to Zero-order hold.

This figure illustrates zero-crossing detection for data accessed by a From File block that has the following settings:

- **Data extrapolation before first data point** — Linear extrapolation
- **Data interpolation within time range** (for internal points) — Zero order hold
- **Data extrapolation after last data point** — Linear extrapolation

This figure is another illustration of zero-crossing detection for data accessed by a From File block. The block has the following settings for the time stamps (points):

- **Data extrapolation before first data point** — Hold first value
- **Data interpolation within time range** — Zero order hold
- **Data extrapolation after last data point** — Hold last value

Examples

From File Block Loading Timeseries Data

Create a MATLAB® `timeseries` object with time and signal values. Save the `timeseries` object to a MAT-file and load into a model using a From File block.

Create an array with the time and signal data, specifying signal data for 10 time steps.

```
t = .1*(1:10);
d = .2*(1:10);
x = [t;d];
```

Create a MATLAB `timeseries` object.

```
ts = timeseries(x(2:end,:),x(1,:))
```

```
timeseries

Common Properties:
    Name: 'unnamed'
    Time: [10x1 double]
    TimeInfo: tsdata.timemetadata
    Data: [1x1x10 double]
    DataInfo: tsdata.datametadata
```

Save the `timeseries` object in a Version 7.3 MAT-file.

```
save('mySignals', 'ts', '-v7.3')
```

Add a From File block and set the **File name** parameter of that block to `mySignals.mat`.

Simulate the model. The Scope block reflects the data loaded from the `mySignals.mat` file.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed Point Enumerated Bus
Sample Time	Specified in the Sample time parameter
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	Yes, if enabled
Code Generation	Yes

From Spreadsheet

Read data from spreadsheet

Library

Sources

Description

The From Spreadsheet block reads data from Microsoft Excel® (all platforms) or CSV (Microsoft Windows® platform with Microsoft Office installed only) spreadsheets and outputs the data as a signal.

The From Spreadsheet icon displays the spreadsheet file name and sheet name specified in the block **File name** and **Sheet name** parameters.

Storage Formats

The data that the From Spreadsheet block reads from a spreadsheet must be appropriately formatted.

For Microsoft Excel spreadsheets:

- The From Spreadsheet block interprets the first row as a signal name. If you do not specify a signal name, the From Spreadsheet block assigns a default one with the format `Signal #`, where `#` increments with each additional unnamed signal.
- The From Spreadsheet block interprets the first column as time. In this column, the time values must monotonically increase.
- The From Spreadsheet block interprets the remaining columns as signals.

This example shows an acceptably formatted Microsoft Excel spreadsheet. The first column is Time and the first row contains signal names. Each worksheet contains a signal group.

1	Time	DC In	Trigger	AC In	
2	0	1	2	3	
3	1	2	3	4	
4	2	3	4	5	
5	3	4	5	6	
6	4	5	6	7	
7	5	6	7	8	
8	6	7	8	9	
9	7	8	9	10	
10	8	9	10	11	
11	9	10	11	12	
12	10	11	12	13	
13	11	12	13	14	
14	12	13	14	15	
15	13	14	15	16	
16	14	15	16	17	
17	15	16	17	18	
18					

Navigation: < > Group1 Group2 Group3

For CSV text files (Microsoft platform with Microsoft Office installed only):

- The From Spreadsheet block interprets the first column as time. In this column, the time values must increase.
- The From Spreadsheet block interprets the remaining columns as signals.
- Each column must have the same number of entries.
- The From Spreadsheet block interprets each file as one signal group.

This example shows an acceptably formatted CSV file. The contents represent one signal group.

```
0,0,0,5,0
1,0,1,5,0
```

2,0,1,5,0
3,0,1,5,0
4,5,1,5,0
5,5,1,5,0
6,5,1,5,0
7,0,1,5,0
8,0,1,5,1
9,0,1,5,1
10,0,1,5,0

Block Behavior During Simulation

The From Spreadsheet block incrementally reads data from the spreadsheet during simulation.

The **Sample time** parameter specifies the sample time that the From Spreadsheet block uses to read data from the spreadsheet. For details, see “Parameters” on page 1-641. The time stamps in the file must be monotonically nondecreasing.

For each simulation time hit for which the spreadsheet contains no matching time stamp, Simulink software interpolates or extrapolates to obtain the needed data using the selected method. For details, see “Simulation Time Hits That Have No Corresponding Spreadsheet Time Stamps” on page 1-638.

Simulation Time Hits That Have No Corresponding Spreadsheet Time Stamps

If the simulation time hit does not have a corresponding spreadsheet time stamp, the From Spreadsheet block output depends on:

- Whether the simulation time hit occurs before the first time stamp, within the range of time stamps, or after the last time stamp
- The interpolation or extrapolation methods that you select
- The data type of the spreadsheet data

For details about interpolation and extrapolation options, see the descriptions of the following parameters in “Parameters and Dialog Box”:

- **Data extrapolation before first data point**

- **Data interpolation within time range**
- **Data extrapolation after last data point**

Sometimes the spreadsheet includes two or more data values that have the same time stamp. In such cases, the From Spreadsheet block action depends on when the simulation time hit occurs, relative to the duplicate time stamps in the spreadsheet.

For example, suppose that the spreadsheet contains this data. Three data values have a time stamp value of 2.

```
time stamps:    0 1 2 2 2 3 4
data values:   2 3 6 4 9 1 5
```

The table describes the From Spreadsheet block output.

Simulation Time, Relative to Duplicate Time Stamp Values in Spreadsheet	From Spreadsheet Block Action
Before the duplicate time stamps	Performs the same actions as when the time stamps are distinct, using the first of the duplicate time stamp values as the basis for interpolation. (In this example, the time stamp value is 6.)
At or after the duplicate time stamps	Performs the same actions as when the times stamps are distinct, using the last of the duplicate time stamp values as the basis for interpolation. (In this example, that time stamp value is 9.)

Rounding Mode

The From Spreadsheet block rounds positive and negative numbers toward negative infinity. This mode is equivalent to the MATLAB `floor` function.

Saturation on Integer Overflow

For data type conversion, the From Spreadsheet block deals with saturation overflow by wrapping to the appropriate value that the data type can represent. For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126 .

Code Generation Requirements

Simulating in accelerator, rapid accelerator, model reference accelerator mode, or model reference rapid accelerator mode behaves the same way, and has the same requirements, as simulating in normal mode.

The From Spreadsheet block does not support generating code that involves building ERT or GRT targets, or using SIL or PIL simulation modes.

Data Type Support

The From Spreadsheet block supports these data types:

- Inherit: auto — Default
- double
- single
- int8
- uint8
- int16
- uint16
- int32
- uint32
- Boolean
- `fixdt(1,16,0)` — Data type is fixed point (1,16,0).
- `fixdt(1,16,2^0,0)` — Data type is fixed point (1,16,2^0,0).
- Enum: `<class_name>` — Data type is enumerated.
- `data type expression` — The name of a data type object, for example `Simulink.NumericType`. Do not specify a bus object as the expression.

The From Spreadsheet block accepts data type specifications at a block level.

If you want to specify different data types for each signal, consider selecting **Output Data Type > Inherit: Auto**. This option resolves back signal data types using back propagation. For example, assume that there are two signals in the From Spreadsheet block, In1 and In2, which the block sends to ports that have int8 and Boolean data types. With back propagation, the block recasts In1 as int8 and In2 as boolean.

Parameters

File name

Enter full path and file name of a spreadsheet file.

This block supports non-English full paths and file names only on Microsoft platforms.

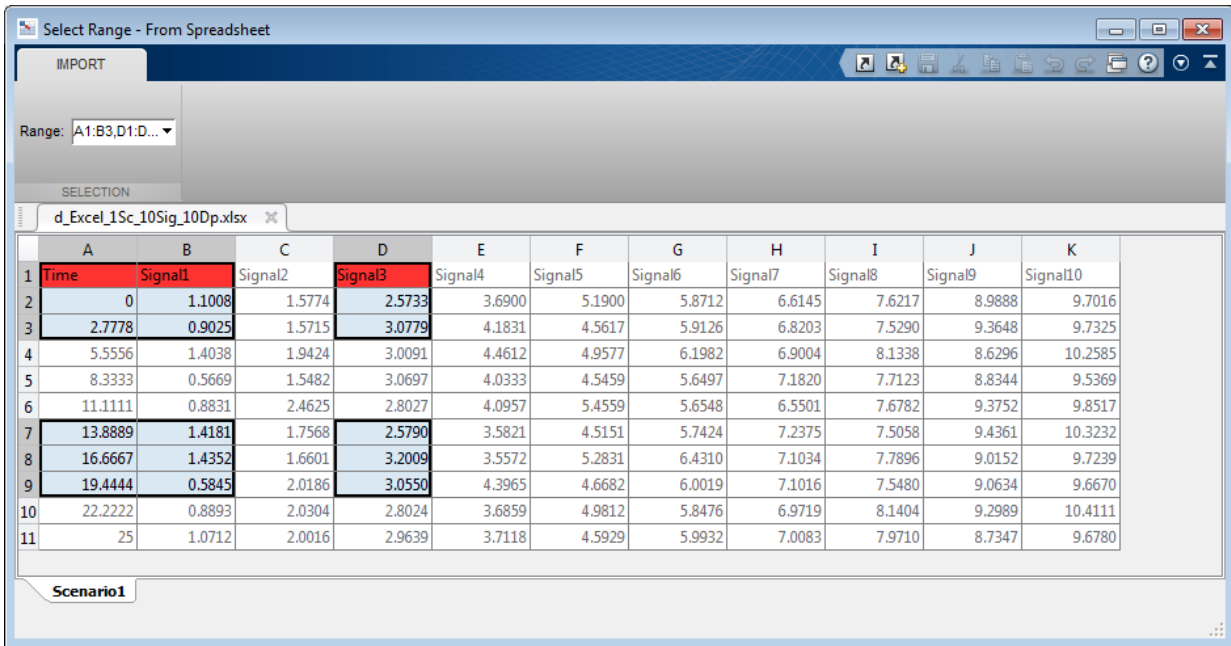

Default: `untitled.xlsx`

FileName	character vector
----------	------------------

Sheet name

Enter the name of the sheet in the spreadsheet. You can type the sheet name in this edit box, or select the sheet name after you open the sheet.

To open the sheet, click . In the sheet, you can select the range of data by dragging over the desired range of values.

Alternatively, you can select the range of data by specifying the range of values in the **Range** parameter.

Default: Sheet1

SheetName	character vector
-----------	------------------

Range

To specify the range, use the format *column:row*, with multiple specifications separated by commas. For example, A1:B3, D1:D3, A7:B9, D7:D9. If unspecified, or empty, the block automatically detects the used range, which is all the data in the sheet.

A	B	C	D	E	F	G	H	I	J	K
Time	Signal1	Signal2	Signal3	Signal4	Signal5	Signal6	Signal7	Signal8	Signal9	Signal10
0	1.1008	1.5774	2.5733	3.6900	5.1900	5.8712	6.6145	7.6217	8.9888	9.7016
2.7778	0.9025	1.5715	3.0779	4.1831	4.5617	5.9126	6.8203	7.5290	9.3648	9.7325
5.5556	1.4038	1.9424	3.0091	4.4612	4.9577	6.1982	6.9004	8.1338	8.6296	10.2585
8.3333	0.5669	1.5482	3.0697	4.0333	4.5459	5.6497	7.1820	7.7123	8.8344	9.5369
11.1111	0.8831	2.4625	2.8027	4.0957	5.4559	5.6548	6.5501	7.6782	9.3752	9.8517
13.8889	1.4181	1.7568	2.5790	3.5821	4.5151	5.7424	7.2375	7.5058	9.4361	10.3232
16.6667	1.4352	1.6601	3.2009	3.5572	5.2831	6.4310	7.1034	7.7896	9.0152	9.7239
19.4444	0.5845	2.0186	3.0550	4.3965	4.6682	6.0019	7.1016	7.5480	9.0634	9.6670
22.2222	0.8893	2.0304	2.8024	3.6859	4.9812	5.8476	6.9719	8.1404	9.2989	10.4111
25	1.0712	2.0016	2.9639	3.7118	4.5929	5.9932	7.0083	7.9710	8.7347	9.6780

If the selections overlap, the block resolves the selection information as appropriate. For example, if you specify multiple ranges that overlap, such as A1:B4, B1:E7, the block resolves the selection to A1 to E7, inclusive.

Default: Empty

Range	character vector
-------	------------------

Output data type

The data type for the From Spreadsheet block output. The From Spreadsheet block accepts spreadsheets that contain many data types. However, the block reads the spreadsheet data type as doubles. It then outputs the data type according to the value of **Output data type**.

To allow the block to cast the output data type to match that of the receiving block, use `Inherit: auto`.

For more information, see “Control Signal Data Types”.

Default: `Inherit: auto`

Cast output data type to match that of the receive block.

`Inherit: auto`

Cast output data type to match that of the receive block.

double

Output data type is double.

single

Output data type is single.

int8

Output data type is int8.

uint8

Output data type is uint8.

int16

Output data type is int16.

uint16

Output data type is uint16.

int32

Output data type is int32.

uint32

Output data type is uint32.

boolean

Output data type is boolean.

fixdt(1,16,0)

Output data type is fixed point fixdt(1,16,0).

fixdt(1,16,2^0,0)

Output data type is fixed point fixdt(1,16,2^0,0).

Enum: <class name>

Output data type is enumerated, for example, Enum: Basic Colors.

<data type expression>

The name of a data type object, for example Simulink.NumericType

OutDataTypeStr	character vector — {'Inherit: auto'} 'double' 'single' 'int8' 'uint8' 'int16' 'uint16' 'int32' 'uint32' 'boolean' 'fixdt(1,16,0)' 'fixdt(1,16,2^0,0)' 'Enum: <class name>'
----------------	--

>> (Show data type assistant)

Displays the **Data Type Assistant**, to help you to set the **Output data type** parameter.

Mode

The category of data to specify. For more information, see “Control Signal Data Types”.

Default: `Inherit`

Inheritance rule for data types. Selecting `Inherit` enables a second menu/text box to the right.

- `Inherit`

Inheritance rule for data types. Selecting `Inherit` enables a second menu/text box to the right.

- `Built in`

Built-in data types. Selecting `Built in` enables a second menu/text box to the right. Select one of the following choices:

- `double` — Default
- `single`
- `int8`
- `uint8`
- `int16`
- `uint16`
- `int32`
- `uint32`

- `boolean`
- `Fixed point` — Fixed-point data types
- `Enumerated` — Enumerated data types. Selecting `Enumerated` enables a second menu/text box to the right, where you can enter the class name.
- `Expression` — Expression that evaluates to a data type. Selecting `Expression` enables a second menu/text box to the right, where you enter the expression.

Data type override

Specify data type override mode for this signal.

Default: `Inherit`

`Inherit`

Inherits the data type override setting from its context, that is, from the block, `Simulink.Signal` object or Stateflow chart in Simulink that is using the signal.

`Off`

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

This parameter appears only when the **Mode** is `Built in` or `Fixed point`.

Signedness

Specify whether you want the fixed-point data as signed or unsigned.

Default: `Signed`

`Signed`

Specify the fixed-point data as signed.

Unsigned

Specify the fixed-point data as unsigned.

Selecting **Mode** > Fixed point enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Word length

Specify the bit size of the word that holds the quantized integer.

Default: 16

Minimum: 0

Maximum: 32

Selecting **Mode** > Fixed point enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Scaling

Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

Default: Binary point

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

Selecting **Mode** > `Fixed point` enables this parameter.

Selecting `Binary point` enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting `Slope` and `bias` enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

See “Specifying a Fixed-Point Data Type”.

Fraction length

Specify fraction length for fixed-point data type.

Default: 0

Binary points can be positive or negative integers.

Selecting **Scaling** > `Binary point` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Slope

Specify slope for the fixed-point data type.

Default: 2^0

Specify any positive real number.

Selecting **Scaling** > `Slope` and `bias` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Bias

Specify bias for the fixed-point data type.

Default: 0

Specify any real number.

Selecting **Scaling** > `Slope` and `bias` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Treat first column as

Select how the block should treat the first column of the spreadsheet:

- `Time` — Treat first column as time.
- `Data` — Treat first column as data. Selecting this option disables:
 - **Data extrapolation before first data point**
 - **Data interpolation within time range**
 - **Data extrapolation after last data point**
- Selecting this option enables **Output after last data point**.

Sample time

The sample period and offset.

The From Spreadsheet block reads data from a spreadsheet using a sample time that either:

- You specify for the From Spreadsheet block
- The From Spreadsheet block inherits from the blocks into which the From Spreadsheet block feeds data

The default is 0, which specifies a continuous sample time. The spreadsheet is read at the base (fastest) rate of the model. For details, see “Specify Sample Time”.

SampleTime	character vector — {'0'}
------------	--------------------------

Data extrapolation before first data point

Extrapolation method that Simulink uses for a simulation time hit that is before the first time stamp in the spreadsheet. Choose one of the following extrapolation methods.

Method	Description
Linear extrapolation	<p>(Default)</p> <p>If the spreadsheet contains only one sample, the From Spreadsheet block outputs the corresponding data value.</p> <p>If the spreadsheet contains more than one sample, the From Spreadsheet block linearly extrapolates using the first two samples:</p> <ul style="list-style-type: none"> • For <code>double</code> data, linearly extrapolates the value using the first two samples • For <code>Boolean</code> data, outputs the first data value • For a built-in data type other than <code>double</code> or <code>Boolean</code>: <ul style="list-style-type: none"> • Upcasts the data to <code>double</code>. • Performs linear extrapolation (as described above for <code>double</code> data). • Downcasts the extrapolated data value to the original data type. <p>You cannot use the <code>Linear extrapolation</code> option with enumerated (<code>enum</code>) data.</p>
Hold first value	Uses the first data value in the file

Method	Description
Ground value	<p>Uses a value that depends on the data type of spreadsheet sample data values:</p> <ul style="list-style-type: none"> • Fixed-point data types — Uses the ground value • Numeric types other than fixed-point — Uses 0 • Boolean — Uses false • Enumerated data types — Uses default value
ExtrapolationBeforeFirstDataPoint	<p>character vector — {'Linear extrapolation'} 'Hold first value' 'Ground value'</p>

Data interpolation within time range

The interpolation method that Simulink uses for a simulation time hit between two time stamps in the spreadsheet. Choose one of the following interpolation methods.

Method	Description
Linear interpolation	<p>(Default)</p> <p>The From Spreadsheet block interpolates using the two corresponding spreadsheet samples:</p> <ul style="list-style-type: none"> • For <code>double</code> data, linearly interpolates the value using the two corresponding samples • For <code>Boolean</code> data, uses <code>false</code> for the first half of the sample and <code>true</code> for the second half. • For a built-in data type other than <code>double</code> or <code>Boolean</code>: <ul style="list-style-type: none"> • Upcasts the data to <code>double</code>. • Performs linear interpolation (as described above for <code>double</code> data). • Downcasts the interpolated value to the original data type. <p>You cannot use the <code>Linear interpolation</code> option with enumerated (<code>enum</code>) data.</p>
Zero order hold	Uses the data from the first of the two samples
<code>InterpolationWithinTimeRange</code>	character vector — {'Linear interpolation'} 'Zero order hold'

Data extrapolation after last data point

The extrapolation method that Simulink uses for a simulation time hit that is after the last time stamp in the spreadsheet. Choose one of the following extrapolation methods.

Method	Description
Linear extrapolation	<p>(Default)</p> <p>If the spreadsheet contains only one sample, the From Spreadsheet block outputs the corresponding data value.</p> <p>If the spreadsheet contains more than one sample, the From Spreadsheet block linearly extrapolates using data values of the last two samples:</p> <ul style="list-style-type: none"> • For double data, extrapolates the value using the last two samples • For Boolean data, outputs the last data value • For a built-in data type other than double or Boolean: <ul style="list-style-type: none"> • Upcasts the data to double. • Performs linear extrapolation (as described above for double data). • Downcasts the extrapolated value to the original data type. <p>You cannot use the Linear extrapolation option with enumerated (enum) data.</p>
Hold last value	Uses the last data value in the file
Ground value	<p>Uses a value that depends on the data type of spreadsheet sample data values:</p> <ul style="list-style-type: none"> • Fixed-point data types — uses the ground value • Numeric types other than fixed-point — uses 0 • Boolean — uses false • Enumerated data types — uses default value
ExtrapolationAfterLastDataPoint	character vector — {'Linear extrapolation'} 'Hold last value' 'Ground value'

Output after last data point

Select action after last data point:

- `Repeat sequence` — Repeat the sequence by reading the data from the first row of the range specified in **Range** (default)
- `Hold final value` — Output the last defined value for the remainder of the simulation.
- `Ground value` — Output a ground value depending on the data type value specified in **Output data type**.

Enable zero-crossing detection

Select to enable zero-crossing detection.

The “Zero-Crossing Detection” parameter applies only if the **Sample time** parameter is set to 0 (continuous).

Simulink uses a technique known as zero-crossing detection to locate accurately a discontinuity, without resorting to excessively small time steps. This section uses “zero-crossing” to represent discontinuities.

For the From Spreadsheet block, zero-crossing detection can only occur at time stamps in the file. Simulink examines only the time stamps, not the data values.

If the input array contains duplicate time stamps (more than one entry with the same time stamp), Simulink detects a zero crossing at that time stamp. For example, suppose that the input array has this data:

```
time:      0 1 2 2 3
signal:    2 3 4 5 6
```

At time 2, there is a zero crossing from the input signal discontinuity.

For data with nonduplicate time stamps, zero-crossing detection depends on the settings of the following parameters:

- **Data extrapolation before first data point**
- **Data interpolation within time range**
- **Data extrapolation after last data point**

The block applies the following rules when determining when:

- Zero-crossing occurs for the first time stamp.
- For time stamps between the first and last time stamp.
- For the last time stamp.

Time Stamp	When Zero-Crossing Detection Occurs
First	Data extrapolation before first data point is set to Ground value.
Between first and last	Data interpolation within time range is set to Zero-order hold.
Last	One or both of these settings occur: <ul style="list-style-type: none"> • Data extrapolation after last data point is set to Ground value. • Data interpolation within time range is set to Zero-order hold.

The following figure illustrates zero-crossing detection for data accessed by a From Spreadsheet block that has the following settings:

- **Data extrapolation before first data point** — Linear extrapolation
- **Data interpolation within time range** (for internal points) — Zero order hold
- **Data extrapolation after last data point** — Linear extrapolation

The following figure is another illustration of zero-crossing detection for data accessed by a From Spreadsheet block. The block has the following settings for the time stamps (points):

- **Data extrapolation before first data point** — Hold first value
- **Data interpolation within time range** — Zero order hold
- **Data extrapolation after last data point** — Hold last value

ZeroCross

character vector — 'off' | {'on'}

Characteristics

From Workspace

Load signal data from workspace

Library

Sources

Description

The From Workspace block reads signal data from a workspace and outputs the data as a signal.

The From Workspace icon displays the expression specified in the **Data** parameter. For details about how Simulink software evaluates this expression, see “Symbol Resolution”.

You can specify how the data is loaded, including sample time, how to handle data for missing data points, and whether to use zero-crossing detection. For more information, see “Load Data Using the From Workspace Block”.

Specifying the Workspace Data

In the Block Parameters dialog box of the From Workspace block, in the **Data** parameter, specify the workspace data to load. Specify a MATLAB expression (for example, the name of a variable in the MATLAB workspace) that evaluates to one of the following:

- A MATLAB `timeseries` object
- A structure of MATLAB `timeseries` objects
- A structure, with or without time
- A two-dimensional matrix

For additional information, see “Load Data Using the From Workspace Block” .

Use With Data Dictionary

When you link a model to a data dictionary, you:

- Store design data, which contribute to the fundamental design of the model, in the Design Data section of the dictionary. Design data include numeric variables and `Simulink.Parameter` objects that you use to set block parameter values.
- Store simulation input data, which you use to stimulate and experiment with the model, in the base workspace. Typically, you create simulation input data as MATLAB `timeseries` objects.

For more information about storing variables, objects, and other data that a model uses, see “Determine Where to Store Variables and Objects for Simulink Models”.

- To access design data by using a From Workspace block, store the target variable in the Design Data section of the dictionary and set the **Data** parameter of the block to the name of the variable.
- To access simulation input data, store the target variable in the base workspace and set the **Data** parameter by using a call to the `evalin` function. In the call to `evalin`, specify the `ws` argument as `'base'` so that the block seeks the variable in the base workspace instead of the data dictionary. For example, if the name of the variable is `myTimeseriesObject`, set **Data** to `evalin('base', 'myTimeseriesObject')`.

Data Type Support

The From Workspace block accepts data from the workspace. The block outputs real or complex signals of any type that Simulink supports, including fixed-point and enumerated data types.

The From Workspace block also accepts a bus object as a data type. To load bus data, use a structure of MATLAB `timeseries` objects. For details, see “Load Bus Data to Root-Level Input Ports”.

Real signals of type `double` can be in any data format that the From Workspace block supports. For complex signals and real signals of a data type other than `double`, use any format except `Array`.

Parameters

Data

In the **Data** parameter, specify the workspace data to load. Specify a MATLAB expression (for example, the name of a variable in the MATLAB workspace) that evaluates to one of the following:

- A MATLAB `timeseries` object
- A structure of MATLAB `timeseries` objects
- A structure, with or without time
- A two-dimensional matrix

For additional information, see “Specify the Workspace Data”.

Parameter: `VariableName`

Type: character vector

Default: `'simin'`

Output data type

The required data type for the data for the workspace variable that the From Workspace block loads. For non-bus types, to skip any data type verification, you can use `Inherit: auto`. For more information, see “Control Signal Data Types”.

To load bus data, use a structure of MATLAB `timeseries` objects. For details, see “Load Bus Data to Root-Level Input Ports”.

- `Inherit: auto` — Default.
- `double`
- `single`
- `int8`
- `uint8`
- `int16`
- `uint16`

- `int32`
- `uint32`
- `boolean`
- `fixdt(1,16,0)` — Data type is fixed point (1,16,0).
- `fixdt(1,16,2^0,0)` — Data type is fixed point (1,16,2^0,0).
- `Enum: <class_name>` — Data type is enumerated, for example, `Enum: Basic Colors`.
- `Bus: <bus_object>` — Data type is a bus object.
- `<data type expression>` — The name of a data type object, for example `Simulink.NumericType`. Do not specify a bus object as the expression.

Parameter: `OutDataTypeStr`

Type: character vector

`'Inherit: auto' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'boolean' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | 'Enum: <class name>' | 'Bus: <object name>'`

Default: `'Inherit: auto'`

>> (Show data type assistant)

Displays the **Data Type Assistant**, to help you to set the **Output data type** parameter.

Mode

The category of data to specify. For more information, see “Control Signal Data Types”.

- `Inherit` — Inheritance rule for data types. Selecting `Inherit` enables a second menu/text box to the right. (Default)
- `Built in` — Built-in data types. Selecting `Built in` enables a second menu/text box to the right. Select one of the following choices:
 - `double` — Default
 - `single`
 - `int8`
 - `uint8`

- `int16`
- `uint16`
- `int32`
- `uint32`
- `boolean`
- `Fixed point` — Fixed-point data types
- `Enumerated` — Enumerated data types. Selecting `Enumerated` enables a second menu/text box to the right, where you can enter the class name.
- `Bus object` — Bus object. Selecting `Bus` enables a **Bus object** parameter, where you enter the name of a bus object that you want to use to define the structure of the bus. To create or change a bus object, click **Edit** (to the right of the **Bus object** field) to open the Simulink Bus Editor. For details, see “Create Bus Objects with the Bus Editor”.
- `Expression` — Expression that evaluates to a data type. Selecting `Expression` enables a second menu/text box to the right, where you enter the expression. Do not specify a bus object as the expression.

Sample time

Sample rate of loaded data. For details, see “Specify Sample Time”.

Parameter: `SampleTime`

Type: character vector

Default: `'0'`

Interpolate data

To have the block linearly interpolate at time hits for which no corresponding workspace data exist, select this option. Otherwise, the current output equals the output at the most recent time for which data exists.

The From Workspace block interpolates by using the two corresponding workspace samples:

- For `double` data, linearly interpolates the value by using the two corresponding samples

- For `Boolean` data, uses `false` for the first half of the time between two time values and `true` for the second half
- For a built-in data type other than `double` or `Boolean`:
 - Upcasts the data to `double`
 - Performs linear interpolation (as described for `double` data)
 - Downcasts the interpolated value to the original data type

You cannot use linear interpolation with enumerated (`enum`) data.

The block uses the value of the last known data point as the value of time hits that occur after the last known data point.

To determine the block output after the last time hit for which workspace data is available, combine the settings of these parameters:

- **Interpolate data**
- **Form output after final data value by**

For details, see the **Form output after final data value by** parameter.

Parameter: Interpolate

Type: character vector

'off' | 'on'

Default: 'on'

Enable zero-crossing detection

If you select the **Enable zero-crossing detection** parameter, then when the input array contains multiple entries for the same time hit, Simulink detects a zero crossing. For example, suppose that the input array has this data:

```
time:      0 1 2 2 3
signal:    2 3 4 5 6
```

At time 2, there is a zero crossing from input signal discontinuity. For more information, see “Zero-Crossing Detection”.

For bus signals, Simulink detects zero crossings across all leaf bus elements.

Parameter: ZeroCross

Type: character vector

'off' | 'on'

Default: 'on'

Form output after final data value by

To determine the block output after the last time hit for which workspace data is available, combine the settings of these parameters:

- **Interpolate data**
- **Form output after final data value by**

This table lists the block output, based on the values of the two options.

Setting for Form Output After Final Data Value By	Setting for Interpolate Data	Block Output After Final Data
Extrapolation	On	Extrapolated from final data value
	Off	Error
Setting to zero	On	Zero
	Off	Zero
Holding final value	On	Final value from workspace
	Off	Final value from workspace
Cyclic repetition	On	Error
	Off	Repeated from workspace if the workspace data is in structure-without-time format. Error otherwise.

For example, the block uses the last two known data points to extrapolate data points that occur after the last known point if you:

- Select **Interpolate data**.
- Set **Form output after final data value by** to `Extrapolation`.

Consider this model.

The From Workspace block reads data from the workspace. The data consists of the output of the Simulink Sine block sampled at one-second intervals. The workspace contains the first 16 samples of the output. The top and bottom X-Y plots display the output of the Sine Wave and From Workspace blocks, respectively, from 0 to 20 seconds. The straight line in the output of the From Workspace block reflects the linear extrapolation of missing data points at the end of the simulation.

Parameter: OutputAfterFinalValue

Type: character vector

'Extrapolation' | 'Setting to zero' | 'Holding final value' | 'Cyclic repetition'

Default: 'Extrapolation'

Examples

With the From Workspace block, you can read 1-D and 2-D signals into Simulink. The From Workspace block does not read n-D signals into Simulink.

Read 1-D Signals in Array Format

Create two signals x and y with a time vector t . Import the values into Simulink with an array.

- 1 In the MATLAB Command Window, enter:

```
t = 0.2 * [0:49]';  
x = sin(t);  
y = 10*sin(t);
```

The time vector must be a column vector.

- 2 Add a From Workspace block to your model.
- 3 For the From Workspace block, in **Data** parameter, enter the array $[t, x, y]$.

Read 1-D Signals in Structure Format

Create two signals x and y with a time vector t . Import the values into Simulink with a structure.

- 1 In the MATLAB Command Window, enter:

```
t = 0.2 * [0:49]';  
x = sin(t);  
y = 10*sin(t);  
wave.time = t;  
wave.signals.values = [x,y];  
wave.signals.dimensions =2;
```

The time vector must be a column vector. The `signals.dimensions` field for the signal is a scalar corresponding to the number of columns in the `signals.values` field.

- 2 Add a From Workspace block to your model.
- 3 In the From Workspace block parameters dialog box, in the **Data** field, enter the structure name.

Use Sample Time from Model

If you do not have a time vector, you can define the sample time in your model.

- 1 In the MATLAB Command Window, enter

```
wave.time = [];
```

- 2 In the From Workspace block parameters dialog box, in the **Sample time** field, enter a time interval. For example, enter 0.2. Clear the **Interpolate data** check box.
- 3 In the **Form output after final data value by**, select Setting to zero, Holding final value, or Cyclic repetition. Do not select Extrapolation.

Read 2-D Signals in Structure Format

To load 2-D signals from the MATLAB workspace into Simulink, you must have the signals in a structure format. This example creates a 10-by-10 matrix (2-D signal) by using the `magic` function, and then creates a 3-D matrix by adding a time vector.

- 1 In the MATLAB Command Window, enter:

```
t1 = 0.2 * [0:49]';  
m = magic(10);  
M = repmat(m, [1 1 length(t1)]);  
data.time=t1;  
data.signals.values = M;  
data.signals.dimensions=[10 10];
```

The time vector must be a column vector. The `signals.values` field is a 3-D matrix where the third dimension corresponds to time. The `signals.dimensions` field is a two-element vector. The first element is the number of rows and the second element is the number of columns in the `signals.values` field.

- 2 In the From Workspace block parameters dialog box, in the **Data** field, enter the name of the structure.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated Bus
Sample Time	Specified in the Sample time parameter
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	Yes, if enabled
Code Generation	No

Function-Call Feedback Latch

Break feedback loop involving data signals between function-call blocks

Library: Ports & Subsystems

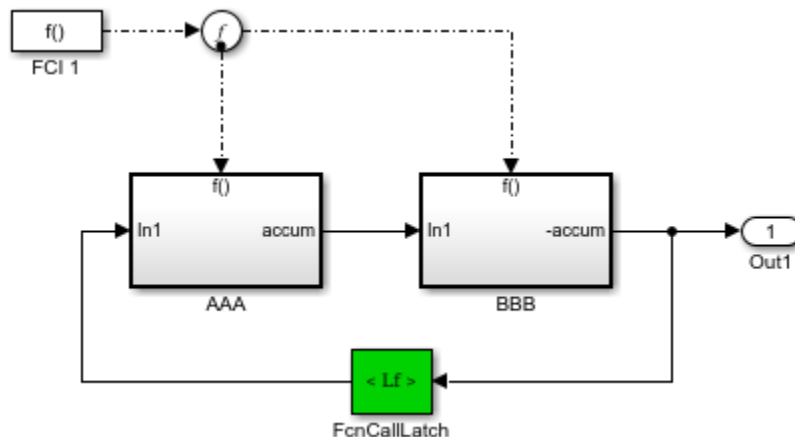

Description

Use the Function-Call Feedback Latch block to break a feedback loop of data signals between one or more function-call blocks. Specifically, break a feedback loop formed in one of the following ways.

- **When function-call blocks connect to branches of the same function-call signal**

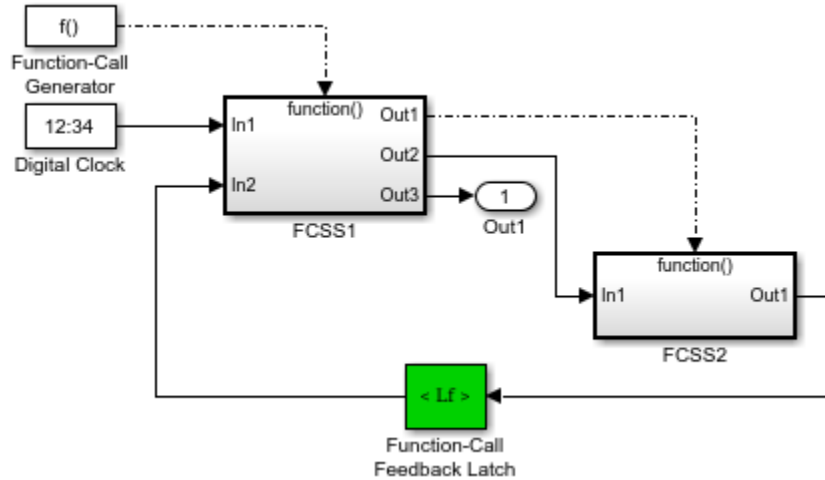

Place the Function-Call Feedback Latch block on the feedback signal between the branched blocks. As a result, the latch block delays the signal at the input of the destination function-call block, and the destination function-call block executes prior to the source function-call block of the latch block.

- **When the loop involves parent and child function-call blocks, where the child initiator is inside the parent**

Place the Function-Call Feedback Latch block on the feedback signal between the child and the parent. This arrangement prevents the signal value, read by the parent

(FCSS1), from changing during execution of the child. In other words, the parent reads the value from the previous execution of the child (FCSS2).

Using the latch block is equivalent to selecting the **Latch input for function-call feedback signals** check box on the Inport block in the destination function-call subsystem or model. However, an advantage of the latch block over using the dialog parameter is that one can design the destination function-call subsystem or model in a modular fashion and then use it either in or out of the context of loops.

The Function-Call Feedback Latch block is better suited than Unit Delay or Memory blocks in breaking function-call feedback loops for the following reasons:

- The latch block delays the feedback signal for exactly one execution of the source function-call block. This behavior is different from the Unit Delay or Memory blocks for cases where the function-call subsystem blocks may execute multiple times in a given simulation step.
- Unlike the Unit Delay or Memory blocks, the latch block may be used to break loops involving asynchronous function-call subsystems.
- The latch block can result in better performance, in terms of memory optimization, for generated code.

Ports

Input

In — Signal from a function-call subsystem block

scalar | vector | matrix

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Output

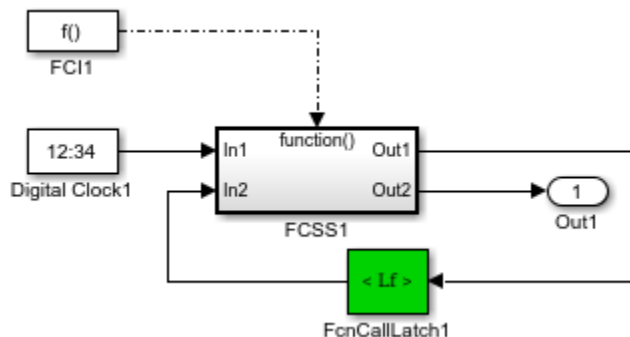

Out — Signal to a function-call subsystem

scalar | vector | matrix

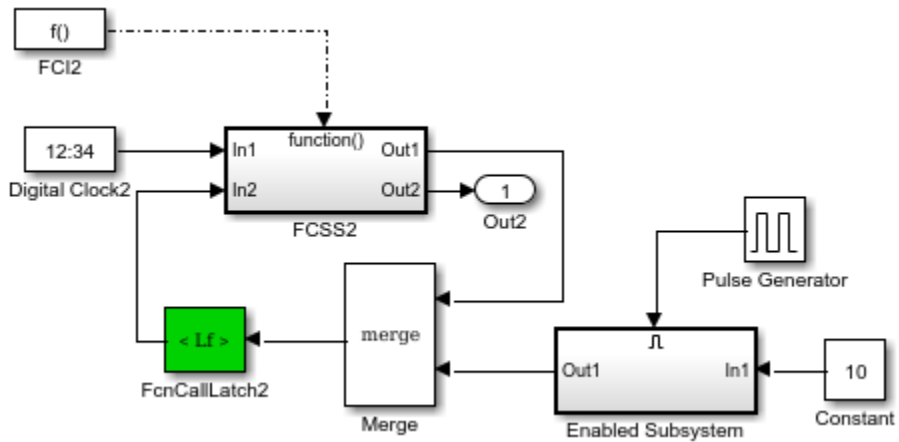

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Examples

In the following model, a single function-call subsystem output serves as its own input.

A more complex case occurs when a merged signal serves as the input to a function-call subsystem. Latching is necessary if one of the signals entering the Merge block forms a feedback loop with the function-call subsystem. In this example, one of the output signals from FCSS2 combines with the output of an Enabled Subsystem block and then feeds back into an input of FCSS2.

Topics

“Using Function-Call Subsystems”

Introduced in R2011a

Function-Call Generator

Provide function-call signal to control execution of a subsystem or model

Library: Ports & Subsystems

Description

The Function-Call Generator block provides a function-call signal to execute a function-call subsystem or function-call model at the rate that you specify with the **Sample time** parameter. To iteratively execute each function-call block multiple times at each time step, use the **Number of Iterations** parameter.

To execute multiple function-call subsystems or models in a specified order, use the Function-Call Generator block with a Function-Call Split block. For an example, see the Function-Call Split block documentation.

Ports

Output

Function Call — Function-call signal to a function-call subsystem or function-call model
scalar

Parameters

Sample time — Specify time interval

-1 (default) | T_s | [T_s , T_o]

Specify the time interval between function calls to a subsystem or model containing a Trigger block with **Trigger type** set to `function-call`. If the actual calling rate for the

subsystem or model differs from the time interval this parameter specifies, Simulink displays an error.

Settings

-1

Inherit time interval from the trigger signal.

Ts

Scalar where Ts is the time interval.

[Ts, To]

Vector where Ts is the time interval and To is the initial time offset.

Programmatic Use

Block parameter: `sample_time`

Type: character vector

Value: '-1' | 'Ts' | '[Ts, To]'

Default: '-1'

Number of iterations — Specify number of times to provide a function-call at each time step

1 (default) | integer

The value of this parameter can be a vector where each element of the vector specifies a number of times to execute a function-call subsystem. The total number of times that a function-call subsystem executes per time step equals the sum of the values of the elements of the generator signal entering its control port.

Suppose that you specify the number of iterations to be [2 2] and connect the output of this block to the control port of a function-call subsystem. In this case, the function-call subsystem executes four times at each time step.

Settings

1

Provide function-call once during each time step.

integer

Signed or unsigned integer number. Provide the specified number of function calls at each time step.

Programmatic Use

Parameter: numberOfIterations

Type: character vector

Value: '1' | '<integer>'

Default: '1'

Function-Call Split

Provide junction for splitting function-call signal

Library: Ports & Subsystems

Description

The Function-Call Split block allows a function-call signal to branch and connect to several function-call subsystems or function-call models.

A Function-Call Split outputs multiple function-call signals to create multiple branches from a single function-call signal. In some cases, when you use this block, you do not need the function-call initiator to create multiple function-call signals to invoke a set of function-call subsystems or function-call models.

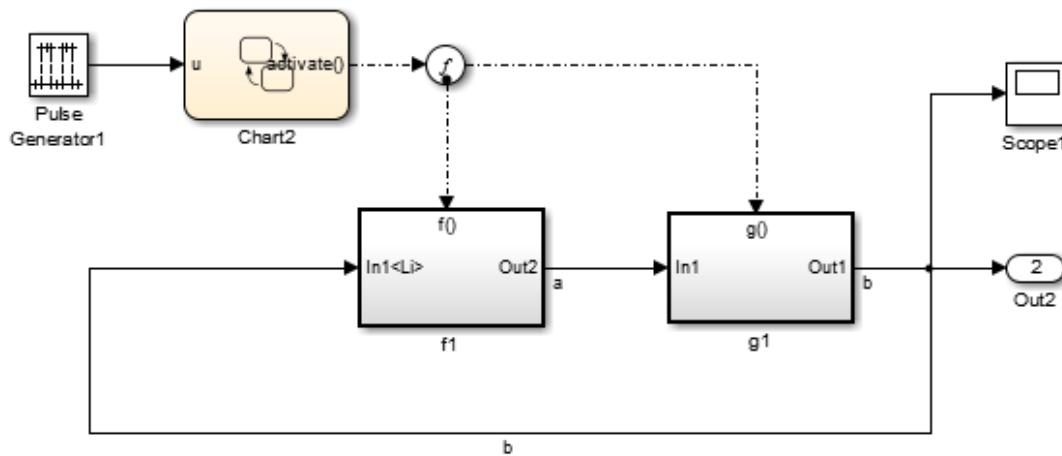

The function-call subsystem or function-call model connected to the output port of the Function-Call Split block that is marked with a dot execute before the subsystems or models connected to other output ports. If data dependencies between subsystems or models do not support the specified execution order, the Function-Call Split block returns an error. To eliminate this error, consider selecting the **Latch input for feedback signals of function-call subsystem outputs** parameter on one or more Inport blocks of the function-call subsystems models involved in a data-dependency loop. Selecting this option delays the corresponding input signal, thereby eliminating the data-dependency loop.

For a model to contain Function-Call Split blocks, you must set the following diagnostic to error: **Model Configuration Parameters > Diagnostics > Connectivity > Invalid function-call connection.**

If you select the model menu option **Display > Blocks > Sorted Execution Order**, then the execution order of function-call subsystems connected to branches of a given function-call signal appears on the blocks . Each subsystem has an execution order of the form $s: [B\#]$ where # is a number that ranges from 0 to one less than the total number of subsystems or models connected to branches of a given signal. The subsystems execute in ascending order based on this number.

The Function-Call Split block supports “Signal Label Propagation”.

The following model shows how to apply the **Latch input for feedback signals of function-call subsystem outputs** parameter to work around a data-dependency error caused by using a Function-Call Split block. By turning this parameter on in the f1 subsystem Inport block, the Function-Call Split block ignores the data dependency of signal b. The block breaks the loop of data dependencies between subsystems f1 and g1. The model achieves the behavior of consistently calling f1 to execute before g1. For a given execution step, subsystem f1 uses the g1 output computed at the previous execution step.

Limitations

The Function-Call Split block has these limitations:

- All function-call subsystems and models connected to a given function-call signal must reside within the same nonvirtual layer of the model hierarchy.
- You cannot connect branched function-call subsystems or models and their children directly back to the function-call initiator.
- Function-call subsystems and models connected to branches of a function-call signal cannot have multiple (muxed) initiators.
- A Function-Call Split block cannot have its input from a signal with multiple function-call elements.

Ports

Input

Function Call — Function-call signal

scalar

A Function-Call Generator block or a Stateflowchart can provide function-call signals.

Output

Function Call — Function-call signal

scalar

Function-call signal connected to a function-call subsystem or function-call model.

Parameters

Icon shape — Select block icon shape

distinctive (default) | round

Select block icon shape.

Settings

distinctive

Rectangular block icon.

round

Circular block icon.

Programmatic Use*Parameter:* IconShape*Type:* character vector*Value:* 'distinctive' | 'round'*Default:* 'distinctive'**Number of output ports — Specify number of output ports**

2 (default) | integer

Specify number of function-call signal output ports.

Settings

2

Two function-call signal output ports.

integer

Integer number

Programmatic Use

Parameter: NumOutputPorts

Type: character vector

Value: '2' | '<integer>'

Default: '2'

Output port layout — Select order of output ports

default (default) | reverse

Select the order of output ports with respect to which port provides a function-call first.

Settings

default

Top port provides function-call signal first.

reverse

Bottom port provides function-call signal first.

Programmatic Use

Parameter: OutputPortLayout

Type: character vector

Value: 'default' | 'reverse'

Default: 'default'

Topics

“Using Function-Call Subsystems”

Introduced in R2010a

Function-Call Subsystem

Subsystem whose execution is triggered by external function call input

Library: Ports & Subsystems

Description

The Function-Call Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem that executes when a control signal has a function call event.

Use Function-Call Subsystem blocks to:

- Schedule the execution order of model components.
- Control the rate of model component execution.

For an explanation of Function-Call Subsystem blocks parameters, see [Subsystem](#), [Atomic Subsystem](#), [Nonvirtual Subsystem](#), [CodeReuse Subsystem](#)

Ports

Input

In — Signal input to a subsystem block

scalar | vector | matrix

Placing an Inport block in a subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Function Call — Function-call control signal to a subsystem block

scalar

Placing a Trigger block in a subsystem block adds an external input port to the block. Selecting `function-call` from the **Trigger type** list, allows the Trigger block to accept function-call signals.

Output

Out — Signal output from a subsystem

scalar | vector | matrix

Placing an Outport block in a subsystem block adds an output port from the block. The port label on the subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Function Caller

Call Simulink or exported Stateflow function

Library: User-Defined Functions

Function Caller

Description

A Function Caller block calls and executes a function defined with a Simulink Function block or an exported Stateflow function. Using Function Caller blocks, you can call a function from anywhere in a model or chart hierarchy.

Ports

Input

Input argument — Input signal for an input argument

scalar | vector | matrix

Input signal for an input argument that is sent to the function.

The function prototype determines the number and name of input ports that appear on the Function Caller block. Connect signal lines to the input ports to send data to a function through the function input arguments.

For example, `y = myfunction(u)` creates one input port (`u`) on the Function Caller block.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Output

Output argument — Output signal for an output argument

scalar | vector | matrix

Output signal for an output argument that the function returns.

The function prototype determines the number and name of output ports that appear on the Function Caller block. Connect signal lines to the output ports to receive data from a function through the function output arguments.

For example, `y = myfunction(u)` creates one output port (`y`) on the Function Caller block.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Function prototype — Specify function interface

`y=f(u)` (default) | `<function prototype>`

Specify the function interface between a Function Caller block and a Simulink function. A Simulink function can be a Simulink Function block, an exported Stateflow graphical function, or an exported Stateflow MATLAB function. For a call to a Simulink Function block:

- Function call argument names must match the function arguments.
- Function names, input arguments, and output arguments must be valid MATLAB identifiers.

Programmatic Use

Block Parameter: `FunctionPrototype`

Type: character vector

Values: `'y=f(u)'` | `'<function prototype>'`

Default: `'y-f(u)'`

Input argument specifications — Specify input argument data type, dimensions, and complexity

`<Enter example>` (default) | `<MATLAB expression>`

Specify a comma-separated list of MATLAB expressions that combine data type, dimensions, and complexity (real or imaginary) for each input argument. For examples, see “Argument Specification for Simulink Functions”.

This specification must match the Simulink Function block data type specified with the **Data type** parameter of the Argument Inport block.

Programmatic Use

Block Parameter: 'InputArgumentSpecifications'

Type: character vector

Values: '' | '<MATLAB expression>'

Default: ''

Output argument specifications — Specify output argument data type, dimensions, and complexity

<Enter example> (default) | <MATLAB Expression>

Specify a comma-separated list of MATLAB expressions that combine data type, dimensions, and complexity (real or imaginary) for each output argument. For examples, see “Argument Specification for Simulink Functions”.

This specification must match the Simulink Function block data type specified with the **Data type** parameter of the Argument Output Block.

Programmatic Use

Block Parameter: 'OutputArgumentSpecifications'

Type: character vector

Values: '' | '<MATLAB expression>'

Default: ''

Sample time — Time interval between function calls

-1 (default) | Ts | [Ts, To]

Specify the time interval between function calls to a subsystem or model containing this Trigger block. If the actual calling rate for the subsystem or model differs from the time interval this parameter specifies, Simulink displays an error.

Settings

-1

Inherit time interval from the trigger signal.

Ts

Scalar where Ts is the time interval.

[Ts, To]

Vector where Ts is the time interval and To is the initial time offset.

Programmatic Use

Block parameter: SampleTime

Type: character vector

Value: '-1' | 'Ts' | '[Ts, To]'

Default: '-1'

Gain

Multiply input by constant

Library

Math Operations

Description

The Gain block multiplies the input by a constant value (gain). The input and the gain can each be a scalar, vector, or matrix.

You specify the value of the gain in the **Gain** parameter. The **Multiplication** parameter lets you specify element-wise or matrix multiplication. For matrix multiplication, this parameter also lets you indicate the order of the multiplicands.

The gain is converted from doubles to the data specified in the block mask offline using round-to-nearest and saturation. The input and gain are then multiplied, and the result is converted to the output data type using the specified rounding and overflow modes.

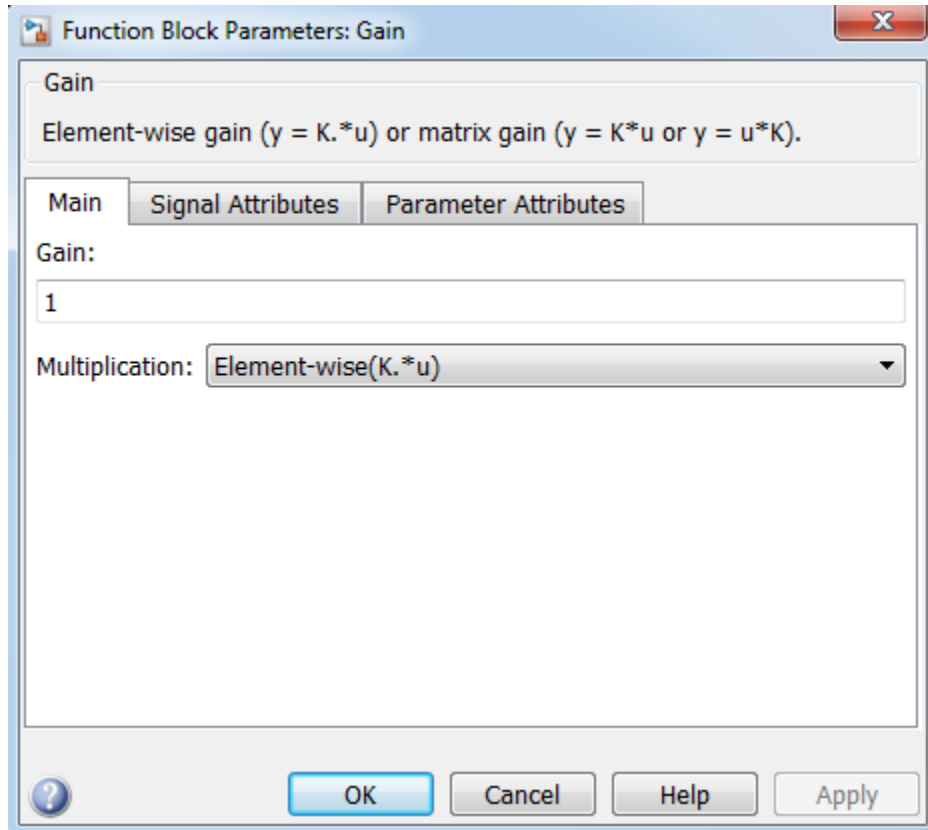

Data Type Support

The Gain block accepts a real or complex scalar, vector, or matrix of any numeric data type that Simulink supports. The Gain block supports fixed-point data types. If the input of the Gain block is real and the gain is complex, the output is complex.

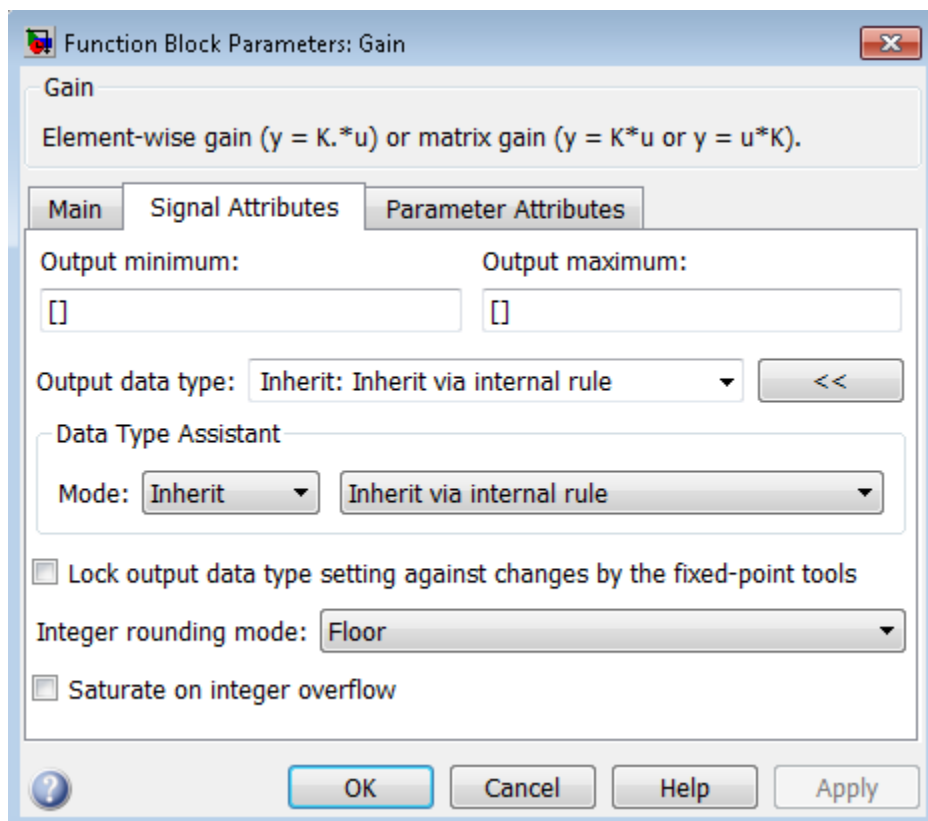

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters and Dialog Box

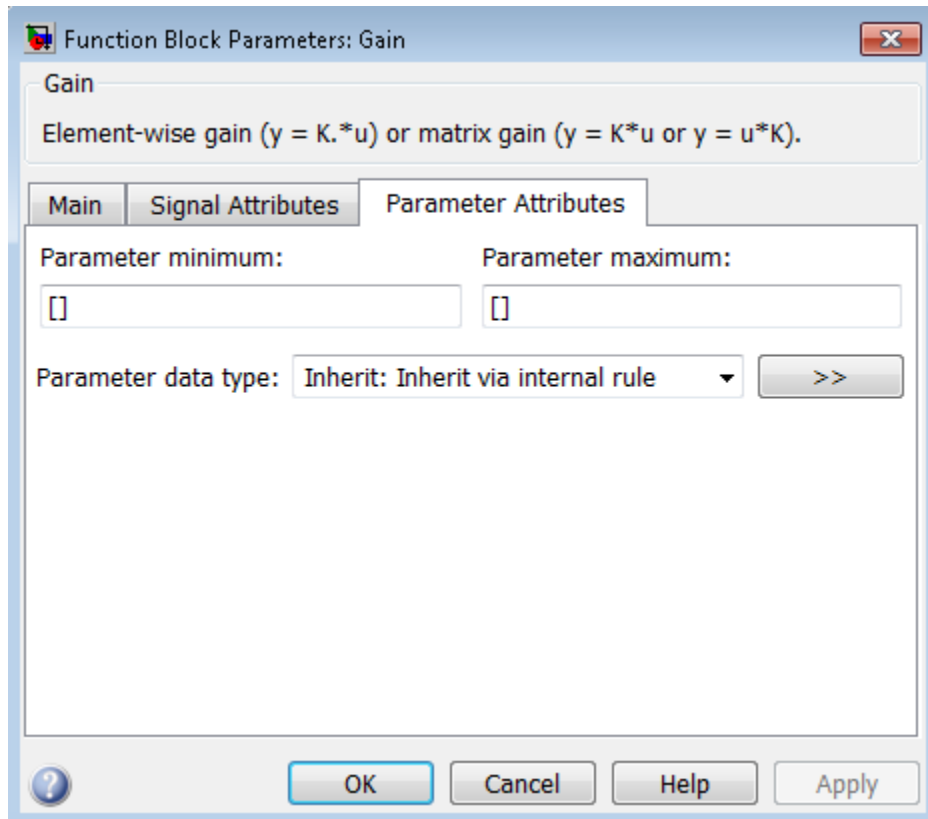

The **Main** pane of the Gain block dialog box appears as follows:

The **Signal Attributes** pane of the Gain block dialog box appears as follows:

The **Parameter Attributes** pane of the Gain block dialog box appears as follows:

Gain

Specify the value by which to multiply the input.

Default: 1

Minimum: value of **Parameter minimum** parameter

Maximum: value of **Parameter maximum** parameter

The gain can be a scalar, vector, or matrix.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Multiplication

Specify the multiplication mode.

Default: Element-wise ($K \cdot u$)

Element-wise ($K \cdot u$)

Each element of the input is multiplied by each element of the gain. The block performs expansions, if necessary, so that the input and gain have the same dimensions.

Matrix ($K \cdot u$)

The input and gain are matrix multiplied with the input as the second operand.

Matrix ($u \cdot K$)

The input and gain are matrix multiplied with the input as the first operand.

Matrix ($K \cdot u$) (u vector)

The input and gain are matrix multiplied with the input as the second operand. This mode is identical to `Matrix ($K \cdot u$)`, except for how dimensions are determined.

Suppose that K is an m -by- n matrix. `Matrix ($K \cdot u$) (u vector)` sets the input to a vector of length n and the output to a vector of length m . In contrast, `Matrix ($K \cdot u$)` uses propagation to determine dimensions for the input and output. For an m -by- n gain matrix, the input can propagate to an n -by- q matrix, and the output becomes an m -by- q matrix.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1 . To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Output minimum

Lower value of the output range that Simulink checks.

Default: [] (unspecified)

Specify this number as a finite, real, double, scalar value.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Parameter: OutMin

Type: character vector

Value: ' [] '

Default: ' [] '

Output maximum

Upper value of the output range that Simulink checks.

Default: [] (unspecified)

Specify this number as a finite, real, double, scalar value.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.

- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Note **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Parameter: OutMax

Type: character vector

Value: ' [] '

Default: ' [] '

Output data type

Specify the output data type.

Default: Inherit: Inherit via internal rule

Inherit: Inherit via internal rule

Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. For example, if the block multiplies an input of type `int8` by a gain of `int16` and ASIC/FPGA is specified as the targeted hardware type, the output data type is `sfix24`. If `Unspecified` (assume 32-bit Generic), i.e., a generic 32-bit microprocessor, is specified as the target hardware, the output data type is `int32`. If none of the word lengths provided by the target microprocessor can accommodate the output range, Simulink software displays an error in the Diagnostic Viewer.

It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use the simple choice of `Inherit: Same as input`.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
- To specify your own inheritance rule, use `Inherit: Inherit via back propagation` and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.

`Inherit: Inherit via back propagation`

Use data type of the driving block.

`Inherit: Same as input`

Use data type of input signal.

`double`

Output data type is double.

`single`

Output data type is single.

`int8`

Output data type is int8.

`uint8`

Output data type is uint8.

`int16`

Output data type is int16.

`uint16`

Output data type is uint16.

`int32`

Output data type is int32.

`uint32`

Output data type is uint32.

`fixdt(1,16,0)`

Output data type is fixed point `fixdt(1,16,0)`.

```
fixdt(1,16,2^0,0)
```

Output data type is fixed point `fixdt(1,16,2^0,0)`.

<data type expression>

Use a data type object, for example, `Simulink.NumericType`.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Control Signal Data Types” for more information.

Mode

Select the category of data to specify.

Default: `Inherit`

`Inherit`

Inheritance rules for data types. Selecting `Inherit` enables a second menu/text box to the right. Select one of the following choices:

- `Inherit via internal rule (default)`
- `Inherit via back propagation`
- `Same as input`

`Built in`

Built-in data types. Selecting `Built in` enables a second menu/text box to the right. Select one of the following choices:

- `double (default)`
- `single`
- `int8`
- `uint8`
- `int16`
- `uint16`
- `int32`

- `uint32`

Fixed point

Fixed-point data types.

Expression

Expressions that evaluate to data types. Selecting `Expression` enables a second menu/text box to the right, where you can enter the expression.

Clicking the **Show data type assistant** button enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specify Data Types Using Data Type Assistant”.

Data type override

Specify data type override mode for this signal.

Default: `Inherit`

`Inherit`

Inherits the data type override setting from its context, that is, from the block, `Simulink.Signal` object or Stateflow chart in Simulink that is using the signal.

`Off`

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

This parameter appears only when the **Mode** is `Built in` or `Fixed point`.

Signedness

Specify whether you want the fixed-point data as signed or unsigned.

Default: Signed

Signed

Specify the fixed-point data as signed.

Unsigned

Specify the fixed-point data as unsigned.

Selecting **Mode** > Fixed point enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Word length

Specify the bit size of the word that holds the quantized integer.

Default: 16

Minimum: 0

Maximum: 32

Selecting **Mode** > Fixed point enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

Default: Binary point

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting Slope and bias enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specifying a Fixed-Point Data Type”.

Fraction length

Specify fraction length for fixed-point data type.

Default: 0

Binary points can be positive or negative integers.

Selecting **Scaling** > Binary point enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Slope

Specify slope for the fixed-point data type.

Default: 2^0

Specify any positive real number.

Selecting **Scaling** > `Slope` and `bias` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Bias

Specify bias for the fixed-point data type.

Default: 0

Specify any real number.

Selecting **Scaling** > `Slope` and `bias` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

Default: Off

On

Locks the output data type setting for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change the output data type setting for this block.

Parameter: LockScale

Type: character vector

Value: 'off' | 'on'

Default: 'off'

For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Integer rounding mode

Specify the rounding mode for fixed-point operations.

Default: Floor

Ceiling

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

Floor

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

Simplest

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

Parameter: `RndMeth`

Type: character vector

Value: `'Ceiling'` | `'Convergent'` | `'Floor'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Default: `'Floor'`

For more information, see “Rounding” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

Saturate on integer overflow

Specify whether overflows saturate.

Default: Off

On

Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Off

Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Parameter: SaturateOnIntegerOverflow

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Parameter minimum

Specify the minimum value of the gain.

Default: []

The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Parameter maximum

Specify the maximum value of the gain.

Default: []

The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Parameter data type

Specify the data type of the **Gain** parameter.

Default: Inherit: Inherit via internal rule

Inherit: Inherit via internal rule

Use an internal rule to inherit the data type.

Inherit: Same as input

Use data type of sole input signal.

Inherit: Inherit from 'Gain'

Use data type of the **Gain** value. For example:

If you set Gain to...	The parameter data type inherits...
2	double
single(2)	single
int8(2)	int8

double

Data type is double.

single

Data type is single.

int8

Data type is int8.

uint8

Data type is uint8.

int16

Data type is int16.

`uint16`

Data type is `uint16`.

`int32`

Data type is `int32`.

`uint32`

Data type is `uint32`.

`fixdt(1,16)`

Data type is `fixdt(1,16)`.

`fixdt(1,16,0)`

Data type is `fixdt(1,16,0)`.

`fixdt(1,16,2^0,0)`

Data type is `fixdt(1,16,2^0,0)`.

`<data type expression>`

Use a data type object, for example, `Simulink.NumericType`.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Mode

Select the category of data to specify.

Default: `Inherit`

`Inherit`

Inheritance rules for data types. Selecting `Inherit` enables a second menu/text box to the right. Select one of the following choices:

- `Inherit` via internal rule (default)
- Same as input
- `Inherit` from 'Gain'

Built in

Built-in data types. Selecting `Built in` enables a second menu/text box to the right. Select one of the following choices:

- `double (default)`
- `single`
- `int8`
- `uint8`
- `int16`
- `uint16`
- `int32`
- `uint32`

Fixed point

Fixed-point data types.

Expression

Expressions that evaluate to data types. Selecting `Expression` enables a second menu/text box to the right, where you can enter the expression.

Clicking the **Show data type assistant** button enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specify Data Types Using Data Type Assistant” in the Simulink documentation.

Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

Default: `Best precision`

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

Best precision

Specify best-precision values.

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting Slope and bias enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

For more information, see “Specifying a Fixed-Point Data Type”.

Examples

The following Simulink examples show how to use the Gain block:

- sldemo_bounce
- sldemo_tonegen_fixpt
- sldemo_hardstop
- sldemo_enginewc

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point
Sample Time	Inherited from driving block

Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Gauge

Display input value on circular scale

Library: Simulink / Dashboard

Description

The Gauge block displays the connected signal on a circular scale during simulation. You can use the Gauge block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model. The Gauge block provides an indication of the instantaneous value of the connected signal throughout simulation. You can modify the range of the Gauge block to fit your data. You can also customize the appearance of the Gauge block to provide more information about your signal. For example, you can color-code in-specification and out-of-specification ranges.

Connection

Dashboard blocks do not use ports to connect to signals. To connect a signal to a Dashboard block, use the **Connection** table in the block's parameters.

- 1 Double-click the block.
- 2 Populate the **Connection** table by selecting signals of interest in your model.
- 3 Mark the option button next to the signal you want to display.
- 4 Click **Apply**.

Limitations

- You cannot save the block connections or properties in model files that use the MDL format.

To save connections and properties, save the model file in the SLX format.

- Dashboard blocks can only connect to real scalar signals.
- Dashboard blocks cannot connect to blocks that are commented out.
- Dashboard blocks cannot connect to signals inside reference models.
- If you turn off logging for a signal connected to a Dashboard block, the model stops sending data from that signal to the block. To view the signal again, reconnect the signal.
- External mode simulation does not support visualization Dashboard blocks.

Parameters

Connection — Select a signal to connect and display

signal connection options

Signal connection options. Populate the **Connection** table by selecting signals of interest in your model. Mark the check box next to the signal you want to display. Click **Apply** to connect the signal.

Minimum — Minimum tick mark value

0 (default) | scalar

A finite, real, double, scalar value specifying the minimum tick mark value for the scale. The minimum must be less than the value entered for the maximum.

Maximum — Maximum tick mark value

100 (default) | scalar

A finite, real, double, scalar value specifying the maximum tick mark value for the scale. The maximum must be greater than the value entered for the minimum.

Tick Interval — Interval between major tick marks

auto (default) | scalar

A finite, real, positive, integer, scalar value specifying the interval of major tick marks on the scale. When set to `auto`, the block automatically adjusts the tick interval based on the minimum and maximum values.

Scale Colors — Color indications on Gauge scale

colors for scale ranges

Color specifications for ranges on the scale. Press the **+** button to add a color. For each color added, specify the minimum and maximum values of the range where you want to display that color.

Label — Block label position

'Top' (default) | 'Bottom' | 'Hide'

Position of the block label. When the block is connected to a signal, the label is the name of the connected signal. When the block is not connected, the label is the instructional text.

Goto

Pass block input to From blocks

Library

Signal Routing

Description

The Goto block passes its input to its corresponding From blocks. The input can be a real- or complex-valued signal or vector of any data type. From and Goto blocks allow you to pass a signal from one block to another without actually connecting them.

A Goto block can pass its input signal to more than one From block, although a From block can receive a signal from only one Goto block. The input to that Goto block is passed to the From blocks associated with it as though the blocks were physically connected. Goto blocks and From blocks are matched by the use of Goto tags.

The **Tag Visibility** parameter determines whether the location of From blocks that access the signal is limited:

- `local`, the default, means that From and Goto blocks using the same tag must be in the same subsystem. A local tag name is enclosed in brackets (`[]`).
- `scoped` means that From and Goto blocks using the same tag must be in the same subsystem or at any level in the model hierarchy below the Goto Tag Visibility block that does not entail crossing a nonvirtual subsystem boundary, i.e., the boundary of an atomic, conditionally executed, or function-call subsystem or a model reference. A scoped tag name is enclosed in braces (`{}`).
- `global` means that From and Goto blocks using the same tag can be anywhere in the model except in locations that span nonvirtual subsystem boundaries.

The rule that From-Goto block connections cannot cross nonvirtual subsystem boundaries has the following exception. A Goto block connected to a state port in one conditionally executed subsystem is visible to a From block inside another conditionally executed subsystem.

Note A *scoped* Goto block in a masked system is visible only in that subsystem and in the nonvirtual subsystems it contains. Simulink generates an error if you run or update a diagram that has a Goto Tag Visibility block at a higher level in the block diagram than the corresponding *scoped* Goto block in the masked subsystem.

Use local tags when the Goto and From blocks using the same tag name reside in the same subsystem. You must use global or scoped tags when the Goto and From blocks using the same tag name reside in different subsystems. When you define a tag as global, all uses of that tag access the same signal. A tag defined as *scoped* can be used in more than one place in the model.

The Goto block supports signal label propagation.

Data Type Support

The Goto block accepts real or complex signals of any data type that Simulink supports, including fixed-point and enumerated data types.

For more information, see “Data Types Supported by Simulink”.

Parameters

Goto Tag

The Goto block identifier. This parameter identifies the Goto block whose scope is defined in this block.

Rename All

Rename the Goto tag. The new name propagates to the From and Goto Tag Visibility blocks that are listed in the **Corresponding blocks** box.

Tag Visibility

The scope of the Goto block tag: `local`, `scoped`, or `global`. The default is `local`.

Corresponding blocks

List of the From blocks and Goto Tag Visibility blocks connected to this Goto block. Click an entry in the list to display and highlight the corresponding From or Goto Tag Visibility block.

Icon Display

Specifies the text to display on the block's icon. The options are the block's tag, the name of the signal that the block represents, or both the tag and the signal name.

Examples

The following models show how to use the Goto block:

- `sldemo_auto_climatecontrol`
- `sldemo_hardstop`

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated Bus
Sample Time	Inherited from driving block

From, Goto Tag Visibility

Introduced before R2006a

Goto Tag Visibility

Define scope of Goto block tag

Library

Signal Routing

Description

The Goto Tag Visibility block defines the accessibility of Goto block tags that have scoped visibility. The tag specified as the **Goto tag** parameter is accessible by From blocks in the same subsystem that contains the Goto Tag Visibility block and in subsystems below it in the model hierarchy.

A Goto Tag Visibility block is required for Goto blocks whose **Tag Visibility** parameter value is `scoped`. No Goto Tag Visibility block is needed if the tag visibility is either `local` or `global`. The block shows the tag name enclosed in braces (`{}`).

Data Type Support

Not applicable.

Parameters

Goto tag

The Goto block tag whose visibility is defined by the location of this block.

If you use multiple From and Goto Tag Visibility blocks to refer to the same Goto tag, you can simultaneously rename the tag in all of the blocks. Use the **Rename All** button in the Goto block dialog box.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated Bus
Sample Time	Not applicable
Multidimensional Signals	No
Variable-Size Signals	No
Code Generation	Yes

Introduced before R2006a

Ground

Ground unconnected input port

Library

Sources

Description

The Ground block connects to blocks whose input ports do not connect to other blocks. If you run a simulation with blocks having unconnected input ports, Simulink issues warnings. Using a Ground block to ground those unconnected blocks can prevent these warnings.

The Ground block outputs a signal of the same data type as the port to which it connects. For example, consider the following model:

In this example, the output of the Constant block determines the data type (`int8`) of the port to which the Ground block is connected. That port determines the output data type of the Ground block.

The Ground block outputs a signal with zero value. When the output data type cannot represent zero exactly, the Ground block outputs a nonzero value that is the closest possible value to zero. This behavior applies only to fixed-point data types with nonzero bias. The following expressions are examples of fixed-point data types that cannot represent zero:

- `fixdt(0, 8, 1, 1)` — an unsigned 8-bit type with slope of 1 and bias of 1
- `fixdt(1, 8, 6, 3)` — a signed 8-bit type with slope of 6 and bias of 3

If the output is an enumerated data type, the Ground block outputs the default value of the enumeration. This behavior applies whether or not:

- The enumeration can represent zero.
- The default value of the enumeration is zero.

If the enumerated type does not have a default value, the Ground block outputs the first enumeration value in the type definition.

Data Type Support

The Ground block supports all data types that Simulink supports, including fixed-point and enumerated data types. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Examples

The following Simulink examples show how to use the Ground block:

- `sldemo_doublebounce`

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated Bus
Sample Time	Constant (<i>inf</i>)
Multidimensional Signals	Yes
Variable-Size Signals	No
Code Generation	Yes

Introduced before R2006a

Half Gauge

Display input value on semicircular scale

Library: Simulink / Dashboard

Description

The Half Gauge block displays the connected signal on a semicircular scale during simulation. You can use the Half Gauge block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model. The Half Gauge block provides an indication of the instantaneous value of the connected signal throughout simulation. You can modify the range of the Half Gauge block to fit your data. You can also customize the appearance of the Half Gauge block to provide more information about your signal. For example, you can color-code in-specification and out-of-specification ranges.

Connection

Dashboard blocks do not use ports to connect to signals. To connect a signal to a Dashboard block, use the **Connection** table in the block's parameters.

- 1 Double-click the block.
- 2 Populate the **Connection** table by selecting signals of interest in your model.
- 3 Mark the option button next to the signal you want to display.
- 4 Click **Apply**.

Limitations

- You cannot save the block connections or properties in model files that use the MDL format.

To save connections and properties, save the model file in the SLX format.

- Dashboard blocks can only connect to real scalar signals.
- Dashboard blocks cannot connect to blocks that are commented out.
- Dashboard blocks cannot connect to signals inside reference models.
- If you turn off logging for a signal connected to a Dashboard block, the model stops sending data from that signal to the block. To view the signal again, reconnect the signal.
- External mode simulation does not support visualization Dashboard blocks.

Parameters

Connection — Select a signal to connect and display

signal connection options

Signal connection options. Populate the **Connection** table by selecting signals of interest in your model. Mark the check box next to the signal you want to display. Click **Apply** to connect the signal.

Minimum — Minimum tick mark value

0 (default) | scalar

A finite, real, double, scalar value specifying the minimum tick mark value for the scale. The minimum must be less than the value entered for the maximum.

Maximum — Maximum tick mark value

100 (default) | scalar

A finite, real, double, scalar value specifying the maximum tick mark value for the scale. The maximum must be greater than the value entered for the minimum.

Tick Interval — Interval between major tick marks

auto (default) | scalar

A finite, real, positive, integer, scalar value specifying the interval of major tick marks on the scale. When set to `auto`, the block automatically adjusts the tick interval based on the minimum and maximum values.

Scale Colors — Color indications on Gauge scale

colors for scale ranges

Color specifications for ranges on the scale. Press the + button to add a color. For each color added, specify the minimum and maximum values of the range where you want to display that color.

Label — Block label position

'Top' (default) | 'Bottom' | 'Hide'

Position of the block label. When the block is connected to a signal, the label is the name of the connected signal. When the block is not connected, the label is the instructional text.

HDL Counter

Free-running or count-limited hardware counter

Library

HDL Coder / HDL Operations

Description

The HDL Counter block models a free-running or count-limited hardware counter that supports signed and unsigned integer and fixed-point data types.

The counter emits its value for the current sample time.

This block does not report wrap on overflow warnings during simulation. To report these warnings, see the `Simulink.restoreDiagnostic` reference page. The block does report errors due to wrap on overflow.

Control Ports

By default, the counter does not have input ports. Optionally, you can add control ports that enable, disable, load, reset or set the direction of the counter.

The table shows the priority of the control signals and how the counter value is updated in relation to the control signals.

Local reset, rst	Load trigger, load	Count enable, enb	Count direction, dir	Next Counter Value
1	–	–	–	initial value
0	1	–	–	load_val value
0	0	0	–	current value
0	0	1	1	current value + step value
0	0	1	0	current value - step value

Count direction

The **Step value** parameter and optional count direction port, `dir`, interact to determine the actual count direction.

dir Signal Value	Step Value Sign	Actual Count Direction
1	+ (positive)	Up
1	- (negative)	Down
0	+ (positive)	Down
0	- (negative)	Up

Parameters

Counter type

Counter behavior.

- **Free running (default):** The counter continues to increment or decrement by the **Step value** until reset.
- **Count limited:** The counter increments or decrements by the **Step value** until it is exactly equal to the **Count to value**.

Initial value

Counter value after reset. The default is 0.

Step value

Value added to counter at each sample time. The default is 1.

Count to value

When the count is exactly equal to **Count to value**, the count restarts at the **Initial value**. This option is available when **Counter type** is set to `Count limited`. The default is 100.

Count from

Specifies the parameter that sets the start value after rollover. When set to `Specify`, the **Count from value** parameter is the start value after rollover. The default is `Initial value`.

Count from value

Counter value after rollover when **Count from** is set to `Specify`. The default is 0.

Local reset port

When selected, creates a local reset port, `rst`.

Load ports

When selected, creates a load data port, `load_val`, and load trigger port, `load`.

Count enable port

When selected, creates a count enable port, `enb`.

Count direction port

When selected, creates a count direction port, `dir`.

Counter output data is

Output data type signedness. The default is `Unsigned`.

Word length

Bit width, including sign bit, for an integer counter; word length for a fixed-point data type counter. The minimum value if `Output data type` is `Unsigned` is 1, 2 if `Signed`. The maximum value is 125. The default is 8.

Fraction length

Fixed-point data type fraction length. The default is 0.

Sample time

Sample time. The default is 1.

This parameter is not available, and the block inherits its sample time from the input ports when any of these parameters is selected:

- **Local reset port**
- **Load ports**
- **Count enable port**
- **Count direction port**

Ports

The block has the following ports:

`rst`

Resets the counter value. Active-high.

This port is available when you select **Local reset port**.

Data type: Boolean

`load`

Sets the counter to the load value, `load_val`. Active-high.

This port is available when you select **Load ports**.

Data type: Boolean

`load_val`

Data value to load.

This port is available when you select **Load ports**.

Data type: Same as `count`.

`enb`

Enables counter operation. Active-high.

This port is available when you select **Count enable port**.

Data type: Boolean

`dir`

Count direction. This port interacts with **Step value** to determine count direction.

- 1: **Step value** is added to the current counter value to compute the next value.
- 0: **Step value** is subtracted from the current counter value to compute the next value.

This port is available when you select **Count direction port**.

Data type: Boolean

count

Counter value.

Data type: Determined automatically based on **Counter output data is**, **Word length**, and **Fraction length**.

Introduced in R2014a

HDL FIFO

Stores sequence of input samples in first in, first out (FIFO) register

Library

HDL Coder / HDL Operations

Description

The HDL FIFO block stores a sequence of input samples in a first in, first out (FIFO) register.

HDL Code Generation

For simulation results that match the generated HDL code, in the Solver pane of the Configuration Parameters dialog box, clear the checkbox for **Treat each discrete rate as a separate task**. When the checkbox is cleared, single-tasking mode is enabled.

If you simulate this block with **Treat each discrete rate as a separate task** selected, multitasking mode is enabled. The output data can update in the same cycle but in the generated HDL code, the output data is updated one cycle later.

Parameters

Register size

Specify the number of entries that the FIFO register can hold. The minimum is 4. The default is 10.

The ratio of output sample time to input sample time

Inputs (In, Push) and outputs (Out, Pop) can run at different sample times. Enter the ratio of output sample time to input sample time. Use a positive integer or $1/N$, where N is a positive integer. The default is 1.

For example:

- If you enter 2, the output sample time is twice the input sample time, meaning the outputs run slower.
- If you enter $1/2$, the output sample time is half the input sample time, meaning the outputs run faster.

The Full, Empty, and Num signals run at the faster rate.

Push onto full register

Response (Ignore, Error, or Warning) to a trigger received at the Push port when the register is full. The default is Warning.

Pop empty register

Response (Ignore, Error, or Warning) to a trigger received at the Pop port when the register is empty. The default is Warning.

Show empty register indicator port (Empty)

Enable the Empty output port, which is high (1) when the FIFO register is empty and low (0) otherwise.

Show full register indicator port (Full)

Enable the Full output port, which is high (1) when the FIFO register is full and low (0) otherwise.

Show number of register entries port (Num)

Enable the Num output port, which tracks the number of entries currently in the queue.

Ports

The block has the following ports:

In

Data input signal.

Push

Control signal. When this port receives a value of 1, the block pushes the input at the In port onto the end of the FIFO register.

Pop

Control signal. When this port receives a value of 1, the block pops the first element off the FIFO register and holds the Out port at that value.

Out

Data output signal.

Empty

The block asserts this signal when the FIFO register is empty. This port is optional.

Full

The block asserts this signal when the FIFO register is full. This port is optional.

Num

Current number of data values in the FIFO register. This port is optional.

If two or more of the control input ports are triggered in the same time step, the operations execute in the following order:

- 1 Pop
- 2 Push

See Also

Dual Rate Dual Port RAM

Introduced in R2014a

HDL Reciprocal

Calculate reciprocal with Newton-Raphson approximation method

HDL Reciprocal

Library

HDL Coder / HDL Operations

Description

The HDL Reciprocal block uses the Newton-Raphson iterative method to compute the reciprocal of the block input. The Newton-Raphson method uses linear approximation to successively find better approximations to the roots of a real-valued function.

The reciprocal of a real number a is defined as a zero of the function:

$$f(x) = \frac{1}{x} - a$$

HDL Coder chooses an initial estimate in the range $0 < x_0 < \frac{2}{a}$ as this is the domain of convergence for the function.

To successively compute the roots of the function, specify the **Number of iterations** parameter in the Block Parameters dialog box. The process is repeated as:

$$x_{i+1} = x_i - \frac{f(x_i)}{f'(x_i)} = x_i + (x_i - ax_i^2) = x_i \cdot (2 - ax_i)$$

$f'(x)$ is the derivative of the function $f(x)$.

Following table shows comparison of simulation behavior of HDL Reciprocal with Math Reciprocal block:

Math Reciprocal	HDL Reciprocal
Computes the reciprocal as 1/N by using the HDL divide operator (/) to implement the division.	Uses the Newton-Raphson iterative method. The block computes an approximate value of reciprocal of the block input and can yield different simulation results compared to the Math Reciprocal block. To match the simulation results with the Math Reciprocal block, increase the number of iterations for the HDL Reciprocal block.

Parameters

Number of iterations

Number of Newton-Raphson iterations. The default is 3.

Ports

The block has the following ports:

Input

- Supported data types: Fixed-point, integer (signed or unsigned), double, single
- Minimum bit width: 2
- Maximum bit width: 128

Output

Input data type	Output data type
double	double
single	single

Input data type	Output data type
built-in integer	built-in integer
built-in fixed-point	built-in fixed-point
$f_i(\text{value}, 0, \text{word_length}, \text{fraction_length})$	$f_i(\text{value}, 0, \text{word_length}, \text{word_length} - \text{fraction_length} - 1)$
$f_i(\text{value}, 1, \text{word_length}, \text{fraction_length})$	$f_i(\text{value}, 1, \text{word_length}, \text{word_length} - \text{fraction_length} - 2)$

Hit Crossing

Detect crossing point

Library

Discontinuities

Description

The Hit Crossing block detects when the input reaches the **Hit crossing offset** parameter value in the direction specified by the **Hit crossing direction** property.

The block accepts one input of type double. If you select the **Show output port** check box, the block output indicates when the crossing occurs. If the input signal is exactly the value of the offset value after the hit crossing is detected, the block continues to output a value of 1. If the input signals at two adjacent points bracket the offset value (but neither value is exactly equal to the offset), the block outputs a value of 1 at the second time step. If the **Show output port** check box is *not* selected, the block ensures that the simulation finds the crossing point but does not generate output. If the input signal is constant and equal to the offset value, the block outputs 1 only if the **Hit crossing direction** property is set to either.

When the block's **Hit crossing direction** property is set to either, the block serves as an "Almost Equal" block, useful in working around limitations in finite mathematics and computer precision. Used for these reasons, this block might be more convenient than adding logic to your model to detect this condition.

When the block's **Hit crossing direction** property is set to either and the model uses a fixed-step solver, the block has the following behavior. If the output signal is 1, the block sets the output signal to 0 at the next time step, unless the input signal equals the offset value.

Data Type Support

The Hit Crossing block outputs a signal of type `Boolean` if Boolean logic signals are enabled (see “Implement logic signals as Boolean data (vs. double)”). Otherwise, the block outputs a signal of type `double`.

Parameters

Hit crossing offset

The value whose crossing is to be detected.

Hit crossing direction

The direction from which the input signal approaches the hit crossing offset for a crossing to be detected.

Show output port

If selected, draw an output port.

Enable zero-crossing detection

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

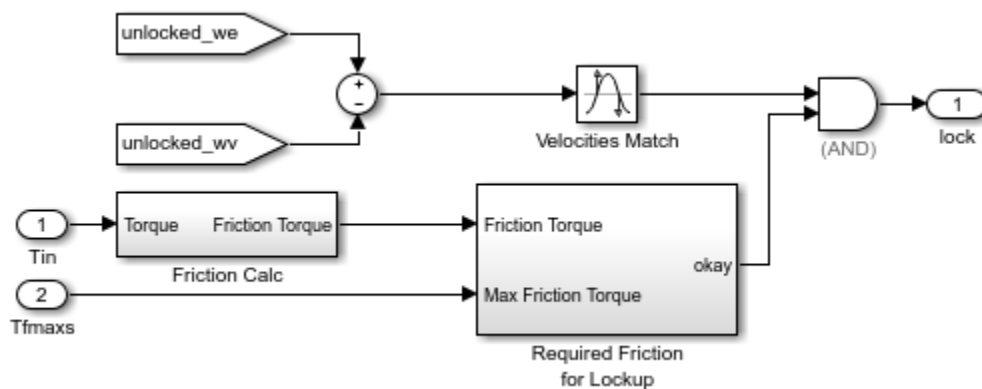

Examples

The `sldemo_hardstop` and `sldemo_clutch` models show how you can use the Hit Crossing block.

In the `sldemo_hardstop` model, the Hit Crossing block is in the Friction Model subsystem.

In the `sldemo_clutch` model, the Hit Crossing block is in the Friction Mode Logic/Lockup Detection subsystem.

Characteristics

Data Types	Double
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	Yes, if enabled
Code Generation	Yes

Introduced before R2006a

IC

Set initial value of signal

Library

Signal Attributes

Description

The IC block sets the initial condition of the signal at its input port, for example, the value of the signal at the simulation start time (t_{start}). The block does this by outputting the specified initial condition when you start the simulation, regardless of the actual value of the input signal. Thereafter, the block outputs the actual value of the input signal.

Note If an IC block has a nonzero sample time offset (t_{offset}), the IC block outputs its initial value at time t ,

$$t = n * t_{period} + t_{offset}$$

where n is the smallest integer such that $t \geq t_{start}$.

That is, the IC block outputs its initial value the first time blocks with sample time $[t_{period}, t_{offset}]$ execute, which can be after t_{start} .

The IC block is useful for providing an initial guess for the algebraic state variables in a loop. For more information, see “Algebraic Loops”.

Data Type Support

The IC block accepts and outputs signals of any Simulink built-in and fixed-point data type. The **Initial value** parameter accepts any built-in data type that Simulink supports. For more information, see “Data Types Supported by Simulink”.

Parameters

Initial value

Specify the initial value for the input signal.

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1 . To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Examples

The following examples show how to use the IC block:

- `sldemo_bounce`
- `sldemo_hardstop`
- `sldemo_enginewc`

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	No

Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

If

Model if-else control flow

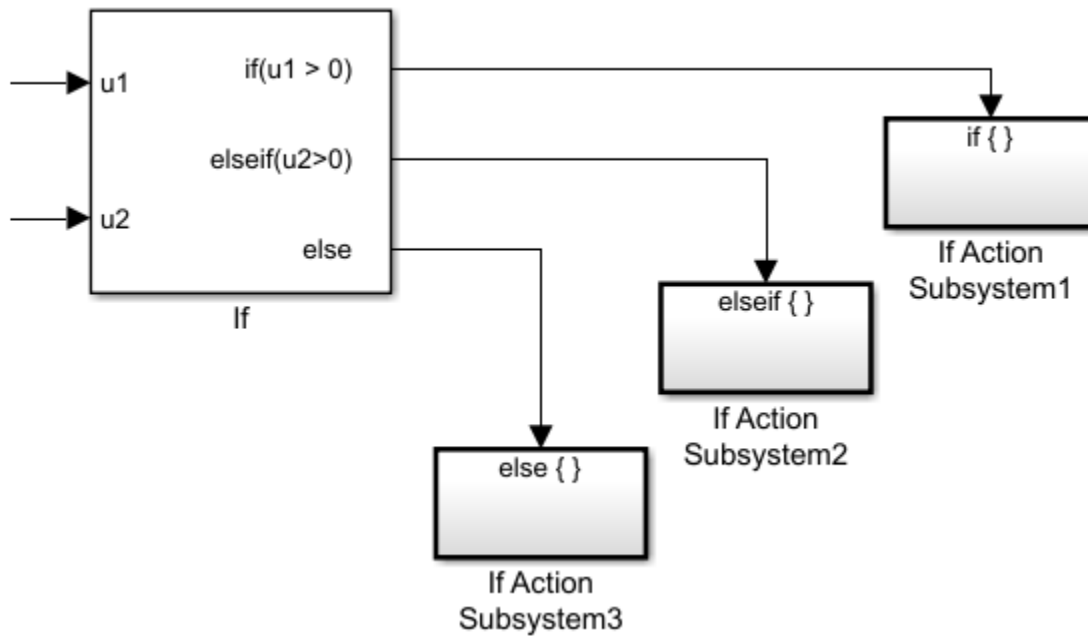

Library

Ports & Subsystems

Description

The If block, along with the If Action Subsystem block containing an Action Port, implements if-else logic.

The following shows a completed if-else control flow statement.

In this example, the inputs to the If block determine the values of conditions represented as output ports. Each output port is attached to an If Action Subsystem block. The conditions are evaluated top down starting with the `if` condition. If a condition is true, its If Action Subsystem is executed and the If block does not evaluate any remaining conditions.

The preceding if-else control flow statement can be represented by the following pseudocode.

```
if (u1 > 0) {
    If Action Subsystem1;
}
else if (u2 > 0){
    If Action Subsystem2;
}
else {
    If Action Subsystem3;
}
```

You construct a Simulink if-else control flow statement like the preceding example as follows:

- 1 Place an If block in the current system.
- 2 Open the dialog of the If block and enter as follows:
 - Enter the **Number of inputs** field with the required number of inputs necessary to define conditions for the `if-else` control flow statement.

Elements of vector inputs can be accessed for conditions using (row, column) arguments. For example, you can specify the fifth element of the vector `u2` in the condition `u2(5) > 0` in an **If expression** or **Elseif expressions** field.

- Enter the expression for the if condition of the `if-else` control flow statement in the **If expression** field.

This creates an if output port for the If block with a label of the form `if(condition)`. This is the only required If Action signal output for an If block.

- Enter expressions for any elseif conditions of the `if-else` control flow statement in the **Elseif expressions** field.

Use a comma to separate one condition from another. Entering these conditions creates an output port for the If block for each condition, with a label of the form `elseif(condition)`. elseif ports are optional and not required for operation of the If block.

- Check the **Show else condition** check box to create an else output port.

The else port is optional and not required for the operation of the If block.

- 3 Add If Action Subsystem blocks to connect to each of the if, else, and elseif ports.

These consist of a subsystem with an Action Port block. When you place an Action Port block inside each subsystem, an input port named Action is added to the subsystem.

- 4 Connect each if, else, and elseif port of the If block to the action port of an If Action Subsystem block.

When you make the connection, the icon for the If Action block is renamed to the type of the condition that it attaches to.

Note During simulation of an `if-else` control flow statement, the Action signal lines from the If block to the If Action subsystems turn from solid to dashed.

- 5 In each If Action Subsystem, enter the Simulink blocks appropriate to the body to be executed for the condition it handles.

Limitations

The If block has the following limitations:

- You cannot tune an if or elseif expression during simulation in Normal or Accelerator mode (see “How Acceleration Modes Work”), or in generated code. The If block does not support tunable parameters. To implement tunable if-else expressions, tune the expression outside the If block. For example, use the Relational operator block to evaluate the expression outside or add the tunable parameter as an input to the If block.
- The If block does not support custom storage classes. See “Custom Storage Classes” (Embedded Coder) in the Embedded Coder documentation.
- The **If expression** and **Elseif expressions** cannot accept certain operators, such as +, -, *, and /. See If Expression and Elseif Expressions in “Parameters” on page 1-744

Data Type Support

Inputs u_1, u_2, \dots, u_n can be scalars or vectors of any built-in Simulink data type and must all be of the same data type. The inputs cannot be of any user-defined type, such as an enumerated type. Outputs from the `if`, `else`, and `elseif` ports are action signals to If Action Subsystem blocks that you create by using Action Port blocks and subsystems.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Number of inputs

Specify the number of inputs to the If block. These appear as data input ports labeled with a 'u' character followed by a number, 1, 2, . . . , n, where n equals the number of inputs that you specify.

If expression

Specify the condition for the `if` output port. This condition appears on the If block adjacent to the `if` output port. The **If expression** can include only the operators `<`, `<=`, `==`, `~=`, `>`, `>=`, `&`, `|`, `~`, `()`, unary-minus, and cannot include

operators such as `+`, `-`, `*`, `/`, and `^`. The If Action Subsystem attached to the `if` port executes if its condition is true. The expression must not contain data type expressions, for example, `int8(6)`, and must not reference workspace variables whose data type is other than `double` or `single`.

Note There are limitations to the tunability of the **If expression**. See “Limitations” on page 1-744 for more information.

Elseif expressions

Specify a character vector list of `elseif` conditions delimited by commas. These conditions appear below the `if` port and above the `else` port when you select the **Show else condition** check box. **Elseif expressions** can include only the operators `<`, `<=`, `==`, `~=`, `>`, `>=`, `&`, `|`, `~`, `()`, unary-minus, and cannot include operators such as `+`, `-`, `*`, `/`, and `^`. The If Action Subsystem attached to an `elseif` port executes if its condition is true and all of the `if` and `elseif` conditions are false. The expression must not contain data type expressions, for example, `int8(6)`, and must not reference workspace variables whose data type is other than `double` or `single`.

Note There are limitations to the tunability of **Elseif expressions**. See “Limitations” on page 1-744 for more information.

Show else condition

If you select this check box, an `else` port is created. The If Action subsystem attached to the `else` port executes if the `if` port and all the `elseif` ports are false.

Enable zero-crossing detection

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

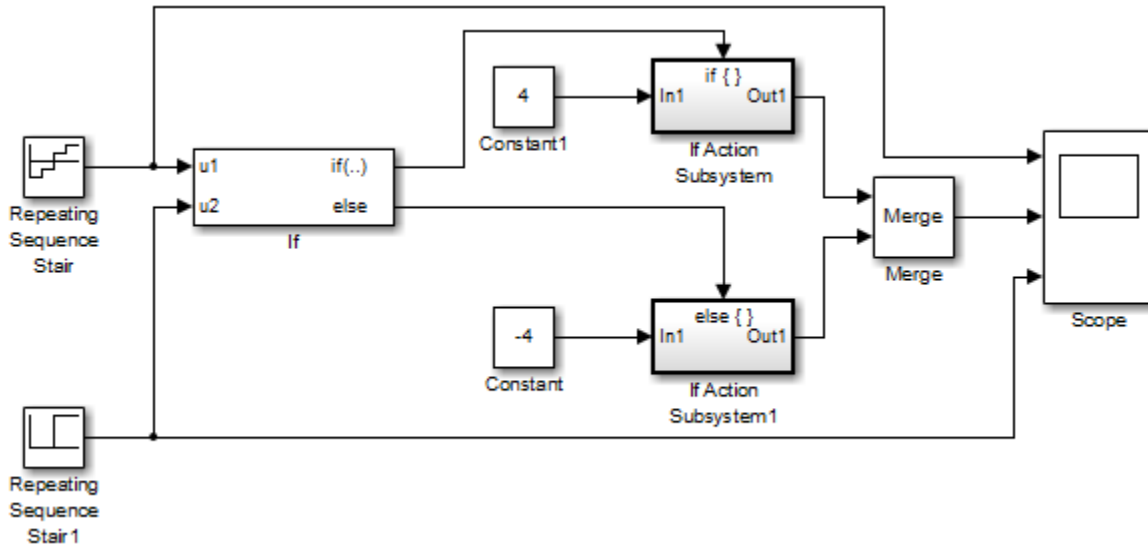

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Examples

The If block does not directly support fixed-point data types. However, you can use the Compare To Constant block to work around this limitation.

For example, consider the following floating-point model:

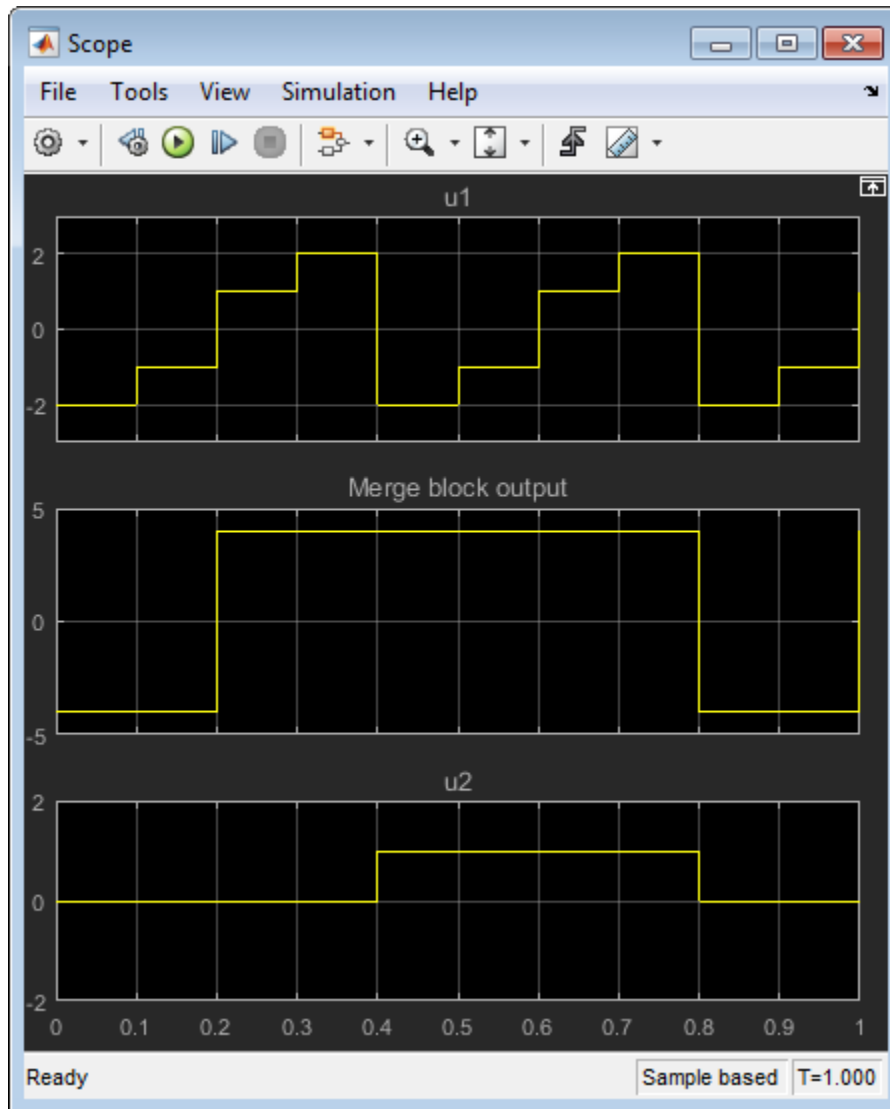

In this model, the If Action subsystems use their default configurations. The block and simulation parameters for the model are set to their default values except as follows:

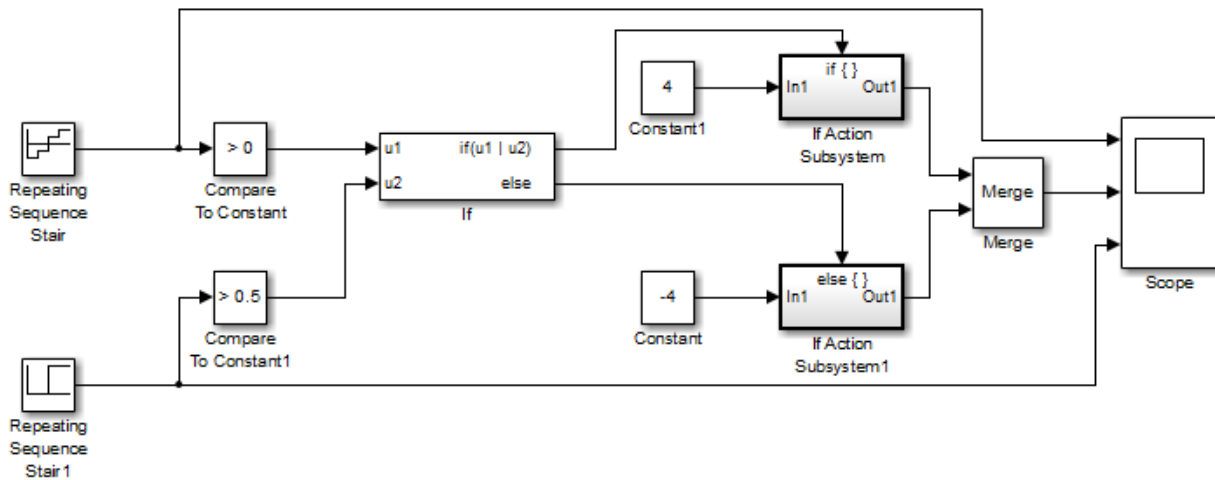

Block or Dialog Box	Parameter	Setting
Configuration Parameters — Solver pane	Start time	0.0
	Stop time	1.0
	Type	Fixed-step
	Solver	discrete (no continuous states)
	Fixed-step size	0.1
Repeating Sequence Stair	Vector of output values	[-2 -1 1 2].'

Block or Dialog Box	Parameter	Setting
Repeating Sequence Stair1	Vector of output values	[0 0 0 0 1 1 1 1].'
If	Number of inputs	2
	If expression	(u1 > 0) (u2 > 0.5)
	Show else condition	selected
Constant	Constant value	-4
Constant1	Constant value	4
Scope	Number of axes	3
	Time range	1

For this model, if input u1 is greater than 0 or input u2 is greater than 0.5, the output is 4. Otherwise, the output is -4. The Scope block shows the output, u1, and u2:

You can implement this block diagram as a model with fixed-point data types:

The Repeating Sequence Stair blocks now output fixed-point data types.

The Compare To Constant blocks implement two parts of the **If expression** that is used in the If block in the floating-point version of the model, $(u1 > 0)$ and $(u2 > 0.5)$. The OR operation, $(u1 | u2)$, can still be implemented inside the If block. For a fixed-point model, the expression must be partially implemented outside of the If block as it is here.

The block and simulation parameters for the fixed-point model are the same as for the floating-point model with the following exceptions and additions:

Block	Parameter	Setting
Compare To Constant	Operator	>
	Constant value	0
	Output data type mode	Boolean
	Enable zero-crossing detection	off
Compare To Constant1	Operator	>
	Constant value	0.5
	Output data type mode	Boolean
	Enable zero-crossing detection	off

Block	Parameter	Setting
If	Number of inputs	2
	If expression	u1 u2

Characteristics

Data Types	Double Single Boolean Base Integer
Sample Time	Inherited from driving block

Variable-Size Signals	No
Zero-Crossing Detection	Yes, if enabled
Code Generation	Yes

Introduced before R2006a

If Action Subsystem

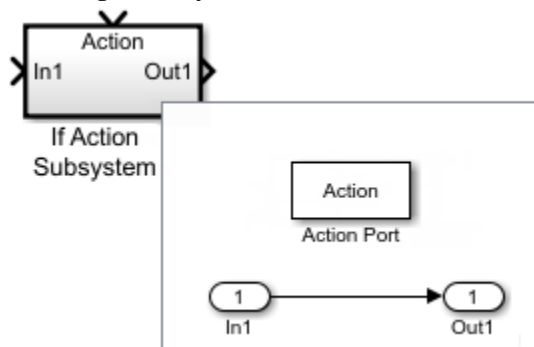

Subsystem whose execution is triggered by If block

Library: Ports & Subsystems

Description

The If Action Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem whose execution is triggered by an If block.

All blocks in an If Action Subsystem block must run at the same rate as the driving If block. You can achieve this requirement by setting each block's sample time parameter to be either inherited (-1) or the same value as the If block sample time.

Ports

Input

In_n — Signal input to a subsystem block

scalar | vector | matrix

Placing an Inport block in a subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Action — Control signal input to a subsystem block

`scalar` | `vector` | `matrix`

Placing an Action Port block in a subsystem block adds an external input port to the block and changes the block to an If Action Subsystem.

Dot-dash lines from an If block to an If Action Subsystem block represent *Action* signals. Action signals control the execution of a subsystem.

Data Types: `action`

Output

out — Signal output from a subsystem

`scalar` | `vector` | `matrix`

Placing an Outport block in a subsystem block adds an output port from the block. The port label on the subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

In Bus Element

Select bus element or entire bus that is connected to subsystem input port

Library: Simulink / Ports & Subsystems
Simulink / Sources

InBus.signal1 

Description

Note This block has two different names, depending on the library in which it appears. The functionality of both blocks is the same.

- In the Sources library and the Ports & Subsystems library — In Bus Element
 - In the Signal Routing library — Bus Element In
-

Select an element from a bus (or the entire bus) that is connected to the input port of the subsystem. This block integrates into one block the functionality of using an Inport block and a Bus Selector block. The In Bus Element block is of the Inport block type. There are no specifications allowed on an In Bus Element block, which supports only an inherited workflow. You cannot use the Block Parameters dialog box of an In Bus Element block to specify bus element attributes, such as data type or dimensions.

To work with buses at subsystem interfaces, consider using In Bus Element and Out Bus Element blocks. This bus element port block combination:

- Reduces signal line complexity and clutter in a block diagram.
- Makes it easy to change the interface incrementally.
- Allows access to a bus element closer to the point of usage.
 - For input, avoid a duplicate Inport blocks and a Bus Selector, Goto, and From block configuration.
 - For output, avoid a Goto, From, and Bus Creator block configuration.

The In Bus Element block selects signals from a subsystem input port. Feed the output of the In Bus Element block to another block in the subsystem.

For bus input signals, either specify the signal that you want to select from the input port or to pass through the whole bus signal, leave the element empty. For a nonbus input signal for a subsystem, leave the element section of the block icon text empty. The block passes through the value of the nonbus signal. To select multiple signals from an input bus signal, create multiple In Bus Element blocks, one for each selected signal.

You can specify the background color for bus element port blocks, using the Block Parameters dialog box **Set color** option. This action sets the color of blocks associated with selected elements, or to all blocks if you do not select elements.

Ports

The block does not have an input port. Use the Block Parameters dialog box or Property Inspector to specify the subsystem input port from which the block receives its input signal.

Output

Port_1 — Pass selected signal to another block
signal

The output port passes the value of the selected input signal to another block. The signal can have a real or complex value of any data type that Simulink supports.

Parameters

Port name — Name of associated subsystem input port
InBus (default) | text

Specify a name for a subsystem port. That name appears on the Subsystem and In Bus Element block icons. If you specify a port name, that name cannot already be in use by another In Bus Element block or port. All In Bus Element blocks that access the same subsystem input port reflect the port name that you specify.

Programmatic Use

Block Parameter: PortName

Type: text

Default: InBus

Port number — Position in which port appears for subsystem input ports

1 (default) | integer

Specify the order in which the port appears on the subsystem, with 1 being the top port, 2 the second port down, and so on.

- If you specify a number that exceeds the number of subsystem input ports, new ports are added above the port associated with the In Bus Element block.
- If you add an In Bus Element block that creates another subsystem input port, the port number is the next available number.
- If you delete all In Bus Element blocks associated with a port, other port numbers are renumbered so that the blocks are in sequence and that no numbers are omitted.

Programmatic Use

Block Parameter: Port

Value: integer

Default: 1

Model Examples

Block Characteristics

Increment Real World

Increase real world value of signal by one

Library: Simulink / Additional Math & Discrete / Additional
Math: Increment — Decrement

Description

The Increment Real World block increases the real world value of the signal by one.

Overflows always wrap.

Ports

Input

Port_1 (u) — Input signal

Scalar

The Increment Real World block accepts signals of the data types listed below.

For more information, see “Data Types Supported by Simulink”.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` |
`fixed point`

Output

Port_1 (y) — Calculated output signal

Scalar

Output data type always matches input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Block Characteristics

Data Types	<code>double</code> <code>single</code> <code>base integer</code> <code>fixed point</code>
Sample Time	<code>Inherit</code>
Direct Feedthrough	<code>Yes</code>
Multidimensional Signals	<code>Scalar</code>
Variable-Size Signals	<code>Yes</code>
Zero-Crossing Detection	<code>No</code>

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting the **Treat as atomic unit** option.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block has a single, default HDL architecture.

ConstrainedOutputPipeline

Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0.

See also “ConstrainedOutputPipeline” (HDL Coder).

InputPipeline

Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0.

See also “InputPipeline” (HDL Coder).

OutputPipeline

Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0.

See also “OutputPipeline” (HDL Coder).

Fixed-Point Conversion

Design and simulate fixed-point algorithms using Fixed-Point Designer™.

Decrement Real World | Increment Stored Integer

Introduced before R2006a

Increment Stored Integer

Increase stored integer value of signal by one

Library

Additional Math & Discrete / Additional Math: Increment - Decrement

Description

The Increment Stored Integer block increases the stored integer value of a signal by one.

Floating-point signals also increase by one, and overflows always wrap.

Data Type Support

The Increment Stored Integer block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Characteristics

Data Types	Double Single Base Integer Fixed-Point

Introduced before R2006a

Initialize Function

Executes contents on a model initialize event

Library: User-Defined Functions

Description

The Initialize Function block is a pre-configured subsystem block that executes on a model initialize event. By default, the Initialize Function block includes an Event Listener block with **Event** set to `Initialize`, a Constant block with **Constant value** set to `0`, and a State Writer block.

Replace the Constant block with blocks that generate the state value for the State Writer block.

For a list of unsupported blocks and features, see “Initialize, Reset, and Terminate Function Limitations”.

The input and output ports of a component containing Initialize Function and Terminate Function blocks must connect to input and output port blocks.

The code generated from this block is part of the `model_initialize` function that is called once at the beginning of model execution.

Inport

Create input port for subsystem or external input

Library

Ports & Subsystems, Sources

Description

Inport blocks are the links from outside a system into the system.

Simulink software assigns Inport block port numbers according to these rules:

- It automatically numbers the Inport blocks within a top-level system or subsystem sequentially, starting with 1.
- If you add an Inport block, the label is the next available number.
- If you delete an Inport block, other port numbers are automatically renumbered to ensure that the Inport blocks are in sequence and that no numbers are omitted.
- If you copy an Inport block into a system, its port number is *not* renumbered unless its current number conflicts with an Inport block already in the system. If the copied Inport block port number is not in sequence, renumber the block. Otherwise, you get an error message when you run the simulation or update the block diagram.

You can specify the dimensions of the input to the Inport block using the **Port dimensions** parameter. Entering a value of -1 lets Simulink determine the port dimension.

The **Sample time** parameter is the rate at which the signal is coming into the system. A value of -1 causes the block to inherit its sample time from the block driving it. You might need to set this parameter for:

- Inport blocks in a top-level system.
- Models with blocks where Simulink cannot determine the sample time, but these blocks drive Inport blocks.

For more information, see “Specify Sample Time”.

Inport Blocks in a Top-Level System

You can use an Inport block in a top-level system to:

- Supply external inputs from the workspace using one of these approaches. If no external outputs are supplied, then the default output is the ground value.
 - Use the **Configuration Parameters > Data Import/Export > Input** parameter. See “Load Data to Root-Level Input Ports”.

Tip To import many signals to root-level input ports, consider using the Root Inport Mapper tool. For more information, see “Map Data Using Root Inport Mapper Tool”.

- Use the `ut` argument of the `sim` command (see `sim`) to specify the inputs.
- Provide a means for perturbation of the model by the `linmod` and `trim` analysis functions.
 - Use Inport blocks to inject inputs into the system. See “Linearizing Models”.
- To load logged signal data using root Inport blocks, you can use the `createInputDataset` function to create a `Dataset` object that contains elements that correspond to root-level Inport blocks in the model.

Inport Blocks in a Subsystem

Inport blocks in a subsystem represent inputs to the subsystem. A signal arriving at an input port on a Subsystem block flows out of the associated Inport block in that subsystem. The Inport block associated with an input port on a Subsystem block is the block whose **Port number** parameter matches the relative position of the input port on the Subsystem block. For example, the Inport block whose **Port number** parameter is 1 gets its signal from the block connected to the topmost port on the Subsystem block.

If you renumber the **Port number** of an Inport block, the block becomes connected to a different input port, although the block continues to receive its signal from the same block outside the subsystem.

The Inport block name appears in the Subsystem icon as a port label. To suppress display of the label, select the Inport block and choose **Format > Hide Name**.

Inport blocks inside a subsystem support signal label propagation, but root-level Inport blocks do not.

You can use a subsystem inport to supply fixed-point data in a structure or any other format.

Tip For models that include bus signals composed of many bus elements that feed subsystems, consider using the In Bus Element and Out Bus Element blocks. You can use these bus element port blocks instead of Inport with Bus Selector blocks for inputs, and Outport with Bus Creator blocks for outputs. These bus element port blocks:

- Reduce signal line complexity and clutter in a block diagram.
- Make it easier to change the interface incrementally.
- Allow access to a bus element closer to the point of usage, avoiding the use of a Bus Selector and Goto block configuration.

The In Bus Element block is of block type Inport. However, there are no specifications allowed on bus element port blocks, which support inherited workflows. You cannot use the Block Parameters dialog box of an In Bus Element block to specify bus element attributes, such as data type or dimensions.

Creating Duplicate Inports

You can create any number of duplicates of an Inport block. The duplicates are graphical representations of the original intended to simplify block diagrams by eliminating unnecessary lines. The duplicate has the same port number, properties, and output as the original. Changing properties of a duplicate changes properties of the original and vice versa.

To create a duplicate of an Inport block:

- 1 In the block diagram, select the block that you want to duplicate.

- 2 In the Model Editor menu bar, select **Edit > Copy**.
- 3 In the block diagram, place your cursor where you want to place the duplicate.
- 4 Select **Edit > Paste Duplicate Inport**.

Connecting Buses to Root-Level Inports

If you want a root-level Inport of a model to produce a bus signal, you must set the **Data type** parameter to the name of a bus object that defines the bus that the Inport produces. For more information, see “When to Use Bus Objects”.

Data Type Support

The Inport block accepts complex or real signals of any data type that Simulink supports, including fixed-point and enumerated data types. The Inport block also accepts a bus object as a data type.

Note If you specify a bus object as the data type for this block, do not set the minimum and maximum values for bus data on the block. Simulink ignores these settings. Instead, set the minimum and maximum values for bus elements of the bus object specified as the data type. The values should be finite real double scalar.

For information on the Minimum and Maximum properties of a bus element, see `Simulink.BusElement`.

For more information, see “Data Types Supported by Simulink”.

The numeric and data types of the block output are the same as those of its input. You can specify the signal type and data type of an external input to a root-level Inport block using the **Signal type** and **Data type** parameters.

The elements of a signal array connected to a root-level Inport block must be of the same numeric and data types. Signal elements connected to a subsystem input port can be of differing numeric and data types, except in the following circumstance: If the subsystem contains an Enable, Trigger, or Atomic Subsystem block and the input port, or an element of the input port, connects directly to an output port, the input elements must be of the same type. For example, consider the following enabled subsystem:

In this example, the elements of a signal vector connected to In1 must be of the same type. The elements connected to In2, however, can be of differing types.

Port number

Specify the port number of the block.

Default: 1

This parameter controls the order in which the port that corresponds to the block appears on the parent subsystem or model block.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Icon display

Specify the information to be displayed on the icon of this input port.

Default: Port number

Signal name

Display the name of the signal connected to this port (or signals if the input is a bus).

Port number

Display port number of this port.

Port number and signal name

Display both the port number and the names of the signals connected to this port.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Latch input by delaying outside signal

Output the value of the input signal at the previous time step.

Default: Off

On

Output the value of the input signal at the previous time step.

Off

Do not output the value of the input signal at the previous time step.

- This option applies only to triggered subsystems and is enabled only if the Inport block resides in a triggered subsystem.
- Selecting this check box enables Simulink to resolve data dependencies among triggered subsystems that are part of a loop.
- Type `sl_subsys_semantics` at the MATLAB prompt for examples using latched inputs with triggered subsystems.
- The Inport block indicates that this option is selected by displaying `<Lo>`.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Latch input for feedback signals of function-call subsystem outputs

Latch the value of the input to this subsystem and prevent this value from changing during the execution of the subsystem. For a single function call that is branched to invoke multiple function-call subsystems, this option allows you to break a loop formed by a signal fed back from one of these function-call subsystems into the other. A second functionality of this option is to prevent any change to the values of a feedback signal from a function-call subsystem that is invoked during the execution of this subsystem.

Default: Off

On

Latch the input value.

Off

Do not latch the input value.

- This parameter applies only to function-call subsystems and is enabled only if the Inport block resides in a function-call subsystem.
- This parameter ensures that the subsystem inputs, including those generated within the subsystem's context, do not change during execution of the subsystem.
- The Inport block indicates that this option is selected by displaying ``.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Interpolate data

When loading data from the workspace, cause the block to linearly interpolate and extrapolate output at time steps for which no corresponding data exists.

To load discrete signal data from the workspace, in the Inport block dialog box:

- 1 Set the **Sample time** parameter to a discrete value, such as 2.
- 2 Clear the **Interpolate data** parameter.

Specifying the discrete sample time causes the simulation to have hit times exactly at those instances when the discrete data is sampled. You only need to specify the data values, not time values.

Turning interpolation off avoids unexpected data values at other simulation time points as a result of double precision arithmetic processing. For more information, see “Load Data to Test a Discrete Algorithm”.

Default: On

On

When loading data from the workspace, cause the block to linearly interpolate and extrapolate output at time steps for which no corresponding data exists.

Off

When loading data from the workspace, do not cause the block to linearly interpolate or extrapolate output at time steps for which no corresponding data exists. Simulink uses the following interpolation and extrapolation:

- For time steps between the first specified data point and the last specified data point — zero-order hold
- For time steps before the first specified data point and after the last specified data point — ground value
- For variable-sized signals for time steps before the first specified data point — a NaN is logged for single or double data types and ground for other data types. For time steps after the last specified data point, uses ground values.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Connect Input

To import, visualize, and map signal and bus data to root-level inports, click this button. The Root Inport Mapper tool displays.

This button appears only if this block is a root inport block.

Output function call

Specify that the input signal is outputting a function-call trigger signal.

Default: Off

On

Input signal is a function-call trigger signal.

Off

Input signal is not a function-call trigger signal.

- Select this option if it is necessary for a current model to accept a function-call trigger signal when referenced in the top model.
- This feature is limited to an asynchronous function call.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Minimum

Specify the minimum value that the block should output.

Default: [] (unspecified)

This number must be a finite real double scalar value.

Note If you specify a bus object as the data type for this block, do not set the minimum value for bus data on the block. Simulink ignores this setting. Instead, set the minimum

values for bus elements of the bus object specified as the data type. For information on the `Minimum` property of a bus element, see `Simulink.BusElement`.

Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Maximum

Specify the maximum value that the block should output.

Default: [] (unspecified)

This number must be a finite real double scalar value.

Note If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For information on the `Maximum` property of a bus element, see `Simulink.BusElement`.

Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Data type

Specify the output data type of the external input.

Default: `Inherit: auto`

`Inherit: auto`

A rule that inherits a data type

`double`

Data type is `double`.

`single`

Data type is `single`.

`int8`

Data type is `int8`.

`uint8`

Data type is `uint8`.

`int16`

Data type is `int16`.

`uint16`

Data type is `uint16`.

`int32`

Data type is `int32`.

`uint32`

Data type is `uint32`.

`boolean`

Data type is `boolean`.

`fixdt(1,16,0)`

Data type is fixed point `fixdt(1,16,0)`.

```
fixdt(1,16,2^0,0)
```

Data type is fixed point `fixdt(1,16,2^0,0)`.

```
Enum: <class name>
```

Data type is enumerated, for example, `Enum: Basic Colors`.

```
Bus: <object name>
```

Data type is a bus object.

```
<data type expression>
```

The name of a data type object, for example `Simulink.NumericType`

Do not specify a bus object as the expression.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Show data type assistant

Display the **Data Type Assistant**.

The **Data Type Assistant** helps you set the **Output data type** parameter.

For more information, see “Control Signal Data Types”.

Mode

Select the category of data to specify.

Default: `Inherit`

```
Inherit
```

Inheritance rule for data types. Selecting `Inherit` enables a second menu/text box to the right.

```
Built in
```

Built-in data types. Selecting `Built in` enables a second menu/text box to the right. Select one of the following choices:

- `double` (default)
- `single`
- `int8`
- `uint8`
- `int16`
- `uint16`
- `int32`
- `uint32`
- `boolean`

Fixed point

Fixed-point data types.

Enumerated

Enumerated data types. Selecting `Enumerated` enables a second menu/text box to the right, where you can enter the class name.

Bus object

Bus object. Selecting `Bus` enables a **Bus object** parameter to the right, where you enter the name of a bus object that you want to use to define the structure of the bus. If you need to create or change a bus object, click **Edit** to the right of the **Bus object** field to open the Simulink Bus Editor. For details, see “Create Bus Objects with the Bus Editor”.

Expression

Expressions that evaluate to data types. Selecting `Expression` enables a second menu/text box to the right, where you can enter the expression.

Do not specify a bus object as the expression.

Clicking the **Show data type assistant** button enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specify Data Types Using Data Type Assistant”.

Data type override

Specify data type override mode for this signal.

Default: `Inherit`

`Inherit`

Inherits the data type override setting from its context, that is, from the block, `Simulink.Signal` object or Stateflow chart in Simulink that is using the signal.

`Off`

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

This parameter appears only when the **Mode** is `Built in` or `Fixed point`.

Signedness

Specify whether you want the fixed-point data as signed or unsigned.

Default: `Signed`

`Signed`

Specify the fixed-point data as signed.

`Unsigned`

Specify the fixed-point data as unsigned.

Selecting **Mode** > `Fixed point` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Word length

Specify the bit size of the word that holds the quantized integer.

Default: 16

Minimum: 0

Maximum: 32

Selecting **Mode** > Fixed point enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

Default: Best precision

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

Best precision

Specify best-precision values.

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting `Slope` and `bias` enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

For more information, see “Specifying a Fixed-Point Data Type”.

Fraction length

Specify fraction length for fixed-point data type.

Default: 0

Binary points can be positive or negative integers.

Selecting **Scaling** > `Binary point` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Slope

Specify slope for the fixed-point data type.

Default: 2^0

Specify any positive real number.

Selecting **Scaling** > `Slope` and `bias` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Bias

Specify bias for the fixed-point data type.

Default: 0

Specify any real number.

Selecting **Scaling** > Slope and bias enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Output as nonvirtual bus

Output a nonvirtual bus.

Default: Off

On

Output a nonvirtual bus.

Off

Output a virtual bus.

- All signals in a nonvirtual bus must have the same sample time, even if the elements of the associated bus object specify inherited sample times. Any bus operation that would result in a nonvirtual bus that violates this requirement generates an error. For referenced models, buses are single-rate. For details, see “Connect Multirate Buses to Referenced Models”.
- For the top model in a model reference hierarchy, code generation creates a C structure to represent the bus signal output by this block.
- For referenced models, select this option to create a C structure. Otherwise, code generation creates an argument for each leaf element of the bus used in the referenced model.

Selecting **Data type** > Bus: <object name> enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

Default: Off

On

Locks the output data type setting for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change the output data type setting for this block.

Parameter: LockScale

Type: character vector

Value: 'off' | 'on'

Default: 'off'

For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Unit (e.g., m, m/s², N*m)

Specify physical unit of the input signal to the block.

Default: inherit

To specify a unit, begin typing in the text box. As you type, the parameter displays potential matching units. For a list of supported units, see Allowed Unit Systems.

To constrain the unit system, click the link to the right of the parameter:

- If a Unit System Configuration block exists in the component, its dialog box opens. Use that dialog box to specify allowed and disallowed unit systems for the component.
- If a Unit System Configuration block does not exist in the component, the model Configuration Parameters dialog box displays. Use that dialog box to specify allowed and disallowed unit systems for the model.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Port dimensions (-1 for inherited)

Specify the dimensions of the input signal to the block.

Default: -1

Valid values are:

-1	Dimensions are inherited from input signal
n	Vector signal of width n accepted
[m n]	Matrix signal having m rows and n columns accepted

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Variable-size signal

Specify the type of signals allowed into this port.

Default: `Inherit`

`Inherit`

Allow variable-size and fixed-size signals.

`No`

Do not allow variable-size signals.

`Yes`

Allow only variable-size signals.

When the signal at this port is a variable-size signal, the **Port dimensions** parameter specifies the maximum dimensions of the signal.

Parameter: VarSizeSig

Type: character vector

Value: 'Inherit' | 'No' | 'Yes'

Default: 'Inherit'

Sample time (-1 for inherited)

Specify the time interval between samples.

Default: -1

To inherit the sample time, set this parameter to -1.

See “Specify Sample Time” in the online documentation for more information.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Signal type

Specify the numeric type of the external input.

Default: auto

auto

Accept either `real` or `complex` as the numeric type.

real

Specify the numeric type as a real number.

complex

Specify the numeric type as a complex number.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated Bus
Sample Time	Specified in the Sample time parameter
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Integrator, Integrator Limited

Integrate signal

Library

Continuous

Description

The Integrator block outputs the value of the integral of its input signal with respect to time.

The Integrator Limited block is identical to the Integrator block with the exception that the output of the block is limited based on the upper and lower saturation limits. See “Limiting the Integral” on page 1-789 for details.

Simulink treats the Integrator block as a dynamic system with one state. The block dynamics are given by:

$$\begin{cases} \dot{x}(t) = u(t) \\ y(t) = x(t) \end{cases} \quad x(t_0) = x_0$$

where:

- u is the block input.
- y is the block output.
- x is the block state.
- x_0 is the initial condition of x .

While these equations define an exact relationship in continuous time, Simulink uses numerical approximation methods to evaluate them with finite precision. Simulink can

use a number of different numerical integration methods to compute the Integrator block's output, each with advantages in particular applications. Use the **Solver** pane of the Configuration Parameters dialog box (see “Solver Pane”) to select the technique best suited to your application.

The selected solver computes the output of the Integrator block at the current time step, using the current input value and the value of the state at the previous time step. To support this computational model, the Integrator block saves its output at the current time step for use by the solver to compute its output at the next time step. The block also provides the solver with an initial condition for use in computing the block's initial state at the beginning of a simulation. The default value of the initial condition is 0. Use the block parameter dialog box to specify another value for the initial condition or create an initial value input port on the block.

Use the parameter dialog box to:

- Define upper and lower limits on the integral
- Create an input that resets the block's output (state) to its initial value, depending on how the input changes
- Create an optional state output so that the value of the block's output can trigger a block reset

Use the Discrete-Time Integrator block to create a purely discrete system.

Defining Initial Conditions

You can define the initial conditions as a parameter on the block dialog box or input them from an external signal:

- To define the initial conditions as a block parameter, specify the **Initial condition source** parameter as `internal` and enter the value in the **Initial condition** field.
- To provide the initial conditions from an external source, specify the **Initial condition source** parameter as `external`. An additional input port appears under the block input.

Note If the integrator limits its output (see “Limiting the Integral” on page 1-789), the initial condition must fall inside the integrator’s saturation limits. If the initial condition is outside the block saturation limits, the block displays an error message.

Limiting the Integral

To prevent the output from exceeding specifiable levels, select the **Limit output** check box and enter the limits in the appropriate parameter fields. This action causes the block to function as a limited integrator. When the output reaches the limits, the integral action is turned off to prevent integral wind up. During a simulation, you can change the limits but you cannot change whether the output is limited. The block determines output as follows:

- When the integral is less than or equal to the **Lower saturation limit**, the output is held at the **Lower saturation limit**.
- When the integral is between the **Lower saturation limit** and the **Upper saturation limit**, the output is the integral.
- When the integral is greater than or equal to the **Upper saturation limit**, the output is held at the **Upper saturation limit**.

To generate a signal that indicates when the state is being limited, select the **Show saturation port** check box. A saturation port appears below the block output port.

The signal has one of three values:

- 1 indicates that the upper limit is being applied.
- 0 indicates that the integral is not limited.
- -1 indicates that the lower limit is being applied.

When you select this check box, the block has three zero crossings: one to detect when it enters the upper saturation limit, one to detect when it enters the lower saturation limit, and one to detect when it leaves saturation.

Note For the Integrator Limited block, by default, **Limit output** is selected, **Upper saturation limit** is set to 1, and **Lower saturation limit** is set to 0.

Wrapping Cyclic States

Several physical phenomena are cyclic, periodic, or rotary in nature. Objects or machinery that exhibit rotational movement and oscillators are examples of such phenomena.

Modeling these phenomena in Simulink involves integrating the rate of change of the periodic or cyclic signals to obtain the state of the movement.

The drawback with this approach, however, is that over long simulation time spans, the states representing periodic or cyclic signals integrate to large values. Further, computing the sine or cosine of these signals takes an increasingly large amount of time because of angle reduction. The large signals values also negatively impact solver performance and accuracy.

One approach for overcoming this drawback is to reset the angular state to 0 when it reaches 2π (or to $-\pi$ when it reaches π , for numerical symmetry). This approach improves the accuracy of sine and cosine computations and reduces angle reduction time. But it also requires zero-crossing detection and introduces solver resets, which slow down the simulation for variable step solvers, particularly in large models.

To eliminate solver resets at wrap points, the Integrator block supports wrapped states that you can enable by checking **Wrap state** on the block parameter dialog box. When you enable **Wrap state**, the block icon changes to indicate that the block has wrapping states.

Simulink allows wrapping states that are bounded by upper and lower values parameters of the wrapped state. The algorithm for determining wrapping states is given by:

$$y = \begin{cases} x \\ x - (x_u - x_l) \left\lfloor \frac{x - x_l}{x_u - x_l} \right\rfloor & x \in [x_l, x_u) \text{ otherwise} \end{cases}$$

where:

- x_l is the lower value of the wrapped state.
- x_u is the upper value of the wrapped state.
- y is the output.

The support for wrapping states provides these advantages.

- It eliminates simulation instability when your model approaches large angles and large state values.
- It reduces the number of solver resets during simulation and eliminates the need for zero-crossing detection, improving simulation time.
- It eliminates large angle values, speeding up computation of trigonometric functions on angular states.
- It improves solver accuracy and performance and enables unlimited simulation time.

Resetting the State

The block can reset its state to the specified initial condition based on an external signal. To cause the block to reset its state, select one of the **External reset** choices. A trigger port appears below the block's input port and indicates the trigger type.

- Select `rising` to reset the state when the reset signal rises from a negative or zero value to a positive value.
- Select `falling` to reset the state when the reset signal falls from a positive value to a zero or negative value.
- Select `either` to reset the state when the reset signal changes from zero to a nonzero value, from a nonzero value to zero, or changes sign.
- Select `level` to reset the state when the reset signal is nonzero at the current time step or changes from nonzero at the previous time step to zero at the current time step.
- Select `level hold` to reset the state when the reset signal is nonzero at the current time step.

The reset port has direct feedthrough. If the block output feeds back into this port, either directly or through a series of blocks with direct feedthrough, an algebraic loop results (see “Algebraic Loops”). Use the Integrator block's state port to feed back the block's output without creating an algebraic loop.

Note To be compliant with the Motor Industry Software Reliability Association (MISRA®) software standard, your model must use Boolean signals to drive the external reset ports of Integrator blocks.

About the State Port

Selecting the **Show state port** check box on the Integrator block's parameter dialog box causes an additional output port, the state port, to appear at the top of the Integrator block.

The output of the state port is the same as the output of the block's standard output port except for the following case. If the block is reset in the current time step, the output of the state port is the value that would have appeared at the block's standard output if the block had not been reset. The state port's output appears earlier in the time step than the output of the Integrator block's output port. Use the state port to avoid creating algebraic loops in these modeling scenarios:

- Self-resetting integrators (see “Creating Self-Resetting Integrators” on page 1-793)
- Handing off a state from one enabled subsystem to another (see “Handing Off States Between Enabled Subsystems” on page 1-794)

Note When updating a model, Simulink checks that the state port applies to one of these two scenarios. If not, an error message appears. Also, you cannot log the output of this port in a referenced model that executes in Accelerator mode. If logging is enabled for the port, Simulink generates a "signal not found" warning during execution of the referenced model.

Creating Self-Resetting Integrators

The Integrator block's state port helps you avoid an algebraic loop when creating an integrator that resets itself based on the value of its output. Consider, for example, the following model.

This model tries to create a self-resetting integrator by feeding the integrator's output, subtracted from 1, back into the integrator's reset port. However, the model creates an algebraic loop. To compute the integrator block's output, Simulink software needs to know the value of the block's reset signal, and vice versa. Because the two values are mutually dependent, Simulink software cannot determine either. Therefore, an error message appears if you try to simulate or update this model.

The following model uses the integrator's state port to avoid the algebraic loop.

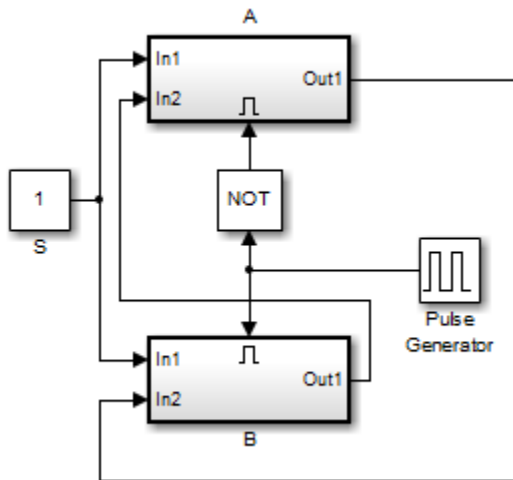

In this version, the value of the reset signal depends on the value of the state port. The value of the state port is available earlier in the current time step than the value of the integrator block's output port. Therefore, Simulink can determine whether the block

needs to be reset before computing the block's output, thereby avoiding the algebraic loop.

Handing Off States Between Enabled Subsystems

The state port helps you avoid an algebraic loop when passing a state between two enabled subsystems. Consider, for example, the following model.

The enabled subsystems, A and B, contain the following blocks:

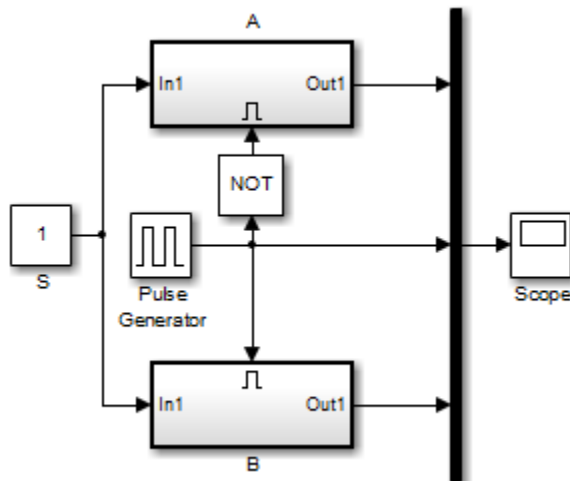

Subsystem A	Subsystem B
<p>Subsystem A contains an integrator block with inputs In1 and In2, and output Out1. The integrator is labeled with $\frac{1}{s}$ and x_0. An enable block is shown above the integrator.</p>	<p>Subsystem B contains a gain block with input In1 and output -1, followed by an integrator block with input In2 and output Out1. The integrator is labeled with $\frac{1}{s}$ and x_0. An enable block is shown above the gain block.</p>

In this model, a constant input signal drives two enabled subsystems that integrate the signal. A pulse generator generates an enabling signal that causes execution to alternate

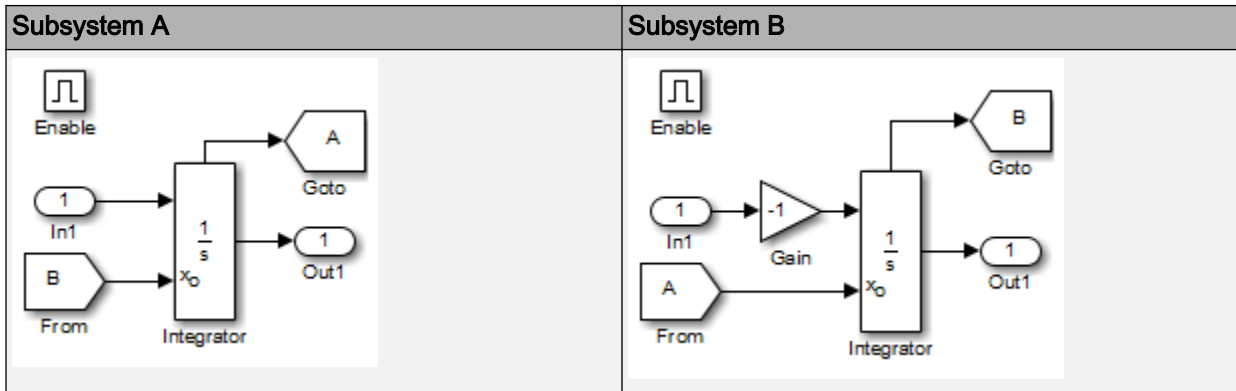

between the two subsystems. The enable port of each subsystem is set to reset, which causes the subsystem to reset its integrator when it becomes active. Resetting the integrator causes the integrator to read the value of its initial condition port. The initial condition port of the integrator in each subsystem is connected to the output port of the integrator in the other subsystem.

This connection is intended to enable continuous integration of the input signal as execution alternates between two subsystems. However, the connection creates an algebraic loop. To compute the output of A, Simulink needs to know the output of B, and vice versa. Because the outputs are mutually dependent, Simulink cannot compute the output values. Therefore, an error message appears if you try to simulate or update this model.

The following version of the same model uses the integrator state port to avoid creating an algebraic loop when handing off the state.

The enabled subsystems, A and B, contain the following blocks:

In this model, the initial condition of the integrator in A depends on the value of the state port of the integrator in B, and vice versa. The values of the state ports are updated earlier in the simulation time step than the values of the integrator output ports. Therefore, Simulink can compute the initial condition of either integrator without knowing the final output value of the other integrator. For another example of using the state port to hand off states between conditionally executed subsystems, see the `sldemo_clutch` model.

Specifying the Absolute Tolerance for the Block Outputs

By default Simulink software uses the absolute tolerance value specified in the Configuration Parameters dialog box (see “Error Tolerances for Variable-Step Solvers”) to compute the output of the Integrator block. If this value does not provide sufficient error control, specify a more appropriate value in the **Absolute tolerance** field of the Integrator block dialog box. The value that you specify is used to compute all the block outputs.

Selecting All Options

When you select all options, the block icon looks like this.

Data Type Support

The Integrator block accepts and outputs signals of type `double` on its data ports. The external reset port accepts signals of type `double` or `Boolean`.

Parameters

External reset

Reset the states to their initial conditions when a trigger event occurs in the reset signal.

Default: `none`

`none`

Do not reset the state to initial conditions.

`rising`

Reset the state when the reset signal rises from a zero to a positive value or from a negative to a positive value.

`falling`

Reset the state when the reset signal falls from a positive value to zero or from a positive to a negative value.

`either`

Reset the state when the reset signal changes from a zero to a nonzero value or changes sign.

`level`

Reset the state when the reset signal is nonzero at the current time step or changes from nonzero at the previous time step to zero at the current time step.

`level hold`

Reset the state when the reset signal is nonzero at the current time step.

Parameter: `ExternalReset`

Type: character vector

Value: `'none' | 'rising' | 'falling' | 'either' | 'level' | 'level hold'`

Default: 'none'

Initial condition source

Get the initial conditions of the states.

Default: `internal`

`internal`

Get the initial conditions of the states from the **Initial condition** parameter.

`external`

Get the initial conditions of the states from an external block.

Simulink software does not allow the initial condition of this block to be `inf` or `NaN`.

Selecting `internal` enables the **Initial condition** parameter.

Selecting `external` disables the **Initial condition** parameter.

Parameter: `InitialConditionSource`

Type: character vector

Value: `'internal' | 'external'`

Default: `'internal'`

Initial condition

Specify the states' initial conditions.

Default: 0

Simulink software does not allow the initial condition of this block to be `inf` or `NaN`.

Setting **Initial condition source** to `internal` enables this parameter.

Setting **Initial condition source** to `external` disables this parameter.

Parameter: `InitialCondition`

Type: scalar or vector

Value: `'0'`

Default: `'0'`

Limit output

Limit the block's output to a value between the **Lower saturation limit** and **Upper saturation limit** parameters.

Default: Off

On

Limit the block's output to a value between the **Lower saturation limit** and **Upper saturation limit** parameters.

Off

Do not limit the block's output to a value between the **Lower saturation limit** and **Upper saturation limit** parameters.

This parameter enables **Upper saturation limit**.

This parameter enables **Lower saturation limit**.

Parameter: `LimitOutput`

Type: character vector

Value: `'off' | 'on'`

Default: `'off'`

Upper saturation limit

Specify the upper limit for the integral.

Default: `inf`

Minimum: value of **Output minimum** parameter

Maximum: value of **Output maximum** parameter

Limit output enables this parameter.

Parameter: UpperSaturationLimit

Type: scalar or vector

Value: 'inf'

Default: 'inf'

Lower saturation limit

Specify the lower limit for the integral.

Default: -inf

Minimum: value of **Output minimum** parameter

Maximum: value of **Output maximum** parameter

Limit output enables this parameter.

Parameter: LowerSaturationLimit

Type: scalar or vector

Value: '-inf'

Default: '-inf'

Wrap state

Enable wrapping of states between the **Wrapped state upper value** and **Wrapped state lower value** parameters. Enabling wrap states eliminates the need for zero-crossing detection, reduces solver resets, improves solver performance and accuracy, and increases simulation time span when modeling rotary and cyclic state trajectories.

Default: off

On

Enable wrap states between the **Wrapped state upper value** and **Wrapped state lower value** parameters.

If you specify **Wrapped state upper value** as `inf` and **Wrapped state lower value** as `-inf`, wrapping will never occur.

 Off

Do not enable wrap states.

This parameter enables **Wrapped state upper value**.

This parameter enables **Wrapped state lower value**.

Parameter: `WrapState`

Type: character vector

Value: `'off' | 'on'`

Default: `'off'`

Wrapped state upper value

Specify the upper value for the wrap state.

Default: `'pi'`

Wrap state enables this parameter.

Parameter: `WrappedStateUpperValue`

Type: scalar or vector

Value: `'2*pi'`

Default: `'pi'`

Wrapped state lower value

Specify the lower value for the wrap state.

Default: `-pi`

Wrap state enables this parameter.

Parameter: `WrappedStateLowerValue`

Type: scalar or vector

Value: `'0'`

Default: `'-pi'`

Show saturation port

Add a saturation output port to the block.

Default: Off

On

Add a saturation output port to the block.

Off

Do not add a saturation output port to the block.

Parameter: `ShowSaturationPort`

Type: character vector

Value: `'off' | 'on'`

Default: `'off'`

Show state port

Add an output port to the block for the block's state.

Default: Off

On

Add an output port to the block for the block's state.

Off

Do not add an output port to the block for the block's state.

Parameter: ShowStatePort

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Absolute tolerance

Specify the absolute tolerance for computing block states.

Default: auto

- You can enter `auto`, `-1`, a positive real scalar or vector.
- If you enter `auto` or `-1`, then Simulink uses the absolute tolerance value in the Configuration Parameters dialog box (see “Solver Pane”) to compute block states.
- If you enter a real scalar, then that value overrides the absolute tolerance in the Configuration Parameters dialog box for computing all block states.
- If you enter a real vector, then the dimension of that vector must match the dimension of the continuous states in the block. These values override the absolute tolerance in the Configuration Parameters dialog box.

Parameter: AbsoluteTolerance

Type: character vector, scalar, or vector

Value: 'auto' | '-1' | any positive real scalar or vector

Default: 'auto'

Ignore limit and reset when linearizing

Cause Simulink linearization commands to treat this block as unresettable and as having no limits on its output, regardless of the settings of the block's reset and output limitation options.

Default: Off

On

Cause Simulink linearization commands to treat this block as unresettable and as having no limits on its output, regardless of the settings of the block's reset and output limitation options.

Off

Do not cause Simulink linearization commands to treat this block as unresettable and as having no limits on its output, regardless of the settings of the block's reset and output limitation options.

Use this check box to linearize a model around an operating point that causes the integrator to reset or saturate.

Parameter: IgnoreLimit

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Enable zero-crossing detection

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Default: On

On

Use zero crossings to detect and take a time step at any of the following events: reset, entering or leaving an upper saturation state, entering or leaving a lower saturation state.

Off

Do not use zero crossings to detect and take a time step at any of the following events: reset, entering or leaving an upper saturation state, entering or leaving a lower saturation state.

If you select this check box, **Limit output**, and zero-crossing detection for the model as a whole, the Integrator block uses zero crossings as described.

Parameter: ZeroCross

Type: character vector

Value: 'off' | 'on'

Default: 'on'

State Name (e.g., 'position')

Assign a unique name to each state.

Default: ' '

If this field is blank, no name assignment occurs.

- To assign a name to a single state, enter the name between quotes, for example, 'velocity'.
- To assign names to multiple states, enter a comma-delimited list surrounded by braces, for example, {'a', 'b', 'c'}. Each name must be unique.
- The state names apply only to the selected block.
- The number of states must divide evenly among the number of state names.
- You can specify fewer names than states, but you cannot specify more names than states.

For example, you can specify two names in a system with four states. The first name applies to the first two states and the second name to the last two states.

- To assign state names with a variable in the MATLAB workspace, enter the variable without quotes. A variable can be a character vector, cell array, or structure.

Parameter: ContinuousStateAttributes

Type: character vector

Value: ' ' | user-defined

Default: ' '

Examples

The following example models show how to use the Integrator block:

- `sldemo_hardstop`
- `sldemo_suspn`
- `sldemo_wheelspeed_absbrake`

Characteristics

Data Types	Double
Sample Time	Continuous
Direct Feedthrough	Yes, of the reset and external initial condition source ports
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	Yes, if enabled and you select the Limit output check box, one for detecting reset, one each to detect upper and lower saturation limits, and one when leaving saturation
Code Generation	Yes

Discrete-Time Integrator

Introduced before R2006a

Interpolation Using Prelookup

Use precalculated index and fraction values to accelerate approximation of N -dimensional function

Library

Lookup Tables

Description

The Prelookup block calculates the index and interval fraction that specify how its input value u relates to the breakpoint data set. The Interpolation Using Prelookup block works best with the Prelookup block. Feed the resulting index and fraction values into an Interpolation Using Prelookup block to interpolate an n -dimensional table. These two blocks have distributed algorithms. When combined together, they perform the same operation as the integrated algorithm in the n -D Lookup Table block. However, the Prelookup and Interpolation Using Prelookup blocks offer greater flexibility that can provide more efficient simulation and code generation. For more information, see “Efficiency of Performance” in the Simulink documentation.

Supported Block Operations

To use the Interpolation Using Prelookup block, you specify a set of table data values directly on the dialog box or feed values into the T input port. Typically, these table values correspond to the breakpoint data sets specified in Prelookup blocks. The Interpolation Using Prelookup block generates output by looking up or estimating table values based on index and interval fraction values fed from Prelookup blocks. Labels for the index and interval fraction appear as k and f on the Interpolation Using Prelookup block icon.

When inputs for index and interval fraction...	The Interpolation Using Prelookup block...
Map to values in breakpoint data sets	Outputs the table value at the intersection of the row, column, and higher dimension breakpoints
Do not map to values in breakpoint data sets, but are within range	Interpolates appropriate table values, using the Interpolation method you select
Do not map to values in breakpoint data sets, and are out of range	Extrapolates the output value, using the Extrapolation method you select

How The Block Interpolates a Subset of Table Data

You can use the **Number of sub-table selection dimensions** parameter to specify that interpolation occur only on a subset of the table data. To activate this interpolation mode, set this parameter to a positive integer. This value defines the number of dimensions to select, starting from the highest dimension of table data. Therefore, the value must be less than or equal to the **Number of table dimensions**.

Suppose that you have 3-D table data in your Interpolation Using Prelookup block. This behavior applies.

Number of Selection Dimensions	Action by the Block	Block Appearance
0	Interpolates the entire table and does not activate subtable selection	Does not change
1	Interpolates the first two dimensions and selects the third dimension	Displays an input port with the label <code>sel1</code> that you use to select and interpolate 2-D tables
2	Interpolates the first dimension and selects the second and third dimensions	Displays two input ports with the labels <code>sel1</code> and <code>sel2</code> that you use to select and interpolate 1-D tables

Subtable selection uses zero-based indexing. For an example of interpolating a subset of table data, type `sldemo_bpcheck` at the MATLAB command prompt.

Data Type Support

The Interpolation Using Prelookup block accepts as input:

- Real signals of any numeric data type supported by Simulink software, except Boolean.
- Fixed-point data types for signals, table data, and intermediate results
- Bus data types

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

- “Main Tab” on page 1-809
- “Data Types Tab” on page 1-814

Main Tab

Number of dimensions

Specify the number of dimensions that the table data must have. This value defines the number of independent variables for the table. Enter an integer between 1 and 30 into this field.

Require index and fraction as bus

Input index and fraction signals to a bus port, with the index and fraction signals combined in a nonvirtual bus.

If you select this parameter, subtable selection ports continue to work in nonbus mode.

To enable the Prelookup block to supply input to the Interpolation Using Prelookup block, set:

- **Output selection** to Index and fraction as bus
- **Output** to Bus: <object name>, where <object name> must be a valid bus object name accessible to the model

Specification

Specify whether to enter table data directly or use a lookup table object. If you set this parameter to:

- `Explicit values`, the **Source** and **Value** parameters are visible on the dialog box.
- `Lookup table object`, the **Name** parameter is visible on the dialog box.

Source

Specify whether to enter table data in the dialog box or to inherit the data from an input port. This parameter is available when **Specification** is set to `Explicit values`. If you set **Source** to:

- `Dialog`, enter table data in the text box under **Value**.
- `Input port`, verify that an upstream signal supplies table data to the table input port.

Value

If you set **Specification** to `Explicit values` and **Source** to `Dialog`, explicitly specify the table data.

You can edit the block diagram without specifying a correctly dimensioned matrix by entering an empty matrix (`[]`) or an undefined workspace variable in the **Value** edit field. For information about how to construct multidimensional arrays in MATLAB, see “Multidimensional Arrays” (MATLAB).

If you set **Source** to `Input port`, verify that an upstream signal supplies table data to the T input port. The size of table data must match the **Number of table dimensions**. For this option, your block inherits table attributes from the T input port.

To edit lookup tables using the Lookup Table Editor, click **Edit** (see “Edit Lookup Tables” in the Simulink documentation).

Name

Specify the name of an existing `Simulink.LookupTable` object. An existing lookup table object references Simulink breakpoint objects.

Interpolation method

Select `Flat`, `Nearest`, or `Linear`. See “Interpolation Methods” in the Simulink documentation for more information.

Extrapolation method

Select `Clip` or `Linear`. See “Extrapolation Methods” in the Simulink documentation for more information. The **Extrapolation method** parameter is visible only when you select `Linear` as the **Interpolation method** parameter.

The Interpolation Using Prelookup block does not support `Linear` extrapolation when the input or output signals specify integer or fixed-point data types.

Valid index input may reach last index

Specify how block inputs for index (k) and interval fraction (f) access the last elements of n -dimensional table data. Index values are zero based.

Check Box	Block Behavior
Selected	Returns the value of the last element in a dimension of its table when: <ul style="list-style-type: none"> • k indexes the last table element in the corresponding dimension • f is 0
Cleared	Returns the value of the last element in a dimension of its table when: <ul style="list-style-type: none"> • k indexes the next-to-last table element in the corresponding dimension • f is 1

This check box is visible only when:

- **Interpolation method** is `Linear`.
- **Extrapolation method** is `Clip`.

Tip When you select **Valid index input may reach last index** for an Interpolation Using Prelookup block, you must also select **Use last breakpoint for input at or above upper limit** for all Prelookup blocks that feed it. This action allows the blocks

to use the same indexing convention when accessing the last elements of their breakpoint and table data sets.

Diagnostic for out-of-range input

Specify whether to produce a warning or error when the input `k` or `f` is out of range. Options include:

- `None` — Simulink software takes no action.
- `Warning` — Simulink software displays a warning and continues the simulation.
- `Error` — Simulink software terminates the simulation and displays an error.

Remove protection against out-of-range index in generated code

Specify whether or not to include code that checks for out-of-range index inputs.

Check Box	Result	When to Use
Selected	Generated code does not include conditional statements to check for out-of-range index inputs. When the input <code>k</code> or <code>f</code> is out-of-range, it may cause undefined behavior for generated code and simulations using accelerator mode.	For code efficiency
Cleared	Generated code includes conditional statements to check for out-of-range index inputs.	For safety-critical applications

If your input is not out-of-range, you can select the **Remove protection against out-of-range index in generated code** check box for code efficiency. By default, this check box is cleared. For safety-critical applications, do not select this check box. If you want to select the **Remove protection against out-of-range index in generated code** check box, first check that your model inputs are in range. For example:

- 1 Clear the **Remove protection against out-of-range index in generated code** check box.
- 2 Set the **Diagnostic for out-of-range input** parameter to `Error`.
- 3 Simulate the model in normal mode.
- 4 If there are out-of-range errors, fix them to be in range and run the simulation again.
- 5 When the simulation no longer generates out-of-range input errors, select the **Remove protection against out-of-range index in generated code** check box.

Note When you select the **Remove protection against out-of-range index in generated code** check box and the input `k` or `f` is out-of-range, the behavior is undefined for generated code and simulations using accelerator mode.

Depending on your application, you can run the following Model Advisor checks to verify the usage of this check box:

- **By Product > Embedded Coder > Identify lookup table blocks that generate expensive out-of-range checking code**
- **By Product > Simulink Check > Modeling Standards > DO-178C/DO-331 Checks > Check usage of lookup table blocks**

For more information about the Model Advisor, see “Run Model Checks” in the Simulink documentation.

This check box has no effect on the generated code when one of the following is true:

- The Prelookup block feeds index values to the Interpolation Using Prelookup block.

Because index values from the Prelookup block are always valid, no check code is necessary.

- The data type of the input `k` restricts the data to valid index values.

For example, unsigned integer data types guarantee nonnegative index values. Therefore, unsigned input values of `k` do not require check code for negative values.

Number of sub-table selection dimensions

Specify the number of dimensions of the subtable that the block uses to compute the output. Follow these rules:

- To enable subtable selection, enter a positive integer.

This integer must be less than or equal to the **Number of table dimensions**.

- To disable subtable selection, enter 0 to interpolate the entire table.

For more information, see “How The Block Interpolates a Subset of Table Data” on page 1-808.

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Data Types Tab

Note The parameters for table attributes (data type, minimum, and maximum) are not available when you set **Source** to `Input port`. In this case, the block inherits all table attributes from the `T` input port.

Table data > Data Type

Specify the table data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as output`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the table data type.

Tip Specify a table data type different from the output data type for these cases:

- Lower memory requirement for storing table data that uses a smaller type than the output signal
 - Sharing of prescaled table data between two Interpolation Using Prelookup blocks with different output data types
 - Sharing of custom storage table data in Simulink Coder generated code for blocks with different output data types
-

Table data > Minimum

Specify the minimum value for table data. The default value is [] (unspecified).

Table data > Maximum

Specify the maximum value for table data. The default value is [] (unspecified).

Intermediate results > Data Type

Specify the intermediate results data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as output`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the intermediate results data type.

Tip Use this parameter to specify higher precision for internal computations than for table data or output data.

Output > Data Type

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`

- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the output data type.

See “Control Signal Data Types” in the *Simulink User's Guide* for more information.

Output > Minimum

Specify the minimum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Output > Maximum

Specify the maximum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Internal rule priority

Specify the internal rule for intermediate calculations. Select `Speed` for faster calculations. If you do, a loss of accuracy might occur, usually up to 2 bits.

Lock data type settings against changes by the fixed-point tools

Select to lock all data type settings of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function in the mask field.

Saturate on integer overflow

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.

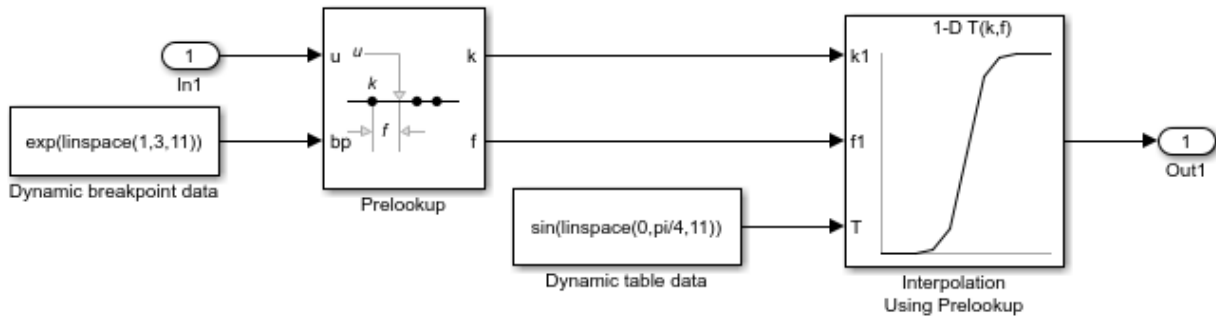

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Do not select this check box.	<p>You want to optimize efficiency of your generated code.</p> <p>You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.</p>	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Examples

Prelookup with External Breakpoint Specification

In the following model, a Constant block feeds the table data values to the `T` input port of the Interpolation Using Prelookup block.

The Interpolation Using Prelookup block inherits the following table attributes from the T input port:

Table Attribute	Value
Minimum	-Inf
Maximum	Inf
Data type	single

Similarly, a Constant block feeds the breakpoint data set to the bp input port of the Prelookup block, which inherits the following breakpoint attributes:

Breakpoint Attribute	Value
Minimum	-Inf
Maximum	Inf
Data type	single

Simulink uses double-precision, floating-point data to perform the computations in this model. However, the model stores the breakpoint and table data as single-precision, floating-point data. Using a lower-precision data type to store breakpoint and table data reduces the memory requirement.

For other examples, see “Prelookup and Interpolation Blocks” in the Simulink documentation.

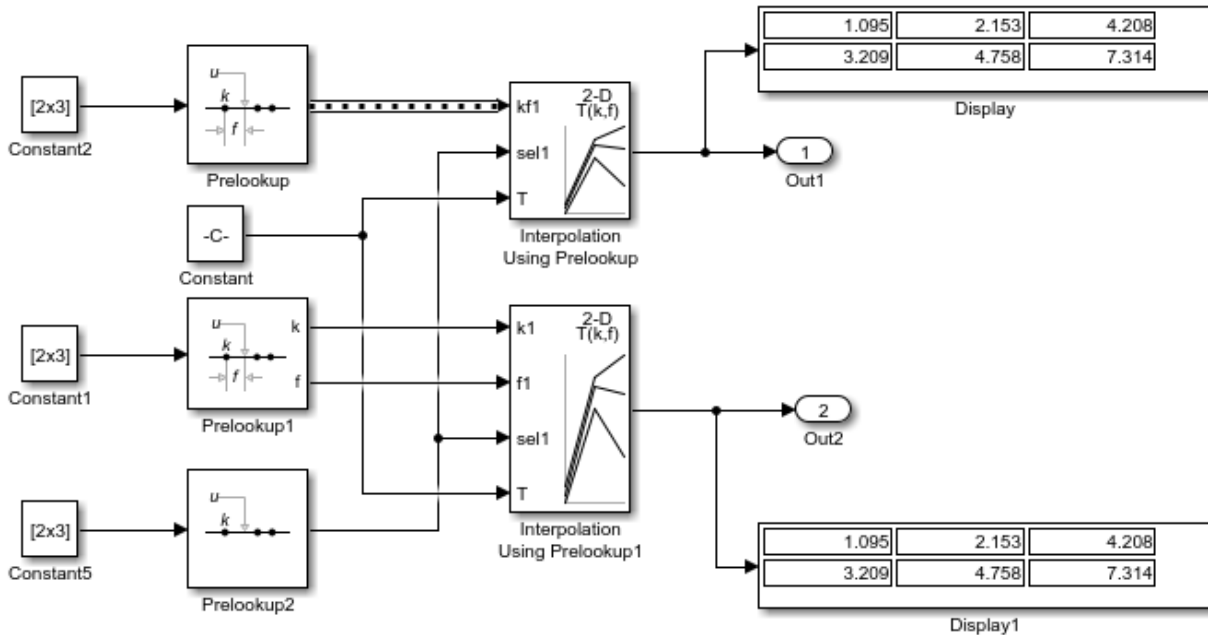

Use a Bus for Index and Fraction

You can use a bus object to specify the index (k) and fraction (f) in the Prelookup block and then use that bus as input to an Interpolation Using Prelookup block. This example

shows how to use a bus signal and how to get the same results without using a bus object.

Open the model and simulate it.

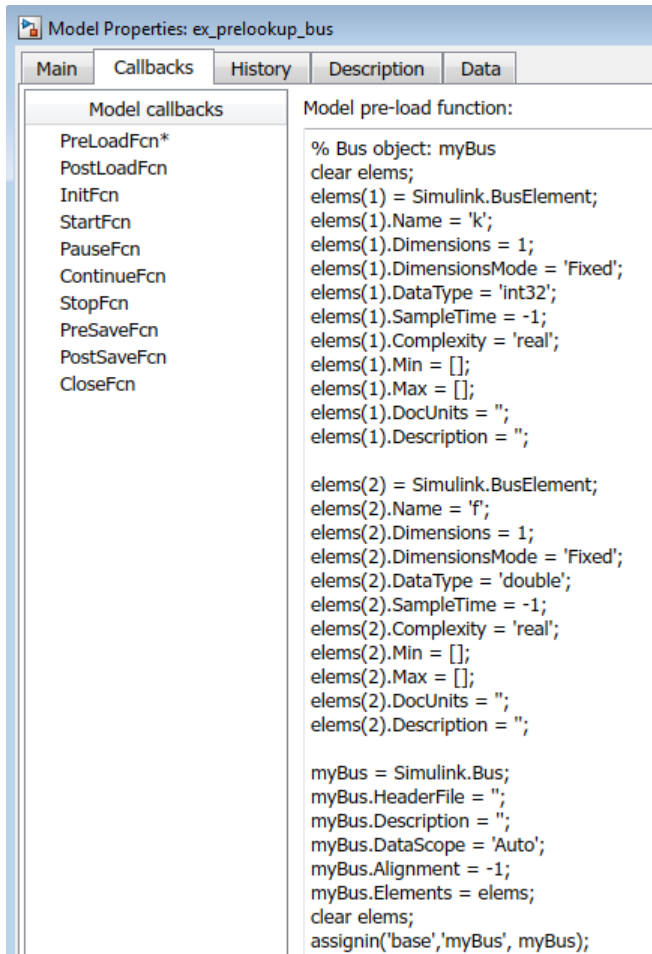

```
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
    'examples', 'ex_prelookup_bus.slx')))
sim('ex_prelookup_bus')
```

At the top of the model, open the Prelookup block parameters dialog box. In the **Main** tab, note that **Output selection** is set to Index and fraction as bus.

In the **Data Types** tab, note that **Output** is set to Bus: myBus.

In the Simulink Editor, select **File > Model Properties** and open the **Callbacks** tab. The code defines the bus object myBus, which specifies the index as the first bus element and the fraction as the second element.

In the Interpolation Using Prelookup block parameters dialog box, in the **Main** tab, note that **Require index and fraction as bus** check box is selected. That option configures the block to use the bus output from the Prelookup block.

Characteristics

Prelookup

Introduced in R2006b

Interpreted MATLAB Function

Apply MATLAB function or expression to input

Library

User-Defined Functions

Description

The Interpreted MATLAB Function block applies the specified MATLAB function or expression to the input. The output of the function must match the output dimensions of the block.

Some valid expressions for this block are:

```
sin
atan2(u(1), u(2))
u(1)^u(2)
```

Note This block is slower than the Fcn block because it calls the MATLAB parser during each integration step. Consider using built-in blocks (such as the Fcn block or the Math Function block) instead. Alternatively, you can write the function as a MATLAB S-function or MEX-file S-function, then access it using the S-Function block.

Data Type Support

The Interpreted MATLAB Function block accepts one real or complex input of type `double` and generates real or complex output of type `double`, depending on the setting of the **Output signal type** parameter.

Parameters

MATLAB function

Specify the function or expression. If you specify a function only, it is not necessary to include the input argument in parentheses.

Output dimensions

Specify the dimensions of the block output signal, for example, 2 for a two-element vector. The output dimensions must match the dimensions of the value returned by the function or expression in the **MATLAB function** field.

Specify -1 to inherit the dimensions from the output of the specified function or expression. To determine the output dimensions, Simulink runs the function or expression once before simulation starts.

Note If you specify -1 for this parameter and your function has persistent variables, then the variables might update before the simulation starts. If you need to use persistent variables, consider setting this parameter to a value other than -1.

Output signal type

Specify the output signal type of the block as `real`, `complex`, or `auto`. A value of `auto` sets the output type to be the same as the type of the input signal.

Collapse 2-D results to 1-D

Select this check box to output a 2-D array as a 1-D array containing the 2-D array's elements in column-major order.

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Characteristics

Data Types	Double
------------	--------

Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	No

Introduced in R2011a

Interval Test

Determine if signal is in specified interval

Library

Logic and Bit Operations

Description

The Interval Test block outputs TRUE if the input is between the values specified by the **Lower limit** and **Upper limit** parameters. The block outputs FALSE if the input is outside those values. The output of the block when the input is equal to the **Lower limit** or the **Upper limit** is determined by whether the boxes next to **Interval closed on left** and **Interval closed on right** are selected in the dialog box.

Data Type Support

The Interval Test block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean
- Enumerated

In this case, the **Upper limit** and **Lower limit** values must be of the same enumerated type.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Interval closed on right

When you select this check box, the **Upper limit** is included in the interval for which the block outputs TRUE.

Upper limit

The upper limit of the interval for which the block outputs TRUE.

Interval closed on left

When you select this check box, the **Lower limit** is included in the interval for which the block outputs TRUE.

Lower limit

The lower limit of the interval for which the block outputs TRUE.

Output data type

Select the output data type: `boolean` or `uint8`.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

See Also

Interval Test Dynamic

Introduced before R2006a

Interval Test Dynamic

Determine if signal is in specified interval

Library

Logic and Bit Operations

Description

The Interval Test Dynamic block outputs TRUE if the input is between the values of the external signals up and lo. The block outputs FALSE if the input is outside those values. The output of the block when the input is equal to the signal up or the signal lo is determined by whether the boxes next to **Interval closed on left** and **Interval closed on right** are selected in the dialog box.

Data Type Support

The Interval Test Dynamic block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean
- Enumerated

In this case, all inputs must be of the same enumerated type.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Interval closed on right

When you select this check box, the value of the signal connected to the block's “up” input port is included in the interval for which the block outputs TRUE.

Interval closed on left

When you select this check box, the value of the signal connected to the block's “lo” input port is included in the interval for which the block outputs TRUE.

Output data type

Select the output data type: `boolean` or `uint8`.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Interval Test

Introduced before R2006a

Knob

Tune parameter value with dial

Library: Simulink / Dashboard

Description

The Knob block tunes the value of the connected block parameter to during simulation. For example, you can connect the Knob block to a Gain block in your model and adjust its value during simulation. You can modify the range of the Knob block's scale to fit your data. Use the Knob block with other Dashboard blocks to create an interactive dashboard to control your model.

Connection

Dashboard block controls connect to variables and block parameters. To connect a Dashboard block to a variable or parameter, use the **Connection** table in the block's parameters.

- 1 Double-click the block.
- 2 Populate the **Connection** table by selecting blocks of interest in your model.
- 3 Mark the option button next to the parameter or variable you want to adjust during simulation.
- 4 Click **Apply**.

Limitations

- You cannot save the block connections or properties in model files that use the MDL format.

To save connections and properties, save the model file in the SLX format.

- Dashboard blocks can only connect to real scalar signals.
- Dashboard blocks cannot connect to blocks that are commented out.
- Dashboard blocks cannot connect to signals inside reference models.
- Parameters specified by indexing a variable array do not appear in the **Connection** table. For example, a block parameter defined using the variable `engine(1)` does not appear in the table.

To access the parameter in the **Connection** table, assign the indexed value to a scalar variable, such as `engine_1`. Then, use the scalar variable to define the block parameter.

Parameters

Connection — Select a block parameter to connect

signal connection options

Select the block parameter to control using the **Connection** table. To open the dialog box, double-click the block. Then, populate the **Connection** table by selecting a block in your model. Select the variable parameter you want to control, and click **Apply**.

Note To see workspace variables in the connection table, update the model diagram with **Ctrl+D**.

Scale Type — Type of scale

'Linear' (default) | 'Log'

Type of scale displayed on the control. **Linear** specifies a linear scale, and **Log** specifies a logarithmic scale.

Minimum — Minimum tick mark value

0 (default) | scalar

A finite, real, double, scalar value specifying the minimum tick mark value for the scale. The minimum must be less than the value entered for the maximum.

Maximum — Maximum tick mark value

100 (default) | scalar

A finite, real, double, scalar value specifying the maximum tick mark value for the scale. The maximum must be greater than the value entered for the minimum.

Tick Interval — Interval between major tick marks

auto (default) | scalar

A finite, real, positive, integer, scalar value specifying the interval of major tick marks on the scale. When set to `auto`, the block automatically adjusts the tick interval based on the minimum and maximum values.

Label — Block label position

'Top' (default) | 'Bottom' | 'Hide'

Position of the block label. When the block is connected to a signal, the label is the name of the connected signal. When the block is not connected, the label is the instructional text.

“Tune and Visualize Your Model with Dashboard Blocks”

“Decide How to Visualize Simulation Data”

Introduced in R2015a

Lamp

Display color reflecting input value

Library: Simulink / Dashboard

Description

The Lamp block displays a color indicating the value of the input signal. You can use the Lamp block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model. You can specify pairs of input values and colors to provide the information you want during simulation.

Connection

Dashboard blocks do not use ports to connect to signals. To connect a signal to a Dashboard block, use the **Connection** table in the block's parameters.

- 1 Double-click the block.
- 2 Populate the **Connection** table by selecting signals of interest in your model.
- 3 Mark the option button next to the signal you want to display.
- 4 Click **Apply**.

Limitations

- You cannot save the block connections or properties in model files that use the MDL format.

To save connections and properties, save the model file in the SLX format.

- Dashboard blocks can only connect to real scalar signals.
- Dashboard blocks cannot connect to blocks that are commented out.
- Dashboard blocks cannot connect to signals inside reference models.

- If you turn off logging for a signal connected to a Dashboard block, the model stops sending data from that signal to the block. To view the signal again, reconnect the signal.
- External mode simulation does not support visualization Dashboard blocks.

Parameters

Connection — Select a signal to connect and display

signal connection options

Signal connection options. Populate the **Connection** table by selecting signals of interest in your model. Mark the check box next to the signal you want to display. Click **Apply** to connect the signal.

States

state — Input value corresponding to a color

0 (default) | scalar

Input value that causes the specified color indication. The [undefined] state specifies the Lamp block's behavior when the input value is anything other than values specified in the **States** table. Click the + button to add another state.

Color — Color of lamp indicating input value

green (default)

Color indicating the input value specified in the corresponding **State**. You can select from a palette of standard colors or specify a custom color with RGB values. The Lamp block displays the color specified for the [undefined] state when the input's value does not correspond to a value in the **States** table. Click the + button to add another state.

Label — Block label position

'Top' (default) | 'Bottom' | 'Hide'

Position of the block label. When the block is connected to a signal, the label is the name of the connected signal. When the block is not connected, the label is the instructional text.

Level-2 MATLAB S-Function

Use Level-2 MATLAB S-function in model

Library: User-Defined Functions

Description

This block allows you to use a Level-2 MATLAB S-function (see “Write Level-2 MATLAB S-Functions”) in a model. To do this, create an instance of this block in the model. Then enter the name of the Level-2 MATLAB S-function in the **S-function name** field of the block's parameter dialog box.

Note Use the S-Function block to include a Level-1 MATLAB S-function in a block.

If the Level-2 MATLAB S-function defines any additional parameters, you can enter them in the **Parameters** field of the block's parameter dialog box. Enter the parameters as MATLAB expressions that evaluate to their values in the order defined by the MATLAB S-function. Use commas to separate each expression.

If a model includes a Level-2 MATLAB S-Function block, and an error occurs in the S-function, the Level-2 MATLAB S-Function block displays MATLAB stack trace information for the error in a dialog box. Click **OK** to close the dialog box.

Parameters

S-Function Name — Specify S-Function name

no default (default)

Specify the name of a MATLAB function that defines the behavior of this block. The MATLAB function must follow the Level-2 standard for writing MATLAB S-functions (see “Write Level-2 MATLAB S-Functions” for details).

Parameters — Specify values of parameters for this block

no default (default)

Specify values of parameters for this block.

Linear Gauge

Display input value on linear scale

Library: Simulink / Dashboard

Description

The Linear Gauge block displays the connected signal on a straight linear scale during simulation. Use the Linear Gauge block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model. The Linear Gauge block provides an indication of the instantaneous value of the connected signal throughout simulation. You can modify the range of the Linear Gauge block to fit your data. You can also customize the appearance of the Linear Gauge block to provide more information about your signal. For example, you can color-code in-specification and out-of-specification ranges.

Connection

Dashboard blocks do not use ports to connect to signals. To connect a signal to a Dashboard block, use the **Connection** table in the block's parameters.

- 1 Double-click the block.
- 2 Populate the **Connection** table by selecting signals of interest in your model.
- 3 Mark the option button next to the signal you want to display.
- 4 Click **Apply**.

Limitations

- You cannot save the block connections or properties in model files that use the MDL format.

To save connections and properties, save the model file in the SLX format.

- Dashboard blocks can only connect to real scalar signals.
- Dashboard blocks cannot connect to blocks that are commented out.
- Dashboard blocks cannot connect to signals inside reference models.
- If you turn off logging for a signal connected to a Dashboard block, the model stops sending data from that signal to the block. To view the signal again, reconnect the signal.
- External mode simulation does not support visualization Dashboard blocks.

Parameters

Connection — Select a signal to connect and display

signal connection options

Signal connection options. Populate the **Connection** table by selecting signals of interest in your model. Mark the check box next to the signal you want to display. Click **Apply** to connect the signal.

Minimum — Minimum tick mark value

0 (default) | scalar

A finite, real, double, scalar value specifying the minimum tick mark value for the scale. The minimum must be less than the value entered for the maximum.

Maximum — Maximum tick mark value

100 (default) | scalar

A finite, real, double, scalar value specifying the maximum tick mark value for the scale. The maximum must be greater than the value entered for the minimum.

Tick Interval — Interval between major tick marks

auto (default) | scalar

A finite, real, positive, integer, scalar value specifying the interval of major tick marks on the scale. When set to `auto`, the block automatically adjusts the tick interval based on the minimum and maximum values.

Scale Colors — Color indications on Gauge scale

colors for scale ranges

Color specifications for ranges on the scale. Press the + button to add a color. For each color added, specify the minimum and maximum values of the range where you want to display that color.

Label — Block label position

'Top' (default) | 'Bottom' | 'Hide'

Position of the block label. When the block is connected to a signal, the label is the name of the connected signal. When the block is not connected, the label is the instructional text.

Logical Operator

Perform specified logical operation on input

Library

Logic and Bit Operations

Description

The Logical Operator block performs the specified logical operation on its inputs. An input value is TRUE (1) if it is nonzero and FALSE (0) if it is zero.

You select the Boolean operation connecting the inputs with the **Operator** parameter list. If you select *rectangular* as the **Icon shape** property, the block updates to display the name of the selected operator. The supported operations are given below.

Operation	Description
AND	TRUE if all inputs are TRUE
OR	TRUE if at least one input is TRUE
NAND	TRUE if at least one input is FALSE
NOR	TRUE when no inputs are TRUE
XOR	TRUE if an odd number of inputs are TRUE
NXOR	TRUE if an even number of inputs are TRUE
NOT	TRUE if the input is FALSE

If you select *distinctive* as the **Icon shape**, the block's appearance indicates its function. Simulink software displays a distinctive shape for the selected operator, conforming to the IEEE Standard Graphic Symbols for Logic Functions:

The number of input ports is specified with the **Number of input ports** parameter. The output type is specified with the **Output data type** parameter. An output value is 1 if TRUE and 0 if FALSE.

Note The output data type should represent zero exactly. Data types that satisfy this condition include signed and unsigned integers, and any floating-point data type.

The size of the output depends on input vector size and the selected operator:

- If the block has more than one input, any nonscalar inputs must have the same dimensions. For example, if any input is a 2-by-2 array, all other nonscalar inputs must also be 2-by-2 arrays.

Scalar inputs are expanded to have the same dimensions as the nonscalar inputs.

If the block has more than one input, the output has the same dimensions as the inputs (after scalar expansion) and each output element is the result of applying the specified logical operation to the corresponding input elements. For example, if the specified operation is AND and the inputs are 2-by-2 arrays, the output is a 2-by-2 array whose top left element is the result of applying AND to the top left elements of the inputs, etc.

- For a single vector input, the block applies the operation (except the NOT operator) to all elements of the vector. The output is always a scalar.
- The NOT operator accepts only one input, which can be a scalar or a vector. If the input is a vector, the output is a vector of the same size containing the logical complements of the input vector elements.

When configured as a multi-input XOR gate, this block performs an addition- modulo-two operation as mandated by the IEEE Standard for Logic Elements.

Data Type Support

The Logical Operator block accepts real signals of any numeric data type that Simulink supports, including fixed-point data types.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Show data type assistant

Display the **Data Type Assistant**.

The **Data Type Assistant** helps you set the **Output data type** parameter.

For more information, see “Control Signal Data Types”.

Operator

Select logical operator to apply to block inputs.

Default: AND

AND

TRUE if all inputs are TRUE

OR

TRUE if at least one input is TRUE

NAND

TRUE if at least one input is FALSE

NOR

TRUE when no inputs are TRUE

XOR

TRUE if an odd number of inputs are TRUE

NXOR

TRUE if an even number of inputs are TRUE

NOT

TRUE if the input is FALSE

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Number of input ports

Specify number of block inputs.

Default: 2

- The value must be appropriate for the selected operator.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Icon shape

Specify shape of the block icon.

Default: rectangular

rectangular

Result in a rectangular block that displays the name of the selected operator.

distinctive

Use the graphic symbol for the selected operator as specified by the IEEE standard.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Require all inputs and output to have the same data type

Require all inputs and the output to have the same data type.

Default: Off

On

Require all inputs and the output to have the same data type.

Off

Do not require all inputs and the output to have the same data type.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Output data type

Specify the output data type.

Default: `boolean`

Inherit: `Logical` (see Configuration Parameters: Optimization)

Uses the **Implement logic signals as Boolean data** configuration parameter (see “Implement logic signals as Boolean data (vs. double)”) to specify the output data type.

Note This option supports models created before the `boolean` option was available. Use one of the other options, preferably `boolean`, for new models.

boolean

Specifies output data type is boolean.

fixdt(1,16)

Specifies output data type is fixdt(1,16).

<data type expression>

Uses the name of a data type object, for example, Simulink.NumericType.

Tip To enter a built-in data type (double, single, int8, uint8, int16, uint16, int32, or uint32), enclose the expression in single quotes. For example, enter 'double' instead of double.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Mode

Select the category of data to specify.

Default: Built in

Inherit

Specifies inheritance rules for data types. Selecting Inherit enables Logical (see Configuration Parameters: Optimization).

Built in

Specifies built-in data types. Selecting Built in enables boolean.

Fixed point

Specifies fixed-point data types.

Expression

Specifies expressions that evaluate to data types.

Clicking the **Show data type assistant** button enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specify Data Types Using Data Type Assistant”.

Data type override

Specify data type override mode for this signal.

Default: `Inherit`

`Inherit`

Inherits the data type override setting from its context, that is, from the block, `Simulink.Signal` object or Stateflow chart in Simulink that is using the signal.

`Off`

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

This parameter appears only when the **Mode** is `Built in` or `Fixed point`.

Signedness

Specify whether you want the fixed-point data as signed or unsigned.

Default: `Signed`

`Signed`

Specify the fixed-point data as signed.

`Unsigned`

Specify the fixed-point data as unsigned.

Selecting **Mode** > `Fixed point` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Word length

Specify the bit size of the word that holds the quantized integer.

Default: 16

Minimum: 0

Maximum: 32

Selecting **Mode** > Fixed point enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

Default: Integer

Integer

Specify integer. This setting has the same result as specifying a binary point location and setting fraction length to 0.

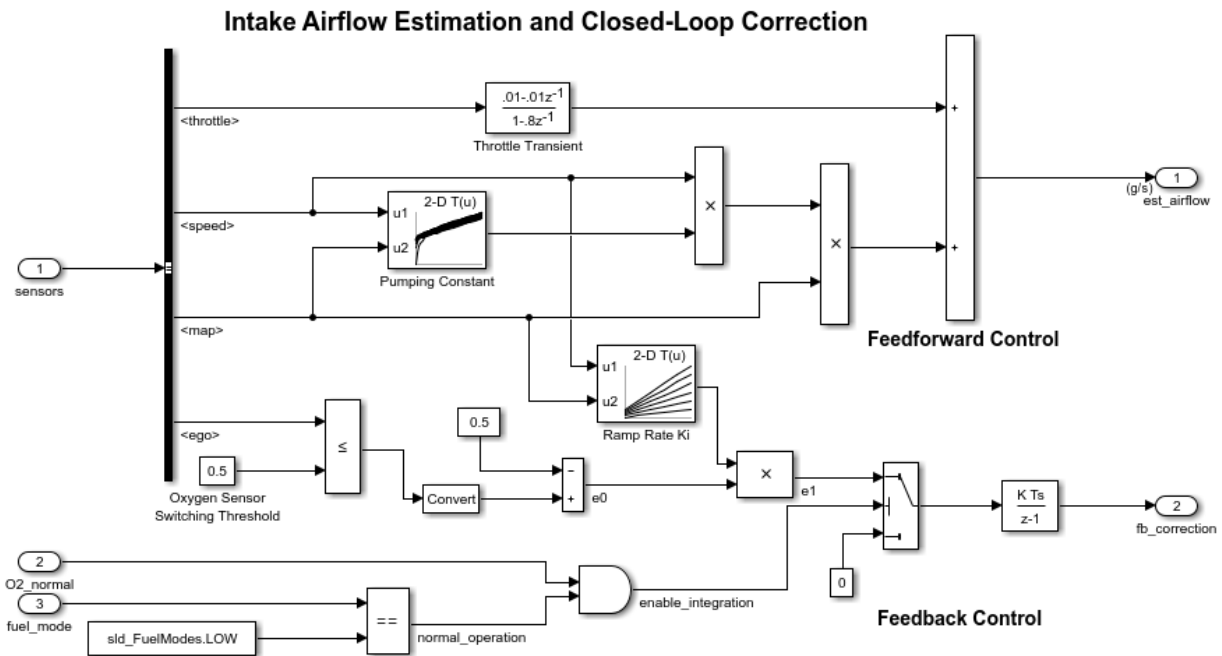

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specifying a Fixed-Point Data Type”.

Examples

Logical Operator Block: AND Operator

In the `sldemo_fuelsys` model, the `fuel_rate_control/airflow_calc` subsystem uses a Logical Operator block as an AND operator:

The output of the Logical Operator block (the `enable_integration` signal) feeds into the control port of a Switch block that activates feedback control.

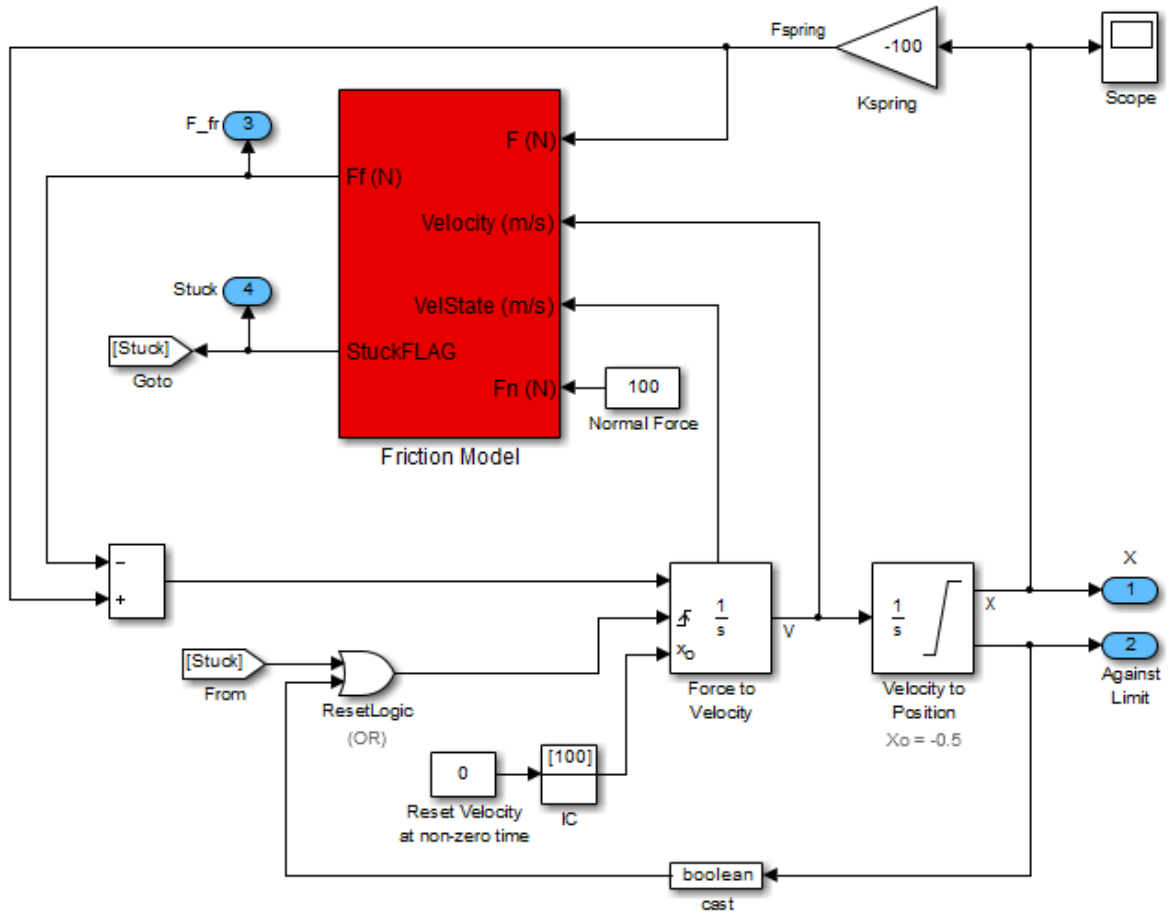

When the Logical Operator block output is...	Feedback control...
1	Occurs
0	Does not occur

Logical Operator Block: OR Operator

In the `sldemo_hardstop` model, the Logical Operator block appears as an OR operator:

Friction Model with Hard Stops

The output of the Logical Operator block feeds into the trigger port of an Integrator block to control whether velocity resets to the initial condition.

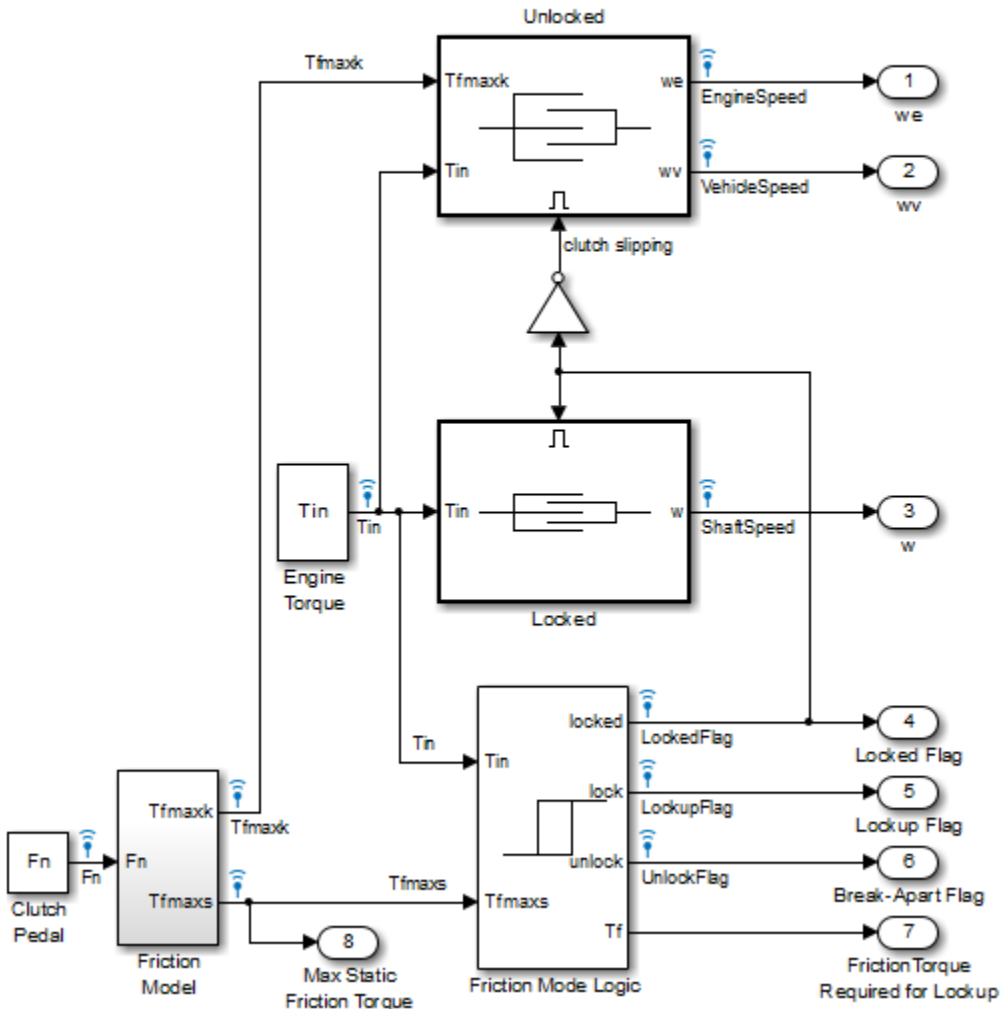

When the Logical Operator block output changes...	The Integrator block...
From 0 to 1	Resets the velocity
From 1 to 0	Does not reset velocity

Logical Operator Block: NOT Operator

In the `sldemo_clutch` model, the Logical Operator block appears as a NOT operator:

Building a Clutch Lock-Up Model An Example of Enabled Subsystems

The output of the Logical Operator block (the `clutch_slipping` signal) feeds into the trigger port of an enabled subsystem.

When the Logical Operator block outputs...	The Unlocked subsystem is...
1	Enabled
0	Disabled

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

1-D Lookup Table

Approximate one-dimensional function

Library

Lookup Tables

Description

The 1-D Lookup Table block is a one-dimensional version of the n-D Lookup Table block.

Characteristics

Data Types	Double Single Base Integer Fixed-Point
Multidimensional Signals	No
Variable-Size Signals	No
Code Generation	Yes

Introduced in R2011a

2-D Lookup Table

Approximate two-dimensional function

Library

Lookup Tables

Description

The 2-D Lookup Table block is a two-dimensional version of the n-D Lookup Table block.

Characteristics

Data Types	Double Single Base Integer Fixed-Point
Multidimensional Signals	No
Variable-Size Signals	No
Code Generation	Yes

Introduced in R2011a

n-D Lookup Table

Approximate N-dimensional function

Library

Lookup Tables

Description

Supported Block Operations

The n-D Lookup Table block evaluates a sampled representation of a function in N variables

$$y = F(x_1, x_2, x_3, \dots, x_N)$$

where the function F can be empirical. The block maps inputs to an output value by looking up or interpolating a table of values you define with block parameters. The block supports flat (constant), linear, and cubic-spline interpolation methods. You can apply these methods to a table of any dimension from 1 through 30.

In the following block, the first input identifies the first dimension (row) breakpoints, the second input identifies the second dimension (column) breakpoints, and so on.

See “Port Location After Rotating or Flipping” in the Simulink documentation for a description of the port order for various block orientations.

Specification of Breakpoint and Table Data

The following block parameters define the breakpoint and table data.

Block Parameter	Purpose
Number of table dimensions	Specifies the number of dimensions of your lookup table.
Breakpoints	Specifies a breakpoint vector that corresponds to each dimension of your lookup table.
Table data	Defines the associated set of output values.

Tip Evenly spaced breakpoints can make the generated code division-free. For more information, see `fixpt_evenspace_cleanup` in the Simulink documentation and “Identify questionable fixed-point operations” (Embedded Coder) in the Simulink Coder documentation.

How the Block Generates Output

The n-D Lookup Table block generates output by looking up or estimating table values based on the input values:

When block inputs...	The n-D Lookup Table block...
Match the values of indices in breakpoint data sets	Outputs the table value at the intersection of the row, column, and higher dimension breakpoints
Do not match the values of indices in breakpoint data sets, but are within range	Interpolates appropriate table values, using the Interpolation method you select
Do not match the values of indices in breakpoint data sets, and are out of range	Extrapolates the output value, using the Extrapolation method you select

Other Blocks That Perform Equivalent Operations

You can use the Interpolation Using Prelookup block with the Prelookup block to perform the equivalent operation of one n-D Lookup Table block. This combination of blocks offers greater flexibility that can result in more efficient simulation performance for linear interpolations.

When the lookup operation is an array access that does not require interpolation, use the Direct Lookup Table (n-D) block. For example, if you have an integer value k and you want the k th element of a table, $y = \text{table}(k)$, interpolation is unnecessary.

Data Type Support

The n-D Lookup Table block supports all numeric data types that Simulink supports, including fixed-point data types. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

For cubic spline interpolation and linear extrapolation modes, the following parameters must use the same floating-point type:

- Table data
- Breakpoints
- Fraction
- Intermediate results
- Output

Inputs for indexing must be real, but table data can be complex.

Parameters

- “Table and Breakpoints Tab” on page 1-858
- “Algorithm Tab” on page 1-860
- “Data Types Tab” on page 1-865

Table and Breakpoints Tab

Number of table dimensions

Enter the number of dimensions of the lookup table by specifying an integer from 1 to 30. This parameter determines:

- The number of independent variables for the table and the number of block inputs
- The number of breakpoint sets to specify

Data specification

From the list, select:

- **Table and breakpoints** — Specify the table data and breakpoints. Selecting this option enables these parameters:
 - **Table data**
 - **Breakpoints specification**
 - **Breakpoints 1**
 - **Breakpoints 2**
 - **Breakpoints 3**
 - **Edit table and breakpoints**
- **Lookup table object** — Use an existing lookup table (`Simulink.LookupTable`) object. Selecting this option enables the **Name** field and **Edit table and breakpoints** button.

Name

Enter the name of the lookup table (`Simulink.LookupTable`) object.

Table data

Enter the table of output values.

During simulation, the matrix size must match the dimensions defined by the **Number of table dimensions** parameter. However, during block diagram editing, you can enter an empty matrix (specified as `[]`) or an undefined workspace variable. This technique lets you postpone specifying a correctly dimensioned matrix for the table data and continue editing the block diagram. For information about how to construct multidimensional arrays in MATLAB, see “Multidimensional Arrays” (MATLAB) in the MATLAB online documentation.

Breakpoints specification

Specify whether to enter data as explicit breakpoints or as parameters that generate evenly spaced breakpoints.

- To explicitly specify breakpoint data, set this parameter to `Explicit values` and enter breakpoint data in the text box next to the **Breakpoints** parameters.
- To specify parameters that generate evenly spaced breakpoints, set this parameter to `Even spacing` and enter values for the **First point** and **Spacing** parameters for each dimension of breakpoint data. The block calculates the number of points to generate from the table data.

First point

Specify the first point in your evenly spaced breakpoint data. This parameter is available when **Breakpoints specification** is set to `Even spacing`.

Spacing

Specify the spacing between points in your evenly-spaced breakpoint data. This parameter is available when **Breakpoints specification** is set to `Even spacing`.

Breakpoints

Specify the breakpoint data explicitly or as evenly-spaced breakpoints, based on the value of the **Breakpoints specification** parameter.

- If you set **Breakpoints specification** to `Even spacing`, enter the parameters **First point** and **Spacing** in each **Breakpoints** row to generate evenly-spaced breakpoints in the respective dimension. Your table data determines the number of evenly spaced points.
- If you set **Breakpoints specification** to `Explicit values`, enter the breakpoint set that corresponds to each dimension of table data in each **Breakpoints** row. For each dimension, specify breakpoints as a 1-by-n or n-by-1 vector whose values are strictly monotonically increasing.

Edit table and breakpoints

Click this button to open the Lookup Table Editor. For more information, see “Edit Lookup Tables” in the Simulink documentation.

Clicking this button for a lookup table object lets you edit the object and save the new values for the object.

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Algorithm Tab

Interpolation method

Select `Flat`, `Nearest`, `Linear`, or `Cubic spline`. See “Interpolation Methods” in the Simulink documentation for more information.

If you select `Cubic spline`, the block supports only scalar signals. The other interpolation methods support nonscalar signals.

Extrapolation method

Select `Clip`, `Linear`, or `Cubic spline`. See “Extrapolation Methods” in the Simulink documentation for more information.

To select `Cubic spline` for **Extrapolation method**, you must also select `Cubic spline` for **Interpolation method**.

Use last table value for inputs at or above last breakpoint

Using this check box, specify the indexing convention that the block uses to address the last element of a breakpoint set and its corresponding table value. This check box is relevant if the input is larger than the last element of the breakpoint data. This parameter is visible only when:

- **Interpolation method** is `Linear`.
- **Extrapolation method** is `Clip`.

Check Box	Block Uses Index Of The...	Interval Fraction
Selected	Last element of breakpoint data on the Table and Breakpoints tab	0

Check Box	Block Uses Index Of The...	Interval Fraction
Cleared	Next-to-last element of breakpoint data on the Table and Breakpoints tab	1

Given an input u within range of a breakpoint set bp , the interval fraction f , in the range $0 \leq f \leq 1$, is computed as shown below.

Suppose the breakpoint set is [1 4 5] and input u is 5.5. If you select this check box, the index is that of the last element (5) and the interval fraction is 0. If you clear this checkbox, the index is that of the next-to-last element (4) and the interval fraction is 1.

Diagnostic for out-of-range input

Specify whether to produce a warning or error when the input is out of range.

Options include:

- None — Simulink software takes no action.
- Warning — Simulink software displays a warning and continues the simulation.
- Error — Simulink software terminates the simulation and displays an error.

Remove protection against out-of-range input in generated code

Specify whether or not to include code that checks for out-of-range breakpoint input values.

Check Box	Result	When to Use
Selected	Generated code does not include conditional statements to check for out-of-range breakpoint inputs. When the input k or f is out-of-range, it may cause undefined behavior for generated code and simulations using accelerator mode.	For code efficiency
Cleared	Generated code includes conditional statements to check for out-of-range breakpoint inputs.	For safety-critical applications

If your input is not out-of-range, you can select the **Remove protection against out-of-range index in generated code** check box for code efficiency. By default, this check box is cleared. For safety-critical applications, do not select this check box. If you want to select the **Remove protection against out-of-range index in generated code** check box, first check that your model inputs are in range. For example:

- 1 Clear the **Remove protection against out-of-range index in generated code** check box.
- 2 Set the **Diagnostic for out-of-range input** parameter to `Error`.
- 3 Simulate the model in normal mode.
- 4 If there are out-of-range errors, fix them to be in range and run the simulation again.
- 5 When the simulation no longer generates out-of-range input errors, select the **Remove protection against out-of-range index in generated code** check box.

Note When you select the **Remove protection against out-of-range index in generated code** check box and the input `k` or `f` is out-of-range, the behavior is undefined for generated code and simulations using accelerator mode.

Depending on your application, you can run the following Model Advisor checks to verify the usage of this check box:

- **By Product > Embedded Coder > Identify lookup table blocks that generate expensive out-of-range checking code**
- **By Product > Simulink Check > Modeling Standards > DO-178C/DO-331 Checks > Check usage of lookup table blocks**

For more information about the Model Advisor, see “Run Model Checks” in the Simulink documentation.

Index search method

Select `Evenly spaced points`, `Linear search`, or `Binary search`. Each search method has speed advantages in different circumstances:

- For evenly spaced breakpoint sets (for example, 10, 20, 30, and so on), you achieve optimal speed by selecting `Evenly spaced points` to calculate table indices.

This algorithm uses only the first two breakpoints of a set to determine the offset and spacing of the remaining points.

Note Set **Index search method** to `Evenly spaced points` when using the `Simulink.LookupTable` object to specify table data and the **Breakpoints Specification** parameter of the referenced `Simulink.LookupTable` object is set to `Even spacing`.

- For unevenly spaced breakpoint sets, follow these guidelines:
 - If input signals do not vary much between time steps, selecting `Linear search` with **Begin index search using previous index result** produces the best performance.
 - If input signals jump more than one or two table intervals per time step, selecting `Binary search` produces the best performance.

A suboptimal choice of index search method can lead to slow performance of models that rely heavily on lookup tables.

Note The generated code stores only the first breakpoint, the spacing, and the number of breakpoints when:

- The breakpoint data is not tunable.
 - The index search method is `Evenly spaced points`.
-

Begin index search using previous index result

Select this check box when you want the block to start its search using the index found at the previous time step. For inputs that change slowly with respect to the interval size, enabling this option can improve performance. Otherwise, the linear search and binary search methods can take longer, especially for large breakpoint sets.

Use one input port for all input data

Select this check box to use only one input port that expects a signal that is N elements wide for an N -dimensional table. This option is useful for removing line clutter on a block diagram with many lookup tables.

Note When you select this check box, one input port with the label `u` appears on the block.

Support tunable table size in code generation

Select this check box to enable tunable table size in the generated code. This option enables you to change the size and values of the lookup table and breakpoint data in the generated code without regenerating or recompiling the code.

If you set **Interpolation method** to `Cubic spline`, this check box is not available.

Maximum indices for each dimension

Specify the maximum index values for each table dimension using zero-based indexing. You can specify a scalar or vector of positive integer values using the following data types:

- Built-in floating-point types: `double` and `single`
- Built-in integer types: `int8`, `int16`, `int32`, `uint8`, `uint16`, and `uint32`

Here are some examples of valid specifications:

- [4 6] for a 5-by-7 table
- [int8(2) int16(5) int32(9)] for a 3-by-6-by-10 table
- A `Simulink.Parameter` whose value on generating code is one less than the dimensions of the table data. For more information, see “Tunable Table Size in the Generated Code” on page 1-870.

This parameter is available when you select **Support tunable table size in code generation**. On tuning this parameter in the generated code, provide the new table data and breakpoints along with the tuned parameter value.

Data Types Tab

Note The dialog box can expand to show additional data type options. Up to 30 breakpoint data type specifications can appear.

Table data > Data Type

Specify the table data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as output`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the table data type.

Tip Specify a table data type different from the output data type for these cases:

- Lower memory requirement for storing table data that uses a smaller type than the output signal
 - Sharing of prescaled table data between two n-D Lookup Table blocks with different output data types
 - Sharing of custom storage table data in the generated code for blocks with different output data types
-

Table data > Minimum

Specify the minimum value for table data. The default value is [] (unspecified).

Table data > Maximum

Specify the maximum value for table data. The default value is [] (unspecified).

Breakpoints > Data Type

Specify the data type for a set of breakpoint data. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as corresponding input`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the breakpoint data type.

See “Specify Data Types Using Data Type Assistant” in the Simulink documentation for more information.

Tip Specify a breakpoint data type different from the corresponding input data type for these cases:

- Lower memory requirement for storing breakpoint data that uses a smaller type than the input signal
 - Sharing of prescaled breakpoint data between two n-D Lookup Table blocks with different input data types
 - Sharing of custom storage breakpoint data in the generated code for blocks with different input data types
-

Breakpoints > Minimum

Specify the minimum value that a set of breakpoint data can have. The default value is [] (unspecified).

Breakpoints > Maximum

Specify the maximum value that a set of breakpoint data can have. The default value is [] (unspecified).

Fraction > Data Type

Specify the fraction data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the fraction data type.

See “Specify Data Types Using Data Type Assistant” in the Simulink documentation for more information.

Intermediate results > Data Type

Specify the intermediate results data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as output`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the intermediate results data type.

Tip Use this parameter to specify higher (or lower) precision for internal computations than for table data or output data.

Output > Data Type

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the output data type.

See “Control Signal Data Types” for more information.

Output > Minimum

Specify the minimum value that the block outputs. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Output > Maximum

Specify the maximum value that the block outputs. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Internal rule priority

Specify the internal rule for intermediate calculations. Select *Speed* for faster calculations. If you do, a loss of accuracy might occur, usually up to 2 bits.

Require all inputs to have the same data type

Select to require all inputs to have the same data type.

Lock data type settings against changes by the fixed-point tools

Select to lock all data type settings of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Fixed-Point Tool” (Fixed-Point Designer) and “Preparation for Fixed-Point Conversion” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

Integer rounding mode

Specify the rounding mode for fixed-point lookup table calculations that occur during simulation or execution of code generated from the model. For more information, see “Rounding” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

This option does not affect rounding of values of block parameters. Simulink rounds such values to the nearest representable integer value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the edit field on the block dialog box.

Saturate on integer overflow

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	An overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Do not select this check box.	<p>You want to optimize efficiency of your generated code.</p> <p>You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.</p>	Overflows wrap to the appropriate value that is representable by the data type.	The number 130 does not fit in a signed 8-bit integer and wraps to -126.

Tip If you save your model as version R2009a or earlier, this check box setting has no effect and no saturation code appears. This behavior preserves backward compatibility.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Examples

Interpolation and Extrapolation Behavior

For an example that illustrates linear interpolation and extrapolation methods of this block, see “Create a Logarithm Lookup Table” in the Simulink documentation.

For an example of entering breakpoint and table data, see “Entering Data in a Block Parameter Dialog Box” in the Simulink documentation.

Tunable Table Size in the Generated Code

Suppose that you have a lookup table and want to make the size tunable in the generated code. When you use `Simulink.LookupTable` and `Simulink.Breakpoint` objects to

configure lookup table data for calibration in the generated code, use the `SupportTunableSize` property of the objects to enable a tunable table size. When you do not use these classes, use the **Support tunable table size in code generation** parameter in an n-D Lookup Table block to enable a tunable table size.

Assume that:

- You define a `Simulink.Parameter` structure in the preload function of your model:

```
p = Simulink.Parameter;
p.Value.MaxIdx = [2 2];
p.Value.BP1 = [1 2 3];
p.Value.BP2 = [1 4 16];
p.Value.Table = [4 5 6; 16 19 20; 10 18 23];
p.DataType = 'Bus: slLookupTable';
p.CoderInfo.StorageClass = 'ExportedGlobal';

% Create bus object slBus1 from MATLAB structure
Simulink.Bus.createObject(p.Value);
slLookupTable = slBus1;
slLookupTable.Elements(1).DataType = 'uint32';
```

- The following block parameters apply in the n-D Lookup Table block dialog box:

Parameter	Value
Number of table dimensions	2
Table data	p.Table
Breakpoints 1	p.BP1
Breakpoints 2	p.BP2
Support tunable table size in code generation	on
Maximum indices for each dimension	p.MaxIdx

The generated `model_types.h` header file contains a type definition that looks something like this:

```
typedef struct {
    uint32_T MaxIdx[2];
    real_T BP1[3];
    real_T BP2[3];
    real_T Table[9];
} slLookupTable;
```

The generated `model.c` file contains code that looks something like this:

```

/* Exported block parameters */
slLookupTable p = {
    { 2U, 2U },

    { 1.0, 2.0, 3.0 },

    { 1.0, 4.0, 16.0 },

    { 4.0, 16.0, 10.0, 5.0, 19.0, 18.0, 6.0, 20.0, 23.0 }
};

/* More code */

/* Model output function */
static void ex_lut_nd_tunable_table_output(int_T tid)
{
    /* Lookup_n-D: '<Root>/n-D Lookup Table' incorporates:
     * Inport: '<Root>/In1'
     * Inport: '<Root>/In2'
     */
    Y = look2_binlcpw(U1, U2, p.BP1, p.BP2, p.Table, ...
p.MaxIdx, p.MaxIdx[0] + 1U);

    /* Outport: '<Root>/Out1' */
    ex_lut_nd_tunable_table_Y.Out1 = Y;

    /* tid is required for a uniform function interface.
     * Argument tid is not used in the function. */
    UNUSED_PARAMETER(tid);
}

```

The highlighted line of code specifies a tunable table size for the lookup table. You can change the size and values of the lookup table and breakpoint data without regenerating or recompiling the code.

Characteristics

Lookup Table Dynamic

Approximate one-dimensional function using dynamic table

Library

Lookup Tables

Description

How This Block Differs from Other Lookup Table Blocks

The Lookup Table Dynamic block computes an approximation of a function $y = f(x)$ using `xdat` and `ydat` vectors. The lookup method can use interpolation, extrapolation, or the original values of the input.

Using the Lookup Table Dynamic block, you can change the table data without stopping the simulation. For example, you can incorporate new table data if the physical system you are simulating changes.

Inputs for Breakpoint and Table Data

The `xdat` vector is the breakpoint data, which must be *strictly monotonically increasing*. The value of the next element in the vector must be greater than the value of the preceding element after conversion to a fixed-point data type. Due to quantization, `xdat` can be strictly monotonic for a floating-point data type, but not after conversion to a fixed-point data type.

The `ydat` vector is the table data, which is an evaluation of the function at the breakpoint values.

Note The inputs to `xdat` and `ydat` cannot be scalar (one-element array) values. If you provide a scalar value to either of these inputs, you see an error upon simulation. Provide a 1-by-n vector to both the `xdat` and `ydat` inputs.

Lookup Table Definition

You define the lookup table by feeding `xdat` and `ydat` as 1-by-n vectors to the block. To reduce ROM usage in the generated code for this block, you can use different data types for `xdat` and `ydat`. However, these restrictions apply:

- The `xdat` breakpoint data and the `x` input vector must have the same sign, bias, and fractional slope. Also, the precision and range for `x` must be greater than or equal to the precision and range for `xdat`.
- The `ydat` table data and the `y` output vector must have the same sign, bias, and fractional slope.

Tip Breakpoints with even spacing can make Simulink Coder generated code division-free. For more information, see `fixpt_evenspace_cleanup` in the Simulink documentation and “Identify questionable fixed-point operations” (Embedded Coder) in the Simulink Coder documentation.

How the Block Generates Output

The block uses the input values to generate output using the method you select for **Lookup Method**:

Lookup Method	Block Action
Interpolation-Extrapolation	<p>Performs linear interpolation and extrapolation of the inputs.</p> <ul style="list-style-type: none"> • If the input matches a breakpoint, the output is the corresponding element in the table data. • If the input does not match a breakpoint, the block performs linear interpolation between two elements of the table to determine the output. If the input falls outside the range of breakpoint values, the block extrapolates using the first two or last two points. <p>Note If you select this lookup method, Simulink Coder software cannot generate code for this block.</p>
Interpolation-Use End Values (default)	Performs linear interpolation but does not extrapolate outside the end points of the breakpoint data. Instead, the block uses the end values.
Use Input Nearest	Finds the element in <code>xdat</code> nearest the current input. The corresponding element in <code>ydat</code> is the output.
Use Input Below	Finds the element in <code>xdat</code> nearest and below the current input. The corresponding element in <code>ydat</code> is the output. If there is no element in <code>xdat</code> below the current input, the block finds the nearest element.
Use Input Above	Finds the element in <code>xdat</code> nearest and above the current input. The corresponding element in <code>ydat</code> is the output. If there is no element in <code>xdat</code> above the current input, the block finds the nearest element.

Note The Use Input Nearest, Use Input Below, and Use Input Above methods perform the same action when the input x matches a breakpoint value.

Some continuous solvers subdivide the simulation time span into major and minor time steps. A minor time step is a subdivision of the major time step. The solver produces a result at each major time step and uses results at minor time steps to improve the accuracy of the result at the major time step. For continuous solvers, the output of the

Lookup Table Dynamic block can appear like a stair step because the signal is fixed in minor time step to avoid incorrect results. For more information about the effect of solvers on block output, see “Solvers” in the Simulink documentation.

Data Type Support

The Lookup Table Dynamic block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

- “Main tab” on page 1-877
- “Signal Attributes tab” on page 1-877

Main tab

Lookup Method

Specify the lookup method. For details, see “How the Block Generates Output” on page 1-875.

Signal Attributes tab

Output data type

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`

- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt('double')`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” for more information.

Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer), in the Fixed-Point Designer documentation.

Saturate to max or min when overflows occur

Select to have overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Examples

Magnitude-Angle to Complex

Convert magnitude and/or a phase angle signal to complex signal

Library

Math Operations

Description

Supported Operations

The Magnitude-Angle to Complex block converts magnitude and phase angle inputs to a complex output. The angle input must be in radians.

The block supports the following combinations of input dimensions when there are two block inputs:

- Two inputs of equal dimensions
- One scalar input and the other an n-dimensional array

If the block input is an array, the output is an array of complex signals. The elements of a magnitude input vector map to the magnitudes of the corresponding complex output elements. Similarly, the elements of an angle input vector map to the angles of the corresponding complex output elements. If one input is a scalar, it maps to the corresponding component (magnitude or angle) of all the complex output signals.

Effect of Out-of-Range Input on CORDIC Approximations

If you use the CORDIC approximation method (see “Definitions” on page 1-881), the block input for phase angle has the following restrictions:

- For signed fixed-point types, the input angle must fall within the range $[-2\pi, 2\pi)$ radians.
- For unsigned fixed-point types, the input angle must fall within the range $[0, 2\pi)$ radians.

The following table summarizes what happens for an out-of-range input:

Block Usage	Effect of Out-of-Range Input
Simulation	An error appears.
Generated code	Undefined behavior occurs.
Accelerator modes	

Ensure that you use an in-range input for the Magnitude-Angle to Complex block when you use the CORDIC approximation. Avoid relying on undefined behavior for generated code or Accelerator modes.

Definitions

CORDIC

CORDIC is an acronym for COordinate Rotation DIgital Computer. The Givens rotation-based CORDIC algorithm is one of the most hardware-efficient algorithms available because it requires only iterative shift-add operations (see References). The CORDIC algorithm eliminates the need for explicit multipliers. Using CORDIC, you can calculate various functions, such as sine, cosine, arc sine, arc cosine, arc tangent, and vector magnitude. You can also use this algorithm for divide, square root, hyperbolic, and logarithmic functions.

Increasing the number of CORDIC iterations can produce more accurate results, but doing so also increases the expense of the computation and adds latency.

Data Type Support

The block accepts real input signals of the following data types:

- Floating point
- Fixed point (only when **Approximation method** is CORDIC)

The following restrictions also apply:

- If one input uses a floating-point type, the other input must use the same data type. For example, both signals must be `double` or `single`.
- If one input uses a fixed-point type, the other input must also use a fixed-point type.

Parameters

Input

Specify the kind of input: a magnitude input, an angle input, or both.

Angle (Magnitude)

Input	What to Specify
Magnitude	The constant phase angle of the output signal in radians
Angle	The constant magnitude of the output signal

This parameter is not available when **Input** is `Magnitude` and `angle`.

Approximation method

Specify the type of approximation for computing output.

Approximation Method	Data Types Supported	When to Use This Method
None (default)	Floating point	You want to use the default Taylor series algorithm.
CORDIC	Floating point and fixed point	You want a fast, approximate calculation.

When you use the CORDIC approximation, follow these guidelines:

- For signed fixed-point types, the input angle must fall within the range $[-2\pi, 2\pi)$ radians.
- For unsigned fixed-point types, the input angle must fall within the range $[0, 2\pi)$ radians.

The block uses the following data type propagation rules:

Data Type of Magnitude Input	Approximation Method	Data Type of Complex Output
Floating point	None or CORDIC	Same as input
Signed, fixed point	CORDIC	$\text{fixdt}(1, WL + 2, FL)$ where WL and FL are the word length and fraction length of the magnitude
Unsigned, fixed point	CORDIC	$\text{fixdt}(1, WL + 3, FL)$ where WL and FL are the word length and fraction length of the magnitude

Number of iterations

Specify the number of iterations to perform the CORDIC algorithm. The default value is 11.

Data Type of Block Inputs	Value You Can Specify
Floating point	A positive integer
Fixed point	A positive integer that does not exceed the word length of the magnitude input or the word length of the phase angle input, whichever value is smaller

Entering a value that is not a positive integer causes an error.

This parameter is available when you set **Approximation method** to CORDIC.

Scale output by reciprocal of gain factor

Select this check box to scale the real and imaginary parts of the complex output by a factor of $(1/\text{CORDIC gain})$. This value depends on the number of iterations you specify. As the number of iterations goes up, the value approaches 1.647.

This check box is selected by default, which leads to a more numerically accurate result for the complex output, $X + iY$. However, scaling the output adds two extra multiplication operations, one for X and one for Y .

This parameter is available when you set **Approximation method** to CORDIC.

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1 . To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Characteristics

Data Types	Double Single Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Manual Switch

Switch between two inputs

Library

Signal Routing

Description

The Manual Switch block is a toggle switch that selects one of its two inputs to pass through to the output. To toggle between inputs, double-click the block. The block propagates the selected input to the output, while the block discards the unselected input. You can interactively control the signal flow by setting the switch before you start the simulation or by changing the switch while the simulation is executing. The Manual Switch block retains its current state when you save the model.

Data Type Support

The Manual Switch block accepts real or complex signals of any data type that Simulink supports, including fixed-point and enumerated data types. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

- “Allow the two inputs to differ in size” on page 1-887
- “Sample time” on page 1-887

Allow the two inputs to differ in size

Select this check box to allow input signals with different sizes.

Default: Off

On

Block allows input signals with different sizes, and propagates the input signal size to the output signal.

Off

Block expands scalar inputs to have the same dimensions as nonscalar inputs. For more information, see “Scalar Expansion of Inputs and Parameters”.

Parameter: `varsize`

Type: character vector

Value: 'on' | 'off'

Default: 'off'

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Examples

The following models show how to use the Manual Switch block:

- `sldemo_auto_climatecontrol`
- `sldemo_fuelsys`
- `sldemo_doublebounce`

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated Bus
Sample Time	Inherited from driving block

Manual Variant Sink

Switch amongst multiple variant choices at output

Library

Signal Routing

Description

The Manual Variant Sink block is a toggle switch that activates one of its variant choices at the output to pass the input.

It can have two or more output ports and has one input port. Each output port is associated with a variant control.

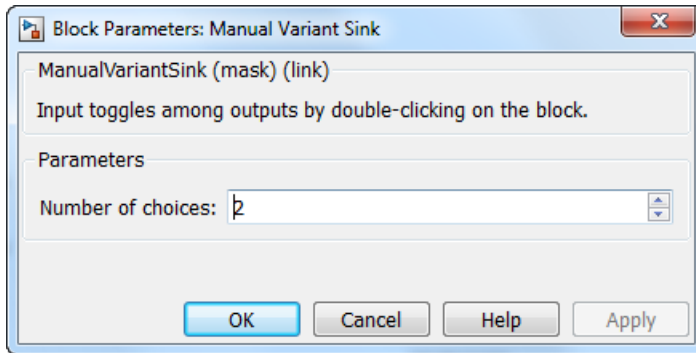

To toggle between the variant choices at output, double-click the block. The block propagates the active variant choice at output and discards the blocks connected to inactive output ports during simulation.

Data Type Support

The Manual Variant Sink block accepts real or complex signals of any data type that Simulink supports, including fixed-point and enumerated data types. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Dialog Box and Parameters

To open the block dialog box, right-click the block and select **Mask > Mask Parameters**.

By default, the number of output choice is 2. You can change the number of outputs by typing a value in the **Number of choices** box. The maximum number of output choices can be 25.

Note Double-clicking the Manual Variant Sink block does not open the block dialog box instead it toggles the output choice.

Command-Line Information

Parameter: NumChoices

Type: character vector

Value: 2-25

Default: 2

Examples

To view how to use the Manual Variant Sink block, click Manual Variant Source and Sink Blocks.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated Bus

Manual Variant Source

Switch amongst multiple variant choices at input

Library

Signal Routing

Description

The Manual Variant Source block is a toggle switch that activates one of its variant choices at the input to pass through to the output.

A Manual Variant Source block can have two or more input ports and has one output port. Each input port is associated with a variant control.

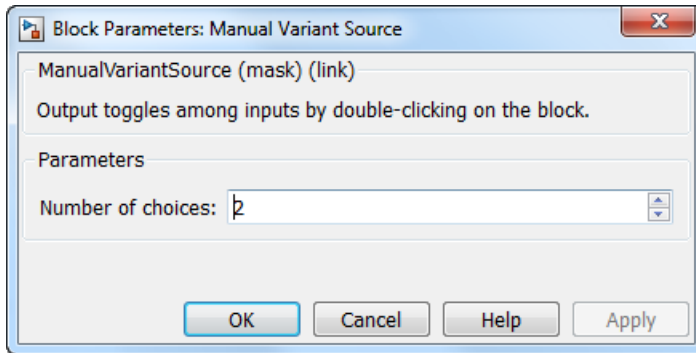

To toggle between the variant choices at input, double-click the block. The block propagates the active variant choice at input directly to the output and discards the blocks connected to inactive input ports during simulation.

Data Type Support

The Manual Variant Source block accepts real or complex signals of any data type that Simulink supports, including fixed-point and enumerated data types. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Dialog Box and Parameters

To open the block dialog box, right-click the block and select **Mask > Mask Parameters**.

By default, the number of input choices is 2. You can change the number of inputs by typing a value in the **Number of choices** box. The maximum number of input choices can be 25.

Note Double-clicking the Manual Variant Source block does not open the block dialog box instead it toggles the input choice.

Command-Line Information

Parameter: NumChoices

Type: character vector

Value: 2-25

Math Function

Perform mathematical function

Library

Math Operations

Description

The Math Function block performs numerous common mathematical functions.

Tip To perform square root calculations, use the Sqrt block.

You can select one of the following functions from the **Function** parameter list.

Function	Description	Mathematical Expression	MATLAB Equivalent
exp	Exponential	e^u	exp
log	Natural logarithm	$\ln u$	log
10^u	Power of base 10	10^u	10.^u (see power)
log10	Common (base 10) logarithm	$\log u$	log10
magnitude^2	Complex modulus	$ u ^2$	(abs(u)).^2 (see abs and power)

Function	Description	Mathematical Expression	MATLAB Equivalent
square	Power 2	u^2	<code>u.^2</code> (see <code>power</code>)
pow	Power	u^v	<code>power</code>
conj	Complex conjugate	\bar{u}	<code>conj</code>
reciprocal	Reciprocal	$1/u$	<code>1./u</code> (see <code>rdivide</code>)
hypot	Square root of sum squares	$(u^2+v^2)^{0.5}$	<code>hypot</code>
rem	Remainder after division	—	<code>rem</code>
mod	Modulus after division	—	<code>mod</code>
transpose	Transpose	u^T	<code>u.'</code> (see “Array vs. Matrix Operations” (MATLAB))
hermitian	Complex conjugate transpose	u^H	<code>u'</code> (see “Array vs. Matrix Operations” (MATLAB))

The block output is the result of the operation of the function on the input or inputs. The functions support the following types of operations.

Function	Scalar Operations	Element-Wise Vector and Matrix Operations	Vector and Matrix Operations
<code>exp</code>	yes	yes	—
<code>log</code>	yes	yes	—
<code>10^u</code>	yes	yes	—
<code>log10</code>	yes	yes	—
<code>magnitude^2</code>	yes	yes	—
<code>square</code>	yes	yes	—
<code>pow</code>	yes	yes	—

Function	Scalar Operations	Element-Wise Vector and Matrix Operations	Vector and Matrix Operations
conj	yes	yes	—
reciprocal	yes	yes	—
hypot	yes, on two inputs	yes, on two inputs (two vectors or two matrices of the same size, a scalar and a vector, or a scalar and a matrix)	—
rem	yes, on two inputs	yes, on two inputs (two vectors or two matrices of the same size, a scalar and a vector, or a scalar and a matrix)	—
mod	yes, on two inputs	yes, on two inputs (two vectors or two matrices of the same size, a scalar and a vector, or a scalar and a matrix)	—
transpose	yes	—	yes
hermitian	yes	—	yes

The name of the function appears on the block. The appropriate number of input ports appears automatically.

Tip Use the Math Function block instead of the Fcn block when you want vector or matrix output, because the Fcn block produces only scalar output.

Data Type Support

The following table shows the input data types that each function of the block can support.

Function	single	double	boolean	built-in integer	fixed point
exp	yes	yes	—	—	—

Function	single	double	boolean	built-in integer	fixed point
log	yes	yes	—	—	—
10 ^u	yes	yes	—	—	—
log10	yes	yes	—	—	—
magnitude ²	yes	yes	—	yes	yes
square	yes	yes	—	yes	yes
pow	yes	yes	—	—	—
conj	yes	yes	—	yes	yes
reciprocal	yes	yes	—	yes	yes
hypot	yes	yes	—	—	—
rem	yes	yes	—	yes	—
mod	yes	yes	—	yes	—
transpose	yes	yes	yes	yes	yes
hermitian	yes	yes	—	yes	yes

All supported modes accept both real and complex inputs, except for reciprocal, which does not accept complex fixed-point inputs.

The block output is real or complex, depending on what you select for **Output signal type**.

Parameters

Function

Specify the mathematical function. See Description on page 1-895 for more information about the options for this parameter.

Output signal type

Specify the output signal type of the Math Function block as auto, real, or complex.

Function	Input Signal Type	Output Signal Type		
		Auto	Real	Complex
exp, log, 10u, log10, square, pow, reciprocal, conjugate, transpose, hermitian	real	real	real	complex
	complex	complex	error	complex
magnitude squared	real	real	real	complex
	complex	real	real	complex
hypot, rem, mod	real	real	real	complex
	complex	error	error	error

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1 . To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Note Some parameters on this pane are available only when the function you select in the **Function** parameter supports fixed-point data types.

Output minimum

Specify the minimum value that the block can output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Output maximum

Specify the maximum value that the block can output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)

- Automatic scaling of fixed-point data types

Output data type

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” in *Simulink User's Guide* for more information.

Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer). in the Fixed-Point Designer documentation.

Saturate on integer overflow

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box.	<p>You want to optimize efficiency of your generated code.</p> <p>You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.</p>	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. Usually, the code generation process can detect

when overflow is not possible. In this case, the code generator does not produce saturation code.

Characteristics

Direct Feedthrough	Yes
Sample Time	Inherited from driving block
Scalar Expansion	Yes, of the input when the function requires two inputs
Dimensionalized	Yes
Multidimensionalized	Yes, for all functions except <i>hermitian</i> and <i>transpose</i>
Zero-Crossing Detection	No

Sqrt, Trigonometric Function

Introduced before R2006a

MATLAB Function

Include MATLAB code in models that generate embeddable C code

Library

User-Defined Functions

Description

With a MATLAB Function block, you can write a MATLAB function for use in a Simulink model. The MATLAB function you create executes for simulation and generates code for a Simulink Coder target. If you are new to the Simulink and MATLAB products, see “What Is a MATLAB Function Block?” and “Create Model That Uses MATLAB Function Block” for an overview.

Double-clicking the MATLAB Function block opens its editor, where you write the MATLAB function, as in this example:

```

1  function [mean,stdev] = stats(vals)
2  % #codegen
3
4  % calculates a statistical mean and a standard
5  % deviation for the values in vals.
6
7  - len = length(vals);
8  - mean = avg(vals,len);
9  - stdev = sqrt(sum(((vals-avg(vals,len)).^2))/len);
10 - coder.extrinsic('plot');
11 - plot(vals,'-+');
12 |
13 function mean = avg(array,size)
14 - mean = sum(array)/size;

```

To learn more about this editor, see “MATLAB Function Block Editor”.

You specify input and output data to the MATLAB Function block in the function header as arguments and return values. The argument and return values of the preceding example function correspond to the inputs and outputs of the block in the model:

You can also define data, input triggers, and function call outputs using the Ports and Data Manager, which you access from the MATLAB Function Block Editor by selecting **Edit Data**. See “Ports and Data Manager”.

The MATLAB Function block generates efficient embeddable code based on an analysis that determines the size, class, and complexity of each variable. This analysis imposes the following restrictions:

- The first assignment to a variable defines its, size, class, and complexity.

See “Best Practices for Defining Variables for C/C++ Code Generation”.

- You cannot reassign variable properties after the initial assignment except when using variable-size data or reusing variables in the code for different purposes.

See “Reassignment of Variable Properties”.

In addition to language restrictions, the MATLAB Function block supports a subset of the functions available in MATLAB. A list of supported functions is given in “Functions and Objects Supported for C/C++ Code Generation — Alphabetical List”. These functions include functions in common categories, such as:

- Arithmetic operators like `plus`, `minus`, and `power`. For more information, see “Array vs. Matrix Operations” (MATLAB).
- Matrix operations like `size`, and `length`
- Advanced matrix operations like `lu`, `inv`, `svd`, and `chol`
- Trigonometric functions like `sin`, `cos`, `sinh`, and `cosh`

See “Functions and Objects Supported for C/C++ Code Generation — Category List” for a complete list of function categories.

Note Although the code for this block attempts to produce exactly the same results as MATLAB, differences might occur due to rounding errors. These numerical differences, which might be a few `eps` initially, can magnify after repeated operations. Reliance on the behavior of `nan` is not recommended. Different C compilers can yield different results for the same computation.

Note In the MATLAB Function block, the `%#codegen` directive is included to emphasize that the block’s MATLAB algorithm is always intended for code generation. The `%#codegen` directive, or the absence of it, does not change the error checking behavior in the context of the MATLAB Function block. For more information see “Compilation Directive `%#codegen`”.

To support visualization of data, the MATLAB Function block supports calls to MATLAB functions for simulation only. See “Extrinsic Functions” to understand some of the limitations of this capability, and how it integrates with code analysis for this block. If

these function calls do not directly affect any of the Simulink inputs or outputs, the calls do not appear in Simulink Coder generated code.

From MATLAB Function blocks, you can also call functions defined in a Simulink Function block. You can call Stateflow functions with **Export Chart Level Functions (Make Global)** and **Allow exported functions to be called by Simulink** checked in the chart Properties dialog box.

In the Ports and Data Manager, you can declare a block input to be a Simulink parameter instead of a port. The MATLAB Function block also supports inheritance of types and size for inputs, outputs, and parameters. You can also specify these properties explicitly. See “Type Function Arguments”, “Size Function Arguments”, and “Add Parameter Arguments” for descriptions of variables that you use in MATLAB Function blocks.

Recursive calls are not allowed in MATLAB Function blocks.

By default, MATLAB Function blocks have direct feedthrough enabled. To disable it, in the Ports and Data Manager, clear the **Allow direct feedthrough** check box. Nondirect feedthrough enables semantics to ensure that outputs rely only on current state. Using nondirect feedthrough enables you to use MATLAB Function blocks in a feedback loop and prevent algebraic loops.

Data Type Support

The MATLAB Function block accepts inputs of any type that Simulink supports, including fixed-point and enumerated types. For more information, see “Data Types Supported by Simulink”.

Data types supported by MATLAB but not supported by Simulink may not be passed between the Simulink model and the function within the MATLAB Function block. These types may be used within the MATLAB Function block.

For more information on fixed-point support for this block, refer to “Fixed-Point Data Types with MATLAB Function Block” (Fixed-Point Designer) and “MATLAB Function Block with Data Type Override” (Fixed-Point Designer).

Parameters

See the reference page for the Subsystem, Atomic Subsystem, Nonvirtual Subsystem, CodeReuse Subsystem blocks for information about each block parameter.

Examples

The following models shows how to use the MATLAB Function block:

- `sldemo_radar_eml`
- `sldemo_eml_galaxy`

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated Bus
Sample Time	Specified in the Sample time parameter
Direct Feedthrough	Yes (default). To disable, in the Ports and Data Manager, clear the Allow direct feedthrough check box.
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Introduced in R2011a

MATLAB System

Include System object in model

Library

User-Defined Functions

Description

The MATLAB System block brings existing System objects (based on `matlab.System`) into Simulink. It also enables you to use System object APIs to develop new blocks for Simulink. For more information on this block, see “MATLAB System Block”.

For interpreted execution, the model simulates the block using the MATLAB execution engine.

For code generation, the model simulates the block using code generation (using the subset of MATLAB® code supported for code generation). The MATLAB System block supports only a subset of the functions available in MATLAB. See “Functions and Objects Supported for C/C++ Code Generation — Alphabetical List” for a complete list of functions. These functions include those in common categories, such as:

- “Array vs. Matrix Operations” (MATLAB), like `plus`, `minus`, and `power`
- Matrix operations, like `size` and `length`
- Advanced matrix operations, like `lu`, `inv`, `svd`, and `chol`
- Trigonometric functions, like `sin`, `cos`, `sinh`, and `cosh`

System Objects

To use the MATLAB System block, you must first have a new System object or use an existing one. For more information, see “System Object Integration”.

Data Type Support

The MATLAB System block accepts inputs of most types that Simulink supports. It does not support virtual buses as input or output. It does not support nonvirtual buses that contain variable-size signals. For more information, see “Data Types Supported by Simulink”.

For information on fixed-point support for this block, see “Code Acceleration and Code Generation from MATLAB” (Fixed-Point Designer).

The MATLAB System block supports Simulink frames. For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Parameters

System object name

Specify the full name of the user-defined System object class without the file extension. This entry is case sensitive. The class name must exist on the MATLAB path.

You can specify a System object name in one of these ways:

- Enter the name in the text box.
- Click the list arrow attached to the text box. If valid System objects exist in the current folder, the names appear in the list. Select a System object from this list.
- Browse to a folder that contains a valid System object. If the folder is not on your MATLAB path, the software prompts you to add it.

If you need to create a System object, you can create one from a template by clicking **New**.

After you save the System object, the name appears in the **System object name** text box.

Default: None

Use the full name of the user-defined System object class name. The block does not accept a MATLAB variable that you have assigned to a System object class name.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

New

Click this button to create a System object from a template.

Select one of these options.

- Basic

Starts MATLAB Editor and displays a template for a simple System object using the fewest System object methods.

- Advanced

Starts MATLAB Editor and displays a template for a more advanced System object using most of the System object methods.

- Simulink Extension

Starts MATLAB Editor and displays a file that contains utilities for customizing the block for Simulink. This is the same file available in MATLAB when you select **New > System Object > Simulink Extension**.

After you save the System object, you can enter the name in the **System object name** text box.

Default: Basic

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Simulate using

Select the simulation mode.

Default: Code generation

Code generation

On the first model run, simulate and generate code for MATLAB System block using only MATLAB functions supported for code generation. If the structure of the block does not change, subsequent model runs do not regenerate the code.

If the simulation mode is Code generation, system objects accept a maximum of 32 inputs.

Interpreted execution

Simulate model using all supported MATLAB functions. Choosing this option can slow simulation performance.

After you assign a valid System object class name to the block, the next time you open the block dialog box, the parameter is visible. This parameter appears for every MATLAB System block. You cannot remove it.

- If the block has no tabs, this parameter appears at the bottom of the dialog box.
- If the block has multiple tabs, this parameter appears at the bottom of the first tab of the dialog box.

Saturate on integer overflow

Specify whether overflows saturate.

Default: Off

On

Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Off

Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

This check box appears when you use the `showFiSettingsImpl` method in the `System` object.

Parameter: `SaturateOnIntegerOverflow`

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Treat these inherited Simulink signal types as fi objects

Specify which inherited data types to treat as fi data types.

Default: Fixed-point

Fixed-point

Treat fixed-point data types as fi data types.

Fixed-point & Integer

Treat fixed-point and integer data types as fi data types.

This check box appears when you use the `showFiSettingsImpl` method in the `System` object.

MATLAB System fimath

Specify which fixed-point math settings to use.

Default: Same as MATLAB

Fixed-point

Use the current MATLAB fixed-point math settings.

Specify Other

Enable the edit box for specifying the desired fixed-point math settings. For information on setting fixed-point math, see `fimath`.

This check box appears when you use the `showFiSettingsImpl` method in the System object.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point
Sample Time	Inherited
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Introduced in R2013b

Memory

Output input from previous time step

Library

Discrete

Description

The Memory block holds and delays its input by one major integration time step. When placed in an iterator subsystem, it holds and delays its input by one iteration. This block accepts continuous and discrete signals. The block accepts one input and generates one output. Each signal can be scalar or vector. If the input is a vector, the block holds and delays all elements of the vector by the same time step.

You specify the block output for the first time step using the **Initial condition** parameter. Careful selection of this parameter can minimize unwanted output behavior. However, you cannot specify the sample time. This block's sample time depends on the type of solver used, or you can specify to inherit it. The **Inherit sample time** parameter determines whether sample time is inherited or based on the solver.

Tip Avoid using the Memory block when both these conditions are true:

- Your model uses the variable-step solver `ode15s` or `ode113`.
 - The input to the block changes during simulation.
-

When the Memory block inherits a discrete sample time, the block is analogous to the Unit Delay block. However, the Memory block does not support state logging. If logging the final state is necessary, use a Unit Delay block instead.

Comparison with Similar Blocks

Blocks with Similar Functionality

The Unit Delay, Memory, and Zero-Order Hold blocks provide similar functionality but have different capabilities. Also, the purpose of each block is different. The sections that follow highlight some of these differences.

Recommended Usage for Each Block

Block	Purpose of the Block	Reference Examples
Unit Delay	Implement a delay using a discrete sample time that you specify. The block accepts and outputs signals with a discrete sample time.	<ul style="list-style-type: none"> sldemo_enginewc (Compression subsystem)
Memory on page 1-915	Implement a delay by one major integration time step. Ideally, the block accepts continuous (or fixed in minor time step) signals and outputs a signal that is fixed in minor time step.	<ul style="list-style-type: none"> sldemo_bounce sldemo_clutch (Friction Mode Logic/Lockup FSM subsystem)
Zero-Order Hold	Convert an input signal with a continuous sample time to an output signal with a discrete sample time.	<ul style="list-style-type: none"> sldemo_radar_eml aero_dap3dof

Overview of Block Capabilities

Capability	Block		
	Unit Delay	Memory	Zero-Order Hold
Specification of initial condition	Yes	Yes	No, because the block output at time $t = 0$ must match the input value.

Capability	Block		
	Unit Delay	Memory	Zero-Order Hold
Specification of sample time	Yes	No, because the block can only inherit sample time (from the driving block or the solver used for the entire model).	Yes
Support for frame-based signals	Yes	No	Yes
Support for state logging	Yes	No	No

Data Type Support

The Memory block accepts real or complex signals of any data type that Simulink supports, including fixed-point and enumerated data types.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Initial condition

Specify the output at the initial integration step. This value must be 0 when you do not use a built-in input data type. Simulink does not allow the initial output of this block to be `inf` or `NaN`.

Inherit sample time

Select to inherit the sample time from the driving block:

- If the driving block has a discrete sample time, the block inherits the sample time.
- If the driving block has a continuous sample time, selecting this checkbox has no effect. The sample time depends on the type of solver used for simulating the model.

When this check box is cleared, the block sample time depends on the type of solver used for simulating the model:

- If the solver is a variable-step solver, the block sample time is continuous but fixed in minor time step: $[0, 1]$.
- If the solver is a fixed-step solver, the $[0, 1]$ sample time converts to the solver step size after sample-time propagation.

Direct feedthrough of input during linearization

Select to output the input during linearization and trim. This selection sets the block mode to direct feedthrough.

Selecting this check box can cause a change in the ordering of states in the model when using the functions `linmod`, `dlinmod`, or `trim`. To extract this new state ordering, use the following commands.

First compile the model using the following command, where `model` is the name of the Simulink model.

```
[sizes, x0, x_str] = model([], [], [], 'lincompile');
```

Next, terminate the compilation with the following command.

```
model([], [], [], 'term');
```

The output argument, `x_str`, which is a cell array of the states in the Simulink model, contains the new state ordering. When passing a vector of states as input to the `linmod`, `dlinmod`, or `trim` functions, the state vector must use this new state ordering.

Treat as a unit delay when linearizing with discrete sample time

Select to linearize the Memory block to a unit delay when the Memory block is driven by a signal with a discrete sample time.

State name

Use this parameter to assign a unique name to the block state. The default is ' '. When this field is blank, no name is assigned. When using this parameter, remember these considerations:

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.

- The state name applies only to the selected block.

This parameter enables **State name must resolve to Simulink signal object** when you click **Apply**.

For more information, see “Discrete Block State Naming in Generated Code” (Simulink Coder).

State name must resolve to Simulink signal object

Select this check box to require that the state name resolve to a Simulink signal object. This check box is cleared by default.

State name enables this parameter. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than `None`.

Selecting this check box disables **Code generation storage class**.

Signal object class

Choose a custom storage class package by selecting a signal object class that the target package defines. For example, to apply custom storage classes from the built-in package `mpt`, select `mpt.Signal`. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes do not affect the generated code.

If the class that you want does not appear in the list, select `Customize class lists`. For instructions, see “Apply Custom Storage Classes Directly to Signal Lines, Block States, and Output Blocks” (Embedded Coder).

To programmatically set this parameter, use `StateSignalObject`.

For information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

Code generation storage class

Select state storage class for code generation.

Default: `Auto`

`Auto`

`Auto` is the appropriate storage class for states that you do not need to interface to external code.

StorageClass

Applies the storage class or custom storage class that you select from the list. For information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than `Simulink`.

State name enables this parameter.

To programmatically set this parameter, use `StateStorageClass` or `StateSignalObject`. See “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder).

TypeQualifier

Note **TypeQualifier** will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

Specify a storage type qualifier such as `const` or `volatile`.

Setting **Code generation storage class** to `ExportedGlobal`, `ImportedExtern`, `ImportedExternPointer`, or `SimulinkGlobal` enables this parameter. This parameter is hidden unless you previously set its value.

During simulation, the block uses the following values:

- The initial value of the signal object to which the state name is resolved
- Min and Max values of the signal object

See “Discrete Block State Naming in Generated Code” (Simulink Coder) in the Simulink Coder documentation for more information.

Examples of Memory Block Usage

Usage with the Clock Block

The following model shows how to display the step size in a simulation. The Sum block subtracts the time at the previous step, which the Memory block generates, from the current time, which the Clock block generates.

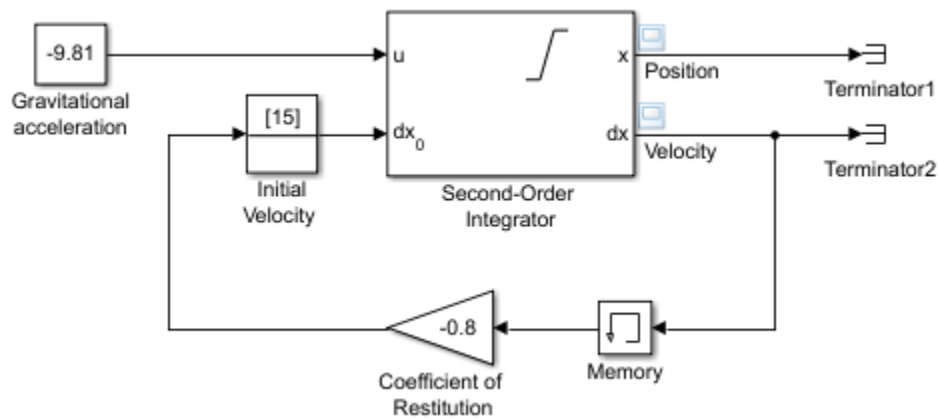

Because **Inherit sample time** is not selected for the Memory block, the block sample time depends on the type of solver for simulating the model. In this case, the model uses a fixed-step solver. Therefore, the sample time of the Memory block is the solver step size, or 1.

If you replace the Memory block with a Unit Delay block, you get the same results. The Unit Delay block inherits a discrete sample time of 1.

Usage with the Second-Order Integrator Block

The `sldemo_bounce` model shows how a bouncing ball reacts after being tossed into the air. The **dx** port of the Second-Order Integrator block and the Memory block capture the velocity of the ball just before it hits the ground.

Because **Inherit sample time** is not selected for the Memory block, the block sample time depends on the type of solver for simulating the model. In this case, the model uses a variable-step (`ode23`) solver. Therefore, the sample time of the Memory block is continuous but fixed in minor time step: $[0, 1]$. When you run the model, you get the following results:

If you replace the Memory block with a Unit Delay block, you get the same results. However, a warning also appears due to the discrete Unit Delay block inheriting a continuous sample time.

Usage with the Combinatorial Logic Block

The `sldemo_clutch` model shows how you can use the Memory block with the Combinatorial Logic block to implement a finite-state machine. This construct appears in the Friction Mode Logic/Lockup FSM subsystem.

Because **Inherit sample time** is not selected for the Memory block, the block sample time depends on the type of solver for simulating the model. In this case, the model uses a variable-step (`ode23`) solver. Therefore, the sample time of the Memory block is continuous but fixed in minor time step: $[0, 1]$.

Bus Support

The Memory block is a bus-capable block. The input can be a virtual or nonvirtual bus signal subject to the following restrictions:

- **Initial condition** must be zero, a nonzero scalar, or a finite numeric structure.
- If **Initial condition** is zero or a structure, and you specify a **State name**, the input cannot be a virtual bus.
- If **Initial condition** is a nonzero scalar, you cannot specify a **State name**.

For information about specifying an initial condition structure, see “Specify Initial Conditions for Bus Signals”.

All signals in a nonvirtual bus input to a Memory block must have the same sample time, even if the elements of the associated bus object specify inherited sample times. You can use a Rate Transition block to change the sample time of an individual signal, or of all signals in a bus. See “Specify Bus Signal Sample Times” and Bus-Capable Blocks for more information.

You can use an array of buses as an input signal to a Memory block. You can specify the **Initial condition** parameter with:

- The value 0. In this case, all of the individual signals in the array of buses use the initial value 0.
- An array of structures that specifies an initial condition for each of the individual signals in the array of buses.
- A single scalar structure that specifies an initial condition for each of the elements that the bus type defines. Use this technique to specify the same initial conditions for each of the buses in the array.

For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated Bus
Sample Time	Depends on the type of solver used. If you select the Inherit sample time check box, the block inherits sample time from the driving block.
Direct Feedthrough	No, except when you select Direct feedthrough of input during linearization
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Merge

Combine multiple signals into single signal

Library

Signal Routing

Description

The Merge block combines its inputs into a single output line whose value at any time is equal to the most recently computed output of its driving blocks. You can specify any number of inputs by setting the block's **Number of inputs** parameter.

Use Merge blocks only to interleave input signals that update at different times into a combined signal in which the interleaved values retain their separate identities and times. To combine signals that update at the same time into an array or matrix signal, use a Concatenate block.

Merge blocks assume that all driving signals share the same signal memory. The shared signal memory should be accessed only in mutually exclusive fashion. Therefore, always use alternately executing subsystems to drive Merge blocks.

All signals that connect to a Merge block, or exist anywhere in a network of Merge blocks, are functionally the same signal, and are therefore subject to the restriction that a given signal can have at most one associated signal object. See `Simulink.Signal` for more information.

Run-time diagnostics do not run if the inputs to a merge block are from a single initiator. For example, a single initiator could be a Stateflow chart executing function-call subsystems that are connected to a merge block.

Guidelines for Using the Merge Block

When you use the Merge block, follow these guidelines:

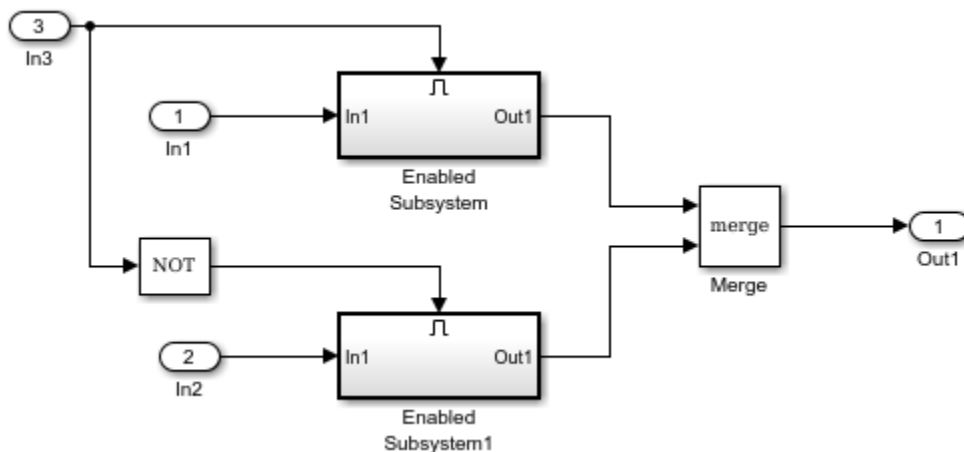

- Always use conditionally-executed subsystems to drive Merge blocks.
- Write your control logic to ensure that at most one of the driving conditionally-executed subsystems executes at any time step.
- Do not connect more than one input of a Merge block to the same conditionally-executed subsystem.
- Always connect a Merge block to at least two input signals.
- Ensure that all input signals have the same sample time.
- Always set the **Initial output** parameter of the Merge block, unless the output port of the Merge block connects to another Merge block.
- Do not branch a signal that inputs to a Merge block, if you use the default setting of `Classic` for the **Model Configuration Parameters > Diagnostics > Underspecified initialization detection** parameter. See the last example in “Merge Block Usage” on page 1-928 for additional usage guidelines relating to branched signals.
- For all conditionally-executed subsystem Output blocks that drive Merge blocks, set the **Output when disabled** parameter to `held`.
- If the output of a Model block is coming from a MATLAB Function block or a Stateflow chart, do not connect that output port to the input port of the Merge block.
- In the code generation workflow, when the Merge block receives a constant value and non-constant sample times, one of these conditions must hold. Otherwise Simulink displays an error.
 - The source of the constant value is a grounded signal.
 - The source of the constant value is a constant block with a non-tunable parameter.
 - There is only one constant block that feeds the Merge block.
 - All other input signals to the Merge block are from conditionally executed subsystems.
 - The Merge block and output blocks of all conditionally executed subsystems should not specify any initial outputs.

Merge Block Usage

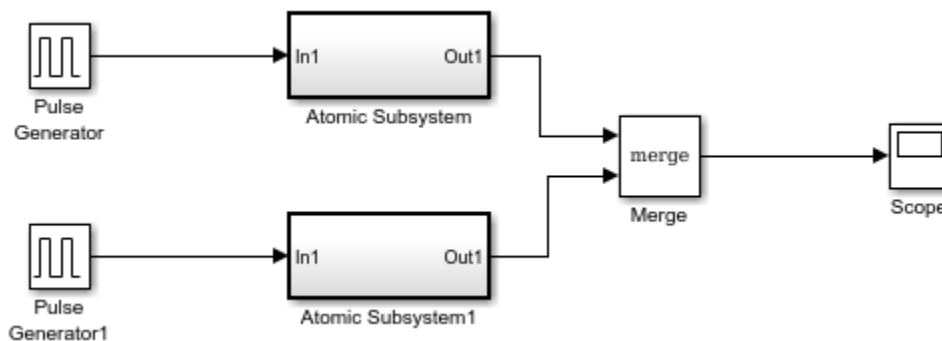

For each input of a Merge block, the topmost non-atomic and nonvirtual source must be a conditionally-executed subsystem that is not an Iterator Subsystem.

You can use the Model Advisor to check Merge block usage in your model. For more information, see “Check usage of Merge blocks” on page 8-32.

The following schematic shows valid Merge block usage, merging signals from two conditionally-executed subsystems.

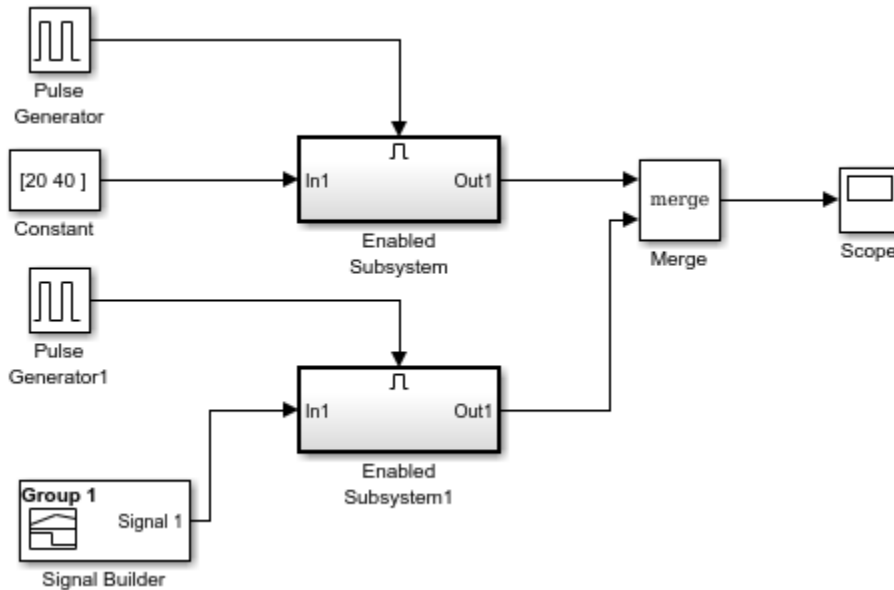

The following example is also a valid Merge block usage, where the topmost nonatomic, nonvirtual source is a conditionally executed subsystem.

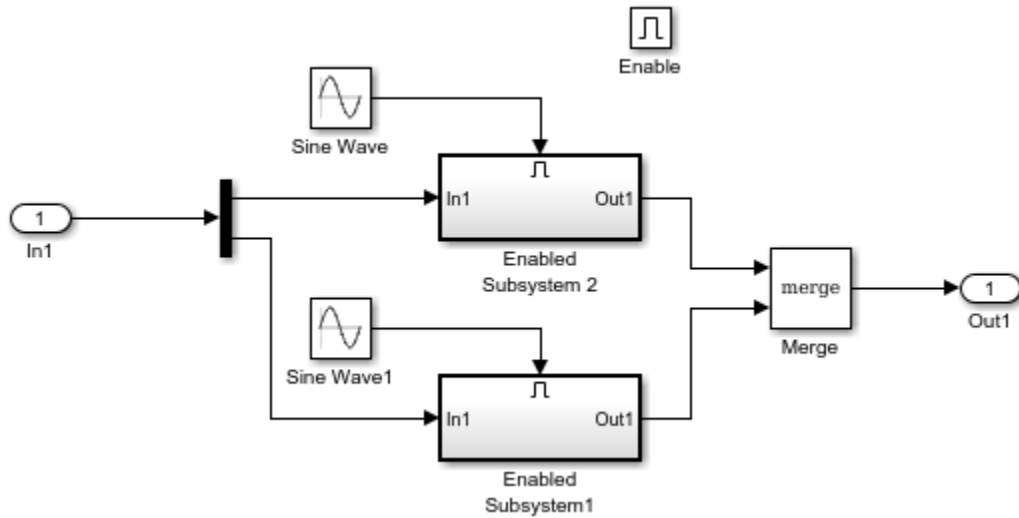

Each Atomic Subsystem block contains an enabled subsystem.

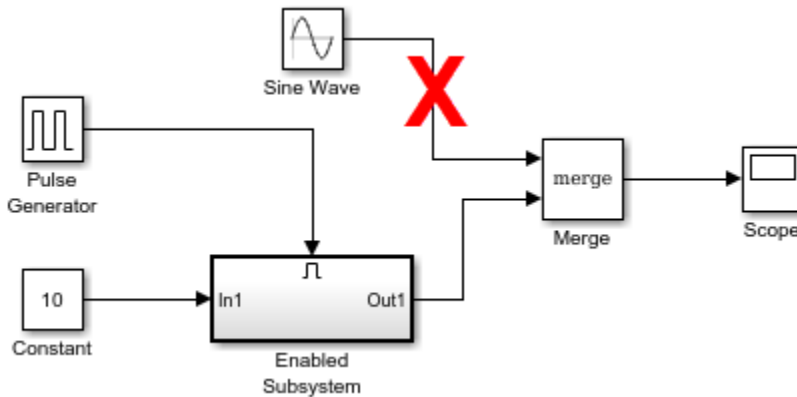

You can also use multiple Merge blocks at different levels of the model hierarchy. The following example contains a Merge block at the model root.

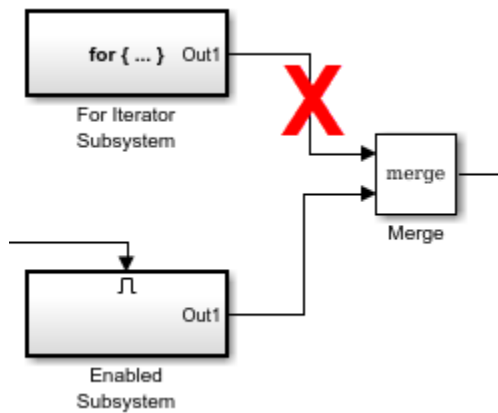

A Merge block is also located inside the Enabled Subsystem block, one level down.

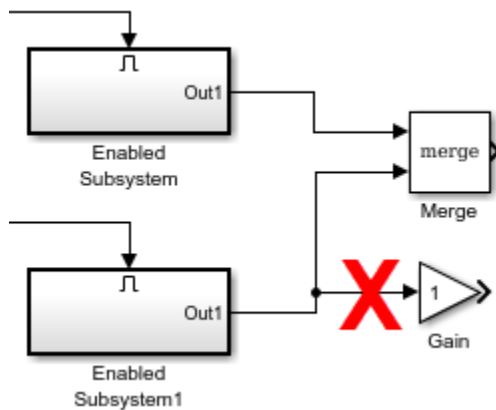

A Merge block *cannot* connect to a Sine Wave block because a Sine Wave block is not a conditionally-executed subsystem.

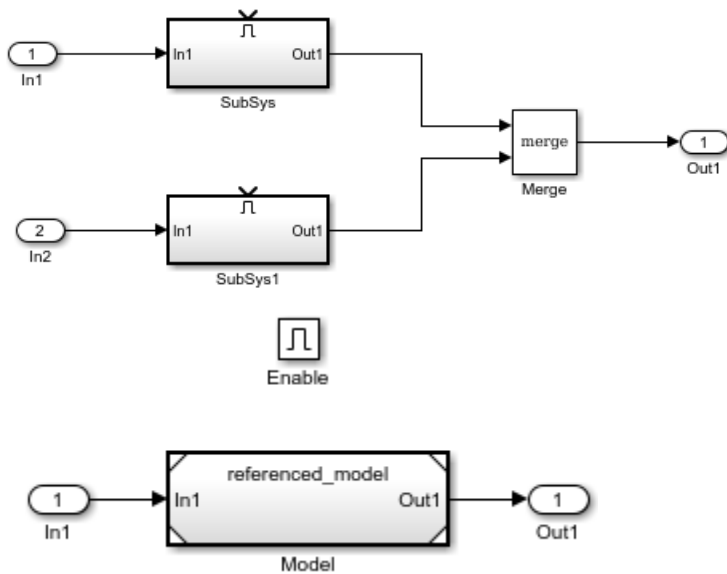

A Merge block *cannot* connect to a For Iterator Subsystem.

A Merge block *cannot* connect to a branched signal.

In the following model, the referenced model has a signal that branches. The subsystem `Subsys1` includes a Model block that references `referenced_model`. It includes a block that inputs to a block in the referenced model and also inputs to the Merge block that is outside of the referenced model.

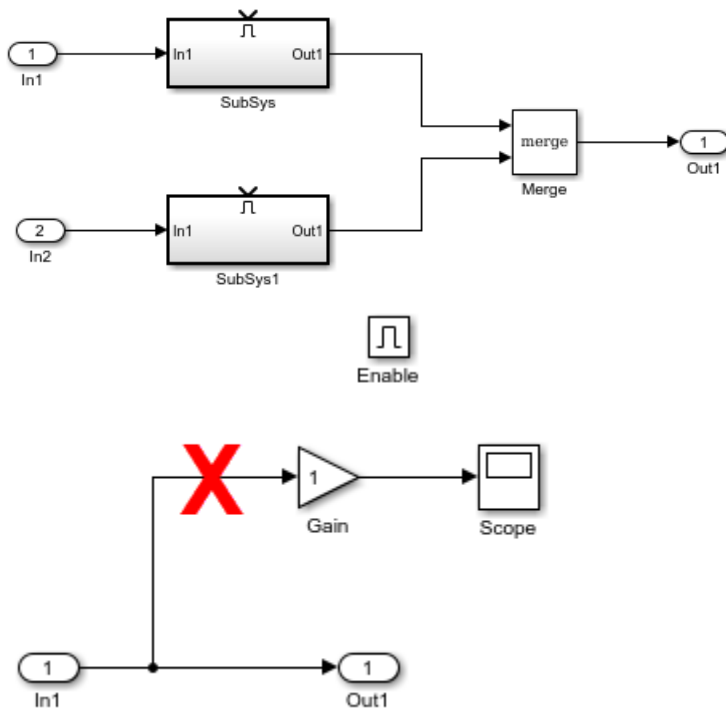

The referenced model includes a signal that incorrectly branches to a Gain block and to the Out1 Outputport block, which connects to the Merge block that is outside of the referenced model.

The following example also shows a branched signal in a subsystem that connects to a Merge block, which is *not allowed* if you use the default setting of `Classic` for the **Model Configuration Parameters > Diagnostics > Underspecified initialization detection** parameter.

If you set the **Underspecified initialization detection** parameter to `Simplified`, then the following example does *not* generate an error. For more information on simplified initialization mode, see “Underspecified initialization detection”.

You can specify an initial output value for the Merge block by setting the **Initial output** parameter.

If you do not specify an initial output value, the block's initial output depends on the initialization mode and the driving blocks. In Simplified initialization mode, for an unspecified (empty matrix `[]`) value of **Initial output**, the block uses the default initial value of the output data type. For information on the default initial value, see “Initializing Signal Values”. In Classic initialization mode, for an unspecified (empty matrix `[]`) value of **Initial output**, the initial output of the block equals the most recently evaluated initial output of the driving blocks. Since the initialization ordering for these sources may vary, initialization may be inconsistent for the simulation and the code generation of a model. For example, the following model can produce inconsistent initialization:

- The model contains a Merge block with two inputs: one driven by a Stateflow chart and the other driven by a conditionally executed subsystem (such as an Enabled Subsystem).
- The Merge block **Initial output** parameter is unspecified (that is, specified as empty matrix ([])) and the model uses Classic initialization mode.
- The Stateflow chart initializes the output being merged to `val1`.
- The conditionally executed subsystem initializes the output being merged to different value `val2`.
- Both the Stateflow chart and the conditionally executed subsystem do not execute at the first time step.

Because the initialization ordering may vary, the output of the Merge block at the first time step is `val1` if the Stateflow chart initializes last and `val2` if the conditionally executed subsystem initializes last. The initialization ordering is different for simulation and code generation.

To address this issue, use one of the following approaches:

- Set the **Initial output** parameter of the Merge block, unless the output port of the Merge block connects to another Merge block.
- Turn on simplified initialization mode. Set **Underspecified initialization detection** to `Simplified` on the **Configuration Parameters** dialog box.

To use the `Simplified` initialization setting, specify the **Initial output** value for all root Merge blocks. A root Merge block is any Merge block with an output port that does not connect to another Merge block.

To upgrade your model to simplified initialization mode, use the Model Advisor check “Check usage of Merge blocks” on page 8-32.

For more information on simplified initialization mode, see “Underspecified initialization detection”.

Single-input merge is not supported. Each Merge block must have at least two inputs.

Use Merge blocks only for signals that require merging. If you were previously connecting a Merge block input to a Mux block, use a multi-input Merge block instead.

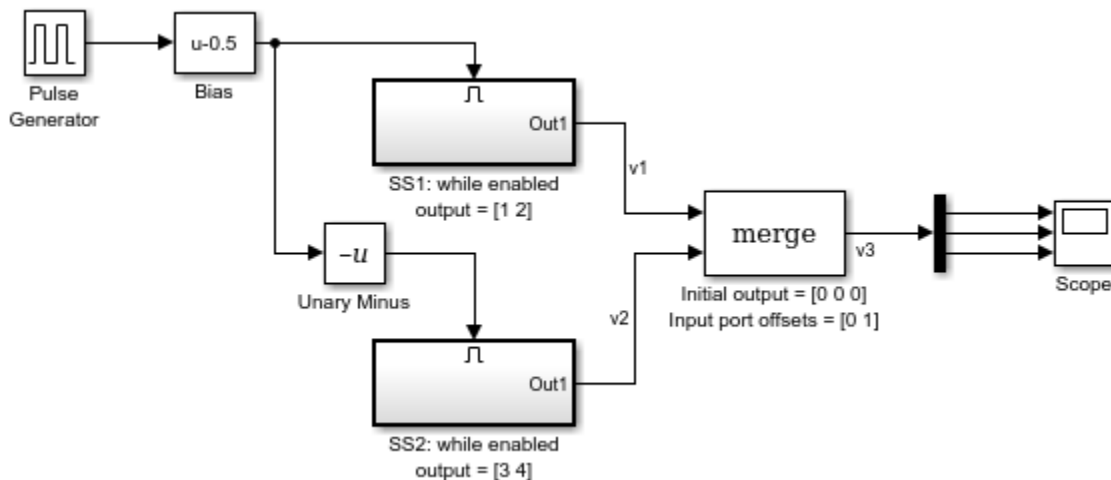

The Merge block accepts only inputs of equal dimensions and outputs a signal of the same dimensions as the inputs, unless you select the **Allow unequal port widths** parameter.

If you select **Allow unequal port widths**, the block accepts scalars and vectors (but not matrices) having differing numbers of elements. Further, the block allows you to specify an offset for each input signal relative to the beginning of the output signal. The width of the output signal is

$$\max(w_1+o_1, w_2+o_2, \dots, w_n+o_n)$$

where w_1, \dots, w_n are the widths of the input signals and o_1, \dots, o_n are the offsets for the input signals.

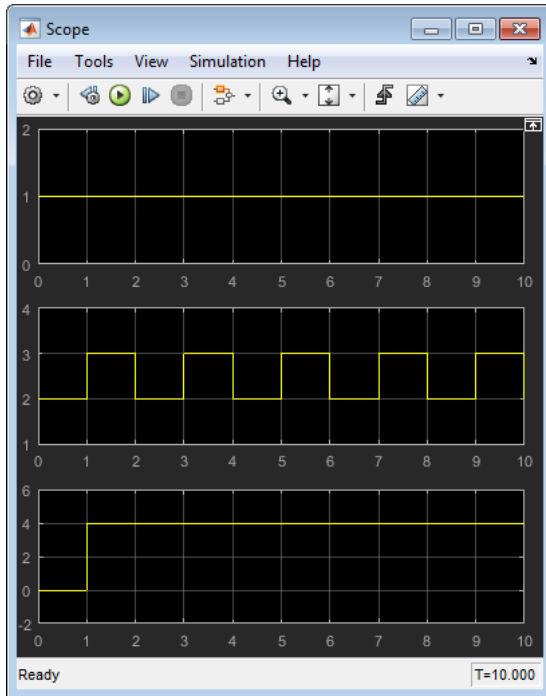

Suppose that you have the following block diagram:

The Merge block has the following output width:

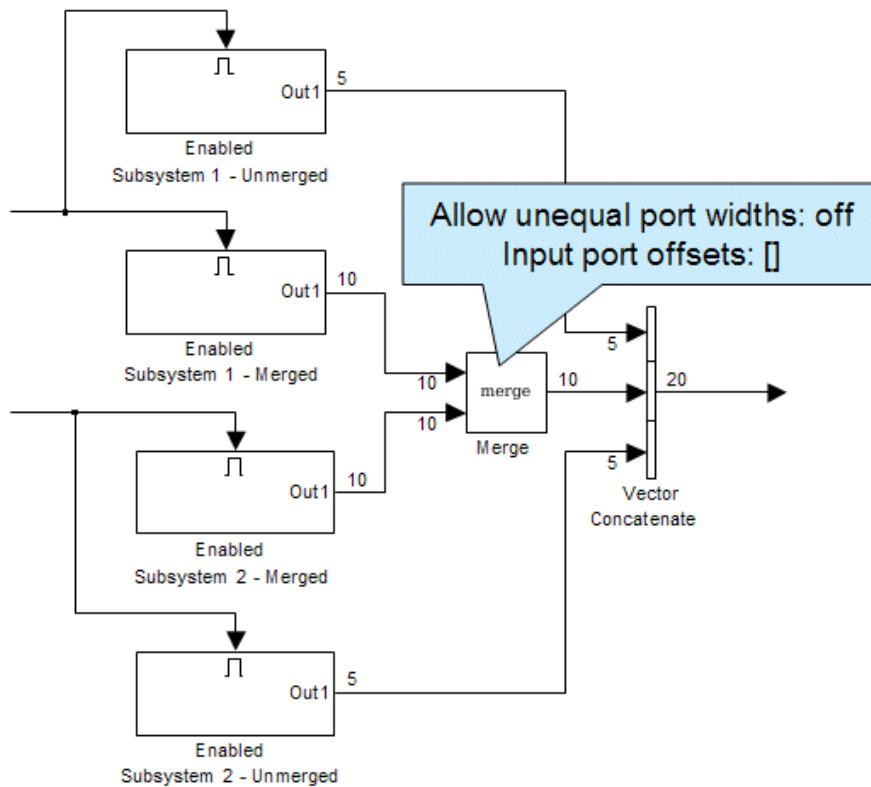

$\max(2+0, 2+1) = 3$

In this example, the offset of v_1 is 0 and the offset of v_2 is 1. The Merge block maps the elements of v_1 to the first two elements of v_3 and the elements of v_2 to the last two elements of v_3 . Only the second element of v_3 is effectively merged, as shown in the scope output:

If you use Simplified Initialization Mode, you must clear the **Allow unequal port widths** check box. The input port offsets for all input signals must be zero.

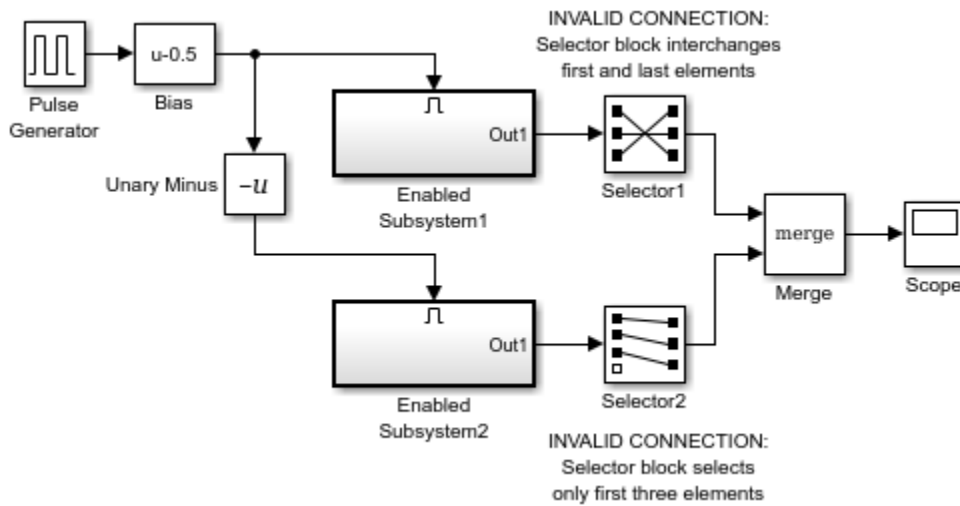

Consider using Merge blocks only for signal elements that require true merging. Other elements can be combined with merged elements using the Concatenate block, as shown in the following example.

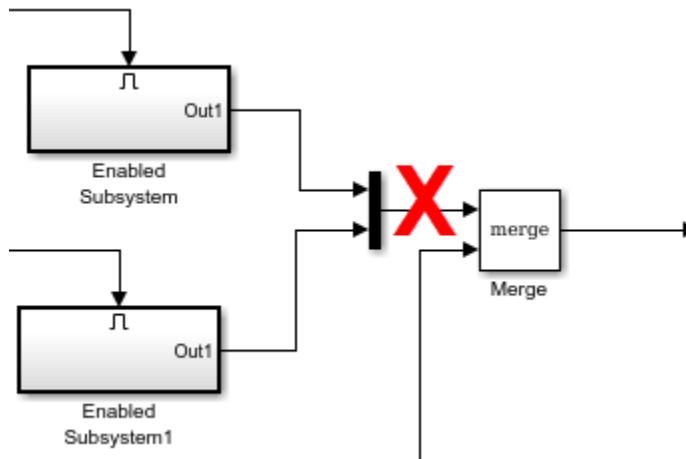

For more information on simplified initialization mode, see “Underspecified initialization detection”.

A Merge block does not accept input signals whose elements have been reordered or partially selected. In addition, you should not connect input signals to the Merge block that have been combined outside of a conditionally-executed subsystem.

For example, in the following block diagram, the Merge block does not accept the output of the first Selector block because the Selector block interchanges the first and last elements of the vector signal. Similarly, the Merge block does not accept the output of the second Selector block because the Selector block selects only the first three elements.

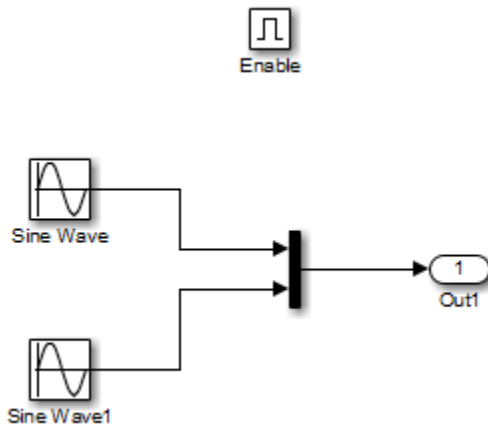

If you use simplified initialization mode, the following arrangement is *not allowed* because two signals are being combined outside of a conditionally-executed subsystem.

You can, however, combine or reorder Merge block input signals within a conditionally-executed subsystem. For example, the following model is valid.

Each Enabled Subsystem contains the following blocks.

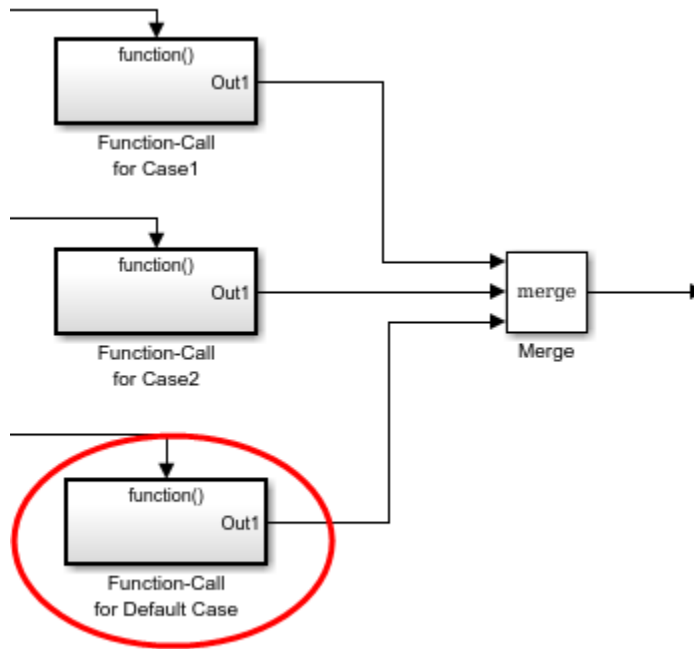

For more information on simplified initialization mode, see “Underspecified initialization detection”.

The Outports of conditionally-executed subsystems being merged should not reset when disabled. This action can cause multiple subsystems to update the Merge block at the same time. Specifically, the disabled subsystem updates the Merge block by resetting its output, while the enabled subsystem updates the Merge block by computing its output.

To prevent this behavior, set the Output block parameter **Output when disabled** to held for each conditionally-executed subsystem being merged.

Note If you are using Simplified Initialization Mode, you *must* set the Output block parameter **Output when disabled** to held.

Instead of resetting the subsystem output when it is disabled, add an additional subsystem for the default case, and use control logic to run this subsystem if nothing else runs. For example, see the following block layout:

For more information on simplified initialization mode, see “Underspecified initialization detection”.

Merging S-Function Outputs

The Merge block can merge a signal from an S-Function block only if the memory used to store the S-Function block's output is reusable. Simulink software displays an error message if you attempt to update or simulate a model that connects a nonreusable port of an S-Function block to a Merge block. See `ssSetOutputPortOptimOpts` for more information.

Data Type Support

The Merge block accepts real or complex signals of any data type that Simulink supports, including fixed-point and enumerated data types. All inputs must be of the same data type and numeric type.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Number of inputs

Specify the number of input ports to merge.

Initial output

Specify the initial value of output For more information, see “Initial Output Value” on page 1-933.

Allow unequal port widths

Select this check box to allow the block to accept inputs having different numbers of elements.

Input port offsets

Enter a vector to specify the offset of each input signal relative to the beginning of the output signal.

Bus Support

The Merge block is a bus-capable block. The inputs can be virtual or nonvirtual bus signals subject to the following restrictions:

- The number of inputs must be greater than one.
- **Initial output** must be zero, a nonzero scalar, or a finite numeric structure.
- **Allow unequal port widths** must be disabled.
- All inputs to the merge must be buses and must be equivalent (same hierarchy with identical names and attributes for all elements).

For information about specifying an initial condition structure, see “Specify Initial Conditions for Bus Signals”.

All signals in a nonvirtual bus input to a Merge block must have the same sample time, even if the elements of the associated bus object specify inherited sample times. You can use a Rate Transition block to change the sample time of an individual signal, or of all signals in a bus. See “Composite Signals” and Bus-Capable Blocks for more information.

You can use an array of buses as an input signal to a Merge block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”. Using an array of buses with a Merge block involves these limitations:

- **Allow unequal port widths** — Clear this parameter.
- **Number of inputs** — Set to a value of 2 or greater.
- **Initial condition** — You can specify this parameter with:
 - The value 0. In this case, all of the individual signals in the array of buses use the initial value 0.
 - An array of structures that specifies an initial condition for each of the individual signals in the array of buses.
 - A single scalar structure that specifies an initial condition for each of the elements that the bus type defines. Use this technique to specify the same initial conditions for each of the buses in the array.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated Bus
Sample Time	Inherited from driving block
Direct Feedthrough	Yes

Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

MinMax

Output minimum or maximum input value

Library

Math Operations

Description

The MinMax block outputs either the minimum or the maximum element or elements of the inputs. You can choose the function to apply by selecting one of the choices from the **Function** parameter list.

If the block has one input port, the input must be a scalar or a vector. The block outputs a scalar equal to the minimum or maximum element of the input vector.

If the block has multiple input ports, all nonscalar inputs must have the same dimensions. The block expands any scalar inputs to have the same dimensions as the nonscalar inputs. The block outputs a signal having the same dimensions as the input. Each output element equals the minimum or maximum of the corresponding input elements.

The MinMax block ignores any input value that is NaN, except when every input value is NaN. When all input values are NaN, the output is NaN, either as a scalar or the value of each output vector element.

Data Type Support

The MinMax block accepts and outputs real signals of the following data types:

- Boolean (If one input is a boolean, all inputs must be booleans. In this case, all outputs are also booleans.)
- Floating point
- Built-in integer
- Fixed point

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Function

Specify whether to apply the function `min` or `max` to the input.

Number of input ports

Specify the number of inputs to the block.

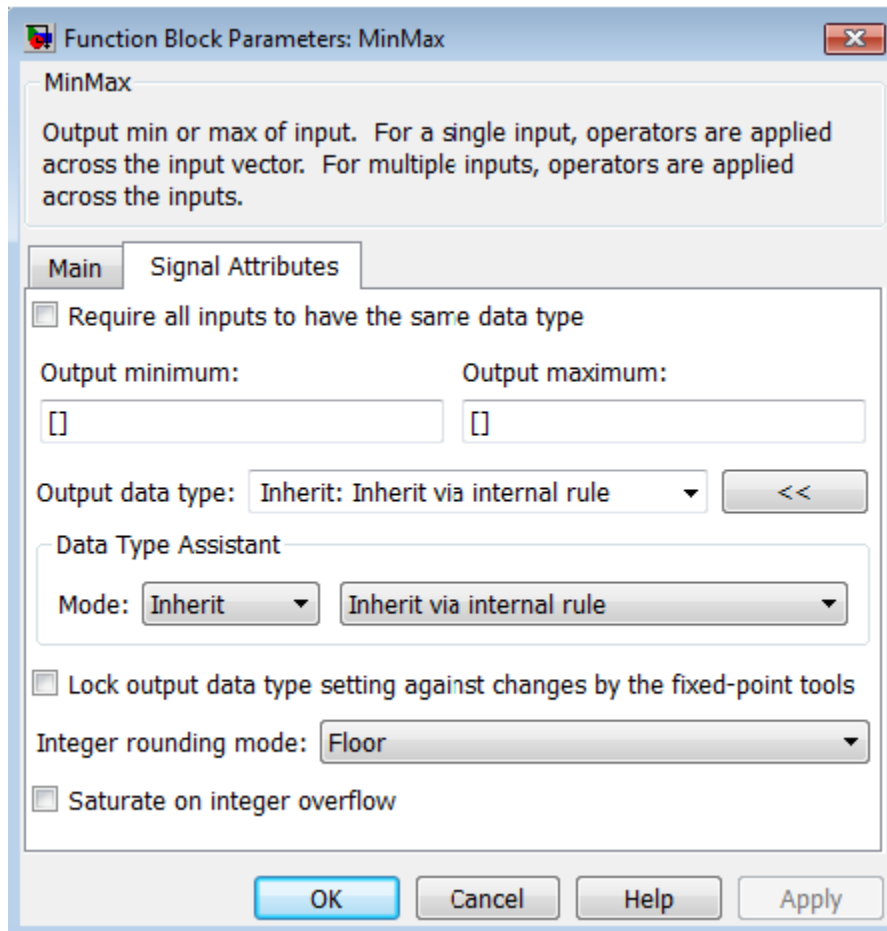

Enable zero-crossing detection

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

The **Signal Attributes** pane of the MinMax block dialog box appears as follows:

Require all inputs to have the same data type

Select this check box to require that all inputs have the same data type.

Output minimum

Specify the minimum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.

- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Output maximum

Specify the maximum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Output data type

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” in the *Simulink User's Guide* for more information.

Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer). in the Fixed-Point Designer documentation.

Saturate on integer overflow

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box.	<p>You want to optimize efficiency of your generated code.</p> <p>You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.</p>	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

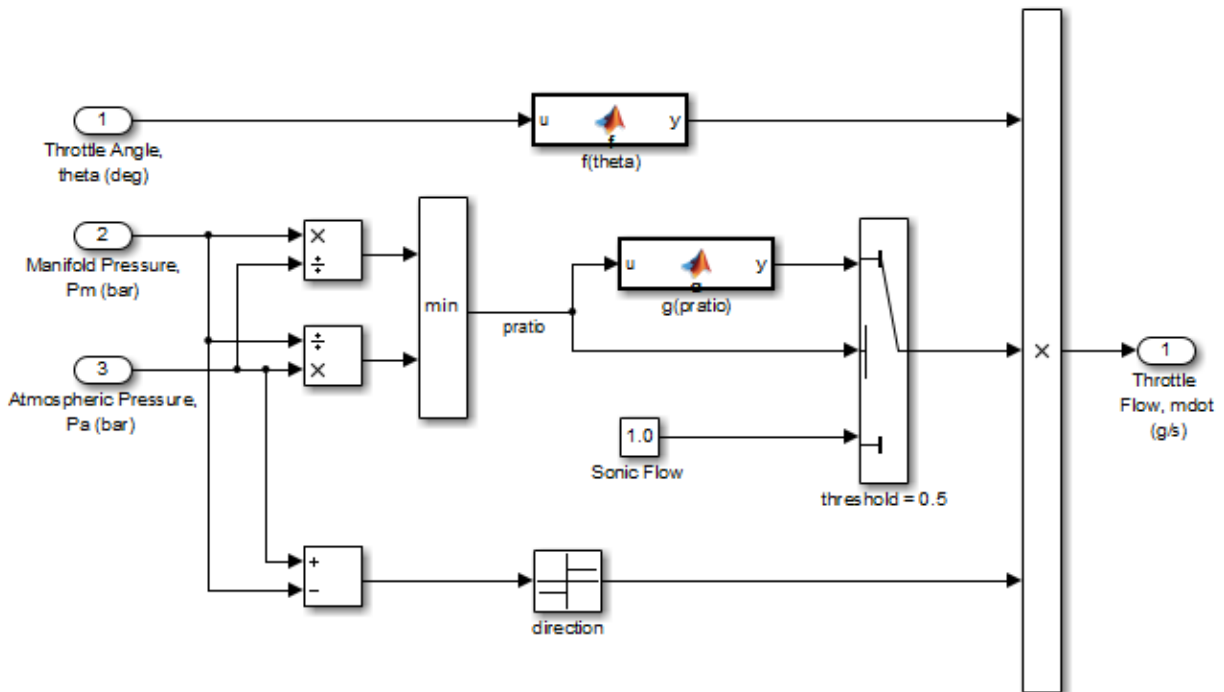

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. Usually, the code generation process can detect

when overflow is not possible. In this case, the code generator does not produce saturation code.

Examples

The `sldemo_fuelsys` model shows how to use the MinMax block.

In the Engine Gas Dynamics/Throttle & Manifold/Throttle subsystem, the MinMax block uses the min operator:

In the Engine Gas Dynamics/Mixing & Combustion subsystem, the MinMax block uses the max operator:

Characteristics

Data Types	Boolean Double Single Base Integer Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	Yes, if enabled
Code Generation	Yes

MinMax Running Resettable

Introduced before R2006a

MinMax Running Resettable

Determine minimum or maximum of signal over time

Library

Math Operations

Description

The MinMax Running Resettable block outputs the minimum or maximum of all past inputs u . You specify whether the block outputs the minimum or the maximum with the **Function** parameter.

The block can reset its state based on an external reset signal R . When the reset signal R is `TRUE`, the block resets the output to the value of the **Initial condition** parameter.

The input can be a scalar, vector, or matrix signal. If you specify a scalar **Initial condition** parameter, the block expands the parameter to have the same dimensions as a nonscalar input. The block outputs a signal having the same dimensions as the input. Each output element equals the running minimum or maximum of the corresponding input elements.

Data Type Support

The MinMax Running Resettable block accepts and outputs real signals of any numeric data type that Simulink supports, except `boolean`. The MinMax Running Resettable block supports fixed-point data types.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Function

Specify whether the block outputs the minimum or the maximum.

Initial condition

Specify initial condition.

Characteristics

Data Types	Double Single Base Integer Fixed-Point
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Code Generation	Yes

Model

Include multiple model implementations as block in another model

Library: Ports & Subsystems

Description

The Model block allows you to include a model as a block in another model. The included model is called a *referenced model*, and the model containing it (using the Model block) is called the *parent model*.

The Model block displays input and output ports corresponding to the top-level input and output ports of the referenced model. Using these ports allow you to connect the referenced model to other blocks in the parent model. See “Model Referencing” for more information.

As an alternative to specifying a particular referenced model in the **Main** tab, you can dynamically reference one of several model variants, depending on a model workspace value. A *variant* describes one possible mode in which a Model block can operate. Each variant of the Model block references a specific model with optional model-specific arguments. Only one variant is active for simulation. To create model variants, click **Enable Variants** button, which opens a dialog box for implementing model variants. For more information about how to specify a referenced model for multiple specifications, see “Set up Model Variants Using a Model Block”.

Note For new models, use a Model block for model variants only if you need to use variants that are conditionally executed models (models with control ports). Model variants are supported for backward compatibility. However, support for model variants will be removed in a future release. Use of a Variant Subsystem block provides these advantages:

- Allows you to mix Model and Subsystem blocks as variant systems
- Supports flexible I/O, so that all variants do not need to have the same number of input and output ports

To convert a Model block that contains variant models to a Variant Subsystem block that contains Model blocks that reference the variant models, right-click the Model block and select **Subsystems & Model Reference > Convert to > Variant Subsystem**.

Alternatively, you can use the `Simulink.VariantManager.convertToVariant` function. Specify the Model block path or block handle. The converted model produces the same results as the original model.

Alternatively, to set up model variants for a new model, you can use the Variant Model block, which is a subsystem variant template block that contains two Model blocks that you can use for variants.

By default, the contents of a referenced model are user-visible by double-clicking the Model block. However, you can hide the contents of a referenced model by making the model a protected model.

Depending on whether you want to reference a single model or variant models, and whether you want to use model arguments, you need to use different parts of the Model block interface.

Modeling Goal	Model Block Interface to Use
Reference a single model (nonvariant model)	Use the Main tab.
Reference variant models	On the Main tab, click Enable Variants , which opens the model variants dialog box.
Specify values for model arguments	For a nonvariant model reference, use the Arguments tab. For variant models, use the variant dialog box.

To manage various variants that are modeled using variant blocks in a model, in the model variants dialog box click **Open block in Variant Manager** link.

Ports

Input

Input_Port_1 — Input port corresponding to root-level Inport, Enable, and Trigger blocks of referenced model

real or complex values of any data type supported by Simulink

The Model block has an input port for each root-level Inport, Enable, or Trigger block in the referenced model. The name of the Model block port matches the name of the corresponding referenced model input block. The Model block input signals must be valid for the corresponding referenced model input blocks. See “Define Referenced Model Inputs and Outputs”.

Input signals can have real or complex values of any data type supported by Simulink, including bus objects, arrays of buses, fixed-point, and enumerated data types. For details about data types, see Simulink, “Data Types Supported by Simulink”.

Output

Output_Port_1 — Output port corresponding to root-level Outport block of referenced model

real or complex values of any data type supported by Simulink

The Model block has an output port for each root-level Outport block in the referenced model. The name of the Model block port matches the name of the corresponding Outport block. The Model block output signals are the signals from the corresponding referenced model Outport blocks. See “Define Referenced Model Inputs and Outputs”.

Output signals can have real or complex values of any data type supported by Simulink, including bus objects, arrays of buses, fixed-point, and enumerated data types. For details about data types, see Simulink, “Data Types Supported by Simulink”.

Parameters

Main Tab

Model name — File name of referenced model

' ' (default) | character vector

Path to the referenced model. The file name must be a valid MATLAB identifier. The extension, for example, `.slx`, is optional. The file name must contain fewer than 60 characters, exclusive of the `.slx` or `.mdl` suffix.

To navigate to the model that you want to reference, click **Browse**.

To view the model that you specified, click **Open Model**.

Programmatic Use

Parameter: `ModelFile`

Type: character vector

Value: ' ' | '<file name>'

Default: ' '

Simulation mode — Simulation mode for referenced model

Normal (default) | Accelerator | Software-in-the-loop (SIL) | Processor-in-the-loop (PIL)

Specify the simulation mode for the referenced model. The simulation mode for models in a model referencing hierarchy do not have to match. For information about model reference simulation modes and precedence of the simulation mode in a hierarchy, see “Simulate Model Reference Hierarchies”.

- `Accelerator` — Create a MEX-file for the referenced model and then executes the referenced model by running the S-function.
- `Normal` — Execute the referenced model interpretively, as if the referenced model is an atomic subsystem implemented directly within the parent model.
- `Software-in-the-loop (SIL)` — This option requires the Embedded Coder software. Generate production code based on the **Code Interface** parameter setting. The code is compiled for, and executed on, the host platform.
- `Processor-in-the-loop (PIL)` — This option requires the Embedded Coder software. Generate production code based on the **Code Interface** parameter setting.

This code is compiled for, and executed on, the target platform. A documented target connectivity API supports exchange of data between the host and target at each time step during the PIL simulation.

The corners of the Model block reflect the simulation mode for the referenced model. For normal mode, the corners have empty triangles. For accelerator mode, the corner triangles are filled in. For SIL and PIL modes, the corners are filled in and the word (SIL) or (PIL) appears on the block icon.

Programmatic Use

Parameter: `SimulationMode`

Type: character vector

Value: 'Normal' | 'Accelerator' | 'Software-in-the-loop' | 'Processor-in-the-loop'

Default: 'Normal'

Code interface — Generate code from top model or referenced model

`Model reference (default) | Top model`

Specify whether to generate the code from the top model or the referenced model for SIL and PIL simulation modes. To deploy the generated code as part of a larger application that uses the referenced model, specify `Model reference`. To deploy the generated code as a standalone application, specify `Top model`.

`Model reference`

Code generated from referenced model as part of a model reference hierarchy. Code generation uses the `slbuild('model', 'ModelReferenceRTWTarget')` command.

`Top model`

Code generated from top model with the standalone code interface. Code generation uses the `slbuild('model')` command.

Dependencies

To display and enable this parameter, select either `Software-in-the-loop (SIL)` or `Processor-in-the-loop (SIL)` from the **Simulation mode** drop-down list.

Programmatic Use

Parameter: `CodeInterface`

Type: character vector

Value: 'Model reference' | 'Top model'

Default: 'Model reference'

Show model initialize port — Control display of initialize event port

off (default) | on

Control display of initialize event port on the Model block.

off

Remove port.

on

Display model initialize event port.

Programmatic Use

Block parameter: ShowModelInitializePort

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Show model reset port — Control display of reset event ports

off (default) | on

Control display of reset event ports on the Model block.

off

Remove port.

on

Display model reset event ports.

Programmatic Use

Block parameter: ShowModelResetPorts

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Show model terminate port — Control display of terminate event port

off (default) | on

Control display of terminate event port on Model block.

off

Remove port.

on

Display model block port.

Programmatic Use

Block parameter: ShowModelTerminatePort

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Show model periodic event ports — Control display of periodic event ports

off (default) | on

Control display of periodic event ports on Model block.

off

Hide ports.

on

Display ports for rate-based models. A rate-based model is a model with the **Sample time** for a connected Inport block specified.

If you want to manually specify the port rates, set the parameter `AutoFillPortDiscreteRates` to 'off', and then add the port rates to the parameter `PortDiscreteRates`.

Programmatic Use

Block parameter: ShowModelPeriodicEventPorts

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Enable variants — Enable variants and open dialog box for defining model variants

off (default) | on

Opens a dialog box for defining model variants. The dialog box includes a **Variant choices** table, with a separate row for defining each variant.

Programmatic Use

Block parameter: Variants

Type: array

Value: array of variant structures where each element specifies one variant. The structure fields are:

- `variant.Name` (character vector) — The variant control can be a boolean condition expression, or a `Simulink.Variant` object representing a boolean condition expression. If you want to generate code for your model, you must define the control variables as `Simulink.Parameter` objects.
- `variant.ModelName` (character vector) — The name of the referenced model associated with the specified variant control in the Model block.
- `variant.ParameterArgumentNames` (character vector) — Read-only character vector containing the names of the model arguments for which the Model block must supply values.
- `variant.ParameterArgumentValues` (character vector) — The values to supply for the model arguments when this variant is the active variant.
- `variant.SimulationMode` (character vector) — The execution mode to use when this variant is the active variant. Possible values are 'Accelerator' | 'Normal' | 'Software-in-the-loop (SIL)' | 'Processor-in-the-loop (PIL)'

Arguments Tab

Model arguments — Display model arguments and specify argument values for referenced model

number | workspace variable | mathematical expression | structure or structure field

Display model arguments and specify model argument values. Model arguments enable the referenced model to use a different value for a variable used by a referenced model. To specify model argument values, use the **Value** column in the table. For more information about configuring model arguments in a referenced model and specifying argument values, see “Parameterize Instances of a Reusable Referenced Model”.

Programmatic Use

Block parameter: `ParameterArgumentValues` (corresponding to the **Value** column in the table)

Type: structure

Value: Structure with one field for each model argument that the referenced model defines. Fields of the structure are names of the model arguments. Values are character vector representations of the values.

Default: Structure with no fields

Model Variants Dialog Box

Variant choices — Table of variant models

row for the model specified in **Model name** parameter in the **Main** tab (default)

Table containing a row for each variant object in the base workspace. The **Variant choices** table includes the **Model name**, associated **Variant control**, and **Condition (read-only)** columns. For details, see the descriptions of each of the parameters.

To modify the table, use buttons to the left of the **Variant choices** table.

Function	Button
Add a new variant: Add a new, empty row below the currently selected row	
Delete selected variant: Delete the currently selected row. Models and objects are not affected.	
Create/Edit selected variant object: Creates a Simulink.Variant object in the base workspace and opens the Simulink.Variant object parameter dialog box for specifying the variant Condition . This button is enabled only for valid Simulink.Variant objects.	
Move variant up: Move up the currently selected row one slot in the table	
Move variant down: Move the currently selected row down one slot in the table	

Dependency

Enable variants on the **Main** tab opens the variant model dialog box that contains this parameter.

Programmatic Use

Block parameter: Variants

Type: array

Value: array of variant structures where each element specifies one variant. The structure fields are:

- `variant.Name` (character vector) — The variant control can be a Boolean condition expression, or a `Simulink.Variant` object representing a Boolean condition expression. To generate code for your model, define the control variables as `Simulink.Parameter` objects.
- `variant.ModelName` (character vector) — The name of the referenced model associated with the specified variant control in the Model block.
- `variant.ParameterArgumentNames` (character vector) — Read-only character vector containing the names of the model arguments for which the Model block must supply values.
- `variant.ParameterArgumentValues` (character vector) — The values to supply for the model arguments when this variant is the active variant.
- `variant.SimulationMode` (character vector) — The execution mode to use when this variant is the active variant.
 - Possible values are 'Accelerator' | 'Normal' | 'Software-in-the-loop (SIL)' | 'Processor-in-the-loop (PIL)'

Model name — Display or enter name of model associated with variant control

' ' (default) | character vector

Path to the variant model, specified as a character vector. The name must be a valid MATLAB identifier. The extension, for example, `.slx`, is optional. The model name must contain fewer than 60 characters, exclusive of the `.slx` or `.mdl` suffix.

To navigate to the model that you want to reference for the selected variant in the table, click **Browse**.

To view the model that you specified is the model you want to reference, click **Open Model**.

Dependency

Enable variants on the **Main** tab opens the variant model dialog box that contains this parameter.

Programmatic Use**Parameter:** ModelName**Type:** character vector**Value:** '' | '<file name>'**Default:** ''**Variant control — Variant activation condition or variant control that contains expression for variant activation**

Variant (default) | Simulink.Variant object representing a Boolean condition expression | Simulink.Parameter object

The variant control can be a boolean condition expression or a Simulink.Variant object representing a boolean condition expression. If you want to generate code for your model, define control variables as Simulink.Parameter objects.

The variant condition must be a Boolean expression that references at least one base workspace variable or parameter. For example, `FUEL == 2 && EMIS == 1`. Do not surround the condition with parentheses or single quotes. The expression can include:

- MATLAB variables defined in the base workspace
- Simulink parameter objects defined in the base workspace
- Scalar variables
- Enumerated values
- Operators `==`, `~=`, `&&`, `||`, `~`
- Parentheses for grouping

During model compilation, Simulink evaluates variant objects before calling the `InitFcn` callback. Therefore, do not modify the condition of the variant object in the `InitFcn` callback.

Dependency

Enable variants on the **Main** tab opens the variant model dialog box that contains this parameter.

Programmatic Use**Structure field:** Represented by the `variant.Name` field in the `Variants` parameter structure**Type:** character vector

Value: Variant control associated with the variant

Default: ''

Condition (read-only) — Display condition for Simulink.Variant object

a Boolean expression that references at least one base workspace variable or parameter

This read-only field displays the condition for the associated model variant in the base workspace. To specify the condition for the selected variant object, click the **Edit selected variant object** button.

The variant condition must be a Boolean expression that references at least one base workspace variable or parameter. For example, `FUEL == 2 && EMIS == 1`. Do not surround the condition with parentheses or single quotes. The expression can include:

- MATLAB variables defined in the base workspace
- Simulink parameter objects defined in the base workspace
- Scalar variables
- Enumerated values
- Operators `==`, `~=`, `&&`, `||`, `~`
- Parentheses for grouping

Dependency

Enable variants on the **Main** tab opens the variant model dialog box that contains this parameter.

Override variant conditions and use the following variant — Override variant conditions and make variant the active variant

off (default) | on

By default, Simulink determines the active variant by the value of the variant conditions. To override the variant conditions and set the active variant to the value of the **Variant**, enable the **Override variant conditions and use the following variant** parameter.

Dependency

Selecting this parameter, enables the **Variant** parameter.

Programmatic Use

Parameter: `OverrideUsingVariant`

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Variant — Specify variant

varObject(<Enter Model Name>) (default) | character vector

Specify overriding variant.

Dependency

To enable this parameter, select the **Override variant conditions and use the following variant** parameter.

Programmatic Use

Parameter: ActiveVariant

Type: character vector

Value: '' if no overriding variant control is specified.

Default: ''

Model name — Display or enter name of model associated with variant control

'' (default) | character vector

Path to the variant model, specified as a character vector. The name must be a valid MATLAB identifier. The extension, for example, .slx, is optional. The model name must contain fewer than 60 characters, exclusive of the .slx or .mdl suffix.

To navigate to the model that you want to reference for the selected variant in the table, click **Browse**.

To view the model that you specified is the model you want to reference, click **Open Model**.

Dependency

Enable variants on the **Main** tab opens the variant model dialog box that contains this parameter.

Model arguments — Display model arguments

comma-separated list of argument names

Display model arguments for the selected referenced model. For more information about configuring model arguments in a referenced model and specifying argument values, see “Parameterize Instances of a Reusable Referenced Model”.

Dependency

Enable variants enables this parameter.

Programmatic Use

Structure field: Represented by the `variant.ParameterArgumentNames` field in the Variants parameter structure `OneArgName`

Type: character vector

Value: Enter model arguments as a comma separated list

Default: ''

Model argument values (for this instance) — Specify model argument values for referenced model variant

number | workspace variable | mathematical expression | structure or structure field

Enter the argument values in this parameter as a list, in the same order as the corresponding argument names in the **Model arguments** parameter. To separate the items in the list, use commas, spaces, or semicolons. For information about valid values, see “Set Block Parameter Values”.

To define model arguments, see “Model Arguments for Model Blocks That Contain Model Variants”.

Dependency

Enable variants on the **Main** tab opens the variant model dialog box that contains this parameter.

Programmatic Use

Structure field: Represented by the `variant.ParameterArgumentValues` field in the Variants parameter structure `OneArgName`

Type: character vector

Value: Any valid value

Default: ''

Simulation mode — Simulation mode for model variant

Accelerator (default) | Normal | Software-in-the-loop (SIL) | Processor-in-the-loop (PIL)

Simulation mode for the highlighted model variant control.

- `Accelerator` — Creates a MEX-file for the referenced model and then executes the referenced model by running the S-function.
- `Normal` — Executes the referenced model interpretively, as if the referenced model is an atomic subsystem implemented directly within the parent model.
- `Software-in-the-loop (SIL)` — This option requires the Embedded Coder software. Generates production code using model reference target for the referenced model. This code is compiled for, and executed on, the host platform.
- `Processor-in-the-loop (PIL)` — This option requires the Embedded Coder software. Generates production code using a model reference target for the referenced model. This code is compiled for, and executed on, the target platform. A documented target connectivity API supports exchange of data between the host and target at each time step during the PIL simulation.

Generate preprocessor conditionals — For ERT target, specify whether variant choices are enclosed within C preprocessor conditional statements

off (default) | on

When generating code for an ERT target, this parameter determines whether variant choices are enclosed within C preprocessor conditional statements (`#if`). When you enable this option, Simulink analyzes all variant choices during an update diagram or simulation. This analysis provides early validation of the code generation readiness of all variant choices.

Dependencies

- The check box is available for generating only ERT targets.
- **Override variant conditions and use following variant** is cleared.

Programmatic Use

Parameter: `GeneratePreprocessorConditionals`

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Disable variants — Disable model reference variants and display Main tab

off (default) | on

Disable model reference variants and display the **Main** tab. The block retains any information you have entered and approved by clicking **Apply** or **OK**.

Programmatic Use

Parameter: Variant

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Model Info

Display model properties and text in model

Library

Model-Wide Utilities

Description

The Model Info block displays model properties and text about a model on the mask of the block. Use the Model Info block dialog box to specify the content and format of the text that the block displays. You can select model properties to display on the block. In the text displayed on the block mask, Simulink replaces the property name with the current value of the property in the model.

Data Type Support

Not applicable.

Parameters

Specify Text and Properties to Display

Use the **Enter text and tokens to display on Model Info block** edit box to specify the text and properties to display.

- In the edit box, enter any text you want to display on the block mask. Edit the default text `Model Info`.
- To display a model property on the block mask, select a property in the **Model properties** list and click the right arrow button.

The block adds a token of the form `%<modelpropertyname>` to the edit box. In the text the block mask displays, Simulink will replace the token with the value of the property.

- 1 For example, if you select `Description` in the **Model properties** list and click the right arrow button, then the token

`%<Description>`

appears in the right edit box.

- 2 You could add some explanatory text before the model property, e.g. “`Model description:`”.
- 3 When you click **Apply** or **OK**, Simulink displays your new text and the current value of the model property on the block mask in the Model Editor.

See “Version Information Properties” for descriptions of the model properties.

If you are interested in source control information, for a flexible interface to source control tools, use Simulink Project. See “Source Control in Simulink Project”.

Tip To add text, images, links, and equation annotations to a model, see instead “Describe Models Using Annotations”.

Characteristics

Data Types	Not applicable
Multidimensional Signals	No
Variable-Size Signals	No
Code Generation	Yes

Introduced before R2006a

Multiply-Accumulate

Perform a multiply-accumulate operation on the inputs

Library: HDL Coder / HDL Operations / Multiply-Accumulate

Multiply-Accumulate

Description

The Multiply-Accumulate block performs this operation on the inputs u_1 and u_2 , and the bias k , to compute the result y .

$$y = \text{sum}(u_1 .* u_2) + k$$

The inputs u_1 and u_2 can be scalars or vectors. By default, the bias k is equal to zero, and the block computes the dot product of the inputs u_1 and u_2 . You can specify a nonzero value for k using `Dialog` or `Input port` as the **Source**. The block adds this bias to the dot product of u_1 and u_2 . The multiplication operation is full precision irrespective of the **Output data type** setting. The **Output data type** and **Integer rounding mode** settings apply to the addition operation.

Ports

Input

a — Input signal

vector | matrix | array | bus

Port to provide input to the block.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

b — Input signal

scalar | vector | matrix | array | bus

Port to provide input to the block.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated | bus

c — Bias signal

scalar | vector | matrix | array | bus

Port to provide the bias signal to the block. The block adds this bias to the inputs. Make sure that the bias signal data type matches that of the dot product of the inputs.

Dependencies

To enable this port, set **Source** to external.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

Output

y — Output signal

scalar | vector | matrix | array | bus

Port that generates output of the multiply-accumulate operation.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

Parameters

Bias — Offset to add to the input dot product

{ '0.0' } (default)

You can specify the bias with:

- **Source** as Dialog. Then, specify the **Value**.
- **Source** as Input port. This setting creates an external input port c to input the bias signal to the block.

Output data type — Data type of the block output

Inherit: `Inherit` via internal rule (default)

Set the output data type to:

- A rule that inherits a data type, such as `Inherit: Same as first input`.
- A built-in data type, such as `single` or `int16`.
- The name of a data type object. for instance, a `Simulink.NumericType` object.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

When you set the **Output data type**, you can use the **Data Type Assistant**. To display

the assistant, click the **Show data type assistant** .

Programmatic Use

Block parameter: `OutDataTypeStr`

Type: character vector

Default: `{'Inherit: Inherit via internal rule'}`

To see possible values that you can specify for this parameter, see “Block-Specific Parameters” on page 6-128.

Integer rounding mode — Rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding action as:

`Ceiling`

Rounds positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

`Convergent`

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

`Floor`

Rounds positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

`Nearest`

Rounds the number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

Simplest

Chooses between rounding toward floor and rounding toward zero to generate rounding code that is as efficient as possible.

Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

Programmatic Use

Block parameter: `RndMeth`

Type: character vector

Default: `{'Floor'}`

To see possible values that you can specify for this parameter, see “Block-Specific Parameters” on page 6-128.

Block Characteristics

Data Types	double single base integer fixed point bus
Sample Time	Inherit
Direct Feedthrough	Yes
Multidimensional Signals	Scalar
Variable-Size Signals	Yes
Zero-Crossing Detection	No

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

If you have HDL Coder installed, you can map the generated HDL code for the block efficiently to DSP slices on the FPGA when you synthesize your design. For more information, see Multiply-Accumulate.

You can use the data types listed above for the ports when you simulate the block. To generate HDL code, make sure that you use vector inputs and a scalar bias signal. If you use single or double data types for the inputs, the block may not map the generated code to DSP slices on the FPGA.

Fixed-Point Conversion

Design and simulate fixed-point algorithms using Fixed-Point Designer™.

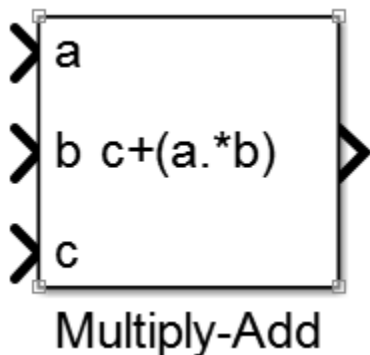

See Also

Dot Product | Multiply-Add

Introduced in R2017b

Multiply-Add

Multiply-add combined operation

Library

HDL Coder / HDL Operations

Description

The Multiply-Add block computes the product of the first two inputs, a and b, and adds the result to the third input, c. The inputs can be vectors or scalars.

Operation Precision

The multiplication operation is full precision, regardless of the output type. The **Integer rounding mode**, **Output data type**, and **Saturate on integer overflow** settings apply only to the addition operation.

HDL Code Generation

Use the Multiply-Add block to map a combined multiply-add or a multiply-subtract operation to a DSP unit in your target hardware.

When you generate HDL code for your model, HDL Coder configures the multiply-add operation so that your synthesis tool can map to a DSP unit.

Data Type Support

The Multiply-Add block accepts and outputs signals of any numeric data type that Simulink supports, including fixed-point data types.

For more information, see “Data Types Supported by Simulink”.

Parameters

Function

Specify the function to perform a combined multiply and add or a multiply and subtract operation.

Default: `c+ (a.*b)`

You can set the function to:

- `c+ (a.*b)`
- `c- (a.*b)`
- `(a.*b) -c`

Output data type

Specify the output data type.

Default: `Inherit: Inherit via internal rule`

Set the output data type to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button  to display the Data Type Assistant dialog box, which helps you to set the **Output data type** parameter.

For more information, see “Control Signal Data Types” in *Simulink User's Guide* .

Integer rounding mode

Specify the rounding mode for fixed-point operations.

Default: Floor

Ceiling

Rounds positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

Floor

Rounds positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

Simplest

Chooses between rounding toward floor and rounding toward zero to generate rounding code that is as efficient as possible.

Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

For more information, see “Rounding” (Fixed-Point Designer).

Saturate on integer overflow

Specify whether overflows saturate.

Default: Off

On

Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Off

Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Parameter: SaturateOnIntegerOverflow

Type: character vector

Value: 'off' | 'on'

Default: 'off'

See Also

Introduced in R2015b

Multiport Switch

Choose between multiple block inputs

Library

Signal Routing

Description

Note A variant of the Multiport Switch block is the Index Vector block. For information on the Index Vector block, see “Multiport Switch Configured as an Index Vector Block” on page 1-982.

The Multiport Switch block determines which of several inputs to the block passes to the output. The block bases this decision on the value of the first input. The first input is the control input and the remaining inputs are the data inputs. The value of the control input determines which data input passes to the output.

The table summarizes how the block interprets the control input and determines the data input that is passed to the output.

Control Input	Truncation	Setting for Data Port Order	Block Behavior During Simulation	
			Indexing to select data input	Out-of-range condition
Integer value	None	Zero-based contiguous	Zero-based indexing	The control input is less than 0 or greater than the number of data inputs minus one.
		One-based contiguous	One-based indexing	The control input is less than 1 or greater than the number of data inputs.
		Specify indices	Indices you specify	The control input does not correspond to any specified data port index.
Not an integer value	The block truncates the value to an integer by rounding to zero.	Zero-based contiguous	Zero-based indexing	The truncated control input is less than 0 or greater than the number of data inputs minus one.
		One-based contiguous	One-based indexing	The truncated control input is less than 1 or greater than the number of data inputs.
		Specify indices	Indices you specify	The truncated control input does not correspond to any specified data port index.

For information on how the block handles the out-of-range condition, see “How the Block Handles an Out-of-Range Control Input” on page 1-983.

Multiport Switch Configured as an Index Vector Block

An Index Vector is a special configuration of a Multiport Switch block in which you specify one data input and the control input is zero-based. The block output is the element of the input vector whose index matches the control input. For example, if the input vector is [18 15 17 10] and the control input is 3, the element that matches the index of 3 (zero-based) is 10, and that becomes the output value.

This model shows how the Index Vector works with zero-based and one-based indexing.

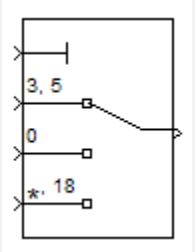

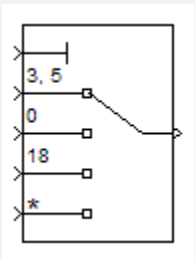

Index Vector is a block in the Simulink **Signal Routing** library. Alternatively, configure a Multiport Switch block to work as an Index Vector block by setting **Number of data ports** to 1 and **Data port order** to Zero-based contiguous.

How the Block Handles an Out-of-Range Control Input

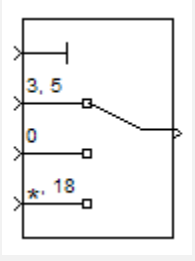

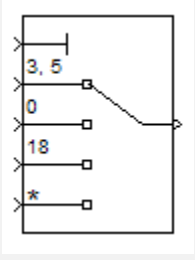

For an input with an integer value less than `intmax('int32')`, the input is out of range when the value does not match any data port indices. For a control input that is not an integer value, the input is out of range when the *truncated* value does not match any data port indices. In both cases, the block behavior depends on your settings for **Data port for default case** and **Diagnostic for default case**.

Note If the control input is larger than `intmax('int32')`, the block wraps the input value to an integer.

The following behavior applies only to simulation for your model.

Data port for default case	Diagnostic for default case		
	None	Warning	Error
<p>Last data port</p> 	<p>Use the last data port and do not report any warning or error.</p>	<p>Use the last data port and report a warning.</p>	<p>Report an error and stop simulation.</p>
<p>Additional data port</p> 	<p>Use the additional data port with a * label and do not report any warning or error.</p>	<p>Use the additional data port with a * label and report a warning.</p>	<p>Report an error and stop simulation.</p>

The following behavior applies to code generation for your model.

Data port for default case	Diagnostic for default case		
	None	Warning	Error
Last data port 	Use the last data port.	Use the last data port.	Use the last data port.
Additional data port 	Use the additional data port with a * label.	Use the additional data port with a * label.	Use the additional data port with a * label.

Use Data Inputs That Have Different Dimensions

If two signals have a different number of dimensions or different dimension lengths, you can use the signals as data inputs to a Multiport Switch block. In the block dialog box, select the parameter **Allow different data input sizes**. In this case, the output of the block is a variable-size signal. If you do not select this parameter, the block generates an error.

For more information about the parameter, see “Allow different data input sizes” on page 1-995. For more information about variable-size signals, see “Variable-Size Signal Basics”.

Rules That Determine the Block Behavior

You specify the number of data inputs with **Number of data ports**.

- If you set **Number of data ports** to 1, the block behaves as an *index selector* or *index vector* and not as a multiport switch. For more details, see “Multiport Switch Configured as an Index Vector Block” on page 1-982.
- If you set **Number of data ports** to an integer greater than 1, the block behaves as a multiport switch. The block output is the data input that corresponds to the value of the control input. If at least one of the data inputs is a vector, the block output is a vector. In this case, the block expands any scalar inputs to vectors.
- If all the data inputs are scalar, the output is a scalar.

Guidelines on Setting Parameters for Enumerated Control Port

When the control port on the Multiport Switch block is of enumerated type, follow these guidelines:

Scenario	What to Do	Rationale
The enumerated type contains a value that represents invalid, out-of-range, or uninitialized values.	<ul style="list-style-type: none"> • Set Data port order to <code>Specify indices</code>. • Set Data port indices to use this value for the last data port. • Set Data port for default case to <code>Last data port</code>. 	This block configuration handles invalid values that the enumerated type explicitly represents.
The enumerated type contains only valid enumerated values. However, a data input port can get invalid values of enumerated type.	<ul style="list-style-type: none"> • Set Data port for default case to <code>Additional data port</code>. 	This block configuration handles invalid values that the enumerated type does not explicitly represent.

Scenario	What to Do	Rationale
The enumerated type contains only valid enumerated values. Data input ports can never get invalid values of enumerated type.	<ul style="list-style-type: none"> Set Data port for default case to <code>Last data port</code>. Set Diagnostic for default case to <code>None</code>. 	This block configuration avoids unnecessary diagnostic action.
The block does not have a data input port for every value of the enumerated type.	<ul style="list-style-type: none"> Set Data port for default case to <code>Additional data port</code>. 	This block configuration handles enumerated values that do not have a data input port, along with invalid values.

Data Type Support

The control signal can be of any data type that Simulink supports, including fixed-point and enumerated types. If the control signal is numeric, it cannot be complex. If the control signal is an enumerated signal, the block uses the value of the underlying integer to select a data port. If the underlying integer does not correspond to a data port, an error occurs.

The data signals can be of any data type that Simulink supports. If any data signal is of an enumerated type, all others must be of the same enumerated type.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

- “Data port order” on page 1-988
- “Number of data ports” on page 1-989
- “Data port indices” on page 1-990
- “Data port for default case” on page 1-991
- “Diagnostic for default case” on page 1-991

- “Sample time” on page 1-992
- “Require all data port inputs to have the same data type” on page 1-992
- “Lock output data type setting against changes by the fixed-point tools” on page 1-992
- “Integer rounding mode” on page 1-993
- “Saturate on integer overflow” on page 1-994
- “Allow different data input sizes” on page 1-995
- “Output minimum” on page 1-996
- “Output maximum” on page 1-996
- “Output data type” on page 1-997
- “Mode” on page 1-998
- “Data type override” on page 1-999
- “Signedness” on page 1-1000
- “Word length” on page 1-1000
- “Scaling” on page 1-1001
- “Fraction length” on page 1-1002
- “Slope” on page 1-1002
- “Bias” on page 1-1002

Data port order

Specify the type of ordering for your data input ports.

Default: One-based contiguous (for Multiport Switch block), Zero-based contiguous (for Index Vector block)

Zero-based contiguous

Block uses zero-based indexing for ordering contiguous data ports.

One-based contiguous

Block uses one-based indexing for ordering contiguous data ports.

Specify indices

Block uses noncontiguous indexing for ordering data ports.

- When the control port is of enumerated type, select `Specify indices`.
- If you select `Zero-based contiguous` or `One-based contiguous`, verify that the control port is not of enumerated type. This configuration is deprecated and produces an error. You can run the Upgrade Advisor on your model to replace each Multiport Switch block of this configuration with a block that explicitly specifies data port indices. See “Model Upgrades”.
- Avoid situations where the block contains unused data ports for simulation or code generation. When the control port is of fixed-point or built-in data type, verify that all data port indices are representable with that type. Otherwise, the following block behavior occurs:

If the block has unused data ports and data port order is...	You get...
<code>Zero-based contiguous</code> or <code>One-based contiguous</code>	A warning
<code>Specify indices</code>	An error

Selecting `Zero-based contiguous` or `One-based contiguous` enables the **Number of data ports** parameter.

Selecting `Specify indices` enables the **Data port indices** parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Number of data ports

Specify the number of data input ports to the block.

Default: 3 (for Multiport Switch block), 1 (for Index Vector block)

The block icon changes to match the number of data input ports you specify.

Selecting `Zero-based contiguous` or `One-based contiguous` for **Data port order** enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Data port indices

Specify an array of indices for your data ports.

Default: {1, 2, 3}

The block icon changes to match the data port indices you specify.

- To specify an array of indices that correspond to all values of an enumerated type, enter `enumeration('type_name')` for this parameter. Do not include braces.

For example, `enumeration('MyColors')` is a valid entry.

- To enter specific values of an enumerated type, use the `type_name.enumerated_name` format. Do not enter the underlying integer value.

For example, `{MyColors.Red, MyColors.Green, MyColors.Blue}` is a valid entry.

- To indicate that more than one value maps to a data port, use brackets.

For example, the following entries are both valid:

- `{MyColors.Red, MyColors.Green, [MyColors.Blue, MyColors.Yellow]}`
- `{[3,5],0,18}`
- If the control port is of fixed-point or built-in data type, the values for **Data port indices** must be representable with that type. Otherwise, an error appears at compile time to alert you to unused data ports.
- If the control port is of enumerated data type, the values for **Data port indices** must be enumerated values of that type.
- If **Data port indices** contains values of enumerated type, the control port must be of that data type.

Selecting `Specify indices for Data port order` enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Data port for default case

Specify whether to use the last data port for out-of-range inputs, or to use an additional port.

Default: Last data port

Last data port

Block uses the last data port for output when the control port value does not match any data port indices.

Additional data port

Block uses an additional data port for output when the control port value does not match any data port indices.

If you set this parameter to Additional data port and **Number of data ports** is 3, the number of input ports on the block is 5. The first input is the control port, the next three inputs are data ports, and the fifth input is the default port for out-of-range inputs.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Diagnostic for default case

Specify the diagnostic action to take when the control port value does not match any data port indices.

Default: Error

None

Simulink software takes no action.

Warning

Simulink software displays a warning and continues the simulation.

Error

Simulink software terminates the simulation and displays an error. In this case, the **Data port for default case** is used only for code generation and not simulation.

For more information, see “How the Block Handles an Out-of-Range Control Input” on page 1-983.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1 . To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Require all data port inputs to have the same data type

Specify allowed data types.

Default: Off

On

Requires all data port inputs to have the same data type.

Off

Allows data port inputs to have different data types.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

Default: Off

On

Locks the output data type setting for this block.

 Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change the output data type setting for this block.

Parameter: LockScale

Type: character vector

Value: 'off' | 'on'

Default: 'off'

For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Integer rounding mode

Specify the rounding mode for fixed-point operations.

Default: Floor

Ceiling

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

Floor

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

Simplest

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

Parameter: `RndMeth`

Type: character vector

Value: `'Ceiling'` | `'Convergent'` | `'Floor'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Default: `'Floor'`

For more information, see “Rounding” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

Saturate on integer overflow

Specify whether overflows saturate.

Default: Off

On

Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Off

Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Parameter: SaturateOnIntegerOverflow

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Allow different data input sizes

Select this check box to allow input signals with different sizes.

Default: Off

On

Allows input signals with different sizes, and propagate the input signal size to the output signal.

Off

Requires that input signals be the same size.

Parameter: AllowDiffInputSizes

Type: character vector

Value: 'on' | 'off'

Default: 'off'

Output minimum

Specify the minimum value that the block outputs.

Default: []

The default value is [] (unspecified).

Simulink uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

This number must be a finite real double scalar value.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Output maximum

Specify the maximum value the block outputs.

Default: []

The default value is [] (unspecified).

Simulink uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

This number must be a finite real double scalar value.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Output data type

Specify the output data type.

Default: `Inherit: Inherit via internal rule`

`Inherit: Inherit via internal rule`

Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
- To specify your own inheritance rule, use `Inherit: Inherit via back propagation` and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.

`Inherit: Inherit via back propagation`

Uses the data type of the driving block.

`double`

Specifies output data type `double`.

`single`

Specifies output data type `single`.

`int8`

Specifies output data type `int8`.

`uint8`

Specifies output data type `uint8`.

`int16`

Specifies output data type `int16`.

`uint16`

Specifies output data type `uint16`.

`int32`

Specifies output data type `int32`.

`uint32`

Specifies output data type `uint32`.

`fixdt(1,16,0)`

Specifies output data type fixed point `fixdt(1,16,0)`.

`fixdt(1,16,2^0,0)`

Specifies output data type fixed point `fixdt(1,16,2^0,0)`.

`<data type expression>`

Uses a data type object, for example, `Simulink.NumericType`.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Mode

Select the category of data to specify.

Default: `Inherit`

`Inherit`

Specifies inheritance rules for data types. Selecting `Inherit` enables a list of possible values:

- `Inherit` via internal rule (default)
- `Inherit` via back propagation

`Built in`

Specifies built-in data types. Selecting `Built in` enables a list of possible values:

- `double` (default)
- `single`
- `int8`
- `uint8`
- `int16`
- `uint16`
- `int32`
- `uint32`

Fixed point

Specifies fixed-point data types.

Expression

Specifies expressions that evaluate to data types. Selecting `Expression` enables you to enter an expression.

Clicking the **Show data type assistant** button enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specify Data Types Using Data Type Assistant”.

Data type override

Specify data type override mode for this signal.

Default: `Inherit`

`Inherit`

Inherits the data type override setting from its context, that is, from the block, `Simulink.Signal` object or Stateflow chart in Simulink that is using the signal.

`Off`

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

This parameter appears only when the **Mode** is `Built in` or `Fixed point`.

Signedness

Specify fixed-point data as signed or unsigned.

Default: `Signed`

`Signed`

Specifies the fixed-point data as signed.

`Unsigned`

Specifies the fixed-point data as unsigned.

Selecting **Mode** > `Fixed point` enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specifying a Fixed-Point Data Type”.

Word length

Specify the bit size of the word that holds the quantized integer.

Default: `16`

Minimum: `0`

Maximum: `32`

Large word sizes represent large values with greater precision than small word sizes.

Selecting **Mode** > Fixed point enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specifying a Fixed-Point Data Type”.

Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

Default: Best precision

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

Best precision

Specify best-precision values.

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting Slope and bias enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

For more information, see “Specifying a Fixed-Point Data Type”.

Fraction length

Specify fraction length for fixed-point data type.

Default: 0

Binary points can be positive or negative integers.

Selecting **Scaling** > `Binary point` enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specifying a Fixed-Point Data Type”.

Slope

Specify slope for the fixed-point data type.

Default: 2^0

Specify any positive real number.

Selecting **Scaling** > `Slope and bias` enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specifying a Fixed-Point Data Type”.

Bias

Specify bias for the fixed-point data type.

Default: 0

Specify any real number.

Selecting **Scaling** > `Slope` and `bias` enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specifying a Fixed-Point Data Type”.

Bus Support

The Multiport Switch block is a bus-capable block. The data inputs can be virtual or nonvirtual bus signals subject to the following restrictions:

- All the buses must be equivalent (same hierarchy with identical names and attributes for all elements).
- All signals in a nonvirtual bus input to a Multiport Switch block must have the same sample time. This requirement holds even when the elements of the associated bus object specify inherited sample times.

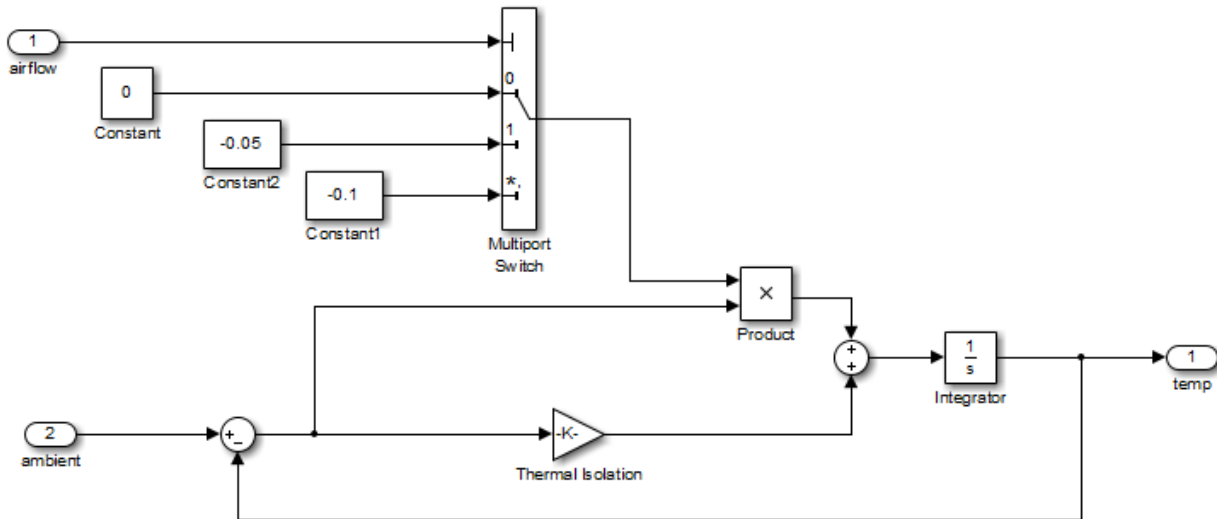

You can use a Rate Transition block to change the sample time of an individual signal, or of all signals in a bus. See “Specify Bus Signal Sample Times” and “Bus-Capable Blocks” for more information.

You can use an array of buses as an input signal to a Multiport Switch block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”. When you use an array of buses with a Multiport Switch block, set **Number of data ports** to a value of 2 or greater.

Examples

Zero-Based Indexing for Data Ports

The `sf_aircontrol` model uses a Multiport Switch block in the `Physical Plant` subsystem. This block uses zero-based indexing for contiguous ordering of three data ports.

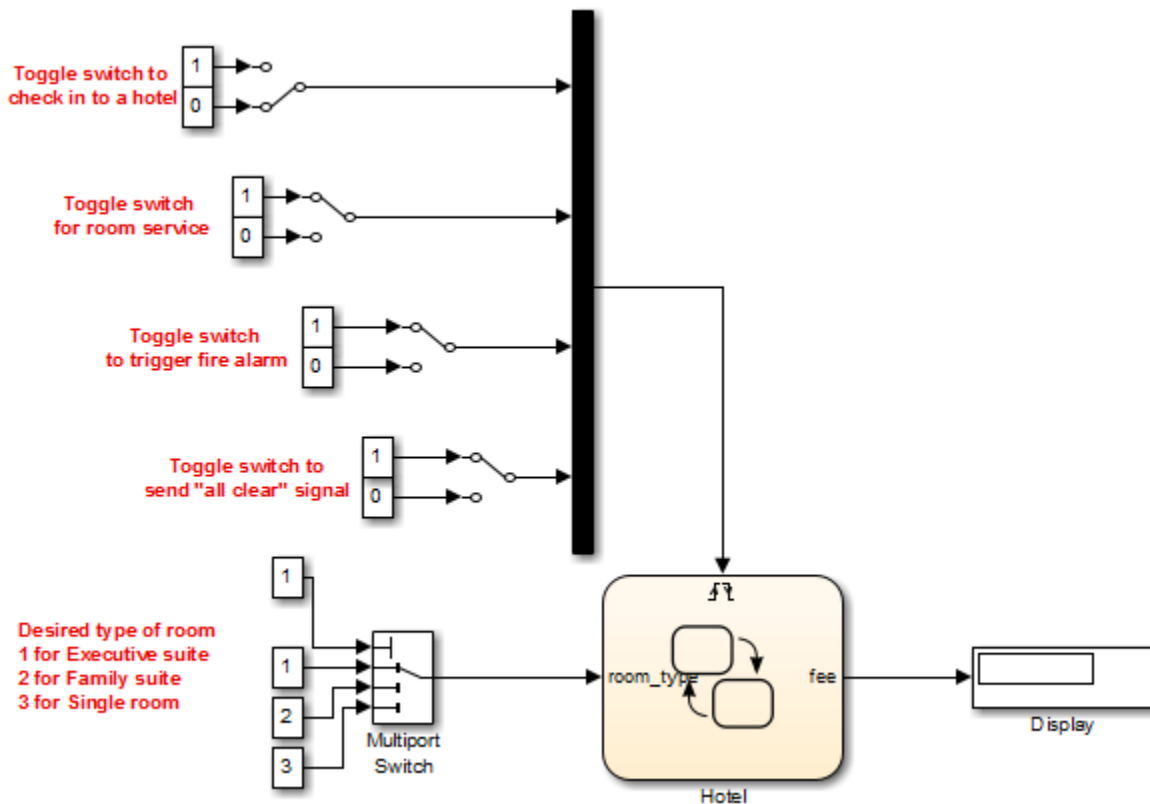

The indices are visible on the data port labels. You do not have to open the block dialog box to determine whether the data ports use zero-based or one-based indexing.

When you set **Data port for default case** to `Last data port`, the last data port includes a * on the label. The comma after the * indicates that the data port index has a value. This port corresponds to the default case, which applies when the control input does not match the data port indices 0, 1, or 2. In this case, the Multiport Switch block outputs a value of `-0.1`.

One-Based Indexing for Data Ports

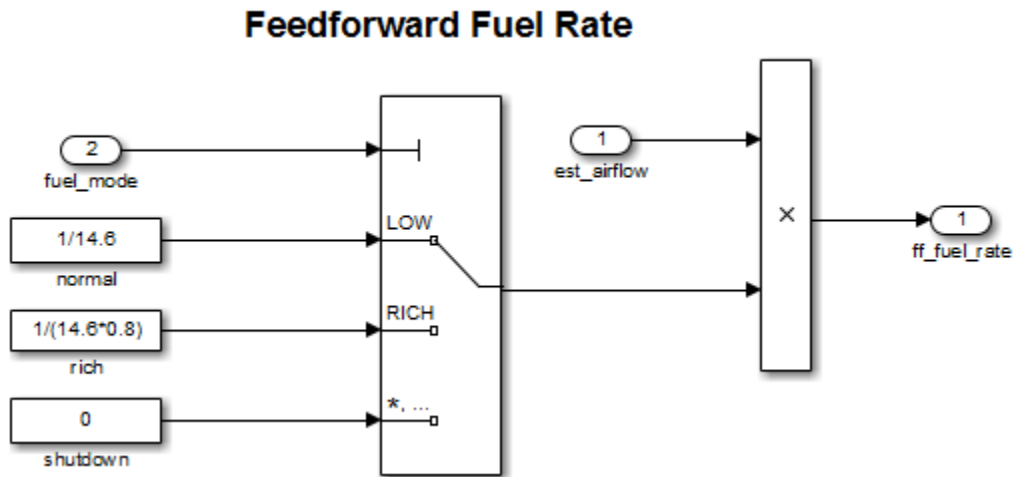

The `sf_semantics_hotel_checkin` model uses a Multiport Switch block. This block uses one-based indexing for contiguous ordering of three data ports.

If you increase the size of the block icon, the indices are visible on the data port labels. You do not have to open the block dialog box to determine whether the data ports use zero-based or one-based indexing.

Enumerated Names for Data Port Indices

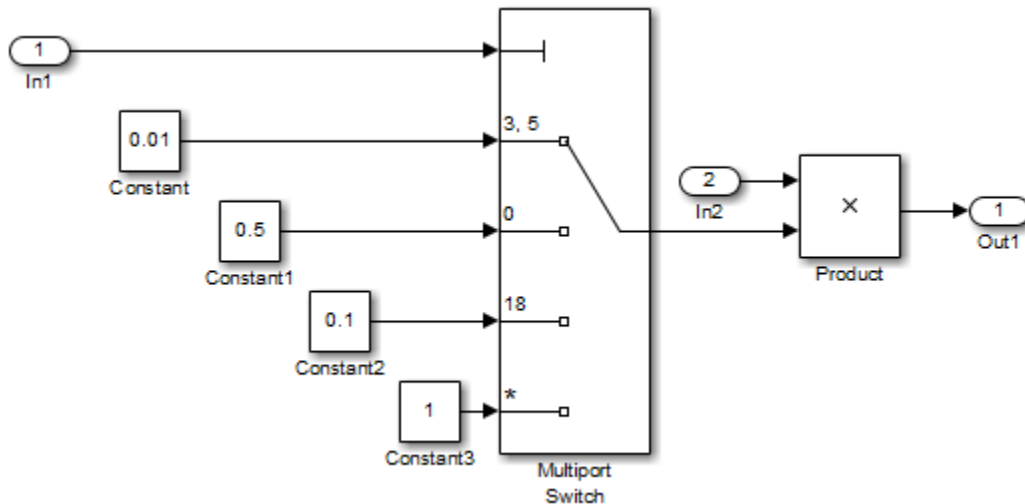

The `sldemo_fuelsys` model uses a Multiport Switch block in the `fuel_rate_control/fuel_calc/feedforward_fuel_rate` subsystem. This block uses the enumerated type `sld_FuelModes` to specify three data port indices: `LOW`, `RICH`, and `DISABLED`.

When you set **Data port for default case** to Last data port, the last data port includes a * on the label. The comma and ellipsis after the * indicate that the data port index has a value. This port corresponds to the default case, which applies when the control input does not match the data port indices LOW, RICH, or DISABLED. In this case, the Multiport Switch block outputs a value of 0.

Noncontiguous Values for Data Port Indices

The following model uses a Multiport Switch block that specifies noncontiguous integer values for data ports.

The values of the indices are visible on the data port labels. You do not have to open the block dialog box to determine which value maps to each data port.

When you set **Data port for default case** to Additional data port, an extra port with a * label appears. This port corresponds to the default case, which applies when the control input does not match the data port indices 3, 5, 0, or 18. In this case, the Multiport Switch block outputs a value of 1.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated Bus
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

MultiStateImage

Display image reflecting input value

Library: Simulink / Dashboard

Description

The MultiStateImage block displays an image to indicate the value of the input signal. You can use the MultiStateImage block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model. You can specify pairs of input values and images to provide the information you want during simulation.

Connection

Dashboard blocks do not use ports to connect to signals. To connect a signal to a Dashboard block, use the **Connection** table in the block's parameters.

- 1 Double-click the block.
- 2 Populate the **Connection** table by selecting signals of interest in your model.
- 3 Mark the option button next to the signal you want to display.
- 4 Click **Apply**.

Limitations

- You cannot save the block connections or properties in model files that use the MDL format.

To save connections and properties, save the model file in the SLX format.

- Dashboard blocks can only connect to real scalar signals.
- Dashboard blocks cannot connect to blocks that are commented out.
- Dashboard blocks cannot connect to signals inside reference models.

- If you turn off logging for a signal connected to a Dashboard block, the model stops sending data from that signal to the block. To view the signal again, reconnect the signal.
- External mode simulation does not support visualization Dashboard blocks.

Parameters

Connection — Select a signal to connect and display

signal connection options

Signal connection options. Populate the **Connection** table by selecting signals of interest in your model. Mark the check box next to the signal you want to display. Click **Apply** to connect the signal.

Scale Mode — Specify how to scale image

'Fill with fixed Aspect Ratio' (default) | Fixed | Fill

Specify how to scale the image.

Fill with fixed Aspect Ratio scales the image to the size of the block while retaining its original aspect ratio.

Fixed displays the image with its fixed true size.

Fill adjusts the image to fill the block.

States

State — Input signal value

1 (default) | scalar

Input signal value that causes the block to display an image. Click the + button to add another state.

Thumbnail — Image to display

image file

Image the block displays when the input signal has the value specified in **State**. The MultiStateImage block can display png, jpg, tif, and bmp image files.

Label — **Block label position**

'Top' (default) | 'Bottom' | 'Hide'

Position of the block label. When the block is connected to a signal, the label is the name of the connected signal. When the block is not connected, the label is the instructional text.

Mux

Combine input signals of same data type and numeric type into virtual vector

Library: Simulink / Commonly Used Blocks
Simulink / Signal Routing

Description

The Mux block combines its inputs into a single vector output. An input can be a scalar or vector signal. All inputs must be of the same data type and numeric type. For information about creating and decomposing vectors, see “Mux Signals”.

The elements of the vector output signal take their order from the top to bottom, or left to right, input port signals. See “Port Location After Rotating or Flipping” for a description of the port order for various block orientations.

The nonvirtual components of a virtual signal are called *regions*. A virtual signal can contain the same region more than once. For example, if the same nonvirtual signal is connected to two input ports of a Mux block, the block outputs a virtual signal that has two regions. The regions behave as they would if they had originated in two different nonvirtual signals, even though the resulting behavior duplicates information.

Note Simulink provides several techniques for combining signals into a composite signal. For more information, see “Composite Signal Techniques”.

Ports

Input

Port_1 — Accept nonbus vector signal to extract and output signals from real or complex values of any nonbus data type supported by Simulink

Port that accepts the input nonbus vector signal from which to extract and output signals.

Output

Port_1 — Output signals extracted from input vector signal

nonbus signal with real or complex values of any data type supported by Simulink

Output signals extracted from the input vector. The output signal ports are ordered from top to bottom. See “Port Location After Rotating or Flipping” for a description of the port order for various block orientations.

Parameters

Number of inputs — Inputs

2 (default) | scalar | vector | cell array | comma-separated list of signal names

Specify the number of input signals. You can also specify signal names and sizes. Use one of these formats.

Format	Block Behavior
Scalar	<p>Specifies the number of inputs to the Mux block.</p> <p>When you use this format, the block accepts scalar or vector signals of any size. Simulink assigns each input the name <code>signalN</code>, where N is the input port number.</p>
Vector	<p>The length of the vector specifies the number of inputs. Each element specifies the size of the corresponding input.</p> <p>A positive value specifies that the corresponding port can accept only vectors of that size. For example, <code>[2 3]</code> specifies two input ports of sizes 2 and 3, respectively. If an input signal width does not match the expected width, an error message appears. A value of <code>-1</code> specifies that the corresponding port can accept scalars or vectors of any size.</p>

Format	Block Behavior
Cell array	<p>The length of the cell array specifies the number of inputs. The value of each cell specifies the size of the corresponding input.</p> <p>A scalar value <i>N</i> specifies a vector of size <i>N</i>. A value of <i>-1</i> means that the corresponding port can accept scalar or vector signals of any size.</p>
Signal name list	<p>You can enter a list of signal names separated by commas. Simulink assigns each name to the corresponding port and signal. For example, if you enter <code>position, velocity</code>, the Mux block has two inputs, named <code>position</code> and <code>velocity</code>.</p>

Tip If you specify a scalar for the **Number of inputs** parameter and all of the input ports are connected, as you draw a new signal line close to input side of a Mux block, Simulink adds a port and updates the parameter.

Programmatic Use

Block Parameter:Inputs

Type:scalar, vector, cell array, signal name list

Values:number, vector of port numbers, cell array, or list of signal names

Default:{ '2' }

Display option — Displayed block icon

`bar` (default) | `nonesignal`

By default, the block icon is a solid bar of the block foreground color. To display the icon as a hollow bar containing input signal names, select `signals`. To display the icon as a box containing the block type name, select `none`.

Programmatic Use

Block Parameter:DisplayOption

Type:character vector

Values:'bar' 'signals' 'none' 'bar'

Default:'bar'

Introduced before R2006a

Out Bus Element

Output signals from a subsystem as a virtual bus

Library: Simulink / Ports & Subsystems
Simulink / Sinks

Description

Note This block has two different names, depending on the library in which it appears. The functionality of both blocks is the same.

- In the Sinks library and the Ports & Subsystems library— Out Bus Element
 - In the Signal Routing library — Bus Element Out
-

To output signals in a virtual bus from a subsystem, use an Out Bus Element block for each signal in the subsystem that you want the bus to contain. This block integrates into one block the functionality of using an Outport block and a Bus Creator block. The Out Bus Element block is of the Outport block type. There are no specifications allowed on an Out Bus Element block, which supports only an inherited workflow. You cannot use the Block Parameters dialog box of an Out Bus Element block to specify bus element attributes, such as data type or dimensions.

To work with buses at subsystem interfaces, consider using In Bus Element and Out Bus Element blocks. This bus element port block combination:

- Reduces signal line complexity and clutter in a block diagram.
- Makes it easy to change the interface incrementally.
- Allows access to a bus element closer to the point of usage.
 - For output, avoid a Goto, From, and Bus Creator block configuration.
 - For input, avoid a duplicate Outport blocks and a Bus Selector, Goto, and From block configuration.

To output multiple signals from a subsystem as a bus signal, create multiple Out Bus Element blocks, one for each signal.

If an Out Bus Element block creates a signal A, then another Out Bus Element block for the same port cannot specify signal A (or a child of signal A) as an element

To add a subbus, in the Block Parameters dialog box, click . To remove blocks associated with selected elements, click .

You can reorder bus elements by dragging and dropping a signal in the list of signals in the Block Parameters dialog box.

You can specify the background color for bus element port blocks, using the Block Parameters dialog box **Set color** option. This action sets the color of blocks associated with selected elements, or to all blocks if you do not select elements.

Ports

The block does not have an output port. Use the Block Parameters dialog box to specify the subsystem output port to which the block sends its input signal.

Input

Port_1 — Input port for bus signal or bus element from within subsystem
signal

The selected input signal is included in a bus signal that the subsystem outputs. The signal can have a real or complex values of any data type that Simulink supports.

Parameters

Port name — Name of subsystem output port
OutBus (default) | text

Specify a name for a subsystem port. That name appears on the Subsystem and Out Bus Element block icons. If you specify a port name, that name cannot already be in use by another block or port. All Out Bus Element blocks that access the same subsystem output port reflect the port name that you specify.

Programmatic Use**Block Parameter:** PortName**Type:** text**Default:** OutBus**Port number — Order in which port appears for subsystem output ports**

1 (default) | integer

Specify the order in which the port appears on the subsystem, with 1 being the top port, 2 the second port down, and so on.

- If you specify a number that exceeds the number of subsystem output ports, new ports are added above the port associated with the Outport Bus Element block.
- If you add an Out Bus Element block that creates another subsystem output port, the port number is the next available number.
- If you delete all Out Bus Element blocks associated with a port, other port numbers are renumbered so that the blocks are in sequence and that no numbers are omitted.

Programmatic Use**Block Parameter:** Port**Value:** integer**Default:** 1

Introduced in R2017a

Output

Create output port for subsystem or external output

Library

Ports & Subsystems, Sinks

Description

Output blocks are the links from a system to a destination outside the system.

Simulink software assigns Output block port numbers according to these rules:

- It automatically numbers the Output blocks within a root-level system or subsystem sequentially, starting with 1.
- If you add an Output block, it is assigned the next available number.
- If you delete an Output block, other port numbers are automatically renumbered to ensure that the Output blocks are in sequence and that no numbers are omitted.

Output Blocks in a Subsystem

Output blocks in a subsystem represent outputs from the subsystem. A signal arriving at an Output block in a subsystem flows out of the associated output port on that Subsystem block. The Output block associated with an output port on a Subsystem block is the block whose **Port number** parameter matches the relative position of the output port on the Subsystem block. For example, the Output block whose **Port number** parameter is 1 sends its signal to the block connected to the topmost output port on the Subsystem block.

If you renumber the **Port number** of an Outport block, the block becomes connected to a different output port, although the block continues to send the signal to the same block outside the subsystem.

When you create a subsystem by selecting existing blocks, if more than one Outport block is included in the grouped blocks, Simulink software automatically renumbers the ports on the blocks.

The Outport block name appears in the Subsystem icon as a port label. To suppress display of the label, click the Outport block and select **Format > Hide Name**.

Tip For models that include bus signals composed of many bus elements that feed subsystems, consider using the In Bus Element and Out Bus Element blocks. You can use these bus element port blocks instead of Inport with Bus Selector blocks for inputs, and Outport with Bus Creator blocks for outputs. These bus element port blocks:

- Reduce signal line complexity and clutter in a block diagram.
- Make it easier to change the interface incrementally.
- Allow access to a bus element closer to the point of usage, avoiding the use of a Bus Selector and Goto block configuration.

The Out Bus Element block is of block type Outport. However, there are no specifications allowed on bus element port blocks, which support inherited workflows. You cannot use the Block Parameters dialog box of an Out Bus Element block to specify bus element attributes, such as data type or dimensions.

Initializing Outport Blocks in Conditionally Executed Contexts

To set initial conditions for an Outport block in a conditionally executed subsystem, use one of these approaches.

- Inherit initial values from input signals for the subsystem.
- Explicitly specify initial values

For details, see “Conditional Subsystem Initial Output Values”.

Note If the conditional subsystem is driving a Merge block in the same model, you do not need to specify an Initial Condition (IC) for the subsystem’s Outport block. For more information, see “Underspecified initialization detection”.

Top-level Output Block in a Model Hierarchy

Output blocks at the top-level of a model hierarchy have two uses: to supply external outputs to the base MATLAB workspace, which you can do by using either **Configuration Parameters** pane parameters or the `sim` command, and to provide a means for analysis functions to obtain output from the system.

- To supply external outputs to the workspace, use the **Configuration Parameters** > **Data Import/Export** pane (see Exporting Output Data to the MATLAB Workspace) or the `sim` command. For example, if a system has more than one Output block and the save format is array, the following command

```
[t,x,y] = sim(...);
```

writes `y` as a matrix, with each column containing data for a different Output block. The column order matches the order of the port numbers for the Output blocks.

If you specify more than one variable name after the second (state) argument, data from each Output block is written to a different variable. For example, if the system has two Output blocks, to save data from Output block 1 to `speed` and the data from Output block 2 to `dist`, you could specify this command:

```
[t,x,speed,dist] = sim(...);
```

- To provide a means for the `linmod` and `trim` analysis functions to obtain output from the system (see “Linearizing Models”).

Connecting Buses to Root-level Outputs

A root-level Output of a model can accept a virtual bus only if all elements of the bus have the same data type. The Output block automatically unifies the bus to a vector having the same number of elements as the bus, and outputs that vector.

If you want a root-level Output of a model to accept a bus signal that contains mixed types, you must set the Output block **Data type** parameter to use a bus object name for the Bus: `<object name>` or `<data type expression>` option, to define the type of bus that the Output produces. If the bus signal is virtual, it will be converted to nonvirtual, as described in “Bus Conversion”. For more information, see “When to Use Bus Objects”.

Associate Root-Level Output Block with `Simulink.Signal` Object

To associate a root-level Output block with a `Simulink.Signal` object, use the Model Data Editor. See “For Signals”.

Data Type Support

The Output block accepts real or complex signals of any data type that Simulink supports. An Output block can also accept fixed-point and enumerated data types when the block is not a root-level output port. The complexity and data type of the block output are the same as those of its input. The Output block also accepts a bus object as a data type.

Note If you specify a bus object as the data type for this block, do not set the minimum and maximum values for bus data on the block. Simulink ignores these settings. Instead, set the minimum and maximum values for bus elements of the bus object specified as the data type. The values should be finite real double scalar.

For information on the Minimum and Maximum properties of a bus element, see `Simulink.BusElement`.

For more information, see “Data Types Supported by Simulink”.

The elements of a signal array connected to an Output block can be of differing complexity and data types except in the following circumstance: If the output port is in a conditionally executed subsystem and the initial output is specified, all elements of an input array must be of the same complexity and data types.

Typical Simulink data type conversion rules apply to an output port's **Initial output** parameter. If the initial output value is in the range of the block's output data type, Simulink software converts the initial output to the output data type. If the specified initial output is out of the range of the output data type, Simulink software halts the simulation and signals an error.

Parameters

- “Port number” on page 1-1026
- “Specify output when source is unconnected” on page 1-1026
- “Signal name” on page 1-1026
- “Icon display” on page 1-1027

Port number

Specify the port number of the block.

Default: 1

This parameter controls the order in which the port that corresponds to the block appears on the parent subsystem or model block.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Specify output when source is unconnected

Specify a constant output value to be displayed when source is not connected.

Default: `Off`

When this option is selected on a non-driven Output block of a Variant Subsystem block, you can specify a constant value as an output of that block.

Specify a constant value as an output for the block.

Select this check box to output a vector of length N if the **Constant value** parameter evaluates to an N-element row or column vector.

Signal name

Specify the name of the corresponding signal data in the generated code. Use this parameter to specify a name for the signal data when you apply a storage class to a root-level Outport block by using **View > Model Data**.

Default: `''` (empty character vector)

Specify a name by using text.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Icon display

Specify the information to be displayed on the icon of this input port.

Default: Port number

Signal name

Display the name of the signal connected to this port (or signals if the input is a bus).

Port number

Display port number of this port.

Port number and signal name

Display both the port number and the names of the signals connected to this port.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Ensure output is virtual

This parameter applies to these blocks:

- Conditional subsystem
- Assignment
- Merge
- Model with root Output block

For examples with conditional writes and partial writes, see “Ensure output is virtual”.

Default: Clear

Clear

Use signal buffer on output port. This buffer ensures consistent initialization of the Output block signal.

Select

Simulink tries to remove the signal buffer.

- If the signal buffer is not needed, Simulink remove the buffer.
- If the signal buffer is needed for data consistency and proper execution, Simulink displays an error indicating the buffer could not be removed.

Allow partial writes through Assignment blocks.

Source of initial output value

Select the source of the initial output value of the block.

Default: Dialog

Dialog

The initial output value is specified by the **Initial output** parameter on the dialog.

Input signal

The initial output value is inherited from the input signal. See “Conditional Subsystem Initial Output Values”.

- If you are using classic initialization mode, selecting `Input signal` will cause an error. To inherit the initial output value from the input signal, set this parameter to `Dialog` and specify `[]` (empty matrix) for the **Initial output** value. For more information, see “Conditional Subsystem Initial Output Values”.

This parameter is enabled when the Outport resides in an Conditional Subsystem.

Selecting `Dialog` enables the following parameters:

- **Output when disabled**
- **Initial output**

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Output when disabled

Specify what happens to the block output when the subsystem is disabled.

Default: held

held

Output is held when the subsystem is disabled.

reset

Output is reset to the value given by **Initial output** when the subsystem is disabled.

- When connecting the output of a conditional subsystem to a Merge block, set this parameter to held. Setting it to reset will return an error.
- Selecting `Dialog` in **Source of initial output value** enables this parameter.
- This parameter is enabled when the Output resides in a conditional subsystem with valid enabling and disabling semantics. For example, this parameter is disabled when the Output is placed inside a Triggered Subsystem but is enabled when the Output is placed inside an Enabled Subsystem.
- If an Output is placed inside a function-call subsystem, this parameter is meaningful only if the function-call subsystem is bound to a state in a Stateflow chart. For more information, see “Bind a Function-Call Subsystem to a State” (Stateflow).

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Initial output

For conditionally executed subsystems, specify the block output before the subsystem executes and while it is disabled.

Default: []

Simulink does not allow the initial output of this block to be `inf` or `NaN`. When the input is a virtual bus, an **Initial output** value [] is treated as `double(0)`.

- Specify [] (empty matrix) to inherit the initial output value from the input signal. For more information, see “Conditional Subsystem Initial Output Values”.
- For information about specifying an initial condition structure, see “Specify Initial Conditions for Bus Signals”

- Selecting `Dialog` in **Source of initial output value** enables this parameter.
- This parameter is enabled when the Outport resides in an Conditional Subsystem.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Minimum

Specify the minimum value that the block should output.

Default: [] (unspecified)

This number must be a finite real double scalar value.

Note If you specify a bus object as the data type for this block, do not set the minimum value for bus data on the block. Simulink ignores this setting. Instead, set the minimum values for bus elements of the bus object specified as the data type. For information on the `Minimum` property of a bus element, see `Simulink.BusElement`.

Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Maximum

Specify the maximum value that the block should output.

Default: [] (unspecified)

This number must be a finite real double scalar value.

Note If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For information on the Maximum property of a bus element, see `Simulink.BusElement`.

Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Data type

Specify the output data type of the external input.

Default: `Inherit: auto`

`Inherit: auto`

A rule that inherits a data type

`double`

Data type is double.

single

Data type is single.

int8

Data type is int8.

uint8

Data type is uint8.

int16

Data type is int16.

uint16

Data type is uint16.

int32

Data type is int32.

uint32

Data type is uint32.

boolean

Data type is boolean.

fixdt(1,16,0)

Data type is fixed point fixdt(1,16,0).

fixdt(1,16,2^0,0)

Data type is fixed point fixdt(1,16,2^0,0).

Enum: <class name>

Data type is enumerated, for example, Enum: BasicColors.

Bus: <object name>

Data type is a bus object.

<data type expression>

The name of a data type object, for example Simulink.NumericType

Do not specify a bus object as the expression.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Show data type assistant

Display the **Data Type Assistant**.

The **Data Type Assistant** helps you set the **Output data type** parameter.

For more information, see “Control Signal Data Types”.

Mode

Select the category of data to specify.

Default: `Inherit`

`Inherit`

Inheritance rule for data types. Selecting `Inherit` enables a second menu/text box to the right.

`Built in`

Built-in data types. Selecting `Built in` enables a second menu/text box to the right. Select one of the following choices:

- `double (default)`
- `single`
- `int8`
- `uint8`
- `int16`
- `uint16`
- `int32`
- `uint32`
- `boolean`

`Fixed point`

Fixed-point data types.

Enumerated

Enumerated data types. Selecting `Enumerated` enables a second menu/text box to the right, where you can enter the class name.

Bus object

Bus object. Selecting `Bus` enables a **Bus object** parameter to the right, where you enter the name of a bus object that you want to use to define the structure of the bus. If you need to create or change a bus object, click **Edit** to the right of the **Bus object** field to open the Simulink Bus Editor. For details, see “Create Bus Objects with the Bus Editor”.

Expression

Expressions that evaluate to data types. Selecting `Expression` enables a second menu/text box to the right, where you can enter the expression.

Do not specify a bus object as the expression.

Clicking the **Show data type assistant** button enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specify Data Types Using Data Type Assistant”.

Data type override

Specify data type override mode for this signal.

Default: `Inherit`

`Inherit`

Inherits the data type override setting from its context, that is, from the block, `Simulink.Signal` object or Stateflow chart in Simulink that is using the signal.

`Off`

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

This parameter appears only when the **Mode** is `Built in` or `Fixed point`.

Signedness

Specify whether you want the fixed-point data as signed or unsigned.

Default: `Signed`

`Signed`

Specify the fixed-point data as signed.

`Unsigned`

Specify the fixed-point data as unsigned.

Selecting **Mode** > `Fixed point` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Word length

Specify the bit size of the word that holds the quantized integer.

Default: `16`

Minimum: `0`

Maximum: `32`

Selecting **Mode** > `Fixed point` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

Default: Best precision

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

Best precision

Specify best-precision values.

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting Slope and bias enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

For more information, see “Specifying a Fixed-Point Data Type”.

Fraction length

Specify fraction length for fixed-point data type.

Default: 0

Binary points can be positive or negative integers.

Selecting **Scaling** > `Binary point` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Slope

Specify slope for the fixed-point data type.

Default: 2^0

Specify any positive real number.

Selecting **Scaling** > `Slope and bias` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Bias

Specify bias for the fixed-point data type.

Default: 0

Specify any real number.

Selecting **Scaling** > `Slope and bias` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

Default: Off

On

Locks the output data type setting for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change the output data type setting for this block.

Parameter: LockScale

Type: character vector

Value: 'off' | 'on'

Default: 'off'

For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Output as nonvirtual bus in parent model

Select this parameter if you want the bus emerging in the parent model to be nonvirtual. The bus that is input to the port can be virtual or nonvirtual, regardless of the setting of **Output as nonvirtual bus in parent model**.

Default: Off

On

Select this parameter if you want the bus emerging in the parent model to be nonvirtual.

Off

Clear this parameter if you want the bus emerging in the parent model to be virtual.

- In a nonvirtual bus, all signals must have the same sample time, even if the elements of the associated bus object specify inherited sample times. Any bus operation that would result in a nonvirtual bus that violates this requirement generates an error. For details, see “Connect Multirate Buses to Referenced Models”.
- For a virtual bus, to use a multirate signal, in the root-level Output block, set the **Sample time** parameter to inherited (-1).
- For the top model in a model reference hierarchy, code generation creates a C structure to represent the bus signal output by this block.
- For referenced models, select this option to create a C structure. Otherwise, code generation creates an argument for each leaf element of the bus.

Selecting **Data type** > Bus: <object name> enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Unit (e.g., m, m/s², N*m)

Specify physical unit of the input signal to the block.

Default: `inherit`

To specify a unit, begin typing in the text box. As you type, the parameter displays potential matching units. For a list of supported units, see Allowed Unit Systems.

To constrain the unit system, click the link to the right of the parameter:

- If a Unit System Configuration block exists in the component, its dialog box opens. Use that dialog box to specify allowed and disallowed unit systems for the component.
- If a Unit System Configuration block does not exist in the component, the model Configuration Parameters dialog box displays. Use that dialog box to specify allowed and disallowed unit systems for the model.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Port dimensions (-1 for inherited)

Specify the dimensions that a signal must have in order to be connected to this Output block.

Default: -1

Valid values are:

-1	A signal of any dimensions can be connected to this port.
N	The signal connected to this port must be a vector of size N.
[R C]	The signal connected to this port must be a matrix having R rows and C columns.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Variable-size signal

Specify the type of signals allowed out of this port.

Default: `Inherit`

`Inherit`

Allow variable-size and fixed-size signals.

`No`

Do not allow variable-size signals.

`Yes`

Allow only variable-size signals.

When the signal at this port is a variable-size signal, the **Port dimensions** parameter specifies the maximum dimensions of the signal.

Parameter: `VarSizeSig`

Type: character vector

Value: `'Inherit' | 'No' | 'Yes'`

Default: 'Inherit'

Sample time (-1 for inherited)

Enter the discrete interval between sample time hits or specify another appropriate sample time such as continuous or inherited.

Default: -1

By default, the block inherits its sample time based upon the context of the block within the model. To set a different sample time, enter a valid sample time based upon the table in “Types of Sample Time”.

See also “Specify Sample Time” in the online documentation for more information.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Signal type

Specify the numeric type of the signal output by this block.

Default: auto

auto

Output the numeric type of the signal that is connected to its input.

real

Output a real-valued signal. The signal connected to this block must be real. If it is not, Simulink software displays an error if you try to update the diagram or simulate the model that contains this block.

complex

Output a complex signal. The signal connected to this block must be complex. If it is not, Simulink software displays an error if you try to update the diagram or simulate the model that contains this block.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated Bus
Sample Time	Inherited from the driving block
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

See Also

Introduced before R2006a

Permute Dimensions

Rearrange dimensions of multidimensional array dimensions

Library

Math Operations

Description

The block reorders the elements of the input signal so that they are in the order you specify in the **Order** parameter.

Data Type Support

This block accepts signals of any data type that Simulink supports, including fixed-point, enumerated, and nonvirtual bus data types. Output must be the same data type as the input.

You can use an array of buses as an input signal to a Permute Dimensions block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Order

Specify the permutation order to apply to the dimensions of the input signal. This parameter is a vector of elements, where the number of elements in the vector is the number of dimensions of the input signal.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated Bus
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Math Function ([transpose](#)), [permute](#) (in the MATLAB reference documentation)

Introduced in R2007a

PID ControllerDiscrete PID Controller

Simulate continuous- or discrete-time PID controllers

Library

Continuous, Discrete

Description

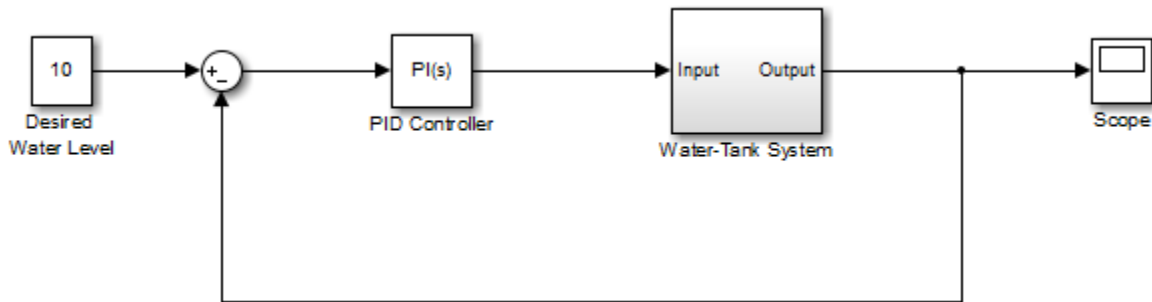

Implement a continuous- or discrete-time controller (PID, PI, PD, P, or I) in your Simulink model. PID controller gains are tunable either manually or automatically. Automatic tuning requires Simulink Control Design™ software.

The PID Controller block output is a weighted sum of the input signal, the integral of the input signal, and the derivative of the input signal. The weights are the proportional, integral, and derivative gain parameters. A first-order pole filters the derivative action.

Configurable options in the PID Controller block include:

- Controller type (PID, PI, PD, P, or I)
- Controller form (Parallel or Ideal)
- Time domain (continuous or discrete)
- Initial conditions and reset trigger
- Output saturation limits and built-in anti-windup mechanism
- Signal tracking for bumpless control transfer and multiloop control

In one common implementation, the PID Controller block operates in the feedforward path of the feedback loop:

The input of the block is typically an error signal, which is the difference between a reference signal and the system output. For a two-input block that permits setpoint weighting, see the PID Controller (2 DOF) block reference page.

You can generate code to implement your controller using any Simulink data type, including fixed-point data types. (Code generation requires Simulink Coder software; fixed-point implementation requires the Fixed-Point Designer product.)

For examples illustrating some applications of the PID Controller block, see the following Simulink examples:

- Anti-Windup Control Using a PID Controller
- Bumpless Control Transfer Between Manual and PID Control

Data Type Support

The PID Controller block accepts real signals of any numeric data type that Simulink software supports, including fixed-point data types. See “Data Types Supported by Simulink” in the Simulink documentation for more information.

Parameters

The following table summarizes the PID Controller block parameters, accessible on the block parameter dialog box.

Task	Parameters
Choose controller form and type.	<ul style="list-style-type: none"> • Controller Form on page 1-1049 in Main tab • Controller on page 1-1052
Choose discrete or continuous time.	<ul style="list-style-type: none"> • Time-domain on page 1-1053 • Sample time on page 1-1055
Choose an integration method (discrete time).	<ul style="list-style-type: none"> • Integrator method on page 1-1053 • Filter method on page 1-1054
Set and tune controller gains.	<ul style="list-style-type: none"> • Controller Parameters Source on page 1-1056 in Main tab • Proportional (P) on page 1-1057 in Main tab • Integral (I) on page 1-1057 in Main tab • Derivative (D) on page 1-1058 in Main tab • Filter coefficient (N) on page 1-1058 in Main tab • Use filtered derivative on page 1-1059 in Main tab
Set integrator and filter initial conditions.	<ul style="list-style-type: none"> • Initial conditions Source on page 1-1060 in Main tab • Integrator Initial condition on page 1-1061 in Main tab • Filter Initial condition on page 1-1061 in Main tab • Initial condition setting on page 1-1062 (command line only) • External reset on page 1-1062 in Main tab • Ignore reset when linearizing on page 1-1063 in Main tab

Task	Parameters
Limit block output.	<ul style="list-style-type: none"> • Limit output on page 1-1064 in PID Advanced tab • Lower saturation limit on page 1-1065 in PID Advanced tab • Upper saturation limit on page 1-1065 in PID Advanced tab • Ignore saturation when linearizing on page 1-1067 in PID Advanced tab
Configure anti-windup mechanism (when you limit block output).	<ul style="list-style-type: none"> • Anti-windup method on page 1-1065 in PID Advanced tab • Back-calculation gain (Kb) on page 1-1067 in PID Advanced tab
Enable signal tracking.	<ul style="list-style-type: none"> • Enable tracking mode on page 1-1068 in PID Advanced tab • Tracking gain (Kt) on page 1-1071 in PID Advanced tab

Task	Parameters
Configure data types.	<ul style="list-style-type: none"> • Parameter data type on page 1-1071 in Data Type Attributes tab • Product output data type on page 1-1073 in Data Type Attributes tab • Summation output data type on page 1-1074 in Data Type Attributes tab • Accumulator data type on page 1-1076 in Data Type Attributes tab • Integrator output data type on page 1-1077 in Data Type Attributes tab • Filter output data type on page 1-1078 in Data Type Attributes tab • Saturation output data type on page 1-1080 in Data Type Attributes tab • Lock output data type setting against changes by the fixed-point tools on page 1-1090 in Data Type Attributes tab • Saturate on integer overflow on page 1-1091 in Data Type Attributes tab • Integer rounding mode on page 1-1092 in Data Type Attributes tab
Configure block for code generation.	<ul style="list-style-type: none"> • State name on page 1-1093 in State Attributes tab • State name must resolve to Simulink signal object on page 1-1093 in State Attributes tab • Code generation storage class on page 1-1094 in State Attributes tab • Code generation storage type qualifier on page 1-1095 in State Attributes tab

Controller form

Select the controller form.

Parallel (Default)

Selects a controller form in which the output is the sum of the proportional, integral, and derivative actions, weighted according to the independent gain parameters **P**, **I**, and **D**. The filter coefficient **N** sets the location of the pole in the derivative filter. For a continuous-time parallel PID controller, the transfer function is:

$$C_{par}(s) = \left[P + I \left(\frac{1}{s} \right) + D \left(\frac{Ns}{s+N} \right) \right]$$

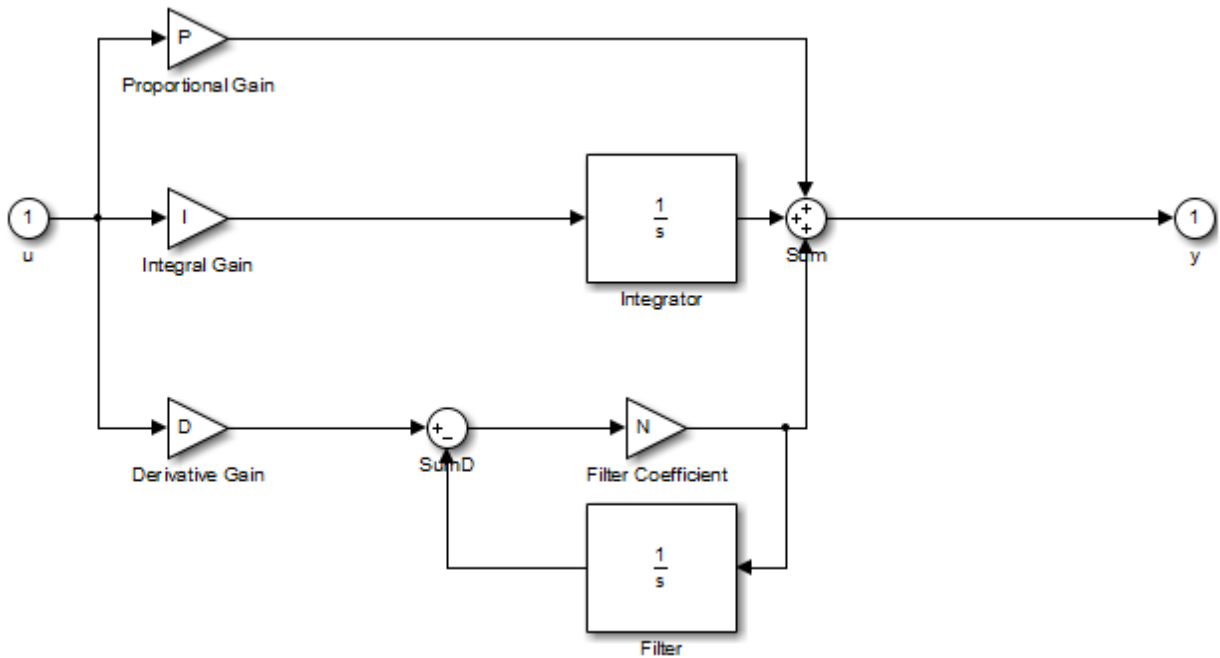

For a discrete-time parallel PID controller, the transfer function takes the form:

$$C_{par}(z) = P + Ia(z) + D \left[\frac{N}{1 + Nb(z)} \right]$$

where the **Integrator method** determines a(z) and the **Filter method** determines b(z) (for sampling time T_s):

	Forward Euler method	Backward Euler method	Trapezoidal method
a(z) (determined by Integrator method)	$\frac{T_s}{z-1}$	$\frac{T_s z}{z-1}$	$\frac{T_s}{2} \frac{z+1}{z-1}$
b(z) (determined by Filter method)	$\frac{T_s}{z-1}$	$\frac{T_s z}{z-1}$	$\frac{T_s}{2} \frac{z+1}{z-1}$

The controller transfer function for the current settings is displayed in the block dialog box.

Parallel PID Controller

Ideal

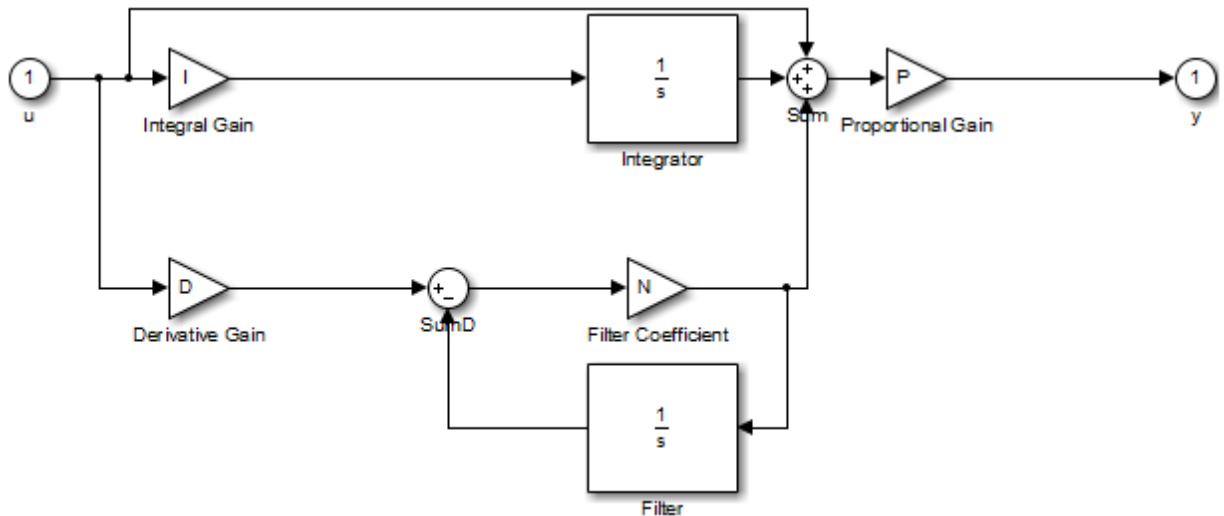

Selects a controller form in which the proportional gain P acts on the sum of all actions. The transfer functions are the same as for the parallel form, except that P multiplies all terms. For a continuous-time ideal PID controller, the transfer function is:

$$C_{id}(s) = P \left[1 + I \left(\frac{1}{s} \right) + D \left(\frac{Ns}{s+N} \right) \right]$$

For a discrete-time ideal PID controller the transfer function is:

$$C_{id}(z) = P \left[1 + Ia(z) + D \frac{N}{1 + Nb(z)} \right]$$

where the **Integrator method** determines $a(z)$ and the **Filter method** determines $b(z)$ as described previously for the parallel controller form.

Ideal PID Controller

Controller

Specify the controller type.

PID (Default)

Implements a controller with proportional, integral, and derivative action.

PI

Implements a controller with proportional and integral action.

PD

Implements a controller with proportional and derivative action.

P

Implements a controller with proportional action.

I

Implements a controller with integral action.

The controller transfer function for the current settings is displayed in the block dialog box.

Time-domain

Select continuous or discrete time domain. The appearance of the block changes to reflect your selection.

Continuous-time (Default)

Selects the continuous-time representation.

When the PID Controller block is in a model with synchronous state control (see the State Control block), you cannot select `Continuous-time`.

Discrete-time

Selects the discrete-time representation. Selecting `Discrete-time` also allows you to specify the:

- **Sample time**, which is the discrete interval between samples.
- Discrete integration methods for the integrator and the derivative filter using the **Integrator method** and **Filter method** menus.

Integrator method

(Available only when you set **Time-domain** to `Discrete-time`.) Specify the method used to compute the integrator output. For more information about discrete-time integration methods, see the Discrete-Time Integrator block reference page.

Forward Euler (Default)

Selects the Forward Rectangular (left-hand) approximation.

This method is best for small sampling times, where the Nyquist limit is large compared to the bandwidth of the controller. For larger sampling times, the Forward Euler method can result in instability, even when discretizing a system that is stable in continuous time.

Backward Euler

Selects the Backward Rectangular (right-hand) approximation.

An advantage of the Backward Euler method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result.

Trapezoidal

Selects the Bilinear approximation.

An advantage of the Trapezoidal method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result. Of all available integration methods, the Trapezoidal method yields the closest match between frequency-domain properties of the discretized system and the corresponding continuous-time system.

Note For integrator methods `BackwardEuler` or `Trapezoidal`, you cannot generate HDL code for the block if either:

- **Limit output** is selected and **Anti-windup method** is set to back-calculation or clamping.
 - **Enable tracking mode** is selected.
-

Filter method

(Available only when you set **Time-domain** to `Discrete-time`.) Specify the method used to compute the derivative filter output. For more information about discrete-time integration methods, see the [Discrete-Time Integrator block reference page](#).

Forward Euler (Default)

Selects the Forward Rectangular (left-hand) approximation.

This method is best for small sampling times, where the Nyquist limit is large compared to the bandwidth of the controller. For larger sampling times, the Forward Euler method can result in instability, even when discretizing a system that is stable in continuous time.

Backward Euler

Selects the Backward Rectangular (right-hand) approximation.

An advantage of the Backward Euler method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result. Any filter parameter value $N > 0$ yields a stable result with this method.

Trapezoidal

Selects the Bilinear approximation.

An advantage of the Trapezoidal method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result. Any filter parameter value $N > 0$ yields a stable result with this method. Of all available filter methods, the Trapezoidal method yields the closest match between frequency-domain properties of the discretized system and the corresponding continuous-time system.

Sample time (-1 for inherited)

(Available only when you set **Time-domain** to `Discrete-time`.) Specify the discrete interval between samples.

Default: 1

By default, the block uses a discrete sample time of 1. To specify a different sample time, enter another discrete value, such as 0.1.

If you specify a value of -1, the PID Controller block inherits the sample time from the upstream block. Do not enter a value of 0; to implement a continuous-time controller, select the **Time-domain** `Continuous-time`.

See “Specify Sample Time” in the online documentation for more information.

Controller Parameters Source

Select the source of the controller gains and filter coefficient. You can provide these parameters explicitly in the block dialog box, or enable external inputs for them on the block. Enabling external inputs for the parameters allows you to compute PID gains and filter coefficients externally to the block and provide them to the block as signal inputs.

External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control, in which controller gains are determined by logic or other calculation in the Simulink model and passed to the block.

`internal` (Default)

Specify the PID gains and filter coefficient explicitly using the **P**, **I**, **D**, and **N** parameters.

`external`

Specify the PID gains and filter coefficient externally. An additional input port appears under the block input for each parameter that is required for the current controller type:

When you supply gains externally, time variations in the integral and derivative gain values are integrated and differentiated, respectively. This result occurs because of the way the PID gains are implemented within the block. For example, for a continuous-time PID controller with external inputs, the integrator term is implemented as shown in the following illustration.

Within the block, the block's input signal is multiplied by the externally-supplied integrator gain, I , before integration. This implementation yields:

$$y_i = \int uI dt.$$

Thus, the integrator gain is included in the integral. Similarly, in the derivative term of the block, multiplication by the derivative gain precedes the differentiation, which causes the derivative gain D to be differentiated.

Proportional (P)

(Available for PID, PD, PI, and P controllers.) Specify the proportional gain P .

Default: 1

Enter a finite, real gain value into the **Proportional (P)** field. Use either scalar or vector gain values. For a **Parallel PID Controller form**, the proportional action is independent of the integral and derivative actions. For an **Ideal PID Controller form**, the proportional action acts on the integral and derivative actions. See “Controller form” on page 1-1049 for more information about the role of P in the controller transfer function.

When you have Simulink Control Design software installed, you can automatically tune the controller gains. See “Choose a Control Design Approach” (Simulink Control Design).

Integral (I)

(Available for PID, PI, and I controllers.) Specify the integral gain I .

Default: 1

Enter a finite, real gain value into the **Integral (I)** field. Use either scalar or vector gain values.

When you have Simulink Control Design software installed, you can automatically tune the controller gains. See “Choose a Control Design Approach” (Simulink Control Design).

Derivative (D)

(Available for PID and PD controllers.) Specify the derivative gain D .

Default: 0

Enter a finite, real gain value into the **Derivative (D)** field. Use either scalar or vector gain values.

When you have Simulink Control Design software installed, you can automatically tune the controller gains. See “Choose a Control Design Approach” (Simulink Control Design).

Filter coefficient (N)

(Available for PID and PD controllers, when **Use filtered derivative** is checked.) Specify the filter coefficient N , which determines the pole location of the filter in the derivative action:

The filter pole falls at $s = -N$ in the Continuous-time **Time-domain**. For Discrete-time, the location of the pole depends on which **Filter method** you select (for sampling time T_s):

- Forward Euler:

$$z_{pole} = 1 - NT_s$$

- Backward Euler:

$$z_{pole} = \frac{1}{1 + NT_s}$$

- Trapezoidal:

$$z_{pole} = \frac{1 - NT_s / 2}{1 + NT_s / 2}$$

Default: 100.

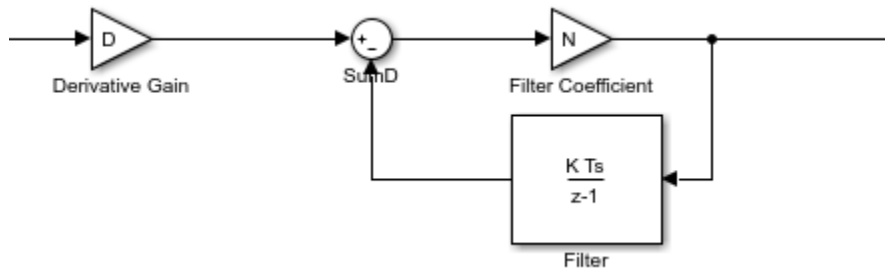

Enter a finite, real gain value into the **Filter Coefficient (N)** field. Use either scalar or vector gain values. Note that the PID controller block does not support $N = \text{inf}$ (ideal unfiltered derivative).

When you have Simulink Control Design software installed, you can automatically tune the controller gains using. See “Choose a Control Design Approach” (Simulink Control Design). Automatic tuning requires $N > 0$.

Use Filtered Derivative

Specify whether derivative term is filtered (finite N) or unfiltered. Unfiltered derivative is available only for discrete-time controllers.

Unchecking this option replaces the filtered derivative with a discrete differentiator. For example, if **Filter Method** is Forward Euler, then the filtered derivative term is represented by:

When you uncheck **Use filtered derivative**, the derivative term becomes:

- On (Default)
Use derivative filter (finite N).
- Off
Derivative is unfiltered.

Select Tuning Method

(Requires Simulink Control Design) Select a PID tuning tool. The specified tool opens when you click **Tune**.

Transfer Function Based (PID Tuner App) (Default)

Clicking **Tune** opens the PID Tuner, which lets you interactively tune PID gains while examining relevant system responses to validate performance. By default, PID Tuner works with a linearization of your plant model. For models that cannot be linearized, you can tune PID gains against a plant model estimated from simulated or measured response data. For more information, see “Introduction to Model-Based PID Tuning in Simulink” (Simulink Control Design).

Frequency Response Based

Clicking **Tune** opens the Frequency Response Based PID Tuner, which tunes PID controller gains based on a frequency-response estimation experiment. Frequency Response Based PID Tuner is especially useful for plants that are not linearizable. For more information, see “Design PID Controller from Plant Frequency-Response Data” (Simulink Control Design).

Initial conditions Source

(Only available for controllers with integral or derivative action.) Select the source of the integrator and filter initial conditions. Simulink uses initial conditions to initialize the

integrator and filter output at the start of a simulation or at a specified trigger event (See “External reset” on page 1-1062). The integrator and filter initial conditions in turn determine the initial block output.

internal (Default)

Specifies the integrator and filter initial conditions explicitly using the **Integrator Initial condition** and **Filter Initial condition** parameters.

external

Specifies the integrator and filter initial conditions externally. An additional input port appears under the block input for each initial condition: I_0 for the integrator and D_0 for the filter:

Integrator Initial condition

(Available only when **Initial conditions Source** is *internal* and the controller includes integral action.) Specify the integrator initial value. Simulink uses the initial condition to initialize the integrator output at the start of a simulation or at a specified trigger event (see “External reset” on page 1-1062). The integrator initial condition, together with the filter initial condition, determines the initial output of the PID controller block.

Default: 0

Simulink does not permit the integrator initial condition to be *inf* or *NaN*.

Filter Initial condition

(Available only when **Initial conditions Source** is *internal*, the controller includes derivative action, and **Use filtered derivative** is checked.) Specify the filter initial value. Simulink uses the initial condition to initialize the filter output at the start of a simulation or at a specified trigger event (see “External reset” on page 1-1062). The filter

initial condition, together with the integrator initial condition, determines the initial output of the PID controller block.

Default: 0

Simulink does not permit the filter initial condition to be `inf` or `NaN`.

Initial condition setting

Specify whether to apply the **Integrator Initial condition** and **Filter Initial condition** parameter to the corresponding block state or output. This parameter can be changed only at the command line using `set_param` to set the `InitialConditionSetting` parameter of the block.

State (most efficient) (Default)

Use this option in all situations except when the block is in a triggered subsystem or a function-call subsystem and simplified initialization mode is enabled.

Output

Use this option when the block is in a triggered subsystem or a function-call subsystem and simplified initialization mode is enabled.

For more information about the **Initial condition setting** parameters, see the Discrete-Time Integrator block.

External reset

Select the trigger event that resets the integrator and filter outputs to the initial conditions you specify in the **Integrator Initial condition** and **Filter Initial condition** fields. Selecting any option other than `none` enables a reset input on the block for the external reset signal, as shown:

Or, if the **Initial conditions Source** is `External`,

The reset signal must be a scalar of type single, double, boolean, or integer. Fixed point data types, except for `ufix1`, are not supported.

Note To be compliant with the Motor Industry Software Reliability Association (MISRA) software standard, your model must use Boolean signals to drive the external reset ports of the PID controller block.

`none` (Default)

Does not reset the integrator and filter outputs to initial conditions.

`rising`

Resets the outputs when the reset signal has a rising edge.

`falling`

Resets the outputs when the reset signal has a falling edge.

`either`

Resets the outputs when the reset signal either rises or falls.

`level`

Resets and holds the outputs to the initial conditions while the reset signal is nonzero.

Ignore reset when linearizing

Force Simulink linearization commands to ignore any reset mechanism that you have chosen with the **External reset** menu. Ignoring reset states allows you to linearize a model around an operating point even if that operating point causes the PID Controller block to reset.

Off (Default)

Simulink linearization commands do not ignore states corresponding to the reset mechanism.

On

Simulink linearization commands ignore states corresponding to the reset mechanism.

Enable zero-crossing detection

Enable zero-crossing detection in continuous-time models upon reset and upon entering or leaving a saturation state.

Zero-crossing detection can accurately locate signal discontinuities without resorting to excessively small time steps that can lead to lengthy simulation times. If you select **Limit output** or activate an **External reset** in your PID Controller block, activating zero-crossing detection can reduce computation time in your simulation. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

On (Default)

Uses zero-crossing detection at any of the following events: reset; entering or leaving an upper saturation state; and entering or leaving a lower saturation state.

Off

Does not use zero-crossing detection.

Enabling zero-crossing detection for the PID Controller block also enables zero-crossing detection for all under-mask blocks that include the zero-crossing detection feature.

Limit output

Limit the block output to values you specify as the **Lower saturation limit** and **Upper saturation limit** parameters.

Activating this option limits the block output internally to the block, obviating the need for a separate Saturation on page 1-1307 block after the controller in your Simulink

model. It also allows you to activate the block's built-in anti-windup mechanism (see “Anti-windup method” on page 1-1065).

Off (Default)

Does not limit the block output, which equals the weighted sum of the proportional, integral, and derivative actions.

On

Limits the block output to the **Lower saturation limit** or the **Upper saturation limit** whenever the weighted sum exceeds those limits. Allows you to select an **Anti-windup method**.

Lower saturation limit

(Available only when you select the **Limit output** check box.) Specify the lower limit for the block output. The block output is held at the **Lower saturation limit** whenever the weighted sum of the proportional, integral, and derivative actions goes below that value.

Default: `-inf`

Upper saturation limit

(Available only when you select the **Limit output** check box.) Specify the upper limit for the block output. The block output is held at the **Upper saturation limit** whenever the weighted sum of the proportional, integral, and derivative actions exceeds that value.

Default: `inf`

Anti-windup method

(Available only when you select the **Limit output** option and the controller includes integral action.) Select an anti-windup mechanism to discharge the integrator when the block is saturated, which occurs when the sum of the block components exceeds the output limits.

When you select the **Limit output** check box and the weighted sum of the controller components exceeds the specified output limits, the block output holds at the specified limit. However, the integrator output can continue to grow (integrator wind-up),

increasing the difference between the block output and the sum of the block components. Without a mechanism to prevent integrator wind-up, two results are possible:

- If the sign of the input signal never changes, the integrator continues to integrate until it overflows. The overflow value is the maximum or minimum value for the data type of the integrator output.
- If the sign of the input signal changes once the weighted sum has grown beyond the output limits, it can take a long time to discharge the integrator and return the weighted sum within the block saturation limit.

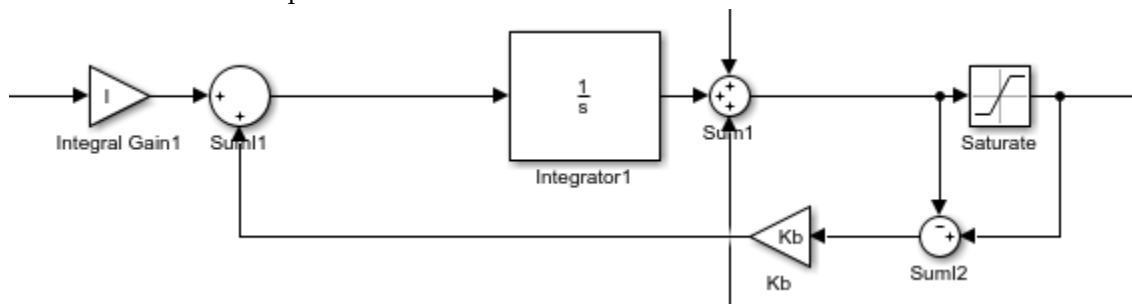

In both cases, controller performance can suffer. To combat the effects of wind-up without an anti-windup mechanism, it may be necessary to detune the controller (for example, by reducing the controller gains), resulting in a sluggish controller. Activating an anti-windup mechanism can improve controller performance.

none (Default)

Does not use an anti-windup mechanism. This setting may cause the block's internal signals to be unbounded even if the output appears to be bounded by the saturation limits. This can result in slow recovery from saturation or unexpected overflows.

back-calculation

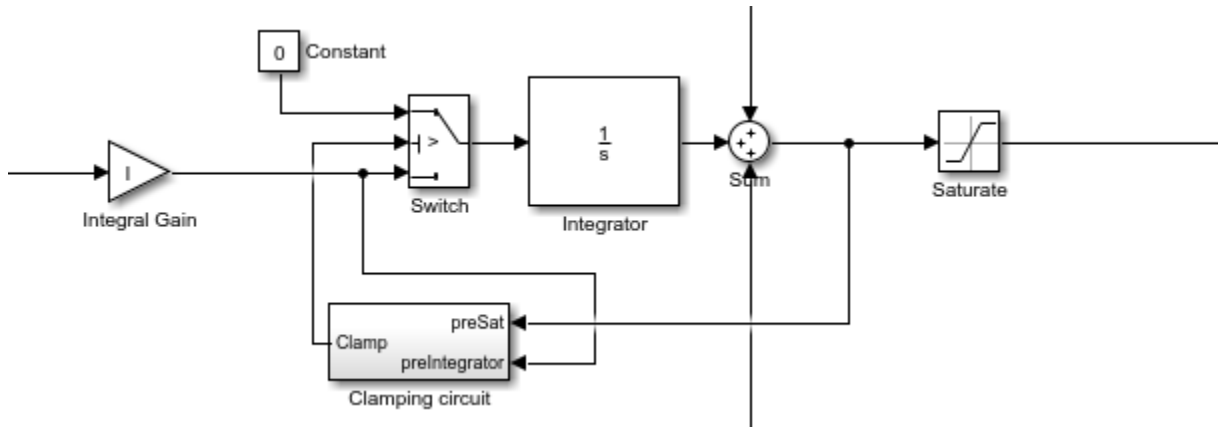

Discharges the integrator when the block output saturates using the integral-gain feedback loop:

You can also specify a value for the **Back-calculation coefficient (Kb)**.

clamping

Stops integration when the sum of the block components exceeds the output limits and the integrator output and block input have the same sign. Resumes integration when the sum of the block components exceeds the output limits and the integrator output and block input have opposite sign. The integrator portion of the block is:

The clamping circuit implements the logic necessary to determine whether integration continues.

Back-calculation gain (Kb)

(Available only when the back-calculation **Anti-windup method** is active.) Specify the gain coefficient of the anti-windup feedback loop.

The back-calculation anti-windup method discharges the integrator on block saturation using a feedback loop having gain coefficient Kb.

Default: 1

Ignore saturation when linearizing

Force Simulink linearization commands ignore PID Controller block output limits. Ignoring output limits allows you to linearize a model around an operating point even if that operating point causes the PID Controller block to exceed the output limits.

On (Default)

Simulink linearization commands ignore states corresponding to saturation.

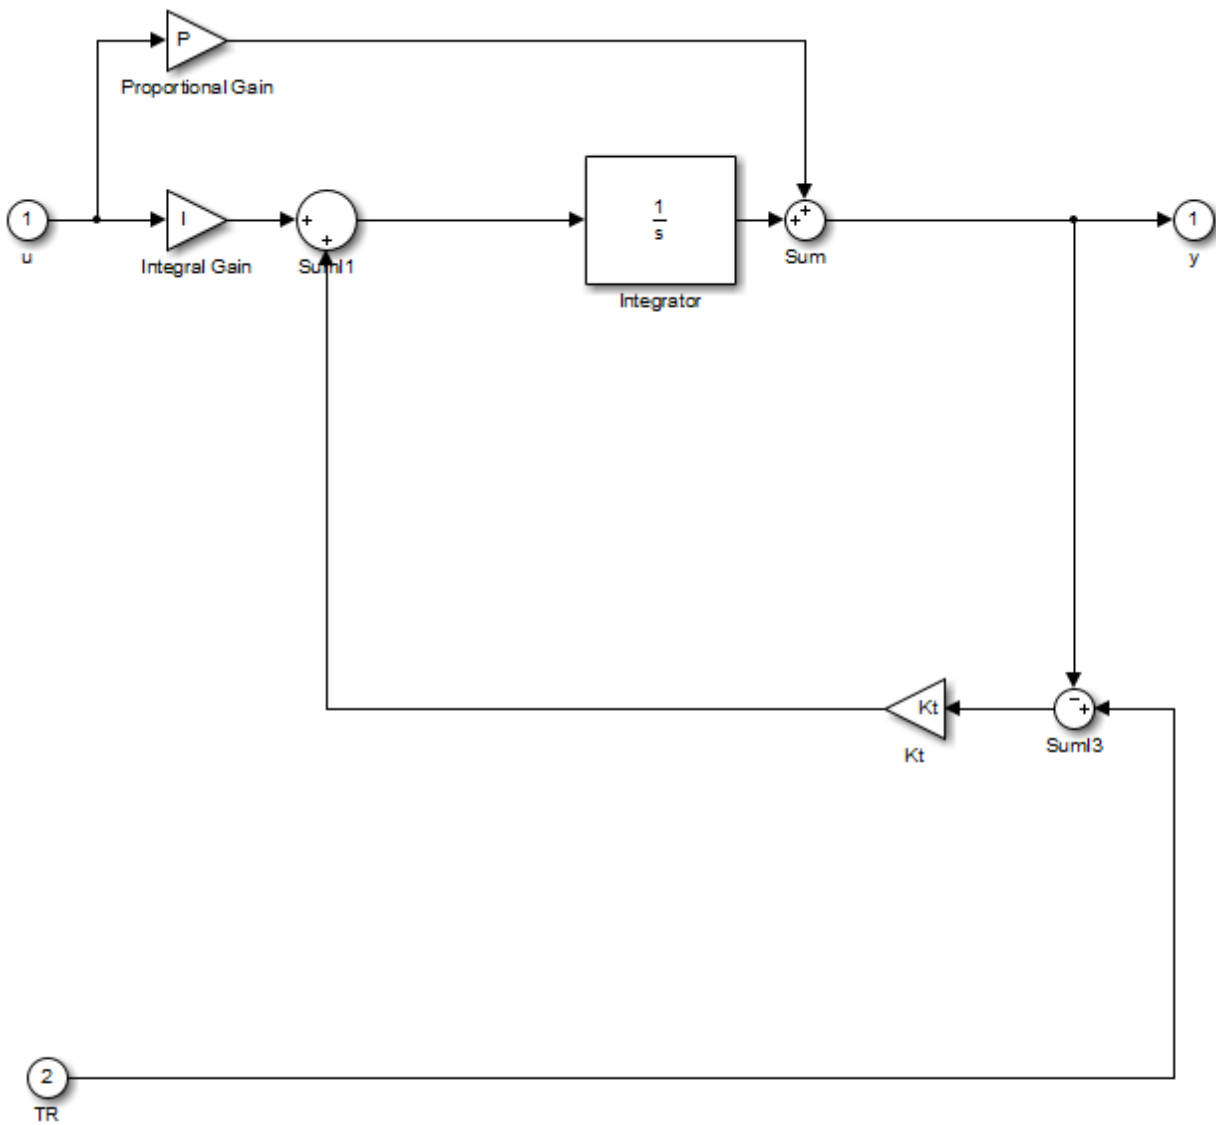

Off

Simulink linearization commands do not ignore states corresponding to saturation.

Enable tracking mode

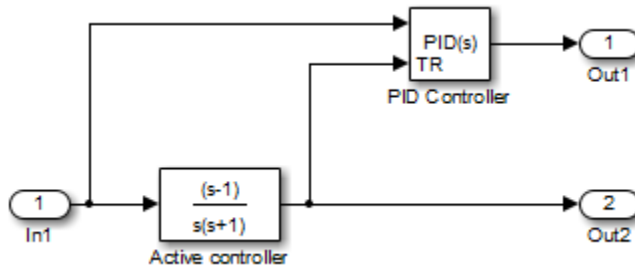

(Available for any controller with integral action.) Activate signal tracking, which lets the output of the PID Controller block follow a tracking signal. Provide the tracking signal to the block at the TR port, which becomes active when you select **Enable tracking mode**.

When signal tracking is active, the difference between the tracked signal and the block output is fed back to the integrator input with a gain K_t . The structure is illustrated for a PI controller:

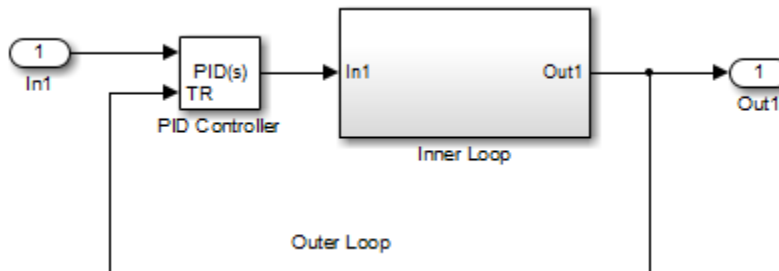

You can also specify the **Tracking coefficient (Kt)**.

Use signal tracking, for example, to achieve bumpless control transfer in systems that switch between two controllers. You can make one controller track the output of the other controller by connecting the TR port to the signal you want to track. For example:

In this example, the outputs Out1 and Out2 can drive a controlled system (not shown) through a switch that transfers control between the “Active controller” block and the PID Controller block. The signal tracking feature of the PID Controller block provides smooth operation upon transfer of control from one controller to another, ensuring that the two controllers have the same output at the time of transfer.

Use signal tracking to prevent block wind-up in multiloop control approaches, as this example illustrates:

The inner-loop subsystem contains the following blocks:

In this example, the inner loop has an effective gain of 1 when it does not saturate. Without signal tracking, the inner loop winds up in saturation. Signal tracking ensures that the PID Controller output does not exceed the saturated output of the inner loop.

Off (Default)

Disables signal tracking and removes TR block input.

On

Enables signal tracking and activates TR input.

Tracking gain (Kt)

(Available only when you select **Enable tracking mode**.) Specify K_t , which is the gain of the signal tracking feedback loop.

Default: 1

Parameter data type

Select the data type of the gain parameters **P**, **I**, **D**, **N**, **Kb**, and **Kt**.

See “Data Types Supported by Simulink” in the Simulink documentation for more information.

Inherit: Inherit via internal rule (Default)

Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the

internal rule might change. It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use the simple choice of `Inherit: Same as input`.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
- To specify your own inheritance rule, use `Inherit: Inherit via back propagation` and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.

`Inherit: Inherit via back propagation`

Use data type of the driving block.

`Inherit: Same as input`

Use data type of input signal.

`double`

`single`

`int8`

`uint8`

`int16`

`uint16`

`int32`

`uint32`

`fixdt(1,16)`

`fixdt(1,16,0)`

`fixdt(1,16,2^0,0)`

<data type expression>

Name of a data type object. For example, `Simulink.NumericType`.

Product output data type

Select the product output data type of the gain parameters **P**, **I**, **D**, **N**, **Kb**, or **Kt**, or the product output data type of the derivative filter numerator and denominator.

See “Data Types Supported by Simulink” in the Simulink documentation for more information.

Inherit: Inherit via internal rule (Default)

Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use the simple choice of Inherit: Same as input.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
- To specify your own inheritance rule, use Inherit: Inherit via back propagation and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.

Inherit: Inherit via back propagation

Use data type of the driving block.

Inherit: Same as input

Use data type of input signal.

double

```
single
int8
uint8
int16
uint16
int32
uint32
fixdt(1,16)
fixdt(1,16,0)
fixdt(1,16,2^0,0)
<data type expression>
```

Name of a data type object. For example, `Simulink.NumericType`.

Summation output data type

Select the summation output data type of the sums **Sum**, **Sum D**, **Sum I1** , **SumI2** , **SumI3**, and the summations in the trapezoidal discrete filter numerator and denominator, **SumNum** and **SumDen**. These sums are computed internally within the block, and might not all be present, depending upon the controller configuration. To see where Simulink computes each of these sums , right-click the PID Controller block in your model and select **Look Under Mask**:

- **Sum** is the weighted sum of the proportional, derivative, and integral signals.
- **SumD** is the sum in the derivative filter feedback loop.
- **SumI1** is the sum of the block input signal (weighted by the integral gain I) and **SumI2**. **SumI1** is computed only when **Limit output** and **Anti-windup method back-calculation** are active.
- **SumI2** is the difference between the weighted sum **Sum** and the limited block output. **SumI2** is computed only when **Limit output** and **Anti-windup method back-calculation** are active.

- **SumI3** is the difference between the block output and the signal at the block's tracking input. **SumI3** is computed only when you select the **Enable tracking mode** box.

See “Data Types Supported by Simulink” in the Simulink documentation for more information.

Inherit: Inherit via internal rule (Default)

Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use the simple choice of Inherit: Same as first input.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.

Note The accumulator internal rule favors greater numerical accuracy, possibly at the cost of less efficient generated code. To get the same accuracy for the output, set the output data type to Inherit: Same as accumulator.

Inherit: Inherit via back propagation

Use data type of the driving block.

Inherit: Same as first input

Use data type of first input signal.

Inherit: Same as accumulator

Use the same data type as the corresponding accumulator on page 1-1076.

double

single

int8

uint8

int16

uint16

int32

uint32

fixdt(1,16)

fixdt(1,16,0)

fixdt(1,16,2^0,0)

<data type expression>

Name of a data type object. For example, `Simulink.NumericType`.

Accumulator data type

Specify the accumulator data type.

Default: Inherit: Inherit via internal rule

Inherit: Inherit via internal rule

Use internal rule to determine accumulator data type.

Inherit: Same as first input

Use data type of first input signal.

double

Accumulator data type is double.

single

Accumulator data type is single.

int8

Accumulator data type is int8.

uint8

Accumulator data type is uint8.

`int16`

Accumulator data type is `int16`.

`uint16`

Accumulator data type is `uint16`.

`int32`

Accumulator data type is `int32`.

`uint32`

Accumulator data type is `uint32`.

`fixdt(1,16,0)`

Accumulator data type is fixed point `fixdt(1,16,0)`.

`fixdt(1,16,2^0,0)`

Accumulator data type is fixed point `fixdt(1,16,2^0,0)`.

<data type expression>

The name of a data type object, for example `Simulink.NumericType`

See “Block-Specific Parameters” on page 6-128 for the command-line information.

For more information, see “Specify Data Types Using Data Type Assistant”.

Integrator output data type

Select the data type of the integrator output.

See “Data Types Supported by Simulink” in the Simulink documentation for more information.

Inherit: Inherit via internal rule (Default)

Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet

your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use `Inherit: Inherit via back propagation`.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.

`fixdt(1,16,2^0,0)`

`<data type expression>`

Name of a data type object. For example, `Simulink.NumericType`.

Saturation output data type

Select the saturation output data type.

See “Data Types Supported by Simulink” in the Simulink documentation for more information.

Inherit: Same as input (Default)

Use data type of input signal.

Inherit: Inherit via back propagation

Use data type of the driving block.

double

single

int8

uint8

int16

uint16

int32

uint32

fixdt(1,16)

fixdt(1,16,0)

fixdt(1,16,2^0,0)

<data type expression>

Name of a data type object. For example, `Simulink.NumericType`.

Mode

Select the category of data to specify.

Default: `Inherit`

Inherit

Inheritance rules for data types. Selecting `Inherit` enables a second menu/text box to the right. Select one of the following choices:

- `Inherit via internal rule (default)`
- `Inherit via back propagation`
- `Same as first input`
- `Same as accumulator`

Built in

Built-in data types. Selecting `Built in` enables a second menu/text box to the right. Select one of the following choices:

- `double (default)`
- `single`
- `int8`
- `uint8`
- `int16`
- `uint16`
- `int32`
- `uint32`

Fixed point

Fixed-point data types.

Expression

Expressions that evaluate to data types. Selecting `Expression` enables a second menu/text box to the right, where you can enter the expression.

Clicking the **Show data type assistant** button enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specify Data Types Using Data Type Assistant”.

Mode

Select the category of data to specify.

Default: `Inherit`

`Inherit`

Inheritance rules for data types. Selecting `Inherit` enables a second menu/text box to the right. Select one of the following choices:

- `Inherit` via back propagation
- Same as input (default)

`Built in`

Built-in data types. Selecting `Built in` enables a second menu/text box to the right. Select one of the following choices:

- `double` (default)
- `single`
- `int8`
- `uint8`
- `int16`
- `uint16`
- `int32`
- `uint32`

`Fixed point`

Fixed-point data types.

`Expression`

Expressions that evaluate to data types. Selecting `Expression` enables a second menu/text box to the right, where you can enter the expression.

Clicking the **Show data type assistant** button enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specify Data Types Using Data Type Assistant”.

Mode

Select the category of accumulator data to specify

Default: `Inherit`

`Inherit`

Specifies inheritance rules for data types. Selecting `Inherit` enables a list of possible values:

- `Inherit via internal rule (default)`
- `Same as first input`

`Built in`

Specifies built-in data types. Selecting `Built in` enables a list of possible values:

- `double (default)`
- `single`
- `int8`
- `uint8`
- `int16`
- `uint16`
- `int32`
- `uint32`

`Fixed point`

Specifies fixed-point data types.

`Expression`

Specifies expressions that evaluate to data types. Selecting `Expression` enables you to enter an expression.

Clicking the **Show data type assistant** button for the accumulator data type enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specify Data Types Using Data Type Assistant”.

Data type override

Specify data type override mode for this signal.

Default: `Inherit`

`Inherit`

Inherits the data type override setting from its context, that is, from the block, `Simulink.Signal` object or Stateflow chart in Simulink that is using the signal.

`Off`

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

This parameter appears only when the **Mode** is `Built in` or `Fixed point`.

Signedness

Specify whether you want the fixed-point data as signed or unsigned.

Default: `Signed`

`Signed`

Specify the fixed-point data as signed.

`Unsigned`

Specify the fixed-point data as unsigned.

Selecting **Mode** > Fixed point enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Signedness

Specify whether you want the fixed-point data to be signed or unsigned.

Default: Signed

Signed

Specify the fixed-point data to be signed.

Unsigned

Specify the fixed-point data to be unsigned.

Selecting **Mode** > Fixed point for the accumulator data type enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specifying a Fixed-Point Data Type” for more information.

Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

Default: Best precision, Binary point, Integer

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

Best precision

Specify best-precision values. This option appears for some blocks.

Integer

Specify integer. This setting has the same result as specifying a binary point location and setting fraction length to 0. This option appears for some blocks.

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting Slope and bias enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

See “Block-Specific Parameters” on page 6-128 for the command-line information.

For more information, see “Specifying a Fixed-Point Data Type”.

Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

Default: Binary point

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

Selecting **Mode** > `Fixed point` for the accumulator data type enables this parameter.

Selecting `Binary point` enables:

- **Fraction length**

Selecting `Slope` and `bias` enables:

- **Slope**
- **Bias**

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specifying a Fixed-Point Data Type” for more information.

Word length

Specify the bit size of the word that holds the quantized integer.

Default: 16

Minimum: 0

Maximum: 32

Selecting **Mode** > `Fixed point` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Word length

Specify the bit size of the word that will hold the quantized integer.

Default: 16

Minimum: 0

Maximum: 32

Large word sizes represent large values with greater precision than small word sizes.

Selecting **Mode** > `Fixed point` for the accumulator data type enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specifying a Fixed-Point Data Type” for more information.

Fraction length

Specify fraction length for fixed-point data type.

Default: 0

Binary points can be positive or negative integers.

Selecting **Scaling** > `Binary point` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Fraction length

Specify fraction length for fixed-point data type.

Default: 0

Binary points can be positive or negative integers.

Selecting **Scaling** > `Binary point` for the accumulator data type enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specifying a Fixed-Point Data Type” for more information.

Slope

Specify slope for the fixed-point data type.

Default: 2^0

Specify any positive real number.

Selecting **Scaling** > `Slope` and `bias` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Slope

Specify slope for the fixed-point data type.

Default: 2^0

Specify any positive real number.

Selecting **Scaling** > `Slope` and `bias` for the accumulator data type enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specifying a Fixed-Point Data Type” for more information.

Bias

Specify bias for the fixed-point data type.

Default: 0

Specify any real number.

Selecting **Scaling** > `Slope` and `bias` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Bias

Specify bias for the fixed-point data type.

Default: 0

Specify any real number.

Selecting **Scaling** > `Slope` and `bias` for the accumulator data type enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specifying a Fixed-Point Data Type” for more information.

Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

Default: Off

On

Locks the output data type setting for this block.

 Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change the output data type setting for this block.

Parameter: LockScale

Type: character vector

Value: 'off' | 'on'

Default: 'off'

For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Saturate on integer overflow

Specify whether overflows saturate.

Default: Off

 On

Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

 Off

Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Parameter: SaturateOnIntegerOverflow

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Integer rounding mode

Specify the rounding mode for fixed-point operations.

Default: Floor

Ceiling

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

Floor

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

Simplest

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

Parameter: RndMeth

Type: character vector

Value: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Default: 'Floor'

For more information, see “Rounding” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

State name

Assign unique name to each state. The state names apply only to the selected block.

To assign a name to a single state, enter the name between quotes; for example, 'velocity'.

To assign names to multiple states, enter a comma-delimited list surrounded by braces; for example, {'a', 'b', 'c'}. Each name must be unique. To assign state names with a variable that has been defined in the MATLAB workspace, enter the variable without quotes. The variable can be a character vector, cell, or structure.

Default: ' ' (no name)

State name must resolve to Simulink signal object

Require that state name resolve to Simulink signal object.

Default: Off

On

Require that state name resolve to Simulink signal object.

Off

Do not require that state name resolve to Simulink signal object.

State name enables this parameter. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than `None`.

Selecting this check box disables **Code generation storage class**.

Parameter: `StateMustResolveToSignalObject`

Type: character vector

Value: `'off' | 'on'`

Default: `'off'`

Code generation storage class

Select state storage class for code generation.

Default: `Auto`

`Auto`

`Auto` is the appropriate storage class for states that you do not need to interface to external code.

StorageClass

Applies the storage class or custom storage class that you select from the list. For information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than `Simulink`.

State name enables this parameter.

Command-Line Information

Parameter: StateStorageClass

Type: character vector

Value: 'Auto' | 'ExportedGlobal' | 'ImportedExtern' |
'ImportedExternPointer' | 'SimulinkGlobal' | 'Custom'

Default: 'Auto'

TypeQualifier

Note **TypeQualifier** will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

Specify a storage type qualifier such as `const` or `volatile`.

- **Default:** ' ' (empty character vector)
- `const`
- `volatile`

Setting **Code generation storage class** to `ExportedGlobal`, `ImportedExtern`, `ImportedExternPointer`, or `SimulinkGlobal` enables this parameter. This parameter is hidden unless you previously set its value.

Parameter Name: RTWStateStorageTypeQualifier

Value Type: character vector

Default: ' ' (empty character vector)

Characteristics

Direct Feedthrough	The following ports support direct feedthrough: <ul style="list-style-type: none">• Reset port• Integrator and filter initial condition port• Input port, for every integration method except Forward Euler
Sample Time	Specified in the Sample time parameter
Scalar Expansion	Supported for gain parameters P , I , and D and for filter coefficient N
States	Inherited from driving block and parameters
Dimensionalized	Yes
Zero-Crossing Detection	Yes (in continuous-time domain)

PID Controller (2 DOF) Discrete PID Controller (2 DOF)

Simulate continuous- or discrete-time two-degree-of-freedom PID controllers

Library

Continuous, Discrete

Description

Implement a continuous- or discrete-time two-degree-of-freedom controller (PID, PI, or PD) in your Simulink model. The PID Controller (2DOF) block allows you to implement setpoint weighting in your controller to achieve both smooth setpoint tracking and good disturbance rejection.

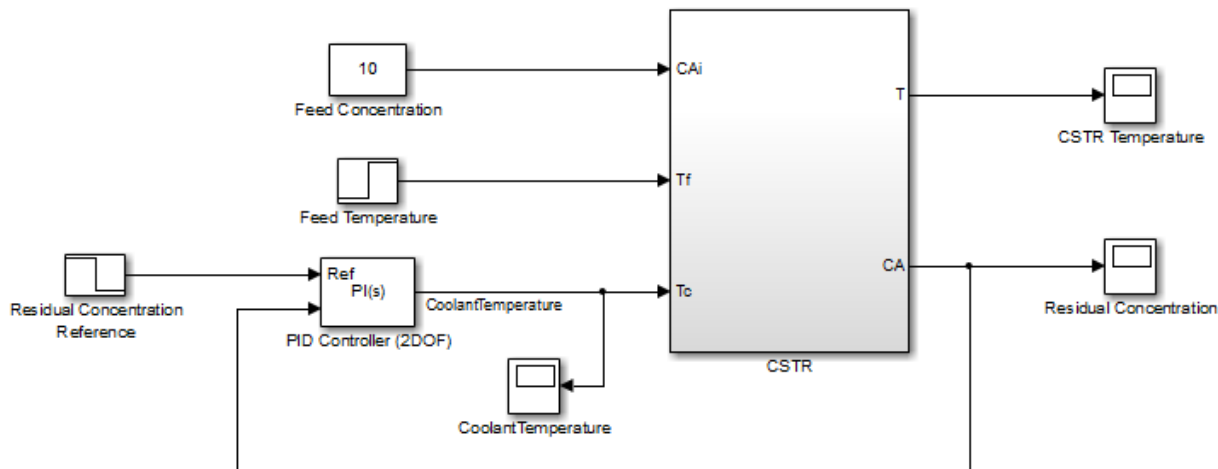

The PID Controller (2DOF) block generates an output signal based on the difference between a reference signal and a measured system output. The block computes a weighted difference signal for each of the proportional, integral, and derivative actions according to the setpoint weights you specify. The block output is the sum of the proportional, integral, and derivative actions on the respective difference signals, where each action is weighted according to the gain parameters. A first-order pole filters the derivative action. Controller gains are tunable either manually or automatically. Automatic tuning requires Simulink Control Design software.

Configurable options in the PID Controller (2DOF) block include:

- Controller type (PID, PI, or PD)
- Controller form (Parallel or Ideal)

- Time domain (continuous or discrete)
- Initial conditions and reset trigger
- Output saturation limits and built-in anti-windup mechanism
- Signal tracking for bumpless control transfer and multiloop control

In one common implementation, the PID Controller (2DOF) block operates in the feedforward path of the feedback loop. The block receives a reference signal at the `Ref` input and a measured system output at the other input. For example:

For a single-input block that accepts an error signal (a difference between a setpoint and a system output), see the PID Controller, block reference page.

You can generate code to implement your controller using any Simulink data type, including fixed-point data types. (Code generation requires Simulink Coder software; fixed-point implementation requires the Fixed-Point Designer product.)

For an example illustrating an application of the PID Controller (2 DOF) block, see the Simulink example Two Degree-of-Freedom PID Control for Setpoint Tracking.

Data Type Support

The PID Controller (2DOF) block accepts real signals of any numeric data type that Simulink software supports, including fixed-point data types. See “Data Types Supported by Simulink” in the Simulink documentation for more information.

Parameters

The following table summarizes the PID Controller (2DOF) block parameters, accessible via the block parameter dialog box.

Task	Parameters
Choose controller form and type.	<ul style="list-style-type: none"> • Controller Form on page 1-1101 in Main tab • Controller on page 1-1105
Choose discrete or continuous time.	<ul style="list-style-type: none"> • Time-domain on page 1-1105 • Sample time on page 1-1108
Choose an integration method (discrete time).	<ul style="list-style-type: none"> • Integrator method on page 1-1106 • Filter method on page 1-1107
Set and tune controller gains.	<ul style="list-style-type: none"> • Controller Parameters Source on page 1-1108 in Main tab • Proportional (P) on page 1-1110 in Main tab • Integral (I) on page 1-1110 in Main tab • Derivative (D) on page 1-1110 in Main tab • Filter coefficient (N) on page 1-1111 in Main tab • Use filtered derivative on page 1-1112 in Main tab • Setpoint weight (b) on page 1-1113 in Main tab • Setpoint weight (c) on page 1-1114 in Main tab

Task	Parameters
Set integrator and filter initial conditions.	<ul style="list-style-type: none"> • Initial conditions Source on page 1-1116 in Main tab • Integrator Initial condition on page 1-1117 in Main tab • Filter Initial condition on page 1-1117 in Main tab • Initial condition setting on page 1-1117 (command line only) • External reset on page 1-1118 in Main tab • Ignore reset when linearizing on page 1-1119 in Main tab
Limit block output.	<ul style="list-style-type: none"> • Limit output on page 1-1120 in PID Advanced tab • Lower saturation limit on page 1-1121 in PID Advanced tab • Upper saturation limit on page 1-1121 in PID Advanced tab • Ignore saturation when linearizing on page 1-1123 in PID Advanced tab
Configure anti-windup mechanism (when you limit block output).	<ul style="list-style-type: none"> • Anti-windup method on page 1-1121 in PID Advanced tab • Back-calculation gain (Kb) on page 1-1123 in PID Advanced tab
Enable signal tracking.	<ul style="list-style-type: none"> • Enable tracking mode on page 1-1124 in PID Advanced tab • Tracking gain (Kt) on page 1-1124 in PID Advanced tab

Task	Parameters
Configure data types.	<ul style="list-style-type: none"> • Parameter data type on page 1-1124 in Data Type Attributes tab • Product output data type on page 1-1126 in Data Type Attributes tab • Summation output data type on page 1-1127 in Data Type Attributes tab • Accumulator data type on page 1-1129 in Data Type Attributes tab • Integrator output data type on page 1-1131 in Data Type Attributes tab • Filter output data type on page 1-1132 in Data Type Attributes tab • Saturation output data type on page 1-1133 in Data Type Attributes tab • Lock output data type setting against changes by the fixed-point tools on page 1-1144 in Data Type Attributes tab • Saturate on integer overflow on page 1-1144 in Data Type Attributes tab • Integer rounding mode on page 1-1145 in Data Type Attributes tab
Configure block for code generation.	<ul style="list-style-type: none"> • State name on page 1-1146 in State Attributes tab • State name must resolve to Simulink signal object on page 1-1147 in State Attributes tab • Code generation storage class on page 1-1147 in State Attributes tab • Code generation storage type qualifier on page 1-1148 in State Attributes tab

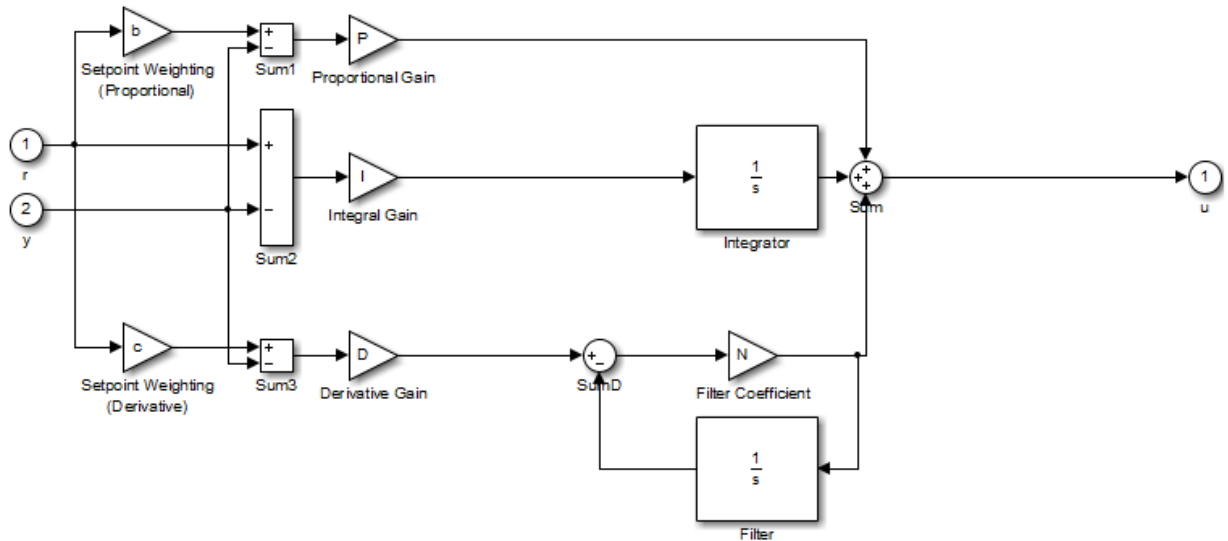

Controller form

Select the controller form.

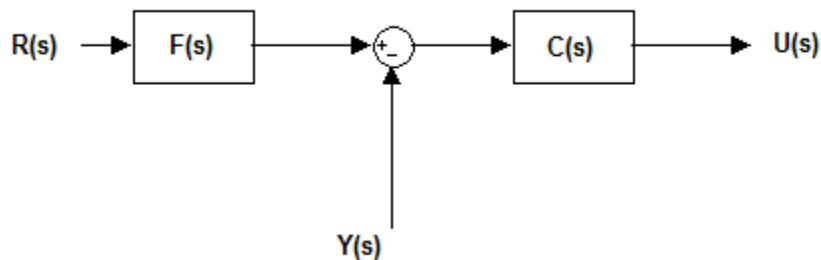

Parallel (Default)

Selects a controller form in which the proportional, integral, and derivative gains **P**, **I**, and **D** operate independently. The filter coefficient **N** sets the location of the pole in the derivative filter.

Parallel two-degree-of-freedom PID controller, where input 1 receives a reference signal and input 2 receives feedback from the measured system output:

The parallel two-degree-of-freedom PID controller can be equivalently modeled by the following block diagram:

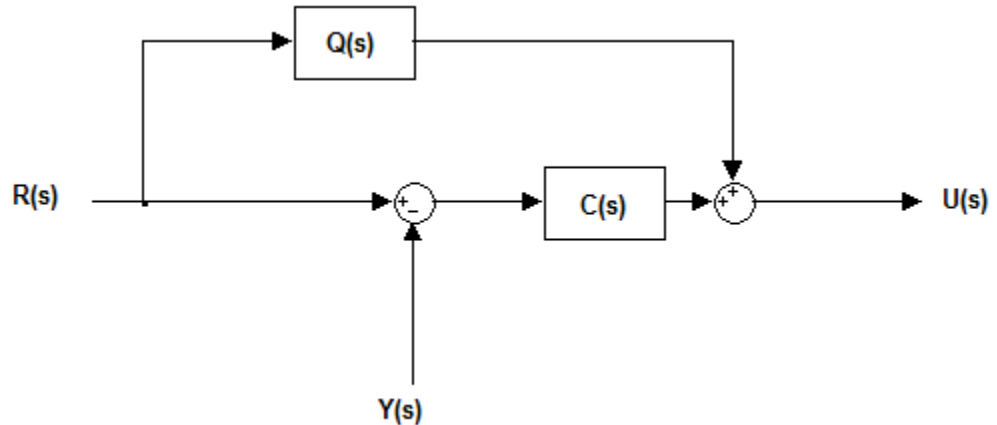

$R(s)$ represents the reference signal and $Y(s)$ represents the feedback from measured system output. In this model, $C(s)$ is a single degree-of-freedom controller, and $F(s)$ acts as a prefilter on the reference signal. For a parallel two-degree-of-freedom PID controller in the Continuous-time **Time-domain**, the transfer functions $F(s)$ and $C(s)$ are:

$$F_{par}(s) = \frac{(bP + cDN)s^2 + (bPN + I)s + IN}{(P + DN)s^2 + (PN + I)s + IN}$$

$$C_{par}(s) = \frac{(P + DN)s^2 + (PN + I)s + IN}{s(s + N)}$$

where b and c are the **Setpoint weight** parameters.

Alternatively, the parallel two-degree-of-freedom PID controller can be modeled by the following block diagram:

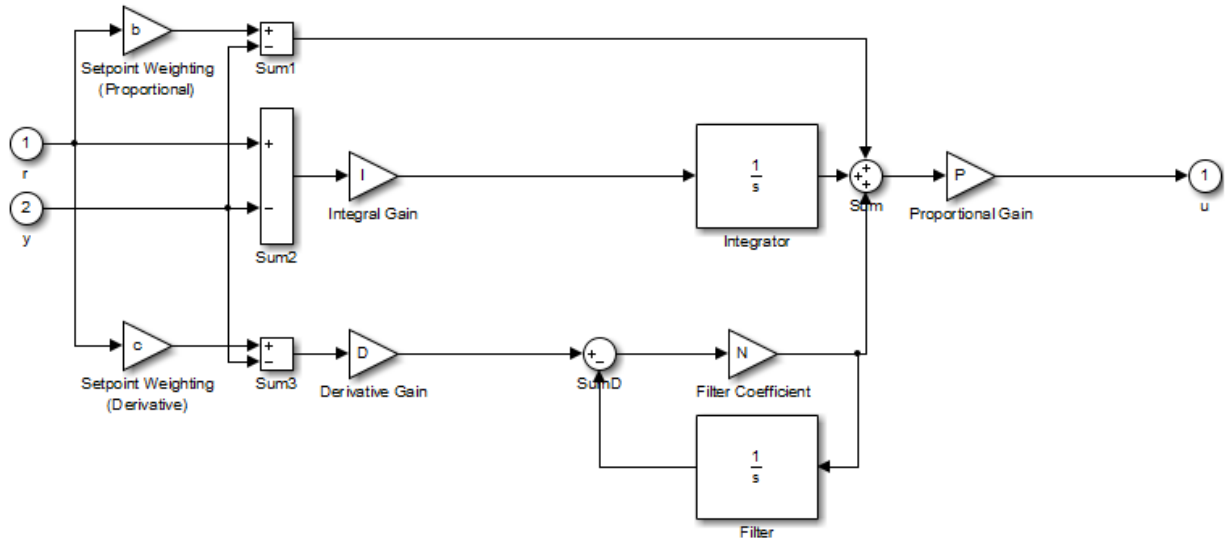

$R(s)$, $Y(s)$, and $C(s)$ are as discussed previously. In this realization, $Q(s)$ acts as feed-forward conditioning on the reference signal $R(s)$. For a parallel PID controller in the Continuous-time **Time-domain**, the transfer function $Q(s)$ is:

$$Q_{par}(s) = \frac{((b-1)P + (c-1)DN)s + (b-1)PN}{s + N}$$

Ideal

Selects a controller form in which the proportional gain P acts on the sum of all actions.

Ideal two-degree-of-freedom PID controller, where input 1 receives a reference signal and input 2 receives feedback from the measured system output:

Similarly to the parallel controller form discussed previously, the ideal two-degree-of-freedom PID controller can be modeled as a single degree-of-freedom controller $C(s)$ with a prefilter $F(s)$. For an ideal two-degree-of-freedom PID controller in the Continuous-time **Time-domain**, the transfer functions $F(s)$ and $C(s)$ are:

$$F_{id}(s) = \frac{(b + cDN)s^2 + (bN + I)s + IN}{(1 + DN)s^2 + (N + I)s + IN}$$

$$C_{id}(s) = P \frac{(1 + DN)s^2 + (N + I)s + IN}{s(s + N)}$$

where b and c are the **Setpoint weight** parameters.

Alternatively, modeling the ideal two-degree-of-freedom PID controller as a one-degree-of-freedom controller $C(s)$ with feed-forward conditioning $Q(s)$ on the reference signal gives, in continuous-time:

$$Q_{id}(s) = P \frac{((b-1) + (c-1)DN)s + (b-1)N}{s + N}$$

The controller transfer function for the current settings is displayed in the block dialog box.

Controller

Specify the controller type.

PID (Default)

Implements a controller with proportional, integral, and derivative action.

PI

Implements a controller with proportional and integral action.

PD

Implements a controller with proportional and derivative action.

The controller transfer function for the current settings is displayed in the block dialog box.

Time-domain

Select continuous or discrete time domain. The appearance of the block changes to reflect your selection.

Continuous-time (Default)

Selects the continuous-time representation.

When the PID Controller (2DOF) block is in a model with synchronous state control (see the State Control block), you cannot select `Continuous-time`.

Discrete-time

Selects the discrete-time representation. Selecting `Discrete-time` also allows you to specify the:

- **Sample time**, which is the discrete interval between samples.
- Discrete integration methods for the integrator and the derivative filter using the **Integrator method** and **Filter method** menus.

Integrator method

(Available only when you set **Time-domain** to `Discrete-time`.) Specify the method used to compute the integrator output. For more information about discrete-time integration methods, see the Discrete-Time Integrator block reference page.

Forward Euler (Default)

Selects the Forward Rectangular (left-hand) approximation.

This method is best for small sampling times, where the Nyquist limit is large compared to the bandwidth of the controller. For larger sampling times, the Forward Euler method can result in instability, even when discretizing a system that is stable in continuous time.

Backward Euler

Selects the Backward Rectangular (right-hand) approximation.

An advantage of the `Backward Euler` method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result.

`Trapezoidal`

Selects the Bilinear approximation.

An advantage of the `Trapezoidal` method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result. Of all available integration methods, the `Trapezoidal` method yields the closest match between frequency-domain properties of the discretized system and the corresponding continuous-time system.

Note For integrator methods `BackwardEuler` or `Trapezoidal`, you cannot generate HDL code for the block if either:

- **Limit output** is selected and **Anti-windup method** is set to back-calculation or clamping.
 - **Enable tracking mode** is selected.
-

Filter method

(Available only when you set **Time-domain** to `Discrete-time`.) Specify the method used to compute the derivative filter output. For more information about discrete-time integration methods, see the `Discrete-Time Integrator` block reference page.

`Forward Euler (Default)`

Selects the Forward Rectangular (left-hand) approximation.

This method is best for small sampling times, where the Nyquist limit is large compared to the bandwidth of the controller. For larger sampling times, the `Forward Euler` method can result in instability, even when discretizing a system that is stable in continuous time.

`Backward Euler`

Selects the Backward Rectangular (right-hand) approximation.

An advantage of the `Backward Euler` method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result. Any filter parameter value $N > 0$ yields a stable result with this method.

Trapezoidal

Selects the Bilinear approximation.

An advantage of the `Trapezoidal` method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result. Any filter parameter value $N > 0$ yields a stable result with this method. Of all available filter methods, the `Trapezoidal` method yields the closest match between frequency-domain properties of the discretized system and the corresponding continuous-time system.

Sample time (-1 for inherited)

(Available only when you set **Time-domain** to `Discrete-time`.) Specify the discrete interval between samples.

Default: 1

By default, the block uses a discrete sample time of 1. To specify a different sample time, enter another discrete value, such as 0.1.

If you specify a value of -1 , the `PID Controller (2DOF)` block inherits the sample time from upstream blocks. Do not enter a value of 0; to implement a continuous-time controller, select the **Time-domain** `Continuous-time`.

See “Specify Sample Time” in the online documentation for more information.

Controller Parameters Source

Select the source of the controller gains, filter coefficient, and setpoint weights. You can provide these parameters explicitly in the block dialog box, or enable external inputs for them on the block. Enabling external inputs for the parameters allows you to compute PID gains and filter coefficients externally to the block and provide them to the block as signal inputs.

External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to

implement gain-scheduled PID control, in which controller gains are determined by logic or other calculation in the Simulink model and passed to the block.

`internal` (Default)

Specify the PID gains and filter coefficient explicitly using the **P**, **I**, **D**, **N**, **b**, and **c** parameters.

`external`

Specify the PID gains and filter coefficient externally. An additional input port appears under the block input for each parameter that is required for the current controller type:

When you supply gains externally, time variations in the integral and derivative gain values are integrated and differentiated, respectively. This result occurs because of the way the PID gains are implemented within the block. For example, for a continuous-time PID controller with external inputs, the integrator term is implemented as shown in the following illustration.

Within the block, the signal to be integrated is multiplied by the externally-supplied integrator gain, I , before integration. This implementation yields:

$$y_i = \int u I dt.$$

Thus, the integrator gain is included in the integral. Similarly, in the derivative term of the block, multiplication by the derivative gain precedes the differentiation, which causes the derivative gain D to be differentiated.

Proportional (P)

Specify the proportional gain P .

Default: 1

Enter a finite, real gain value into the **Proportional (P)** field. Use either scalar or vector gain values. For a **parallel PID Controller form**, the proportional action is independent of the integral and derivative actions. For an **ideal PID Controller form**, the proportional action acts on the integral and derivative actions. See “Controller form” on page 1-1101 for more information about the role of P in the controller transfer function.

When you have Simulink Control Design software installed, you can automatically tune the controller gains. See “Choose a Control Design Approach” (Simulink Control Design).

Integral (I)

(Available for PID and PI controllers.) Specify the integral gain I .

Default: 1

Enter a finite, real gain value into the **Integral (I)** field. Use either scalar or vector gain values.

When you have Simulink Control Design software installed, you can automatically tune the controller gains. See “Choose a Control Design Approach” (Simulink Control Design).

Derivative (D)

(Available for PID and PD controllers.) Specify the derivative gain D .

Default: 0

Enter a finite, real gain value into the **Derivative (D)** field. Use either scalar or vector gain values.

When you have Simulink Control Design software installed, you can automatically tune the controller gains using. See “Choose a Control Design Approach” (Simulink Control Design).

Filter coefficient (N)

Specifies the filter coefficient of the controller.

(Available for PID and PD controllers, when **Use filtered derivative** is checked.) Specify the filter coefficient N, which determines the pole location of the filter in the derivative action:

The filter pole falls at $s = -N$ in the Continuous-time **Time-domain**. For Discrete-time, the location of the pole depends on which **Filter method** you select (for sampling time T_s):

- Forward Euler:

$$z_{pole} = 1 - NT_s$$

- Backward Euler:

$$z_{pole} = \frac{1}{1 + NT_s}$$

- Trapezoidal:

$$z_{pole} = \frac{1 - NT_s / 2}{1 + NT_s / 2}$$

Default: 100.

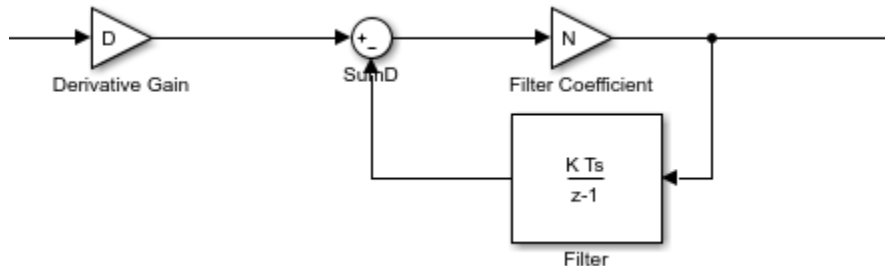

Enter a finite, real gain value into the **Filter Coefficient (N)** field. Use either scalar or vector gain values. Note that the PID controller (2DOF) block does not support $N = \text{inf}$ (ideal unfiltered derivative).

When you have Simulink Control Design software installed, you can automatically tune the controller gains. See “Choose a Control Design Approach” (Simulink Control Design). Automatic tuning requires $N > 0$.

Use Filtered Derivative

Specify whether derivative term is filtered (finite N) or unfiltered. Unfiltered derivative is available only for discrete-time controllers.

Unchecking this option replaces the filtered derivative with a discrete differentiator. For example, if **Filter Method** is Forward Euler, then the filtered derivative term is represented by:

When you uncheck **Use filtered derivative**, the derivative term becomes:

- On (Default)
Use derivative filter (finite N).
- Off
Derivative is unfiltered.

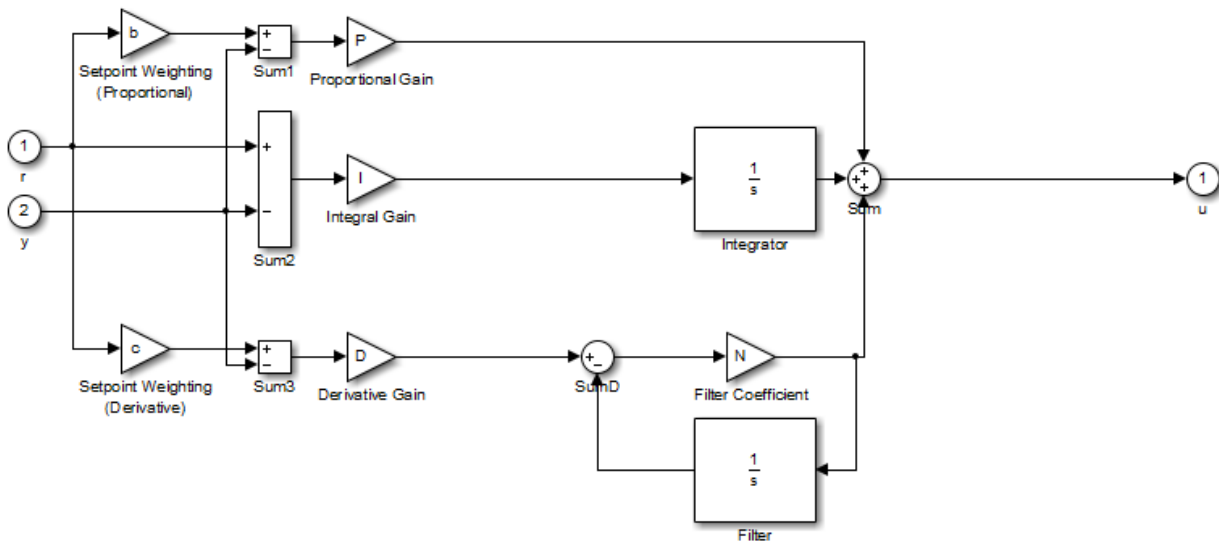

Setpoint weight (b)

Specify the proportional setpoint weight b.

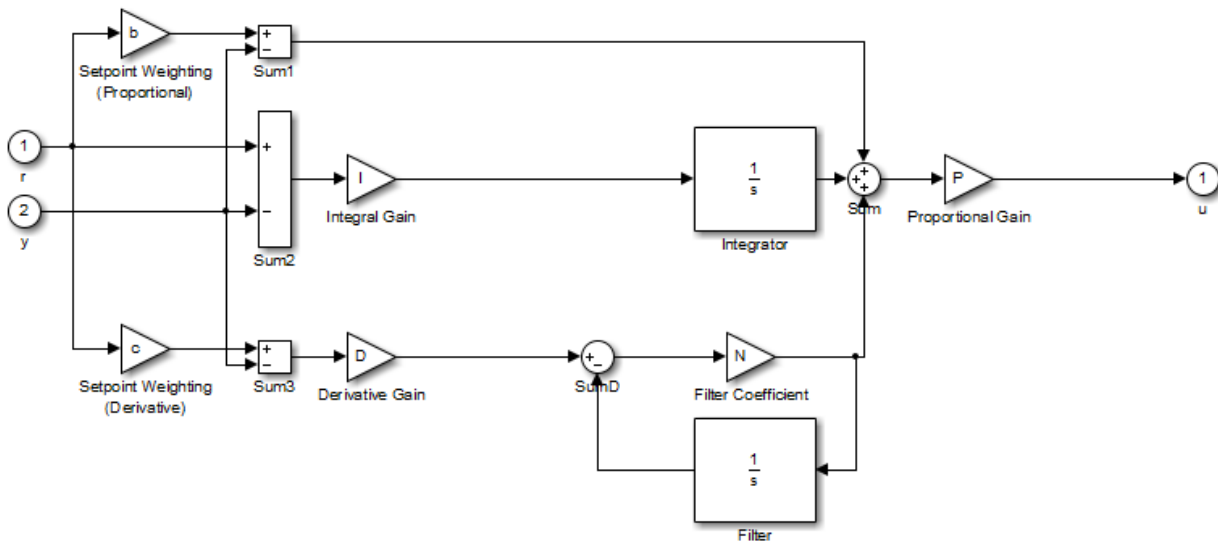

Default: 1

Enter the proportional setpoint weight value into the **Setpoint weight (b)** field. Setting $b = 0$ eliminates the proportional action on the reference signal, which can reduce overshoot in the system response to step changes in the setpoint.

The following diagrams show the role of **Setpoint weight (b)** in PID controllers of Parallel and Ideal form. See “Controller form” on page 1-1101 for a discussion of the corresponding transfer functions.

Parallel Two-Degree-of-Freedom PID Controller

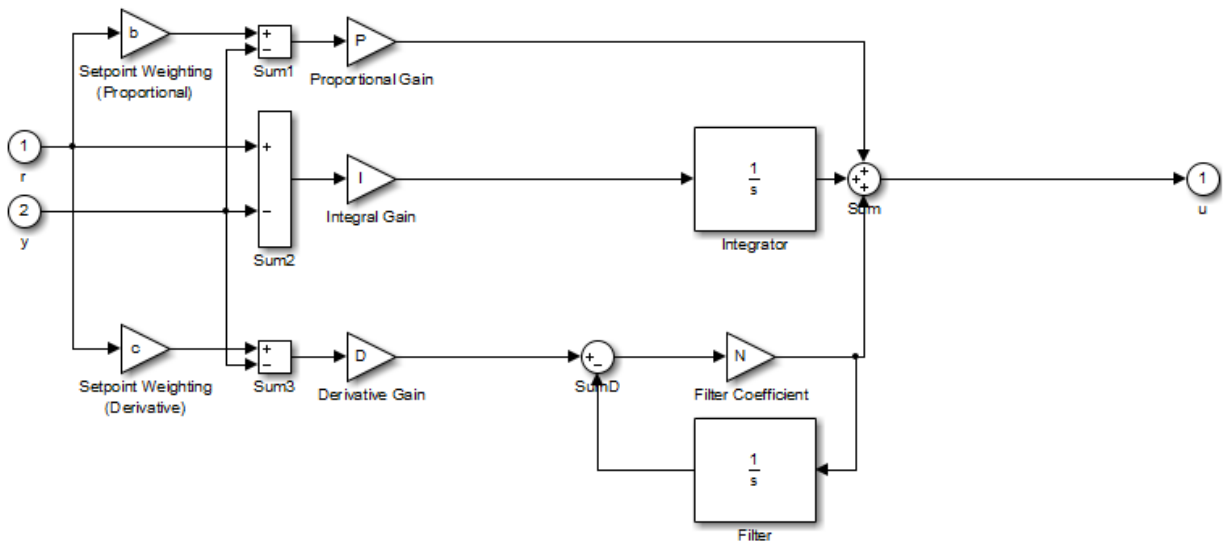

Ideal Two-Degree-of-Freedom PID Controller

Setpoint weight (c)

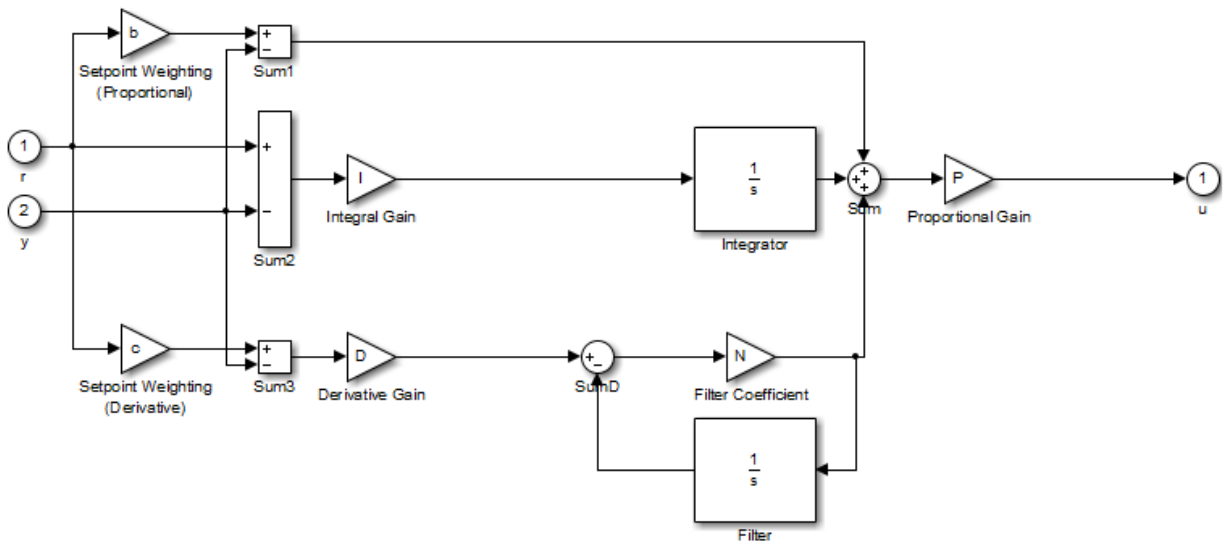

(Available for PID and PD controllers.) Specify the derivative setpoint weight c .

Enter the derivative setpoint weight value into the **Setpoint weight (c)** field. To implement a controller that achieves both effective disturbance rejection and smooth setpoint tracking without excessive transient response, set $c = 0$. Setting $c = 0$ yields a controller with derivative action on the measured system response but not on the reference input.

The following diagrams show the role of **Setpoint weight (c)** in Parallel and Ideal PID controllers. See “Controller form” on page 1-1101 for a discussion of the corresponding transfer functions.

Parallel Two-Degree-of-Freedom PID Controller

Ideal Two-Degree-of-Freedom PID Controller

Select Tuning Method

(Requires Simulink Control Design) Select a PID tuning tool. The specified tool opens when you click **Tune**.

Transfer Function Based (PID Tuner App) (Default)

Clicking **Tune** opens the PID Tuner, which lets you interactively tune PID gains while examining relevant system responses to validate performance. By default, PID Tuner works with a linearization of your plant model. For models that cannot be linearized, you can tune PID gains against a plant model estimated from simulated or measured response data. For more information, see “Introduction to Model-Based PID Tuning in Simulink” (Simulink Control Design).

Frequency Response Based

Clicking **Tune** opens the Frequency Response Based PID Tuner, which tunes PID controller gains based on a frequency-response estimation experiment. Frequency Response Based PID Tuner is especially useful for plants that are not linearizable. For more information, see “Design PID Controller from Plant Frequency-Response Data” (Simulink Control Design).

Initial conditions Source

Select the source of the integrator and filter initial conditions. Simulink uses initial conditions to initialize the integrator and filter output at the start of a simulation or at a specified trigger event (see “External reset” on page 1-1118). The integrator and filter initial conditions in turn determine the initial block output.

internal (Default)

Specifies the integrator and filter initial conditions explicitly using the **Integrator Initial condition** and **Filter Initial condition** parameters.

external

Specifies the integrator and filter initial conditions externally. An additional input port appears under the block inputs for each initial condition: I_0 for the integrator and D_0 for the filter:

Integrator Initial condition

(Available only when **Initial conditions Source** is *internal* and the controller includes integral action.) Specify the integrator initial value. Simulink uses the initial condition to initialize the integrator output at the start of a simulation or at a specified trigger event (see “External reset” on page 1-1118). The integrator initial condition, together with the filter initial condition, determines the initial output of the PID Controller (2DOF) block.

Default: 0

Simulink does not permit the integrator initial condition to be *inf* or NaN.

Filter Initial condition

(Available only when **Initial conditions Source** is *internal*, the controller includes derivative action, and **Use filtered derivative** is checked.) Specify the filter initial value. Simulink uses the initial condition to initialize the filter output at the start of a simulation or at a specified trigger event (see “External reset” on page 1-1118). The filter initial condition, together with the integrator initial condition, determines the initial output of the PID Controller (2DOF) block.

Default: 0

Simulink does not permit the filter initial condition to be *inf* or NaN.

Initial condition setting

Specify whether to apply the **Integrator Initial condition** and **Filter Initial condition** parameter to the corresponding block state or output. This parameter can be

changed only at the command line using `set_param` to set the `InitialConditionSetting` parameter of the block.

State (most efficient) (Default)

Use this option in all situations except when the block is in a triggered subsystem or a function-call subsystem and simplified initialization mode is enabled.

Output

Use this option when the block is in a triggered subsystem or a function-call subsystem and simplified initialization mode is enabled.

For more information about the **Initial condition setting** parameters, see the Discrete-Time Integrator block.

External reset

Select the trigger event that resets the integrator and filter outputs to the initial conditions you specify in the **Integrator Initial condition** and **Filter Initial condition** fields. Selecting any option other than `none` enables a reset input on the block for the external reset signal, as shown:

Or, if the **Initial conditions Source** is External:

The reset signal must be a scalar of type `single`, `double`, `boolean`, or `integer`. Fixed point data types, except for `ufix1`, are not supported.

Note To be compliant with the Motor Industry Software Reliability Association (MISRA) software standard, your model must use Boolean signals to drive the external reset ports of the PID controller (2DOF) block.

`none` (Default)

Does not reset the integrator and filter outputs to initial conditions.

`rising`

Resets the outputs when the reset signal has a rising edge.

`falling`

Resets the outputs when the reset signal has a falling edge.

`either`

Resets the outputs when the reset signal either rises or falls.

`level`

Resets and holds the outputs to the initial conditions while the reset signal is nonzero.

Ignore reset when linearizing

Force Simulink linearization commands to ignore any reset mechanism that you have chosen with the **External reset** menu. Ignoring reset states allows you to linearize a model around an operating point even if that operating point causes the PID Controller (2DOF) block to reset.

Off (Default)

Simulink linearization commands do not ignore states corresponding to the reset mechanism.

On

Simulink linearization commands ignore states corresponding to the reset mechanism.

Enable zero-crossing detection

Enable zero-crossing detection in continuous-time models upon reset and upon entering or leaving a saturation state.

Zero-crossing detection can accurately locate signal discontinuities without resorting to excessively small time steps that can lead to lengthy simulation times. If you select **Limit output** or activate an **External reset** in your PID Controller (2DOF) block, activating zero-crossing detection can reduce computation time in your simulation. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

On (Default)

Uses zero-crossing detection at any of the following events: reset; entering or leaving an upper saturation state; and entering or leaving a lower saturation state.

Off

Does not use zero-crossing detection.

Enabling zero-crossing detection for the PID Controller (2DOF) block also enables zero-crossing detection for all under-mask blocks that include the zero-crossing detection feature.

Limit output

Limit the block output to values you specify as the **Lower saturation limit** and **Upper saturation limit** parameters.

Activating this option limits the block output internally to the block, obviating the need for a separate Saturation on page 1-1307 block after the controller in your Simulink model. It also allows you to activate the built-in anti-windup mechanism (see “Anti-windup method” on page 1-1121).

Off (Default)

Does not limit the block output, which is the weighted sum of the proportional, integral, and derivative actions.

Limits the block output to the **Lower saturation limit** or the **Upper saturation limit** whenever the weighted sum exceeds those limits. Allows you to select an **Anti-windup method**.

Lower saturation limit

(Available only when you select the **Limit Output** box.) Specify the lower limit for the block output. The block output is held at the **Lower saturation limit** whenever the weighted sum of the proportional, integral, and derivative actions goes below that value.

Default: `-inf`

Upper saturation limit

(Available only when you select the **Limit Output** box.) Specify the upper limit for the block output. The block output is held at the **Upper saturation limit** whenever the weighted sum of the proportional, integral, and derivative actions exceeds that value.

Default: `inf`

Anti-windup method

(Available only when you select the **Limit Output** option and the controller includes integral action.) Select an anti-windup mechanism to discharge the integrator when the block is saturated, which occurs when the sum of the block components exceeds the output limits.

When you select the **Limit output** check box and the weighted sum of the controller components exceeds the specified output limits, the block output holds at the specified limit. However, the integrator output can continue to grow (integrator wind-up), increasing the difference between the block output and the sum of the block components. Without a mechanism to prevent integrator wind-up, two results are possible:

- If the sign of the input signal never changes, the integrator continues to integrate until it overflows. The overflow value is the maximum or minimum value for the data type of the integrator output.

- If the sign of the input signal changes once the weighted sum has grown beyond the output limits, it can take a long time to discharge the integrator and return the weighted sum within the block saturation limit.

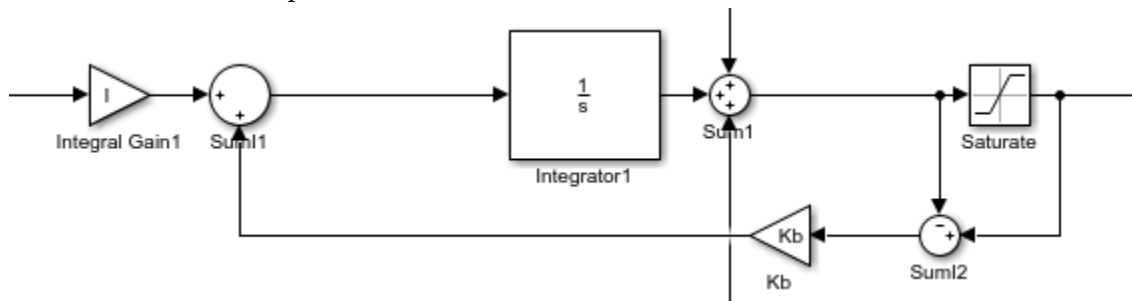

In both cases, controller performance can suffer. To combat the effects of wind-up without an anti-windup mechanism, it may be necessary to detune the controller (for example, by reducing the controller gains), resulting in a sluggish controller. Activating an anti-windup mechanism can improve controller performance.

none (Default)

Does not use an anti-windup mechanism. This setting can cause the block's internal signals to be unbounded even if the output appears to be bounded by the saturation limits. This can result in slow recovery from saturation or unexpected overflows.

back-calculation

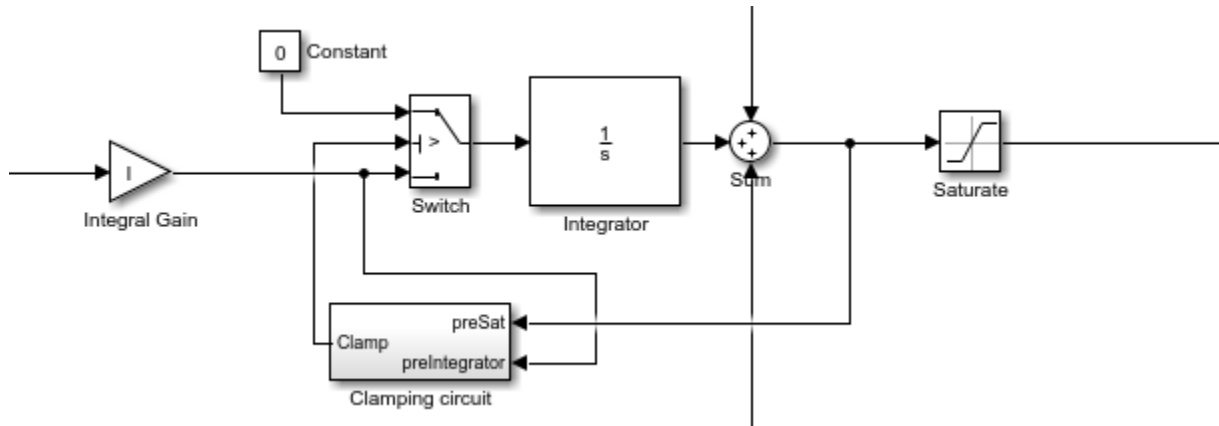

Discharges the integrator when the block output saturates using the integral-gain feedback loop:

You can also specify a value for the **Back-calculation coefficient (Kb)**.

clamping

Stops integration when the sum of the block components exceeds the output limits and the integrator output and block input have the same sign. Resumes integration when the sum of the block components exceeds the output limits and the integrator output and block input have opposite sign. The integrator portion of the block is:

The clamping circuit implements the logic necessary to determine whether integration continues.

Back-calculation gain (Kb)

(Available only when the back-calculation **Anti-windup method** is active.) Specify the gain coefficient of the anti-windup feedback loop.

The back-calculation anti-windup method discharges the integrator on block saturation using a feedback loop having gain coefficient Kb.

Default: 1

Ignore saturation when linearizing

Force Simulink linearization commands ignore PID Controller (2DOF) block output limits. Ignoring output limits allows you to linearize a model around an operating point even if that operating point causes the PID Controller (2DOF) block to exceed the output limits.

On (Default)

Simulink linearization commands ignore states corresponding to saturation.

Off

Simulink linearization commands do not ignore states corresponding to saturation.

Enable tracking mode

(Available for any controller with integral action.) Activate signal tracking, which lets the output of the PID Controller (2DOF) block follow a tracking signal. Provide the tracking signal to the block at the TR port, which becomes active when you select **Enable tracking mode**.

When signal tracking is active, the difference between the tracked signal and the block output is fed back to the integrator input with a gain K_t . You can also specify the value of the **Tracking coefficient (Kt)**.

For information about using tracking mode to implement bumpless control transfer scenarios and multiloop controllers, see “Enable tracking mode” on page 1-1068 in the PID Controller reference page.

Off (Default)

Disables signal tracking and removes TR block input.

On

Enables signal tracking and activates TR input.

Tracking gain (Kt)

(Available only when you select **Enable tracking mode**.) Specify K_t , which is the gain of the signal tracking feedback loop.

Default: 1

Parameter data type

Select the data type of the gain parameters **P**, **I**, **D**, **N**, **Kb**, and **Kt** and the setpoint weighting parameters **b** and **c**.

See “Data Types Supported by Simulink” in the Simulink documentation for more information.

Inherit: Inherit via internal rule (Default)

Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use the simple choice of Inherit: Same as input.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
- To specify your own inheritance rule, use Inherit: Inherit via back propagation and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.

Inherit: Inherit via back propagation

Use data type of the driving block.

Inherit: Same as input

Use data type of input signal.

double

single

int16

uint16

`int32`

`uint32`

`fixdt(1,16)`

`fixdt(1,16,0)`

`fixdt(1,16,2^0,0)`

`<data type expression>`

Name of a data type object. For example, `Simulink.NumericType`.

Product output data type

Select the product output data type of the gain parameters **P**, **I**, **D**, **N**, **Kb**, and **Kt**, the setpoint weighting parameters **b** and **c**, or the product output data type of the derivative filter numerator and denominator.

See “Data Types Supported by Simulink” in the Simulink documentation for more information.

Inherit: Inherit via internal rule (Default)

Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use the simple choice of `Inherit: Same as input`.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
- To specify your own inheritance rule, use `Inherit: Inherit via back propagation` and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.

Inherit: Inherit via back propagation

Use data type of the driving block.

Inherit: Same as input

Use data type of input signal.

int16

uint16

int32

uint32

fixdt(1,16)

fixdt(1,16,0)

fixdt(1,16,2⁰,0)

<data type expression>

Name of a data type object. For example, Simulink.NumericType.

Summation output data type

Select the summation output data type of the sums **Sum**, **Sum D**, **Sum I1**, **SumI2**, **SumI3**, and the summations in the trapezoidal discrete filter numerator and denominator, **SumNum** and **SumDen**. These sums are computed internally within the block, and might not all be present, depending upon the controller configuration. To see where Simulink computes each of these sums, right-click the PID Controller (2 DOF) block in your model and select **Look Under Mask**:

- **Sum** is the weighted sum of the proportional, derivative, and integral signals.
- **Sum1** is the difference between the reference input weighted by **b** and the measured system response.

- **Sum2** is the difference between the reference input weighted by **c** and the measured system response.
- **Sum3** is the difference between the unweighted reference input and the measured system response.
- **SumD** is the sum in the derivative filter feedback loop.
- **SumI1** is the sum of the block input signal (weighted by the integral gain **I**) and **SumI2**. **SumI1** is computed only when **Limit output** and **Anti-windup method back-calculation** are active.
- **SumI2** is the difference between the weighted sum **Sum** and the limited block output. **SumI2** is computed only when **Limit output** and **Anti-windup method back-calculation** are active.
- **SumI3** is the difference between the block output and the signal at the block's tracking input. **SumI3** is computed only when you select the **Enable tracking mode** box.

See “Data Types Supported by Simulink” in the Simulink documentation for more information.

Inherit: `Inherit via internal rule (Default)`

Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use the simple choice of `Inherit: Same as first input`.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.

Note The accumulator internal rule favors greater numerical accuracy, possibly at the cost of less efficient generated code. To get the same accuracy for the output, set the output data type to `Inherit: Same as accumulator`.

Inherit: Inherit via back propagation

Use data type of the driving block.

Inherit: Same as first input

Use data type of first input signal.

Inherit: Same as accumulator

Use the same data type as the corresponding accumulator on page 1-1129.

double

fixdt(1,16)

fixdt(1,16,0)

fixdt(1,16,2⁰,0)

<data type expression>

Name of a data type object. For example, Simulink.NumericType.

Accumulator data type

Specify the accumulator data type.

Default: Inherit: Inherit via internal rule

Inherit: Inherit via internal rule

Use internal rule to determine accumulator data type.

Inherit: Same as first input

Use data type of first input signal.

double

Accumulator data type is double.

single

Accumulator data type is single.

int8

Accumulator data type is int8.

uint8

Accumulator data type is uint8.

int16

Accumulator data type is int16.

uint16

Accumulator data type is uint16.

int32

Accumulator data type is int32.

uint32

Accumulator data type is uint32.

fixdt(1,16,0)

Accumulator data type is fixed point fixdt(1,16,0).

fixdt(1,16,2^0,0)

Accumulator data type is fixed point fixdt(1,16,2^0,0).

<data type expression>

The name of a data type object, for example `Simulink.NumericType`

See “Block-Specific Parameters” on page 6-128 for the command-line information.

For more information, see “Specify Data Types Using Data Type Assistant”.

Integrator output data type

Select the data type of the integrator output.

See “Data Types Supported by Simulink” in the Simulink documentation for more information.

Inherit: Inherit via internal rule (Default)

Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use Inherit: Inherit via back propagation.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.

`uint32`

`fixdt(1,16)`

`fixdt(1,16,0)`

`fixdt(1,16,2^0,0)`

`<data type expression>`

Name of a data type object. For example, `Simulink.NumericType`.

Mode

Select the category of data to specify.

Default: `Inherit`

`Inherit`

Inheritance rules for data types. Selecting `Inherit` enables a second menu/text box to the right. Select one of the following choices:

- `Inherit via internal rule (default)`
- `Inherit via back propagation`
- `Same as first input`
- `Same as accumulator`

`Built in`

Built-in data types. Selecting `Built in` enables a second menu/text box to the right. Select one of the following choices:

- `double (default)`
- `single`
- `int8`
- `uint8`
- `int16`

- `uint16`
- `int32`
- `uint32`

Fixed point

Fixed-point data types.

Expression

Expressions that evaluate to data types. Selecting `Expression` enables a second menu/text box to the right, where you can enter the expression.

Clicking the **Show data type assistant** button enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specify Data Types Using Data Type Assistant”.

Mode

Select the category of data to specify.

Default: `Inherit`

`Inherit`

Inheritance rules for data types. Selecting `Inherit` enables a second menu/text box to the right. Select one of the following choices:

- `Inherit via back propagation`
- `Same as input (default)`

`Built in`

Built-in data types. Selecting `Built in` enables a second menu/text box to the right. Select one of the following choices:

- `double (default)`

- `single`
- `int8`
- `uint8`
- `int16`
- `uint16`
- `int32`
- `uint32`

Fixed point

Fixed-point data types.

Expression

Expressions that evaluate to data types. Selecting `Expression` enables a second menu/text box to the right, where you can enter the expression.

Clicking the **Show data type assistant** button enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specify Data Types Using Data Type Assistant”.

Mode

Select the category of accumulator data to specify

Default: `Inherit`

`Inherit`

Specifies inheritance rules for data types. Selecting `Inherit` enables a list of possible values:

- `Inherit via internal rule (default)`
- `Same as first input`

Built in

Specifies built-in data types. Selecting `Built in` enables a list of possible values:

- `double` (default)
- `single`
- `int8`
- `uint8`
- `int16`
- `uint16`
- `int32`
- `uint32`

Fixed point

Specifies fixed-point data types.

Expression

Specifies expressions that evaluate to data types. Selecting `Expression` enables you to enter an expression.

Clicking the **Show data type assistant** button for the accumulator data type enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specify Data Types Using Data Type Assistant”.

Data type override

Specify data type override mode for this signal.

Default: `Inherit`

`Inherit`

Inherits the data type override setting from its context, that is, from the block, `Simulink.Signal` object or Stateflow chart in Simulink that is using the signal.

Off

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

This parameter appears only when the **Mode** is `Built in` or `Fixed point`.

Signedness

Specify whether you want the fixed-point data as signed or unsigned.

Default: Signed

Signed

Specify the fixed-point data as signed.

Unsigned

Specify the fixed-point data as unsigned.

Selecting **Mode** > `Fixed point` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Signedness

Specify whether you want the fixed-point data to be signed or unsigned.

Default: Signed

Signed

Specify the fixed-point data to be signed.

Unsigned

Specify the fixed-point data to be unsigned.

Selecting **Mode** > Fixed point for the accumulator data type enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specifying a Fixed-Point Data Type” for more information.

Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

Default: Best precision, Binary point, Integer

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

Best precision

Specify best-precision values. This option appears for some blocks.

Integer

Specify integer. This setting has the same result as specifying a binary point location and setting fraction length to 0. This option appears for some blocks.

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting Slope and bias enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

See “Block-Specific Parameters” on page 6-128 for the command-line information.

For more information, see “Specifying a Fixed-Point Data Type”.

Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

Default: Binary point

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

Selecting **Mode** > Fixed point for the accumulator data type enables this parameter.

Selecting Binary point enables:

- **Fraction length**

Selecting Slope and bias enables:

- **Slope**
- **Bias**

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specifying a Fixed-Point Data Type” for more information.

Word length

Specify the bit size of the word that holds the quantized integer.

Default: 16

Minimum: 0

Maximum: 32

Selecting **Mode** > `Fixed point` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Word length

Specify the bit size of the word that will hold the quantized integer.

Default: 16

Minimum: 0

Maximum: 32

Large word sizes represent large values with greater precision than small word sizes.

Selecting **Mode** > `Fixed point` for the accumulator data type enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specifying a Fixed-Point Data Type” for more information.

Fraction length

Specify fraction length for fixed-point data type.

Default: 0

Binary points can be positive or negative integers.

Selecting **Scaling** > Binary point enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Fraction length

Specify fraction length for fixed-point data type.

Default: 0

Binary points can be positive or negative integers.

Selecting **Scaling** > Binary point for the accumulator data type enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specifying a Fixed-Point Data Type” for more information.

Slope

Specify slope for the fixed-point data type.

Default: 2⁰

Specify any positive real number.

Selecting **Scaling** > Slope and bias enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Slope

Specify slope for the fixed-point data type.

Default: 2^0

Specify any positive real number.

Selecting **Scaling** > Slope and bias for the accumulator data type enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specifying a Fixed-Point Data Type” for more information.

Bias

Specify bias for the fixed-point data type.

Default: 0

Specify any real number.

Selecting **Scaling** > Slope and bias enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Bias

Specify bias for the fixed-point data type.

Default: 0

Specify any real number.

Selecting **Scaling** > Slope and bias for the accumulator data type enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specifying a Fixed-Point Data Type” for more information.

Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

Default: Off

On

Locks the output data type setting for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change the output data type setting for this block.

Parameter: LockScale

Type: character vector

Value: 'off' | 'on'

Default: 'off'

For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Saturate on integer overflow

Specify whether overflows saturate.

Default: Off On

Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

 Off

Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Parameter: SaturateOnIntegerOverflow

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Integer rounding mode

Specify the rounding mode for fixed-point operations.

Default: Floor

Ceiling

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

Floor

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

Simplest

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

Parameter: `RndMeth`

Type: character vector

Value: `'Ceiling'` | `'Convergent'` | `'Floor'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Default: `'Floor'`

For more information, see “Rounding” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

State name

Assign unique name to each state. The state names apply only to the selected block.

To assign a name to a single state, enter the name between quotes; for example, 'velocity'.

To assign names to multiple states, enter a comma-delimited list surrounded by braces; for example, {'a', 'b', 'c'}. Each name must be unique. To assign state names with a variable that has been defined in the MATLAB workspace, enter the variable without quotes. The variable can be a character vector, cell, or structure.

Default: ' ' (no name)

State name must resolve to Simulink signal object

Require that state name resolve to Simulink signal object.

Default: Off

On

Require that state name resolve to Simulink signal object.

Off

Do not require that state name resolve to Simulink signal object.

State name enables this parameter. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than None.

Selecting this check box disables **Code generation storage class**.

Parameter: StateMustResolveToSignalObject

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Code generation storage class

Select state storage class for code generation.

Default: Auto

Auto

Auto is the appropriate storage class for states that you do not need to interface to external code.

StorageClass

Applies the storage class or custom storage class that you select from the list. For information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than Simulink.

State name enables this parameter.

Command-Line Information

Parameter: StateStorageClass

Type: character vector

Value: 'Auto' | 'ExportedGlobal' | 'ImportedExtern' | 'ImportedExternPointer' | 'SimulinkGlobal' | 'Custom'

Default: 'Auto'

TypeQualifier

Note **TypeQualifier** will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

Specify a storage type qualifier such as `const` or `volatile`.

- **Default:** ' ' (empty character vector)
- `const`
- `volatile`

Setting **Code generation storage class** to `ExportedGlobal`, `ImportedExtern`, `ImportedExternPointer`, or `SimulinkGlobal` enables this parameter. This parameter is hidden unless you previously set its value.

Parameter Name: `RTWStateStorageTypeQualifier`

Value Type: character vector

Default: ' ' (empty character vector)

Characteristics

Direct Feedthrough	The following ports support direct feedthrough: <ul style="list-style-type: none"> • Reset port • Integrator and filter initial condition port • Input port, for every integration method except Forward Euler
Sample Time	Specified in the Sample time parameter
Scalar Expansion	Supported for gain parameters P , I , and D and for filter coefficient N , and for setpoint weights b and c
States	Inherited from driving block and parameters
Dimensionalized	Yes
Zero-Crossing Detection	Yes (in continuous-time domain)

Introduced in R2009b

Polynomial

Perform evaluation of polynomial coefficients on input values

Library

Math Operations

Description

You define a set of polynomial coefficients in the form that the MATLAB `polyval` command accepts. The block evaluates $P(u)$ at each time step for the input u . The inputs and coefficients must be real. The inputs must be vector or scalar.

Data Type Support

The Polynomial block accepts real signals of type `double` or `single`. The **Polynomial coefficients** parameter must be of the same type as the inputs. The output data type is the same as the input data type.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Polynomial coefficients

Specify polynomial coefficients in MATLAB `polyval` form. The first coefficient corresponds to x^N and the remaining coefficients correspond to decreasing orders of x . The last coefficient represents the constant for the polynomial. See `polyval` in the MATLAB documentation for more information.

Examples

The `sldemo_boiler` model shows how to use the Polynomial block.

In the Boiler Plant model/digital thermometer subsystem, the Polynomial block models a first-order polynomial using the coefficients `[0.05 0.75]`:

This subsystem models a digital thermometer composed of a simple temperature sensor and an ADC. The transfer function of the sensor is:

$$V = .05 * T + 0.75$$
 for T in degrees C.

The conversion block inverts the combined transfer function of the sensor and ADC so that the output is an sfix(8) code representing T in degrees C.

Characteristics

Data Types	Double Single
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Prelookup

Compute index and fraction for Interpolation Using Prelookup block

Library

Lookup Tables

Description

The Prelookup block calculates the index and interval fraction that specify how its input value u relates to the breakpoint dataset. The Prelookup block works best with the Interpolation Using Prelookup block. Feed the resulting index and fraction values into an Interpolation Using Prelookup block to interpolate an n -dimensional table. These two blocks have distributed algorithms. When combined together, they perform the same operation as the integrated algorithm in the n -D Lookup Table block. However, the Prelookup and Interpolation Using Prelookup blocks offer greater flexibility and more efficient simulation and code generation than the n -D Lookup Table block. For more information, see “Efficiency of Performance”.

Supported Block Operations

To use the Prelookup block, you specify a set of breakpoint values directly on the dialog box or feed values into the `bp` input port. Typically, this breakpoint data set corresponds to one dimension of the table data in an Interpolation Using Prelookup block. The Prelookup block generates a pair of outputs for each input value u by calculating:

- The index of the breakpoint set element that is less than or equal to u and forms an interval containing u

- The interval fraction in the range $0 \leq f < 1$, representing the normalized position of u on the breakpoint interval between the index and the next index value for in-range input

For example, if the breakpoint data set is [0 5 10 20 50 100] and the input value u is 55, the index is 4 and the fractional value is 0.1. Labels for the index and interval fraction appear as k and f on the Prelookup block icon. The index value is zero based.

The interval fraction can be negative or greater than 1 for out-of-range input. See the documentation for the **Extrapolation method** block parameter for more information.

Data Type Support

The Prelookup block accepts real signals of numeric data types that Simulink supports, except Boolean. The Prelookup block supports fixed-point data types for signals and breakpoint data. You can also use a bus object as the output data type, which can help to simplify a model.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

- “Main Tab” on page 1-1153
- “Data Types Tab” on page 1-1160

Main Tab

Specification

Specify whether to enter data as explicit breakpoints, as parameters that generate evenly spaced breakpoints, or via a breakpoint object. If you set this parameter to:

- `Explicit values`, the **Source** and **Value** parameters are visible on the dialog box.
- `Even spacing`, the **First point**, **Spacing**, and **Number of points** parameters are visible on the dialog box.

- Breakpoint object, the **Name** parameter is visible on the dialog box.

Source

Specify whether to enter breakpoint data in the dialog box or to inherit the data from an input port. This parameter is available when **Specification** is set to `Explicit` values. If you set **Source** to:

- `Dialog`, enter breakpoint data in the text box under **Value**.
- `Input port`, verify that an upstream signal supplies breakpoint data to the `bp` input port. Each breakpoint data set must be a strictly monotonically increasing vector that contains two or more elements. For this option, your block inherits breakpoint attributes from the `bp` input port.

Value

If you set:

- **Specification** to `Explicit` values and **Source** to `Dialog`, explicitly specify the breakpoint data. Each breakpoint data set must be a strictly monotonically increasing vector that contains two or more elements. For this option, you specify breakpoint attributes on the **Data Types** pane.
- **Source** to `Input port`, verify that an upstream signal supplies table data to the `bp` input port. Each breakpoint data set must be a strictly monotonically increasing vector that contains two or more elements. For this option, you specify breakpoint attributes on the **Data Types** pane.

Click **Edit** to open the Lookup Table Editor (see “Edit Lookup Tables” in the Simulink documentation).

First point

Specify the first point in your evenly spaced breakpoint data. To enable this parameter, set **Specification** to `Even spacing`.

Spacing

Specify the spacing between points in your evenly spaced breakpoint data. To enable this parameter, set **Specification** to `Even spacing`.

Number of points

Specify the number of evenly spaced points in your breakpoint data. To enable this parameter, set **Specification** to `Even spacing`.

Name

If you set **Specification** to `Breakpoint` object, specify the name of an existing `Simulink.Breakpoint` object. An existing breakpoint object already contains breakpoint data.

Index search method

Select `Evenly spaced points`, `Linear search`, or `Binary search`. Each search method has speed advantages in different situations:

- For evenly spaced breakpoint sets (for example, 10, 20, 30, and so on), you achieve optimal speed by selecting `Evenly spaced points` to calculate table indices. This algorithm uses only the first two breakpoints of a set to determine the offset and spacing of the remaining points.
- For unevenly spaced breakpoint sets, follow these guidelines:
 - If input values for `u` do not vary significantly between time steps, selecting `Linear search` with **Begin index search using previous index result** produces the best performance.
 - If input values for `u` jump more than one or two table intervals per time step, selecting `Binary search` produces the best performance.

A suboptimal choice of index search method can lead to slow performance of models that rely heavily on lookup tables.

Note The generated code stores only the first breakpoint, the spacing, and the number of breakpoints when:

- The breakpoint data is not tunable.
 - The index search method is `Evenly spaced points`.
-

Output selection

Specify the signals (`index`, `fraction`, or both) that the block outputs. If you want the block to output the index and interval fraction, you can have it output either individual signals or a bus signal that includes both the index and fraction signals.

- `Index only` outputs just the index, without the fraction. Typical applications for this option include:

- Feeding a Direct Lookup Table (n-D) block, with no interpolation on the interval
- Feeding selection ports of a subtable selection for an Interpolation Using Prelookup block
- Performing nonlinear quantizations
- Index and fraction outputs the index and fraction as individual signals.
- Index and fraction as bus outputs a bus signal that includes the index and fraction signals. Using a bus for these signals:
 - Simplifies the model by tying these two related signals together.
 - Creates a testpoint `DpResult` structure for the AUTOSAR 4.0 library.
 - For the AUTOSAR 4.0 library, avoids the creation of extra copies during code generation when the Prelookup and Interpolation Using Prelookup blocks are in separate models.

Note Selecting `Index and fraction as bus` displays the **Output** parameter in the **Data Types** pane and sets the **Output** parameter to `Inherit: auto`. Change this default value to specify a user-defined bus object. For details about defining the bus object, see the **Output** parameter description.

Begin index search using previous index result

Select this check box when you want the block to start its search using the index found at the previous time step. For input values of `u` that change slowly with respect to the interval size, enabling this option can improve performance. Otherwise, the linear search and binary search methods can take longer, especially for large breakpoint sets.

Extrapolation method

Specify how to handle out-of-range values for the block input `u`. Options include:

- `Clip`

Block Input	Block Outputs
Less than the first breakpoint	<ul style="list-style-type: none"> • Index of the first breakpoint (for example, 0) • Interval fraction of 0

Block Input	Block Outputs
Greater than the last breakpoint	<ul style="list-style-type: none"> • Index of the next-to-last breakpoint • Interval fraction of 1

Suppose the range is [1 2 3] and you select this option. If u is 0.5, the index is 0 and the interval fraction is 0. If u is 3.5, the index is 1 and the interval fraction is 1.

- Linear

Block Input	Block Outputs
Less than the first breakpoint	<ul style="list-style-type: none"> • Index of the first breakpoint (for example, 0) • Interval fraction that represents the linear distance from u to the first breakpoint
Greater than the last breakpoint	<ul style="list-style-type: none"> • Index of the next-to-last breakpoint • Interval fraction that represents the linear distance from the next-to-last breakpoint to u

Suppose the range is [1 2 3] and you select this option. If u is 0.5, the index is 0 and the interval fraction is -0.5. If u is 3.5, the index is 1 and the interval fraction is 1.5.

Note The Prelookup block supports linear extrapolation only when all of these conditions apply:

- The input u , breakpoint data, and fraction output use floating-point data types.
 - The index uses a built-in integer data type.
-

Use last breakpoint for input at or above upper limit

Specify how to index input values of u that are greater than or equal to the last breakpoint. The index value is zero-based. When input equals the last breakpoint, block outputs differ as follows:

Check Box	Block Outputs
Selected	<ul style="list-style-type: none">• Index of the last element in the breakpoint data set• Interval fraction of 0
Cleared	<ul style="list-style-type: none">• Index of the next-to-last breakpoint• Interval fraction of 1

This check box is visible only when:

- **Output only the index** is cleared.
- **Extrapolation method** is `Clip`.

However, when **Output only the index** is selected and **Extrapolation method** is `Clip`, the block behaves as if this check box is selected even though it is invisible.

Tip When you select **Use last breakpoint for input at or above upper limit** for a Prelookup block, you must also select **Valid index input may reach last index** for the Interpolation Using Prelookup block to which it connects. This action allows the blocks to use the same indexing convention when accessing the last elements of their breakpoint and table data sets.

Diagnostic for out-of-range input

Specify whether to produce a warning or error when the input `u` is out of range. Options include:

- `None` — Simulink software takes no action.
- `Warning` — Simulink software displays a warning and continues the simulation.
- `Error` — Simulink software terminates the simulation and displays an error.

Remove protection against out-of-range input in generated code

Specify whether or not to include code that checks for out-of-range breakpoint inputs.

Check Box	Result	When to Use
Selected	Generated code does not include conditional statements to check for out-of-range breakpoint inputs. When the input k or f is out-of-range, it may cause undefined behavior for generated code and simulations using accelerator mode.	For code efficiency
Cleared	Generated code includes conditional statements to check for out-of-range breakpoint inputs.	For safety-critical applications

If your input is not out-of-range, you can select the **Remove protection against out-of-range index in generated code** check box for code efficiency. By default, this check box is cleared. For safety-critical applications, do not select this check box. If you want to select the **Remove protection against out-of-range index in generated code** check box, first check that your model inputs are in range. For example:

- 1 Clear the **Remove protection against out-of-range index in generated code** check box.
- 2 Set the **Diagnostic for out-of-range input** parameter to `Error`.
- 3 Simulate the model in normal mode.
- 4 If there are out-of-range errors, fix them to be in range and run the simulation again.
- 5 When the simulation no longer generates out-of-range input errors, select the **Remove protection against out-of-range index in generated code** check box.

Note When you select the **Remove protection against out-of-range index in generated code** check box and the input `k` or `f` is out-of-range, the behavior is undefined for generated code and simulations using accelerator mode.

Depending on your application, you can run the following Model Advisor checks to verify the usage of this check box:

- **By Product > Embedded Coder > Identify lookup table blocks that generate expensive out-of-range checking code**
- **By Product > Simulink Check > Modeling Standards > DO-178C/DO-331 Checks > Check usage of lookup table blocks**

For more information about the Model Advisor, see “Run Model Checks” in the Simulink documentation.

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Data Types Tab

Note The parameters for breakpoint attributes (data type, minimum, and maximum) are not available when you set **Source** to `Input port`. In this case, the block inherits all breakpoint attributes from the `bp` input port.

Breakpoint > Data Type

Specify the breakpoint data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the breakpoint data type.

See “Specify Data Types Using Data Type Assistant” in the *Simulink User’s Guide* for more information.

Tip Specify a breakpoint data type different from the data type of input *u* for these cases:

- Lower memory requirement for storing breakpoint data that uses a smaller type than the input signal *u*
- Sharing of prescaled breakpoint data between two Prelookup blocks with different data types for input *u*
- Sharing of custom storage breakpoint data in the generated code for blocks with different data types for input *u*

Breakpoint > Minimum

Specify the minimum value that the breakpoint data can have. The default value is [] (unspecified).

Breakpoint > Maximum

Specify the maximum value that the breakpoint data can have. The default value is [] (unspecified).

Index > Data Type

Note This parameter displays only when you set **Output selection** on the **Main** tab to `Index and fraction` or `Index only`.

Specify a data type that can index all elements in the breakpoint data set. You can:

- Select a built-in integer data type from the list.
- Specify an integer data type using a fixed-point representation.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the index data type.

See “Specify Data Types Using Data Type Assistant” in the *Simulink User's Guide* for more information.

Fraction > Data Type

Note This parameter displays only when you set **Output selection** on the **Main** tab to `Index and fraction`

Specify the data type of the interval fraction. You can:

- Select a built-in data type from the list.
- Specify data type inheritance through an internal rule.
- Specify a fixed-point data type using the [Slope Bias] or binary-point-only scaling representation.
 - If you use the [Slope Bias] representation, the scaling must be trivial — that is, the slope is 1 and the bias is 0.
 - If you use the binary-point-only representation, the fixed power-of-two exponent must be less than or equal to zero.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the fraction data type.

See “Specify Data Types Using Data Type Assistant” in the *Simulink User's Guide* for more information.

Output

Note This parameter displays only when you set **Output selection** on the **Main** tab to `Index and fraction as bus`.

Output a nonvirtual bus. Use the `Bus: <object name>` template to specify a bus object. Replace `<object name>` with the name of a bus object that contains the index and fraction signals.

- The bus object must contain two elements. The first element corresponds to the index signal and the second to the fraction signal.
- The index and fraction bus element signals cannot be bus signals.
- The data type and the complexity of the bus elements must meet the same constraints that apply to the index and fraction signals if you set **Output selection** to `Index and fraction`.

To create the bus object with the index and fraction bus elements, use MATLAB code similar to this, customizing the bus object name and the names and data types of the bus elements.

```
% Bus object: kfBus
elems(1) = Simulink.BusElement;
elems(1).Name = 'Index';
elems(1).DataType = 'int8';

elems(2) = Simulink.BusElement;
elems(2).Name = 'Fraction';
elems(2).DataType = 'double';

kfBus = Simulink.Bus;
kfBus.Elements = elems;
clear elems;
```

Alternatively, you can use the Bus Editor to create or modify the bus object to use with the Prelookup block.

If you feed the bus output signal from this block to an Interpolation Using Prelookup block, select the **Require index and fraction as bus** check box in that block.

Note Using the Fixed-Point Tool data type override option overrides bus objects with new bus objects that replace fixed-point data types with floating-point data types.

Overridden bus objects used with the Prelookup block can cause an error because the block does not accept floating-point data types for the first element in the bus.

If you encounter this issue, using the **Fix** button redefines the original bus object to protect it from being overridden. For example, suppose you define the first element of the bus object to be an `int32`.

```
myBus.Elements(1).DataType  
  
int32
```

Clicking the **Fix** button redefines the first bus element to be:

```
myBus.Elements(1).DataType = 'fixdt('int32','DataTypeOverride','Off')
```

Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Integer rounding mode

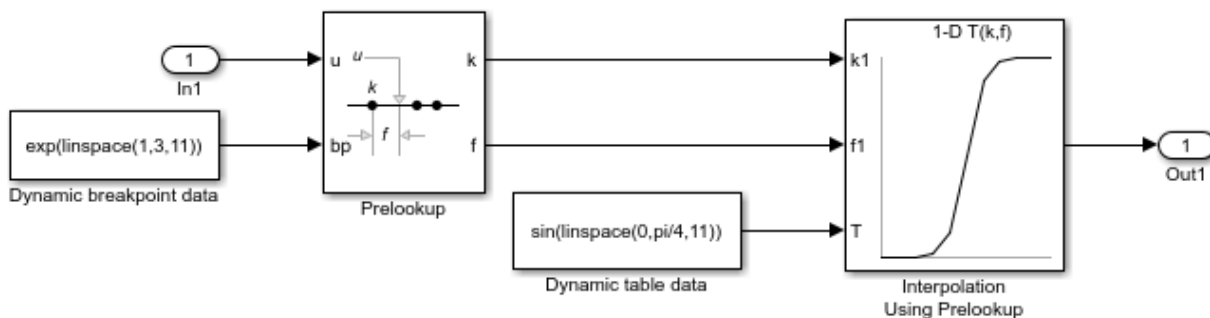

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer) in the Simulink Fixed Pointo documentation.

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Examples

Prelookup with External Breakpoint Specification

In the following model, a Constant block feeds the breakpoint dataset to the `bp` input port of the Prelookup block.

The Prelookup block inherits the following breakpoint attributes from the `bp` input port:

Breakpoint Attribute	Value
Minimum	-Inf
Maximum	Inf
Data type	single

Similarly, a Constant block feeds the table data values to the `T` input port of the Interpolation Using Prelookup block, which inherits the following table attributes:

Table Attribute	Value
Minimum	-Inf
Maximum	Inf
Data type	single

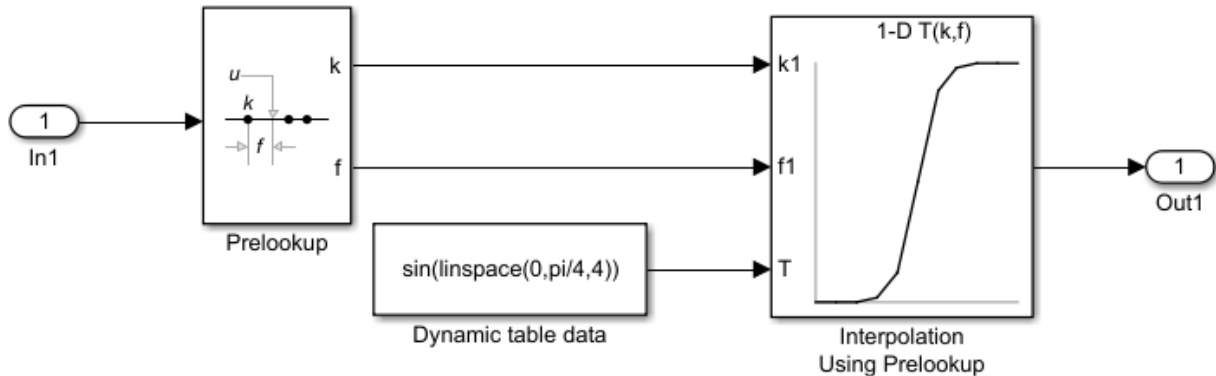

Simulink uses double-precision, floating-point data to perform the computations in this model. However, the model stores the breakpoint and table data as single-precision, floating-point data. Using a lower-precision data type to store breakpoint and table data reduces the memory requirement.

Prelookup with Even Spaced Breakpoint Specification

In this model, you specify evenly spaced breakpoint data to the Prelookup block.

The **Breakpoint Specification** parameter is set to `Even Spacing`. The parameters **First point**, **Spacing**, and **Number of points** are set to 25, 12, and 4 respectively. Specifying these parameters creates four evenly spaced breakpoints: [25, 37, 49, 61].

Specifying even spacing is an alternative way to specify breakpoints that are evenly spaced. You can also set **Breakpoint Specification** to `Explicit` values and set **Value** to `[25:12:61]`.

Simulink uses double-precision, floating-point data to perform the computations in this model. However, the model stores the breakpoints and table data as double.

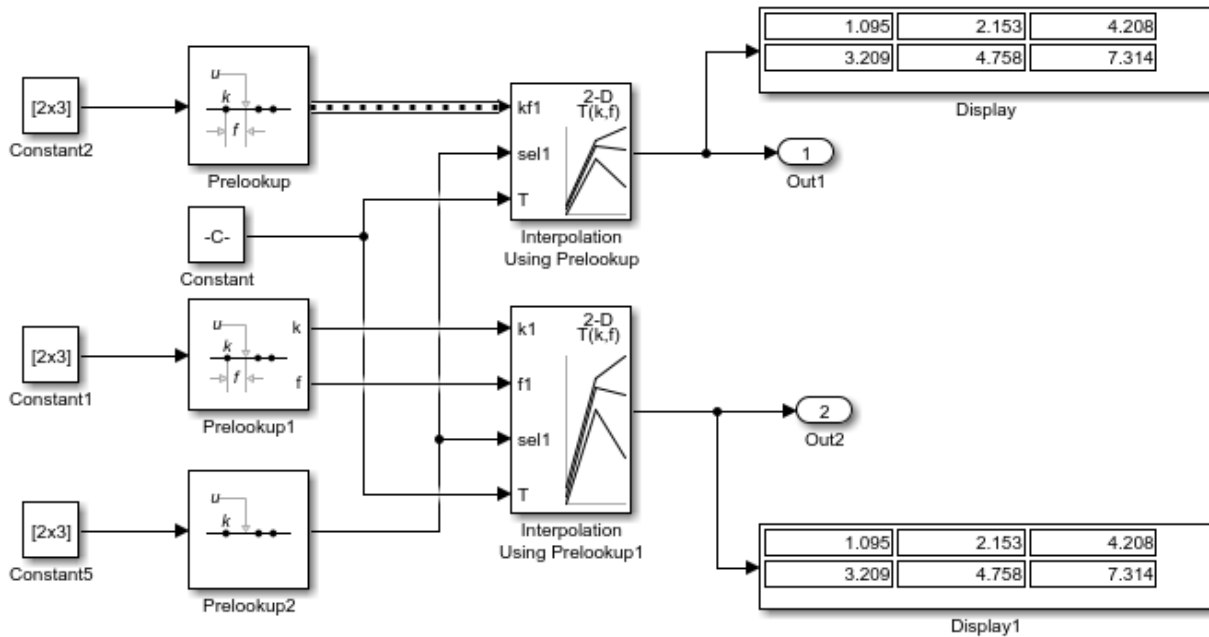

For other examples, see “Prelookup and Interpolation Blocks” in the Simulink documentation.

Use a Bus for Index and Fraction

You can use a bus object to specify the index (k) and fraction (f) in the Prelookup block and then use that bus as input to an Interpolation Using Prelookup block. This example shows how to use a bus signal and how to get the same results without using a bus object.

Open the model and simulate it.

```
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
    'examples', 'ex_prelookup_bus.slx')))
sim('ex_prelookup_bus')
```

At the top of the model, open the Prelookup block parameters dialog box. In the **Main** tab, note that **Output selection** is set to Index and fraction as bus.

In the **Data Types** tab, note that **Output** is set to Bus: myBus.

In the Simulink Editor, select **File > Model Properties** and open the **Callbacks** tab. The code defines the bus object myBus, which specifies the index as the first bus element and the fraction as the second element.

In the Interpolation Using Prelookup block parameters dialog box, in the **Main** tab, note that **Require index and fraction as bus** check box is selected. That option configures the block to use the bus output from the Prelookup block.

Characteristics

Interpolation Using Prelookup

Introduced in R2006b

Probe

Output signal attributes, including width, dimensionality, sample time, and complex signal flag

Library

Signal Attributes

Description

The Probe block outputs selected information about the signal on its input. The block can output the input signal's width, dimensionality, sample time, and a flag indicating whether the input is a complex-valued signal. The block has one input port. The number of output ports depends on the information that you select for probing, that is, signal dimensionality, sample time, and/or complex signal flag. Each probed value is output as a separate signal on a separate output port. The block accepts real or complex-valued signals of any built-in data type. It outputs signals of type `double`. During simulation, the block icon displays the probed data.

Data Type Support

The Probe block accepts signals of the following data types:

- Floating point
- Built-in integer

- Fixed point
- Boolean
- Enumerated (input only)
- Bus object

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

You can use an array of buses as an input signal to a Probe block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

Parameters

Probe width

Select to output the width, or number of elements, of the probed signal.

Probe sample time

Select to output the sample time of the probed signal. The output is a two-element vector that specifies the period and offset of the sample time, respectively. See “Specify Sample Time” for more information.

Detect complex signal

Select to output 1 if the probed signal is complex; otherwise, 0.

Probe signal dimensions

Select to output the dimensions of the probed signal.

Note The Probe block ignores the **Data type override** setting of the Fixed-Point Tool.

Data type for width

Select the output data type for the width information.

Data type for sample time

Select the output data type for the sample time information.

Data type for signal complexity

Select the output data type for the complexity information.

Data type for signal dimensions

Select the output data type for the dimensions information.

Note For **Data type for width**, **Data type for sample time**, and **Data type for signal dimensions**, the Boolean data type is not supported. Furthermore, if you select Same as input in any of these drop-down lists, and the block's input signal data type is Boolean, when you simulate your model, you see an error.

Examples

The `sldemo_fuelsys` model shows how you can use the Probe block.

In the `fuel_rate_control/validate_sample_time` subsystem, the Probe block determines the sample time of the input signal to verify that it matches the assumed value of the design:

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated Bus
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No

Code Generation	Yes
-----------------	-----

Introduced before R2006a

Product

Multiply and divide scalars and nonscalars or multiply and invert matrices

Library

Math Operations

Description

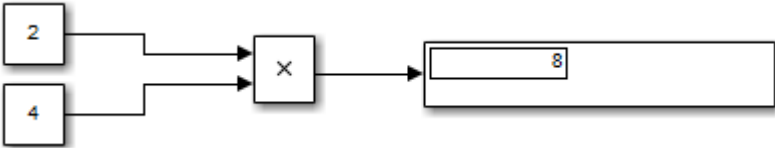

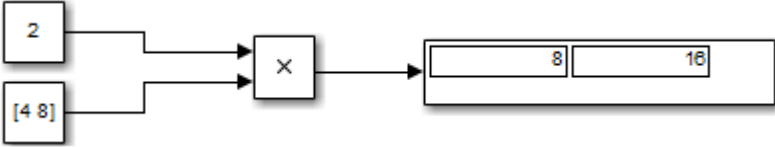

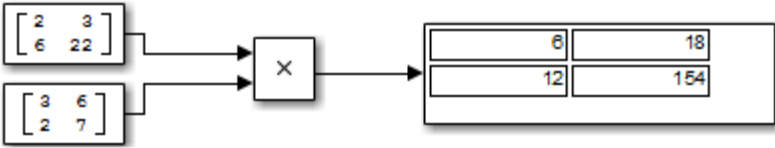

The Divide and Product of Elements blocks are variants of the Product block.

- For information on the Divide block, see Divide.
- For information on the Product of Elements block, see Product of Elements.

The Product block outputs the result of multiplying two inputs: two scalars, a scalar and a nonscalar, or two nonscalars that have the same dimensions. The default parameter values that specify this behavior are:

- **Multiplication:** `Element-wise (.*)`
- **Number of inputs:** 2

The following table shows the output of the Product block for example inputs using default block parameter values.

Inputs and Behavior	Example
<p>Scalar X Scalar</p> <p>Output the product of the two inputs.</p>	
<p>Scalar X Nonscalar</p> <p>Output a nonscalar having the same dimensions as the input nonscalar. Each element of the output nonscalar is the product of the input scalar and the corresponding element of the input nonscalar.</p>	
<p>Nonscalar X Nonscalar</p> <p>Output a nonscalar having the same dimensions as the inputs. Each element of the output is the product of corresponding elements of the inputs.</p>	

The Product block (or the Divide block or Product of Elements block, if appropriately configured) can:

- Numerically multiply and divide any number of scalar, vector, or matrix inputs
- Perform matrix multiplication and division on any number of matrix inputs

The Product block performs scalar or matrix multiplication, depending on the value of the **Multiplication** parameter. The block accepts one or more inputs, depending on the **Number of inputs** parameter. The **Number of inputs** parameter also specifies the operation to perform on each input.

The Product block can input any combination of scalars, vectors, and matrices for which the operation to perform has a mathematically defined result. The block performs the specified operations on the inputs, then outputs the result.

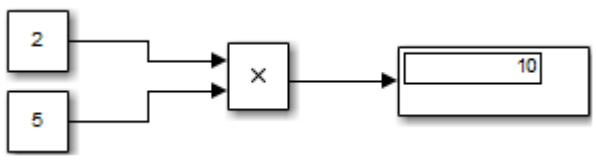

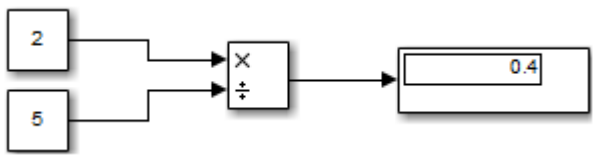

The Product block has two modes: *Element-wise mode*, which processes nonscalar inputs element by element, and *Matrix mode*, which processes nonscalar inputs as matrices. The next two sections describe these two modes.

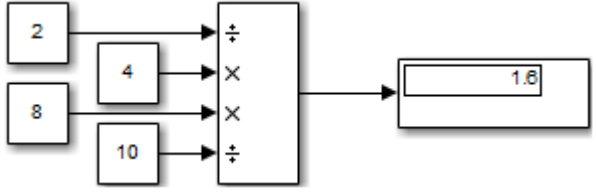

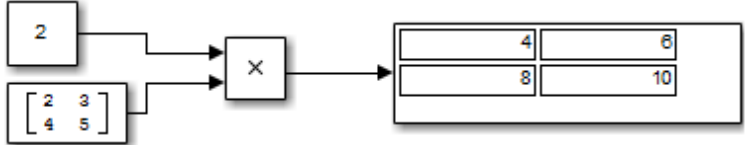

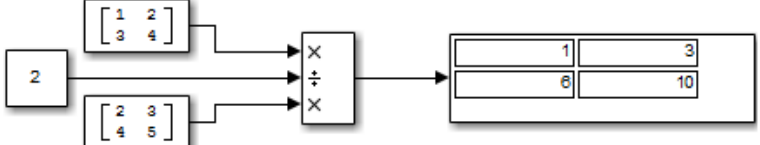

Element-wise Mode

When the value of the **Multiplication** parameter is `Element-wise (.*)`, the Product block is in *Element-wise mode*, in which it operates on the individual numeric elements of any nonscalar inputs. The MATLAB equivalent is the `.*` operator. In element-wise mode, the Product block can perform a variety of multiplication, division, and arithmetic inversion operations.

The value of the **Number of inputs** parameter controls both how many inputs exist and whether each is multiplied or divided to form the output. When the Product block in Element-wise mode has only one input, it is functionally equivalent to a Product of Elements block. When the block has multiple inputs, any nonscalar inputs must have identical dimensions, and the block outputs a nonscalar with those dimensions. To calculate the output, the block first expands any scalar input to a nonscalar that has the same dimensions as the nonscalar inputs.

This table shows the output of the Product block for example inputs, using the indicated values for the **Number of inputs** parameter.

Parameter Values	Examples
Number of inputs: 2	 <p>A block diagram showing two input boxes containing the numbers 2 and 5. Arrows from both boxes point to a central square block containing a multiplication symbol (×). An arrow from this block points to a rectangular output box containing the number 10.</p>
Number of inputs: */	 <p>A block diagram showing two input boxes containing the numbers 2 and 5. Arrows from both boxes point to a central square block containing a division symbol (÷). An arrow from this block points to a rectangular output box containing the number 0.4.</p>

Parameter Values	Examples
Number of inputs: /**/	
Number of inputs: **	
Number of inputs: */*	

Matrix Mode

When the value of the **Multiplication** parameter is `Matrix(*)`, the Product block is in *Matrix mode*, in which it processes nonscalar inputs as matrices. The MATLAB equivalent is the `*` operator. In Matrix mode, the Product block can invert a single square matrix, or multiply and divide any number of matrices that have dimensions for which the result is mathematically defined.

The value of the **Number of inputs** parameter controls both how many inputs exist and whether each input matrix is multiplied or divided to form the output. The syntax of **Number of inputs** is the same as in Element-wise mode. The difference between the modes is in the type of multiplication and division that occur.

Expected Differences Between Simulation and Code Generation

For element-wise operations on complex floating-point inputs, simulation and code generation results might differ in near-overflow cases. Although **complex numbers** is selected and **non-finite numbers** is not selected on the **Code Generation > Interface**

pane of the Configuration Parameters dialog box, the code generator does not emit special case code for intermediate overflows. This method improves the efficiency of embedded operations for the general case that does not include extreme values. If the inputs might include extreme values, please manage these cases explicitly.

The generated code might not produce the exact same pattern of NaN and inf values as simulation when these values are mathematically meaningless. For example, if the simulation output contains a NaN, output from the generated code also contains a NaN, but not necessarily in the same place.

Data Type Support

The Product block accepts real or complex signals of any numeric data type that Simulink supports, including fixed-point data types. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

The Product block does not support numeric division for complex signals with `boolean` or fixed-point data types. For other types, the block accepts complex signals as divisors only when the input and output signals all specify the same built-in data type. In this case, however, the block ignores its specified rounding mode.

The Product block accepts multidimensional signals when operating in Element-wise mode, but not when operating in Matrix mode. See “Signal Dimensions”, “Element-wise Mode” on page 1-1176, and “Matrix Mode” on page 1-1177 for more information.

Parameters

Number of inputs

Control two properties of the block:

- The number of input ports on the block
- Whether each input is multiplied or divided into the output

Default: 2 for Product block, */ for Divide block, and * for Product of Elements block

- **1 or * or /**

Has one input. In element-wise mode, processes the input as described for the Product of Elements block. In matrix mode, if the parameter value is 1 or *, the block outputs the input value. If the value is /, the input must be a square matrix (including a scalar as a degenerate case) and the block outputs the matrix inverse. See “Element-wise Mode” on page 1-1176 and “Matrix Mode” on page 1-1177 for more information.

- **Integer value > 1**

Has the number of inputs given by the integer value. The inputs are multiplied together in element-wise mode or matrix mode, as specified by the **Multiplication** parameter. See “Element-wise Mode” on page 1-1176 and “Matrix Mode” on page 1-1177 for more information.

- **Unquoted string of two or more * and / characters**

Has the number of inputs given by the length of the character vector. Each input that corresponds to a * character is multiplied into the output. Each input that corresponds to a / character is divided into the output. The operations occur in element-wise mode or matrix mode, as specified by the **Multiplication** parameter. See “Element-wise Mode” on page 1-1176 and “Matrix Mode” on page 1-1177 for more information.

Setting **Number of inputs** to * and selecting `Element-wise(.*)` for **Multiplication** enables the **Multiply over** parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Multiplication

Specify whether the Product block operates in Element-wise mode or Matrix mode.

Default: `Element-wise(.*)`

`Element-wise(.*)`

Operate in Element-wise mode.

`Matrix(*)`

Operate in Matrix mode.

Selecting `Element-wise (.*)` and setting **Number of inputs** to `*` enable the following parameter:

- **Multiply over**

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Multiply over

Affect multiplication on matrix input.

Default: All dimensions

All dimensions

Output a scalar that is product of all elements of the matrix, or the product of their inverses, depending on the value of **Number of inputs**.

Specified dimension

Output a vector, the composition of which depends on the value of the **Dimension** parameter.

- Enable this parameter by selecting `Element-wise (.*)` for **Multiplication** and setting **Number of inputs** to `*` or `1` or `/`.
- Setting this parameter to `Specified dimension` enables the **Dimension** parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Dimension

Affect multiplication on matrix input.

Default: 1

Minimum: 1

Maximum: 2

1

Output a vector that contains an element for each column of the input matrix.

2

Output a vector that contains an element for each row of the input matrix.

Each element of the output vector contains the product of all elements in the corresponding column or row of the input matrix, or the product of the inverses of those elements, depending on the value of **Number of inputs**:

- 1 or *

Multiply the values of the column or row elements

- /

Multiply the inverses of the column or row elements

Enable this parameter by selecting `Specified dimension` for **Multiply over**.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Require all inputs to have the same data type

Require that all inputs have the same data type.

Default: Off

On

Require that all inputs have the same data type.

Off

Do not require that all inputs have the same data type.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Output minimum

Lower value of the output range that Simulink checks.

Default: [] (unspecified)

Specify this number as a finite, real, double, scalar value.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Parameter: OutMin

Type: character vector

Value: ' [] '

Default: ' [] '

Output maximum

Upper value of the output range that Simulink checks.

Default: [] (unspecified)

Specify this number as a finite, real, double, scalar value.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Note **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Parameter: OutMax

Type: character vector

Value: ' [] '

Default: ' [] '

Output data type

Specify the output data type.

Default: Inherit: Inherit via internal rule

Inherit: Inherit via internal rule

Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target

hardware. If you change the embedded target settings, the data type selected by the internal rule might change. It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use the simple choice of `Inherit: Same as first input`.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
- To specify your own inheritance rule, use `Inherit: Inherit via back propagation` and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.

`Inherit: Inherit via back propagation`

Use data type of the driving block.

`Inherit: Same as first input`

Use data type of the first input signal.

`double`

Output data type is `double`.

`single`

Output data type is `single`.

`int8`

Output data type is `int8`.

`uint8`

Output data type is `uint8`.

`int16`

Output data type is `int16`.

`uint16`

Output data type is `uint16`.

`int32`

Output data type is `int32`.

```
uint32
```

Output data type is `uint32`.

```
fixdt(1,16,0)
```

Output data type is fixed point `fixdt(1,16,0)`.

```
fixdt(1,16,2^0,0)
```

Output data type is fixed point `fixdt(1,16,2^0,0)`.

<data type expression>

Use a data type object, for example, `Simulink.NumericType`.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

For more information, see “Control Signal Data Types”.

Show data type assistant

Display the **Data Type Assistant**.

The **Data Type Assistant** helps you set the **Output data type** parameter.

For more information, see “Control Signal Data Types”.

Mode

Select the category of data to specify.

Default: `Inherit`

`Inherit`

Inheritance rules for data types. Selecting `Inherit` enables a second menu/text box to the right. Select one of the following choices:

- `Inherit via internal rule (default)`
- `Inherit via back propagation`

- Same as first input

Built in

Built-in data types. Selecting `Built in` enables a second menu/text box to the right. Select one of the following choices:

- `double (default)`
- `single`
- `int8`
- `uint8`
- `int16`
- `uint16`
- `int32`
- `uint32`

Fixed point

Fixed-point data types.

Expression

Expressions that evaluate to data types. Selecting `Expression` enables a second menu/text box to the right, where you can enter the expression.

Clicking the **Show data type assistant** button enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specify Data Types Using Data Type Assistant”.

Data type override

Specify data type override mode for this signal.

Default: `Inherit`

Inherit

Inherits the data type override setting from its context, that is, from the block, `Simulink.Signal` object or Stateflow chart in Simulink that is using the signal.

Off

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

This parameter appears only when the **Mode** is `Built in` or `Fixed point`.

Signedness

Specify whether you want the fixed-point data as signed or unsigned.

Default: Signed

Signed

Specify the fixed-point data as signed.

Unsigned

Specify the fixed-point data as unsigned.

Selecting **Mode** > `Fixed point` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Word length

Specify the bit size of the word that holds the quantized integer.

Default: 16

Minimum: 0

Maximum: 32

Selecting **Mode** > Fixed point enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

Default: Best precision

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

Best precision

Specify best-precision values.

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting Slope and bias enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

For more information, see “Specifying a Fixed-Point Data Type”.

Fraction length

Specify fraction length for fixed-point data type.

Default: 0

Binary points can be positive or negative integers.

Selecting **Scaling** > `Binary point` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Slope

Specify slope for the fixed-point data type.

Default: 2^0

Specify any positive real number.

Selecting **Scaling** > `Slope and bias` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Bias

Specify bias for the fixed-point data type.

Default: 0

Specify any real number.

Selecting **Scaling** > `Slope` and `bias` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

Default: Off

On

Locks the output data type setting for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change the output data type setting for this block.

Parameter: `LockScale`

Type: character vector

Value: 'off' | 'on'

Default: 'off'

For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Integer rounding mode

Specify the rounding mode for fixed-point operations.

Default: `Floor`

`Ceiling`

Rounds positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

Floor

Rounds positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

Simplest

Chooses between rounding toward floor and rounding toward zero to generate rounding code that is as efficient as possible.

Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

For more information, see “Rounding” (Fixed-Point Designer).

Saturate on integer overflow

Specify whether overflows saturate.

Default: Off

On

Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Off

Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Parameter: SaturateOnIntegerOverflow

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Product of Elements

Copy or invert one scalar input, or collapse one nonscalar input

Library

Math Operations

Description

The Divide and Product blocks are variants of the Product of Elements block.

- For information on the Divide block, see [Divide](#).
- For information on the Product block, see [Product](#).

The Product of Elements block inputs one scalar, vector, or matrix. You can use the block to:

- Copy a scalar input unchanged
- Invert a scalar input (divide 1 by it)
- Collapse a vector or matrix to a scalar by multiplying together all elements or taking successive inverses of the elements
- Collapse a matrix to a vector by multiplying together the elements of each row or column or taking successive inverses of the elements of each row or column

The Product of Elements block is functionally a Product block that has two preset parameter values:

- **Multiplication:** `Element-wise(.*)`

- **Number of inputs:** *

Setting non-default values for either of those parameters can change a Product of Elements block to be functionally equivalent to a Product block or a Divide block. See the documentation of those two blocks for more information.

Algorithm

The Product of Elements block uses the following algorithms to perform element-wise operations on inputs of floating-point, built-in integer, and fixed-point types:

Input	Element-Wise Operation	Algorithm
Real scalar, u	Multiplication	$y = u$
	Division	$y = 1/u$
Real vector or matrix, with elements $u_1, u_2, u_3, \dots, u_N$	Multiplication	$y = u_1 * u_2 * u_3 * \dots * u_N$
	Division	$y = (((1/u_1) / u_2) / u_3) \dots / u_N$
Complex scalar, u	Multiplication	$y = u$
	Division	$y = 1/u$
Complex vector or matrix, with elements $u_1, u_2, u_3, \dots, u_N$	Multiplication	$y = u_1 * u_2 * u_3 * \dots * u_N$
	Division	$y = (((1/u_1) / u_2) / u_3) \dots / u_N$

If the specified dimension for element-wise multiplication or division is a row or column of a matrix, the algorithm applies to that row or column. For example, consider the following model:

The top Product of Elements block collapses the matrix input to a scalar by taking successive inverses of the four elements:

- $y = (((1/2+i)/3)/4-i)/5)$

The bottom Product of Elements block collapses the matrix input to a vector by taking successive inverses along the second dimension:

- $y(1) = ((1/2+i)/3)$
- $y(2) = ((1/4-i)/5)$

Parameters

Number of inputs

Control two properties of the block:

- The number of input ports on the block
- Whether each input is multiplied or divided into the output

Default: *

- **1 or ***
 - Copies a scalar input unchanged
 - Collapses a vector input to a scalar by multiplying all elements together
 - Collapses a matrix input to a scalar or vector by multiplying elements together based on the **Multiply over** parameter

For more information, see “Algorithm” on page 1-1195.

- **/**
 - Outputs the arithmetic inverse of a scalar input
 - Collapses a vector input to a scalar by taking successive inverses of the elements
 - Collapses a matrix input to a scalar or vector by taking successive inverses of elements based on the **Multiply over** parameter

For more information, see “Algorithm” on page 1-1195.

- **Integer value > 1**

Has the number of inputs given by the integer value. The block becomes a product block and the input are multiplied together in element-wise mode or matrix mode, as specified by the **Multiplication** parameter. See “Element-wise Mode” on page 1-1176 and “Matrix Mode” on page 1-1177 in the Product documentation for more information.

- **Unquoted string of two or more * and / characters**

Has the number of inputs given by the length of the character vector. The block becomes a product or divide block and multiplies each input that corresponds to a * character into the output. Each input that corresponds to a / character is divided into the output. The operations occur in Element-wise mode or Matrix mode, as specified by the **Multiplication** parameter. See “Element-wise Mode” on page 1-1176 and “Matrix Mode” on page 1-1177 in the Product block reference page for more information.

Setting **Number of inputs** to * and selecting `Element-wise(.*)` for **Multiplication** enables the following **Multiply over** parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Multiplication

Specify whether the Product block operates in Element-wise mode or Matrix mode.

Default: `Element-wise(.*)`

`Element-wise(.*)`

Operate in Element-wise mode.

`Matrix(*)`

Operate in Matrix mode.

Selecting `Element-wise(.*)` and setting **Number of inputs** to * enable the following parameter:

- **Multiply over**

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Multiply over

Affect multiplication on matrix input.

Default: All dimensions

All dimensions

Output a scalar that is product of all elements of the matrix, or the product of their inverses, depending on the value of **Number of inputs**.

Specified dimension

Output a vector, the composition of which depends on the value of the **Dimension** parameter.

- Enable this parameter by selecting `Element-wise (.*)` for **Multiplication** and setting **Number of inputs** to `*` or `1` or `/`.
- Setting this parameter to `Specified dimension` enables the **Dimension** parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Dimension

Affect multiplication on matrix input.

Default: 1

Minimum: 1

Maximum: 2

1

Output a vector that contains an element for each column of the input matrix.

2

Output a vector that contains an element for each row of the input matrix.

Each element of the output vector contains the product of all elements in the corresponding column or row of the input matrix, or the product of the inverses of those elements, depending on the value of **Number of inputs**:

- 1 or *

Multiply the values of the column or row elements

- /

Multiply the inverses of the column or row elements

Enable this parameter by selecting `Specified dimension` for **Multiply over**.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Require all inputs to have the same data type

Require that all inputs have the same data type.

Default: Off

On

Require that all inputs have the same data type.

Off

Do not require that all inputs have the same data type.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Output minimum

Lower value of the output range that Simulink checks.

Default: [] (unspecified)

Specify this number as a finite, real, double, scalar value.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Parameter: OutMin

Type: character vector

Value: '[]'

Default: '[]'

Output maximum

Upper value of the output range that Simulink checks.

Default: [] (unspecified)

Specify this number as a finite, real, double, scalar value.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Parameter: OutMax

Type: character vector

Value: ' [] '

Default: ' [] '

Output data type

Specify the output data type.

Default: Inherit: Inherit via internal rule

Inherit: Inherit via internal rule

Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet

your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use the simple choice of `Inherit: Same as first input`.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
- To specify your own inheritance rule, use `Inherit: Inherit via back propagation` and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.

`Inherit: Inherit via back propagation`

Use data type of the driving block.

`Inherit: Same as first input`

Use data type of the first input signal.

`double`

Output data type is double.

`single`

Output data type is single.

`int8`

Output data type is int8.

`uint8`

Output data type is uint8.

`int16`

Output data type is int16.

`uint16`

Output data type is uint16.

`int32`

Output data type is int32.

`uint32`

Output data type is uint32.

```
fixdt(1,16,0)
```

Output data type is fixed point `fixdt(1,16,0)`.

```
fixdt(1,16,2^0,0)
```

Output data type is fixed point `fixdt(1,16,2^0,0)`.

<data type expression>

Use a data type object, for example, `Simulink.NumericType`.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

For more information, see “Control Signal Data Types”.

Show data type assistant

Display the **Data Type Assistant**.

The **Data Type Assistant** helps you set the **Output data type** parameter.

For more information, see “Control Signal Data Types”.

Mode

Select the category of data to specify.

Default: `Inherit`

`Inherit`

Inheritance rules for data types. Selecting `Inherit` enables a second menu/text box to the right. Select one of the following choices:

- `Inherit via internal rule (default)`
- `Inherit via back propagation`
- `Same as first input`

Built in

Built-in data types. Selecting `Built in` enables a second menu/text box to the right. Select one of the following choices:

- `double` (default)
- `single`
- `int8`
- `uint8`
- `int16`
- `uint16`
- `int32`
- `uint32`

Fixed point

Fixed-point data types.

Expression

Expressions that evaluate to data types. Selecting `Expression` enables a second menu/text box to the right, where you can enter the expression.

Clicking the **Show data type assistant** button enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specify Data Types Using Data Type Assistant”.

Data type override

Specify data type override mode for this signal.

Default: `Inherit`

`Inherit`

Inherits the data type override setting from its context, that is, from the block, `Simulink.Signal` object or Stateflow chart in Simulink that is using the signal.

Off

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

This parameter appears only when the **Mode** is `Built in` or `Fixed point`.

Signedness

Specify whether you want the fixed-point data as signed or unsigned.

Default: Signed

Signed

Specify the fixed-point data as signed.

Unsigned

Specify the fixed-point data as unsigned.

Selecting **Mode** > `Fixed point` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Word length

Specify the bit size of the word that holds the quantized integer.

Default: 16

Minimum: 0

Maximum: 32

Selecting **Mode** > `Fixed point` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

Default: `Best precision`

`Binary point`

Specify binary point location.

`Slope and bias`

Enter slope and bias.

`Best precision`

Specify best-precision values.

Selecting **Mode** > `Fixed point` enables this parameter.

Selecting `Binary point` enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting `Slope and bias` enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

For more information, see “Specifying a Fixed-Point Data Type”.

Fraction length

Specify fraction length for fixed-point data type.

Default: 0

Binary points can be positive or negative integers.

Selecting **Scaling** > `Binary point` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Slope

Specify slope for the fixed-point data type.

Default: 2^0

Specify any positive real number.

Selecting **Scaling** > `Slope and bias` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Bias

Specify bias for the fixed-point data type.

Default: 0

Specify any real number.

Selecting **Scaling** > `Slope and bias` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

Default: Off

On

Locks the output data type setting for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change the output data type setting for this block.

Parameter: LockScale

Type: character vector

Value: 'off' | 'on'

Default: 'off'

For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Integer rounding mode

Specify the rounding mode for fixed-point operations.

Default: Floor

Ceiling

Rounds positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

Floor

Rounds positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

Simplest

Chooses between rounding toward floor and rounding toward zero to generate rounding code that is as efficient as possible.

Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

For more information, see “Rounding” (Fixed-Point Designer).

Saturate on integer overflow

Specify whether overflows saturate.

Default: Off On

Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

 Off

Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Parameter: SaturateOnIntegerOverflow

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Examples

This table shows the output of the Product of Elements block for example inputs using default block parameter values, except as shown in the table.

Parameter Values	Examples
Multiplication: Element-wise (.*) Number of inputs: *	
Multiplication: Element-wise (.*) Number of inputs: /

Pulse Generator

Generate square wave pulses at regular intervals

Library

Sources

Description

The Pulse Generator block generates square wave pulses at regular intervals. The block waveform parameters, **Amplitude**, **Pulse Width**, **Period**, and **Phase delay**, determine the shape of the output waveform. The following diagram shows how each parameter affects the waveform.

The Pulse Generator can emit scalar, vector, or matrix signals of any real data type. To cause the block to emit a scalar signal, use scalars to specify the waveform parameters. To cause the block to emit a vector or matrix signal, use vectors or matrices, respectively, to specify the waveform parameters. Each element of the waveform parameters affects

the corresponding element of the output signal. For example, the first element of a vector amplitude parameter determines the amplitude of the first element of a vector output pulse. All the waveform parameters must have the same dimensions after scalar expansion. The data type of the output is the same as the data type of the **Amplitude** parameter.

This block output can be generated in time-based or sample-based modes, determined by the **Pulse type** parameter.

Time-Based Mode

In time-based mode, Simulink computes the block output only at times when the output actually changes. This approach results in fewer computations for the block output over the simulation time period. Activate this mode by setting the **Pulse type** parameter to `Time based`.

The block does not support a time-based configuration that results in a constant output signal. Simulink returns an error if the parameters **Pulse Width** and **Period** satisfy either of these conditions:

$$Period * \frac{PulseWidth}{100} = 0$$

$$Period * \frac{PulseWidth}{100} = Period$$

Depending on the pulse waveform characteristics, the intervals between changes in the block output can vary. For this reason, a time-based Pulse Generator block has a variable sample time. The sample time color of such blocks is brown (see “View Sample Time Information” for more information).

Simulink cannot use a fixed-step solver to compute the output of a time-based pulse generator. If you specify a fixed-step solver for models that contain time-based pulse generators, Simulink computes a fixed sample time for the time-based pulse generators. Then the time-based pulse generators simulate as sample based.

If you use a fixed-step solver and the **Pulse type** is `Time based`, choose the step size such that the period, phase delay, and pulse width (in seconds) are integer multiples of the solver step size. For example, suppose that the period is 4 seconds, the pulse width is 75% (that is, 3 s), and the phase delay is 1 s. In this case, the computed sample time is 1 s. Therefore, choose a fixed-step size of 1 or a number that divides 1 exactly (e.g., 0.25).

You can guarantee this by setting the fixed-step solver step size to `auto` on the **Solver** pane of the Configuration Parameters dialog box.

Sample-Based Mode

In sample-based mode, the block computes its outputs at fixed intervals that you specify. Activate this mode by setting the **Pulse type** parameter to `Sample based`.

An important difference between the time-based and sample-based modes is that in time-based mode, the block output is based on simulation time, and in sample-based mode, the block output depends only on the simulation start, regardless of elapsed simulation time. For more information, see the example “Difference Between Time-Based and Sample-Based Pulse Generation Modes” on page 1-1216.

This block supports reset semantics in sample-based mode. For example, if a Pulse Generator is in a resettable subsystem that hits a reset trigger, the block output resets to its initial condition.

Data Type Support

The Pulse Generator block outputs real signals of any numeric data type that Simulink supports, including fixed-point data types. The data type of the output signal is the same as that of the **Amplitude** parameter.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Pulse type

The pulse type for this block: `Time based` or `Sample based`. The default is `Time based`.

Time (t)

Specifies whether to use simulation time or an external signal as the source of values for the output pulse's time variable. If you specify an external source, the block displays an input port for connecting the source. The output pulse differs as follows:

- `Use simulation time`: The block generates an output pulse where the time variable equals the simulation time.
- `Use external signal`: The block generates an output pulse where the time variable equals the value from the input port, which can differ from the simulation time.

Amplitude

The pulse amplitude. The default is 1.

Period

The pulse period specified in seconds if the pulse type is time-based or as number of sample times if the pulse type is sample-based. The default is 10 seconds.

Pulse Width

The duty cycle specified as the percentage of the pulse period that the signal is on if time-based or as number of sample times if sample-based. The default is 5 percent.

Phase delay

The delay before the pulse is generated specified in seconds if the pulse type is time-based or as number of sample times if the pulse type is sample-based. The default is 0 seconds.

Sample time

The length of the sample time for this block in seconds. This parameter appears only if the block's pulse type is sample-based. See “Specify Sample Time” in the Simulink User's Guide for more information.

Interpret vector parameters as 1-D

If you select this check box and the other parameters are one-row or one-column matrices, after scalar expansion, the block outputs a 1-D signal (vector). Otherwise the output dimensionality is the same as that of the other parameters. See “Determining the Output Dimensions of Source Blocks” in the “Working with Signals” chapter of the Simulink User's Guide.

Examples

The following Simulink examples show how to use the Pulse Generator block:

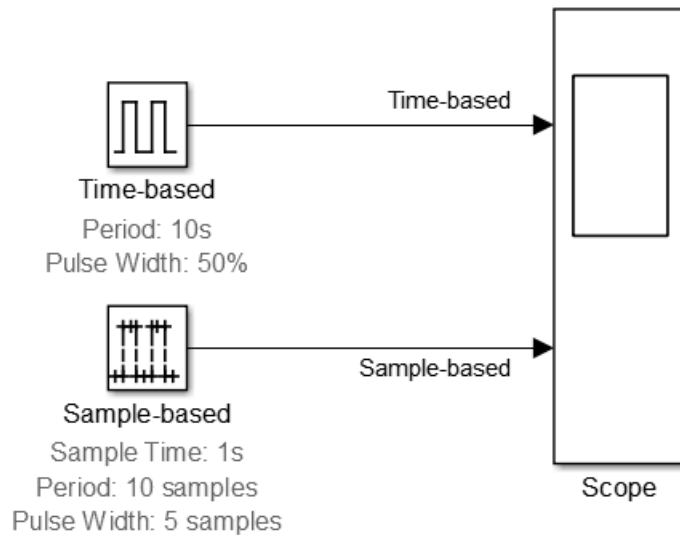

- `sldemo_auto_climatecontrol`

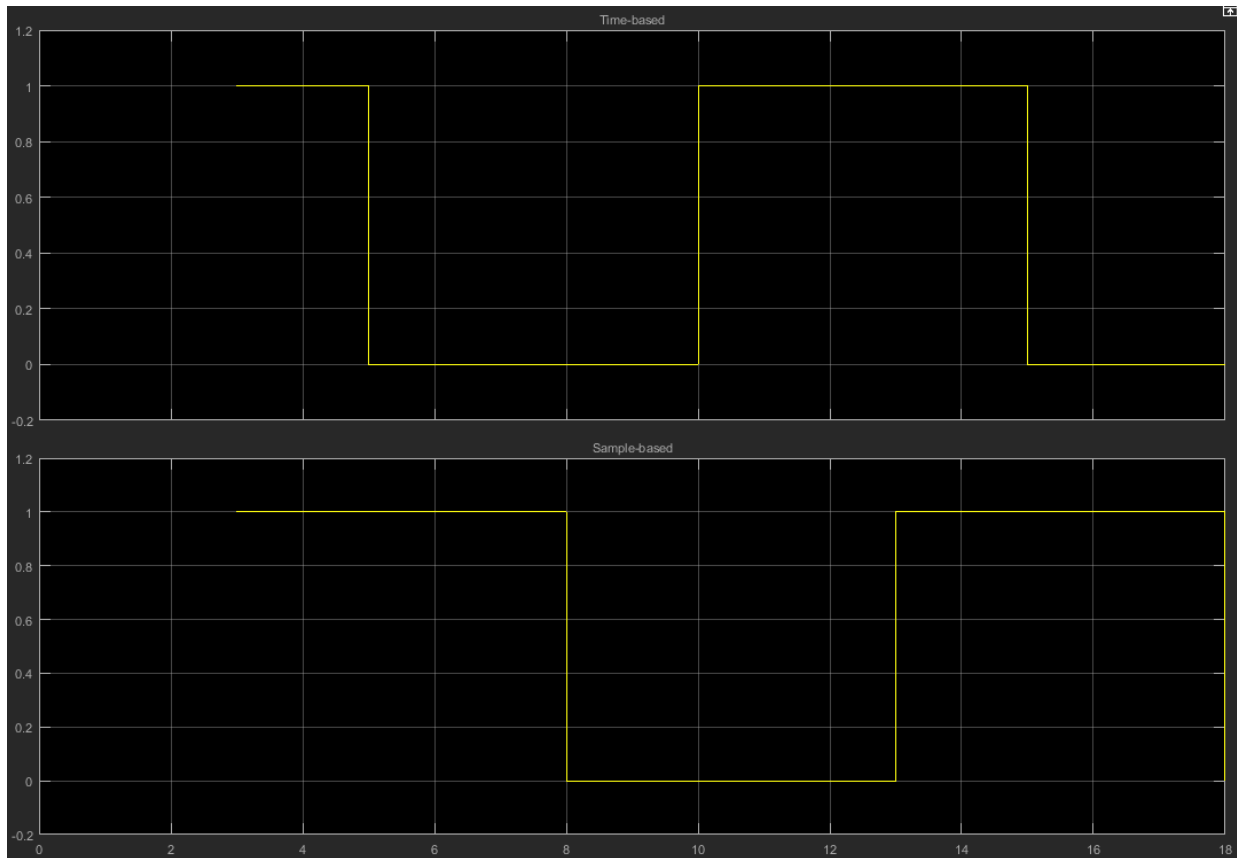

- `sldemo_boiler`

Difference Between Time-Based and Sample-Based Pulse Generation Modes

This example shows the difference in the behavior of the Pulse Generator block in time-based and sample-based modes.

Consider a model with two Pulse Generator blocks. In one block, the **Pulse type** parameter is set to `Time based`. In the other block, it is set to `Sample based`. Both blocks are set up to output a Boolean pulse of 10 seconds: 5 seconds `on` followed by 5 seconds `off`. The simulation runs for 15 seconds from a start time of 3 seconds to a stop time of 18 seconds, specified in the Model Configuration Parameters dialog box. The figure shows the block diagram for this model and the simulation output in the Scope block.

You can see that simulation output starts at 3 seconds, as expected. Notice that the time-based Pulse Generator produces a logical `on` for only 2 seconds, after which its output changes to `off` at $t = 5$ seconds. This is because this block starts computing its output from $t = 0$ seconds, even though it doesn't output it until the simulation starts at $t = 3$ seconds. The time-based block depends on simulation time for its output.

The sample-based block outputs a pulse of 5 seconds `on` followed by 5 seconds `off`. In this case, the block's output does not depend on simulation time, and starts only when the simulation starts.

Tune Phase Delay Parameter During Simulation

You cannot tune the value of the **Phase delay** parameter during simulation. As a workaround, you can add a Constant block and a Variable Time Delay block.

In the Pulse Generator block, set the value of the **Phase delay** parameter to 0. Use the Constant block to specify the delay time (in seconds).

To tune the delay time during simulation, change the value stored in the Constant block.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point
Sample Time	Inherited
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Push Button

Set value of parameter when button is pressed

Library: Simulink / Dashboard

Description

When you press the Push Button block during a simulation, the value of the connected block parameter changes to a specified value. Use the Push Button block with other Dashboard blocks to create an interactive dashboard to control your model.

Connection

Dashboard block controls connect to variables and block parameters. To connect a Dashboard block to a variable or parameter, use the **Connection** table in the block's parameters.

- 1 Double-click the block.
- 2 Populate the **Connection** table by selecting blocks of interest in your model.
- 3 Mark the option button next to the parameter or variable you want to adjust during simulation.
- 4 Click **Apply**.

Limitations

- You cannot save the block connections or properties in model files that use the MDL format.

To save connections and properties, save the model file in the SLX format.

- Dashboard blocks can only connect to real scalar signals.
- Dashboard blocks cannot connect to blocks that are commented out.
- Dashboard blocks cannot connect to signals inside reference models.

- Parameters specified by indexing a variable array do not appear in the **Connection** table. For example, a block parameter defined using the variable `engine(1)` does not appear in the table.

To access the parameter in the **Connection** table, assign the indexed value to a scalar variable, such as `engine_1`. Then, use the scalar variable to define the block parameter.

Parameters

Connection — Select a block parameter to connect

signal connection options

Select the block parameter to control using the **Connection** table. To open the dialog box, double-click the block. Then, populate the **Connection** table by selecting a block in your model. Select the variable parameter you want to control, and click **Apply**.

Note To see workspace variables in the connection table, update the model diagram with **Ctrl+D**.

Button Text — Text displayed on button

'Button' (default) | character vector

The text displayed on the Push Button block in your model.

On Value — Value assigned to parameter when button is pressed

1 (default) | scalar

The value assigned to the connected block parameter when the button is pressed.

Label — Block label position

'Top' (default) | 'Bottom' | 'Hide'

Position of the block label. When the block is connected to a signal, the label is the name of the connected signal. When the block is not connected, the label is the instructional text.

Quantizer

Discretize input at specified interval

Library

Discontinuities

Description

The Quantizer block passes its input signal through a stair-step function so that many neighboring points on the input axis are mapped to one point on the output axis. The effect is to quantize a smooth signal into a stair-step output. The output is computed using the round-to-nearest method, which produces an output that is symmetric about zero.

$$y = q * \text{round}(u/q)$$

where y is the output, u the input, and q the **Quantization interval** parameter.

Data Type Support

The Quantizer block accepts and outputs real or complex signals of type `single` or `double`. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Quantization interval

The interval around which the output is quantized. Permissible output values for the Quantizer block are $n \cdot q$, where n is an integer and q the **Quantization interval**.

The default is 0.5.

Treat as gain when linearizing

Simulink software by default treats the Quantizer block as unity gain when linearizing. This setting corresponds to the large-signal linearization case. If you clear this check box, the linearization routines assume the small-signal case and set the gain to zero.

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Examples

The `sldemo_boiler` model shows how you can use the Quantizer block.

The Quantizer block appears in the Boiler Plant model/digital thermometer/ADC subsystem.

The ADC subsystem digitizes the input analog voltage by:

- Multiplying the analog voltage by 256/5 with the Gain block
- Rounding the value to integer floor with the Quantizer block
- Limiting the output to a maximum of 255 (the largest unsigned 8-bit integer value) with the Saturation block

For more information, see “Explore the Fixed-Point "Bang-Bang Control" Model” (Stateflow) in the Stateflow documentation.

Characteristics

Data Types	Double Single
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Quarter Gauge

Display input value on quadrant scale

Library: Simulink / Dashboard

Description

The Quarter Gauge block displays the connected signal on a quadrant scale during simulation. You can use the Quarter Gauge block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model. The Quarter Gauge block provides an indication of the instantaneous value of the connected signal throughout simulation. You can modify the range of the Quarter Gauge block to fit your data. You can also customize the appearance of the Quarter Gauge block to provide more information about your signal. For example, you can color-code in-specification and out-of-specification ranges.

Connection

Dashboard blocks do not use ports to connect to signals. To connect a signal to a Dashboard block, use the **Connection** table in the block's parameters.

- 1 Double-click the block.
- 2 Populate the **Connection** table by selecting signals of interest in your model.
- 3 Mark the option button next to the signal you want to display.
- 4 Click **Apply**.

Limitations

- You cannot save the block connections or properties in model files that use the MDL format.

To save connections and properties, save the model file in the SLX format.

- Dashboard blocks can only connect to real scalar signals.
- Dashboard blocks cannot connect to blocks that are commented out.
- Dashboard blocks cannot connect to signals inside reference models.
- If you turn off logging for a signal connected to a Dashboard block, the model stops sending data from that signal to the block. To view the signal again, reconnect the signal.
- External mode simulation does not support visualization Dashboard blocks.

Parameters

Connection — Select a signal to connect and display

signal connection options

Signal connection options. Populate the **Connection** table by selecting signals of interest in your model. Mark the check box next to the signal you want to display. Click **Apply** to connect the signal.

Minimum — Minimum tick mark value

0 (default) | scalar

A finite, real, double, scalar value specifying the minimum tick mark value for the scale. The minimum must be less than the value entered for the maximum.

Maximum — Maximum tick mark value

100 (default) | scalar

A finite, real, double, scalar value specifying the maximum tick mark value for the scale. The maximum must be greater than the value entered for the minimum.

Tick Interval — Interval between major tick marks

auto (default) | scalar

A finite, real, positive, integer, scalar value specifying the interval of major tick marks on the scale. When set to `auto`, the block automatically adjusts the tick interval based on the minimum and maximum values.

Scale Colors — Color indications on Gauge scale

colors for scale ranges

Color specifications for ranges on the scale. Press the **+** button to add a color. For each color added, specify the minimum and maximum values of the range where you want to display that color.

Label — Block label position

'Top' (default) | 'Bottom' | 'Hide'

Position of the block label. When the block is connected to a signal, the label is the name of the connected signal. When the block is not connected, the label is the instructional text.

Radio Button

Select parameter value

Library: Simulink / Dashboard

Description

The Radio Button block lets you change the value of the connected parameter during simulation. You can specify a list of values and labels and then select the value for the parameter from that list. Use the Radio Button block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model.

Double-clicking the Radio Button block does not open its dialog box during simulation and when the block is selected. To edit the block's parameters, you can use the **Property Inspector**, or you can right-click the block and select **Block Parameters** from the context menu.

Connection

Dashboard block controls connect to variables and block parameters. To connect a Dashboard block to a variable or parameter, use the **Connection** table in the block's parameters.

- 1 Double-click the block.
- 2 Populate the **Connection** table by selecting blocks of interest in your model.
- 3 Mark the option button next to the parameter or variable you want to adjust during simulation.
- 4 Click **Apply**.

Limitations

- You cannot save the block connections or properties in model files that use the MDL format.

To save connections and properties, save the model file in the SLX format.

- Dashboard blocks can only connect to real scalar signals.
- Dashboard blocks cannot connect to blocks that are commented out.
- Dashboard blocks cannot connect to signals inside reference models.
- Parameters specified by indexing a variable array do not appear in the **Connection** table. For example, a block parameter defined using the variable `engine(1)` does not appear in the table.

To access the parameter in the **Connection** table, assign the indexed value to a scalar variable, such as `engine_1`. Then, use the scalar variable to define the block parameter.

Parameters

Connection — Select a block parameter to connect

signal connection options

Select the block parameter to control using the **Connection** table. To open the dialog box, double-click the block. Then, populate the **Connection** table by selecting a block in your model. Select the variable parameter you want to control, and click **Apply**.

Note To see workspace variables in the connection table, update the model diagram with **Ctrl+D**.

States

value — Values for selected option

0/1/2 (default) | scalar

Values assigned to the connected parameter when you select the option with the corresponding **Label**. Click the **+** button to add options.

Label — Option labels

'Label1'/'Label2'/'Label3' (default) | character vector

Label for each option. You can use the **Label** to display the value the connected parameter takes when the switch is positioned at the bottom, or you can enter a text label.

Example: `Gain = 1`

Group Name — Radio Button group name

RadioButtonGroup (default) | character array

Name for the group of values displayed on the Radio Button block. Unlike the **Block Name** and **Label**, the **Group Name** always shows on the Radio Button block.

Example: `Input Amplitude`

Label — Block label position

'Top' (default) | 'Bottom' | 'Hide'

Position of the block label. When the block is connected to a signal, the label is the name of the connected signal. When the block is not connected, the label is the instructional text.

Ramp

Generate constantly increasing or decreasing signal

Library

Sources

Description

The Ramp block generates a signal that starts at a specified time and value and changes by a specified rate. The block's **Slope**, **Start time**, and **Initial output** parameters determine the characteristics of the output signal. All must have the same dimensions after scalar expansion.

Data Type Support

The Ramp block outputs signals of type `double`. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Slope

Specify the rate of change of the generated signal. The default is 1.

Start time

Specify the time at which the block begins generating the signal. The default is 0.

Initial output

Specify the initial value of the output signal. The default is 0.

Interpret vector parameters as 1-D

If you select this option and the other parameters are one-row or one-column matrices, after scalar expansion, the block outputs a 1-D signal (vector). Otherwise, the output dimensionality is the same as that of the other parameters. See “Determining the Output Dimensions of Source Blocks” in the Simulink documentation.

Examples

The following Simulink examples show how to use the Ramp block:

- `sldemo_VariableTransportDelay_pipe`

Characteristics

Data Types	Double
Sample Time	Inherited from downstream block
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	Yes
Code Generation	Yes

Introduced before R2006a

Random Number

Generate normally distributed random numbers

Library

Sources

Description

The Random Number block generates normally distributed random numbers. To generate uniformly distributed random numbers, use the Uniform Random Number block.

You can generate a repeatable sequence using any Random Number block with the same nonnegative seed and parameters. The seed resets to the specified value each time a simulation starts. By default, the block produces a sequence that has a mean of 0 and a variance of 1. To generate a vector of random numbers with the same mean and variance, specify the **Seed** parameter as a vector.

Avoid integrating a random signal, because solvers must integrate relatively smooth signals. Instead, use the Band-Limited White Noise block.

The numeric parameters of this block must have the same dimensions after scalar expansion. If you select the **Interpret vector parameters as 1-D** check box and the numeric parameters are row or column vectors after scalar expansion, the block outputs a 1-D signal. If you clear the **Interpret vector parameters as 1-D** check box, the block outputs a signal of the same dimensionality as the parameters.

Data Type Support

The Random Number block outputs a real signal of type `double`. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Mean

Specify the mean of the random numbers. The default is 0.

Variance

Specify the variance of the random numbers. The default is 1.

Seed

Specify the starting seed for the random number generator. The default is 0.

The seed must be 0 or a positive integer. Output is repeatable for a given seed.

Sample time

Specify the time interval between samples. The default is 0.1, which matches the default sample time of the Band-Limited White Noise block. See “Specify Sample Time” in the Simulink documentation for more information.

Interpret vector parameters as 1-D

If you select this check box and the other parameters are row or column vectors after scalar expansion, the block outputs a 1-D signal. Otherwise, the block outputs a signal of the same dimensionality as the other parameters. For more information, see “Determining the Output Dimensions of Source Blocks” in the Simulink documentation.

Characteristics

Data Types	Double
Sample Time	Specified in the Sample time parameter
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No

Code Generation	Yes
-----------------	-----

The generator algorithm is identical to the one used in MATLAB Version 4.0 by the `rand` and `randn` functions. For details on the `mcg16807` algorithm, see “Choosing a Random Number Generator” (MATLAB) in the MATLAB documentation.

To use other algorithms supported by MATLAB in a Simulink model, generate a stream of random numbers in MATLAB, and store the output as a `.mat` file. Use this `.mat` file as the random number input for your simulation. For more information, see “Creating and Controlling a Random Number Stream” (MATLAB). To create multiple independent streams using MATLAB, see “Multiple Streams” (MATLAB).

Note Using multiple seeds to generate multiple parallel independent streams for a generator algorithm is not recommended for the `mcg16807` algorithm. Instead, use the method described above.

Rate Limiter

Limit rate of change of signal

Library

Discontinuities

Description

The Rate Limiter block limits the first derivative of the signal passing through it. The output changes no faster than the specified limit. The derivative is calculated using this equation:

$$rate = \frac{u(i) - y(i-1)}{t(i) - t(i-1)}$$

$u(i)$ and $t(i)$ are the current block input and time, and $y(i-1)$ and $t(i-1)$ are the output and time at the previous step. The output is determined by comparing $rate$ to the **Rising slew rate** and **Falling slew rate** parameters:

- If $rate$ is greater than the **Rising slew rate** parameter (R), the output is calculated as
$$y(i) = \Delta t \cdot R + y(i-1).$$
- If $rate$ is less than the **Falling slew rate** parameter (F), the output is calculated as
$$y(i) = \Delta t \cdot F + y(i-1).$$
- If $rate$ is between the bounds of R and F , the change in output is equal to the change in input:
$$y(i) = u(i)$$

When the block is running in continuous mode (for example, **Sample time mode** is inherited and **Sample time** of the driving block is zero), the **Initial condition** is ignored. The block output at $t = 0$ is equal to the initial input:

$$y(0) = u(0)$$

When the block is running in discrete mode (for example, **Sample time mode** is inherited and **Sample time** of the driving block is nonzero), the **Initial condition** is preserved:

$$y(-1) = I_c$$

where I_c is the initial condition. The block output at $t = 0$ is calculated as if $rate$ is outside the bounds of R and F . For $t = 0$, $rate$ is calculated as follows:

$$rate = \frac{u(0) - y(-1)}{sampletime}$$

Note You cannot use a Rate Limiter block inside a Triggered Subsystem. Use the Rate Limiter Dynamic block instead.

Data Type Support

The Rate Limiter block accepts and outputs signals of any numeric data type that Simulink supports, except `boolean`. The Rate Limiter block supports fixed-point data types.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Rising slew rate

Specify the limit of the derivative of an increasing input signal. This parameter is tunable for fixed-point inputs.

Falling slew rate

Specify the limit of the derivative of a decreasing input signal. This parameter is tunable for fixed-point inputs.

Sample time mode

Specify the sample time mode, `continuous` or `inherited` from the driving block.

Initial condition

Set the initial output of the simulation. Simulink software does not allow you to set the initial condition of this block to `inf` or `NaN`.

Treat as gain when linearizing

Linearization commands in Simulink software treat this block as a gain in state space. Select this check box to cause the linearization commands to treat the gain as 1; otherwise, the commands treat the gain as 0.

Characteristics

Data Types	Double Single Base Integer Fixed-Point
Sample Time	Continuous or inherited (specified in the Sample time mode parameter)
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

See Also

Rate Limiter Dynamic

Introduced before R2006a

Rate Limiter Dynamic

Limit rising and falling rates of signal

Library

Discontinuities

Description

The Rate Limiter Dynamic block limits the rising and falling rates of the signal.

- The external signal `up` sets the upper limit on the rising rate of the signal.
- The external signal `lo` sets the lower limit on the falling rate of the signal.

Follow these guidelines when using the Rate Limiter Dynamic block:

- Ensure that the data types of `up` and `lo` are the same as the data type of the input signal `u`.

When the lower limit uses a signed type and the input signal uses an unsigned type, the output signal keeps increasing regardless of the input and the limits.

- Use a fixed-step solver to simulate models that contain this block.

Because the Rate Limiter Dynamic block does not support continuous sample time, simulation with a variable-step solver causes an error.

Data Type Support

The Rate Limiter Dynamic block accepts input signals of the following data types:

- Floating point
- Built-in integer
- Fixed point

The data type of the output signal Y matches the data type of the input signal u .

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Characteristics

Data Types	Double Single Base Integer Fixed-Point
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No

Rate Limiter

Introduced before R2006a

Rate Transition

Handle transfer of data between blocks operating at different rates

Library

Signal Attributes

Description

Transition Handling Options

The Rate Transition block transfers data from the output of a block operating at one rate to the input of a block operating at a different rate. Use the block parameters to trade data integrity and deterministic transfer for faster response or lower memory requirements. To learn about data integrity and deterministic data transfer, see “Data Transfer Problems” (Simulink Coder) in the Simulink Coder documentation.

Transition Handling Options	Block Parameter Settings
<ul style="list-style-type: none"> • Data integrity • Deterministic data transfer • Maximum latency 	Select: <ul style="list-style-type: none"> • Ensure data integrity during data transfer • Ensure deterministic data transfer

Transition Handling Options	Block Parameter Settings
<ul style="list-style-type: none"> • Data integrity • Nondeterministic data transfer • Minimum latency • Higher memory requirements 	Select: <ul style="list-style-type: none"> • Ensure data integrity during data transfer Clear: <ul style="list-style-type: none"> • Ensure deterministic data transfer
<ul style="list-style-type: none"> • Potential loss of data integrity • Nondeterministic data transfer • Minimum latency • Lower memory requirements 	Clear: <ul style="list-style-type: none"> • Ensure data integrity during data transfer • Ensure deterministic data transfer

Dependencies

The behavior of the Rate Transition block depends on:

- Sample times of the ports to which the block connects (see “Effects of Synchronous Sample Times” on page 1-1243 and “Effects of Asynchronous Sample Times” on page 1-1245)
- Priorities of the tasks for the source and destination sample times (see “Sample time properties” in the Simulink documentation)
- Whether the model specifies a fixed- or variable-step solver (see “Solvers” in the Simulink documentation)

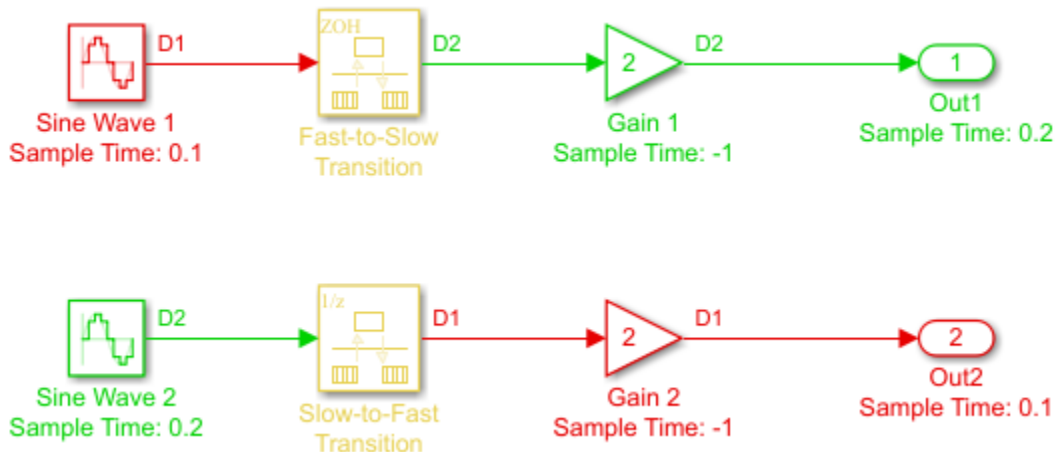

Block Labels

When you update your diagram, a label appears on the Rate Transition block to indicate simulation behavior.

Label	Block Behavior
ZOH	Acts as a zero-order hold
1/z	Acts as a unit delay

Label	Block Behavior
Buf	Copies input to output under semaphore control
Db_buf	Copies input to output using double buffers
Copy	Unprotected copy of input to output
NoOp	Does nothing
Mixed	Expands to multiple blocks with different behaviors

The block behavior label shows the method that ensures safe transfer of data between tasks operating at different rates. You can use the sample-time colors feature (see “View Sample Time Information” in the Simulink documentation) to display the relative rates that the block bridges. Consider, for example, the following model:

Sample-time colors and the block behavior label show that the Rate Transition block at the top of the diagram acts as a zero-order hold in a fast-to-slow transition and the bottom Rate Transition block acts as a unit delay in a slow-to-fast transition.

For more information, see “Handle Rate Transitions” (Simulink Coder) in the Simulink Coder documentation.

Effects of Synchronous Sample Times

The following table summarizes how each label appears if the sample times of the input and output ports ($inTs$ and $outTs$) are periodic, or synchronous.

Block Settings		Block Label		
Rate Transition	Conditions for Rate Transition Block	With Data Integrity and Determinism	With Only Data Integrity	Without Data Integrity or Determinism
(Equal)	$inTsOffset < outTsOffset$	None (error)	Buf	Copy or NoOp (see note that follows the table)
	$inTsOffset = outTsOffset$	Copy or NoOp (see note that follows the table)	Copy or NoOp (see note that follows the table)	
	$inTsOffset > outTsOffset$	None (error)	Db_buf	
(Fast to slow)	$inTs = outTs / N$ $inTsOffset, outTsOffset = 0$	ZOH	Buf	
	$inTs = outTs / N$ $inTsOffset \leq outTsOffset$	None (error)		
	$inTs = outTs / N$ $inTsOffset > outTsOffset$	None (error)	Db_buf	
	$inTs \neq outTs / N$	None (error)		
(Slow to fast)	$inTs = outTs * N$ $inTsOffset, outTsOffset = 0$	$1/z$	Db_buf	
	$inTs = outTs * N$ $inTsOffset \leq outTsOffset$	None (error)		
	$inTs = outTs * N$ $inTsOffset > outTsOffset$	None (error)		
	$inTs \neq outTs * N$	None (error)		

Block Settings		Block Label		
Rate Transition	Conditions for Rate Transition Block	With Data Integrity and Determinism	With Only Data Integrity	Without Data Integrity or Determinism
KEY				
<ul style="list-style-type: none"> • $inTs$, $outTs$: Sample times of input and output ports, respectively • $inTsOffset$, $outTsOffset$: Sample time offsets of input and output ports, respectively • N: Integer value > 1 				

When you select the **Block reduction** parameter on the Configuration Parameters dialog box, `Copy` reduces to `NoOp`. No code generation occurs for a Rate Transition block with a `NoOp` label. To prevent a block from being reduced when block reduction is on, add a test point to the block output (see “Test Points” in the Simulink documentation).

Effects of Asynchronous Sample Times

The following table summarizes how each label appears if the sample time of the input or output port ($inTs$ or $outTs$) is not periodic, or asynchronous.

Block Settings	Block Label		
	With Data Integrity and Determinism	With Only Data Integrity	Without Data Integrity or Determinism
$inTs = outTs$	<code>Copy</code>	<code>Copy</code>	<code>Copy</code>
$inTs \neq outTs$	<code>None (error)</code>	<code>Db_buf</code>	
KEY			
<ul style="list-style-type: none"> • $inTs$, $outTs$: Sample times of input and output ports, respectively 			

Data Type Support

The Rate Transition block accepts most signals that Simulink supports, including fixed-point and enumerated data types. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

However, do not use the Rate Transition block with frame-based signals. For rate transitions with such signals, use one of these blocks from the DSP System Toolbox instead:

- Buffer
- Unbuffer
- CIC Decimation
- CIC Interpolation
- FIR Decimation
- FIR Interpolation
- Downsample
- Upsample

Parameters

Ensure data integrity during data transfer

Selecting this check box results in generated code that ensures data integrity when the block transfers data. If you select this check box and the transfer is nondeterministic (see **Ensure deterministic data transfer** below), depending on the priority of input rate and output rate, the generated code uses a proper algorithm using single or multiple buffers to protect data integrity during data transfer.

Otherwise, the Rate Transition block is either reduced or generates code using a copy operation to effect the data transfer. This unprotected mode consumes less memory. But the copy operation is also interruptible, which can lead to loss of data integrity during data transfers. Select this check box if you want the generated code to operate with maximum responsiveness (i.e., nondeterministically) and data integrity. For more information, see “Rate Transition Block Options” (Simulink Coder) in the Simulink Coder documentation.

Ensure deterministic data transfer (maximum delay)

Selecting this check box results in generated code that transfers data at the sample rate of the slower block, that is, deterministically. If you do not select this check box, data transfers occur as soon as new data is available from the source block and the receiving block is ready to receive the data. You avoid transfer delays, thus ensuring that the system operates with maximum responsiveness. However, transfers can occur unpredictably, which is undesirable in some applications. For more

information, see “Rate Transition Block Options” (Simulink Coder) in the Simulink Coder documentation.

Initial conditions

This parameter applies only to slow-to-fast transitions. It specifies the initial output of the Rate Transition block at the beginning of a transition when there is no output from the slow block connected to the input of the Rate Transition block. Simulink does not allow the initial output of this block to be `Inf` or `NaN`.

Output port sample time options

Specifies a mode for setting the output port sample time. The options are:

- `Specify` — Allows you to use the **Output port sample time** parameter to specify the output rate to which the Rate Transition block converts its input rate.
- `Inherit` — Specifies that the Rate Transition block inherits an output rate from the block to which the output port is connected.
- `Multiple of input port sample time` — Allows you to use the **Sample time multiple (>0)** parameter to specify the Rate Transition block output rate as a multiple of its input rate.

If you specify `Inherit` and all blocks connected to the output port also inherit sample time, the fastest sample time in the model applies.

Output port sample time

This parameter is visible when you set **Output port sample time options** to `Specify`. Enter a value that specifies the output rate to which the block converts its input rate. The default value (`-1`) specifies that the Rate Transition block inherits the output rate from the block to which the output port is connected. See “Specify Sample Time” in the Simulink documentation for information on how to specify the output rate.

Sample time multiple (>0)

This parameter is visible when you set **Output port sample time options** to `Multiple of input port sample time`. Enter a positive value that specifies the output rate as a multiple of the input port sample time. The default value (`1`) specifies that the output rate is the same as the input rate. A value of `0.5` specifies that the output rate is half of the input rate, while a value of `2` specifies that the output rate is twice the input rate.

Bus Support

The Rate Transition block is a bus-capable block. The input can be a virtual or nonvirtual bus signal, with the restriction that **Initial conditions** must be zero, a nonzero scalar, or a finite numeric structure. For information about specifying an initial condition structure, see “Specify Initial Conditions for Bus Signals”.

All signals in a nonvirtual bus input to a Rate Transition block must have the same sample time, even if the elements of the associated bus object specify inherited sample times. You can use a Rate Transition block to change the sample time of an individual signal, or of all signals in a bus. See “Specify Bus Signal Sample Times” and “Bus-Capable Blocks” in the Simulink documentation for more information.

You can use an array of buses as an input signal to a Rate Transition block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated Bus
Sample Time	This block supports discrete-to-discrete transitions
Direct Feedthrough	No, for slow-to-fast transitions for which you select the Ensure data integrity during data transfer check box. Yes, otherwise.
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Real-Imag to Complex

Convert real and/or imaginary inputs to complex signal

Library

Math Operations

Description

The Real-Imag to Complex block converts real and/or imaginary inputs to a complex-valued output signal.

The inputs can both be arrays (vectors or matrices) of equal dimensions, or one input can be an array and the other a scalar. If the block has an array input, the output is a complex array of the same dimensions. The elements of the real input map to the real parts of the corresponding complex output elements. The imaginary input similarly maps to the imaginary parts of the complex output signals. If one input is a scalar, it maps to the corresponding component (real or imaginary) of all the complex output signals.

Data Type Support

The block accepts input signals of the following data types:

- Floating point
- Built-in integer
- Fixed point

Complex fixed-point signals must have trivial slope and zero bias. For more information about support for fixed-point data types, see “Scaling” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

Parameters

Input

Specify the kind of input: a real input, an imaginary input, or both.

Real (Imag) part

This parameter appears only when you set **Input** to `Real` or `Imag`. If the input is a real-part signal, this parameter specifies the constant imaginary part of the output signal. If the input is the imaginary part, this parameter specifies the constant real part of the output signal. The title of this parameter changes to reflect its usage.

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Characteristics

Data Types	Double Single Base Integer Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

See Also

Complex to Real-Imag

Introduced before R2006a

Relational Operator

Perform specified relational operation on inputs

Library

Logic and Bit Operations

Description

Two-Input Mode

By default, the Relational Operator block compares two inputs using the **Relational operator** parameter that you specify. The first input corresponds to the top input port and the second input to the bottom input port. (See “Port Location After Rotating or Flipping” in the Simulink documentation for a description of the port order for various block orientations.)

You can specify one of the following operations in two-input mode:

Operation	Description
==	TRUE if the first input is equal to the second input
~=	TRUE if the first input is not equal to the second input
<	TRUE if the first input is less than the second input
<=	TRUE if the first input is less than or equal to the second input
>=	TRUE if the first input is greater than or equal to the second input
>	TRUE if the first input is greater than the second input

You can specify inputs as scalars, arrays, or a combination of a scalar and an array.

For...	The output is...
Scalar inputs	A scalar
Array inputs	An array of the same dimensions, where each element is the result of an element-by-element comparison of the input arrays
Mixed scalar and array inputs	An array, where each element is the result of a comparison between the scalar and the corresponding array element

The input with the smaller positive range is converted to the data type of the other input offline using round-to-nearest and saturation. This conversion occurs before the comparison.

You can specify the output data type using the **Output data type** parameter. The output equals 1 for TRUE and 0 for FALSE.

Tip Select an output data type that represents zero exactly. Data types that satisfy this condition include signed and unsigned integers and any floating-point data type.

One-Input Mode

When you select one of the following operations for **Relational operator**, the block switches to one-input mode.

Operation	Description
isInf	TRUE if the input is Inf
isNaN	TRUE if the input is NaN
isFinite	TRUE if the input is finite

For an input that is not floating point, the block produces the following output.

Data Type	Operation	Block Output
<ul style="list-style-type: none"> • Fixed point • Boolean • Built-in integer 	isInf	FALSE
	isNaN	FALSE
	isFinite	TRUE

Rules for Data Type Propagation

The following rules apply for data type propagation when your block has one or more input ports with unspecified data types.

When the block is in...	And...	The block uses...
Two-input mode	Both input ports have unspecified data types	<code>double</code> as the default data type for both inputs
	One input port has an unspecified data type	The data type from the specified input port as the default data type of the other port
One-input mode	The input port has an unspecified data type	<code>double</code> as the default data type for the input

Data Type Support

The Relational Operator block accepts real or complex signals of any data type that Simulink supports, including fixed-point and enumerated data types. For two-input mode, one input can be real and the other complex when the operator is `==` or `~=`. Complex inputs work only for `==`, `~=`, `isInf`, `isNaN`, and `isFinite`.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Show data type assistant

Display the **Data Type Assistant**.

The **Data Type Assistant** helps you set the **Output data type** parameter.

For more information, see “Control Signal Data Types”.

Relational operator

Specify the operation for comparing two inputs or determining the signal type of one input.

Default: <=

==

TRUE if the first input is equal to the second input

~=

TRUE if the first input is not equal to the second input

<

TRUE if the first input is less than the second input

<=

TRUE if the first input is less than or equal to the second input

>=

TRUE if the first input is greater than or equal to the second input

>

TRUE if the first input is greater than the second input

isInf

TRUE if the input is Inf

isNaN

TRUE if the input is NaN

isFinite

TRUE if the input is finite

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Enable zero-crossing detection

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Default: On

On

Enable zero-crossing detection.

Off

Do not enable zero-crossing detection.

Parameter: ZeroCross

Type: character vector

Value: 'on' | 'off'

Default: 'on'

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Require all inputs to have the same data type

Require that all inputs have the same data type.

Default: Off

On

Require that all inputs have the same data type.

Off

Do not require that all inputs have the same data type.

This check box is not available when you select `isInf`, `isNaN`, or `isFinite` for **Relational operator**, because the block is in one-input mode.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Output data type

Specify the output data type.

Default: `boolean`

Inherit: Logical (see Configuration Parameters: Optimization)

Uses the **Implement logic signals as Boolean data** configuration parameter (see “Implement logic signals as Boolean data (vs. double)”) to specify the output data type.

Note This option supports models created before the `boolean` option was available. Use one of the other options, preferably `boolean`, for new models.

`boolean`

Specifies output data type is `boolean`.

`fixdt(1,16)`

Specifies output data type is `fixdt(1,16)`.

`<data type expression>`

Uses the name of a data type object, for example, `Simulink.NumericType`.

Tip To enter a built-in data type (`double`, `single`, `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32`), enclose the expression in single quotes. For example, enter `'double'` instead of `double`.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Mode

Select the category of data to specify.

Default: Built in

Inherit

Specifies inheritance rules for data types. Selecting `Inherit` enables `Logical` (see `Configuration Parameters: Optimization`).

Built in

Specifies built-in data types. Selecting `Built in` enables `boolean`.

Fixed point

Specifies fixed-point data types.

Expression

Specifies expressions that evaluate to data types.

Clicking the **Show data type assistant** button enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specify Data Types Using Data Type Assistant”.

Data type override

Specify data type override mode for this signal.

Default: Inherit

Inherit

Inherits the data type override setting from its context, that is, from the block, `Simulink.Signal` object or Stateflow chart in Simulink that is using the signal.

Off

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For

example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

This parameter appears only when the **Mode** is `Built in` or `Fixed point`.

Signedness

Specify whether you want the fixed-point data as signed or unsigned.

Default: `Signed`

`Signed`

Specify the fixed-point data as signed.

`Unsigned`

Specify the fixed-point data as unsigned.

Selecting **Mode** > `Fixed point` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Word length

Specify the bit size of the word that holds the quantized integer.

Default: `16`

Minimum: `0`

Maximum: `32`

Selecting **Mode** > `Fixed point` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

Default: Integer

Integer

Specify integer. This setting has the same result as specifying a binary point location and setting fraction length to 0.

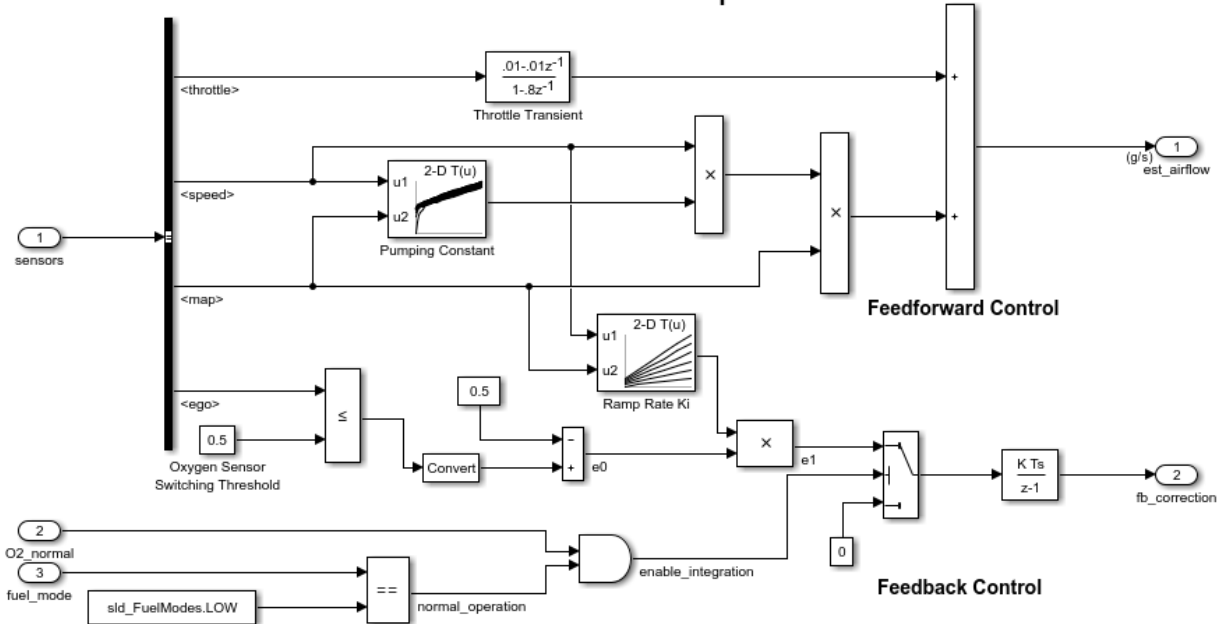

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specifying a Fixed-Point Data Type”.

Examples

In the `sldemo_fuelsys` model, the `fuel_rate_control/airflow_calc` subsystem uses two Relational Operator blocks:

Intake Airflow Estimation and Closed-Loop Correction

Both Relational Operator blocks operate in two-input mode.

The block that uses this operator...	Compares...
<=	The value of the oxygen sensor to the threshold value, 0.5
==	The value of the fuel mode to the ideal value, sld_FuelModes.LOW

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes

Variable-Size Signals	Yes
Zero-Crossing Detection	Yes, if enabled
Code Generation	Yes

Introduced before R2006a

Relay

Switch output between two constants

Library

Discontinuities

Description

The Relay block allows its output to switch between two specified values. When the relay is on, it remains on until the input drops below the value of the **Switch off point** parameter. When the relay is off, it remains off until the input exceeds the value of the **Switch on point** parameter. The block accepts one input and generates one output.

The **Switch on point** value must be greater than or equal to the **Switch off point**. Specifying a **Switch on point** value greater than the **Switch off point** models hysteresis, whereas specifying equal values models a switch with a threshold at that value.

Note When the initial input falls *between* the **Switch off point** and **Switch on point** values, the initial output is the value when the relay is off.

Data Type Support

The Relay block accepts signals of the following data types:

- Floating point
- Built-in integer

- Fixed point
- Boolean
- Enumerated (output only)

If **Output when on** or **Output when off** is an enumerated value, both must be of the same enumerated type as the output.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

The **Main** pane of the Relay block dialog box appears as follows:

Switch on point

The “on” threshold for the relay. The **Switch on point** parameter is converted to the input data type offline using round-to-nearest and saturation.

Switch off point

The “off” threshold for the relay. The **Switch off point** parameter is converted to the input data type offline using round-to-nearest and saturation.

Output when on

The output when the relay is on.

Output when off

The output when the relay is off.

Input processing

Specify whether the block performs sample- or frame-based processing. You can select one of the following options:

- **Elements as channels (sample based)** — Treat each element of the input as a separate channel (sample-based processing).
- **Columns as channels (frame based)** — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

- **Inherited** — Inherit the processing mode from the input signal and delay the input accordingly. You can identify whether the input signal is sample or frame based by looking at the signal line. Simulink represents sample-based signals with a single line and frame-based signals with a double line.

Note When you choose the `Inherited` option for the **Input processing** parameter, and the input signal is frame-based, Simulink will generate a warning or error in future releases.

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input `u`. All other input signals must be sample based.

Input Signal <code>u</code>	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

Enable zero-crossing detection

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Output minimum

Specify the minimum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Output maximum

Specify the maximum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Output data type

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`
- An enumerated data type, for example, `Enum:BasicColors`

In this case, **Output when on** and **Output when off** must be of the same enumerated type.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” in *Simulink User's Guide* for more information.

Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Examples

The `sldemo_househeat` model shows how you can use the Relay block.

The Relay block appears in the Thermostat subsystem.

The thermostat allows fluctuations of 5 degrees Fahrenheit above or below the desired room temperature. If air temperature drops below 65 degrees Fahrenheit, the thermostat turns on the heater. The Relay block outputs a value of 1 to turn on the heater and a value of 0 to turn off the heater.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	No

Variable-Size Signals	No
Zero-Crossing Detection	Yes, if enabled
Code Generation	Yes

Introduced before R2006a

Repeating Sequence

Generate arbitrarily shaped periodic signal

Library

Sources

Description

The Repeating Sequence block outputs a periodic scalar signal having a waveform that you specify using the **Time values** and **Output values** parameters. The **Time values** parameter specifies a vector of output times. The **Output values** parameter specifies a vector of signal amplitudes at the corresponding output times. Together, the two parameters specify a sampling of the output waveform at points measured from the beginning of the interval over which the waveform repeats (the period of the signal).

By default, both parameters are `[0 2]`. These default settings specify a sawtooth waveform that repeats every 2 seconds from the start of the simulation and has a maximum amplitude of 2.

Algorithm

The block sets the input period as the difference between the first and last value of the **Time values** parameter. The output at any time t is the output at time $t = t - n \cdot \text{period}$, where n is an integer. The sequence repeats at $t = n \cdot \text{period}$. The block uses linear interpolation to compute the value of the waveform between the output times that you specify.

In the following model, the Repeating Sequence block defines **Time values** as [0:0.1:0.5] and **Output values** as [0 15 25 09 13 17]. The stop time of the simulation is 0.7 second.

For the Repeating Sequence block:

- The input period is 0.5.
- The output at any time t is the output at time $t = t - 0.5n$, where $n = 0, 1, 2$, and so on.
- The sequence repeats at $t = 0.5n$, where $n = 0, 1, 2$, and so on.

When you run the model, you get the following results:

At $t = 0.5$, the expected output is equal to the output at $t = 0$, which is 0. Therefore, the last value in the **Output values** vector [0 15 25 09 13 17] does not appear.

Data Type Support

The Repeating Sequence block outputs real signals of type `double`.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Time values

Specify a vector of strictly monotonically increasing time values. The default is `[0 2]`.

Output values

Specify a vector of output values. Each element corresponds to the time value in the same column. The default is `[0 2]`.

Examples

The following Simulink examples show how to use the Repeating Sequence block:

- `sldemo_fuelsys`
- `sldemo_hydrod`
- `sldemo_VariableTransportDelay`

Characteristics

Data Types	Double
Sample Time	Continuous
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Repeating Sequence Interpolated, Repeating Sequence Stair

Introduced before R2006a

Repeating Sequence Interpolated

Output discrete-time sequence and repeat, interpolating between data points

Library

Sources

Description

The Repeating Sequence Interpolated block outputs a discrete-time sequence and then repeats it. Between data points, the block uses the method you specify for the **Lookup Method** parameter to determine the output.

Data Type Support

The Repeating Sequence Interpolated block outputs signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Vector of output values

Specify the column vector containing output values of the discrete time sequence.

Vector of time values

Specify the column vector containing time values. The time values must be strictly increasing, and the vector must have the same size as the vector of output values.

Lookup Method

Specify the lookup method to determine the output between data points.

Sample time

Specify the time interval between samples. To inherit the sample time, set this parameter to -1 . See “Specify Sample Time” for more information.

Output minimum

Specify the minimum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Output maximum

Specify the maximum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as

SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Output data type

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” for more information.

Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point
Sample Time	Specified in the Sample time parameter
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

See Also

Repeating Sequence, Repeating Sequence Stair

Introduced before R2006a

Repeating Sequence Stair

Output and repeat discrete time sequence

Library

Sources

Description

The Repeating Sequence Stair block outputs and repeats a stair sequence that you specify with the **Vector of output values** parameter. For example, you can specify the vector as `[3 1 2 4 1]'`, which produces the following stair sequence:

Data Type Support

The Repeating Sequence Stair block outputs signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean
- Enumerated

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Vector of output values

Specify the vector containing values of the repeating stair sequence.

Sample time

Specify the time interval between samples. To inherit the sample time, set this parameter to -1 . See “Specify Sample Time” for more information.

Output minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Output maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Output data type

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” in the *Simulink User's Guide* for more information.

Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point
Sample Time	Specified in the Sample time parameter
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

See Also

Repeating Sequence, Repeating Sequence Interpolated

Introduced before R2006a

Reset

Add reset port to subsystem

Library: Ports & Subsystems

Description

A Reset block at the root level of a Subsystem block adds a control port to the block. When a reset trigger event occurs on the signal connected to the port, the block states of the subsystem are reset to their initial condition.

Parameters

Reset trigger type — Select the type of trigger event

`level` (default) | `rising` | `falling` | `either` | `level hold`

Select the type of trigger event that resets the subsystem block states.

`level`

Reset the block states when the reset signal is nonzero at the current time step or changes from nonzero at the previous time step to zero at the current time step.

`rising`

Reset the block states when the reset signal rises from a zero to a positive value or from a negative to a positive value.

`falling`

Reset the block states when the reset signal falls from a positive value to zero or from a positive to a negative value.

`either`

Reset the block states when the reset signal changes from a zero to a nonzero value or changes sign.

`level hold`

Reset the block states when the reset signal is nonzero at the current time step.

Programmatic Use

Parameter: ResetTriggerType

Type: character vector

Value: 'level' | 'rising' | 'falling' | 'either' | 'level hold'

Default: 'level'

Propagate sizes of variable-size signals — Select when to propagate a variable-size signal

During execution (default) | Only when enabling

Select when to propagate a variable-size signal.

During execution

Propagate variable-size signals at each time step.

Only when resetting

Propagate variable-size signals when resetting a Subsystem block containing a Reset port block. When you select this option, sample time must be periodic.

Programmatic Use

Block parameter: PropagateVarSize

Type: character vector

Value: 'During execution' | 'Only when resetting'

Default: 'During execution'

Enable zero-crossing detection — Control zero-crossing detection

on (default) | off

Control zero-crossing detection.

on

Detect zero crossings.

off

Do not detect zero crossings.

Programmatic Use

Block parameter: ZeroCross

Type: character vector

Value: 'on' | 'off'

Default: 'on'

Reset | Resettable Subsystem | Subsystem

Topics

“Resettable Subsystems”

“Simulink Block Support for Variable-Size Signals”

Introduced in R2015a

Reset Function

Executes contents on a model reset event

Library: User-Defined Functions

Description

The Reset Function block is a preconfigured subsystem block created from an Initialize block that executes on a model reset event.

Note The Reset Function block is not in the Simulink Library Browser.

To create a Reset Function block:

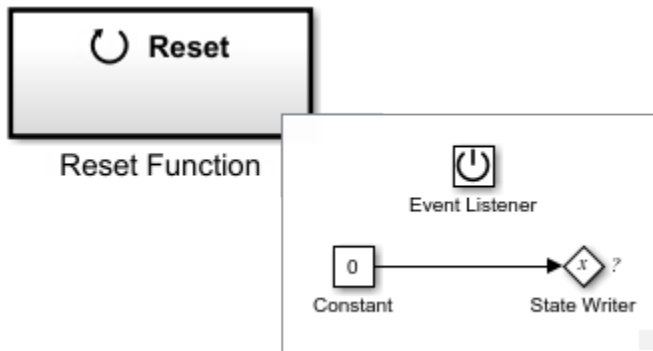

- 1 Add an Initialize block.
- 2 Open the Event Listener block within the Initialize block. From the **Event** drop-down list, select `Reset`.

One parameter appears.

- By default, the **Event name** is set to `Reset`. You can change the name of a reset event by editing this text box.

- 3 Rename the block from `Initialize Function` to `Reset Function`.

The Reset Function block includes an Event Listener block with **Event** set to `Reset`, a Constant block with **Constant value** set to `0`, and a State Writer block.

Replace the Constant block with source blocks that generate the state value for the State Writer block.

For a list of unsupported blocks and features, see “Initialize, Reset, and Terminate Function Limitations”.

A model can potentially have multiple Reset Function blocks with each block having a different **Event name**. Each of these reset events appear in the generated code as a different function.

“Create Test Harness to Generate Function Calls”

“Generate Code That Responds to Initialize, Reset, and Terminate Events” (Simulink Coder)

Resettable Delay

Delay input signal by variable sample period and reset with external signal

Library

Discrete

Description

The Resettable Delay block is a variant of the Delay block that has the source of the initial condition set to `Input port` and the external reset algorithm set to `Rising`, by default.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated Bus
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Code Generation	Yes

See Also

Delay | Tapped Delay | Unit Delay | Variable Integer Delay

Introduced in R2012b

Resettable Subsystem

Subsystem whose block states reset with external trigger

Library: Ports & Subsystems

Description

The Resettable Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem that resets the block states each time the control signal has a trigger event.

Ports

Input

In — Signal input to a subsystem block

scalar | vector | matrix

Placing an Inport block in a Subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Reset — Control signal input to a subsystem block

`scalar` | `vector` | `matrix`

Placing a Reset block in a Subsystem block adds an external input port to the block and changes the block to a Resettable Subsystem block.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Output

out — Signal output from a subsystem

`scalar` | `vector` | `matrix`

Placing an Outport block in a Subsystem block adds an output port from the block. The port label on the Subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Topics

“Resettable Subsystems”

Introduced in R2015a

Resetable Synchronous Subsystem

Represent resettable subsystem that has synchronous reset and enable behavior

Library

HDL Coder / HDL Subsystems

Description

The Resetable Synchronous Subsystem block uses the `Synchronous` mode of the State Control block with the Resetable Subsystem block. If an **S** symbol appears in the subsystem, then it is synchronous. For more information about the block in HDL Coder, see [Resetable Synchronous Subsystem](#).

For more information about the State Control block, see [State Control](#).

Data Type Support

See [Inport](#) for information on the data types accepted by a subsystem's input ports. See [Outport](#) for information on the data types output by a subsystem's output ports.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Show port labels

Display subsystem port labels on the subsystem block.

Default: `FromPortIcon`

`none`

Does not display port labels on the subsystem block.

`FromPortIcon`

If the corresponding port icon displays a signal name, the parameter displays the signal name on the subsystem block. Otherwise, it displays the port block name.

`FromPortBlockName`

Display the name of the corresponding port block on the subsystem block.

`SignalName`

If the signal connected to the subsystem block port is named, this parameter displays the name. Otherwise, it displays the name of the corresponding port block.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Read/Write permissions

Control user access to the contents of the subsystem.

Default: `ReadWrite`

`ReadWrite`

Enables opening and modification of subsystem contents.

`ReadOnly`

Enables the opening but not modification of the subsystem. If the subsystem resides in a block library, you can create and open links to the subsystem, and create and modify local copies of the subsystem. You cannot change the permissions or modify the contents of the original library instance.

NoReadOrWrite

Disables the opening or modification of subsystem. If the subsystem resides in a block library, you can create links to the subsystem in a model. You cannot open, modify, change permissions, or create local copies of the subsystem.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Name of error callback function

Enter the name of the function to be called if an error occurs while Simulink software is executing the subsystem.

Default: ' '

Simulink passes two arguments to the function: the subsystem handle and a character vector that specifies the error type. If no function is specified, you get a generic error message.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Permit hierarchical resolution

Specify whether to resolve names of workspace variables referenced by this subsystem.

Default: All

All

Resolve all names of workspace variables used by this subsystem, including those used to specify block parameter values and Simulink data objects (for example, `Simulink.Signal` objects).

ExplicitOnly

Resolve the names of workspace variables used to specify block parameter values, data store memory (where no block exists), signals, and states marked by using the signal resolution icon.

None

Do not resolve any workspace variable names.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Treat as atomic unit

Causes Simulink to treat the subsystem as a unit when determining the execution order of block methods.

Default: Off

On

Cause Simulink to treat the subsystem as a unit when determining the execution order of block methods. For example, when it needs to compute the output of the subsystem, Simulink software invokes the output methods of all the blocks in the subsystem before invoking the output methods of other blocks at the same level as the subsystem block.

Off

Cause Simulink to treat all blocks in the subsystem as being at the same level in the model hierarchy as the subsystem when determining block method execution order. This can cause the execution of block methods in the subsystem to be interleaved with the execution of block methods outside the subsystem.

This parameter enables:

- “Minimize algebraic loop occurrences” on page 1-0
- “Sample time” on page 1-0
- “Function packaging” on page 1-0 (requires a Simulink Coder license)

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Treat as grouped when propagating variant conditions

Causes Simulink software to treat the subsystem as a unit when propagating variant conditions from Variant Source blocks or to Variant Sink blocks.

Default: On

On

Simulink treats the subsystem as a unit when propagating variant conditions from Variant Source blocks or to Variant Sink blocks. For example, when Simulink computes the variant condition of the subsystem, it propagates that condition to all blocks in the subsystem.

Off

Simulink treats all blocks in the subsystem as being at the same level in the model hierarchy as the subsystem itself when determining their variant condition.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Function packaging

Specify the code format to be generated for an atomic (nonvirtual) subsystem.

Default: Auto

Auto

Simulink Coder chooses the optimal format based on the type and number of subsystem instances in the model.

Inline

Simulink Coder inlines the subsystem unconditionally.

Nonreusable function

Simulink Coder explicitly generates a separate function in a separate file. In some cases, when you apply this setting, the subsystems generate functions with arguments that depend on the “Function interface” on page 1-0 parameter setting. You can name the generated function and file using parameters “Function

name” on page 1-0 and “File name (no extension)” on page 1-0 . These functions are not reentrant.

Reusable function

Simulink Coder generates a function with arguments that allows reuse of subsystem code when a model includes multiple instances of the subsystem.

This option generates a function with arguments that allows subsystem code to be reused in the generated code of a model reference hierarchy. In this case, the subsystem must be in a library.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated Bus
Multidimensional Signals	Yes
Variable-Size Signals	Yes
HDL Code Generation	Yes

Introduced in R2016b

Reshape

Change dimensionality of signal

Library

Math Operations

Description

The Reshape block changes the dimensionality of the input signal to a dimensionality that you specify, using the block's **Output dimensionality** parameter. For example, you can use the block to change an N-element vector to a 1-by-N or N-by-1 matrix signal, and vice versa.

The **Output dimensionality** parameter lets you select any of the following output options.

Output Dimensionality	Description
1-D array	Converts a multidimensional array to a vector (1-D array) array signal. The output vector consists of the first column of the input matrix followed by the second column, etc. (This option leaves a vector input unchanged.)
Column vector	Converts a vector, matrix, or multidimensional input signal to a column matrix, i.e., an M-by-1 matrix, where M is the number of elements in the input signal. For matrices, the conversion is done in column-major order. For multidimensional arrays, the conversion is done along the first dimension.

Output Dimensionality	Description
Row vector	Converts a vector, matrix, or multidimensional input signal to a row matrix, i.e., a 1-by-N matrix where N is the number of elements in the input signal. For matrices, the conversion is done in column-major order. For multidimensional arrays, the conversion is done along the first dimension.
Customize	Converts the input signal to an output signal whose dimensions you specify, using the Output dimensions parameter. The value of the Output dimensions parameter can be a one- or multi-element vector. A value of [N] outputs a vector of size N. A value of [M N] outputs an M-by-N matrix. The number of elements of the input signal must match the number of elements specified by the Output dimensions parameter. For multidimensional arrays, the conversion is done along the first dimension.
Derive from reference input port	Creates a second input port, Ref, on the block. Derives the dimensions of the output signal from the dimensions of the signal input to the Ref input port. Selecting this option disables the Output dimensions parameter. When you select this parameter, the input signals for both inport ports, U and Ref, must have the same sampling mode (sample-based or frame-based).

Data Type Support

The Reshape block accepts and outputs signals of any data type that Simulink supports, including fixed-point, enumerated, and nonvirtual bus data types.

For more information, see “Data Types Supported by Simulink”.

You can use an array of buses as an input signal to a Reshape block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

Parameters

Output dimensionality

Specify the dimensionality of the output signal.

Output dimensions

Specify a custom output dimensionality. This parameter is available only when you set **Output dimensionality** to *Customize*.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated Bus
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Rocker Switch

Toggle parameter between two values

Library: Simulink / Dashboard

Description

The Rocker Switch block toggles the value of the connected block parameter between two values during simulation. For example, you can connect the Rocker Switch block to a Switch block in your model and change its state during simulation. Use the Rocker Switch block with other Dashboard blocks to create an interactive dashboard for your model.

Connection

Dashboard block controls connect to variables and block parameters. To connect a Dashboard block to a variable or parameter, use the **Connection** table in the block's parameters.

- 1 Double-click the block.
- 2 Populate the **Connection** table by selecting blocks of interest in your model.
- 3 Mark the option button next to the parameter or variable you want to adjust during simulation.
- 4 Click **Apply**.

Limitations

- You cannot save the block connections or properties in model files that use the MDL format.

To save connections and properties, save the model file in the SLX format.

- Dashboard blocks can only connect to real scalar signals.
- Dashboard blocks cannot connect to blocks that are commented out.
- Dashboard blocks cannot connect to signals inside reference models.
- Parameters specified by indexing a variable array do not appear in the **Connection** table. For example, a block parameter defined using the variable `engine(1)` does not appear in the table.

To access the parameter in the **Connection** table, assign the indexed value to a scalar variable, such as `engine_1`. Then, use the scalar variable to define the block parameter.

Parameters

Connection — Select a block parameter to connect

signal connection options

Select the block parameter to control using the **Connection** table. To open the dialog box, double-click the block. Then, populate the **Connection** table by selecting a block in your model. Select the variable parameter you want to control, and click **Apply**.

Note To see workspace variables in the connection table, update the model diagram with **Ctrl+D**.

States

Label (Top) — Label for top switch position

'On' (default) | character vector

Labels the top switch position. You can use the **Label** to display the value the connected parameter takes when the switch is positioned at the top, or you can enter a text label.

Example: `Gain = 2`

Value (Top) — Value for top switch position

1 (default) | scalar

The value assigned to the connected parameter when the switch is positioned at the top.

Label (Bottom) — Label for bottom switch position

'Off' (default) | character vector

Labels the bottom switch position. You can use the **Label** to display the value the connected parameter takes when the switch is positioned at the bottom, or you can enter a text label.

Example: `Gain = 1`

Value (Bottom) — Value for bottom switch position

0 (default) | scalar

The value assigned to the connected parameter when the switch is positioned at the bottom.

Label — Block label position

'Top' (default) | 'Bottom' | 'Hide'

Position of the block label. When the block is connected to a signal, the label is the name of the connected signal. When the block is not connected, the label is the instructional text.

Rotary Switch

Switch parameter to set values on dial

Library: Simulink / Dashboard

Description

The Rotary Switch changes the value of the connected block parameter to several specified values during simulation. For example, you can connect the Rotary Switch block to the amplitude or frequency of an input signal in your model and change its characteristics during simulation. Use the Rotary Switch block with other Dashboard blocks to create an interactive dashboard to control your model.

Connection

Dashboard block controls connect to variables and block parameters. To connect a Dashboard block to a variable or parameter, use the **Connection** table in the block's parameters.

- 1 Double-click the block.
- 2 Populate the **Connection** table by selecting blocks of interest in your model.
- 3 Mark the option button next to the parameter or variable you want to adjust during simulation.
- 4 Click **Apply**.

Limitations

- You cannot save the block connections or properties in model files that use the MDL format.

To save connections and properties, save the model file in the SLX format.

- Dashboard blocks can only connect to real scalar signals.
- Dashboard blocks cannot connect to blocks that are commented out.
- Dashboard blocks cannot connect to signals inside reference models.
- Parameters specified by indexing a variable array do not appear in the **Connection** table. For example, a block parameter defined using the variable `engine(1)` does not appear in the table.

To access the parameter in the **Connection** table, assign the indexed value to a scalar variable, such as `engine_1`. Then, use the scalar variable to define the block parameter.

Parameters

Connection — Select a block parameter to connect

signal connection options

Select the block parameter to control using the **Connection** table. To open the dialog box, double-click the block. Then, populate the **Connection** table by selecting a block in your model. Select the variable parameter you want to control, and click **Apply**.

Note To see workspace variables in the connection table, update the model diagram with **Ctrl+D**.

States

value — Values for switch positions

0/1/2/3 (default) | scalar

The values assigned to the connected parameter when the switch is positioned at the corresponding **Label**. Click the **+** button to add positions.

label — Labels for switch positions

'Off'/'Low'/'Medium'/'High' (default) | character vector

Labels the switch positions. You can use the **Label** to display the value the connected parameter takes when the switch points to the **Label**, or you can enter a descriptive text label. Click the **+** button to add positions.

Example: `Gain = 2`

Label — Block label position

'Top' (default) | 'Bottom' | 'Hide'

Position of the block label. When the block is connected to a signal, the label is the name of the connected signal. When the block is not connected, the label is the instructional text.

Rounding Function

Apply rounding function to signal

Library

Math Operations

Description

The Rounding Function block applies a rounding function to the input signal to produce the output signal.

You can select one of the following rounding functions from the **Function** list:

- floor

Rounds each element of the input signal to the nearest integer value towards minus infinity.

- ceil

Rounds each element of the input signal to the nearest integer towards positive infinity.

- round

Rounds each element of the input signal to the nearest integer.

- fix

Rounds each element of the input signal to the nearest integer towards zero.

The name of the selected function appears on the block.

The input signal can be a scalar, vector, or matrix signal having real- or complex-valued elements of type `double`. The output signal has the same dimensions, data type, and numeric type as the input. Each element of the output signal is the result of applying the selected rounding function to the corresponding element of the input signal.

Tip Use the Rounding Function block instead of the Fcn block when you want vector or matrix output, because the Fcn block produces only scalar output.

Also, the Rounding Function block provides two more rounding modes. The Fcn block supports `floor` and `ceil`, but does not support `round` and `fix`.

Data Type Support

The Rounding Function block accepts and outputs real signals of type `double` or `single`.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Function

Specify the rounding function.

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Characteristics

Data Types	Double Single
Sample Time	Inherited from driving block

Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Saturation

Limit range of signal

Library

Discontinuities

Description

The Saturation block imposes upper and lower limits on an input signal.

When the input is...	Where...	The block output is the...
Within the range specified by the Lower limit and Upper limit parameters	$\text{Lower limit} \leq \text{Input value} \leq \text{Upper limit}$	Input value
Less than the Lower limit parameter	$\text{Input value} < \text{Lower limit}$	Lower limit
Greater than the Upper limit parameter	$\text{Input value} > \text{Upper limit}$	Upper limit

When the **Lower limit** and **Upper limit** parameters have the same value, the block output is that value.

Data Type Support

The Saturation block accepts real signals of the following data types:

- Floating point
- Built-in integer
- Fixed point

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Show data type assistant

Display the **Data Type Assistant**.

The **Data Type Assistant** helps you set the **Output data type** parameter.

For more information, see “Control Signal Data Types”.

Upper limit

Specify the upper bound on the input signal.

Default: 0.5

Minimum: value from the **Output minimum** parameter

Maximum: value from the **Output maximum** parameter

- When the input signal to the Saturation block is above this value, the output of the block is clipped to this value.
- The **Upper limit** parameter is converted to the output data type offline using round-to-nearest and saturation.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Lower limit

Specify the lower bound on the input signal.

Default: -0.5

Minimum: value from the **Output minimum** parameter

Maximum: value from the **Output maximum** parameter

- When the input signal to the Saturation block is below this value, the output of the block is clipped to this value.
- The **Lower limit** parameter is converted to the output data type offline using round-to-nearest and saturation.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Treat as gain when linearizing

Select this parameter to cause the linearization commands to treat the gain as 1

Default: On

On

Select to cause the linearization commands to treat the gain as 1.

Off

Clear to cause the linearization commands to treat the gain as 0.

Linearization commands in Simulink software treat this block as a gain in state space.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Enable zero-crossing detection

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Default: On

On

Enable zero-crossing detection.

Off

Do not enable zero-crossing detection.

Parameter: ZeroCross

Type: character vector

Value: 'on' | 'off'

Default: 'on'

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

Default: Off

On

Locks the output data type setting for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change the output data type setting for this block.

Parameter: LockScale

Type: character vector

Value: 'off' | 'on'

Default: 'off'

For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Integer rounding mode

Specify the rounding mode for fixed-point operations.

Default: Floor

Ceiling

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

Floor

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

Simplest

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

Parameter: `RndMeth`

Type: character vector

Value: `'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'`

Default: `'Floor'`

For more information, see “Rounding” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

Output minimum

Lower value of the output range that Simulink checks.

Default: `[]` (unspecified)

Specify this number as a finite, real, double, scalar value.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Parameter: OutMin
Type: character vector
Value: ' [] '
Default: ' [] '

Output maximum

Upper value of the output range that Simulink checks.

Default: [] (unspecified)

Specify this number as a finite, real, double, scalar value.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Note **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Parameter: OutMax
Type: character vector
Value: ' [] '
Default: ' [] '

Output data type

Specify the output data type.

Default: Inherit: Same as input

Inherit: Inherit via back propagation

Use data type of the driving block.

Inherit: Same as input

Use data type of input signal.

double

Output data type is double.

single

Output data type is single.

int8

Output data type is int8.

uint8

Output data type is uint8.

int16

Output data type is int16.

uint16

Output data type is uint16.

int32

Output data type is int32.

uint32

Output data type is uint32.

fixdt(1,16,0)

Output data type is fixed point fixdt(1,16,0).

fixdt(1,16,2^0,0)

Output data type is fixed point fixdt(1,16,2^0,0).

<data type expression>

Use a data type object, for example, Simulink.NumericType.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

For more information, see “Control Signal Data Types”.

Mode

Select the category of data to specify.

Default: `Inherit`

`Inherit`

Inheritance rules for data types. Selecting `Inherit` enables a second menu/text box to the right. Select one of the following choices:

- `Inherit via back propagation`
- `Same as input (default)`

`Built in`

Built-in data types. Selecting `Built in` enables a second menu/text box to the right. Select one of the following choices:

- `double (default)`
- `single`
- `int8`
- `uint8`
- `int16`
- `uint16`
- `int32`
- `uint32`

`Fixed point`

Fixed-point data types.

`Expression`

Expressions that evaluate to data types. Selecting `Expression` enables a second menu/text box to the right, where you can enter the expression.

Clicking the **Show data type assistant** button enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specify Data Types Using Data Type Assistant”.

Signedness

Specify whether you want the fixed-point data as signed or unsigned.

Default: Signed

Signed

Specify the fixed-point data as signed.

Unsigned

Specify the fixed-point data as unsigned.

Selecting **Mode** > Fixed point enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Word length

Specify the bit size of the word that holds the quantized integer.

Default: 16

Minimum: 0

Maximum: 32

Selecting **Mode** > Fixed point enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

Default: Best precision

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

Best precision

Specify best-precision values.

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting Slope and bias enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

For more information, see “Specifying a Fixed-Point Data Type”.

Fraction length

Specify fraction length for fixed-point data type.

Default: 0

Binary points can be positive or negative integers.

Selecting **Scaling** > `Binary point` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Slope

Specify slope for the fixed-point data type.

Default: 2^0

Specify any positive real number.

Selecting **Scaling** > `Slope` and `bias` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Bias

Specify bias for the fixed-point data type.

Default: 0

Specify any real number.

Selecting **Scaling** > `Slope` and `bias` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Examples

The `sldemo_boiler` model shows how you can use the Saturation block.

The Saturation block appears in the Boiler Plant model/digital thermometer/ADC subsystem.

The ADC subsystem digitizes the input analog voltage by:

- Multiplying the analog voltage by 256/5 with the Gain block
- Rounding the value to integer floor with the Quantizer block
- Limiting the output to a maximum of 255 (the largest unsigned 8-bit integer value) with the Saturation block

For more information, see “Explore the Fixed-Point "Bang-Bang Control" Model” (Stateflow) in the Stateflow documentation.

Characteristics

Data Types	Double Single Base Integer Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	Yes, if enabled
Code Generation	Yes

See Also

Saturation Dynamic

Introduced before R2006a

Saturation Dynamic

Bound range of input

Library

Discontinuities

Description

The Saturation Dynamic block bounds the range of an input signal to upper and lower saturation values. An input signal outside of these limits saturates to one of the bounds where:

- The input below the lower limit is set to the lower limit.
- The input above the upper limit is set to the upper limit.

The input for the upper limit is the `up` port, and the input for the lower limit is the `lo` port.

Data Type Support

The Saturation Dynamic block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean

Tip Although this block accepts Boolean signals, avoid this usage.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Output minimum

Specify the minimum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Output maximum

Specify the maximum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Output data type

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as second input`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” in the *Simulink User's Guide* for more information.

Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer). in the Fixed-Point Designer documentation.

Saturate on integer overflow

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Do not select this check box.	<p>You want to optimize efficiency of your generated code.</p> <p>You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.</p>	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Code Generation	Yes

See Also

Saturation

Introduced before R2006a

ScopeTime Scope

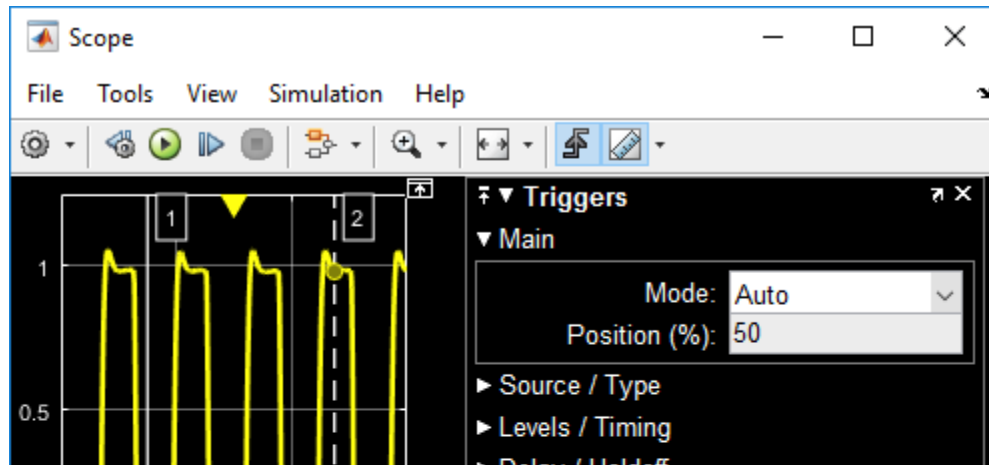

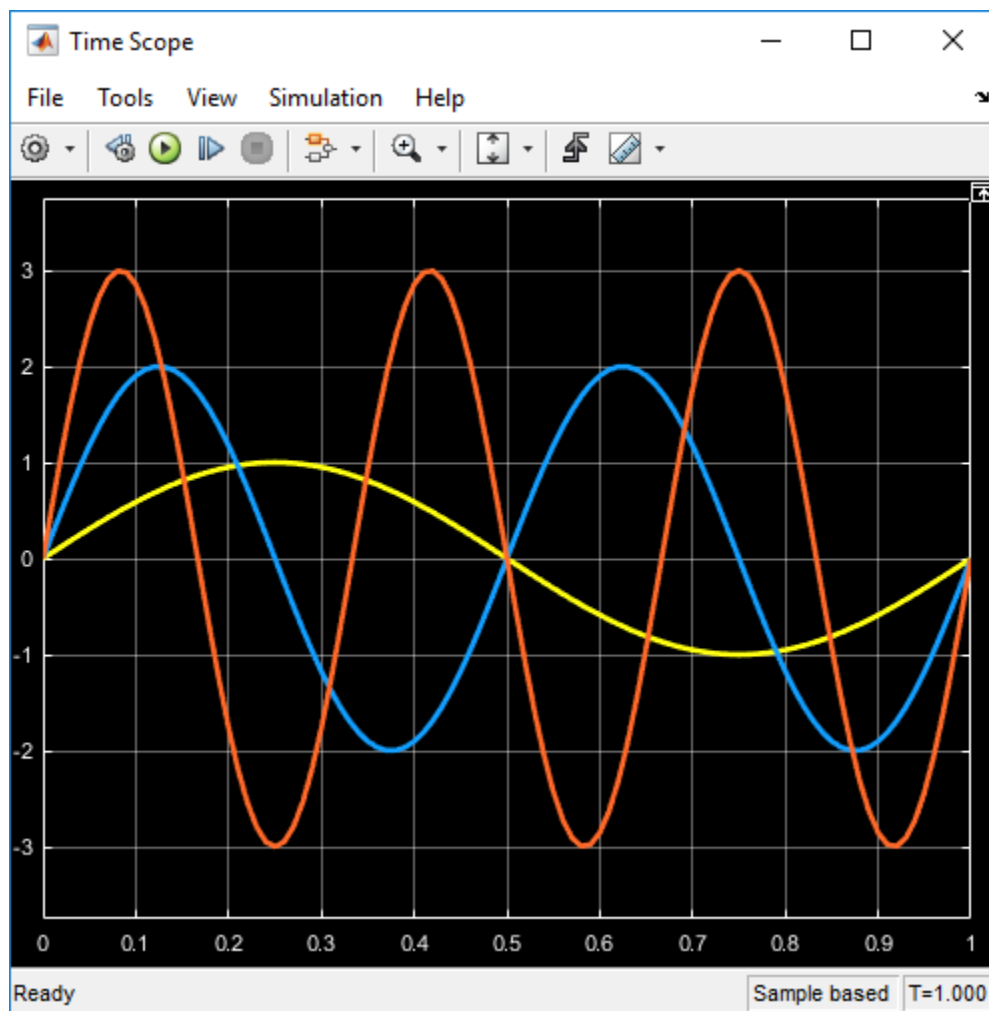

Display signals generated during simulation

Library: Simulink / Sinks

Description

The Simulink Scope block and DSP System Toolbox Time Scope block display time domain signals.

The two blocks have identical functionality, but different default settings. The Time Scope is optimized for discrete time processing. The Scope is optimized for general time-domain simulation. For a side-by-side comparison, see “Simulink Scope Versus DSP System Toolbox Time Scope”.

Oscilloscope features:

- Triggers — Set triggers to sync repeating signals and pause the display when events occur.
- Cursor Measurements — Measure signal values using vertical and horizontal cursors.
- Signal Statistics — Display the maximum, minimum, peak-to-peak difference, mean, median, and RMS values of a selected signal.
- Peak Finder — Find maxima, showing the x -axis values at which they occur.
- Bilevel Measurements — Measure transitions, overshoots, undershoots, and cycles.

You must have a Simscape™ or DSP System Toolbox license to use the Peak Finder, Bilevel Measurements, and Signal Statistics.

Scope display features:

- Simulation control — Debug models from a Scope window using **Run**, **Step Forward**, and **Step Backward** toolbar buttons.
- Multiple signals — Plot multiple signals on the same y -axis (display) using multiple input ports.
- Multiple y -axes (displays) — Display multiple y -axes. All the y -axes have a common time range on the x -axis.
- Modify parameters — Modify scope parameter values before and during a simulation.
- Axis autoscaling — Autoscale axes during or at the end of a simulation. Margins are drawn at the top and bottom of the axes.
- Display data after simulation — If a Scope is closed at the start of a simulation, scope data is still written to the scope during a simulation. As a result, if you open the Scope after a simulation, the Scope displays simulation results for attached input signals.

For information on controlling a scope programmatically, see “Control Scopes Programmatically”.

Limitations

- Do not use scope blocks in a Library. If you place a scope block inside a library block with a locked link or in a locked library, Simulink displays an error when trying to open the scope window. To display internal data from a library block, add an output port to the library block, and then connect the port to a Scope block in your model.
- A Scope block may plot a single point when connected to a constant signal.

Ports

Input

Port_1 — Signal or signals to visualize

scalar | vector | matrix | array | bus | nonvirtual bus

Connect the signals you want to visualize. You can have up to 96 input ports. Input signals can have these characteristics:

- **Type** - Continuous (sample-based) or discrete (sample-based and frame-based).
- **Data type** - Any data type that Simulink supports. See “Data Types Supported by Simulink”.
- **Dimension** — Scalar, one dimensional (vector), two dimensional (matrix), or multidimensional. Display multiple channels within one signal depending on the dimension. See “Signal Dimensions” and “Determine Output Signal Dimensions”.

Bus Support

You can connect nonvirtual bus and arrays of bus signals to a Scope block. To display the bus signals, use normal or accelerator simulation mode. The Scope block displays each bus element signal in the order the elements appear in the bus, from the top to the bottom. Nested bus elements are flattened.

To log nonvirtual bus signals with a Scope block, set the **Save format** block parameter to Dataset. You can use any **Save format** to log virtual bus signals.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated | bus

Properties

Configuration Properties

The Configuration Properties dialog box controls various properties about the scope displays. From the scope menu, select **View > Configuration Properties**.

Main

Open at simulation start — Specify when scope window opens
off (default for Scope) | on (default for Time Scope)

Select this check box to open the scope window when simulation starts.

Programmatic Use

See `OpenAtSimulationStart`.

Display the full path — Display block path on scope title bar
off (default) | on

Select this check box to display the block path in addition to the block name.

Number of input ports — Number of input ports on scope block
1 (default) | integer

Specify number of input ports on a Scope block, specified as an integer. The maximum number of input ports is 96. This property does not apply to floating scopes and scope viewers.

Programmatic Use

See `NumInputPorts`.

Layout — Number and arrangement of displays
1-by-1 display (default) | an arrangement of m-by-n axes

Specify number and arrangement of displays. The maximum layout is 16 rows by 16 columns.

To expand the layout grid beyond 4 by 4, click within the dialog box and drag. Maximum of 16 rows by 16 columns.

If the number of displays is equal to the number of ports, signals from each port appear on separate displays. If the number of displays is less than the number of ports, signals from additional ports appear on the last display. For layouts with multiple columns and rows, ports are mapped down then across.

Programmatic Use

See `LayoutDimensions`.

Sample time — Simulation interval between scope updates

-1 (for inherited) (default) | positive real number

Specify the time interval between updates of the scope display. This property does not apply to floating scopes and scope viewers.

Programmatic Use

See `SampleTime`.

Input processing — Channel or element signal processing

`Elements as channels (sample based) (default for Scope)` | `Columns as channels (frame based) (default for Time Scope)`

- `Elements as channels (sample based)` - Process each element as a unique sample.

- `Columns as channels (frame based)` - Process signal values in a channel as a group of values from multiple time intervals. Frame-based processing is available only with discrete input signals.

Programmatic Use

See `FrameBasedProcessing`.

Maximize axes — Maximize size of plots

`Off` (default for `Scope`) | `Auto` (default for `Time Scope`) | `On`

- `Auto` - If “`Title`” on page 1-0 and “`Y-label`” on page 1-0 properties are not specified, maximize all plots.
- `On` - Maximize all plots. Values in **`Title`** and **`Y-label`** are hidden.
- `Off` - Do not maximize plots.

Programmatic Use

See `MaximizeAxes`.

Time

Time span — Length of x-axis to display

`Auto` (default) | `User defined`

- `Auto` - Difference between the simulation start and stop times.
- The block calculates the beginning and end times of the time range using the “`Time display offset`” on page 1-0 and “`Time span`” on page 1-0 properties. For example, if you set the **`Time display offset`** to 10 and the **`Time span`** to 20, the scope sets the time range from 10 to 30.
- `User defined` - Value less than the total simulation time.

Programmatic Use

See `TimeSpan`.

Time span overrun action — Display data beyond visible x-axis

`Wrap` (default) | `Scroll`

Specify how to display data beyond the visible *x*-axis range.

You can see the effects of this option only when plotting is slow with large models or small step sizes.

- `Wrap` - Draw a full screen of data from left to right, clear the screen, and then restart drawing of data.
- `Scroll` - Move data to the left as new data is drawn on the right. This mode is graphically intensive and can affect run-time performance.

Programmatic Use

See `TimeSpanOverrunAction`.

Time units — *x*-axis units

`None` (default for `Scope`) | `Metric` (default for `Time Scope`) | `Seconds`

- `Metric` - Display time units based on the length of “Time span” on page 1-0 .
- `Seconds` - Display time (seconds).
- `None` - Do not display time units.

Programmatic Use

See `TimeUnits`.

Time display offset — *x*-axis offset

`0` (default) | `scalar` | `vector`

Offset the *x*-axis by a specified time value, specified as a real number or vector of real numbers.

For input signals with multiple channels, you can enter a scalar or vector:

- `Scalar` — Offset all channels of an input signal by the same time value.
- `Vector` — Independently offset the channels.

Programmatic Use

See `TimeDisplayOffset`.

Time-axis labels — Display of *x*-axis labels

`Bottom Displays Only` (default for `Scope`) | `All` (default for `Time Scope`) | `None`

Specify how *x*-axis (time) labels display.

- All - Display *x*-axis labels on all *y*-axes.
- None - Do not display labels. Selecting None also clears the **Show time-axis label** check box.
- Bottom displays only - Display *x*-axis label on the bottom *y*-axis.

Dependencies

The “Active display” on page 1-0 property determines which display is affected.

To activate this property, set:

- “Show time-axis label” on page 1-0 to on.
- “Maximize axes” on page 1-0 to off.

Programmatic Use

See TimeAxisLabels.

Show time-axis label — Display or hide *x*-axis labels

off (default for Scope) | on (default for Time Scope)

Select this check box to show the *x*-axis label for the active display

Dependencies

The “Active display” on page 1-0 property determines which display is affected.

To activate this property, set “Time-axis labels” on page 1-0 to All or Bottom Displays Only.

Programmatic Use

See ShowTimeAxisLabel.

Display

Active display — Selected display

1 (default) | positive integer

Selected display. Use this property to control which display is changed when changing style properties and axes-specific properties.

Specify the desired display using a positive integer that corresponds to the column-wise placement index.

Programmatic Use

See “Active display” on page 1-0 .

Title — Display name

`%<SignalLabel>` (default) | character vector | string

Specify a title for display, specified as a character vector or string. The default value `%<SignalLabel>` uses the input signal name for the title.

Dependency

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See Title.

Show legend — Display signal legend

`off` (default) | `on`

Toggle signal legend. The names listed in the legend are the signal names from the model. For signals with multiple channels, a channel index is appended after the signal name. Continuous signals have straight lines before their names, and discrete signals have step-shaped lines.

From the legend, you can control which signals are visible. This control is equivalent to changing the visibility in the **Style** properties. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again. To show only one signal, right-click the signal name, which hides all other signals. To show all signals, press **Esc**.

Dependency

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See ShowLegend.

Show grid — Show internal grid lines

`on` (default) | `off`

Select this check box to show grid lines.

Dependency

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See ShowGrid.

Plot signals as magnitude and phase — Split display into magnitude and phase plots

off (default) | on

- On - Display magnitude and phase plots. If the signal is real, plots the absolute value of the signal for the magnitude. The phase is 0 degrees for positive values and 180 degrees for negative values. This feature is useful for complex-valued input signals. If the input is a real-valued signal, selecting this check box returns the absolute value of the signal for the magnitude.
- Off - Display signal plot. If the signal is complex, plots the real and imaginary parts on the same *y*-axis.

Dependency

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See PlotAsMagnitudePhase.

Y-limits (Minimum) — Minimum y-axis value

-10 (default) | real scalar

Specify the minimum value of the *y*-axis as a real number.

Tunable: Yes

Dependency

The “Active display” on page 1-0 property determines which display is affected.

If you select **Plot signals as magnitude and phase**, this property only applies to the magnitude plot. The *y*-axis limits of the phase plot are always [-180 180].

Programmatic Use

See YLimits.

Y-limits (Maximum) — Maximum y-axis value

10 (default) | real scalar

Specify the maximum value of the y-axis as a real number.

Tunable: Yes

Dependency

The “Active display” on page 1-0 `ActiveDisplay` property determines which display is affected.

If you select **Plot signals as magnitude and phase**, this property only applies to the magnitude plot. The y-axis limits of the phase plot are always [-180 180].

Programmatic Use

See YLimits.

Y-label — Y-axis label

none (default for Scope) | 'Amplitude' (default for Time Scope) | character vector

Specify the text to display on the y-axis. To display signal units, add (%<SignalUnits>) to the label. At the beginning of a simulation, Simulink replaces (%SignalUnits) with the units associated with the signals.

Example: For a velocity signal with units of m/s, enter `Velocity (%<SignalUnits>)`.

Dependency

The “Active display” on page 1-0 `ActiveDisplay` property determines which display is affected.

If you select **Plot signals as magnitude and phase**, this property does not apply. The y-axes are labeled Magnitude and Phase.

Programmatic Use

See YLabel.

Logging

Limit data points to last — Limit buffered data values

off and 5000 (default) | on | positive integer

Specify to limit buffered data values before plotting and saving signals. Data values are from the end of a simulation. To use this property, you must also specify the number of data values by entering a positive integer in the text box.

- On - Save specified number of data values for each signal. If the signal is frame-based, the number of buffered data values is the specified number of data values multiplied by the frame size.

For simulations with **Stop time** set to `inf`, consider selecting **Limit data points to last**.

In some cases, for example where the sample time is small, selecting this parameter can have the effect of plotting signals for less than the entire time range of a simulation. If a scope plots a portion of your signals, consider increasing the number of data values to save.

- Off - Save and plot all data values. Clearing **Limit data points to last** can cause an out-of-memory error for simulations that generate a large amount of data or for systems without enough available memory.

Dependency

To enable this property, select “Log data to workspace” on page 1-0 .

This property limits the data values plotted in the scope and the data values saved to a MATLAB variable specified in “Variable name” on page 1-0 .

Programmatic Use

See `DataLoggingLimitDataPoints` and `DataLoggingMaxPoints`.

Decimation — Reduce amount of scope data to display and save

off, 2 (default) | on | positive integer

- On - Plot and log (save) scope data every Nth data point, where N is the decimation factor entered in the text box. A value of 1 buffers all data values.
- Off - Save all scope data values.

Dependency

To enable this property, select “Log data to workspace” on page 1-0 .

This property limits the data values plotted in the scope and the data values saved to a MATLAB variable specified in “Variable name” on page 1-0 .

Programmatic Use

See `DataLoggingDecimateData` and `DataLoggingDecimation`.

Log data to workspace — Save data to MATLAB workspace

off (default) | on

Select this check box to activate logging and activate the **Variable name**, **Save format**, and **Decimation** properties. This property does not apply to floating scopes and scope viewers.

For an example of saving signals to the MATLAB Workspace using a Scope block, see “Save Simulation Data Using Floating Scope Block”.

Programmatic Use

See `DataLogging`.

Variable name — Name of saved data variable

`ScopeData` (default) | character vector | string

Specify a variable name for saving scope data in the MATLAB workspace, specified as a character vector or string. This property does not apply to floating scopes and scope viewers.

Dependency

To enable this property, select “Log data to workspace” on page 1-0 .

Programmatic Use

See `DataLoggingVariableName`.

Save format — MATLAB variable format

`Dataset` (default) | `Structure With Time` | `Structure` | `Array`

Select variable format for saving data to the MATLAB workspace. This property does not apply to floating scopes and scope viewers.

- **Dataset** - Save data as a dataset object. This format does not support variable-size data, MAT-file logging, or external mode archiving. See `Simulink.SimulationData.Dataset`.
- **Structure With Time** - Save data as a structure with associated time information.
- **Structure** - Save data as a structure.
- **Array** - Save data as an array with associated time information. This format does not support variable-size data.

Dependency

To enable this property, select “Log data to workspace” on page 1-0 .

Programmatic Use

See `DataLoggingSaveFormat`.

Axes Scaling Properties

The **Axes Scaling** dialog controls the axes limits of the scope. To open the Axes Scaling properties, in the scope menu, select **Tools > Axes Scaling > Axes Scaling Properties**.

Axes scaling — Y-axis scaling mode

Manual (default) | Auto | After N Updates

- **Manual** - Manually scale *y*-axis range with **Scale Y-axis Limits** toolbar button.
- **Auto** - Scale *y*-axis range during and after simulation. Selecting this option displays the “Do not allow Y-axis limits to shrink” on page 1-0 check box.

If you want the *y*-axis range to increase and decrease with the maximum value of a signal, set **Axes scaling** to `Auto` and clear the **Do not allow Y-axis limits to shrink** check box.

- **After N Updates** - Scale *y*-axis after the number of time steps specified in the “Number of updates” on page 1-0 text box (10 by default). Scaling occurs only once during each run.

Programmatic Use

See `AxesScaling`.

Do not allow Y-axis limits to shrink — When y-axis limits can change
on (default) | off

Allow y-axis range limits to increase but not decrease during a simulation.

Dependency

To use this property, set “Axes scaling” on page 1-0 to Auto.

Number of updates — Number of updates before scaling
10 (default) | integer

Set this property to delay auto scaling the y-axis.

Dependency

To use this property, set “Axes scaling” on page 1-0 to After N Updates.

Programmatic Use

See AxesScalingNumUpdates.

Scale axes limits at stop — When y-axis limits can change
on (default) | off

- On - Scale axes when simulation stops.
- Off - Scale axes continually.

Dependency

To use this property, set “Axes scaling” on page 1-0 to Auto.

Y-axis Data range (%) — Percent of y-axis to plot on
80 (default) | integer between [1, 100]

Specify percentage of y-axis range for plotting data. For example, if you set this property to 100, plotted data uses the entire y-axis range.

Y-axis Align — Alignment along y-axis
Center (default) | Top | Bottom

Specify where to align plotted data along the y-axis data range when **Y-axis Data range** is set to less than 100 percent.

- **Top** - Align signals with maximum values at top of *y*-axis range.
- **Center** - Center signals between minimum and maximum values.
- **Bottom** - Align signals with minimum values at bottom of *y*-axis range.

Autoscale X-axis limits — Scale *x*-axis range limits

off (default) | on

Scale *x*-axis range to fit all signal values. If **Axes scaling** is set to `Auto`, scales the data currently within the axes, not the entire signal in the data buffer.

X-axis Data range (%) — Percent of *x*-axis to plot on

100 (default) | integer between [1, 100]

Specify the percentage of the *x*-axis range to plot data on. For example, if you set this property to 100, plotted data uses the entire *x*-axis range.

X-axis Align — Alignment along *x*-axis

Center (default) | Top | Bottom

Specify where to align plotted data along the *x*-axis data range when **X-axis Data range** is set to less than 100 percent.

- **Top** - Align signals with maximum values at top of *x*-axis range.
- **Center** - Center signals between minimum and maximum values.
- **Bottom** - Align signals with minimum values at bottom of *x*-axis range.

Style Properties

To open the Style dialog box, from the scope menu, select **View > Style**.

Figure color — Background color for window

black (default) | color

Background color for the scope

Plot type — How to plot signal

Auto (default for Scope) | Line (default for Time Scope) | Stairs | Stem

When you select `Auto`, the plot type is a line graph for continuous signals, a stair-step graph for discrete signals, and a stem graph for Simulink message signals.

Axes colors — Background and axes color for individual displays

black (default) | color

Select the background color for axes (displays) with the first color palette. Select the grid and label color with the second color palette.

Preserve colors for copy to clipboard — Copy scope without changing colors

off (default) | on

Specify whether to use the displayed color of the scope when copying.

When you select **File > Copy to Clipboard**, the software changes the color of the scope to be printer friendly (white background, visible lines). If you want to copy and paste the scope with the colors displayed, select this check box.

Properties for line — Line to change

Channel 1 (default)

Select active line for setting line style properties.

Visible — Line visibility

on (default) | off

Show or hide a signal on the plot.

Dependency

The values of “Active display” on page 1-0 and “Properties for line” on page 1-0 determine which line is affected.

Line — Line style

style | width | color

Select line style, width, and color.

Dependency

The values of “Active display” on page 1-0 and “Properties for line” on page 1-0 determine which line is affected.

Marker — Data point marker style

None (default) | marker shape

Select marker style.

Dependency

The values of “Active display” on page 1-0 and “Properties for line” on page 1-0 determine which line is affected.

Second-Order Integrator, Second-Order Integrator Limited

Integrate input signal twice

Library

Continuous

Description

The Second-Order Integrator block and the Second-Order Integrator Limited block solve the second-order initial value problem:

$$\begin{aligned}\frac{d^2x}{dt^2} &= u, \\ \left. \frac{dx}{dt} \right|_{t=0} &= dx_o, \\ x|_{t=0} &= x_o,\end{aligned}$$

where u is the input to the system. The block is therefore a dynamic system with two continuous states: x and dx/dt .

Note These two states have a mathematical relationship, namely, that dx/dt is the derivative of x . In order to satisfy this relationship throughout the simulation, Simulink places various constraints on the block parameters and behavior.

The Second-Order Integrator Limited block is identical to the Second-Order Integrator block with the exception that it defaults to limiting the states based on the specified upper and lower limits. For more information, see “Limiting the States” on page 1-1346.

Simulink software can use a number of different numerical integration methods to compute the outputs of the block. Each has advantages for specific applications. Use the **Solver** pane of the Configuration Parameters dialog box to select the technique best suited to your application. (For more information, see “About Solvers”.) The selected solver computes the states of the Second-Order Integrator block at the current time step using the current input value.

Use the block parameter dialog box to:

- Specify whether the source of each state initial condition is internal or external
- Specify a value for the state initial conditions
- Define upper and lower limits on either or both states
- Specify absolute tolerances for each state
- Specify names for both states
- Choose an external reset condition
- Enable zero-crossing detection
- Reinitialize dx/dt when x reaches saturation
- Specify that Simulink disregard the state limits and external reset for linearization operations

Defining Initial Conditions

You can define the initial conditions of each state individually as a parameter on the block dialog box or input one or both of them from an external signal.

- To define the initial conditions of state x as a block parameter, use the **Initial condition source x** drop-down menu to select `internal` and enter the value in the **Initial condition x** field.
- To provide the initial conditions from an external source for state x , specify the **Initial condition source x** parameter as `external`. An additional input port appears on the block.
- To define the initial conditions of state dx/dt as a block parameter, use the **Initial condition source dx/dt** drop-down menu to select `internal` and enter the value in the **Initial condition dx/dt** field.

- To provide the initial conditions from an external source for state dx/dt , specify **Initial condition source dx/dt** as external. An additional input port appears on the block.

If you choose to use an external source for both state initial conditions, your block appears as follows.

Note

- Simulink does not allow initial condition values of `inf` or `NaN`.
 - If you limit state x or state dx/dt by specifying saturation limits (see “Limiting the States” on page 1-1346) and one or more initial conditions are outside the corresponding limits, then the respective states are initialized to the closest valid value and a set of consistent initial conditions is calculated.
-

Limiting the States

When modeling a second-order system, you may need to limit the block states. For example, the motion of a piston within a cylinder is governed by Newton's Second Law and has constraints on the piston position (x). With the Second-Order Integrator block, you can limit the states x and dx/dt independent of each other. You can even change the limits during simulation; however, you cannot change whether or not the states are limited. An important rule to follow is that an upper limit must be strictly greater than its corresponding lower limit.

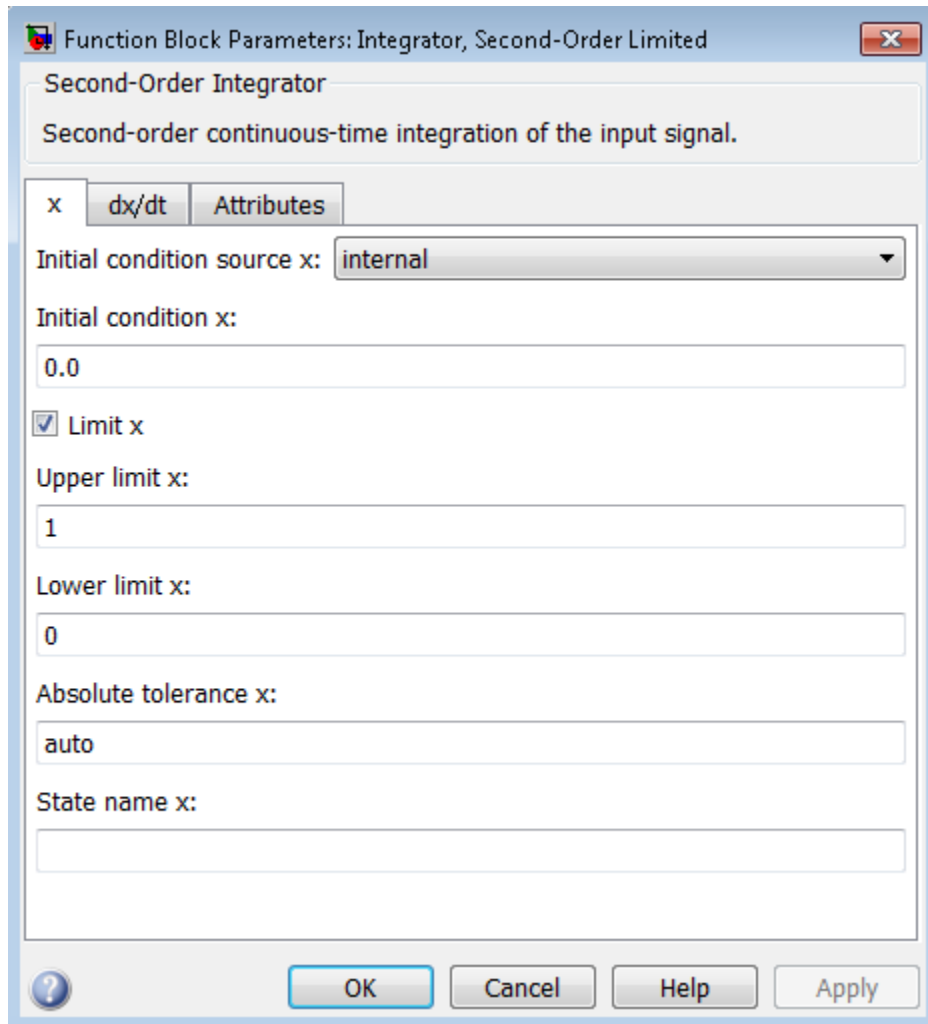

The block appearance changes when you limit one or both states. Shown below is the appearance of the block with both states limited.

For each state, you can use the block parameter dialog box to set appropriate saturation limits.

Limiting x only

If you use the Second-Order Integrator Limited block, both states are limited by default. But you can also manually limit state x on the Second-Order Integrator block by selecting **Limit x** and entering the limits in the appropriate parameter fields.

The block then determines the values of the states as follows:

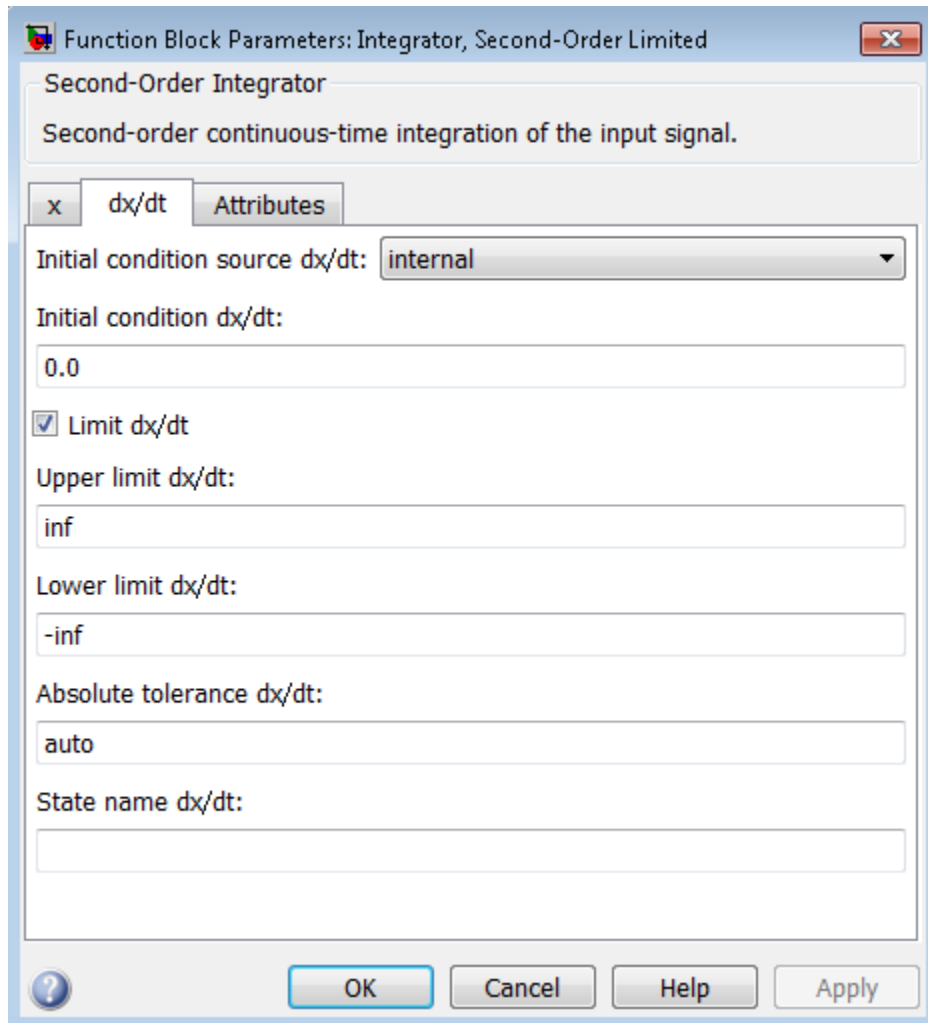

- When x is less than or equal to its lower limit, the value of x is held at its lower limit and dx/dt is set to zero.
- When x is in between its lower and upper limits, both states follow the trajectory given by the second-order ODE.

- When x is greater than or equal to its upper limit, the value of x is held at its upper limit and dx/dt is set to zero.

You can choose to reinitialize dx/dt to a new value at the time when x reaches saturation. See “Reinitializing dx/dt when x reaches saturation” on page 1-1353

Limiting dx/dt only

As with state x , state dx/dt is set as limited by default on the **dx/dt** pane of the Second-Order Integrator Limited parameter dialog box. You can manually set this parameter, **Limit dx/dt** , on the Second-Order Integrator block. In either case, you must enter the appropriate limits for dx/dt .

If you limit only the state dx/dt , then the block determines the values of dx/dt as follows:

- When dx/dt is less than or equal to its lower limit, the value of dx/dt is held at its lower limit.
- When dx/dt is in between its lower and upper limits, both states follow the trajectory given by the second-order ODE.

- When dx/dt is greater than or equal to its upper limit, the value of dx/dt is held at its upper limit.

When state dx/dt is held at its upper or lower limit, the value of x is governed by the first-order initial value problem:

$$\frac{dx}{dt} = L,$$

$$x(t_L) = x_L,$$

where L is the dx/dt limit (upper or lower), t_L is the time when dx/dt reaches this limit, and x_L is the value of state x at that time.

Limiting Both States

When you limit both states, Simulink maintains mathematical consistency of the states by limiting the allowable values of the upper and lower limits for dx/dt . Such limitations are necessary to satisfy the following constraints:

- When x is at its saturation limits, the value of dx/dt must be zero.
- In order for x to leave the upper limit, the value of dx/dt must be strictly negative.
- In order for x to leave its lower limit, the value of dx/dt must be strictly positive.

Consequently, for such cases, the upper limit of dx/dt must be strictly positive and the lower limit of dx/dt must be strictly negative.

When both states are limited, the block determines the states as follows:

- Whenever x reaches its limits, the resulting behavior is the same as that described in “Limiting x only”.
- Whenever dx/dt reaches one of its limits, the resulting behavior is the same as that described in “Limiting dx/dt only” — including the computation of x using a first-order ODE when dx/dt is held at one of its limits. In such cases, when x reaches one of its limits, it is held at that limit and dx/dt is set to zero.
- Whenever both reach their respective limits simultaneously, the state x behavior overrides dx/dt behavior to maintain consistency of the states.

When you limit both states, you can choose to reinitialize dx/dt at the time when state x reaches saturation. If the reinitialized value is outside specified limits on dx/dt , then

dx/dt is reinitialized to the closest valid value and a consistent set of initial conditions is calculated. See “Reinitializing dx/dt when x reaches saturation” on page 1-1353

Resetting the State

The block can reset its states to the specified initial conditions based on an external signal. To cause the block to reset its states, select one of the **External reset** choices on the **Attributes** pane. A trigger port appears on the block below its input port and indicates the trigger type.

- Select **rising** to reset the states when the reset signal rises from zero to a positive value, from a negative to a positive value, or a negative value to zero.
- Select **falling** to reset the states when the reset signal falls from a positive value to zero, from a positive to a negative value, or from zero to negative.
- Select **either** to reset the states when the reset signal changes from zero to a nonzero value or changes sign.

The reset port has direct feedthrough. If the block output feeds back into this port, either directly or through a series of blocks with direct feedthrough, an algebraic loop results (see “Algebraic Loops”).

Enabling Zero-Crossing Detection

This parameter controls whether zero-crossing detection is enabled for this block. By default, the **Enable zero-crossing detection** parameter is selected on the **Attributes** pane. However, this parameter is only in affect if the **Zero-crossing control**, on the **Solver** pane of the Configuration Parameters dialog, is set to `Use local settings`. For more information, see “Zero-Crossing Detection”.

Reinitializing dx/dt when x reaches saturation

For certain modeling applications, dx/dt must be reinitialized when state x reaches its limits in order to pull x out of saturation immediately. You can achieve this by selecting **Reinitialize dx/dt when x reaches saturation** on the **Attributes** pane.

If this option is on, then at the instant when x reaches saturation, Simulink checks whether the current value of the dx/dt initial condition (parameter or signal) allows the state x to leave saturation immediately. If so, Simulink reinitializes state dx/dt with the value of the initial condition (parameter or signal) at that instant. If not, Simulink ignores this parameter at the current instant and sets dx/dt to zero to make the block states consistent.

This parameter only applies at the time when x actually reaches saturation limit. It does not apply at any future time when x is being held at saturation.

Refer to the sections on limiting the states for more information. For an example, see the `sldemo_bounce` example.

Disregarding State Limits and External Reset for Linearization

For cases where you simplify your model by linearizing it, you can have Simulink disregard the limits of the states and the external reset by selecting **Ignore state limits and the reset for linearization**.

Specifying the Absolute Tolerance for the Block Outputs

By default Simulink software uses the absolute tolerance value specified in the Configuration Parameters dialog box (see “Error Tolerances for Variable-Step Solvers”) to compute the output of the integrator blocks. If this value does not provide sufficient error control, specify a more appropriate value for state x in the **Absolute tolerance x** field and for state dx/dt in the **Absolute tolerance dx/dt** field of the parameter dialog box. Simulink uses the values that you specify to compute the state values of the block.

Specifying the Display of the Output Ports

You can control whether or not to display the x or the dx/dt output port using the `ShowOutput` parameter. You can display one output port or both; however, you must select at least one.

Specifying the State Names

You can specify the name of x states and dx/dt states using the `StateNameX` and `StateNameDXDT` parameters. However, you must specify names for either both or neither; you cannot specify names for just x or just dx/dt . Both state names must have identical type and length. Furthermore, the number of names must evenly divide the number of states.

Selecting All Options

When you select all options, the block icon looks like this.

Data Type Support

The Integrator block accepts and outputs signals of type `double` on its data ports. The external reset port accepts signals of type `double` or `Boolean`.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

- “Initial condition source x ” on page 1-1355
- “Initial condition x ” on page 1-1356

Initial condition source x

Specify the initial condition source for state x .

Default: `internal`

`internal`

Get the initial conditions of state x from the **Initial condition x** parameter.

`external`

Get the initial conditions of state x from an external block.

Simulink software does not allow the initial condition of this block to be `inf` or `NaN`.

Selecting `internal` enables the **Initial condition x** parameter.

Selecting `external` disables the **Initial condition x** parameter..

Parameter: `ICSourceX`

Type: character vector

Value: `'internal' | 'external'`

Default: `'internal'`

Initial condition x

Specify the initial condition of state x .

Default: `0.0`

Simulink software does not allow the initial condition of this block to be `inf` or `NaN`.

Setting **Initial condition source x** to `internal` enables this parameter.

Setting **Initial condition source x** to `external` disables this parameter.

Parameter: `ICX`

Type: scalar or vector

Value: `'0'`

Default: `'0'`

Limit x

Limit state x of the block to a value between the **Lower limit x** and **Upper limit x** parameters.

Default: `Off` for Second-Order Integrator, `On` for Second-Order Integrator Limited

On

Limit state x to a value between the **Lower limit x** and **Upper limit x** parameters.

Off

Do not limit the state x output to a value between the **Lower limit x** and **Upper limit x** parameters.

This parameter enables **Upper limit x** parameter.

This parameter enables **Lower limit x** parameter.

Parameter: LimitX

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Upper limit x

Specify the upper limit of state x .

Default: `inf` for Second-Order Integrator, 1 for Second-Order Integrator Limited

The upper saturation limit for state x must be strictly greater than the lower saturation limit.

Limit x enables this parameter.

Parameter: UpperLimitX

Type: scalar or vector

Value: 'inf'

Default: 'inf'

Lower limit x

Specify the lower limit of state x .

Default: $-\infty$ for Second-Order Integrator, 0 for Second-Order Integrator Limited

The lower saturation limit for state x must be strictly less than the upper saturation limit.

Limit x enables this parameter.

Parameter: LowerLimitX

Type: scalar or vector

Value: $-\infty$

Default: $-\infty$

Wrap x

Enable wrapping of x between the **Wrapped upper value x** and **Wrapped lower value x** parameters. Enabling wrapping of x eliminates the need for zero-crossing detection, reduces solver resets, improves solver performance and accuracy, and increases simulation time span when modeling rotary and cyclic state trajectories.

Default: off

On

Enable wrapping of x between the **Wrapped upper value x** and **Wrapped lower value x** parameters.

If you specify **Wrapped upper value x** as ∞ and **Wrapped lower value x** as $-\infty$, wrapping will never occur.

Off

Do not enable wrapping of x .

This parameter enables **Wrapped upper value x** .

This parameter enables **Wrapped lower value x** .

Parameter: WrapX
Type: character vector
Value: 'off' | 'on'
Default: 'off'

Wrapped upper value x

Specify the upper value for wrapping x .

Default: 'pi'

Wrap x enables this parameter.

Parameter: WrappedUpperValueX
Type: scalar or vector
Value: '2*pi'
Default: 'pi'

Wrapped lower value x

Specify the lower value for wrapping x .

Default: -pi

Wrap x enables this parameter.

Parameter: WrappedLowerValueX
Type: scalar or vector
Value: '0'
Default: '-pi'

Absolute tolerance x

Specify the absolute tolerance for computing state x .

Default: auto

- You can enter `auto`, `-1`, a positive real scalar or vector.
- If you enter `auto` or `-1`, Simulink uses the absolute tolerance value in the Configuration Parameters dialog box (see “Solver Pane”) to compute state x .
- If you enter a real scalar value, that value overrides the absolute tolerance in the Configuration Parameters dialog box and is used for computing all x states.
- If you enter a real vector, the dimension of that vector must match the dimension of state x . These values override the absolute tolerance in the Configuration Parameters dialog box.

Parameter: `AbsoluteToleranceX`

Type: character vector, scalar, or vector

Value: `'auto'` | `'-1'` | any positive real scalar or vector

Default: `'auto'`

State name x

Assign a unique name to state x .

Default: `''`

- To assign a name to a single state, enter the name between quotes, for example, `'position'`.
- To assign names to multiple x states, enter a comma-delimited list surrounded by braces, for example, `{'a', 'b', 'c'}`. Each name must be unique.
- The state names apply only to the selected block.
- If you specify a state name for x , you must also specify a state name for dx/dt .
- State names for x and dx/dt must have identical types and lengths.
- The number of states must be evenly divided by the number of state names. You can specify fewer names than x states, but you cannot specify more names than x states. For example, you can specify two names in a system with four states. The first name applies to the first two states and the second name to the last two states. However, you must be consistent and apply the same scheme to the state names for dx/dt .
- To assign state names with a variable in the MATLAB workspace, enter the variable without quotes. A variable can be a character vector or a cell array.

Parameter: StateNameX
Type: character vector
Value: ' ' | user-defined
Default: ' '

Initial condition source dx/dt

Specify the initial condition source for state dx/dt .

Default: `internal`

`internal`

Get the initial conditions of state dx/dt from the **Initial condition dx/dt** parameter.

`external`

Get the initial conditions of state dx/dt from an external block.

Simulink software does not allow the initial condition of this block to be `inf` or `NaN`.

Selecting `internal` enables the **Initial condition dx/dt** parameter.

Selecting `external` disables the **Initial condition dx/dt** parameter.

Parameter: ICSourceDXDT
Type: character vector
Value: 'internal' | 'external'
Default: 'internal'

Initial condition dx/dt

Specify the initial condition of state dx/dt .

Default: 0.0

Simulink software does not allow the initial condition of this block to be `inf` or `NaN`.

Setting **Initial condition source dx/dt** to `internal` enables this parameter.

Setting **Initial condition source dx/dt** to `external` disables this parameter.

Parameter: ICDXDT

Type: scalar or vector

Value: '0'

Default: '0'

Limit dx/dt

Limit the dx/dt state of the block to a value between the **Lower limit dx/dt** and **Upper limit dx/dt** parameters.

Default: `Off` for Second-Order Integrator, `On` for Second-Order Integrator Limited

On

Limit state dx/dt of the block to a value between the **Lower limit dx/dt** and **Upper limit dx/dt** parameters.

Off

Do not limit state dx/dt of the block to a value between the **Lower limit dx/dt** and **Upper limit dx/dt** parameters.

If you set saturation limits for x , then the interval defined by the **Upper limit dx/dt** and **Lower limit dx/dt** must contain zero.

This parameter enables **Upper limit dx/dt**.

This parameter enables **Lower limit dx/dt**.

Parameter: LimitDXDT

Type: character vector

Value: 'Off' | 'On'

Default: 'Off'

Upper limit dx/dt

Specify the upper limit for state dx/dt .

Default: 'inf'

If you limit x , then this parameter must have a strictly positive value.

Limit dx/dt enables this parameter.

Parameter: UpperLimitDXDT

Type: scalar or vector

Value: 'inf'

Default: 'inf'

Lower limit dx/dt

Specify the lower limit for state dx/dt .

Default: '-inf'

If you limit x , then this parameter must have a strictly negative value.

Limit dx/dt enables this parameter.

Parameter: LowerLimitDXDT

Type: scalar or vector

Value: '-inf'

Default: '-inf'

Absolute tolerance dx/dt

Specify the absolute tolerance for computing state dx/dt .

Default: auto

- You can enter `auto`, `-1`, a positive real scalar or vector.
- If you enter `auto` or `-1`, then Simulink uses the absolute tolerance value in the Configuration Parameters dialog box (see “Solver Pane”) to compute the dx/dt output of the block.
- If you enter a numeric value, that value overrides the absolute tolerance in the Configuration Parameters dialog box.

Parameter: `AbsoluteToleranceDXDT`

Type: character vector, scalar, or vector

Value: `'auto'` | `'-1'` | any positive real scalar or vector

Default: `'auto'`

State name dx/dt

Assign a unique name to state dx/dt .

Default: `''`

- To assign a name to a single state, enter the name between quotes, for example, `'velocity'`.
- To assign names to multiple dx/dt states, enter a comma-delimited list surrounded by braces, for example, `{'a', 'b', 'c'}`. Each name must be unique.
- The state names apply only to the selected block.
- If you specify a state name for dx/dt , you must also specify a state name for x .
- State names for x and dx/dt must have identical types and lengths.
- The number of states must be evenly divided by the number of state names. You can specify fewer names than dx/dt states, but you cannot specify more names than dx/dt states. For example, you can specify two names in a system with four states. The first name applies to the first two states and the second name to the last two states. However, you must be consistent and apply the same scheme to the state names for x .
- To assign state names with a variable in the MATLAB workspace, enter the variable without quotes. A variable can be a character vector or a cell array.

Parameter: `StateNameDXDT`

Type: character vector
Value: ' ' | user-defined
Default: ' '

External reset

Reset the states to their initial conditions when a trigger event occurs in the reset signal.

Default: none

none

Do not reset the state to initial conditions.

rising

Reset the state when the reset signal rises from a zero to a positive value or from a negative to a positive value.

falling

Reset the state when the reset signal falls from a positive value to zero or from a positive to a negative value.

either

Reset the state when the reset signal changes from zero to a nonzero value or changes sign.

Parameter: ExternalReset

Type: character vector

Value: 'none' | 'rising' | 'falling' | 'either'

Default: 'none'

Enable zero-crossing detection

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Default: On

On

Enable zero-crossing detection.

Off

Do not enable zero-crossing detection.

Parameter: ZeroCross

Type: character vector

Value: 'on' | 'off'

Default: 'on'

Reinitialize dx/dt when x reaches saturation

At the instant when state x reaches saturation, reset dx/dt to its current initial conditions.

Default: Off

On

Reset dx/dt to its initial conditions when x becomes saturated.

Off

Do not reset dx/dt to its initial conditions when x becomes saturated.

The dx/dt initial condition must have a value that enables x to leave saturation immediately. Otherwise, Simulink ignores the initial conditions for dx/dt to preserve mathematical consistency of block states.

Parameter: ReinitDXDTwhenXreachesSaturation

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Ignore state limits and the reset for linearization

For linearization purposes, have Simulink ignore the specified state limits and the external reset.

Default: Off

On

Ignore the specified state limits and the external reset.

Off

Apply the specified state limits and the external reset setting.

Parameter: IgnoreStateLimitsAndResetForLinearization

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Show output

Specify the output ports on the block.

Default: both

both

Show both x and dx/dt output ports.

x

Show only the x output port.

dx/dt

Show only the dx/dt output port.

Parameter: ShowOutput

Type: character vector

Value: 'both' | 'x' | 'dxdt'

Default: 'both'

Characteristics

Data Types	Double
Multidimensional Signals	No
Variable-Size Signals	No
Code Generation	Yes

Introduced in R2010a

Selector

Select input elements from vector, matrix, or multidimensional signal

Library

Signal Routing

Description

The Selector block generates as output selected or reordered elements of an input vector, matrix, or multidimensional signal.

A Selector block accepts vector, matrix, or multidimensional signals as input. The parameter dialog box and the block's appearance change to reflect the number of dimensions of the input.

Based on the value you enter for the **Number of input dimensions** parameter, a table of indexing settings is displayed. Each row of the table corresponds to one of the input dimensions in **Number of input dimensions**. For each dimension, you define the elements of the signal to work with. Specify a vector signal as a 1-D signal and a matrix signal as a 2-D signal. When you configure the Selector block for multidimensional signal operations, the block icon changes.

For example, assume a 6-D signal with a one-based index mode. The table of the Selector block dialog changes to include one row for each dimension. Suppose that you define each dimension with the following entries:

- Dimension 1

- **Index Option**, select `Select all`
- Dimension 2
 - **Index Option**, select `Starting index (dialog)`
 - **Index**, enter `2`
 - **Output Size**, enter `5`
- Dimension 3
 - **Index Option**, select `Index vector (dialog)`
 - **Index**, enter `[1 3 5]`
- Dimension 4
 - **Index Option**, select `Starting index (port)`
 - **Output Size**, enter `8`
- Dimension 5
 - **Index Option**, select `Index vector (port)`
- Dimension 6
 - **Index Option**, select `Starting and ending indices (port)`

The output will be $Y=U(1:end, 2:6, [1\ 3\ 5], Idx4:Idx4+7, Idx5, Idx6(1):Idx6(2))$, where $Idx4$, $Idx5$, and $Idx6$ are the index ports for dimensions 4, 5, and 6.

You can use an array of buses as an input signal to a Selector block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

Data Type Support

The data port of the Selector block accepts signals of any signal type and any data type that Simulink supports, including fixed-point, enumerated, and nonvirtual bus data types. The data port accepts mixed-type signals. The index port accepts built-in data types, but not Boolean. The elements of the output have the same type as the corresponding selected input elements.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Note The Selector block is not designed to accept virtual bus input signals. For virtual bus inputs, use a Bus Selector block instead of a Selector block.

Parameters

Number of input dimensions

Enter the number of dimensions of the input signal.

Index mode

Specifies the indexing mode: `One-based` or `Zero-based`. If `One-based` is selected, an index of 1 specifies the first element of the input vector, 2, the second element, and so on. If `Zero-based` is selected, an index of 0 specifies the first element of the input vector, 1, the second element, and so on.

Index Option

Define, by dimension, how the elements of the signal are to be indexed. From the list, select:

- `Select all`

No further configuration is required. All elements are selected.

- `Index vector (dialog)`

Enables the **Index** column. Enter the vector of indices of the elements.

- `Index vector (port)`

No further configuration is required.

- `Starting index (dialog)`

Enables the **Index** and **Output Size** columns. Enter the starting index of the range of elements to select in the **Index** column and the number of elements to select in the **Output Size** column.

- `Starting index (port)`

Enables the **Output Size** column. Enter the number of elements to be selected in the **Output Size** column.

- Starting and ending indices (port)

No further configuration is required.

Using this option results in a variable-size output signal. When you update, the output dimension is set to be the same as the input signal dimension. During execution, the output dimension is updated based on the signal feeding the index.

When logging output signal data, signals not selected are padded with NaN values.

The **Index** and **Output Size** columns appear as needed.

Index

If the **Index Option** is `Index vector (dialog)`, enter the index of each element in which you are interested.

If the **Index Option** is `Starting index vector (dialog)`, enter the starting index of the range of elements to be selected.

Output Size

Enter the width (number of elements from the starting point) of the block output signal.

Input port size

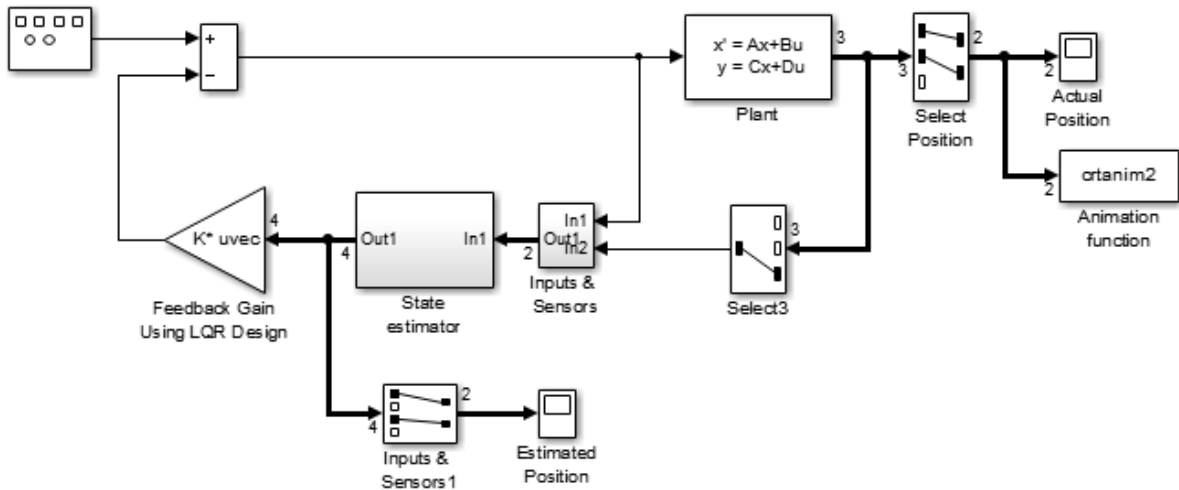

Specify the width of the block input signal (-1 for inherited) — 1-D signals only.

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Examples

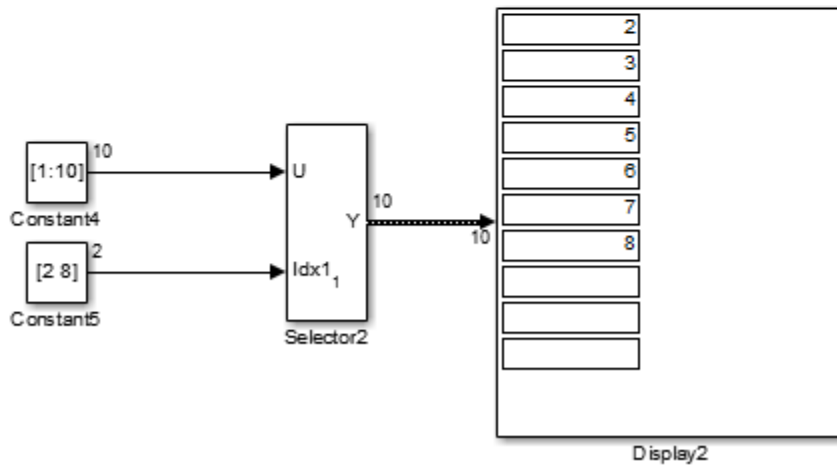

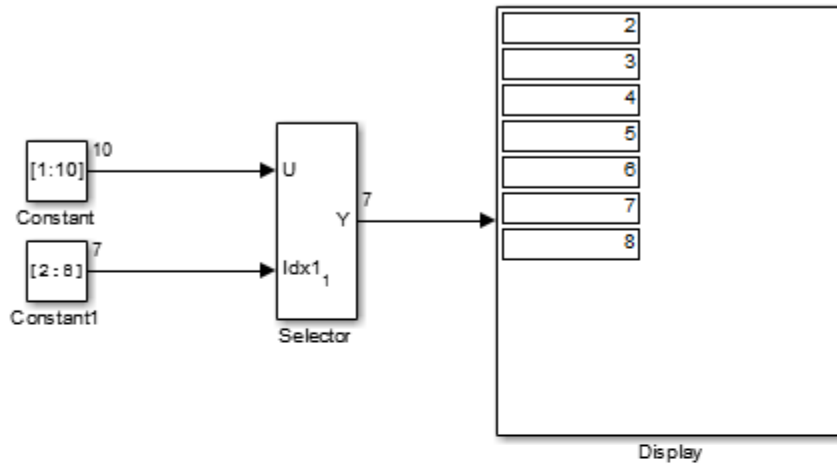

The `sldemo_dbldcart1` model shows the use of three Selector blocks. The following diagram shows what the model looks like after you enable **Display > Signals & Ports > Signal Dimensions** and simulate the model.

All three Selector blocks set the **Index Option** to `Index vector` (dialog), which allows you to specify the indices of the specific signals that you want to select, using the **Index** parameter. The **Input port size** parameter is set to the dimension of the largest input signal.

The following model shows the result of simulating two Selector blocks that have the same kind of input signals, but which have two different **Index Option** settings.

Both Selector blocks select 7 values from the input signal that feeds the `U` port. However, the Selector block outputs a fixed-size signal, whereas the Selector2 block outputs a variable-size signal whose compiled signal dimension is 10 instead of 7.

The Selector block sets **Index Option** to Index vector (port), which uses the input signal from Constant1 as the index vector. The dimension of the input signal is 7, so the Display block shows the 7 values of the Constant1 block. The Selector2 block

sets the **Input port size** parameter to 10, which is the size of the largest input signal to the Selector1 block.

The Selector2 block uses the same configuration as the Selector block, except that the **Index Option** is set to Starting and ending indices (port). The output uses the size of **Input port size** parameter (10), even though the size of the input signal is 7. The Display2 block shows empty boxes for the three extra dimensions.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated
Sample Time	Inherited from driving block
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Serializer1D

Convert vector signal to scalar or smaller vectors

Library

HDL Coder / HDL Operations

Description

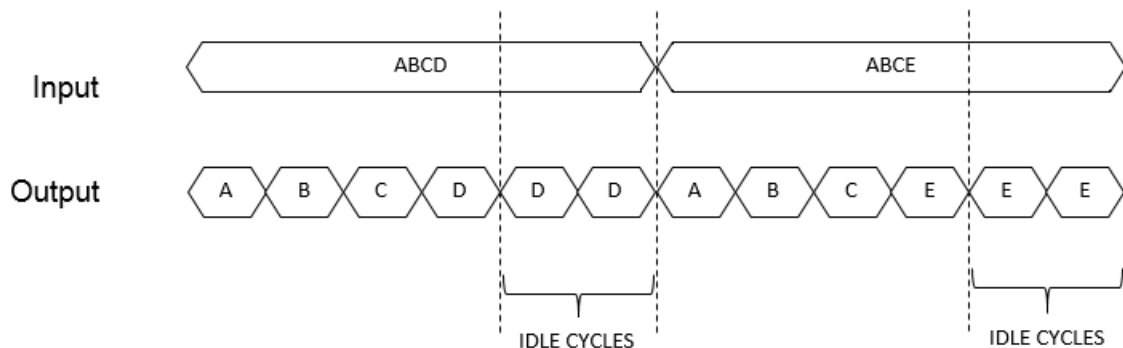

The Serializer1D block converts a slower vector signal into a faster stream of scalar signals or smaller size vector signals based on the **Ratio** and **Idle Cycle** values. To match the faster serialized output, the sample time changes according to this equation:
Output Sample Time = Input Sample Time / (Ratio + Idle Cycles)

Consider this example where the input data is a vector of size 4 and the **Ratio** is set to 4.

The output data serializes each of the vector signals into four scalar signals. The sample time at the output is: $Output\ Sample\ Time = Input\ Sample\ Time / 4$.

To add idle cycles at the end of each output, for **Idle Cycles**, specify an integer greater than zero. Consider this example with **Ratio** set to 4 and **Idle Cycles** set to 2.

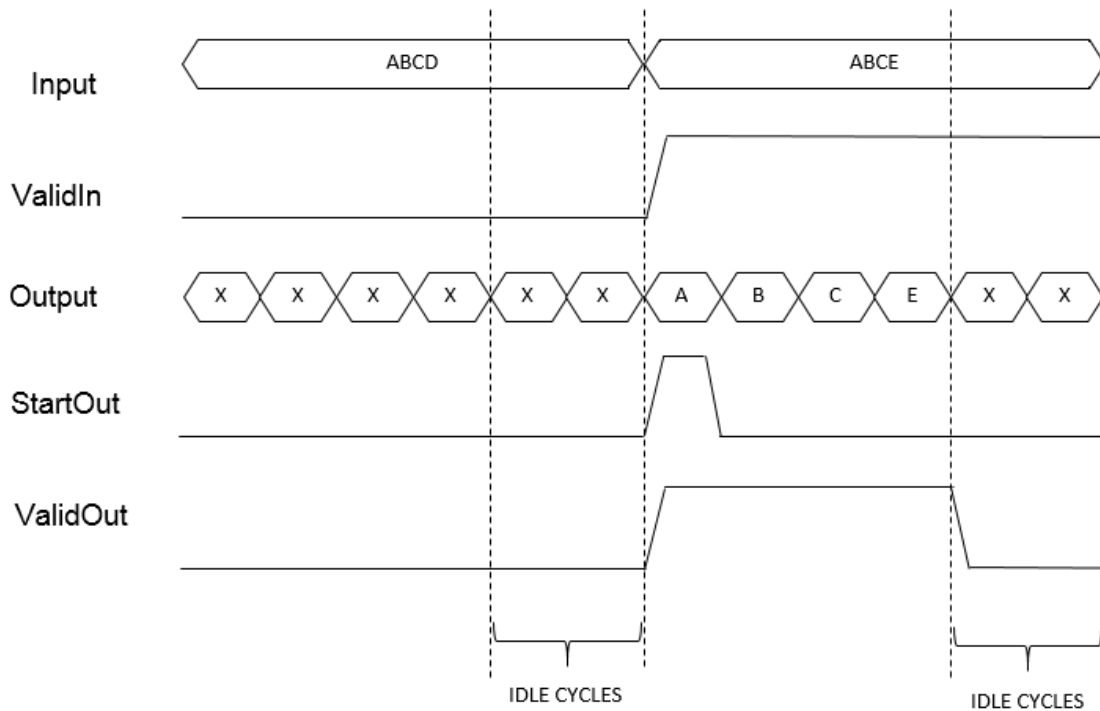

For each slow vector signal, the output has six fast cycles consisting of the four serialized scalar signals and two idle cycles. The sample time at the output is

$$Output\ Sample\ Time = Input\ Sample\ Time / 6$$

The Serializer1D block provides three control signals: **ValidIn**, **ValidOut**, and **StartOut**. You can use **ValidIn** to control **ValidOut** and **StartOut**. The serialized output does not depend on **ValidIn**. To determine whether the output serialized data is

valid, use **ValidIn** and **ValidOut**. If you give a high input to **ValidIn**, and if there are no idle cycles, **ValidOut** gives a high output, which indicates that the output serialized data is valid.

Consider an example that has input data as a vector of size 4, **Ratio** set to 4, **Idle Cycles** set to 2, and uses all three control signals.

For the first input vector, ABCD, **ValidIn** is false. **StartOut** and **ValidOut** become false. This means that the output data values are not valid. In the waveform, the data values are represented as X, which correspond to *don't care* values.

For the second input vector, ABCE, **ValidIn** is true. The output data serializes the vector into four scalar signals. The control signal **StartOut** becomes true at output A to indicate the start of deserialization. In the next cycle, the **StartOut** signal becomes false. **ValidOut** is true for all four output signals indicating valid output data for the four

cycles. **ValidOut** becomes false for the idle cycles, and the output data values are *don't care* values.

HDL Code Generation

For simulation results that match the generated HDL code, in the Solver pane of the Configuration Parameters dialog box, clear the checkbox for **Treat each discrete rate as a separate task**. When the checkbox is cleared, single-tasking mode is enabled.

If you simulate this block with **Treat each discrete rate as a separate task** selected, multitasking mode is enabled. The output data can update in the same cycle but in the generated HDL code, the output data is updated one cycle later.

Parameters

Ratio

Serialization factor, specified as a positive scalar. Default is 1.

The ratio is equal to the size of the input vector divided by the size of the output vector. Input vector size must be divisible by the ratio.

Idle Cycles

Number of idle cycles to add at the end of each output. Default is 0.

ValidIn

Activates the **ValidIn** port. Default is `off`.

StartOut

Activates the **StartOut** port. Default is `off`.

ValidOut

Activates the **ValidOut** port. Default is `off`.

Input data port dimensions (-1 for inherited)

Size of the input data signal. Input vector size must be divisible by the ratio. By default, the block inherits size based on the context within the model.

Input sample time (-1 for inherited)

Time interval between sample time hits, or another appropriate sample time such as continuous. By default, the block inherits sample time based on context within the model. For more information, see “Sample Time”.

Input signal type

Input signal type of the block, specified as `auto`, `real`, or `complex`. Default is `auto`.

Ports

P

Input signal to serialize. Bus data types are not supported.

ValidIn

Input control signal. This port is available when you select the **ValidIn** check box.

Data type: Boolean

S

Serialized output signal. Bus data types are not supported.

StartOut

Output control signal that indicates where to start deserialization. You can use this signal as the **StartIn** input to the Deserializer1D block. To use this port, select the **StartOut** check box.

Data type: Boolean

ValidOut

Output control signal that indicates valid output signal. You can use this signal as the **ValidIn** input to the Deserializer1D block. This port is available when you select the **ValidOut** check box.

Data type: Boolean

Deserializer1D

Introduced in R2014b

S-Function

Include S-function in model

Library

User-Defined Functions

Description

The S-Function block provides access to S-functions from a block diagram. The S-function named as the **S-function name** parameter can be a Level-1 MATLAB or a Level-1 or Level-2 C MEX S-function (see “S-Function Basics” for information on how to create S-functions).

Note Use the Level-2 MATLAB S-Function block to include a Level-2 MATLAB S-function in a block diagram.

The S-Function block allows additional parameters to be passed directly to the named S-function. The function parameters can be specified as MATLAB expressions or as variables separated by commas. For example,

```
A, B, C, D, [eye(2,2);zeros(2,2)]
```

Note that although individual parameters can be enclosed in brackets, the list of parameters must not be enclosed in brackets.

The S-Function block displays the name of the specified S-function and the number of input and output ports specified by the S-function. Signals connected to the inputs must have the dimensions specified by the S-function for the inputs.

Data Type Support

Depends on the implementation of the S-Function block.

Parameters

S-function name

The S-function name.

S-function parameters

Additional S-function parameters. See the preceding block description for information on how to specify the parameters.

S-function modules

This parameter applies only if this block represents a C MEX S-function and you intend to use the Simulink Coder software to generate code from the model containing the block. If you use it, when you are ready to generate code, you must force the coder to rebuild the top model as explained in “Control Regeneration of Top Model Code” (Simulink Coder).

For more information on using this parameter, see “Specify Additional Source Files for an S-Function” (Simulink Coder) in the Simulink Coder documentation.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point
Sample Time	Depends on contents of S-function
Direct Feedthrough	Depends on contents of S-function
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

S-Function Builder

Create S-function from C code that you provide

Library

User-Defined Functions

Description

The S-Function Builder block creates a C MEX S-function from specifications and C source code that you provide. See “Build S-Functions Automatically” for detailed instructions on using the S-Function Builder block to generate an S-function.

Instances of the S-Function Builder block also serve as wrappers for generated S-functions in Simulink models. When simulating a model containing instances of an S-Function Builder block, Simulink software invokes the generated S-function associated with each instance to compute the instance's output at each time step.

Note The S-Function Builder block does not support masking. However, you can mask a Subsystem block that contains an S-Function Builder block. For more information, see “Dynamic Masked Subsystem”.

Data Type Support

The S-Function Builder can accept and output complex, 1-D, or 2-D signals and nonvirtual buses. For each of these cases, the signals must have a data type that Simulink supports.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

See “S-Function Builder Dialog Box” in the online documentation for information on using the S-Function Builder block's parameter dialog box.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point
Multidimensional Signals	Yes
Variable-Size Signals	No
Code Generation	Yes

Introduced before R2006a

Shift Arithmetic

Shift bits or binary point of signal

$$\begin{array}{l} Q_y = Q_u \gg 8 \\ V_y = V_u * 2^{-8} \\ E_y = E_u \end{array}$$

Library

Logic and Bit Operations

Description

Supported Shift Operations

The Shift Arithmetic block can shift the bits or the binary point of an input signal, or both.

For example, shifting the binary point on an input of data type `sfixed(8)`, by two places to the right and left, gives these decimal values.

Shift Operation	Binary Value	Decimal Value
No shift (original number)	11001.011	-6.625
Binary point shift right by two places	1100101.1	-26.5
Binary point shift left by two places	110.01011	-1.65625

This block performs arithmetic bit shifts on signed numbers. Therefore, the block recycles the most significant bit for each bit shift. Shifting the bits on an input of data type `sfixed(8)`, by two places to the right and left, gives these decimal values.

Shift Operation	Binary Value	Decimal Value
No shift (original number)	11001.011	-6.625
Bit shift right by two places	11110.010	-1.75

Shift Operation	Binary Value	Decimal Value
Bit shift left by two places	00101.100	5.5

Data Type Support

The block supports input signals of the following data types:

Input Signal	Supported Data Types
u	<ul style="list-style-type: none"> Floating point Built-in integer Fixed point
s	<ul style="list-style-type: none"> Floating point Built-in integer Fixed-point integer

The following rules determine the output data type:

Data Type of Input u	Output Data Type
Floating point	Same as input u
Built-in integer or fixed point	<ul style="list-style-type: none"> Sign of u Word length of u Slope of $u * 2^{(\max(\text{binary points to shift}))}$ Bias of $u * 2^{(\max(\text{binary points to shift} - \text{bits to shift}))}$, for bit shifts where the direction is bidirectional or right Bias of $u * 2^{(\max(\text{binary points to shift} + \text{bits to shift}))}$, for bit shifts where the direction is left

The block parameters support the following data types:

Parameter	Supported Data Types
Bits to shift: Number	<ul style="list-style-type: none"> Built-in integer Fixed-point integer

Parameter	Supported Data Types
Binary points to shift	<ul style="list-style-type: none"> Built-in integer Fixed-point integer

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Bits to shift: Source

Specify whether to enter the bits to shift on the dialog box or to inherit the values from an input port.

Bits to shift: Direction

Specify the direction in which to shift bits: left, right, or bidirectional.

Bits to shift: Number

Specify a scalar, vector, or array of bit shift values. This parameter is available when **Bits to shift: Source** is Dialog.

If the direction is...	Then...
Left or Right	Use positive integers to specify bit shifts.
Bidirectional	Use positive integers for right shifts and negative integers for left shifts.

Binary points to shift

Specify an integer number of places to shift the binary point of the input signal. A positive value indicates a right shift, while a negative value indicates a left shift.

Diagnostic for out-of-range shift value

Specify whether to produce a warning or error during simulation when the block contains an out-of-range shift value. Options include:

- None — Simulink software takes no action.
- Warning — Simulink software displays a warning and continues the simulation.
- Error — Simulink software terminates the simulation and displays an error

For more information, see “Simulation and Accelerator Mode Results for Out-of-Range Bit Shift Values” on page 1-1390.

Check for out-of-range 'Bits to shift' in generated code

Select this check box to include conditional statements in the generated code that protect against out-of-range bit shift values. This check box is available when **Bits to shift: Source** is `Input port`.

For more information, see “Code Generation for Out-of-Range Bit Shift Values” on page 1-1392.

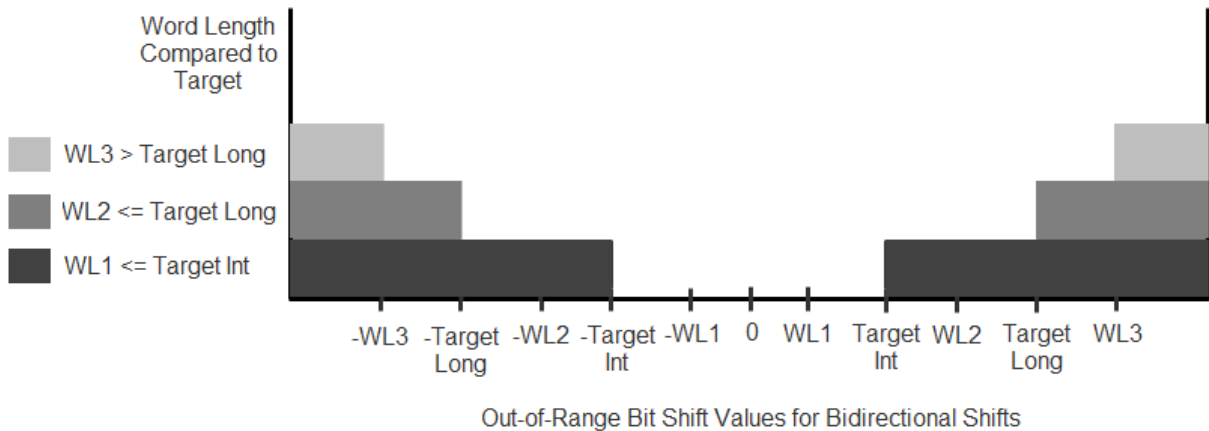

Out-of-Range Bit Shifts

Definition of an Out-of-Range Bit Shift

Suppose that WL is the input word length. The shaded regions in the following diagram show out-of-range bit shift values for left and right shifts.

Similarly, the shaded regions in the following diagram show out-of-range bit shift values for bidirectional shifts.

The diagnostic for out-of-range bit shifts responds as follows, depending on the mode of operation:

Mode	Diagnostic for out-of-range shift value		
	None	Warning	Error
Simulation	Do not report any warning or error.	Report a warning but continue simulation.	Report an error and stop simulation.
Accelerator modes and code generation	Has no effect.		

Simulation and Accelerator Mode Results for Out-of-Range Bit Shift Values

Suppose that U is the input, WL is the input word length, and Y is the output. The output for an out-of-range bit shift value for left shifts is as follows:

Similarly, the output for an out-of-range bit shift value for right shifts is as follows:

For bidirectional shifts, the output for an out-of-range bit shift value is as follows:

Code Generation for Out-of-Range Bit Shift Values

For the generated code, the method for handling out-of-range bit shifts depends on the setting of **Check for out-of-range 'Bits to shift' in generated code**.

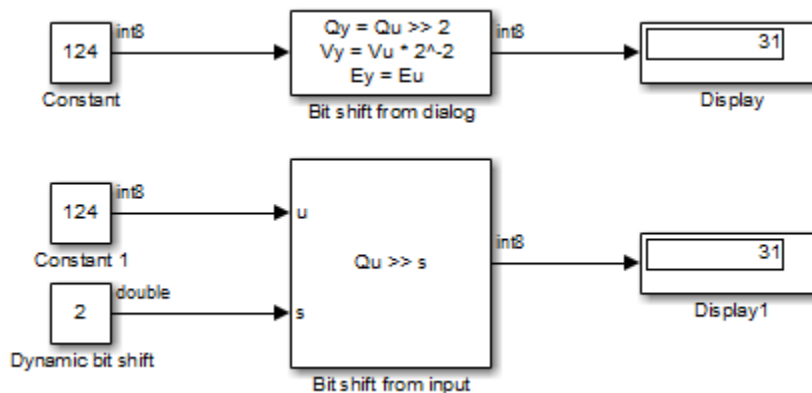

Check Box Setting	Generated Code	Simulation Results Compared to Generated Code
Selected	Includes conditional statements to protect against out-of-range bit shift values.	Simulation and Accelerator mode results match those of code generation.
Cleared	Does not protect against out-of-range bit shift values.	<ul style="list-style-type: none"> For in-range values, simulation and Accelerator mode results match those of code generation. For out-of-range values, the code generation results are compiler specific.

For right shifts on signed negative inputs, most C compilers use an arithmetic shift instead of a logical shift. Generated code for the Shift Arithmetic block depends on this compiler behavior.

Examples

Block Output for Right Bit Shifts

The following model compares the behavior of right bit shifts using the dialog box versus the block input port.

The key block parameter settings of the Constant blocks are:

Block	Parameter	Setting
Constant and Constant1	Constant value	124
	Output data type	int8
Dynamic bit shift	Constant value	2
	Output data type	Inherit: Inherit from 'Constant value'

The key block parameter settings of the Shift Arithmetic blocks are:

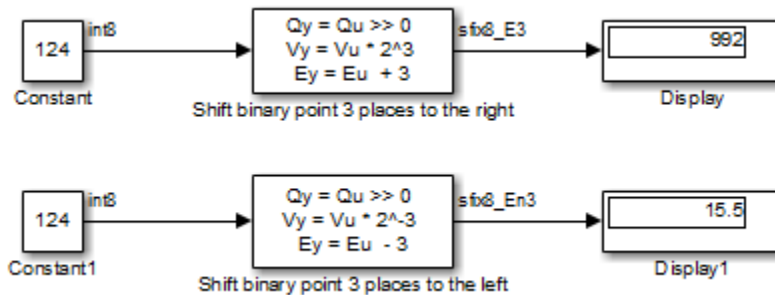

Block	Parameter	Setting
Bit shift from dialog	Bits to shift: Source	Dialog
	Bits to shift: Direction	Right
	Bits to shift: Number	2
Bit shift from input	Bits to shift: Source	Input port
	Bits to shift: Direction	Right

The top Shift Arithmetic block takes an input of 124, which corresponds to 01111100 in binary format. Shifting the number of bits two places to the right produces 00011111 in binary format. Therefore, the block outputs 31.

The bottom Shift Arithmetic block performs the same operation as the top block. However, the bottom block receives the bit shift value through an input port instead of the dialog box. By supplying this value as an input signal, you can change the number of bits to shift during simulation.

Block Output for Binary Point Shifts

The following model shows the effect of binary point shifts.

The key block parameter settings of the Constant blocks are:

Block	Parameter	Setting
Constant and Constant1	Constant value	124
	Output data type	int8

The key block parameter settings of the Shift Arithmetic blocks are:

Block	Parameter	Setting
Shift binary point 3 places to the right	Bits to shift: Source	Dialog
	Bits to shift: Direction	Bidirectional
	Bits to shift: Number	0
	Binary points to shift: Number	3

Block	Parameter	Setting
Shift binary point 3 places to the left	Bits to shift: Source	Dialog
	Bits to shift: Direction	Bidirectional
	Bits to shift: Number	0
	Binary points to shift: Number	-3

The top Shift Arithmetic block takes an input of 124, which corresponds to 01111100 in binary format. Shifting the binary point three places to the right produces 01111100000 in binary format. Therefore, the top block outputs 995.

The bottom Shift Arithmetic block also takes an input of 124. Shifting the binary point three places to the left produces 01111.100 in binary format. Therefore, the bottom block outputs 15.5.

Characteristics

Data Types	Double Single Base Integer Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Sign

Indicate sign of input

Library

Math Operations

Description

Block Behavior for Real Inputs

For real inputs, the Sign block outputs the sign of the input:

Input	Output
Greater than zero	1
Equal to zero	0
Less than zero	-1

For vector and matrix inputs, the block outputs a vector or matrix where each element is the sign of the corresponding input element, as shown in this example:

Block Behavior for Complex Inputs

When the input u is a complex scalar, the block output matches the MATLAB result for:

$$\text{sign}(u) = u ./ \text{abs}(u)$$

When an element of a vector or matrix input is complex, the block uses the same formula that applies to scalar input, as shown in this example:

Data Type Support

The Sign block supports real inputs of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean

The block supports complex inputs only for floating-point data types, double and single. The output uses the same data type as the input.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Enable zero-crossing detection

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Examples

The following Simulink examples show how to use the Sign block:

- `sldemo_fuelsys` (in the Engine Gas Dynamics/Throttle & Manifold/Throttle subsystem)
- `sldemo_hardstop`

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	Yes, if enabled
Code Generation	Yes

Introduced before R2006a

Signal Builder

Create and generate interchangeable groups of signals whose waveforms are piecewise linear

Library

Sources

Description

The Signal Builder block allows you to create interchangeable groups of piecewise linear signal sources and use them in a model. See “Signal Groups”.

Note Use the `signalbuilder` function to create and access Signal Builder blocks programmatically.

Data Type Support

The Signal Builder block accepts signals only of type `double` and outputs a virtual nonhierarchical bus, scalar, or array of real signals of type `double`. It does not support data stores (see “Data Stores”).

For more information, see “Data Types Supported by Simulink”.

Parameters

The Signal Builder block has the same dialog box as that of a Subsystem block. To display the dialog box, right-click the block and select **Subsystem Parameters**.

Examples

The following examples show how to use the Signal Builder block:

- `sldemo_pid2dof`
- `sf_test_vectors`

Characteristics

Data Types	Double
Sample Time	Specified in the Sample time parameter, accessible by selecting File > Simulation Options in the Signal Builder block <ul style="list-style-type: none">• Zero represents a continuous sample time.• A positive integer represents a discrete sample time.
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	Yes
Code Generation	Yes

Signal Conversion

Convert signal to new type without altering signal values

Library

Signal Attributes

Description

The Signal Conversion block converts a signal from one type to another. Use the **Output** parameter to select the type of conversion to perform.

Data Type Support

The Signal Conversion block accepts signals of the following data types:

- Scalar
- Floating point
- Built-in integer
- Fixed point
- Boolean
- Enumerated
- Virtual and nonvirtual bus signals

You can use an array of buses as an input signal to a Signal Conversion block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

For more information about data types, see “Data Types Supported by Simulink”.

Parameters

Output

Specify the type of conversion to perform. The type of conversion that you use depends on your modeling goal.

Modeling Goal	Output Option
Reduce generated code for a muxed signal. For an example involving Simulink Coder software, see “Generate Reentrant Code from Subsystems” (Simulink Coder).	Signal copy
Connect a block with a constant sample time to an output port of an enabled subsystem.	Signal copy
Pass a bus signal, or array of buses signal, whose components have different data types to a nonvirtual Inport block in an atomic subsystem that has direct feedthrough. For more information, see “Composite Signals”.	Signal copy
Save memory by converting a nonvirtual bus to a virtual bus.	Virtual bus
Pass a virtual bus signal to a modeling construct that requires a nonvirtual bus, such as a Model block.	Nonvirtual bus
Pass a nonvirtual bus signal from a Bus Selector block.	Nonvirtual bus

- The `Signal copy` option is the default. The type of conversion that the Signal Conversion block performs using the `Signal copy` option depends on the type of input signal.

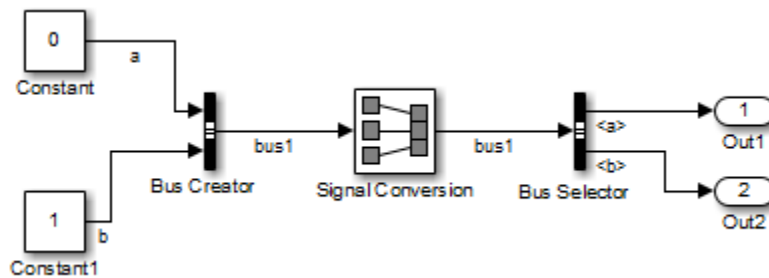

Type of Input Signal	Conversion that the Signal Copy Option Performs
Muxed (nonbus) signal	Converts the muxed signal, whose elements occupy discontinuous areas of memory, to a vector signal, whose elements occupy contiguous areas of memory. The conversion allocates a contiguous area of memory for the elements of the muxed signal and copies the values from the discontinuous areas (represented by the block's input) to the contiguous areas (represented by the block's output) at each time step.
Bus signal	Outputs a contiguous copy of the bus signal that is the input to the Signal Conversion block.

For an array of buses input signal, use the `Signal copy` option.

In the following example, a muxed signal inputs to a Signal Conversion block that has the **Output** parameter set to `Signal copy`. The Signal Conversion block converts the input signal to a vector.

In the following example, a nonvirtual bus signal from a Bus Creator block inputs to a Signal Conversion block that has **Output** set to `Signal copy`. The Signal Conversion block creates another contiguous copy of the input bus signal.

- The `Virtual bus` option converts a nonvirtual bus to a virtual bus.

In the following example, a Bus Creator block inputs to a Signal Conversion block that has **Output** set to `Virtual bus`. The Signal Conversion block converts the nonvirtual bus signal from the Bus Creator block to a virtual bus signal that inputs to the Bus Selector block.

- The `Nonvirtual bus` option converts a virtual bus to a nonvirtual bus.

In the following example, the Signal Conversion block converts a virtual bus signal from the first Bus Selector block to a nonvirtual bus signal that inputs to the second Bus Selector block. The Signal Conversion block has its **Output** parameter set to `Nonvirtual bus`, and specifies a bus object that matches the bus signal hierarchy of the bus that the first Bus Creator block outputs.

Data type

Specify the output data type of the nonvirtual bus that the Signal Conversion block produces.

This option is available only when you set the **Output** parameter to `Nonvirtual bus`.

The default option is `Inherit: auto`, which uses a rule that inherits a data type.

You must specify a `Simulink.Bus` object in the **Data type** parameter for one or both of the following blocks:

- Signal Conversion block
- An upstream Bus Creator block

If you specify a bus object for the Signal Conversion block, but not for its upstream Bus Creator block, then use a bus object that matches the hierarchy of the bus that upstream Bus Creator block outputs.

If you specify a bus object for both the Signal Conversion block and its upstream Bus Creator block, use the same bus object for both blocks.

You can select the button to the right of the Data type parameter to open the Data Type Assistant, which helps you to set the **Data type** parameter.

See “Control Signal Data Types” in *Simulink User's Guide* for more information.

Exclude this block from 'Block reduction' optimization

This option is available only when you set the **Output** parameter to `Signal copy`. If the elements of the input signal occupy contiguous areas of memory, then as an optimization, Simulink software eliminates the block from the compiled model. If you select the **Exclude this block from 'Block reduction' optimization** check box, the optimization occurs the next time you compile the model. For more information, see “Block reduction”.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated

Introduced before R2006a

Signal Editor

Display, create, edit, and switch interchangeable scenarios

Library: Sources

Description

The Signal Editor block displays, creates, and edits interchangeable scenarios. You can also use the block to switch scenarios in and out of models.

The Signal Editor block supports MAT-files that contain one or more scalar `Simulink.SimulationData.Dataset` objects.

Limitations

The Signal Editor block does not support:

- Function-calls
- Array of buses
- Buses while using Rapid Accelerator mode
- `timetable` objects
- Ground signals

Ports

Output Arguments

Signal1 — Signals in scenario
multidimensional

One or more signals, which can be:

- A MATLAB `timeseries` object
- A structure of MATLAB `timeseries` objects
- A two-dimensional matrix

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

File name — Data set file

`untitled.mat` (default) | character vector

Data set file, specified as character vector, containing one or more scalar `Simulink.SimulationData.Dataset` objects. Do not use a file name from one locale in a different locale.

Dependencies

If `untitled.mat` does not exist in the current folder, these parameters are disabled:

- **Active scenario**
- **Signals**
- **Output a bus signal**
- **Unit**
- **Sample time**
- **Interpolate data**
- **Enable zero-crossing detection**
- **Form output after final data value by**

To create a MAT-file, click . This button starts the Signal Editor user interface, which lets you to create and edit scenario MAT-files.

Active scenario — Active scenario

`Scenario` (default) | character vector

Active scenario, specified as a character vector. The specified MAT-file must exist.

Dependencies

To enable this parameter, ensure that the specified MAT-file exists.

To create and edit scenarios, launch Signal Editor user interface — Start Signal Editor

button click

To start Signal Editor user interface, click .

Signals — Signal to configure

Signal 1 (default) | character vector

Signal to configure, specified as a signal name. This signal is considered the active signal. The MAT-file must exist before you can configure signals.

Dependencies

To enable this parameter, ensure that the specified MAT-file exists.

Output a bus signal — Configure signal as bus

off (default) | on

Configure signal as a bus:

On

Configure signal as a bus.

Off

Do not configure signal as a bus.

The specified MAT-file must exist.

Dependencies

- Selecting **Output a bus signal** check box enables the **Select bus object** parameter.
- To enable this parameter, ensure that the specified MAT-file exists.

Select bus object — Bus object

Bus: BusObject (default) | bus object name

Select the bus object name. To edit the bus object or create a bus object using the Data Type Assistant, click >>. The specified MAT-file must exist.

Dependencies

To enable this parameter, ensure that the specified MAT-file exists.

Mode — Bus object mode

Bus Object (default) | bus object data type

Select the bus object name. If you do not have a bus object, create one by clicking **Edit**, which starts the Bus Editor. For more information, see “Create Bus Objects with the Bus Editor”.

Unit — Physical unit

inherit (default) | supported physical unit

Physical unit of the signal, specified as an allowed unit. To specify a unit, begin typing in the text box. As you type, the parameter displays potential matching units. For more information, see “Unit Specification in Simulink Models”. For a list of supported units, see Allowed Unit Systems.

To constrain the unit system, click the link to the right of the parameter:

- If a Unit System Configuration block exists in the component, its dialog box opens. Use that dialog box to specify allowed and disallowed unit systems for the component.
- If a Unit System Configuration block does not exist in the component, the model Configuration Parameters dialog box displays. Use that dialog box to specify allowed and disallowed unit systems for the model.

The specified MAT-file must exist.

Dependencies

To enable this parameter, ensure that the specified MAT-file exists.

Sample time — Time interval between samples

0 (default) | -1 | sample time in seconds

Time interval between samples, specified in seconds. The specified MAT-file must exist.

Dependencies

To enable this parameter, ensure that the specified MAT-file exists.

Interpolate data — Linearly interpolate data

off (default) | on

Linearly interpolate data at time hits for which no corresponding workspace data exist. The specified MAT-file must exist.

The Signal Editor block linearly interpolates:

On

Linearly interpolate at time hits for which no corresponding workspace data exist, select this option.

Off

The current output equals the output at the most recent time for which data exists.

The Signal Editor block interpolates by using the two corresponding workspace samples:

- For `double` data, linearly interpolates the value by using the two corresponding samples
- For `Boolean` data, uses `false` for the first half of the time between two time values and `true` for the second half
- For a built-in data type other than `double` or `Boolean`:
 - Upcasts the data to `double`
 - Performs linear interpolation (as described for `double` data)
 - Downcasts the interpolated value to the original data type

You cannot use linear interpolation with enumerated (`enum`) data.

The block uses the value of the last known data point as the value of time hits that occur after the last known data point.

To determine the block output after the last time hit for which data is available, combine the settings of these parameters:

- **Interpolate data**
- **Form output after final data value by**

For details, see the **Form output after final data value by** parameter.

Dependencies

To enable this parameter, ensure that the specified MAT-file exists.

Enable zero-crossing detection — Detect zero-crossings

off (default) | on

If you select the **Enable zero-crossing detection** parameter, then when the input array contains multiple entries for the same time hit, Simulink detects a zero crossing. For example, suppose that the input array has this data:

```
time:      0 1 2 2 3
signal:   2 3 4 5 6
```

At time 2, there is a zero crossing from input signal discontinuity. For more information, see “Zero-Crossing Detection”.

For bus signals, Simulink detects zero crossings across all leaf bus elements.

The specified MAT-file must exist.

Dependencies

To enable this parameter, ensure that the specified MAT-file exists.

Form output after final data value by — Block output after the last time hit for which data is available

Setting to zero (default) | Extrapolation | Holding final value

To determine the block output after the last time hit for which workspace data is available, combine the settings of these parameters:

- **Interpolate data**
- **Form output after final data value by**

This table lists the block output, based on the values of the two options.

Setting for Form Output After Final Data Value By	Setting for Interpolate Data	Block Output After Final Data
Extrapolation	On	Extrapolated from final data value
	Off	Error
Setting to zero	On	Zero

Setting for Form Output After Final Data Value By	Setting for Interpolate Data	Block Output After Final Data
	Off	Zero
Holding final value	On	Final value from workspace
	Off	Final value from workspace

For example, the block uses the last two known data points to extrapolate data points that occur after the last known point if you:

- Select **Interpolate data**.
- Set **Form output after final data value by** to `Extrapolation`.

The specified MAT-file must exist.

Dependencies

To enable this parameter, ensure that the specified MAT-file exists.

Generate various waveforms

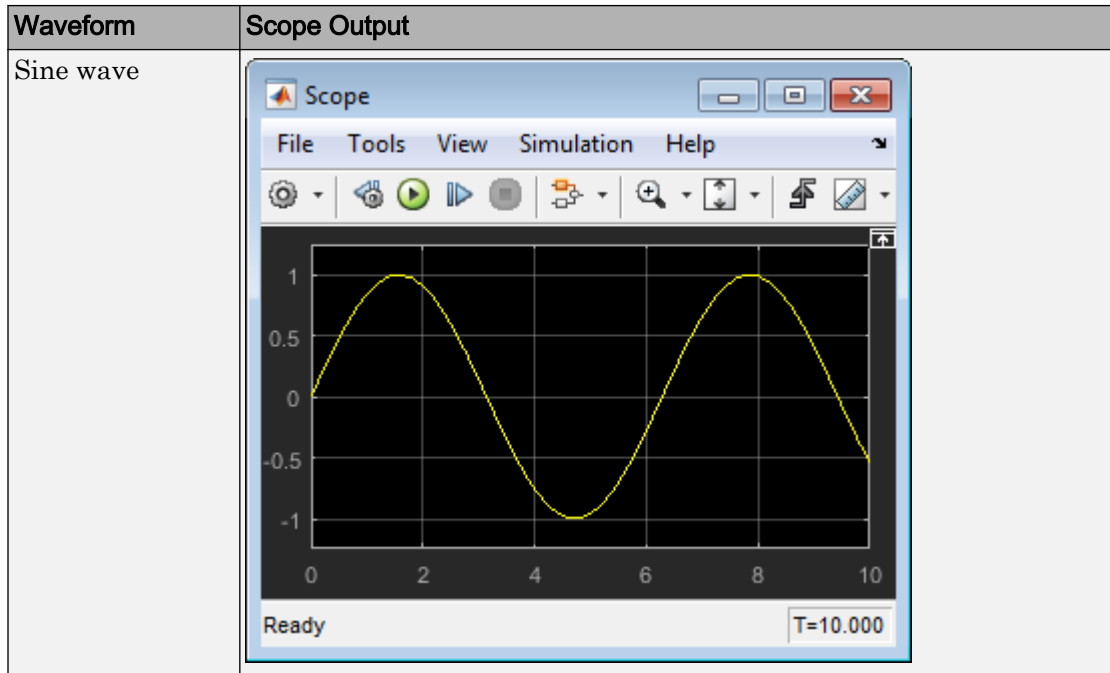

Library

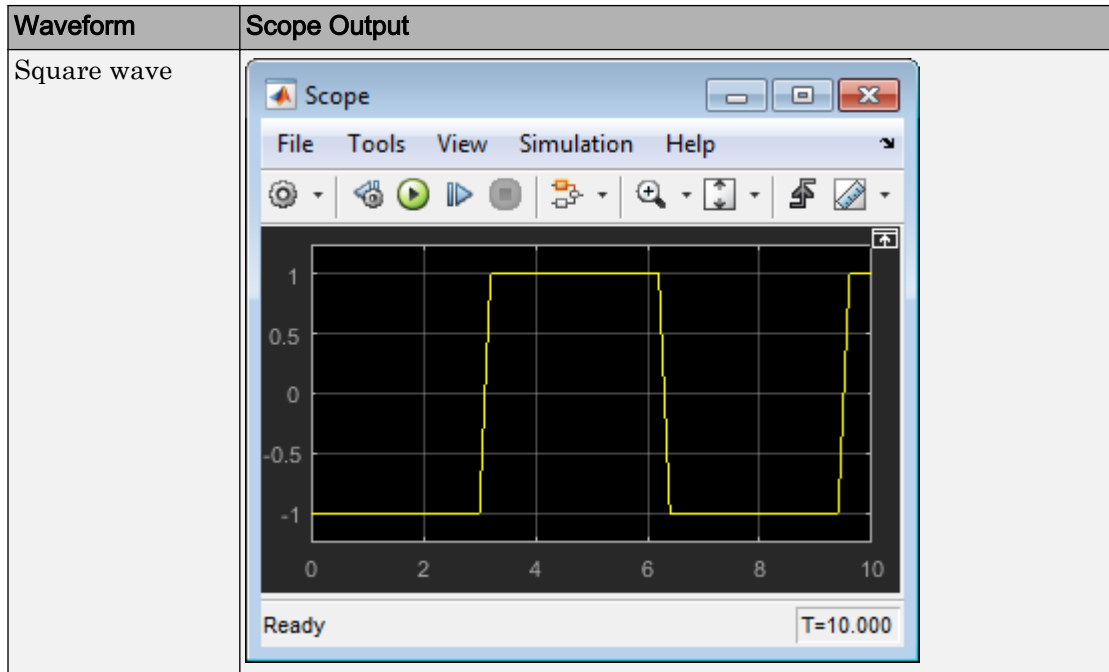

Sources

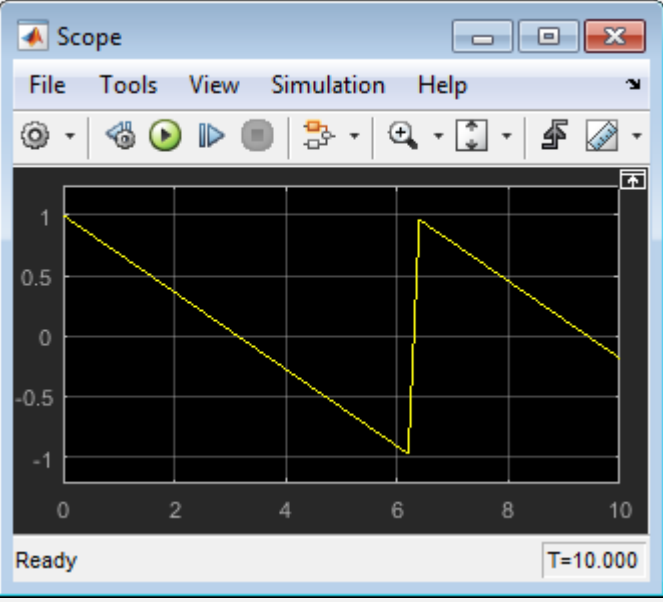

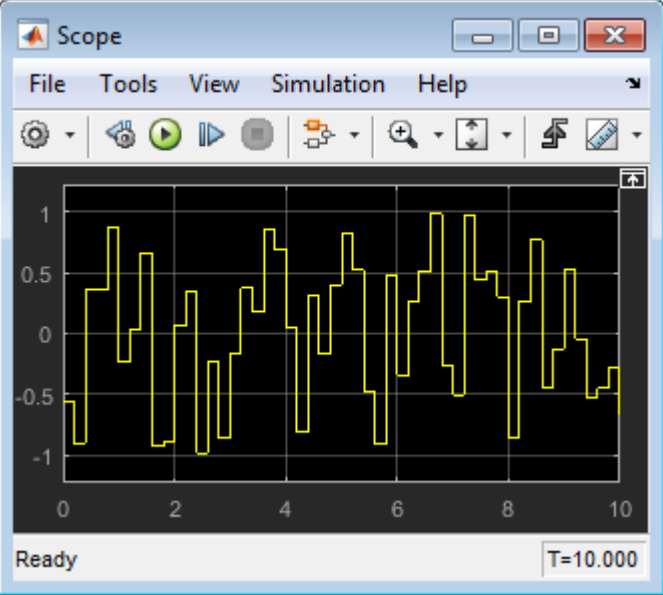

Description

Supported Operations

The Signal Generator block can produce one of four different waveforms: sine wave, square wave, sawtooth wave, and random wave. You can express signal parameters in Hertz (the default) or radians per second. Using default parameter values, you get one of the following waveforms:

Waveform	Scope Output
Sawtooth wave	
Random wave	

A negative **Amplitude** parameter value causes a 180-degree phase shift. You can generate a phase-shifted wave at other than 180 degrees in many ways. For example, you can connect a Clock block signal to a MATLAB Function block and write the equation for the specific wave.

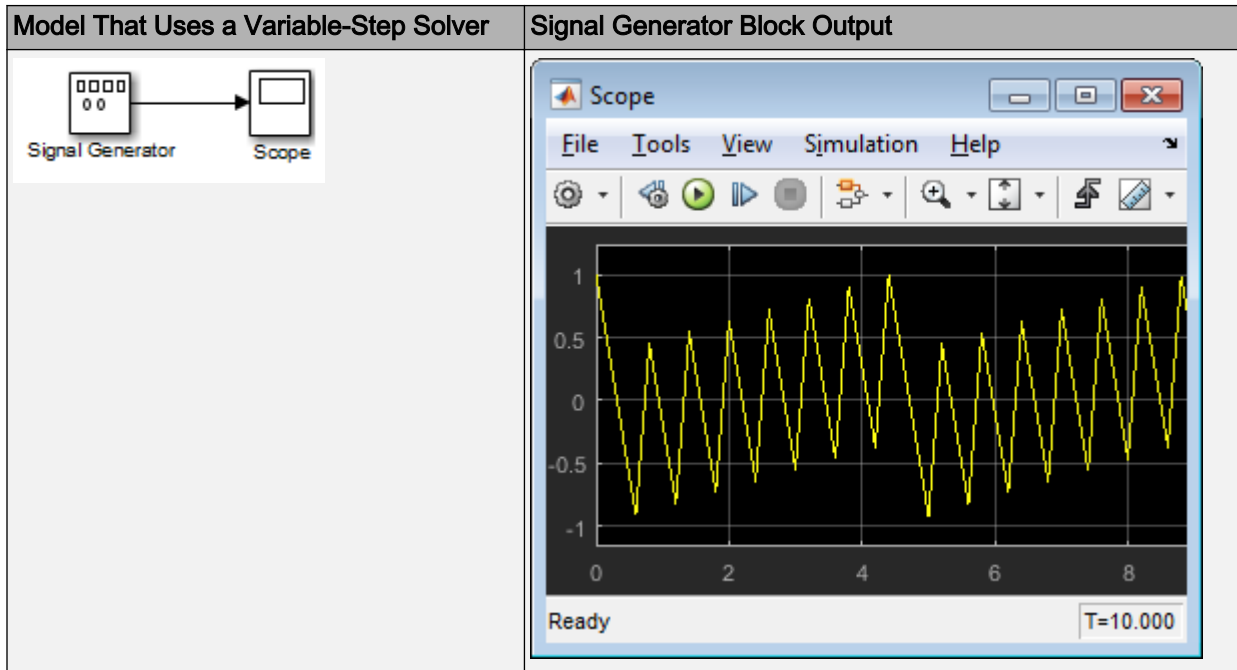

You can vary the output settings of the Signal Generator block while a simulation is in progress. This is useful to determine quickly the response of a system to different types of inputs.

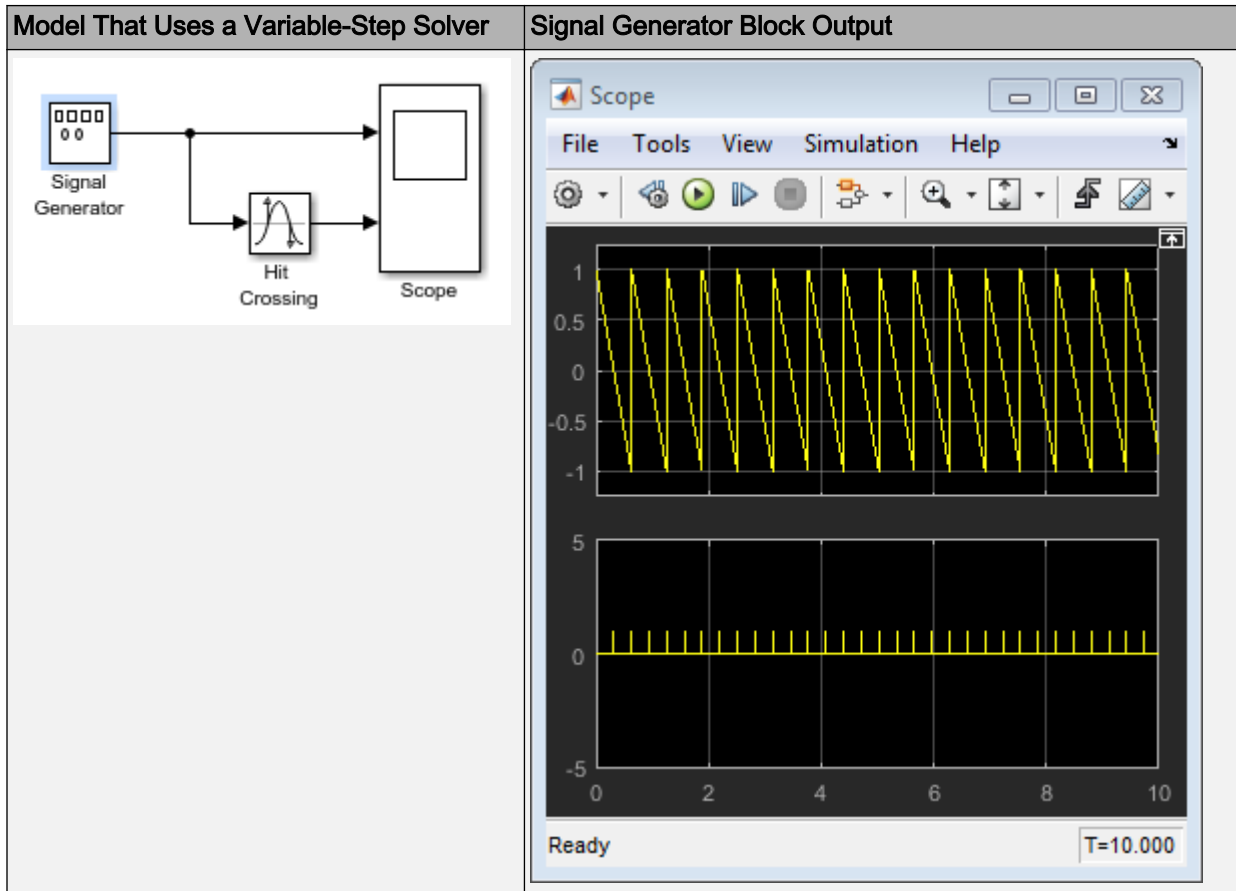

The **Amplitude** and **Frequency** parameters determine the amplitude and frequency of the output signal. The parameters must be of the same dimensions after scalar expansion. If you clear the **Interpret vector parameters as 1-D** check box, the block outputs a signal of the same dimensions as the **Amplitude** and **Frequency** parameters (after scalar expansion). If you select the **Interpret vector parameters as 1-D** check box, the block outputs a vector (1-D) signal if the **Amplitude** and **Frequency** parameters are row or column vectors, that is, single row or column 2-D arrays. Otherwise, the block outputs a signal of the same dimensions as the parameters.

Solver Considerations

If your model uses a fixed-step solver, Simulink uses the same step size for the entire simulation. In this case, the Signal Generator block output provides a uniformly sampled representation of the ideal waveform.

If your model uses a variable-step solver, Simulink might use different step sizes during the simulation. In this case, the Signal Generator block output does not always provide a uniformly sampled representation of the ideal waveform. To ensure that the block output is a uniformly sampled representation, add a Hit Crossing block directly downstream of the Signal Generator block. The following models show the difference in Signal Generator block output with and without the Hit Crossing block.

Data Type Support

The Signal Generator block outputs a scalar or array of real signals of type `double`.

For more information, see “Data Types Supported by Simulink”.

Parameters

Wave form

Specify the wave form: a sine wave, square wave, sawtooth wave, or random wave. The default is a sine wave. This parameter cannot change while a simulation is running.

Time

Specify whether to use simulation time as the source of values for the waveform's time variable or an external signal. If you specify an external time source, the block displays an input port for the time source.

Amplitude

Specify the signal amplitude. The default is 1.

Frequency

Specify the signal frequency. The default is 1.

Units

Specify the signal units as Hertz or rad/sec. The default is rad/sec.

Interpret vector parameters as 1-D

If selected, column or row matrix values for the **Amplitude** and **Frequency** parameters result in a vector output signal (see “Determining the Output Dimensions of Source Blocks”). This option is not available when an external signal specifies time. In this case, if the **Amplitude** and **Frequency** parameters are column or row matrix values, the output is a 1-D vector.

Examples

The following Simulink examples show how to use the Signal Generator block:

- `sldemo_dbldcart1`
- `slexAircraftExample`
- `penddemo`

Characteristics

Data Types	Double
Sample Time	Continuous
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Signal Specification

Specify desired dimensions, sample time, data type, numeric type, and other attributes of signal

Library

Signal Attributes

Description

The Signal Specification block allows you to specify the attributes of the signal connected to its input and output ports. If the specified attributes conflict with the attributes specified by the blocks connected to its ports, Simulink software displays an error when it compiles the model. For example, at the beginning of a simulation, if no conflict exists, Simulink eliminates the Signal Specification block from the compiled model. In other words, the Signal Specification block is a virtual block. It exists only to specify the attributes of a signal and plays no role in the simulation of the model.

You can use the Signal Specification block to ensure that the actual attributes of a signal meet desired attributes. For example, suppose that you and a colleague are working on different parts of the same model. You use Signal Specification blocks to connect your part of the model with your colleague's. If your colleague changes the attributes of a signal without informing you, the attributes entering the corresponding Signal Specification block do not match. When you try to simulate the model, you get an error.

You can also use the Signal Specification block to ensure correct propagation of signal attributes throughout a model. The capability of allowing the Simulink to propagate attributes from block to block is powerful. However, if some blocks have unspecified attributes for the signals they accept or output, the model does not have enough information to propagate attributes correctly. For these cases, the Signal Specification

block is a good way of providing the information Simulink needs. Using the Signal Specification block also helps speed up model compilation when blocks are missing signal attributes.

The Signal Specification block supports signal label propagation.

Data Type Support

The Signal Specification block accepts real or complex signals of any data type that Simulink supports, including fixed-point and enumerated data types, as well as bus objects. The input data type must match the data type specified by the **Data type** parameter.

Note If you specify a bus object as the data type for this block, do not set the minimum and maximum values for bus data on the block. Simulink ignores these settings. Instead, set the minimum and maximum values for bus elements of the bus object specified as the data type. The values should be finite real double scalar.

For information on the Minimum and Maximum properties of a bus element, see `Simulink.BusElement`.

For more information, see “Data Types Supported by Simulink”.

Parameters

- “Minimum” on page 1-1426
- “Maximum” on page 1-1427
- “Data type” on page 1-1427
- “Show data type assistant” on page 1-1429
- “Mode” on page 1-1429
- “Data type override” on page 1-1431
- “Signedness” on page 1-1431
- “Word length” on page 1-1432

- “Scaling” on page 1-1432
- “Fraction length” on page 1-1433
- “Slope” on page 1-1433
- “Bias” on page 1-1434
- “Require nonvirtual bus” on page 1-1434
- “Lock output data type setting against changes by the fixed-point tools” on page 1-1435
- “Unit (e.g., m, m/s², N*m)” on page 1-1435
- “Dimensions (-1 for inherited)” on page 1-1436
- “Variable-size signal” on page 1-1436
- “Sample time (-1 for inherited)” on page 1-1437
- “Signal type” on page 1-1438

Minimum

Specify the minimum value for the block output.

Default: [] (unspecified)

This number must be a finite real double scalar value.

Note If you specify a bus object as the data type for this block, do not set the minimum value for bus data on the block. Simulink ignores this setting. Instead, set the minimum values for bus elements of the bus object specified as the data type. For information on the Minimum property of a bus element, see `Simulink.BusElement`.

Simulink uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Parameter: `OutMin`

Type: character vector

Value: Any valid finite real double scalar value

Default: ' [] '

Maximum

Specify the maximum value for the block output.

Default: [] (unspecified)

This number must be a finite real double scalar value.

Note If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For information on the Maximum property of a bus element, see `Simulink.BusElement`.

Simulink uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Parameter: OutMax

Type: character vector

Value: Any valid finite real double scalar value

Default: ' [] '

Data type

Specify the output data type.

Default: auto

Inherit: auto

Inherits the data type.

double

Specifies the data type is double.

`single`

Specifies the data type is `single`.

`int8`

Specifies the data type is `int8`.

`uint8`

Specifies the data type is `uint8`.

`int16`

Specifies the data type is `int16`.

`uint16`

Specifies the data type is `uint16`.

`int32`

Specifies the data type is `int32`.

`uint32`

Specifies the data type is `uint32`.

`boolean`

Specifies the data type is `boolean`.

`fixdt(1,16,0)`

Specifies the data type is fixed point `fixdt(1,16,0)`.

`fixdt(1,16,2^0,0)`

Specifies the data type is fixed point `fixdt(1,16,2^0,0)`.

Enum: `<class name>`

Specifies the data type as enumerated.

Bus: `<object name>`

Data type is a bus object.

`<data type expression>`

The name of a data type object, for example `Simulink.NumericType`

Do not specify a bus object as the expression.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Data type** parameters.

Parameter: OutDataTypeStr

Type: character vector

Value: 'Inherit: auto' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'boolean' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | 'Enum: <class name>' | 'Bus: <object name>' | <data type expression>

Default: 'Inherit: auto'

“Control Signal Data Types”.

Show data type assistant

Display the **Data Type Assistant**.

The **Data Type Assistant** helps you set the **Output data type** parameter.

For more information, see “Control Signal Data Types”.

Mode

Select the category of data to specify.

Default: Inherit

Inherit

Specifies inheritance rules for data types. Selecting `Inherit` enables `auto`.

Built in

Specifies built-in data types. Selecting `Built in` enables a list of possible values:

- `double` (default)
- `single`

- int8
- uint8
- int16
- uint16
- int32
- uint32
- boolean

Fixed point

Specifies fixed-point data types.

Enumerated

Specifies enumerated data types. Selecting `Enumerated` enables you to enter a class name.

Bus

Bus object. Selecting `Bus` enables a **Bus object** parameter to the right, where you enter the name of a bus object that you want to use to define the structure of the bus. If you need to create or change a bus object, click **Edit** to the right of the **Bus object** field to open the Simulink Bus Editor. For details, see “Create Bus Objects with the Bus Editor”.

Expression

Expressions that evaluate to data types. Selecting `Expression` enables a second menu/text box to the right, where you can enter the expression.

Do not specify a bus object as the expression.

Clicking the **Show data type assistant** button  enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

“Specify Data Types Using Data Type Assistant”.

Data type override

Specify data type override mode for this signal.

Default: `Inherit`

`Inherit`

Inherits the data type override setting from its context, that is, from the block, `Simulink.Signal` object or Stateflow chart in Simulink that is using the signal.

`Off`

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

This parameter appears only when the **Mode** is `Built in` or `Fixed point`.

Signedness

Specify whether you want the fixed-point data signed or unsigned.

Default: `Signed`

`Signed`

Specifies fixed-point data as signed.

`Unsigned`

Specifies the fixed-point data as unsigned.

Selecting **Mode** > `Fixed point` enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

“Specifying a Fixed-Point Data Type”.

Word length

Specify the bit size of the word that holds the quantized integer.

Default: 16

Minimum: 0

Maximum: 32

Large word sizes represent large values with greater precision than small word sizes.

Selecting **Mode** > Fixed point enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

“Specifying a Fixed-Point Data Type”.

Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

Default: Best precision

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

Best precision

Specify best-precision values.

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting Slope and bias enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

For more information, see “Specifying a Fixed-Point Data Type”.

Fraction length

Specify fraction length for fixed-point data type.

Default: 0

Binary points can be positive or negative integers.

Selecting **Scaling** > Binary point enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

“Specifying a Fixed-Point Data Type”.

Slope

Specify slope for the fixed-point data type.

Default: 2^0

Specify any positive real number.

Selecting **Scaling** > `slope` and `bias` enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

“Specifying a Fixed-Point Data Type”.

Bias

Specify bias for the fixed-point data type.

Selecting **Scaling** > `slope` and `bias` enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

“Specifying a Fixed-Point Data Type”.

Require nonvirtual bus

If you specify a bus object as the data type, use this parameter to specify whether to accept only nonvirtual bus signals.

Default: `off`

Off

Specifies that a signal must come from a *virtual* bus.

On

Specifies that a signal must come from a *nonvirtual* bus.

The following **Data type** values enable this parameter:

- Bus: <object name>
- <data type expression> that specifies a bus object

Parameter: BusOutputAsStruct

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

Default: Off

On

Locks the output data type setting for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change the output data type setting for this block.

Parameter: LockScale

Type: character vector

Value: 'off' | 'on'

Default: 'off'

For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Unit (e.g., m, m/s², N*m)

Specify physical unit of the input signal to the block.

Default: inherit

To specify a unit, begin typing in the text box. As you type, the parameter displays potential matching units. For a list of supported units, see [Allowed Unit Systems](#).

To constrain the unit system, click the link to the right of the parameter:

- If a Unit System Configuration block exists in the component, its dialog box opens. Use that dialog box to specify allowed and disallowed unit systems for the component.
- If a Unit System Configuration block does not exist in the component, the model Configuration Parameters dialog box displays. Use that dialog box to specify allowed and disallowed unit systems for the model.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Dimensions (-1 for inherited)

Specify the dimensions of the input and output signals.

Default: -1

-1

Specifies that signals inherit dimensions.

n

Specifies vector signal of width n.

[m n]

Specifies matrix signal having m rows and n columns.

Parameter: Dimensions

Type: character vector

Value: '-1' | n | [m n]

Default: '-1'

Variable-size signal

Specify a variable-size signal, fixed-size signal, or both.

Default: Inherit

Inherit

Allows variable-size and fixed-size signals.

No

Does not allow variable-size signals.

Yes

Allows only variable-size signals.

When the signal is a variable-size signal, the **Dimensions** parameter specifies the maximum dimensions of the signal.

If you specify a bus object, the simulation allows variable-size signals only with a disabled bus object.

Parameter: VarSizeSig

Type: character vector

Value: 'Inherit' | 'No' | 'Yes'

Default: 'Inherit'

“Variable-Size Signal Basics”

Sample time (-1 for inherited)

Specify the time interval when simulation updates the block.

Default: -1

Specify the time interval between samples. To inherit the sample time, set this parameter to -1. See “Specify Sample Time” for more information.

Parameter: SampleTime

Type: character vector

Value: Any valid sample time

Default: '-1'

“Specify Sample Time”

Signal type

Specify the numeric type of the input and output signals.

Default: `auto`

`auto`

Accepts either `real` or `complex` as the numeric type.

`real`

Specifies the numeric type as a real number.

`complex`

Specifies the numeric type as a complex number.

Parameter: `SignalType`

Type: character vector

Value: `'auto' | 'real' | 'complex'`

Default: `'auto'`

Bus Support

The Signal Specification block supports virtual and nonvirtual buses. If you specify a bus object as the data type, then set these other block parameters as follows:

Block Parameter	Required Value for a Bus Data Type
Variable-size signal	No

All elements of the bus input to a Signal Specification block must have the same names as specified in the bus object.

All signals in a nonvirtual bus input to a Signal Specification block must have the same sample time, even if the elements of the associated bus object specify inherited sample times. You can use a Rate Transition block to change the sample time of an individual signal, or of all signals in a bus. See “Specify Bus Signal Sample Times” and Bus-Capable Blocks for more information.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated Bus
Sample Time	Specified by the Sample time parameter
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Simple Dual Port RAM

Dual port RAM with single output port

Library

HDL Coder / HDL Operations

Description

The Simple Dual Port RAM block models RAM that supports simultaneous read and write operations, and has a single output port for read data. You can use this block to generate HDL code that maps to RAM in most FPGAs.

The Simple Dual Port RAM is similar to the Dual Port RAM, but the Dual Port RAM has both a write data output port and a read data output port.

Read-During-Write Behavior

During a write operation, if a read operation occurs at the same address, old data appears at the output.

Parameters

Address port width

Address bit width. Minimum bit width is 2, and maximum bit width is 29. The default is 8.

Ports

The block has the following ports:

`wr_din`

Write data input. The data can have any width. It inherits the width and data type from the input signal.

Data type: scalar fixed point, integer, or complex

`wr_addr`

Write address.

Data type: scalar unsigned integer (`uintN`) or unsigned fixed point (`ufixN`) with a fraction length of 0

`wr_en`

Write enable.

Data type: Boolean

`rd_addr`

Read address.

Data type: scalar unsigned integer (`uintN`) or unsigned fixed point (`ufixN`) with a fraction length of 0

`rd_dout`

Output data from read address, `rd_addr`.

Simulink Function

Function defined with Simulink blocks

Library: User-Defined Functions

Description

The Simulink Function block is a Subsystem block preconfigured as a starting point for graphically defining a function with Simulink blocks. The block provides a text interface to function callers. You can call a Simulink Function block from a Function Caller block, a MATLAB Function block, or a Stateflow Chart.

For a description of the block parameters, see the Subsystem block reference page in the Simulink documentation.

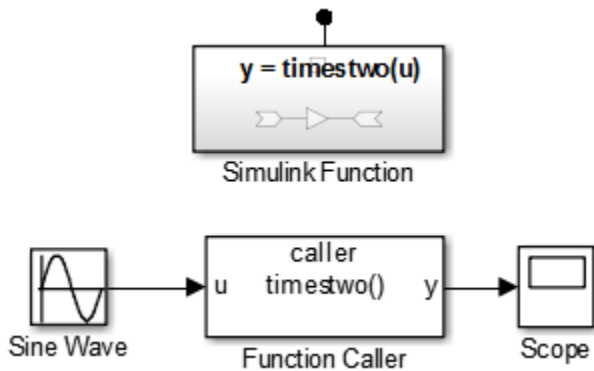

You can visualize Simulink Function calls in the Message Viewer. The viewer shows when calls were made with the argument and the return values. See Message Viewer block reference.

Function Interface

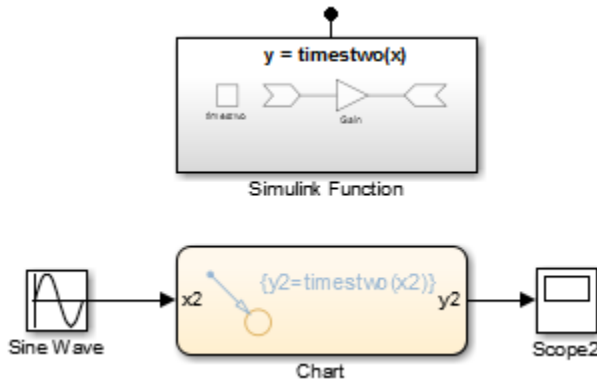

The function interface appears on the face of a Simulink Function block. Editing the block text adds and deletes Argument Inport blocks and Argument Outport blocks from the function definition. Editing also sets the **Function name** parameter in the Trigger block within the Simulink Function block.

For example, entering $y = \text{myfunction}(u)$ on the face of a Simulink Function block adds one Argument Inport block (u) and one Argument Outport block (y) within the subsystem.

When calling a function using a Function Caller block, the parameter **Function prototype** in the Function Caller block must match exactly the function interface you specify on the Simulink Function block. This match includes the name of the function and the names of input and output arguments. For example, the Simulink Function block and the Function Caller block both use the argument names u and y .

When calling a function from a Stateflow transition or state label, you can use different argument names. For example, the Simulink Function block uses x and y arguments while the Stateflow transition uses $x2$ and $y2$ arguments to call the function.

Function-Call Subsystems Versus Simulink Function Blocks

In general, a Function-Call Subsystem block provides better signal traceability with direct signal connections than a Simulink Function block. While a Simulink Function block eliminates the need for routing input and output signal lines through the model hierarchy.

Attribute	Function-Call Subsystem block	Simulink Function block
Method of executing/invoking function	Triggered using a signal line	Called by reference using the function name
Formal input arguments (Argument Inport blocks) and output arguments (Argument Outport blocks)	No	Yes
Local inputs (Inport block) and outputs (Outport block)	Yes	Yes

Ports

Input

In — Signal input to a subsystem block

scalar | vector | matrix

Placing an Inport block in a subsystem block adds an external input port to the Simulink Function block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment. See “Connect to Local Signals”.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

ArgIn — Argument input to a subsystem block

scalar | vector | matrix

An Argument Inport block in a subsystem block provides an input port corresponding to an input argument. A port is not displayed on the subsystem block.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Output

out — Signal output from a subsystem

scalar | vector | matrix

Placing an Output block in a subsystem block adds an output port from the block. The port label on the subsystem block is the name of the Output block.

Use Output blocks to send signals to the local environment. See “Connect to Local Signals”.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

ArgOut — Argument output from a subsystem block

scalar | vector | matrix

An Argument Output block in a subsystem block provides an output port corresponding to an out put argument. A port is not displayed on the subsystem block.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Single Port RAM

Single port RAM

Library

HDL Coder / HDL Operations

Description

The Single Port RAM block models RAM that supports sequential read and write operations.

If you want to model RAM that supports simultaneous read and write operations, use the Dual Port RAM or Simple Dual Port RAM.

Parameters

Address port width

Address bit width. Minimum bit width is 2, and maximum bit width is 29. The default is 8.

Output data during write

Controls the output data, `dout`, during a write access.

- **New data (default):** During a write, new data appears at the output port, `dout`.
- **Old data:** During a write, old data appears at the output port, `dout`.

Ports

The block has the following ports:

`din`

Data input. The data can have any width. It inherits the width and data type from the input signal.

Data type: scalar fixed point, integer, or complex

`addr`

Write address.

Data type: scalar unsigned integer (`uintN`) or unsigned fixed point (`ufixN`) with a fraction length of 0

`we`

Write enable.

Data type: Boolean

`dout`

Output data from address, `addr`.

Sine, Cosine

Implement fixed-point sine or cosine wave using lookup table approach that exploits quarter wave symmetry

Library

Lookup Tables (Sine block or Cosine block)

Description

The Sine and Cosine block implements a sine and/or cosine wave in fixed point using a lookup table method that exploits quarter wave symmetry.

The Sine and Cosine block can output the following functions of the input signal, depending upon what you select for the **Output formula** parameter:

- $\sin(2\pi u)$
- $\cos(2\pi u)$
- $\exp(i2\pi u)$
- $\sin(2\pi u)$ and $\cos(2\pi u)$

You define the number of lookup table points in the **Number of data points for lookup table** parameter. The block implementation is most efficient when you specify the lookup table data points to be $(2^n) + 1$, where n is an integer.

Tip To obtain meaningful block output, the block input values should fall within the range $[0, 1)$. For input values that fall outside this range, the values are cast to an

unsigned data type, where overflows wrap. For these out-of-range inputs, the block output might not be meaningful.

Use the **Output word length** parameter to specify the word length of the fixed-point output data type. The fraction length of the output is the output word length minus 2.

Data Type Support

The Sine and Cosine block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean

The output of the block is a fixed-point data type.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Output formula

Select the signal(s) to output.

Number of data points for lookup table

Specify the number of data points to retrieve from the lookup table. The implementation is most efficient when you specify the lookup table data points to be $(2^n) + 1$, where n is an integer.

Output word length

Specify the word length for the fixed-point data type of the output signal. The fraction length of the output is the output word length minus 2.

Note The block uses double-precision floating-point values to construct lookup tables. Therefore, the maximum amount of precision you can achieve in your output is 53

bits. Setting the word length to values greater than 53 bits does not improve the precision of your output.

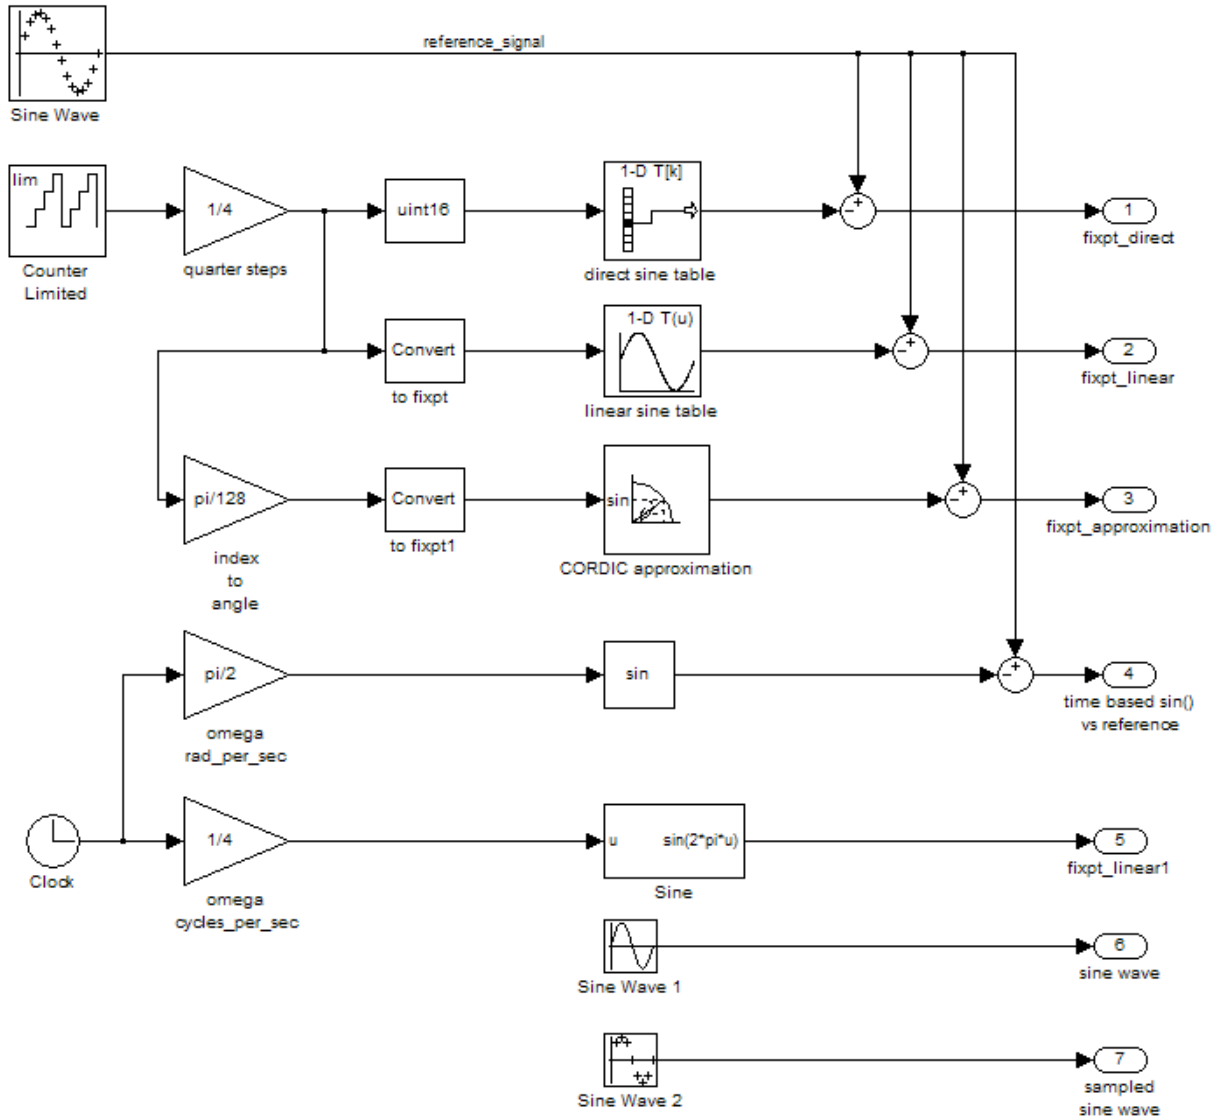

Internal rule priority for lookup table

Specify the internal rule for intermediate calculations. Select *Speed* for faster calculations. If you do, a loss of accuracy might occur, usually up to 2 bits.

Examples

The `sldemo_tonegen_fixpt` model shows how you can use the Sine block to implement a fixed-point sine wave.

Additional blocks to calculate sine and approximate sine using various algorithms.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

See Also

Sine Wave, Trigonometric Function

Introduced before R2006a

Sine HDL Optimized

Implement fixed-point sine wave by using lookup table approach that exploits quarter wave symmetry

Library

HDL Coder / Lookup Tables

Description

The Sine HDL Optimized block implements a fixed-point sine wave by using a lookup table method that exploits quarter-wave symmetry.

You define the number of lookup table points in the **Number of data points** parameter. The block implementation is most efficient for HDL code generation when you specify the lookup table data points to be (2^n) , where n is an integer. For information about the behavior of this block in HDL Coder, see Sine HDL Optimized.

Depending on your selection of the **Output formula** parameter, the blocks can output these functions of the input signal:

- $\sin(2\pi u)$
- $\cos(2\pi u)$
- $\exp(i2\pi u)$
- $\sin(2\pi u)$ and $\cos(2\pi u)$

Use the **Table data type** parameter to specify the word length of the fixed-point output data type. The fraction length of the output is the output word length minus 2.

Data Type Support

The Sine HDL Optimized block accepts signals of these data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean

The output of the block is a fixed-point data type.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Output formula

Select the signal(s) to output.

Number of data points

Specify the number of data points to retrieve from the lookup table. The implementation is most efficient when you specify the lookup table data points to be (2^n) , where n is an integer.

Table data type

Specify the table data type. You can specify an expression that evaluates to a data type, for example, `fixdt(1,16,0)`.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the table data type.

Show data type assistant

Display the **Data Type Assistant**. In the **Data Type Assistant**, you can select the mode to specify the data type.

Mode

Select the mode of data type specification. If you select `Expression`, enter an expression that evaluates to a data type, for example, `fixdt(1,16,0)`.

If you select `Fixed point`, you can use the options in the **Data Type Assistant** to specify the fixed-point data type. In the `Fixed point` mode, you can choose binary point scaling, and specify the signedness, word length, fraction length, and the data type override setting.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point

Introduced in R2016b

Sine Wave

Generate sine wave, using simulation time as time source

Library

Sources

Description

The Sine Wave block outputs a sinusoidal waveform. The block can operate in time-based or sample-based mode.

Note This block is the same as the Sine Wave Function block that appears in the Math Operations library. If you select `Use external signal` for the **Time** parameter in the block dialog box, you get the Sine Wave Function block.

Time-Based Mode

The output of the Sine Wave block is determined by:

$$y = \textit{amplitude} \times \sin(\textit{frequency} \times \textit{time} + \textit{phase}) + \textit{bias}.$$

Time-based mode has two submodes: continuous mode or discrete mode. The value of the **Sample time** parameter determines whether the block operates in continuous mode or discrete mode:

- 0 (the default) causes the block to operate in continuous mode.
- >0 causes the block to operate in discrete mode.

See “Specify Sample Time” in the online documentation for more information.

A **Sample time** parameter value of 0 causes the block to operate in continuous mode. When operating in continuous mode, the Sine Wave block can become inaccurate due to loss of precision as time becomes very large.

A **Sample time** parameter value greater than zero causes the block to behave as if it were driving a Zero-Order Hold block whose sample time is set to that value.

Using the Sine Wave block in this way, you can build models with sine wave sources that are purely discrete, rather than models that are hybrid continuous/discrete systems. Hybrid systems are inherently more complex and as a result take more time to simulate.

In discrete mode, this block uses a differential incremental algorithm instead of one based on absolute time. As a result, the block can be useful in models intended to run for an indefinite length of time, such as in vibration or fatigue testing.

The differential incremental algorithm computes the sine based on the value computed at the previous sample time. This method uses the following trigonometric identities:

$$\sin(t + \Delta t) = \sin(t)\cos(\Delta t) + \sin(\Delta t)\cos(t)$$

$$\cos(t + \Delta t) = \cos(t)\cos(\Delta t) - \sin(t)\sin(\Delta t)$$

In matrix form, these identities are:

$$\begin{bmatrix} \sin(t + \Delta t) \\ \cos(t + \Delta t) \end{bmatrix} = \begin{bmatrix} \cos(\Delta t) & \sin(\Delta t) \\ -\sin(\Delta t) & \cos(\Delta t) \end{bmatrix} \begin{bmatrix} \sin(t) \\ \cos(t) \end{bmatrix}$$

Because Δt is constant, the following expression is a constant:

$$\begin{bmatrix} \cos(\Delta t) & \sin(\Delta t) \\ -\sin(\Delta t) & \cos(\Delta t) \end{bmatrix}$$

Therefore, the problem becomes one of a matrix multiplication of the value of $\sin(t)$ by a constant matrix to obtain $\sin(t + \Delta t)$.

Discrete mode reduces but does not eliminate the accumulation of round-off errors, for example, $(4 * \text{eps})$. This accumulation can happen because computation of the block output at each time step depends on the value of the output at the previous time step.

To handle round-off errors when the Sine Wave block operates in time-based discrete mode, use one of the following methods.

Method	Rationale
Insert a Saturation block directly downstream of the Sine Wave block.	By setting saturation limits on the Sine Wave block output, you can remove overshoot due to accumulation of round-off errors.
<p>Set up the Sine Wave block to use the <code>sin()</code> math library function to calculate block output.</p> <ol style="list-style-type: none"> On the Sine Wave block dialog box, set Time to Use external signal so that an input port appears on the block icon. Connect a clock signal to this input port using a Digital Clock block. Set the sample time of the clock signal to the sample time of the Sine Wave block. 	Unlike the block algorithm, the <code>sin()</code> math library function computes block output at each time step <i>independently</i> of output values from other time steps, preventing the accumulation of round-off errors.

Sample-Based Mode

Sample-based mode uses the following formula to compute the output of the Sine Wave block.

$$y = A \sin(2\pi(k + o) / p) + b$$

where

- A is the amplitude of the sine wave.
- p is the number of time samples per sine wave period.
- k is a repeating integer value that ranges from 0 to $p-1$.
- o is the offset (phase shift) of the signal.
- b is the signal bias.

In this mode, Simulink sets k equal to 0 at the first time step and computes the block output, using the preceding formula. At the next time step, Simulink increments k and

recomputes the output of the block. When k reaches p , Simulink resets k to 0 before computing the block output. This process continues until the end of the simulation.

The sample-based method of computing block output at a given time step does not depend on the output of the previous time steps. Therefore, this mode avoids the accumulation of round-off errors. Additionally, sample-based mode supports reset semantics in subsystems that offer it. For example, if a Sine Wave block is in a resettable subsystem that receives a reset trigger, the repeating integer k resets and the block output resets to its initial condition.

Parameter Dimensions

The numeric parameters of this block must have the same dimensions after scalar expansion.

- If **Interpret vector parameters as 1-D** is not selected, the block outputs a signal of the same dimensions and dimensionality as the parameters.
- If **Interpret vector parameters as 1-D** is selected and the numeric parameters are row or column vectors, the block outputs a vector signal. Otherwise, the block outputs a signal of the same dimensionality and dimensions as the parameters.

Data Type Support

The Sine Wave block accepts and outputs real signals of type `double`.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Sine type

Specify the type of sine wave that this block generates, either time- or sample-based. Some parameters in the dialog box appear depending on whether you select time-based or sample-based.

Time

Specify whether to use simulation time as the source of values for the time variable or an external source. If you specify an external time source, the block displays an input port for the time source.

Amplitude

Specify the amplitude of the signal. The default is 1.

Bias

Specify the constant value added to the sine to produce the output of this block.

Frequency

Specify the frequency, in radians per second. The default is 1. This parameter appears only when you set **Sine type** to time-based.

Samples per period

Specify the number of samples per period. This parameter appears only when you set **Sine type** to sample-based.

Phase

Specify the phase shift, in radians. The default is 0. This parameter appears only when you set **Sine type** to time-based.

You cannot configure this parameter to appear in the generated code as a tunable global variable if you set **Time (t)** to `Use simulation time`. For example, if you set **Default parameter behavior** to `Tunable` or apply a storage class to a `Simulink.Parameter` object, the **Phase** parameter does not appear in the generated code as a tunable global variable.

To generate code so that you can tune the phase during execution, set **Time (t)** to `Use external signal`. You can provide your own time input signal or use a `Digital Clock` block to generate the time signal. For an example, see “Tune Phase Parameter of Sine Wave Block During Code Execution” (Simulink Coder).

Number of offset samples

Specify the offset (discrete phase shift) in number of sample times. This parameter appears only when you set **Sine type** to sample-based.

Sample time

Specify the sample period. The default is 0. If the sine type is sample-based, the sample time must be greater than 0. See “Specify Sample Time” in the online documentation for more information.

Interpret vector parameters as 1-D

If selected, column or row matrix values for numeric parameters result in a vector output signal. Otherwise, the block outputs a signal of the same dimensionality as the parameters. If you do not select this check box, the block always outputs a signal of the same dimensionality as the numeric parameters. See “Determining the Output Dimensions of Source Blocks” in the Simulink documentation. This parameter is not available when an external signal specifies time. In this case, if numeric parameters are column or row matrix values, the output is a 1-D vector.

Examples

The following Simulink examples show how to use the Sine Wave block:

- `sldemo_househeat`
- `sldemo_tonegen_fixpt`
- `sldemo_VariableTransportDelay`
- `sldemo_zeroring`

Characteristics

Data Types	Double
Sample Time	Specified in the Sample time parameter
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Sine Wave Function

Generate sine wave, using external signal as time source

Library

Math Operations

Description

This block is the same as the Sine Wave block that appears in the Sources library. If you select `Use simulation time` for the **Time** parameter in the block dialog box, you get the Sine Wave block. See the documentation for the Sine Wave block for more information.

Characteristics

Data Types	Double
Multidimensional Signals	No
Variable-Size Signals	No
Code Generation	Yes

Introduced before R2006a

Slider

Tune parameter value with sliding scale

Library: Simulink / Dashboard

Description

The Slider block tunes the value of the connected block parameter during simulation. For example, you can connect the Slider block to a Gain block in your model and adjust its value during simulation. You can modify the range of the Slider block's scale to fit your data. Use the Slider block with other Dashboard blocks to create an interactive dashboard to control your model.

Connection

Dashboard block controls connect to variables and block parameters. To connect a Dashboard block to a variable or parameter, use the **Connection** table in the block's parameters.

- 1 Double-click the block.
- 2 Populate the **Connection** table by selecting blocks of interest in your model.
- 3 Mark the option button next to the parameter or variable you want to adjust during simulation.
- 4 Click **Apply**.

Limitations

- You cannot save the block connections or properties in model files that use the MDL format.

To save connections and properties, save the model file in the SLX format.

- Dashboard blocks can only connect to real scalar signals.
- Dashboard blocks cannot connect to blocks that are commented out.
- Dashboard blocks cannot connect to signals inside reference models.
- Parameters specified by indexing a variable array do not appear in the **Connection** table. For example, a block parameter defined using the variable `engine(1)` does not appear in the table.

To access the parameter in the **Connection** table, assign the indexed value to a scalar variable, such as `engine_1`. Then, use the scalar variable to define the block parameter.

Parameters

Connection — Select a block parameter to connect

signal connection options

Select the block parameter to control using the **Connection** table. To open the dialog box, double-click the block. Then, populate the **Connection** table by selecting a block in your model. Select the variable parameter you want to control, and click **Apply**.

Note To see workspace variables in the connection table, update the model diagram with **Ctrl+D**.

Scale Type — Type of scale

'Linear' (default) | 'Log'

Type of scale displayed on the control. **Linear** specifies a linear scale, and **Log** specifies a logarithmic scale.

Minimum — Minimum tick mark value

0 (default) | scalar

A finite, real, double, scalar value specifying the minimum tick mark value for the scale. The minimum must be less than the value entered for the maximum.

Maximum — Maximum tick mark value

100 (default) | scalar

A finite, real, double, scalar value specifying the maximum tick mark value for the scale. The maximum must be greater than the value entered for the minimum.

Tick Interval — Interval between major tick marks

auto (default) | scalar

A finite, real, positive, integer, scalar value specifying the interval of major tick marks on the scale. When set to `auto`, the block automatically adjusts the tick interval based on the minimum and maximum values.

Label — Block label position

'Top' (default) | 'Bottom' | 'Hide'

Position of the block label. When the block is connected to a signal, the label is the name of the connected signal. When the block is not connected, the label is the instructional text.

Introduced in R2015b

Slider Gain

Vary scalar gain using slider

Library

Math Operations

Description

Use the Slider Gain block to modify a scalar gain during a simulation using a slider. The block accepts one input and generates one output.

Data Type Support

Data type support for the Slider Gain block is the same as that for the Gain block (see Gain).

Parameters

Low

Specify the lower limit of the slider range. The default is 0.

High

Specify the upper limit of the slider range. The default is 2.

The edit fields indicate the lower limit and the upper limit. You can change the gain in two ways: by manipulating the slider, or by entering a new value in the current value field. You can change the range of gain values by changing the lower and upper limits.

To apply a vector or matrix gain to the block input, consider using the Gain block.

Examples

The following example models show how to use the Slider Gain block:

- `aero_six_dof`

Characteristics

Data Types	Double Single Boolean Base Integer
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Gain

Introduced before R2006a

Spectrum Analyzer

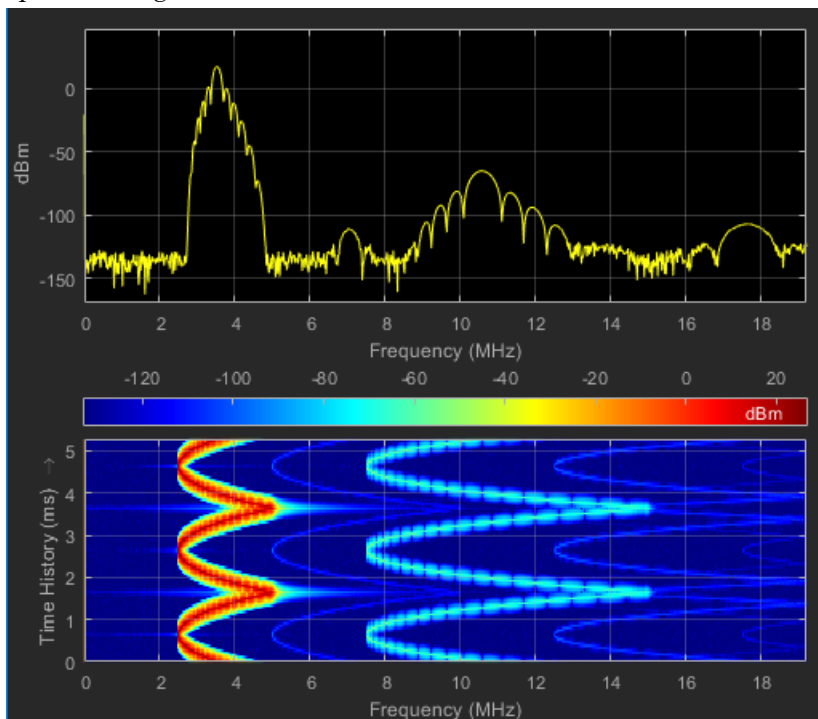

Display frequency spectrum of time-domain signals

Library: DSP System Toolbox / Sinks

Description

The Spectrum Analyzer block, referred to here as the scope, displays the frequency spectra of signals.

The Spectrum Analyzer block accepts input signals that:

- Have discrete sample time
- Are real or complex valued
- Have a fixed number of channels of variable length
- Are floating or fixed point data

You can use the Spectrum Analyzer block in models running in Normal or Accelerator simulation modes. You can also use the Spectrum Analyzer block in models running in Rapid Accelerator or External simulation modes, with some limitations.

You can use the Spectrum Analyzer block inside all subsystems and conditional subsystems. Conditional subsystems include enabled subsystems, triggered subsystems, enabled and triggered subsystems, and function-call subsystems. See “Conditional Subsystems” for more information.

You can configure and display Spectrum Analyzer settings from the command line with `spbscopes.SpectrumAnalyzerConfiguration`.

For information about the Spectrum Analyzer System object, see `dsp.SpectrumAnalyzer`.

Ports

Input

Port_1 — Signals to visualize

scalar | vector | matrix | array

Connect the signals you want to visualize. You can have up to 96 input ports.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

Parameters

Spectrum Settings

The **Spectrum Settings** pane appears at the right side of the Spectrum Analyzer window. This pane controls how the spectrum is calculated. To show the Spectrum

Settings, in the Spectrum Analyzer menu, select **View > Spectrum Settings** or use the  button in the toolbar.

Main options

Type — Type of spectrum to display

Power (default) | Power density | RMS

Power - Spectrum Analyzer shows the power spectrum.

Power density - Spectrum Analyzer shows the power spectral density. The power spectral density is the magnitude of the spectrum normalized to a bandwidth of 1 hertz.

RMS - Spectrum Analyzer shows the root mean squared spectrum.

Tunable: Yes

Programmatic Use

See SpectrumType.

View — Spectrum view

Spectrum (default) | Spectrogram | Spectrum and spectrogram

Spectrum - Spectrum Analyzer shows the spectrum.

Spectrogram - Spectrum Analyzer shows the spectrogram, which displays frequency content over time. The most recent spectrogram update is at the bottom of the display, and time scrolls from the bottom to the top of the display.

Spectrum and spectrogram - Spectrum Analyzer shows both the spectrum and spectrogram.

Tunable: Yes

Programmatic Use

See ViewType.

Sample rate — Sample rate of the input signal in hertz

Inherited (default) | positive scalar

Select `Inherited` to use the same sample rate as the input signal. To specify a sample rate, delete `Inherited` and enter a sample rate value.

Programmatic Use

See `SampleRate`.

Method — Spectrum estimation method

`Welch` (default) | `Filter Bank`

Select `Welch` or `Filter Bank` as the spectrum estimation method. For more details about the two spectrum estimation algorithms, see “Algorithms” (DSP System Toolbox).

Tunable: No

Programmatic Use

See `Method`.

Full frequency span — Use entire Nyquist frequency interval

`on` (default) | `off`

Select this check box to compute and plot the spectrum over the entire “Nyquist frequency interval” (DSP System Toolbox).

Tunable: Yes

Programmatic Use

See `FrequencySpan`.

Span (Hz) — Frequency span in hertz

`10e3` (default) | real positive scalar

Specify the frequency span in hertz. Use this parameter with the `CF` (Hz) parameter to define the frequency span around a center frequency. This parameter defines the range of values shown on the Frequency axis in the Spectrum Analyzer window.

Tunable: Yes

Dependencies

To use this parameter, you must:

- Clear the “Full frequency span” (DSP System Toolbox) check box.
- Set the **Span (Hz)/Fstart (Hz)** dropdown to `Span (Hz)`.

Programmatic Use

See `FrequencySpan` and `Span`.

CF (Hz) — Center frequency in hertz

0 (default) | scalar

Specify the center frequency, in hertz. Use this parameter with the “Span (Hz)” (DSP System Toolbox) parameter to define the frequency span around a center frequency. This parameter defines the value shown at the middle point of the Frequency axis on the Spectrum Analyzer window.

Tunable: Yes

Dependencies

To use this parameter, you must:

- Clear the “Full frequency span” (DSP System Toolbox) check box.
- Set the **Span (Hz)/Fstart (Hz)** dropdown to “Span (Hz)” (DSP System Toolbox).

Programmatic Use

See `CenterFrequency`.

Fstart (Hz) — Start frequency in hertz

-5e3 (default) | scalar

Specify the start frequency in hertz. Use this parameter with the parameter to define the range of frequency-axis values using start frequency and stop frequency. This parameter defines the value shown at the leftmost side of the Frequency axis on the Spectrum Analyzer window.

Tunable: Yes

Dependencies

To use this parameter, you must:

- Clear the “Full frequency span” (DSP System Toolbox) check box.

- Set the **Span (Hz)/FStart (Hz)** dropdown to `FStart (Hz)`.

Programmatic Use

See `StartFrequency`.

FStop (Hz) — Stop frequency in hertz

`5e3` (default) | scalar

Specify the stop frequency, in hertz. Use this parameter with the “`FStart (Hz)`” (DSP System Toolbox) parameter to define the range of Frequency axis values. This parameter defines the value shown at the rightmost side of the Frequency axis on the Spectrum Analyzer window.

Tunable: Yes

Dependencies

To use this parameter, you must:

- Clear the “Full frequency span” (DSP System Toolbox) check box.
- Set the **Span (Hz)/FStart (Hz)** dropdown to “`FStart (Hz)`” (DSP System Toolbox).

Programmatic Use

See `StopFrequency`.

RBW (Hz) — Resolution bandwidth

`Auto` (default) | positive scalar

The resolution bandwidth in hertz. This parameter defines the smallest positive frequency that can be resolved. By default, this parameter is set to `Auto`. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 *RBW* intervals over the specified frequency span.

If you set this parameter to a numeric value, the value must allow at least two *RBW* intervals over the specified frequency span. In other words, the ratio of the overall frequency span to *RBW* must be at least two:

$$\frac{\textit{span}}{\textit{RBW}} > 2$$

Tunable: Yes

Dependency

To use this parameter, set the **RBW (Hz)/Window length/Number of frequency bands** dropdown to `RBW (Hz)`.

Programmatic Use

See `RBW`.

Window length — Length of window in samples

1024 (default) | integer greater than 2

The length of the window, in samples. The window length used to control the frequency resolution and compute the spectral estimates. The window length must be an integer greater than 2.

Dependencies

To use this parameter, set:

- “Method” (DSP System Toolbox) to `Welch`
- Set the **RBW (Hz)/Window length/Number of frequency bands** dropdown to `Window Length`

Programmatic Use

See `WindowLength`.

Number of frequency bands — FFT length

Auto (default) | positive integer

Specify the fast Fourier transform (FFT) length to control the number of frequency bands. If the value is `Auto`, the Spectrum Analyzer uses the entire frame size to estimate the spectrum. If you specify the number of frequency bands, you set the input buffer size.

Dependencies

To use this parameter, set:

- “Method” (DSP System Toolbox) to `Filter Bank`
- Set the **RBW (Hz)/Window length/Number of frequency bands** dropdown to `Number of frequency bands`

Programmatic Use

See `FFTLength`

Taps per band — Number of filter taps

12 (default) | positive integer

Specify the number of filter taps or coefficients for each frequency band. This value corresponds to the number of filter coefficients per polyphase branch. The total number of filter coefficients is equal to `NumTapsPerBand + FFTLength`.

Dependency

To use this parameter, you must set the **RBW (Hz)/Window length/Number of frequency bands** dropdown to “Number of frequency bands” (DSP System Toolbox).

Programmatic Use

See `NumTapsPerBand`.

NFFT — Number of FFT points

Auto (default) | positive integer

Specify the length of the FFT that Spectrum Analyzer uses to compute spectral estimates. Acceptable options are `Auto` or a positive integer.

The **NFFT** value must be greater than or equal to the value of the **Window length** parameter. By default, when **NFFT** is set to `Auto`, the Spectrum Analyzer sets **NFFT** equal to the value of **Window length**. When in RBW mode, the specified RBW value is used to calculate an FFT length that equals the window length.

When this parameter is set to a positive integer, this parameter is equivalent to the `n` parameter of the `fft` function.

Dependencies

To use this parameter, you must set the **RBW (Hz)/Window length/Number of frequency bands** dropdown to “Window length” (DSP System Toolbox).

Programmatic Use

See `FFTLength`.

Samples/update — Required number of input samples

positive scalar

This property is read-only.

The number of input samples required to compute one spectral update. You cannot modify this parameter; it is shown in the spectrum analyzer for informational purposes only. This parameter is directly related to **RBW (Hz)/Window length/Number of frequency bands**. For more details, see “Algorithms” (DSP System Toolbox).

If the input does not have enough samples to achieve the resolution bandwidth that you specify, Spectrum Analyzer produces a message on the display.

Spectrogram Settings

Channel — Spectrogram channel

channel name

Select the signal channel for which the spectrogram settings apply.

Dependencies

To use this option:

- Set “View” (DSP System Toolbox) to Spectrogram or Spectrum and spectrogram.
- There must be more than one signal channel input.

Time res. (s) — Time resolution in seconds

Auto (default) | positive number

Time resolution is the amount of data, in seconds, used to compute a spectrogram line. The minimum attainable resolution is the amount of time it takes to compute a single spectral estimate. The tooltip displays the minimum attainable resolution given the current settings.

The time resolution value is determined based on frequency resolution method, the RBW setting, and the time resolution setting.

Method	Frequency Resolution Method	Frequency Resolution Setting	Time Resolution Setting	Resulting Time Resolution in Seconds
Welch or Filter Bank	RBW (Hz)	Auto	Auto	1/RBW
Welch or Filter Bank	RBW (Hz)	Auto	Manually entered	Time Resolution
Welch or Filter Bank	RBW (Hz)	Manually entered	Auto	1/RBW
Welch or Filter Bank	RBW (Hz)	Manually entered	Manually entered	Must be equal to or greater than the minimum attainable time resolution, 1/RBW. Several spectral estimates are combined into one spectrogram line to obtain the desired time resolution. Interpolation is used to obtain time resolution values that are not integer multiples of 1/RBW.
Welch	Window length	—	Auto	1/RBW

Method	Frequency Resolution Method	Frequency Resolution Setting	Time Resolution Setting	Resulting Time Resolution in Seconds
Welch	Window length	—	Manually entered	Must be equal to or greater than the minimum attainable time resolution. Several spectral estimates are combined into one spectrogram line to obtain the desired time resolution. Interpolation is used to obtain time resolution values that are not integer multiples of $1/\text{RBW}$.
Filter Bank	Number of frequency bands	—	Auto	$1/\text{RBW}$
Filter Bank	Number of frequency bands	—	Manually entered	Must be equal to or greater than the minimum attainable time resolution, $1/\text{RBW}$.

Tunable: Yes

Dependency

To use this option, set “View” (DSP System Toolbox) to Spectrogram or Spectrum and spectrogram.

Programmatic Use

See TimeResolution.

Time span — Time span in seconds

Auto (default) | positive scalar

The time span over which the Spectrum Analyzer displays the spectrogram specified in seconds. The time span is the product of the desired number of spectral lines and the time resolution. The tooltip displays the minimum allowable time span, given the current settings. If the time span is set to Auto, 100 spectral lines are used.

Tunable: Yes

Dependency

To use this option, set “View” (DSP System Toolbox) to Spectrogram or Spectrum and spectrogram.

Programmatic Use

See TimeSpan.

Window Options

Overlap (%) — Segment overlap percentage

0 (default) | scalar between 0 and 100

This parameter defines the amount of overlap between the previous and current buffered data segments. The overlap creates a window segment that is used to compute a spectral estimate. The value must be greater than or equal to zero and less than 100.

Tunable: Yes

Programmatic Use

See OverlapPercent.

window — Windowing method

Hann (default) | Rectangular | Blackman-Harris | Chebyshev | Flat Top | Hamming | Kaiser | custom window function name

The windowing method to apply to the spectrum. Windowing is used to control the effect of sidelobes in spectral estimation. The window you specify affects the window length required to achieve a resolution bandwidth and the required number of samples per update. For more information about windowing, see “Windows” (Signal Processing Toolbox).

Tunable: Yes

Programmatic Use

See Window.

Attenuation — Sidelobe attenuation

60 (default) | scalar greater than or equal to 45

The sidelobe attenuation in decibels (dB). The value must be greater than or equal to 45.

Dependency

This parameter applies only when you set the **Window** parameter to Chebyshev or Kaiser.

Programmatic Use

See SidelobeAttenuation.

NENBW — Normalized effective noise bandwidth

scalar

This property is read-only.

The normalized effective noise bandwidth of the window. You cannot modify this parameter; it is shown for informational purposes only. This parameter is a measure of the noise performance of the window. The value is the width of a rectangular filter that accumulates the same noise power with the same peak power gain.

The rectangular window has the smallest NENBW, with a value of 1. All other windows have a larger NENBW value. For example, the Hann window has an NENBW value of approximately 1.5.

Trace Options

Units — Spectrum units

dBm (default) | dBW | Watts | Vrms | dBV | dBFS

The units of the spectrum. The available values depend on the value of the “Type” (DSP System Toolbox) parameter.

Tunable: Yes

Programmatic Use

See SpectrumUnits.

Full scale — Full scale for dBFS units

Auto (default) | positive real scalar

The full scale used for the dBFS units. By default, the Spectrum Analyzer uses the entire spectrum scale. Specify a positive real scalar for the dBFS full scale.

Tunable: Yes

Dependency

To enable this parameter, set “Units” on page 1-0 to dBFS.

Programmatic Use

See FullScale.

Averages — Number of spectral averages

1 (default) | positive integer

Specify the number of spectral averages as a positive integer. The spectrum analyzer computes the current power spectrum estimate by computing a running average of the last N power spectrum estimates. This parameter defines the number of spectral averages, N .

Dependency

This parameter applies only when the “View” (DSP System Toolbox) parameter is Spectrum or Spectrum and spectrogram.

Programmatic Use

See SpectralAverages.

Reference load — Reference load

1 (default) | positive real scalar

The reference load in ohms that the Spectrum Analyzer uses as a reference to compute power values.

Programmatic Use

See ReferenceLoad.

Scale — Scale of frequency axis

Linear (default) | Logarithmic

Choose a linear or logarithm scale for the frequency axis. When the frequency span contains negative frequency values, you cannot chose the logarithmic option.

Programmatic Use

See FrequencyScale.

Offset — Constant frequency offset

0 (default) | scalar

The constant frequency offset to apply to the entire spectrum, or a vector of frequencies to apply to each spectrum for multiple inputs. The offset parameter is added to the values on the Frequency axis in the Spectrum Analyzer window. This parameter is not used in any spectral computations. You must take the parameter into consideration when you set the **Span (Hz)** and **CF (Hz)** parameters to ensure that the frequency span is within the “Nyquist frequency interval” (DSP System Toolbox).

Programmatic Use

See FrequencyOffset.

Normal trace — Normal trace view

on (default) | off

When this check box is selected, the Spectrum Analyzer calculates and plots the power spectrum or power spectrum density. Spectrum Analyzer performs a smoothing operation by averaging several spectral estimates.

Dependencies

To clear this check box, you must first select either the “Max hold trace” (DSP System Toolbox) or the “Min hold trace” (DSP System Toolbox) parameter. This parameter applies only when “View” (DSP System Toolbox) is Spectrum or Spectrum and spectrogram.

Programmatic Use

See PlotNormalTrace.

Max hold trace — Maximum hold trace view

off (default) | on

Select this check box to enable Spectrum Analyzer to plot the maximum spectral values of all the estimates obtained.

Dependency

This parameter applies only when “View” (DSP System Toolbox) is Spectrum or Spectrum and spectrogram.

Programmatic Use

See PlotMaxHoldTrace.

Min hold trace — Minimum hold trace view

off (default) | on

Select this check box to enable Spectrum Analyzer to plot the minimum spectral values of all the estimates obtained.

Dependency

This parameter applies only when “View” (DSP System Toolbox) is Spectrum or Spectrum and spectrogram.

Programmatic Use

See PlotMinHoldTrace.

Two-sided spectrum — Enable two-sided spectrum view

off (default) | on

Select this check box to enable a two-sided spectrum view. In this view, both negative and positive frequencies are shown. If you clear this check box, Spectrum Analyzer shows a one-sided spectrum with only positive frequencies. Spectrum Analyzer requires that this parameter is selected when the input signal is complex valued.

Programmatic Use

See PlotAsTwoSidedSpectrum.

Configuration Properties

The **Configuration Properties** dialog controls visual aspects of the Spectrum Analyzer. To open the Configuration Properties, in the Spectrum Analyzer menu, select **View >**

Configuration Properties or select the  button in the toolbar dropdown.

Title — Display title

character vector

Specify the display title as a character vector. Enter %<SignalLabel> to use the signal labels in the Simulink model as the axes titles.

Tunable: Yes

Programmatic Use

See Title.

Show legend — Display signal legend

off (default) | on

Show signal legend. The names listed in the legend are the signal names from the model. For signals with multiple channels, a channel index is appended after the signal name. Continuous signals have straight lines before their names and discrete signals have step-shaped lines.

From the legend, you can control which signals are visible. This control is equivalent to changing the visibility in the **Style** parameters. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again. To show only one signal, right-click the signal name, which hides all other signals. To show all signals, press **ESC**.

Dependency

To enable this parameter, set “View” (DSP System Toolbox) to `Spectrum` or `Spectrum` and `spectrogram`.

Programmatic Use

See `ShowLegend`.

Show grid — Show internal grid lines

off (default) | on

Show internal grid lines on the Spectrum Analyzer

Programmatic Use

See ShowGrid.

Y-limits (minimum) — Y-axis minimum

-80 (default) | scalar

Specify the minimum value of the *y*-axis.

Programmatic Use

See YLimits.

Y-limits (maximum) — Y-axis maximum

20 (default) | scalar

Specify the maximum value of the *y*-axis.

Programmatic Use

See YLimits.

Y-label — Y-axis label

character vector

To display signal units, add (%<SignalUnits>) to the label. At the beginning of a simulation, Simulink replaces (%SignalUnits) with the units associated with the signals. For example, if you have a signal for velocity with units of m/s enter

```
Velocity (%<SignalUnits>)
```

Programmatic Use

See YLabel.

Color map — Spectrogram colormap

jet(256) (default) | hot(256) | bone(256) | cool(256) | copper(256) |
gray(256) | 3-column matrix

Select the colormap for the spectrogram, or enter a three-column matrix expression for the colormap. For more information about colormaps, see colormap.

Tunable: Yes

Dependency

To use this parameter, set “View” (DSP System Toolbox) to Spectrogram or Spectrum and spectrogram.

Color-limits (minimum) — Spectrogram minimum

-80 (default) | scalar

Specify the signal power for the minimum color value of the spectrogram.

Tunable: Yes

Dependency

To use this parameter, set “View” (DSP System Toolbox) to Spectrogram or Spectrum and spectrogram.

Programmatic Use

See ColorLimits.

Color-limits (maximum) — Spectrogram maximum

20 (default) | scalar

Specify the signal power for the maximum color value of the spectrogram.

Tunable: Yes

Dependency

To use this parameter, set “View” (DSP System Toolbox) to Spectrogram or Spectrum and spectrogram.

Programmatic Use

See ColorLimits.

Style

The **Style** dialog controls how to Spectrum Analyzer appears. To open the Style properties, in the Spectrum Analyzer menu, select **View > Style** or select the  button in the toolbar dropdown.

Figure color — Window background

gray (default) | color picker

Specify the color that you want to apply to the background of the scope figure.

Plot type — Plot type

Line (default) | Stem

Specify whether to display a Line or Stem plot.

Programmatic Use

See PlotType.

Axes colors — Axes background color

black (default) | color picker

Specify the color that you want to apply to the background of the axes.

Properties for line — Channel for visual property settings

channel names

Specify the channel for which you want to modify the visibility, line properties, and marker properties.

Visible — Channel visibility

on (default) | off

Specify whether the selected channel is visible. If you clear this check box, the line disappears. You can also change signal visibility using the scope legend.

Line — Line style

line, 0.5, yellow (default)

Specify the line style, line width, and line color for the selected channel.

Marker — Data point markers

none (default)

Specify marks for the selected channel to show at its data points. This parameter is similar to the 'Marker' property for plots. You can choose any of the marker symbols from the dropdown.

Axes Scaling

The **Axes Scaling** dialog controls the axes limits of the Spectrum Analyzer. To open the Axes Scaling properties, in the Spectrum Analyzer menu, select **Tools > Axes Scaling > Axes Scaling Properties**.

Axes scaling/Color scaling — Automatic axes scaling

Auto (default) | Manual | After N Updates

Specify when the scope automatically scales the y-axis. If the spectrogram is displayed, specify when the scope automatically scales the color axis. By default, this parameter is set to `Auto`, and the scope does not shrink the y-axis limits when scaling the axes or color. You can select one of the following options:

- `Auto` — The scope scales the axes or color as needed, both during and after simulation. Selecting this option shows the **Do not allow Y-axis limits to shrink** or **Do not allow color limits to shrink**.
- `Manual` — When you select this option, the scope does not automatically scale the axes or color. You can manually scale the axes or color in any of the following ways:
 - Select **Tools > Scaling Properties**.
 - Press one of the **Scale Axis Limits** toolbar buttons.
 - When the scope figure is the active window, press **Ctrl+A**.
- `After N Updates` — Selecting this option causes the scope to scale the axes or color after a specified number of updates. This option is useful, and most efficient, when your frequency signal values quickly reach steady-state after a short period of time. Selecting this option shows the **Number of updates** edit box where you can modify the number of updates to wait before scaling.

Tunable: Yes

Programmatic Use

See `AxesScaling`.

Do not allow Y-axis/color limits to shrink — Axes scaling limits

on (default) | off

When you select this parameter, the y-axis is allowed to grow during axes scaling operations. If the spectrogram is displayed, selecting this parameter allows the color

limits to grow during axis scaling. If you clear this check box, the y-axis or color limits can shrink during axes scaling operations.

Dependency

This parameter appears only when you select `Auto` for the **Axis scaling** or **Color scaling** parameter. When you set the **Axes scaling** or **Color scaling** parameter to `Manual` or `After N Updates`, the y-axis or color limits can shrink.

Number of updates — Number of updates before scaling

10 (default) | positive number

The number of updates after which the axes scale, specified as a positive integer. If the spectrogram is displayed, this parameter specifies the number of updates after which the color axes scales.

Tunable: Yes

Dependency

This parameter appears only when you set “Axes scaling/Color scaling” (DSP System Toolbox) to `After N Updates`.

Scale limits at stop — Scale axes at stop

off (default) | on

Select this check box to scale the axes when the simulation stops. If the spectrogram is displayed, select this check box to scale the color when the simulation stops. The y-axis is always scaled. The x-axis limits are only scaled if you also select the **Scale X-axis limits** check box.

Data range (%) — Percent of axes

100 (default) | number in the range [1,100]

Set the percentage of the axis that the scope uses to display the data when scaling the axes. If the spectrogram is displayed, set the percentage of the power values range within the colormap. Valid values are from 1 through 100. For example, if you set this parameter to 100, the scope scales the axis limits such that your data uses the entire axis range. If you then set this parameter to 30, the scope increases the y-axis or color range such that your data uses only 30% of the axis range.

Tunable: Yes

Align — Alignment along axes

Center (default) | Bottom | Top | Left | Right

Specify where the scope aligns your data along the axis when it scales the axes. If the spectrogram is displayed, specify where the scope aligns your data along the axis when it scales the color. If you are using CCDF Measurements (DSP System Toolbox), the x axis is also configurable.

Tunable: Yes

Model Examples

Algorithms

Welch's Method

When you set the **Method** property to `Welch`, the following algorithms apply. The Spectrum Analyzer uses the `RBW` or the `Window Length` setting in the **Spectrum Settings** pane to determine the data window length. Then, it partitions the input signal into a number of windowed data segments. Finally, Spectrum Analyzer uses the modified periodogram method to compute spectral updates, averaging the windowed periodograms for each segment.

Spectrum Analyzer requires that a minimum number of samples to compute a spectral estimate. This number of input samples required to compute one spectral update is shown as **Samples/update** in the **Main options** pane. This value is directly related to resolution bandwidth, *RBW*, by the following equation, or to the window length, by the equation shown in step 2.

$$N_{\text{samples}} = \frac{\left(1 - \frac{O_p}{100}\right) \times NENBW \times F_s}{RBW}$$

The normalized effective noise bandwidth, *NENBW*, is a factor that depends on the windowing method. Spectrum Analyzer shows the value of *NENBW* in the **Window Options** pane of the **Spectrum Settings** pane. Overlap percentage, *O_p*, is the value of

the **Overlap %** parameter in the **Window Options** pane of the **Spectrum Settings** pane. F_s is the sample rate of the input signal. Spectrum Analyzer shows sample rate in the **Main Options** pane of the **Spectrum Settings** pane.

- 1 When in **RBW (Hz)** mode, the window length required to compute one spectral update, N_{window} , is directly related to the resolution bandwidth and normalized effective noise bandwidth:

$$N_{window} = \frac{NENBW \times F_s}{RBW}$$

When in **Window Length** mode, the window length is used as specified.

- 2 The number of input samples required to compute one spectral update, $N_{samples}$, is directly related to the window length and the amount of overlap by the following equation.

$$N_{samples} = \left(1 - \frac{O_p}{100}\right) N_{window}$$

When you increase the overlap percentage, fewer new input samples are needed to compute a new spectral update. For example, if the window length is 100, then the number of input samples required to compute one spectral update is given as shown in the following table.

O_p	$N_{samples}$
0%	100
50%	50
80%	20

- 3 The normalized effective noise bandwidth, $NENBW$, is a window parameter determined by the window length, N_{window} , and the type of window used. If $w(n)$ denotes the vector of N_{window} window coefficients, then $NENBW$ is given by the following equation.

$$NENBW = N_{window} \frac{\sum_{n=1}^{N_{window}} w^2(n)}{\left[\sum_{n=1}^{N_{window}} w(n)\right]^2}$$

- 4 When in **RBW (Hz)** mode, you can set the resolution bandwidth using the value of the **RBW (Hz)** parameter on the **Main options** pane of the **Spectrum Settings** pane. You must specify a value to ensure that there are at least two RBW intervals over the specified frequency span. The ratio of the overall span to RBW must be greater than two:

$$\frac{span}{RBW} > 2$$

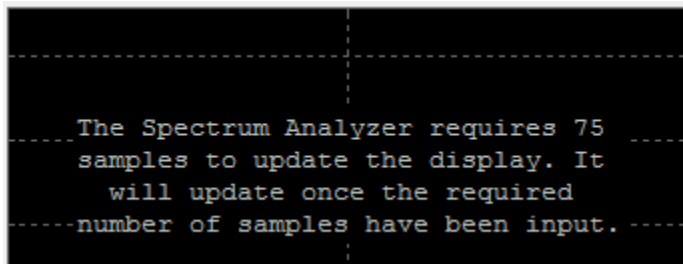

By default, the **RBW (Hz)** parameter on the **Main options** pane is set to `Auto`. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 RBW intervals over the specified frequency span. When you set **RBW (Hz)** to `Auto`, *RBW* is calculated as:

$$RBW_{auto} = \frac{span}{1024}$$

- 5 When in **Window Length** mode, you specify N_{window} and the resulting *RBW* is:

$$\frac{NENBW * F_s}{N_{window}}$$

Sometimes, the number of input samples provided are not sufficient to achieve the resolution bandwidth that you specify. When this situation occurs, Spectrum Analyzer displays a message:

Spectrum Analyzer removes this message and displays a spectral estimate when enough data has been input.

Note The number of FFT points (N_{fft}) is independent of the window length (N_{window}). You can set them to different values if N_{fft} is greater than or equal to N_{window} .

Filter Bank

When you set the **Method** property to `Filter Bank`, the following algorithms apply. The Spectrum Analyzer uses the **RBW (Hz)** or the **Number of frequency band** property in the **Spectrum Settings** pane to determine the input frame length.

Spectrum Analyzer requires a minimum number of samples to compute a spectral estimate. This number of input samples required to compute one spectral update is shown as **Samples/update** in the **Main options** pane. This value is directly related to resolution bandwidth, *RBW*, by the following equation.

$$N_{samples} = \frac{F_s}{RBW}$$

F_s is the sample rate of the input signal. Spectrum Analyzer shows sample rate in the **Main Options** pane of the **Spectrum Settings** pane.

- 1 When in **RBW (Hz)** mode, you can set the resolution bandwidth using the value of the **RBW (Hz)** parameter on the **Main options** pane of the **Spectrum Settings** pane. You must specify a value to ensure that there are at least two RBW intervals over the specified frequency span. The ratio of the overall span to RBW must be greater than two:

$$\frac{span}{RBW} > 2$$

By default, the **RBW** parameter on the **Main options** pane is set to `Auto`. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 RBW intervals over the specified frequency span. Thus, when you set **RBW**

to `Auto`, it is calculated by the following equation. $RBW_{auto} = \frac{span}{1024}$

- 2 When in **Number of frequency bands** mode, you specify the input frame size. When the number of frequency bands is `Auto`, the resulting RBW is:

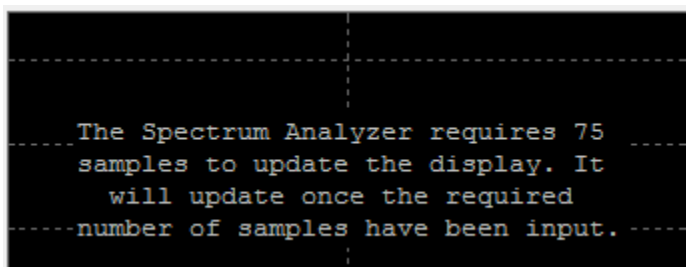

$$RBW = \frac{F_s}{\text{Input Frame Size}}$$

When the number of frequency bands is manually specified, the resulting RBW is:

$$RBW = \frac{F_s}{FFTLengh}$$

For more information about the filter bank algorithm, see “Polyphase Implementation” (DSP System Toolbox).

Sometimes, the number of input samples provided are not sufficient to achieve the resolution bandwidth that you specify. When this situation occurs, Spectrum Analyzer displays a message:

Spectrum Analyzer removes this message and displays a spectral estimate when enough data has been input.

Nyquist frequency interval

When the `PlotAsTwoSidedSpectrum` property is set to `true`, the interval is

$$\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2} \right] + FrequencyOffset \text{ hertz.}$$

When the `PlotAsTwoSidedSpectrum` property is set to `false`, the interval is

$$\left[0, \frac{SampleRate}{2} \right] + FrequencyOffset \text{ hertz.}$$

Periodogram and Spectrogram

Spectrum Analyzer calculates and plots the power spectrum, power spectrum density, and RMS computed by the modified Periodogram estimator. For more information about the Periodogram method, see `periodogram`.

Power Spectral Density — The power spectral density (PSD) is given by the following equation.

$$PSD(f) = \frac{1}{P} \sum_{p=1}^P \frac{\left| \sum_{n=1}^{N_{FFT}} x^{(p)}[n] e^{-j2\pi f(n-1)T} \right|^2}{F_s \times \sum_{n=1}^{N_{window}} w^2[n]}$$

In this equation, $x[n]$ is the discrete input signal. On every input signal frame, Spectrum Analyzer generates as many overlapping windows as possible, with each window denoted as $x^{(p)}[n]$, and computes their periodograms. Spectrum Analyzer displays a running average of the P most current periodograms.

Power Spectrum — The power spectrum is the product of the power spectral density and the resolution bandwidth, as given by the following equation.

$$P_{spectrum}(f) = PSD(f) \times RBW = PSD(f) \times \frac{F_s \times NENBW}{N_{window}} = \frac{1}{P} \sum_{p=1}^P \frac{\left| \sum_{n=1}^{N_{FFT}} x^{(p)}[n] e^{-j2\pi f(n-1)T} \right|^2}{\left[\sum_{n=1}^{N_{window}} w[n] \right]^2}$$

Occupied BW

The *Occupied BW* is calculated as follows.

- 1 Calculate the total power in the measured frequency range.
- 2 Determine the lower frequency value. Starting at the lowest frequency in the range and moving upward, the power distributed in each frequency is summed until this result is

$$\frac{100 - \text{Occupied BW } \%}{2}$$
 of the total power.
- 3 Determine the upper frequency value. Starting at the highest frequency in the range and moving downward, the power distributed in each frequency is summed until the result reaches

$$\frac{100 - \text{Occupied BW } \%}{2}$$

2

of the total power.

- 4 The bandwidth between the lower and upper power frequency values is the occupied bandwidth.
- 5 The frequency halfway between the lower and upper frequency values is the center frequency.

Distortion Measurements

The *Distortion Measurements* are computed as follows.

- 1 Spectral content is estimated by finding peaks in the spectrum. When the algorithm detects a peak, it records the width of the peak and clears all monotonically decreasing values. That is, the algorithm treats all these values as if they belong to the peak. Using this method, all spectral content centered at DC (0 Hz) is removed from the spectrum and the amount of bandwidth cleared (W_0) is recorded.
- 2 The fundamental power (P_1) is determined from the remaining maximum value of the displayed spectrum. A local estimate (Fe_1) of the fundamental frequency is made by computing the central moment of the power in the vicinity of the peak. The bandwidth of the fundamental power content (W_1) is recorded. Then, the power from the fundamental is removed as in step 1.
- 3 The power and width of the higher-order harmonics (P_2, W_2, P_3, W_3 , etc.) are determined in succession by examining the frequencies closest to the appropriate multiple of the local estimate (Fe_1). Any spectral content that decreases monotonically about the harmonic frequency is removed from the spectrum first before proceeding to the next harmonic.
- 4 Once the DC, fundamental, and harmonic content is removed from the spectrum, the power of the remaining spectrum is examined for its sum ($P_{remaining}$), peak value ($P_{maxspur}$), and median value ($P_{estnoise}$).
- 5 The sum of all the removed bandwidth is computed as $W_{sum} = W_0 + W_1 + W_2 + \dots + W_n$.

The sum of powers of the second and higher-order harmonics are computed as

$$P_{harmonic} = P_2 + P_3 + P_4 + \dots + P_n.$$

- 6 The sum of the noise power is estimated as:

$$P_{noise} = (P_{remaining} \cdot dF + P_{est.noise} \cdot W_{sum}) / RBW$$

Where dF is the absolute difference between frequency bins, and RBW is the resolution bandwidth of the window.

- 7 The metrics for SNR, THD, SINAD, and SFDR are then computed from the estimates.

$$THD = 10 \cdot \log_{10} \left(\frac{P_{harmonic}}{P_1} \right)$$

$$SINAD = 10 \cdot \log_{10} \left(\frac{P_1}{P_{harmonic} + P_{noise}} \right)$$

$$SNR = 10 \cdot \log_{10} \left(\frac{P_1}{P_{noise}} \right)$$

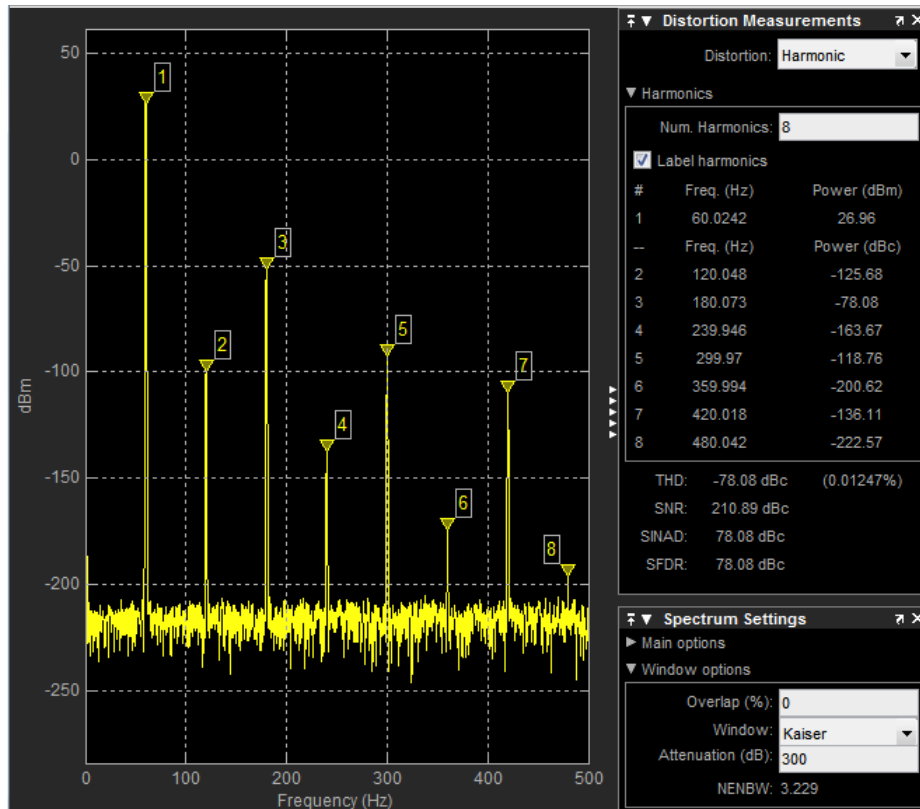

$$SFDR = 10 \cdot \log_{10} \left(\frac{P_1}{\max(P_{maxspur}, \max(P_2, P_3, \dots, P_n))} \right)$$

Harmonic Measurements

- 1 The harmonic distortion measurements use the spectrum trace shown in the display as the input to the measurements. The default Hann window setting of the Spectrum Analyzer may exhibit leakage that can completely mask the noise floor of the measured signal.

The harmonic measurements attempt to correct for leakage by ignoring all frequency content that decreases monotonically away from the maximum of harmonic peaks. If the window leakage covers more than 70% of the frequency bandwidth in your spectrum, you may see a blank reading (–) reported for **SNR** and **SINAD**. If your application can tolerate the increased equivalent noise bandwidth (ENBW), consider using a Kaiser window with a high attenuation (up to 330 dB) to minimize spectral leakage.

- 2 The DC component is ignored.
- 3 After windowing, the width of each harmonic component masks the noise power in the neighborhood of the fundamental frequency and harmonics. To estimate the noise power in each region, Spectrum Analyzer computes the median noise level in the nonharmonic areas of the spectrum. It then extrapolates that value into each region.
- 4 N th order intermodulation products occur at $A * F1 + B * F2$,

where $F1$ and $F2$ are the sinusoid input frequencies and $|A| + |B| = N$. A and B are integer values.

- 5 For intermodulation measurements, the third-order intercept (TOI) point is computed as follows, where P is power in decibels of the measured power referenced to 1 milliwatt (dBm):

- $TOI_{lower} = P_{F1} + (P_{F2} - P_{(2F1-F2)})/2$
- $TOI_{upper} = P_{F2} + (P_{F1} - P_{(2F2-F1)})/2$
- $TOI = + (TOI_{lower} + TOI_{upper})/2$

Slider Switch

Toggle parameter between two values

Library: Simulink / Dashboard

Description

The Slider Switch block toggles the value of the connected block parameter between two values during simulation. For example, you can connect the Slider Switch block to a Switch block in your model and change its state during simulation. Use the Slider Switch block with other Dashboard blocks to create an interactive dashboard for your model.

Connection

Dashboard block controls connect to variables and block parameters. To connect a Dashboard block to a variable or parameter, use the **Connection** table in the block's parameters.

- 1 Double-click the block.
- 2 Populate the **Connection** table by selecting blocks of interest in your model.
- 3 Mark the option button next to the parameter or variable you want to adjust during simulation.
- 4 Click **Apply**.

Limitations

- You cannot save the block connections or properties in model files that use the MDL format.
To save connections and properties, save the model file in the SLX format.
- Dashboard blocks can only connect to real scalar signals.
- Dashboard blocks cannot connect to blocks that are commented out.

- Dashboard blocks cannot connect to signals inside reference models.
- Parameters specified by indexing a variable array do not appear in the **Connection** table. For example, a block parameter defined using the variable `engine(1)` does not appear in the table.

To access the parameter in the **Connection** table, assign the indexed value to a scalar variable, such as `engine_1`. Then, use the scalar variable to define the block parameter.

Parameters

Connection — Select a block parameter to connect

signal connection options

Select the block parameter to control using the **Connection** table. To open the dialog box, double-click the block. Then, populate the **Connection** table by selecting a block in your model. Select the variable parameter you want to control, and click **Apply**.

Note To see workspace variables in the connection table, update the model diagram with **Ctrl+D**.

States

Label (Left) — Label for left switch position

'On' (default) | character vector

Labels the left switch position. You can use the **Label** to display the value the connected parameter takes when the switch is positioned at the left, or you can enter a text label.

Example: `Gain = 2`

Value (Left) — Value for left switch position

1 (default) | scalar

The value assigned to the connected parameter when the switch is positioned at the left.

Label (Right) — Label for right switch position

'Off' (default) | character vector

Labels the right switch position. You can use the **Label** to display the value the connected parameter takes when the switch is positioned at the right, or you can enter a text label.

Example: `Gain = 1`

Value (Right) — Value for right switch position

0 (default) | scalar

The value assigned to the connected parameter when the switch is positioned at the right.

Label — Block label position

'Top' (default) | 'Bottom' | 'Hide'

Position of the block label. When the block is connected to a signal, the label is the name of the connected signal. When the block is not connected, the label is the instructional text.

Introduced in R2015a

Sqrt, Signed Sqrt, Reciprocal Sqrt

Calculate square root, signed square root, or reciprocal of square root

Library

Math Operations

Description

You can select one of the following functions from the **Function** parameter list.

Function	Description	Mathematical Expression	MATLAB Equivalent
<code>sqrt</code>	Square root of the input	$u^{0.5}$	<code>sqrt</code>
<code>signedSqrt</code>	Square root of the absolute value of the input, multiplied by the sign of the input	$\text{sign}(u) * u ^{0.5}$	—
<code>rSqrt</code>	Reciprocal of the square root of the input	$u^{-0.5}$	—

The block output is the result of applying the function to the input. Each function supports:

- Scalar operations
- Element-wise vector and matrix operations

Data Type Support

The block accepts input signals of the following data types:

Function	Input Data Types	Restrictions
sqrt	<ul style="list-style-type: none"> Floating point Built-in integer Fixed point 	None
signedSqrt	<ul style="list-style-type: none"> Floating point Built-in integer Fixed point 	When the input is an integer or fixed-point type, the output must be floating point.
rSqrt	<ul style="list-style-type: none"> Floating point Built-in integer Fixed point 	None

The block accepts real and complex inputs of the following types:

Function	Types of Real Inputs	Types of Complex Inputs
sqrt	Any, except for fixed-point inputs that are negative or have nontrivial slope and nonzero bias	Any, except for fixed-point inputs
signedSqrt		None
rSqrt		None

The block output:

- Uses the data type that you specify for **Output data type**
- Is real or complex, depending on your selection for **Output signal type**

Parameters

Function

Specify the mathematical function. The block icon changes to match the function you select.

Function	Block Icon
sqrt	
signedSqrt	
rSqrt	

Output signal type

Specify the output signal type of the block as auto, real, or complex.

Function	Input Signal Type	Output Signal Type		
		Auto	Real	Complex
sqrt	real	real for nonnegative inputs NaN for negative inputs	real for nonnegative inputs NaN for negative inputs	complex
	complex	complex	error	complex
signedSqrt	real	real	real	complex
	complex	error	error	error
rSqrt	real	real	real	error
	complex	error	error	error

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Note The parameters in the **Algorithm** pane are available only when you set **Function** to rSqrt on the **Main** pane.

Method

Specify the method for computing the reciprocal of a square root.

Method	Data Types Supported	When to Use This Method
Exact	Floating point If you use a fixed-point or built-in integer type, an upcast to a floating-point type occurs.	You do not want an approximation. Note The input or output must be floating point.
Newton-Raphson	Floating-point, fixed-point, and built-in integer types	You want a fast, approximate calculation.

The `Exact` method provides results that are consistent with MATLAB computations.

Note The algorithms for `sqrt` and `signedSqrt` are always of `Exact` type, no matter what selection appears on the block dialog box.

Number of iterations

Specify the number of iterations to perform the Newton-Raphson algorithm. The default value is 3.

This parameter is not available when you select `Exact` for **Method**.

Note If you enter 0, the block output is the initial guess of the Newton-Raphson algorithm.

Intermediate results data type

Specify the data type for intermediate results (available only when you set **Function** to `sqrt` or `rSqrt` on the **Main** pane). You can set the data type to:

- A rule that inherits a data type, for example, `Inherit:Inherit` via internal rule
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object

- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Follow these guidelines on setting an intermediate data type explicitly for the square root function, `sqrt`:

Input and Output Data Types	Intermediate Data Type
Input or output is double.	Use double.
Input or output is single, and any non-single data type is <i>not</i> double.	Use single or double.
Input and output are fixed point.	Use fixed point.

Follow these guidelines on setting an intermediate data type explicitly for the reciprocal square root function, `rSqrt`:

Input and Output Data Types	Intermediate Data Type
Input is double and output is not single.	Use double.
Input is not single and output is double.	Use double.
Input and output are fixed point.	Use fixed point.

Caution Do not set **Intermediate results data type** to `Inherit:Inherit` from output when:

- You select `Newton-Raphson` to compute the reciprocal of a square root.
- The input data type is floating point.
- The output data type is fixed point.

Under these conditions, selecting `Inherit:Inherit` from output yields suboptimal performance and produces an error.

To avoid this error, convert the input signal from a floating-point to fixed-point data type. For example, insert a `Data Type Conversion` block in front of the `Sqrt` block to perform the conversion.

Output data type

Specify the output data type. You can set the data type to:

- A rule that inherits a data type, for example, `Inherit:Inherit` via back propagation

- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” in the *Simulink User's Guide* for more information.

Output minimum

Specify the minimum value that the block can output. The default value is [] (unspecified). Simulink uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Output maximum

Specify the maximum value that the block can output. The default value is [] (unspecified). Simulink uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer). in the Fixed-Point Designer documentation.

Saturate on integer overflow

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box.	<p>You want to optimize efficiency of your generated code.</p> <p>You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.</p>	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

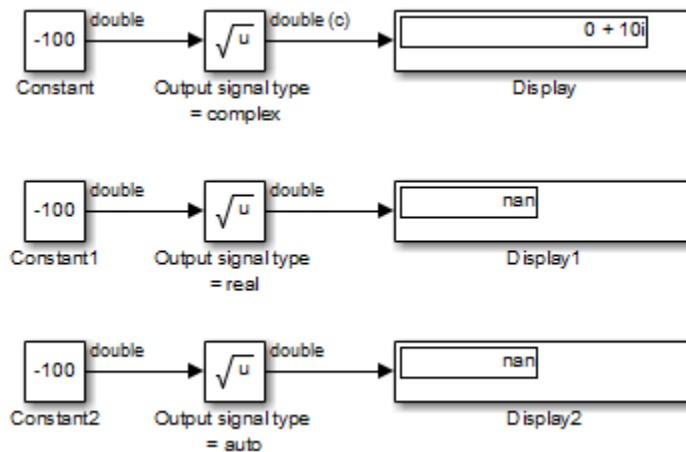

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. Usually, the code generation process can detect

when overflow is not possible. In this case, the code generator does not produce saturation code.

Examples

sqrt Function

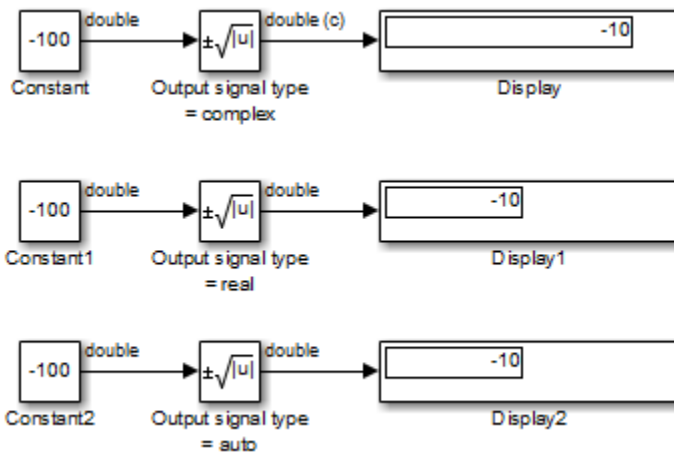

Suppose that you have the following model:

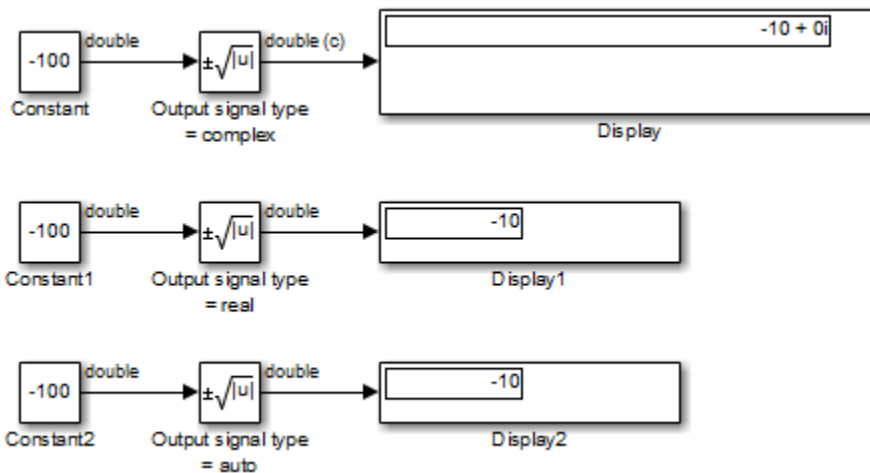

When the input to the Sqrt block is negative and the **Output signal type** is auto or real, the sqrt function outputs NaN. However, setting **Output signal type** to complex produces the correct answer.

signedSqrt Function

Suppose that you have the following model:

When the input to the Sqrt block is negative, the block output is the same for any **Output signal type** setting. If you change the first Display block format from short to decimal (Stored Integer), you see the value of the imaginary part for the complex output.

rSqrt Function with Floating-Point Inputs

Suppose that you have the following model:

In the Sqrt block dialog box, assume that the following parameter settings apply:

Parameter	Setting
Method	Newton-Raphson
Number of iterations	1
Intermediate results data type	Inherit:Inherit from input

After one iteration of the Newton-Raphson algorithm, the block output is within 0.0004 of the final value (0.4834).

rSqrt Function with Fixed-Point Inputs

Suppose that you have the following model:

In the Sqrt block dialog box, assume that the following parameter settings apply:

Parameter	Setting
Method	Newton-Raphson
Number of iterations	1
Intermediate results data type	Inherit:Inherit from input

After one iteration of the Newton-Raphson algorithm, the block output is within 0.0459 of the final value (0.4834).

Characteristics

Data Types	Double Single Base Integer Fixed-Point
------------	--

Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

See Also

Math Function, Trigonometric Function

Introduced in R2010a

Squeeze

Remove singleton dimensions from multidimensional signal

Library

Math Operations

Description

The Squeeze block removes singleton dimensions from its multidimensional input signal. A singleton dimension is any dimension whose size is one. The Squeeze block operates only on signals whose number of dimensions is greater than two. Scalar, one-dimensional (vector), and two-dimensional (matrix) signals pass through the Squeeze block unchanged.

Data Type Support

The Squeeze block accepts input signals of any dimension and of any data type that Simulink supports, including fixed-point and enumerated data types. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Examples

In the following model, the Squeeze block converts a multidimensional array of size 3-by-1-by-2 into a 3-by-2 signal:

Because the Constant block supplies a signal with random values to the Squeeze block, the values in the Display block vary from simulation to simulation.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Reshape

Introduced in R2007b

State Control

Specify synchronous reset and enable behavior for blocks with state

Library

HDL Coder / HDL Subsystems

Description

The State Control block in *Synchronous* mode improves the HDL simulation behavior of blocks with state, or blocks that have reset or enable ports. The simulation behavior in *Classic* mode is the same as when you do not add the State Control block inside the subsystem.

When use the *Synchronous* mode of the block, the Simulink simulation behavior closely matches that of the digital hardware.

If you have HDL Coder installed, you can generate cleaner HDL code with the *Synchronous* mode of the State Control block. For more information, see [State Control](#).

Parameters

State control

Specify whether to use synchronous or classic semantics. The default is *Synchronous*.

Limitations

The following limitations apply to using the State Control block in Simulink. For information about this block in HDL Coder, see State Control in the HDL Coder documentation.

Block-Level Limitations

- For synchronous semantics in S-function blocks, set the method `ssSetStateSemanticsClassicAndSynchronous` to `true`.
- Discrete-Time Integrator blocks with a reset port do not support synchronous semantics.
- All action subsystems connected to If and Switch Case blocks must have the same semantics, either classic or synchronous.
- The following blocks are not allowed in synchronous mode:
 - Continuous time blocks and blocks with continuous rate
 - Simulink blocks with **Input processing** set to `Columns as channels (frame based)`, where this parameter applies.
 - Trigger block
 - From Workspace block
 - The set of unit delay blocks in the **Additional Math & Discrete > Additional Discrete** sublibrary in Simulink, such as the Unit Delay Resettable and Unit Delay External IC blocks

Subsystem-level Limitations

- Conditional subsystems using classic semantics cannot have subsystems with synchronous semantics inside them.
- Conditional subsystems must be single rate when you use the State Control block in synchronous mode.
- Synchronous Enabled Subsystem cannot contain reset subsystems or a reset parameter port. For example, you cannot have a Delay block with an external reset port inside the subsystem.
- These blocks are not supported in synchronous mode:

- For Iterator Subsystem
- While Iterator Subsystem
- Function-Call Subsystem
- Triggered Subsystem

Model-Level Limitations

- Variable-size signals are not supported with synchronous semantics.
- Synchronous semantics do not propagate across model boundaries. If your parent model has synchronous semantics, any referenced model must have synchronous semantics explicitly specified. At the root level of each referenced model, add a State Control block with the **State control** parameter set to *Synchronous*.

Introduced in R2016a

State Reader

Read a block state

Library: Signal Routing

Description

The State Reader block reads the current state of a supported state owner block.

Add a State Reader block to your model from the Simulink Library Browser.

State Reader blocks can read state from these state owner blocks:

- Discrete State-Space
- Discrete-Time Integrator
- Delay
- Unit Delay
- Discrete Transfer Fcn
- Discrete Filter
- S-Function (with one data type work vector declared as a discrete-state vector)

Ports

Output

out — State value

scalar | vector

State value read from a state owner block.

The dimension of the output is the dimension of the full state vector. Refer to the **Initial conditions** parameter for specific blocks. For example, for a Delay block with a **Delay length** of N , the State Reader block returns a state vector of length $[1 \times N]$.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Parameters

State owner block — Show the state owner block

`none` (default)

Show the state owner block whose state this block is reading. To change the state owner block, select a block from the **State Owner Selector Tree**.

Command-Line Information

Parameter: `StateOwnerBlock`

Type: character vector

Value: `'` | `'<model path/block name>'`

Default: `'`

See Also

State Writer

Write to a block state

Library: Signal Routing

Description

The State Writer block sets the state of a supported state owner block.

Add a State Writer block to your model from the Simulink Library Browser.

State Writer blocks can write state to these state owner blocks:

- Discrete State-Space
- Discrete-Time Integrator
- Delay
- Unit Delay
- Discrete Transfer Fcn
- Discrete Filter
- S-Function (with one data type work vector declared as a discrete-state vector)

Ports

Input

I_n — State value

scalar | vector

State value written to a state owner block.

When writing to a state owner block with an input scalar, the scalar value is expanded to match the dimension of the state. All elements of the state are set to the same value.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Parameters

State owner block — Show the state owner block

`none` (default)

Show the state owner block whose state this block is writing. To change the state owner block, select a block from the **State Owner Selector Tree**.

Command-Line Information

Parameter: `StateOwnerBlock`

Type: character vector

Value: `'` | `'<model path/block name>'`

Default: `'`

State-Space

Implement linear state-space system

$$\begin{cases} \dot{x} = Ax + Bu \\ y = Cx + Du \end{cases}$$

Library

Continuous

Description

The State-Space block implements a system whose behavior you define as

$$\dot{x} = Ax + Bu$$

$$y = Cx + Du$$

$$x|_{t=t_0} = x_0,$$

where x is the state vector, u is the input vector, y is the output vector and x_0 is the initial condition of the state vector. The matrix coefficients must have these characteristics:

- A must be an n -by- n matrix, where n is the number of states.
- B must be an n -by- m matrix, where m is the number of inputs.
- C must be an r -by- n matrix, where r is the number of outputs.
- D must be an r -by- m matrix.

	n	m
n	A	B
r	C	D

In general, the block has one input port and one output port. The number of rows in C or D matrix is the same as the width of the output port. The number of columns in the B or D matrix are the same as the width of the input port. If you want to model an autonomous linear system with no inputs, set the B and D matrices to empty. In this

case, the block acts as a source block with no input port and one output port, and implements the following system:

$$\dot{x} = Ax$$

$$y = Cx$$

$$x|_{t=t_0} = x_0.$$

Simulink software converts a matrix containing zeros to a sparse matrix for efficient multiplication.

Data Type Support

A State-Space block accepts and outputs real signals of type double.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

A

Specify the n-by-n matrix coefficient, where n is the number of states.

Default: 1

Parameter: A

Type: matrix

Value: '1'

Default: '1'

B

Specify the n-by-m matrix coefficient, where n is the number of states and m is the number of inputs.

Default: 1

Parameter: B

Type: matrix

Value: '1'

Default: '1'

C

Specify the r-by-n matrix coefficient, where r is the number of outputs and n is the number of states.

Default: 1

Parameter: C

Type: matrix

Value: '1'

Default: '1'

D

Specify the r-by-m matrix coefficient, where r is the number of outputs and m is the number of inputs.

Default: 1

Parameter: D

Type: matrix

Value: '1'

Default: '1'

Initial conditions

Specify the initial state vector.

Default: 0

The initial conditions of this block cannot be `inf` or `NaN`.

Parameter: `X0`

Type: vector

Value: `'0'`

Default: `'0'`

Absolute tolerance

Specify the absolute tolerance for computing block states.

Default: `auto`

- You can enter `auto`, `-1`, a positive real scalar or vector.
- If you enter `auto` or `-1`, then Simulink uses the absolute tolerance value in the Configuration Parameters dialog box (see “Solver Pane”) to compute block states.
- If you enter a real scalar, then that value overrides the absolute tolerance in the Configuration Parameters dialog box for computing all block states.
- If you enter a real vector, then the dimension of that vector must match the dimension of the continuous states in the block. These values override the absolute tolerance in the Configuration Parameters dialog box.

Parameter: `AbsoluteTolerance`

Type: character vector, scalar, or vector

Value: `'auto'` | `'-1'` | any positive real scalar or vector

Default: `'auto'`

State Name (e.g., 'position')

Assign a unique name to each state.

Default: `' '`

If this field is blank, no name assignment occurs.

- To assign a name to a single state, enter the name between quotes, for example, `'velocity'`.

- To assign names to multiple states, enter a comma-delimited list surrounded by braces, for example, {'a', 'b', 'c'}. Each name must be unique.
- The state names apply only to the selected block.
- The number of states must divide evenly among the number of state names.
- You can specify fewer names than states, but you cannot specify more names than states.

For example, you can specify two names in a system with four states. The first name applies to the first two states and the second name to the last two states.

- To assign state names with a variable in the MATLAB workspace, enter the variable without quotes. A variable can be a character vector, cell array, or structure.

Parameter: ContinuousStateAttributes

Type: character vector

Value: ' ' | user-defined

Default: ' '

Examples

The following Simulink examples show how to use the State-Space block:

- `sldemo_dblcart1`
- `aero_vibrati`

Characteristics

Data Types	Double
Sample Time	Continuous
Direct Feedthrough	Only if $D \neq 0$
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Discrete State-Space

Transfer Fcn

Introduced before R2006a

Step

Generate step function

Library

Sources

Description

The Step block provides a step between two definable levels at a specified time. If the simulation time is less than the **Step time** parameter value, the block's output is the **Initial value** parameter value. For simulation time greater than or equal to the **Step time**, the output is the **Final value** parameter value.

The numeric block parameters must be of the same dimensions after scalar expansion. If the **Interpret vector parameters as 1-D** option is off, the block outputs a signal of the same dimensions and dimensionality as the parameters. If the **Interpret vector parameters as 1-D** option is on and the numeric parameters are row or column vectors (that is, single row or column 2-D arrays), the block outputs a vector (1-D array) signal. Otherwise, the block outputs a signal of the same dimensionality and dimensions as the parameters.

Data Type Support

The Step block outputs real signals of type `double`.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Step time

Specify the time, in seconds, when the output jumps from the **Initial value** parameter to the **Final value** parameter. The default is 1 second.

Initial value

Specify the block output until the simulation time reaches the **Step time** parameter. The default is 0.

Final value

Specify the block output when the simulation time reaches and exceeds the **Step time** parameter. The default is 1.

Sample time

Specify the sample rate of step. See “Specify Sample Time” in the online documentation for more information.

Interpret vector parameters as 1-D

If selected, column or row matrix values for the Step block's numeric parameters result in a vector output signal; otherwise, the block outputs a signal of the same dimensionality as the parameters. If this option is not selected, the block always outputs a signal of the same dimensionality as the block's numeric parameters. See “Determining the Output Dimensions of Source Blocks” in the Simulink documentation.

Enable zero-crossing detection

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Examples

The following Simulink examples show how to use the Step block:

- `sldemo_doublebounce`
- `sldemo_enginewc`

Characteristics

Data Types	Double
Sample Time	Specified in the Sample time parameter
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	Yes, if enabled.
Code Generation	Yes

Ramp

Introduced before R2006a

Stop Simulation

Stop simulation when input is nonzero

Library

Sinks

Description

The Stop Simulation block stops the simulation when the input is nonzero. The simulation completes the current time step before terminating. If the block input is a vector, any nonzero vector element causes the simulation to stop.

When you use the Stop Simulation block in a For Iterator subsystem, the stop action occurs after execution of *all* the iterations in the subsystem during a time step. The stop action does not interrupt execution until the start of the next time step.

You cannot use the Stop Simulation block to pause the simulation. To create a block that pauses the simulation, see “Pause Simulation Using Assertion Blocks” in the Simulink documentation.

Data Type Support

The Stop Simulation block accepts real signals of type `double` or `Boolean`. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Examples

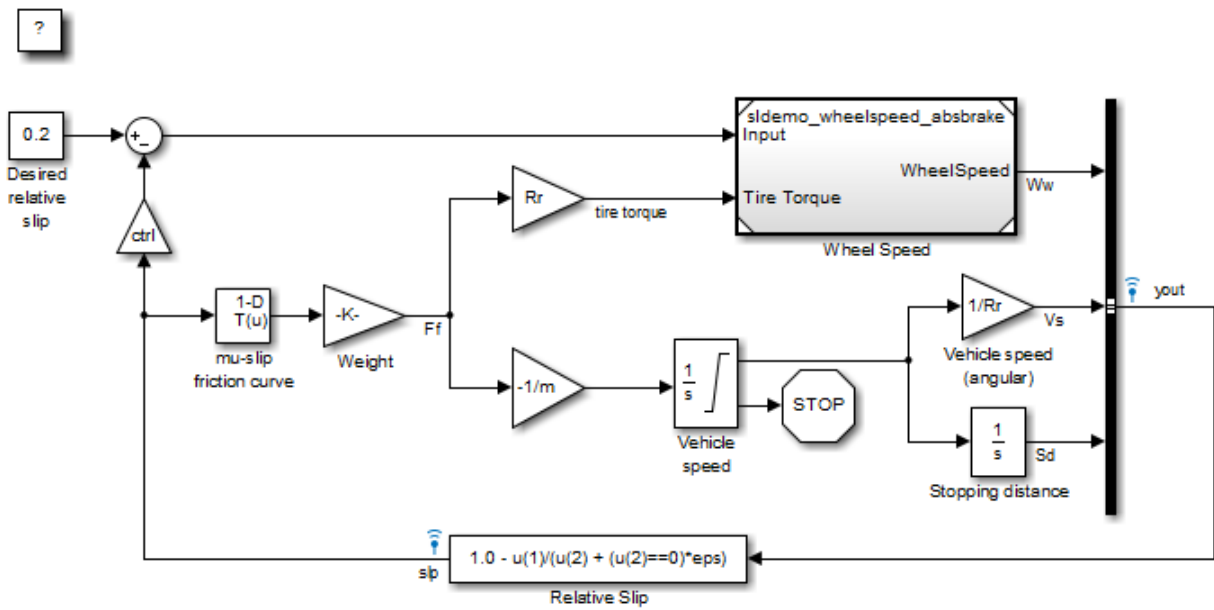

Usage with the Relational Operator Block

You can use the Stop Simulation block with the Relational Operator block to control when a simulation stops. For example, the following model stops simulation when the simulation time reaches 10.

Usage with the Integrator Block

You can use the Stop Simulation block with the Integrator block to control when a simulation stops. For example, the `sldemo_absbrake` model stops simulation when the saturation port of the Integrator block outputs a value of 1 or -1.

Characteristics

Data Types	Double Boolean
Sample Time	Inherited from driving block
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Subsystem, Atomic Subsystem, Nonvirtual Subsystem, CodeReuse Subsystem

Group blocks to create model hierarchy

Library: Ports & Subsystems

Description

A Subsystem block contains a subset of blocks within a model or system. The Subsystem block can represent a virtual subsystem or a nonvirtual subsystem.

- Nonvirtual subsystem – Control when the contents of the subsystem are evaluated as a single unit (atomic execution). Create conditionally executed subsystems that run only when an event occurs on a triggering, function-call, action, or enabling input (see “Conditionally Executed Subsystems”).
- Virtual subsystems – Subsystem is neither conditionally nor atomically executed. Virtual subsystems do not have checksums. To determine if a subsystem is virtual, use the `get_param` function for the Boolean block parameter `IsSubsystemVirtual`.

An atomic subsystem is a Subsystem block with the block parameter **Treat as atomic unit** selected.

A codereuse subsystem is a Subsystem block with the parameter **Treat as atomic unit** selected and the parameter **Function packaging** set to `Reusable function`, specifying the function code generation format for the subsystem.

To create a subsystem, do one of the following:

- Copy a Subsystem block from the Ports & Subsystems library into your model. Then add blocks to the subsystem by opening the Subsystem block and copying blocks into it.
- Select all blocks and lines that make up the subsystem, and select **Diagram > Subsystem & Model Reference > Create Subsystem from Selection**. Simulink replaces the blocks with a Subsystem block, along with the necessary Inport and Outport blocks to reflect signals entering and leaving the subsystem.

The number of input ports drawn on the Subsystem block icon corresponds to the number of Inport blocks in the subsystem. Similarly, the number of output ports drawn on the block corresponds to the number of Outport blocks in the subsystem.

The Subsystem block supports signal label propagation through subsystem Inport and Outport blocks.

Ports

Input

in — Signal input to a subsystem block

scalar | vector | matrix

Placing an Inport block in a subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Output

out — Signal output from a subsystem

scalar | vector | matrix

Placing an Outport block in a subsystem block adds an output port from the block. The port label on the subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Parameters on the Code Generation tab require a Simulink Coder or Embedded Coder license.

Main

Show port labels — Select how to display port labels

`FromPortIcon` (default) | `FromPortBlockName` | `SignalName`

Select how to display port labels on the Subsystem block icon.

`none`

Do not display port labels.

`FromPortIcon`

If the corresponding port icon displays a signal name, display the signal name on the Subsystem block. Otherwise, display the port block name.

`FromPortBlockName`

Display the name of the corresponding port block on the Subsystem block.

`SignalName`

If a signal name exists, display the name of the signal connected to the port on the Subsystem block. Otherwise, display the name of the corresponding port block.

Programmatic Use

Parameter: `ShowPortLabels`

Type: character vector

Value: `'FromPortIcon'` | `'FromPortBlockName'` | `'SignalName'`

Default: `'FromPortIcon'`

Read/Write permissions — Select access to contents of subsystem

`ReadWrite` (default) | `ReadOnly` | `NoReadOrWrite`

Control user access to the contents of the subsystem.

`ReadWrite`

Enable opening and modification of subsystem contents.

`ReadOnly`

Enable opening but not modification of the subsystem. If the subsystem resides in a block library, you can create and open links to the subsystem and can make and modify local copies of the subsystem but cannot change the permissions or modify the contents of the original library instance.

NoReadOrWrite

Disable opening or modification of subsystem. If the subsystem resides in a library, you can create links to the subsystem in a model but cannot open, modify, change permissions, or create local copies of the subsystem.

Programmatic Use

Parameter: Permissions

Type: character vector

Value: 'ReadWrite' | 'ReadOnly' | 'NoReadOrWrite'

Default: 'ReadWrite'

Name of error callback function — Specify name of function

' ' (default) | function name

Enter name of a function to be called if an error occurs while Simulink is executing the subsystem.

Simulink passes two arguments to the function: the handle of the subsystem and a character vector that specifies the error type. If no function is specified, Simulink displays a generic error message if executing the subsystem causes an error.

Programmatic Use

Parameter: ErrorFcn

Type: character vector

Value: ' ' | '<function name>'

Default: ' '

Permit hierarchical resolution — Select how to resolve workspace variable names

All (default) | ExplicitOnly | None

Select whether to resolve names of workspace variables referenced by this subsystem.

See “Symbol Resolution” and “Symbol Resolution Process” in the Simulink User's Guide for more information.

All

Resolve all names of workspace variables used by this subsystem, including those used to specify block parameter values and Simulink data objects (for example, Simulink.Signal objects).

ExplicitOnly

Resolve only names of workspace variables used to specify block parameter values, data store memory (where no block exists), signals, and states marked as “must resolve”.

None

Do not resolve any workspace variable names.

Programmatic Use

Parameter: PermitHierarchicalResolution

Type: character vector

Value: 'All' | 'ExplicitOnly' | 'None'

Default: 'All'

Treat as atomic unit — Control execution of a subsystem as one unit

off (default) | on

Causes Simulink to treat the subsystem as a unit when determining the execution order of block methods.

off

Treat all blocks in the subsystem as being at the same level in the model hierarchy as the subsystem when determining block method execution order. This can cause execution of methods of blocks in the subsystem to be interleaved with execution of methods of blocks outside the subsystem.

on

Treat the subsystem as a unit when determining the execution order of block methods. For example, when it needs to compute the output of the subsystem, Simulink invokes the output methods of all the blocks in the subsystem before invoking the output methods of other blocks at the same level as the subsystem block.

Dependency

Selecting this parameter, enables the **Minimize algebraic loop occurrences**, **Sample time**, and **Function packaging** parameters. Using **Function packaging** requires a Simulink Coder license.

Programmatic Use**Parameter:** TreatAsAtomicUnit**Type:** character vector**Value:** 'off' | 'on'**Default:** 'off'**Minimize algebraic loop occurrences — Control elimination of algebraic loops**

off (default) | on

Try to eliminate any artificial algebraic loops that include the atomic subsystem

See also “Eliminate Artificial Algebraic Loops Caused by Atomic Subsystems”.

 off

Do not try to eliminate any artificial algebraic loops that include the atomic subsystem.

 on

Try to eliminate any artificial algebraic loops that include the atomic subsystem.

Dependency

To enable this parameter, select the **Treat as atomic unit** parameter.

Programmatic Use**Parameter:** MinAlgLoopOccurrences**Type:** character vector**Value:** 'off' | 'on'**Default:** 'off'**Sample time — Specify time interval**

-1 (default) | [Ts 0]

Specify whether all blocks in this subsystem must run at the same rate or can run at different rates.

- If the blocks in the subsystem can run at different rates, specify the subsystem's sample time as inherited (-1).
- If all blocks must run at the same rate, specify the sample time corresponding to this rate as the value of the **Sample time** parameter.

- If any of the blocks in the subsystem specify a different sample time (other than `-1` or `inf`), Simulink displays an error message when you update or simulate the model. For example, suppose all the blocks in the subsystem must run 5 times a second. To ensure this, specify the sample time of the subsystem as `0.2`. In this example, if any of the blocks in the subsystem specify a sample time other than `0.2`, `-1`, or `inf`, Simulink displays an error when you update or simulate the model.

`-1`

Specify inherited sample time. Use this sample time if the blocks in the subsystem can run at different rates.

`[Ts 0]`

Specify periodic sample time.

Dependency

To enable this parameter, select the **Treat as atomic unit** parameter.

Programmatic Use

Parameter: `SystemSampleTime`

Type: character vector

Value: `'-1'` | `'[Ts 0]'`

Default: `'-1'`

Propagate execution context across subsystem boundary — Control execution across block boundary

`off` (default) | `on`

Enable execution context propagation across the boundary of this subsystem.

`off`

Do not enable execution context propagation across this subsystem's boundary.

`on`

Enable execution context propagation across this subsystem's boundary.

Dependency

Enable this parameter by adding an Enable port or Trigger port block to the Subsystem block.

Programmatic Use**Parameter:** PropExecContextOutsideSubsystem**Type:** character vector**Value:** 'off' | 'on'**Default:** 'off'**Variant control — Specify variant control (condition) expression**

Variant (default) | logical expression

Specify variant control (condition) expression that executes a variant Simulink Function block when the expression evaluates to `true`.

See also `Simulink.Variant`

Variant

Default name for a logical (Boolean) expression.

logical expression

A logical (Boolean) expression or a `Simulink.Variant` object representing a logical expression.

The function is activated when the expression evaluates to `true`.

If you want to generate code for your model, define the variables in the expression as `Simulink.Parameter` objects.

Dependency

Enable this parameter by adding a Subsystem block inside a Variant Subsystem block.

Programmatic Use**Block parameter:** VariantControl**Type:** character vector**Value:** 'Variant' | '<logical expression>'**Default:** 'Variant'**Treat as grouped when propagating variant conditions — Control treating subsystem as unit**

on (default) | off

Causes Simulink to treat the subsystem as a unit when propagating variant conditions from Variant Source blocks or to Variant Sink blocks.

on

Simulink treats the subsystem as a unit when propagating variant conditions from Variant Source blocks or to Variant Sink blocks. For example, when Simulink computes the variant condition of the subsystem, it propagates that condition to all the blocks in the subsystem.

off

Simulink treats all blocks in the subsystem as being at the same level in the model hierarchy as the subsystem itself when determining their variant condition.

Programmatic Use

Parameter: `TreatAsGroupedWhenPropagatingVariantConditions`

Type: character vector

Value: 'on' | 'off'

Default: 'on'

Code Generation

Function packaging — Select code format

`Auto` (default) | `Inline` | `Nonreusable function` | `Reusable function`

Select the code format to be generated for an atomic (nonvirtual) subsystem.

`Auto`

Simulink Coder chooses the optimal format for you based on the type and number of instances of the subsystem that exist in the model.

`Inline`

Simulink Coder inlines the subsystem unconditionally.

`Nonreusable function`

Simulink Coder explicitly generates a separate function in a separate file. Subsystems with this setting generate functions that might have arguments depending on the “Function interface” on page 1-0 parameter setting. You can name the generated function and file using parameters “Function name” on page 1-0 and “File name (no extension)” on page 1-0. These functions are not reentrant.

`Reusable function`

Simulink Coder generates a function with arguments that allows reuse of subsystem code when a model includes multiple instances of the subsystem.

This option also generates a function with arguments that allows subsystem code to be reused in the generated code of a model reference hierarchy that includes multiple instances of a subsystem across referenced models. In this case, the subsystem must be in a library.

Tips

- When you want multiple instances of a subsystem to be represented as one reusable function, you can designate each one of them as `Auto` or as `Reusable function`. It is best to use one or the other, as using both creates two reusable functions, one for each designation. The outcomes of these choices differ only when reuse is not possible. Selecting `Auto` does not allow control of the function or file name for the subsystem code.
- The `Reusable function` and `Auto` options both try to determine if multiple instances of a subsystem exist and if the code can be reused. The difference between the options' behavior is that when reuse is not possible:
 - `Auto` yields inlined code, or if circumstances prohibit inlining, separate functions for each subsystem instance.
 - `Reusable function` yields a separate function with arguments for each subsystem instance in the model.
- If you select `Reusable function` while your generated code is under source control, set **File name options** to `Use subsystem name`, `Use function name`, or `User specified`. Otherwise, the names of your code files change whenever you modify your model, which prevents source control on your files.

Dependency

- This parameter requires a Simulink Coder license.
- To enable this parameter, select **Treat as atomic unit**.
- Setting this parameter to `Nonreusable function` or `Reusable function` enables the following parameters:
 - **Function name options**
 - **File name options**
 - Memory section for initialize/terminate functions (requires a license for Embedded Coder and an ERT-based system target file)
 - Memory section for execution functions (requires a license for Embedded Coder and an ERT-based system target file)

- Setting this parameter to `Nonreusable function` enables **Function with separate data** (requires a license for Embedded Coder and an ERT-based system target file).

Programmatic Use

Parameter: `RTWSystemCode`

Type: character vector

Value: `'Auto' | 'Inline' | 'Nonreusable function' | 'Reusable function'`

Default: `'Auto'`

Function name options — Select how to name generated function

`Auto (default) | Use subsystem name | User specified`

Select how Simulink Coder names the function it generates for the subsystem.

If you have an Embedded Coder license, you can control function names with options on the Configuration Parameter **Code Generation** > **Symbols** pane.

`Auto`

Assign a unique function name using the default naming convention, `model_subsystem()`, where `model` is the name of the model and `subsystem` is the name of the subsystem (or that of an identical one when code is being reused).

If you select `Reusable function` for the **Function packaging** parameter and there are multiple instances of the reusable subsystem in a model reference hierarchy, in order to generate reusable code for the subsystem, **Function name options** must be set to `Auto`.

Use subsystem name

Use the subsystem name as the function name. By default, the function name uses the naming convention *model_subsystem*.

Note When a subsystem is in a library block and the subsystem parameter “Function packaging” on page 1-0 is set to `Reusable function`, if you set the `Use subsystem name` option, the code generator uses the name of the library block for the subsystem's function name and file name.

User specified

Enable the **Function name** field. Enter any legal C or C++ function name, which must be unique.

Dependency

- This parameter requires a Simulink Coder license.
- Setting Code generation function packaging to `Nonreusable function` or `Reusable function` enables this parameter.
- Setting this parameter to `User specified` enables the Code generation function name parameter.

Programmatic Use

Parameter: `RTWFcnNameOpts`

Type: character vector

Value: `'Auto'` | `'Use subsystem name'` | `'User specified'`

Default: `'Auto'`

See also

For more information, see “Code Generation of Subsystems” (Simulink Coder).

Function name — Specify function name

`'` (default) | function name

Specify a unique, valid C or C++ function name for subsystem code.

Use this parameter if you want to give the function a specific name instead of allowing the Simulink Coder code generator to assign its own autogenerated name or use the

subsystem name. For more information, see “Code Generation of Subsystems” (Simulink Coder).

Dependency

- This parameter requires a Simulink Coder license.
- To enable this parameter, set the **Function name options** parameter to `User specified`.

Programmatic Use

Parameter: `RTWFcnName`

Type: character vector

Value: `''` | `'<function name>'`

Default: `''`

File name options — Specify how to name generated file

`Auto` (default) | `Use subsystem name` | `Use function name` | `User specified`

Select how Simulink Coder names the separate file for the function it generates for the subsystem.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

`Auto`

Depending on the configuration of the subsystem and how many instances are in the model, `Auto` yields different results:

- If the code generator does *not* generate a separate file for the subsystem, the subsystem code is generated within the code module generated from the subsystem's parent system. If the subsystem's parent is the model itself, the subsystem code is generated within `model.c` or `model.cpp`.
- If you select `Reusable function` for the **Function packaging** parameter and your generated code is under source control, consider specifying a **File name options** value other than `Auto`. This prevents the generated file name from changing due to unrelated model modifications, which is problematic for using source control to manage configurations.
- If you select `Reusable function` for the **Function packaging** parameter and there are multiple instances of the reusable subsystem in a model reference hierarchy, in order to generate reusable code for the subsystem, **File name options** must be set to `Auto`.

Use subsystem name

The code generator generates a separate file, using the subsystem (or library block) name as the file name.

Note When **File name options** is set to Use subsystem name, the subsystem file name is mangled if the model contains Model blocks, or if a model reference target is being generated for the model. In these situations, the file name for the subsystem consists of the subsystem name prefixed by the model name.

Use function name

The code generator uses the function name specified by **Function name options**) as the file name.

User specified

This option enables the **File name (no extension)** text entry field. The code generator uses the name you enter as the file name. Enter any file name, but do not include the .c or .cpp (or any other) extension. This file name need not be unique.

Note While a subsystem source file name need not be unique, you must avoid giving nonunique names that result in cyclic dependencies (for example, `sys_a.h` includes `sys_b.h`, `sys_b.h` includes `sys_c.h`, and `sys_c.h` includes `sys_a.h`).

Dependency

- This parameter requires a Simulink Coder license.
- To enable this parameter, set **Function packaging** to Nonreusable function or Reusable function.
- Setting this parameter to User specified enables the **File name (no extension)** parameter.

Programmatic Use

Parameter: RTWFileNameOpts

Type: character vector

Value: 'Auto' | 'Use subsystem name' | 'Use function name' | 'User specified'

Default: 'Auto'

File name (no extension) — Specify file name

'' (default) | file name

The filename that you specify does not have to be unique. However, avoid giving non-unique names that result in cyclic dependencies (for example, `sys_a.h` includes `sys_b.h`, `sys_b.h` includes `sys_c.h`, and `sys_c.h` includes `sys_a.h`).

For more information, see “Code Generation of Subsystems” (Simulink Coder).

Dependency

- This parameter requires a Simulink Coder license.
- To enable this parameter, set **File name options** to `User specified`.

Programmatic Use**Parameter:** RTWFileName**Type:** character vector**Value:** '' | '<file name>'**Default:** ''**Function with separate data — Control code generation for subsystem**

off (default) | on

Generate subsystem function code in which the internal data for an atomic subsystem is separated from its parent model and is owned by the subsystem.

 off

Do not generate subsystem function code in which the internal data for an atomic subsystem is separated from its parent model and is owned by the subsystem.

 on

Generate subsystem function code in which the internal data for an atomic subsystem is separated from its parent model and is owned by the subsystem. The subsystem data structure is declared independently from the parent model data structures. A subsystem with separate data has its own block I/O and `DWork` data structure. As a result, the generated code for the subsystem is easier to trace and test. The data separation also tends to reduce the maximum size of global data structures throughout the model, because they are split into multiple data structures.

Dependency

- This parameter requires a license for Embedded Coder and an ERT-based system target file.
- To enable this parameter, set **Function packaging** to `Nonreusable function`.
- Selecting this parameter enables these parameters:
 - **Memory section for constants**
 - **Memory section for internal data**
 - **Memory section for parameters**

Programmatic Use

Parameter: `FunctionWithSeparateData`

Type: character vector

Value: `'off' | 'on'`

Default: `'off'`

See also

- See the Subsystem block reference page for more information.
- For details on how to generate modular function code for an atomic subsystem, see “Generate Modular Function Code” (Embedded Coder) in the Embedded Coder documentation.
- For details on how to apply memory sections to atomic subsystems, see “Override Default Placement by Using Atomic Subsystems” (Embedded Coder) in the Embedded Coder documentation.

Function interface — Select to use arguments with generate function

`void_void` (default) | `Allow arguments`

Select to use arguments with generated function.

`void_void`

Generate a function without arguments and pass data as global variables. For example:

```
void subsystem_function(void)
```

`Allow arguments`

Generate a function that uses arguments instead of passing data as global variables. This specification reduces global RAM. It might reduce code size and improve

execution speed, and allow the code generator to apply additional optimizations. For example:

```
void subsystem_function(real_T rtu_In1, real_T rtu_In2,  
                       real_T *rty_Out1)
```

Dependency

- This parameter requires an Embedded Coder license and an ERT-based system target file.
- To enable this parameter, set **Function packaging** to `Nonreusable function`.

Programmatic Use

Parameter: `FunctionInterfaceSpec`

Type: character vector

Value: `'void_void'` | `'Allow arguments'`

Default: `'void_void'`

See also

- “Reduce Global Variables in Nonreusable Subsystem Functions” (Embedded Coder)
- “Generate Modular Function Code” (Embedded Coder) in the Embedded Coder documentation

Memory section for initialize/terminate functions — Select how to apply memory sections

`Inherit from model (default)` | `Default` | `The memory section of interest`

Select how Embedded Coder applies memory sections to the subsystem initialization and termination functions.

`Inherit from model`

Apply the root model's memory sections to the subsystem's function code

`Default`

Do not apply memory sections to the subsystem's system code, overriding any model-level specification

`The memory section of interest`

Apply one of the model's memory sections to the subsystem

Tips

- The possible values vary depending on what (if any) package of memory sections you have set for the model's configuration. See “Control Data and Function Placement in Memory by Inserting Pragmas” (Embedded Coder) and “Model Configuration Parameters: Code Generation Memory Sections” (Embedded Coder) in the Embedded Coder documentation.
- If you have not configured the model with a package, `Inherit from model` is the only value that appears. Otherwise, the list includes `Default` and all memory sections the model's package contains.
- These options can be useful for overriding the model's memory section settings for the given subsystem.

Dependency

- This parameter requires a license for Embedded Coder software and an ERT-based system target file.
- To enable this parameter, set **Function packaging** to `Nonreusable function` or `Reusable function`.

Programmatic Use

Parameter: `RTWMemSecFuncInitTerm`

Type: character vector

Value: `'Inherit from model' | 'Default' | 'The memory section of interest'`

Default: `'Inherit from model'`

See also

- See the Subsystem block reference page for more information.
- For details on how to apply memory sections to atomic subsystems, see “Override Default Placement by Using Atomic Subsystems” (Embedded Coder) in the Embedded Coder documentation.

Memory section for execution functions — Select how to apply memory sections

`Inherit from model (default) | Default | The memory section of interest`

Select how Embedded Coder applies memory sections to the subsystem's execution functions.

Inherit from model

Apply the root model's memory sections to the subsystem's function code

Default

Do not apply memory sections to the subsystem system code, overriding any model-level specification

The memory section of interest

Apply one of the model's memory sections to the subsystem

Tips

- The possible values vary depending on what (if any) package of memory sections you have set for the model's configuration. See “Control Data and Function Placement in Memory by Inserting Pragmas” (Embedded Coder) and “Model Configuration Parameters: Code Generation Memory Sections” (Embedded Coder) in the Embedded Coder documentation.
- If you have not configured the model with a package, `Inherit from model` is the only value that appears. Otherwise, the list includes `Default` and all memory sections the model's package contains.
- These options can be useful for overriding the model's memory section settings for the given subsystem.

Dependency

- This parameter requires a license for Embedded Coder software and an ERT-based system target file.
- To enable this parameter, set **Function packaging** to `Nonreusable function` or `Reusable function`.

Programmatic Use

Parameter: `RTWMemSecFuncExecute`

Type: character vector

Value: `'Inherit from model' | 'Default' | 'The memory section of interest'`

Default: `'Inherit from model'`

See also

- See the Subsystem block reference page for more information.

- For details on how to apply memory sections to atomic subsystems, see “Override Default Placement by Using Atomic Subsystems” (Embedded Coder) in the Embedded Coder documentation.

Memory section for constants — Select how to apply memory sections

`Inherit from model` (default) | `Default` | `The memory section of interest`

Select how Embedded Coder applies memory sections to the subsystem constants.

`Inherit from model`

Apply the root model's memory sections to the subsystem's data

`Default`

Not apply memory sections to the subsystem's data, overriding any model-level specification

`The memory section of interest`

Apply one of the model's memory sections to the subsystem

Tips

- The memory section that you specify applies to the corresponding global data structures in the generated code. For basic information about the global data structures generated for atomic subsystems, see “Default Data Structures in the Generated Code” (Simulink Coder).
- Can be useful for overriding the model's memory section settings for the given subsystem.
- The possible values vary depending on what (if any) package of memory sections you have set for the model's configuration. See “Control Data and Function Placement in Memory by Inserting Pragmas” (Embedded Coder) in the Embedded Coder documentation.
- If you have not configured the model with a package, `Inherit from model` is the only value that appears. Otherwise, the list includes `Default` and all memory sections the model's package contains.

Dependency

- This parameter requires a license for Embedded Coder and an ERT-based system target file.
- To enable this parameter, set **Function packaging** to `Nonreusable function` and select the **Function with separate data** parameter

Programmatic Use

Parameter: RTWMemSecDataConstants

Type: character vector

Value: 'Inherit from model' | 'Default' | 'The memory section of interest'

Default: 'Inherit from model'

See also

- See the Subsystem block reference page for more information.
- For details on how to apply memory sections to atomic subsystems, see “Override Default Placement by Using Atomic Subsystems” (Embedded Coder) in the Embedded Coder documentation.

Memory section for internal data — Select how to apply memory sections

Inherit from model (default) | Default | The memory section of interest

Select how Embedded Coder applies memory sections to the subsystem internal data.

Inherit from model

Apply the root model's memory sections to the subsystem's data

Default

Not apply memory sections to the subsystem's data, overriding any model-level specification

The memory section of interest

Apply one of the model's memory sections to the subsystem

Tips

- The memory section that you specify applies to the corresponding global data structures in the generated code. For basic information about the global data structures generated for atomic subsystems, see “Default Data Structures in the Generated Code” (Simulink Coder).
- Can be useful for overriding the model's memory section settings for the given subsystem.
- The possible values vary depending on what (if any) package of memory sections you have set for the model's configuration. See “Control Data and Function Placement in Memory by Inserting Pragmas” (Embedded Coder) in the Embedded Coder documentation.

- If you have not configured the model with a package, `Inherit from model` is the only value that appears. Otherwise, the list includes `Default` and all memory sections the model's package contains.

Dependency

- This parameter requires a license for Embedded Coder and an ERT-based system target file.
- To enable this parameter, set **Function packaging** to `Nonreusable function` and select the **Function with separate data** parameter.

Programmatic Use**Parameter:** `RTWMemSecDataInternal`**Type:** character vector**Value:** `'Inherit from model' | 'Default' | 'The memory section of interest'`**Default:** `'Inherit from model'`**See also**

- See the Subsystem block reference page for more information.
- For details on how to apply memory sections to atomic subsystems, see “Override Default Placement by Using Atomic Subsystems” (Embedded Coder) in the Embedded Coder documentation.

Memory section for parameters — Select how to apply memory sections`Inherit from model (default) | Default | The memory section of interest`

Select how Embedded Coder applies memory sections to the subsystem parameters.

`Inherit from model`

Apply the root model's memory sections to the subsystem's function code

`Default`

Not apply memory sections to the subsystem's system code, overriding any model-level specification

`The memory section of interest`

Apply one of the model's memory sections to the subsystem

Tips

- The memory section that you specify applies to the corresponding global data structure in the generated code. For basic information about the global data structures generated for atomic subsystems, see “Default Data Structures in the Generated Code” (Simulink Coder).
- Can be useful for overriding the model's memory section settings for the given subsystem.
- The possible values vary depending on what (if any) package of memory sections you have set for the model's configuration. See “Control Data and Function Placement in Memory by Inserting Pragmas” (Embedded Coder) in the Embedded Coder documentation.
- If you have not configured the model with a package, `Inherit from model` is the only value that appears. Otherwise, the list includes `Default` and all memory sections the model's package contains.

Dependency

- This parameter requires a license for Embedded Coder and an ERT-based system target file.
- To enable this parameter, set **Function packaging** to `Nonreusable function` and select the **Function with separate data** parameter.

Programmatic Use

Parameter: `RTWMemSecDataParameters`

Type: character vector

Value: `'Inherit from model' | 'Default' | 'The memory section of interest'`

Default: `'Inherit from model'`

See also

- See the Subsystem block reference page for more information.
- For details on how to apply memory sections to atomic subsystems, see “Override Default Placement by Using Atomic Subsystems” (Embedded Coder) in the Embedded Coder documentation.

Introduced in R2007a

Sum, Add, Subtract, Sum of Elements

Add or subtract inputs

Library

Math Operations

Description

The Sum block performs addition or subtraction on its inputs. This block can add or subtract scalar, vector, or matrix inputs. It can also collapse the elements of a signal.

You specify the operations of the block with the **List of signs** parameter. Plus (+), minus (-), and spacer () characters indicate the operations to be performed on the inputs:

- If there are two or more inputs, then the number of + and - characters must equal the number of inputs. For example, “+-+” requires three inputs and configures the block to subtract the second (middle) input from the first (top) input, and then add the third (bottom) input.
- All nonscalar inputs must have the same dimensions. Scalar inputs will be expanded to have the same dimensions as the other inputs.
- A spacer character creates extra space between ports on the block's icon.
- For a round Sum block, the first input port is the port closest to the 12 o'clock position going in a counterclockwise direction around the block. Similarly, other input ports appear in counterclockwise order around the block.
- If only addition of all inputs is required, then a numeric parameter value equal to the number of inputs can be supplied instead of “+” characters.

- If only one input port is required, a single “+” or “-” collapses the element via the specified operation.

The Sum block first converts the input data type(s) to its accumulator data type, then performs the specified operations. The block converts the result to its output data type using the specified rounding and overflow modes.

Calculation of Block Output

Output calculation for the Sum block depends on the number of block inputs and the sign of input ports:

If the Sum block has...	And...	The formula for output calculation is...	Where...
One input port	The input port sign is +	$y = e[0] + e[1] + e[2] \dots + e[m]$	$e[i]$ is the i^{th} element of input u
	The input port sign is -	$y = 0.0 - e[0] - e[1] - e[2] \dots - e[m]$	
Two or more input ports	All input port signs are -	$y = 0.0 - u[0] - u[1] - u[2] \dots - u[n]$	$u[i]$ is the input to the i^{th} input port
	The k^{th} input port is the first port where the sign is +	$y = u[k] - u[0] - u[1] - u[2] - u[k-1] (+/-) u[k+1] \dots (+/-) u[n]$	

Data Type Support

The Sum block accepts real or complex signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean

The inputs can be of different data types, unless you select the **Require all inputs to have the same data type** parameter. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Show data type assistant

Display the **Data Type Assistant**.

The **Data Type Assistant** helps you set the **Output data type** parameter.

For more information, see “Control Signal Data Types”.

Icon shape

Designate the icon shape of the block.

Default: round

rectangular

Designate the icon shape of the block as rectangular.

round

Designate the icon shape of the block as round.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

List of signs

Enter plus (+) and minus (-) characters.

Default: |++

- Addition is the default operation, so if you only want to add the inputs, enter the number of input ports.

- For a single vector input, “+” or “-” will collapse the vector using the specified operation.
- Enter as many plus (+) and minus (-) characters as there are inputs.

You can manipulate the positions of the input ports on the block by inserting spacers (|) between the signs in the **List of signs** parameter. For example, “++|--” creates an extra space between the second and third input ports.

Entering only one element enables the **Sum over** parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Sum over

Select dimension over which to perform the sum over operation.

Default: All dimensions

All dimensions

Sum all input elements, yielding a scalar.

Specified dimension

Display the **Dimension** parameter, where you specify the dimension over which to perform the operation.

Selecting Specified dimension enables the **Dimension** parameter.

List of signs (when it has only one element) enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Dimension

Specify the dimension over which to perform the operation.

Default: 1

The block follows the same summation rules as the MATLAB `sum` function.

Suppose that you have a 2-by-3 matrix U .

- Setting **Dimension** to 1 results in the output Y being computed as:

$$Y = \sum_{i=1}^2 U(i, j)$$

- Setting **Dimension** to 2 results in the output Y being computed as:

$$Y = \sum_{j=1}^3 U(i, j)$$

If the specified dimension is greater than the dimension of the input, an error message appears.

Setting **Sum over** to `Specified dimension` enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Require all inputs to have the same data type

Require that all inputs have the same data type.

Default: Off

On

Require that all inputs have the same data type.

Off

Do not require that all inputs have the same data type.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Lock data type settings against changes by the fixed-point tools

Select to lock data type settings of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

Default: Off

On

Locks all data type settings for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change data type settings for this block.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Integer rounding mode

Specify the rounding mode for fixed-point operations.

Default: Floor

Ceiling

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

Floor

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

Simplest

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

Parameter: `RndMeth`

Type: character vector

Value: `'Ceiling'` | `'Convergent'` | `'Floor'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Default: `'Floor'`

For more information, see “Rounding” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

Saturate on integer overflow

Specify whether overflows saturate.

Default: Off

On

Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

 Off

Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Parameter: SaturateOnIntegerOverflow

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Accumulator data type

Specify the accumulator data type.

Default: Inherit: Inherit via internal rule

Inherit: Inherit via internal rule

Use internal rule to determine accumulator data type.

Inherit: Same as first input

Use data type of first input signal.

double

Accumulator data type is double.

single

Accumulator data type is single.

int8

Accumulator data type is int8.

uint8

Accumulator data type is uint8.

int16

Accumulator data type is int16.

uint16

Accumulator data type is uint16.

int32

Accumulator data type is int32.

uint32

Accumulator data type is uint32.

fixdt(1,16,0)

Accumulator data type is fixed point fixdt(1,16,0).

fixdt(1,16,2^0,0)

Accumulator data type is fixed point fixdt(1,16,2^0,0).

<data type expression>

The name of a data type object, for example `Simulink.NumericType`

See “Block-Specific Parameters” on page 6-128 for the command-line information.

For more information, see “Specify Data Types Using Data Type Assistant”.

Mode

Select the category of accumulator data to specify

Default: `Inherit`

`Inherit`

Specifies inheritance rules for data types. Selecting `Inherit` enables a list of possible values:

- `Inherit` via internal rule (default)
- Same as first input

`Built in`

Specifies built-in data types. Selecting `Built in` enables a list of possible values:

- `double` (default)
- `single`
- `int8`
- `uint8`
- `int16`
- `uint16`
- `int32`
- `uint32`

`Fixed point`

Specifies fixed-point data types.

`Expression`

Specifies expressions that evaluate to data types. Selecting `Expression` enables you to enter an expression.

Clicking the **Show data type assistant** button for the accumulator data type enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specify Data Types Using Data Type Assistant”.

Data type override

Specify data type override mode for this signal.

Default: `Inherit`

`Inherit`

Inherits the data type override setting from its context, that is, from the block, `Simulink.Signal` object or Stateflow chart in Simulink that is using the signal.

`Off`

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

This parameter appears only when the **Mode** is `Built in` or `Fixed point`.

Signedness

Specify whether you want the fixed-point data to be signed or unsigned.

Default: `Signed`

`Signed`

Specify the fixed-point data to be signed.

`Unsigned`

Specify the fixed-point data to be unsigned.

Selecting **Mode** > `Fixed point` for the accumulator data type enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specifying a Fixed-Point Data Type” for more information.

Word length

Specify the bit size of the word that will hold the quantized integer.

Default: 16

Minimum: 0

Maximum: 32

Large word sizes represent large values with greater precision than small word sizes.

Selecting **Mode** > `Fixed point` for the accumulator data type enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specifying a Fixed-Point Data Type” for more information.

Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

Default: `Binary point`

`Binary point`

Specify binary point location.

`Slope and bias`

Enter slope and bias.

Selecting **Mode** > `Fixed point` for the accumulator data type enables this parameter.

Selecting `Binary point` enables:

- **Fraction length**

Selecting `Slope` and `bias` enables:

- **Slope**
- **Bias**

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specifying a Fixed-Point Data Type” for more information.

Fraction length

Specify fraction length for fixed-point data type.

Default: 0

Binary points can be positive or negative integers.

Selecting **Scaling** > `Binary point` for the accumulator data type enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specifying a Fixed-Point Data Type” for more information.

Slope

Specify slope for the fixed-point data type.

Default: 2^0

Specify any positive real number.

Selecting **Scaling** > `Slope` and `bias` for the accumulator data type enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specifying a Fixed-Point Data Type” for more information.

Bias

Specify bias for the fixed-point data type.

Default: 0

Specify any real number.

Selecting **Scaling** > `Slope` and `bias` for the accumulator data type enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specifying a Fixed-Point Data Type” for more information.

Output minimum

Lower value of the output range that Simulink checks.

Default: [] (unspecified)

Specify this number as a finite, real, double, scalar value.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Parameter: OutMin
Type: character vector
Value: ' [] '
Default: ' [] '

Output maximum

Upper value of the output range that Simulink checks.

Default: [] (unspecified)

Specify this number as a finite, real, double, scalar value.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Parameter: OutMax

Type: character vector

Value: ' [] '

Default: ' [] '

Output data type

Specify the output data type.

Default: Inherit: Inherit via internal rule

Inherit: Inherit via internal rule

Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Use the simple choice of `Inherit: Same as first input`.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
- To specify your own inheritance rule, use `Inherit: Inherit via back propagation` and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.

Note The accumulator internal rule favors greater numerical accuracy, possibly at the cost of less efficient generated code. To get the same accuracy for the output, set the output data type to `Inherit: Inherit same as accumulator`.

Inherit: Inherit via back propagation

Use data type of the driving block.

Inherit: Same as first input

Use data type of first input signal.

Inherit: Same as accumulator

Output data type is the same as accumulator data type.

double

Output data type is double.

single

Output data type is single.

int8

Output data type is int8.

uint8

Output data type is uint8.

int16

Output data type is int16.

uint16

Output data type is uint16.

int32

Output data type is int32.

uint32

Output data type is uint32.

fixdt(1,16,0)

Output data type is fixed point fixdt(1,16,0).

fixdt(1,16,2^0,0)

Output data type is fixed point fixdt(1,16,2^0,0).

<data type expression>

Use a data type object, for example, Simulink.NumericType.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

For more information, see “Control Signal Data Types”.

Mode

Select the category of data to specify.

Default: `Inherit`

`Inherit`

Inheritance rules for data types. Selecting `Inherit` enables a second menu/text box to the right. Select one of the following choices:

- `Inherit via internal rule (default)`
- `Inherit via back propagation`
- `Same as first input`
- `Same as accumulator`

`Built in`

Built-in data types. Selecting `Built in` enables a second menu/text box to the right. Select one of the following choices:

- `double (default)`
- `single`
- `int8`
- `uint8`
- `int16`
- `uint16`
- `int32`
- `uint32`

`Fixed point`

Fixed-point data types.

`Expression`

Expressions that evaluate to data types. Selecting `Expression` enables a second menu/text box to the right, where you can enter the expression.

Clicking the **Show data type assistant** button enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specify Data Types Using Data Type Assistant”.

Signedness

Specify whether you want the fixed-point data as signed or unsigned.

Default: Signed

Signed

Specify the fixed-point data as signed.

Unsigned

Specify the fixed-point data as unsigned.

Selecting **Mode** > Fixed point enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Word length

Specify the bit size of the word that holds the quantized integer.

Default: 16

Minimum: 0

Maximum: 32

Selecting **Mode** > Fixed point enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

Default: Binary point

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting Slope and bias enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specifying a Fixed-Point Data Type”.

Fraction length

Specify fraction length for fixed-point data type.

Default: 0

Binary points can be positive or negative integers.

Selecting **Scaling** > `Binary point` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Slope

Specify slope for the fixed-point data type.

Default: 2^0

Specify any positive real number.

Selecting **Scaling** > `Slope and bias` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Bias

Specify bias for the fixed-point data type.

Default: 0

Specify any real number.

Selecting **Scaling** > `Slope and bias` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Examples

How the Sum Block Reorders Inputs

If you use $-$ on the first input port, the Sum block reorders the inputs so that, if possible, the first input uses a $+$ operation. For example, in the expression $\text{output} = -a-b+c$, the Sum block reorders the inputs so that $\text{output} = c-a-b$. To initialize the accumulator, the Sum block uses the first $+$ input port.

The block avoids performing a unary minus operation on the first operand a because doing so can change the value of a for fixed-point data types. In that case, the output value differs from the result of accumulating the values for a , b , and c .

Tip To explicitly specify a unary minus operation for $\text{output} = -a-b+c$, you can use the Unary Minus block in the Math Operations library.

Suppose that you have the following model:

The following block parameters apply:

- Both Constant blocks, Input1 and Input 2, use `int8` for the **Output data type**.
- The Sum block uses `int8` for both **Accumulator data type** and **Output data type**.
- The Sum block has **Saturate on integer overflow** turned on.

The Sum block reorders the inputs so that the following operations occur and you get the ideal result of 127.

Step	Block Operation
1	Reorders inputs from $(-Input1 + Input2)$ to $(Input2 - Input1)$.
2	Initializes the accumulator by using the first + input port: $Accumulator = int8(-1) = -1$
3	Continues to accumulate values: $Accumulator = Accumulator - int8(-128) = 127$
4	Calculates the block output: $Output = int8(127) = 127$

If the Sum block does *not* reorder the inputs, the following operations occur instead and you get the nonideal result of 126.

Step	Block Operation
1	Initializes the accumulator by using the first input port: $Accumulator = int8(-(-128)) = 127$ Because saturation is on, the initial value of the accumulator saturates at 127 and does not wrap.
2	Continues to accumulate values: $Accumulator = Accumulator + int8(-1) = 126$
3	Calculates the block output: $Output = int8(126) = 126$

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes

Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Switch

Switch output between first input and third input based on value of second input

Library

Signal Routing

Description

Types of Block Inputs

The Switch block passes through the first input or the third input based on the value of the second input. The first and third inputs are called *data inputs*. The second input is called the *control input*. Specify the condition under which the block passes the first input by using the **Criteria for passing first input** and **Threshold** parameters.

To immediately back propagate a known output data type to the first and third input ports, set the **Output data type** parameter to `Inherit: Inherit via internal rule` and select the **Require all data port inputs to have the same data type** check box.

Limitations on Data Inputs

The sizes of the two data inputs can be different if you select **Allow different data input sizes** on the block dialog box. However, this block does not support variable-size input signals. Therefore, the size of each input cannot change during simulation.

If the data inputs to the Switch block are buses, the element names of both buses must be the same. Using the same element names ensures that the output bus has the same element names no matter which input bus the block selects. To ensure that your model meets this requirement, use a bus object to define the buses and set the **Element name**

mismatch diagnostic to **error**. See “Connectivity Diagnostics Overview” for more information.

Block Icon Appearance

The block icon helps you identify **Criteria for passing first input** and **Threshold** without having to open the block dialog box.

For information about port order for various block orientations, see “Port Location After Rotating or Flipping” in the Simulink documentation.

Block Behavior for Boolean Control Input

When the control input is a Boolean signal, use one of these combinations of criteria and threshold value:

- $u2 \geq \text{Threshold}$, where the threshold value equals 1
- $u2 > \text{Threshold}$, where the threshold value equals 0
- $u2 \sim 0$

Otherwise, the Switch block ignores the threshold and uses the Boolean input for signal routing. For a control input of 1, the block passes the first input, and for a control input of 0, the block passes the third input. In this case, the block icon changes *after compile time* and uses **T** and **F** to label the first and third inputs, respectively.

Data Type Support

The control input can be of any data type that Simulink supports, including fixed-point and enumerated types. The control input cannot be complex. If the control input is enumerated, the **Threshold** parameter must be a value of the same enumerated type.

The data inputs can be of any data type that Simulink supports. If either data input is of an enumerated type, the other must be of the same enumerated type.

When the output is of enumerated type, both data inputs should use the same enumerated type as the output.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

- “Criteria for passing first input” on page 1-1588
- “Threshold” on page 1-1589
- “Enable zero-crossing detection” on page 1-1590
- “Sample time” on page 1-1590
- “Require all data port inputs to have the same data type” on page 1-1591
- “Lock output data type setting against changes by the fixed-point tools” on page 1-1591
- “Integer rounding mode” on page 1-1592
- “Saturate on integer overflow” on page 1-1593
- “Allow different data input sizes” on page 1-1594
- “Output minimum” on page 1-1594
- “Output maximum” on page 1-1595
- “Output data type” on page 1-1595
- “Mode” on page 1-1597
- “Data type override” on page 1-1598
- “Signedness” on page 1-1599
- “Word length” on page 1-1599
- “Scaling” on page 1-1600
- “Fraction length” on page 1-1601
- “Slope” on page 1-1601
- “Bias” on page 1-1601

Criteria for passing first input

Select the condition under which the block passes the first input. If the control input meets the condition set in the **Criteria for passing first input** parameter, the block passes the first input. Otherwise, the block passes the third input.

Default: `u2 > Threshold`

`u2 >= Threshold`

Checks whether the control input is greater than or equal to the threshold value.

`u2 > Threshold`

Checks whether the control input is greater than the threshold value.

`u2 ~=0`

Checks whether the control input is nonzero.

Note The Switch block does not support `u2 ~=0` mode for enumerated data types.

When the control input is a Boolean signal, use one of these combinations of condition and threshold value:

- `u2 >= Threshold`, where the threshold value equals 1
- `u2 > Threshold`, where the threshold value equals 0
- `u2 ~=0`

Otherwise, the Switch block ignores threshold values and uses the Boolean value for signal routing. For a value of 1, the block passes the first input, and for a value of 0, the block passes the third input. A warning message that describes this behavior also appears in the MATLAB Command Window.

Selecting `u2 ~=0` disables the **Threshold** parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Threshold

Assign the switch threshold that determines which input the block passes to the output.

Default: 0

Minimum: value from the **Output minimum** parameter

Maximum: value from the **Output maximum** parameter

To specify a nonscalar threshold, use brackets. For example, the following entries are valid:

- [1 4 8 12]
- [MyColors.Red, MyColors.Blue]

Setting **Criteria for passing first input** to `u2 ~=0` disables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Enable zero-crossing detection

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Default: On

On

Enable zero-crossing detection.

Off

Do not enable zero-crossing detection.

Parameter: ZeroCross

Type: character vector

Value: 'on' | 'off'

Default: 'on'

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Require all data port inputs to have the same data type

Require all data inputs to have the same data type.

Default: Off

On

Requires all data inputs to have the same data type.

Off

Does not require all data inputs to have the same data type.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

Default: Off

On

Locks the output data type setting for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change the output data type setting for this block.

Parameter: LockScale

Type: character vector

Value: 'off' | 'on'

Default: 'off'

For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Integer rounding mode

Specify the rounding mode for fixed-point operations.

Default: `Floor`

`Ceiling`

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

`Convergent`

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

`Floor`

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

`Nearest`

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

`Round`

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

`Simplest`

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

`Zero`

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

Parameter: `RndMeth`

Type: character vector

Value: `'Ceiling'` | `'Convergent'` | `'Floor'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Default: `'Floor'`

For more information, see “Rounding” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

Saturate on integer overflow

Specify whether overflows saturate.

Default: Off

On

Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Off

Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Parameter: SaturateOnIntegerOverflow

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Allow different data input sizes

Select this check box to allow input signals with different sizes.

Default: Off

On

Allows input signals with different sizes, and propagates the input signal size to the output signal. If the two data inputs are variable-size signals, the maximum size of the signals can be equal or different.

Off

Inputs signals must be the same size.

Parameter: AllowDiffInputSizes

Type: character vector

Value: 'on' | 'off'

Default: 'off'

Output minimum

Specify the minimum value that the block should output.

Default: []

The default value is [] (unspecified).

Simulink uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL

or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

This number must be a finite real double scalar value.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Output maximum

Specify the maximum value that the block should output.

Default: []

The default value is [] (unspecified).

Simulink uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

This number must be a finite real double scalar value.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Output data type

Specify the output data type.

Default: `Inherit: Inherit via internal rule`

Inherit: Inherit via internal rule

Uses the following rules to determine the output data type.

Data Type of First Input Port	Output Data Type
Has a larger positive range than the third input port	Inherited from the first input port
Has the same positive range as the third input port	Inherited from the third input port
Has a smaller positive range than the third input port	

Inherit: Inherit via back propagation

Uses data type of the driving block.

double

Specifies output data type is double.

single

Specifies output data type is single.

int8

Specifies output data type is int8.

uint8

Specifies output data type is uint8.

int16

Specifies output data type is int16.

uint16

Specifies output data type is uint16.

int32

Specifies output data type is int32.

uint32

Specifies output data type is uint32.

fixdt(1,16,0)

Specifies output data type is fixed point `fixdt(1,16,0)`.

fixdt(1,16,2^0,0)

Specifies output data type is fixed point `fixdt(1,16,2^0,0)`.

Enum: <class name>

Uses an enumerated data type, for example, Enum: BasicColors.

<data type expression>

Uses a data type object, for example, Simulink.NumericType.

When the output is of enumerated type, both data inputs should use the same enumerated type as the output.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Control Signal Data Types” for more information.

Mode

Select the category of data to specify.

Default: Inherit

Inherit

Specifies inheritance rules for data types. Selecting `Inherit` enables a list of possible values:

- `Inherit` via internal rule (default)
- `Inherit` via back propagation

Built in

Specifies built-in data types. Selecting `Built in` enables a list of possible values:

- `double` (default)
- `single`
- `int8`
- `uint8`
- `int16`
- `uint16`

- `int32`
- `uint32`

Fixed point

Specifies fixed-point data types.

Enumerated

Specifies enumerated data types. Selecting `Enumerated` enables you to enter a class name.

Expression

Specifies expressions that evaluate to data types. Selecting `Expression` enables you to enter an expression.

Clicking the **Show data type assistant** button enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specify Data Types Using Data Type Assistant”.

Data type override

Specify data type override mode for this signal.

Default: `Inherit`

`Inherit`

Inherits the data type override setting from its context, that is, from the block, `Simulink.Signal` object or Stateflow chart in Simulink that is using the signal.

`Off`

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For

example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

This parameter appears only when the **Mode** is `Built in` or `Fixed point`.

Signedness

Specify whether you want the fixed-point data as signed or unsigned.

Default: `Signed`

`Signed`

Specifies the fixed-point data as signed.

`Unsigned`

Specifies the fixed-point data as unsigned.

Selecting **Mode** > `Fixed point` enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specifying a Fixed-Point Data Type”.

Word length

Specify the bit size of the word that holds the quantized integer.

Default: `16`

Minimum: `0`

Maximum: `32`

Large word sizes represent large values with greater precision than small word sizes.

Selecting **Mode** > `Fixed point` enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specifying a Fixed-Point Data Type” for more information.

Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

Default: Best precision

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

Best precision

Specify best-precision values.

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Selecting Slope and bias enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

For more information, see “Specifying a Fixed-Point Data Type”.

Fraction length

Specify fraction length for fixed-point data type.

Default: 0

Binary points can be positive or negative integers.

Selecting **Scaling** > `Binary point` enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specifying a Fixed-Point Data Type” for more information.

Slope

Specify slope for the fixed-point data type.

Default: 2^0

Specify any positive real number.

Selecting **Scaling** > `Slope and bias` enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specifying a Fixed-Point Data Type” for more information.

Bias

Specify bias for the fixed-point data type.

Default: 0

Specify any real number.

Selecting **Scaling** > Slope and bias enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specifying a Fixed-Point Data Type” for more information.

Bus Support

The Switch block is a bus-capable block. The data inputs can be virtual or nonvirtual bus signals subject to the following restrictions:

- All the buses must be equivalent (same hierarchy with identical names and attributes for all elements).
- All signals in a nonvirtual bus input to a Switch block must have the same sample time. The requirement holds even if the elements of the associated bus object specify inherited sample times.

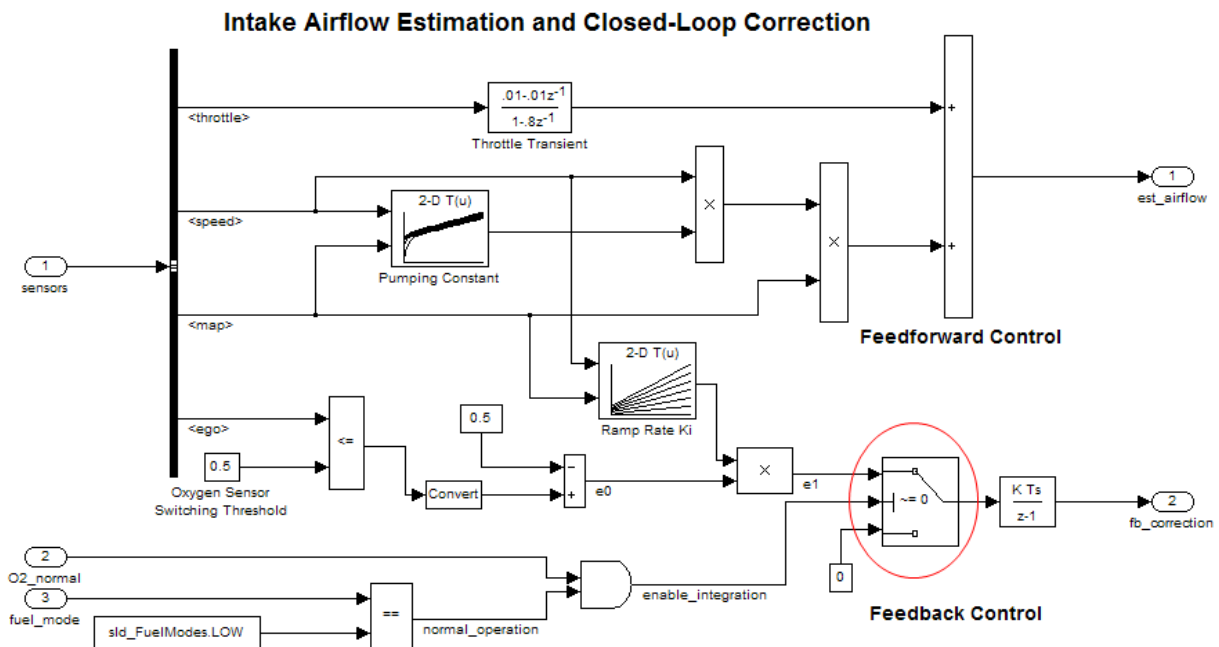

You can use a Rate Transition block to change the sample time of an individual signal, or of all signals in a bus. See “Specify Bus Signal Sample Times” and Bus-Capable Blocks for more information.

You can use an array of buses as an input signal to a Switch block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”. When using an array of buses with a Switch block, set the **Threshold** parameter to a scalar value.

Examples

Use of Boolean Input for the Control Port

In the `sldemo_fuelsys` model, the `fuel_rate_control/airflow_calc` subsystem uses a Switch block:

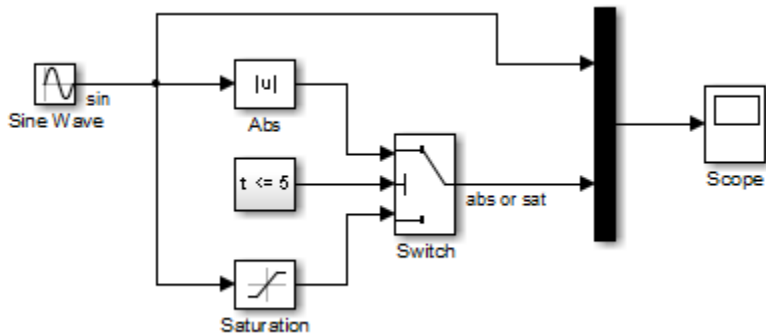

The value of the control port on the Switch block determines whether or not feedback correction occurs. The control port value depends on the output of the Logical Operator block.

When the Logical Operator block output is...	The control port of the Switch block is...	And feedback control...
TRUE	1	Occurs
FALSE	0	Does not occur

Use of Simulation Time for the Control Port

The `sldemo_zerowing` model uses a Switch block:

The value of the control port on the Switch block determines when the output changes from the first input to the third input.

When simulation time is...	The Switch block output is...
Less than or equal to 5	The first input from the Abs block
Greater than 5	The third input from the Saturation block

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated Bus
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	Yes, if enabled
Code Generation	Yes

Multiport Switch

Introduced before R2006a

Switch Case

Implement C-like `switch` control flow statement

Library

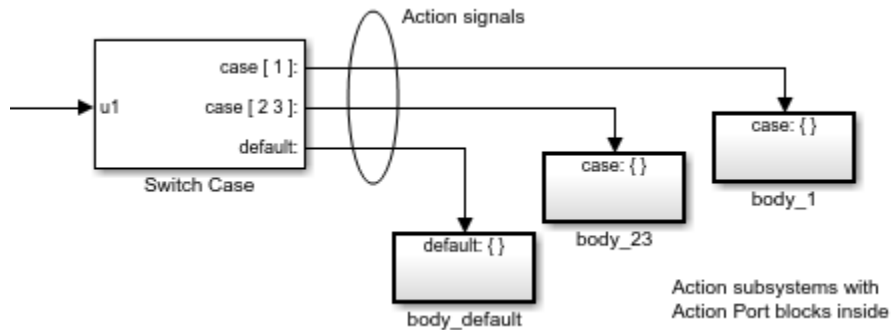

Ports & Subsystems

Description

A Switch Case block receives a single input. Each output port is attached to a Switch Case Action Subsystem. Data outputs are action signals to Switch Case Action subsystems, which you create with Action Port blocks and subsystems.

The Switch Case block uses its input value to select a case condition that determines which subsystem to execute. The cases are evaluated top down starting with the first case. If a case value (in brackets) corresponds to the value of the input, its Switch Case Action Subsystem is executed.

If a `default` case exists, it executes if none of the other cases executes. Providing a `default` case is optional, even if the other case conditions do not exhaust every possible value. The following diagram shows a completed Simulink `switch` control flow statement:

Cases for the Switch Case block contain an implied break after their Switch Case Action subsystems are executed. Thus there is no fall-through behavior for the Simulink switch control flow statement as found in standard C switch statements. The following pseudocode represents generated code for the preceding switch control example:

```
switch (u1) {
    case [u1=1]:
        body_1;
        break;
    case [u1=2 or u1=3]:
        body_23;
        break;
    default:
        body_default;
}
```

To construct the Simulink switch control flow statement shown in the above example:

- 1 Place a Switch Case block in the current system and attach the input port labeled u1 to the source of the data you are evaluating.
- 2 Open the Switch Case block dialog box and update parameters:
 - a Populate the **Case conditions** field with the individual cases.
 - b To show a default case, select the **Show default case** check box.
- 3 Create a Switch Case Action Subsystem for each case port you added to the Switch Case block.

These consist of subsystems with Action Port blocks inside them. When you place the Action Port block inside a subsystem, the subsystem becomes an atomic subsystem with an input port labeled `Action`.

- 4 Connect each case output port and the default output port of the Switch Case block to the Action port of an Action subsystem.

Each connected subsystem becomes a case body. This is indicated by the change in label for the Switch Case Action Subsystem block and the Action Port block inside of it to the name `case{}`.

During simulation of a `switch` control flow statement, the Action signals from the Switch Case block to each Switch Case Action Subsystem turn from solid to dashed.

- 5 In each Switch Case Action Subsystem, enter the Simulink logic appropriate to the case it handles.

Control Algorithm Execution Using Enumerated Signal

This example shows how to use a signal of an enumerated data type to control the execution of a block algorithm. For basic information about using enumerated data types in models, see “Use Enumerated Data in Simulink Models”.

When you use enumerated data in a Switch Case block, follow these best practices:

- Use the same enumerated type for the input `u1` and all of the case condition values.
- Use a different underlying integer for each of the enumerated values that you specify in the **Case conditions** box.

Copy the enumerated type definition `ex_SwitchCase_MyColors` into a script file in your current folder.

```
classdef ex_SwitchCase_MyColors < Simulink.IntEnumType
    enumeration
        Red(0)
        Yellow(1)
        Blue(2)
        Mauve(3)
    end
end
```

Alternatively, you can use the function `Simulink.defineIntEnumType` to define the type.

```
Simulink.defineIntEnumType('ex_SwitchCase_MyColors',...
    {'Red','Yellow','Blue','Mauve'},[0;1;2;3])
```

- 1 Open the example model `ex_enum_switch_case`.
 - 2 Open the Enumerated Constant block dialog box. The constant output value is `ex_SwitchCase_MyColors.Blue`.
 - 3 Open the Switch Case block dialog box. The **Case conditions** box is set to a cell array containing three of the four possible enumeration members. The block has four outputs corresponding to the three specified enumeration members and a default case.
 - 4 Open the Switch Case Action Subsystem blocks. The subsystems each contain a Constant block that uses a unique constant value.
-
- 1 In the Simulink Editor, set the simulation stop time to `Inf`.
 - 2 Simulate the model. The Display block shows the value 5, which corresponds to the case `ex_SwitchCase_MyColors.Blue`.
 - 3 In the Enumerated Constant block dialog box, set **Value** to `ex_SwitchCase_MyColors.Red` and click **Apply**. The Display block shows 19.
 - 4 Set **Value** to `ex_SwitchCase_MyColors.Mauve` and click **Apply**. The Display block shows 3, which corresponds to the default case.

Data Type Support

The input to the port labeled `u1` of a Switch Case block can be:

- A scalar value having a built-in data type that Simulink supports. The block does not support Boolean or fixed-point data types and truncates the numeric inputs to 32-bit signed integers.
- A scalar value of any enumerated data type, as described in “Control Algorithm Execution Using Enumerated Signal” on page 1-1608.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Case conditions

Specify the case conditions using MATLAB cell notation. For example, entering `{1, [7, 9, 4]}` specifies that output port `case[1]` is run when the input value is 1, and output port `case[7 9 4]` is run when the input value is 7, 9, or 4.

You can use colon notation to specify a range of integer case conditions. For example, entering `{[1:5]}` specifies that output port `case[1 2 3 4 5]` is run when the input value is 1, 2, 3, 4, or 5.

Depending on block size, cases with long lists of conditions are displayed in shortened form in the Switch Case block, using a terminating ellipsis (...).

You can use the `enumeration` function to specify a case condition that includes a case for every value in an enumerated type.

Show default case

If you select this check box, the default output port appears as the last case on the Switch Case block, allowing you to specify a default case. This case executes when the input value does not match any of the case values specified in the **Case conditions** field. With **Show default case** selected, a default output port always appears, even if the preceding cases exhaust all possibilities for the input value.

Enable zero-crossing detection

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Characteristics

Data Types	Double Single Base Integer Enumerated
Sample Time	Inherited from driving block

Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	Yes, if enabled
Code Generation	Yes

Introduced before R2006a

Switch Case Action Subsystem

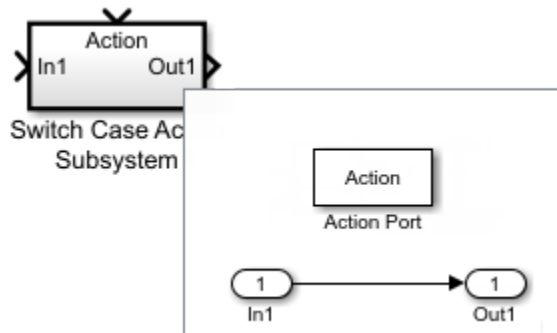

Subsystem whose execution is triggered by Switch Case block

Library: Ports & Subsystems

Description

The Switch Case Action Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem whose execution is triggered by an Switch Case block.

All blocks in a Switch Case Action Subsystem block must run at the same rate as the driving Switch Case block. You can achieve this requirement by setting each block's sample time parameter to be either inherited (-1) or the same value as the Switch Case block sample time.

Ports

Input

In — Signal input to a subsystem block

scalar | vector | matrix

Placing an Inport block in a subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Action — Control signal input to a subsystem block

`scalar` | `vector` | `matrix`

Placing an Action Port block in a subsystem block adds an external input port to the block and changes the block to a Switch Case Action Subsystem block.

Dot-dash lines from a Switch Case block to an Switch Case Action Subsystem block represent *action* signals.

Data Types: `action`

Output

out — Signal output from a subsystem

`scalar` | `vector` | `matrix`

Placing an Outport block in a subsystem block adds an output port from the block. The port label on the subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Topics

“Use Control Flow Logic”

“Action Subsystem”

Introduced before R2006a

Synchronous Subsystem

Represent subsystem that has synchronous reset and enable behavior

Library

HDL Coder / HDL Subsystems

Description

A Synchronous Subsystem is a subsystem that uses the `Synchronous` mode of the State Control block. If an **S** symbol appears in the subsystem, then it is synchronous.

To create a Synchronous Subsystem, add the block to your Simulink model from the HDL Subsystems block library. You can also add a State Control block with **State control** set to `Synchronous` inside a subsystem. For more information about the State Control block, see State Control.

Data Type Support

See Inport for information on the data types accepted by a subsystem's input ports. See Outport for information on the data types output by a subsystem's output ports.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Show port labels

Cause Simulink software to display labels for the subsystem's ports on the subsystem's icon.

Default: `FromPortIcon`

`none`

Does not display port labels on the subsystem block.

`FromPortIcon`

If the corresponding port icon displays a signal name, display the signal name on the subsystem block. Otherwise, display the port block's name.

`FromPortBlockName`

Display the name of the corresponding port block on the subsystem block.

`SignalName`

If a name exists, display the name of the signal connected to the port on the subsystem block; otherwise, the name of the corresponding port block.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Read/Write permissions

Control user access to the contents of the subsystem.

Default: `ReadWrite`

`ReadWrite`

Enables opening and modification of subsystem contents.

`ReadOnly`

Enables opening but not modification of the subsystem. If the subsystem resides in a block library, you can create and open links to the subsystem and can make and

modify local copies of the subsystem but cannot change the permissions or modify the contents of the original library instance.

`NoReadOrWrite`

Disables opening or modification of subsystem. If the subsystem resides in a library, you can create links to the subsystem in a model but cannot open, modify, change permissions, or create local copies of the subsystem.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Name of error callback function

Enter name of a function to be called if an error occurs while Simulink software is executing the subsystem.

Default: ' '

Simulink software passes two arguments to the function: the handle of the subsystem and a character vector that specifies the error type. If no function is specified, Simulink software displays a generic error message if executing the subsystem causes an error.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Permit hierarchical resolution

Specify whether to resolve names of workspace variables referenced by this subsystem.

Default: All

All

Resolve all names of workspace variables used by this subsystem, including those used to specify block parameter values and Simulink data objects (for example, `Simulink.Signal` objects).

`ExplicitOnly`

Resolve only names of workspace variables used to specify block parameter values, data store memory (where no block exists), signals, and states marked as “must resolve”.

None

Do not resolve any workspace variable names.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Treat as atomic unit

Causes Simulink software to treat the subsystem as a unit when determining the execution order of block methods.

Default: Off

On

Cause Simulink software to treat the subsystem as a unit when determining the execution order of block methods. For example, when it needs to compute the output of the subsystem, Simulink software invokes the output methods of all the blocks in the subsystem before invoking the output methods of other blocks at the same level as the subsystem block.

Off

Cause Simulink software to treat all blocks in the subsystem as being at the same level in the model hierarchy as the subsystem when determining block method execution order. This can cause execution of methods of blocks in the subsystem to be interleaved with execution of methods of blocks outside the subsystem.

This parameter enables:

- “Minimize algebraic loop occurrences” on page 1-0 .
- “Sample time” on page 1-0
- “Function packaging” on page 1-0 (requires a Simulink Coder license)

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Treat as grouped when propagating variant conditions

Causes Simulink software to treat the subsystem as a unit when propagating variant conditions from Variant Source blocks or to Variant Sink blocks.

Default: On

On

Simulink treats the subsystem as a unit when propagating variant conditions from Variant Source blocks or to Variant Sink blocks. For example, when Simulink computes the variant condition of the subsystem, it propagates that condition to all the blocks in the subsystem.

Off

Simulink treats all blocks in the subsystem as being at the same level in the model hierarchy as the subsystem itself when determining their variant condition.

“Treat as grouped when propagating variant conditions” on page 1-0 enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Function packaging

Specify the code format to be generated for an atomic (nonvirtual) subsystem.

Default: Auto

Auto

Simulink Coder software chooses the optimal format for you based on the type and number of instances of the subsystem that exist in the model.

Inline

Simulink Coder software inlines the subsystem unconditionally.

Nonreusable function

Simulink Coder software explicitly generates a separate function in a separate file. Subsystems with this setting generate functions that might have arguments

depending on the “Function interface” on page 1-0 parameter setting. You can name the generated function and file using parameters “Function name” on page 1-0 and “File name (no extension)” on page 1-0 . These functions are not reentrant.

Reusable function

Simulink Coder software generates a function with arguments that allows reuse of subsystem code when a model includes multiple instances of the subsystem.

This option also generates a function with arguments that allows subsystem code to be reused in the generated code of a model reference hierarchy that includes multiple instances of a subsystem across referenced models. In this case, the subsystem must be in a library.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated Bus

Introduced in R2016a

Tapped Delay

Delay scalar signal multiple sample periods and output all delayed versions

Library

Discrete

Description

The Tapped Delay block delays an input by the specified number of sample periods and outputs all the delayed versions. Use this block to discretize a signal in time or resample a signal at a different rate.

The block accepts one scalar input and generates an output vector that contains each delay. Specify the order of the delays in the output vector with the **Order output vector starting with** parameter:

- **Oldest** orders the output vector starting with the oldest delay version and ending with the newest delay version.
- **Newest** orders the output vector starting with the newest delay version and ending with the oldest delay version.

Specify the output vector for the first sampling period with the **Initial condition** parameter. Careful selection of this parameter can minimize unwanted output behavior.

Specify the time between samples with the **Sample time** parameter. Specify the number of delays with the **Number of delays** parameter. A value of -1 instructs the block to inherit the number of delays by back propagation. Each delay is equivalent to the z^{-1} discrete-time operator, which the Unit Delay block represents.

Data Type Support

The Tapped Delay block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Initial condition

Specify the initial output of the simulation. The **Initial condition** parameter is converted from a double to the input data type offline using round-to-nearest and saturation. Simulink software does not allow you to set the initial condition of this block to `inf` or `NaN`.

Sample time

Specify the time interval between samples. To inherit the sample time, set this parameter to `-1`. See “Specify Sample Time” in the online Simulink documentation for more information.

Number of delays

Specify the number of discrete-time operators.

Order output vector starting with

Specify whether to output the oldest delay version first, or the newest delay version first.

Include current input in output vector

Select to include the current input in the output vector.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point
Sample Time	Specified in the Sample time parameter
Direct Feedthrough	Yes, when Include current input in output vector check box is selected. No, otherwise.
Multidimensional Signals	No
Variable-Size Signals	No
Code Generation	Yes

See Also

Delay | Resettable Delay | Unit Delay | Variable Integer Delay

Terminate Function

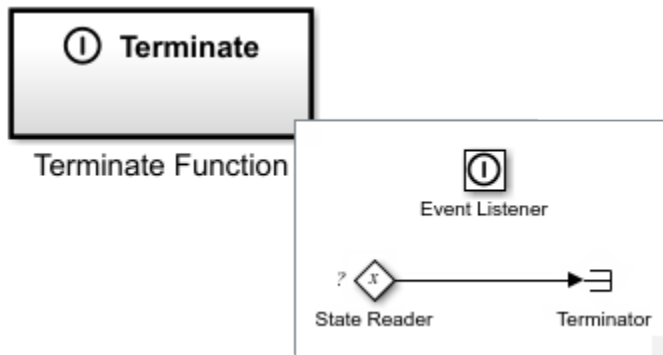

Execute contents on a model terminate event

Library: User-Defined Functions

Description

The Terminate Function block is a pre-configured subsystem block that executes on a model terminate event. By default, the Terminate Function block includes an Event Listener block with **Event** set to `Terminate`, a Terminator block, and a State Reader block.

Replace the Terminator block with blocks to save the state value from the State Reader block.

For a list of unsupported blocks and features, see “Initialize, Reset, and Terminate Function Limitations”.

The input and output ports of a component containing Initialize Function and Terminate Function blocks must connect to input and output port blocks.

The code generated from this block is part of the `model_terminate` function that is called once at the end of model execution.

Terminator

Terminate unconnected output port

Library

Sinks

Description

Use the Terminator block to cap blocks whose output ports do not connect to other blocks. If you run a simulation with blocks having unconnected output ports, Simulink issues warning messages. Using Terminator blocks to cap those blocks helps prevent warning messages.

Data Type Support

The Terminator block accepts real or complex signals of any data type that Simulink supports, including fixed-point and enumerated data types.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Examples

The following Simulink examples show how to use the Terminator block:

- `sldemo_bounce`
- `sldemo_fuelsys`
- `aero_six_dof`

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated Bus
Sample Time	Inherited from driving block
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Timed-Based Linearization

Generate linear models in base workspace at specific times

Library

Model-Wide Utilities

Description

This block calls `linmod` or `dlinmod` to create a linear model for the system when the simulation clock reaches the time specified by the **Linearization time** parameter. No trimming is performed. The linear model is stored in the base workspace as a structure, along with information about the operating point at which the snapshot was taken. Multiple snapshots are appended to form an array of structures.

The block sets the following model parameters to the indicated values:

- `BufferReuse` = 'off'
- `RTWInlineParameters` = 'on'
- `BlockReductionOpt` = 'off'

The name of the structure used to save the snapshots is the name of the model appended by `_Timed_Based_Linearization`, for example, `vdp_Timed_Based_Linearization`. The structure has the following fields:

Field	Description
a	The A matrix of the linearization
b	The B matrix of the linearization

Field	Description
c	The C matrix of the linearization
d	The D matrix of the linearization
StateName	Names of the model's states
OutputName	Names of the model's output ports
InputName	Names of the model's input ports
OperPoint	A structure that specifies the operating point of the linearization. The structure specifies the operating point time (OperPoint.t). The states (OperPoint.x) and inputs (OperPoint.u) fields are not used.
Ts	The sample time of the linearization for a discrete linearization

Use the Trigger-Based Linearization block if you need to generate linear models conditionally.

You can use state and simulation time logging to extract the model states and inputs at operating points. For example, suppose that you want to get the states of the f14 example model at linearization times of 2 seconds and 5 seconds.

- 1 Open the model and drag an instance of this block from the Model-Wide Utilities library and drop the instance into the model.
- 2 Open the block's parameter dialog box and set the **Linearization time** to 2 and 5.
- 3 Open the model's **Model Configuration Parameters** dialog box.
- 4 Select the **Data Import/Export** pane.
- 5 Check **States** and **Time** on the **Save to Workspace** control panel
- 6 Select OK to confirm the selections and close the dialog box.
- 7 Simulate the model.

At the end of the simulation, the following variables appear in the MATLAB workspace: f14_Timed_Based_Linearization, tout, and xout.

- 8 Get the indices to the operating point times by entering the following at the MATLAB command line:

```
ind1 = find(f14_Timed_Based_Linearization(1).OperPoint.t==tout);
ind2 = find(f14_Timed_Based_Linearization(1).OperPoint.t==tout);
```

- 9 Get the state vectors at the operating points.

```
x1 = xout(ind1,:);  
x2 = xout(ind2,:);
```

Data Type Support

Not applicable.

Parameters

Linearization time

Time at which you want the block to generate a linear model. Enter a vector of times if you want the block to generate linear models at more than one time step.

Sample time (of linearized model)

Specify a sample time to create discrete-time linearizations of the model (see “Discrete-Time System Linearization” on page 2-47).

Characteristics

Data Types	Not applicable
Sample Time	Specified in the Sample time parameter
Multidimensional Signals	No
Variable-Size Signals	No
Code Generation	No

Trigger-Based Linearization

Introduced in R2010a

To File

Write data to file

Library

Sinks

Description

The To File block inputs a signal and writes the signal data into a MAT-file. Use the To File block to log signal data.

The To File block icon shows the name of the output file.

The block writes to the output file incrementally, with minimal memory overhead during simulation. If the output file exists when the simulation starts, the block overwrites the file. The file automatically closes when simulation is complete or paused. If simulation terminates abnormally, the To File block saves the data it has logged up until the point of the abnormal termination.

Tip If MATLAB encounters memory issues when you log a large number of signals in a long simulation that has many time steps, consider logging to persistent storage. When you log to persistent storage, the Dataset format logging data is stored in a MAT-file. Compared to logging to persistent storage, connecting a To File block to signals:

- Is a per-signal approach that can clutter a model with several To File blocks attached to individual signals.
- Creates a separate MAT-file for each To File block, compared to the one MAT-file that logging to persistent storage uses.

For details, see “Log Data to Persistent Storage”.

Specifying the Format for Writing Data

Use the **Save format** parameter to specify the format for writing data:

- `Timeseries` (default)
- `Array`

Use the `Array` format only for vector, double, noncomplex signals. To save bus data, use the `Timeseries` format.

For the `Timeseries` format, the `To File` block:

- Writes data in a MATLAB `timeseries` object
- Supports writing multidimensional, real or complex output values
- Supports writing output values that have any built-in data type, including `Boolean`, enumerated (`enum`), and fixed-point data with a word length of up to 32 bits
- For bus input signals, creates a MATLAB structure that matches the bus hierarchy. Each leaf of the structure is a MATLAB `timeseries` object.

For the `Array` format, the `To File` block:

- Writes data into a matrix containing two or more rows. The matrix has the following form:

$$\begin{bmatrix} t_1 & t_2 & \dots & t_{final} \\ u1_1 & u1_2 & \dots & u1_{final} \\ \dots & & & \\ un_1 & un_2 & \dots & un_{final} \end{bmatrix}$$

Simulink writes one column to the matrix for each data sample. The first element of the column contains the time stamp. The remainder of the column contains data for the corresponding output values.

- Supports writing data that is one-dimensional, double, and noncomplex.

The following table shows how simulation mode support depends on the **Save format** value.

Simulation Mode	Timeseries	Array
Normal	Supported.	Supported.
Accelerator	Supported.	Supported.
Rapid Accelerator	Supported.	Supported.
Software-in-the-Loop (SIL)	Not supported.	Supported if MAT-file logging is enabled.
Processor-in-the-Loop (PIL)	Not supported.	Supported if MAT-file logging is available and enabled.
External	Not supported.	Supported if MAT-file logging is enabled.
RSim target	Supported.	Supported if MAT-file logging is enabled.

Controlling When Data Is Written to the File

The To File block **Decimation** and **Sample Time** parameters control when data is written to the file.

The To File block does not log data outside of the intervals specified by the **Model Configuration Parameters > Data Import/Export > Logging intervals** parameter. The block stores the logged data in the file associated with the block instead of storing the data in the variable that you specify for the **Single simulation output** parameter.

Saving Data for Use by a From File Block

The From File block can use data written by a To File block in any format (**Timeseries** or **Array**) without any modifications to the data or other special provisions.

Saving Data for Use by a From Workspace Block

The From Workspace block can read data that is in the **Array** format and is the transposition of the data written by the To File block. To provide the required format, use MATLAB commands to load and transpose the data from the MAT-file.

Simulation Stepper Interaction with To File Block

If you pause using the Simulation Stepper, the To File block captures the simulation data up to the point of the pause. When you step back, the To File data file no longer contains any simulation data past the new reduced time of the last output.

Limitations of To File blocks in a Referenced Model

When a To File block is in a referenced model, that model must be a single-instance model. Only one instance of such a model can exist in a model hierarchy. See “Specify Reusability of Referenced Models” for more information.

Compressing MAT-File Data

To avoid the overhead of compressing data in real time, the To File block writes an uncompressed Version 7.3 MAT-file. To compress the data within the MAT-file, load and save the file in MATLAB. The resaved file is smaller than the original MAT-file that the To File block created, because the **Save** command compresses the data in the MAT-file.

Saving Bus Data

The To File block supports virtual and nonvirtual bus input.

To save bus data, set the **Save format** parameter to `Timeseries`.

If the input signal is a bus, then the To File block creates a MATLAB structure that matches the bus hierarchy. Each leaf of the structure is a MATLAB `timeseries` object.

Pausing a Simulation

After pausing a simulation, do not alter any file that a To File block logs into. For example, do not save such a file with the MATLAB `save` command. Altering the file can cause an error when you resume the simulation. If you want to alter the file after pausing, copy the file and work with the copy of the file.

Generating Code

To generate code for a To File block, on the **Code Generation > Interface** pane, you must select the configuration parameter “MAT-file logging” (Simulink Coder).

Data Type Support

The To File block accepts real or complex signal data of any data type that Simulink supports, with the exception that the word length for fixed-point data must be 32 bits or less.

The To File block accepts bus data.

Parameters

File name

The path or file name of the MAT-file in which to store the output. On UNIX systems, the pathname can start with a tilde (~) character signifying your home folder. The default file name is `untitled.mat`. If you specify a file name without path information, Simulink stores the file in the MATLAB working folder. (To determine the working folder, type `pwd` at the MATLAB command line.) If the file already exists, Simulink overwrites it.

Variable name

The name of the matrix contained in the named file. The default name is `ans`.

Save format

The data format that the To File block uses for writing data:

- `Timeseries` (default)
- `Array`

Decimation

The decimation factor, n , where n specifies writing data at every n th time that the block executes. The default decimation is 1, which writes data at every time step.

Sample time

Specifies the sample period and offset at which to collect points. This parameter is useful when you are using a variable-step solver where the interval between time steps might not be constant. The default is -1, which inherits the sample time from the driving block. See “Specify Sample Time” for more information.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated Bus
Sample Time	Specified in the Sample time parameter
Multidimensional Signals	Yes
Variable-Size Signals	No
Code Generation	Yes

See Also

“Save Runtime Data from Simulation”, “Convert Logged Data to Dataset Format”, From File, From Workspace, To Workspace

Introduced before R2006a

To Workspace

Write data to workspace

Library

Sinks

Description

The To Workspace block inputs a signal and writes the signal data to a workspace. During the simulation, the block writes data to an internal buffer. When the simulation is completed or paused, that data is written to the workspace. Data is not available until the simulation is stopped or paused.

- For menu-based simulation, data is written in the MATLAB base workspace.
- A `sim` command in a MATLAB function sends data logged with the To Workspace block to the workspace of the calling function, not to the MATLAB (base) workspace. To send the logged data to the base workspace, use an `assignin` command in the function. For example:

```
function myfunc
    a = sim('mTest','SimulationMode','normal');
    b = a.get('simout')
    assignin('base','b',b);
end
```

The block icon shows the name of the variable to which the data is written. To specify the name of the workspace variable to which the To Workspace block writes the data, use the **Variable name** parameter.

To specify the data format of the variable, use the **Save format** parameter. You can specify to save the data in one of the following formats:

- A MATLAB `timeseries` object (or structure of MATLAB `timeseries` objects for bus data)
- An array
- Structure
- Structure with time

From one of these formats, you can convert the data to `Dataset` format. Converting to `Dataset` format makes it easier to post-process with other logged data (for example, logged states), which can also use `Dataset` format. For more information, see “Convert Logged Data to Dataset Format”. You can also use signal logging with a variable-size signal exception.

Saving Data for Use by a From Workspace Block

To use a `From Workspace` block to read into Simulink the sample-based data that was saved by a `To Workspace` block in a previous simulation, in the `To Workspace` block, specify time information using the `Timeseries` or `Structure with time` format.

Controlling the Amount of Data Saved

If you specify intervals with the **Model Configuration Parameters > Data Import/Export > Logging intervals** parameter, the block does not log data outside of the intervals. For example, the block logs no data if the intervals are empty (`[]`).

For variable-step solvers, to control the amount of data available to the `To Workspace` block, use the **Model Configuration Parameters > Data Import/Export > Additional parameters > Output options** parameter. For example, to have Simulink write data at identical time points over multiple simulations, select the `Produce specified output only` option.

Then use `To Workspace` block parameters to control when and how much of this data the block writes:

- Use the **Limit data points to last** parameter to specify how many sample points to save. If the simulation generates more data points than the specified maximum, the simulation saves only the most recently generated samples. To capture all the data, set this value to `inf`.

- Use the **Decimation** parameter to have the To Workspace block write data at every n th sample, where n is the decimation factor. The default decimation, 1, writes data at every time hit.
- Use the **Sample time** parameter to specify a sampling interval at which to collect points. This parameter is useful when you are using a variable-step solver where the interval between time hits might not be the same. The default value of -1 causes the block to inherit the sample time from the driving block when determining the points to write. See “Specify Sample Time” in the online documentation for more information.

For example, suppose you have a simulation where the start time is 0, the **Limit data points to last** is 100, the **Decimation** is 1, and the **Sample time** is 0.5. The To Workspace block collects a maximum of 100 points, at time values of 0, 0.5, 1.0, 1.5, ..., seconds. Specifying a **Decimation** value of 1 directs the block to write data at each step.

In a similar example, the **Limit data points to last** is 100 and the **Sample time** is 0.5, but the **Decimation** is 5. In this example, the block collects up to 100 points, at time values of 0, 2.5, 5.0, 7.5, ..., seconds. Specifying a **Decimation** value of 5 directs the block to write data at every fifth sample. The sample time ensures that data is written at these points.

In another example, all parameters are as defined in the first example except that the **Limit data points to last** is 3. In this case, only the last three sample points collected are written to the workspace. If the simulation stop time is 100, data corresponds to times 99.0, 99.5, and 100.0 seconds (three points).

MAT-File Logging

When you enable the **MAT-file logging** parameter in **Configuration Parameters**, To Workspace logs its data to a MAT-file. For information about this parameter, in the Simulink Coder documentation, see “MAT-file logging” (Simulink Coder).

Frame-Based Signals

By default, the To Workspace block treats input signals as sample-based.

To have the To Workspace block treat input signals as frame-based, set:

- 1 **Save format** to either **Array** or **Structure**

2 Save 2-D signals as to 2-D array (concatenate along first dimension)

Data Type Support

The To Workspace block can save to the MATLAB workspace real or complex inputs of any data type that Simulink supports, including fixed-point and enumerated data types, as well as bus objects.

For more information, see “Data Types Supported by Simulink”.

Parameters

Variable name

Specify the name of the variable for the saved the data.

Limit data points to last

Specify the maximum number of input samples to save. The default is `inf`.

Decimation

Specify the decimation factor. The default is 1.

Save format

Specify one of these formats for saving simulation output to the workspace:

- `Timeseries` (Default)

Save non-bus signals as a MATLAB `timeseries` object and bus signals as a structure of MATLAB `timeseries` objects.

- `Array`

Save the input as an N-dimensional array where N is one more than the number of dimensions of the input signal. For example, if the input signal is a vector, the

resulting workspace array is two-dimensional. If the input signal is a matrix, then the array is three-dimensional.

How Simulink stores samples in the array depends on whether the input signal is a scalar, vector, or matrix. If the input is a scalar or a vector, each input sample is output as a row of the array. For example, suppose that the name of the output array is `simout`. Then, `simout(1, :)` corresponds to the first sample, `simout(2, :)` corresponds to the second sample, and so on. If the input signal is a matrix, time corresponds to the third dimension. For example, suppose again that `simout` is the name of the resulting workspace array. Then, `simout(:, :, 1)` is the value of the input signal at the first sample point; `simout(:, :, 2)` is the value of the input signal at the second sample point; and so on.

If you select `Array`, the **Save 2-D signals** parameter appears.

To treat input signals as frame-based, set **Save format** to either `Array` or `Structure` and set the **Save 2-D signals** parameter to `2-D array (concatenate along first dimension)`.

- `Structure`

This format consists of a structure with three fields:

- `time` — This field is empty for this format.
- `signals` — A structure with three fields: `values`, `dimensions`, and `label`. The `values` field contains the array of signal values. The `dimensions` field specifies the dimensions of the corresponding signals. The `label` field contains the label of the input line.
- `blockName` — Name of the To Workspace block

If you select `Structure`, the **Save 2-D signals** parameter appears.

To treat input signals as frame-based, set **Save format** to either `Structure` or `Array` and set the **Save 2-D signals** parameter to `2-D array (concatenate along first dimension)`.

- `Structure With Time`

This format is the same as `Structure`, except that the `time` field contains a vector of simulation time hits.

To read To Workspace block output directly with a From Workspace block, use either the `Timeseries` or `Structure with Time` format. For details, see “Comparison of Signal Loading Techniques”.

`Structure with Time` format does not support frame-based signals. Use `Array` or `Structure` format instead.

The following table shows how simulation mode support depends on the **Save format** value.

Simulation Mode	Timeseries	Array, Structure, or Structure With Time
Normal	Supported.	Supported.
Accelerator	Supported.	Supported only in top model, not referenced models.
Rapid Accelerator	Not supported.	Supported only in top model, not referenced models.
Software-in-the-Loop (SIL)	Not supported.	If MAT-file logging is enabled, supported only in top model, not referenced models.
Processor-in-the-Loop (PIL)	Not supported.	If MAT-file logging is available and enabled, supported only in top model, not referenced models.
External	Not supported.	Supported only in top model, not referenced models.
Simulink Coder Targets	Not supported.	If MAT-file logging is enabled, supported only in top model, not referenced models.

Save 2-D signal as

If you set **Save format** to `Array` or `Structure`, the **Save 2-D signals as** parameter appears.

Specify one of these formats for saving 2-D signals to the workspace:

- 3-D array (concatenate along third dimension) (Default)

This setting is well-suited for sample-based signals. Data is concatenated along the third dimension. For example, 2-by-4 matrix input for 10 samples is stored as a 2x4x10 array.

- 2-D array (concatenate along first dimension)

This setting is well-suited for frame-based signals. The data is concatenated along the first dimension. For example, 2-by-4 matrix input for 10 samples is stored as a 20x4 array

- Inherit from input (this choice will be removed – see release notes)

This setting is for backward compatibility. To configure this block to treat input signals as frame-based in future releases, set this parameter to 2-D array (concatenate along first dimension). To configure this block to treat input signals as sample-based in future releases, set this parameter to 3-D array (concatenate along third dimension).

When the **Save format** is set to Array or Structure, the dimensions of the output depend on the input dimensions and the setting of the **Save 2-D signals as** parameter. The following table summarizes the output dimensions under various conditions. In the table, K represents the value of the **Limit data points to last** parameter.

Input Signal Dimensions	Save 2-D Signals as ...	Signal To Workspace Output Dimension
M -by- N matrix	2-D array (concatenate along first dimension)	<p>K-by-N matrix.</p> <p>If you set the Limit data points to last parameter to <code>inf</code>, K represents the total number of samples acquired in each column by the end of simulation. This is equivalent to multiplying the input frame size (M) by the total number of M-by-N inputs acquired by the block.</p>

Input Signal Dimensions	Save 2-D Signals as ...	Signal To Workspace Output Dimension
M -by- N matrix	3-D array (concatenate along third dimension)	M -by- N -by- K array. If you set the Limit data points to last parameter to <code>inf</code> , K represents the total number of M -by- N inputs acquired by the end of the simulation.
Length- N unoriented vector	Any setting	K -by- N matrix
N -dimensional array where $N > 2$	Any setting	Array with $N+1$ dimensions, where the size of the last dimension is equal to K . If you set the Limit data points to last parameter to <code>inf</code> , K represents the total number of M -by- N inputs acquired by the end of simulation

Log fixed-point data as a fi object

By default, the To Workspace block logs fixed-point data to the MATLAB workspace as a Fixed-Point Designer `fi` object. If you clear this parameter, fixed-point data is logged to the workspace as `double`.

Sample time

Specify the sample period and offset at which to collect data. This parameter is useful when you are using a variable-step solver where the interval between time hits might not be constant. The default is `-1`, which inherits the sample time from the driving block. See “Specify Sample Time” for more information.

Examples

The `sldemo_varsize_basic` example shows how to use the To Workspace block.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated Bus
Sample Time	Specified in the Sample time parameter
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Code Generation	No

Toggle Switch

Toggle parameter between two values
Library: Simulink / Dashboard

On

Off

Description

The Toggle Switch block toggles the value of the connected block parameter between two values during simulation. For example, you can connect the Toggle Switch block to a Switch block in your model and change its state during simulation. Use the Toggle Switch block with other Dashboard blocks to create an interactive dashboard for your model.

Connection

Dashboard block controls connect to variables and block parameters. To connect a Dashboard block to a variable or parameter, use the **Connection** table in the block's parameters.

- 1 Double-click the block.
- 2 Populate the **Connection** table by selecting blocks of interest in your model.
- 3 Mark the option button next to the parameter or variable you want to adjust during simulation.
- 4 Click **Apply**.

Limitations

- You cannot save the block connections or properties in model files that use the MDL format.

To save connections and properties, save the model file in the SLX format.

- Dashboard blocks can only connect to real scalar signals.
- Dashboard blocks cannot connect to blocks that are commented out.
- Dashboard blocks cannot connect to signals inside reference models.
- Parameters specified by indexing a variable array do not appear in the **Connection** table. For example, a block parameter defined using the variable `engine(1)` does not appear in the table.

To access the parameter in the **Connection** table, assign the indexed value to a scalar variable, such as `engine_1`. Then, use the scalar variable to define the block parameter.

Parameters

Connection — Select a block parameter to connect

signal connection options

Select the block parameter to control using the **Connection** table. To open the dialog box, double-click the block. Then, populate the **Connection** table by selecting a block in your model. Select the variable parameter you want to control, and click **Apply**.

Note To see workspace variables in the connection table, update the model diagram with **Ctrl+D**.

States

Label (Top) — Label for top switch position

'On' (default) | character vector

Labels the top switch position. You can use the **Label** to display the value the connected parameter takes when the switch is positioned at the top, or you can enter a text label.

Example: `Gain = 2`

Value (Top) — Value for top switch position

1 (default) | scalar

The value assigned to the connected parameter when the switch is positioned at the top.

Label (Bottom) — Label for bottom switch position

'Off' (default) | character vector

Labels the bottom switch position. You can use the **Label** to display the value the connected parameter takes when the switch is positioned at the bottom, or you can enter a text label.

Example: `Gain = 1`

Value (Bottom) — Value for bottom switch position

0 (default) | scalar

The value assigned to the connected parameter when the switch is positioned at the bottom.

Label — Block label position

'Top' (default) | 'Bottom' | 'Hide'

Position of the block label. When the block is connected to a signal, the label is the name of the connected signal. When the block is not connected, the label is the instructional text.

Transfer Fcn

Model linear system by transfer function

Library

Continuous

Description

The Transfer Fcn block models a linear system by a transfer function of the Laplace-domain variable s . The block can model single-input single-output (SISO) and single-input multiple output (SIMO) systems.

Conditions for Using This Block

The Transfer Fcn block assumes the following conditions:

- The transfer function has the form

$$H(s) = \frac{y(s)}{u(s)} = \frac{num(s)}{den(s)} = \frac{num(1)s^{nn-1} + num(2)s^{nn-2} + \dots + num(nn)}{den(1)s^{nd-1} + den(2)s^{nd-2} + \dots + den(nd)},$$

where u and y are the system input and outputs, respectively, nn and nd are the number of numerator and denominator coefficients, respectively. $num(s)$ and $den(s)$ contain the coefficients of the numerator and denominator in descending powers of s .

- The order of the denominator must be greater than or equal to the order of the numerator.
- For a multiple-output system, all transfer functions have the same denominator and all numerators have the same order.

Modeling a Single-Output System

For a single-output system, the input and output of the block are scalar time-domain signals. To model this system:

- 1 Enter a vector for the numerator coefficients of the transfer function in the **Numerator coefficients** field.
- 2 Enter a vector for the denominator coefficients of the transfer function in the **Denominator coefficients** field.

Modeling a Multiple-Output System

For a multiple-output system, the block input is a scalar and the output is a vector, where each element is an output of the system. To model this system:

- 1 Enter a matrix in the **Numerator coefficients** field.

Each *row* of this matrix contains the numerator coefficients of a transfer function that determines one of the block outputs.
- 2 Enter a vector of the denominator coefficients common to all transfer functions of the system in the **Denominator coefficients** field.

Specifying Initial Conditions

A transfer function describes the relationship between input and output in Laplace (frequency) domain. Specifically, it is defined as the Laplace transform of the response (output) of a system with zero initial conditions to an impulse input.

Operations like multiplication and division of transfer functions rely on zero initial state. For example, you can decompose a single complicated transfer function into a series of simpler transfer functions. Apply them sequentially to get a response equivalent to that of the original transfer function. This will not be correct if one of the transfer functions assumes a non-zero initial state. Furthermore, a transfer function has infinitely many time domain realizations, most of whose states do not have any physical meaning.

For these reasons, Simulink presets the initial conditions of the Transfer Fcn block to zero. To specify initial conditions for a given transfer function, convert the transfer function to its controllable, canonical state-space realization using `tf2ss`. Then, use the State-Space block. The `tf2ss` utility provides the A, B, C, and D matrices for the system.

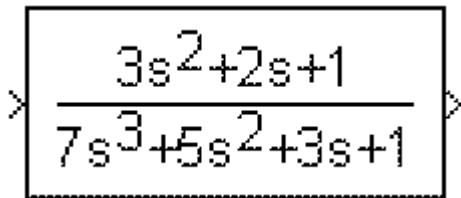

For more information, type `help tf2ss` or see the Control System Toolbox™ documentation.

Transfer Function Display on the Block

The Transfer Fcn block displays the transfer function depending on how you specify the numerator and denominator parameters.

- If you specify each parameter as an expression or a vector, the block shows the transfer function with the specified coefficients and powers of s . If you specify a variable in parentheses, the block evaluates the variable.

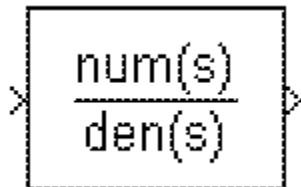

For example, if you specify **Numerator coefficients** as `[3, 2, 1]` and **Denominator coefficients** as `(den)`, where `den` is `[7, 5, 3, 1]`, the block looks like this:

The diagram shows a rectangular block with an input arrow on the left and an output arrow on the right. Inside the block, the transfer function is displayed as a fraction: the numerator is $3s^2 + 2s + 1$ and the denominator is $7s^3 + 5s^2 + 3s + 1$.

- If you specify each parameter as a variable, the block shows the variable name followed by (s) .

For example, if you specify **Numerator coefficients** as `num` and **Denominator coefficients** as `den`, the block looks like this:

The diagram shows a rectangular block with an input arrow on the left and an output arrow on the right. Inside the block, the transfer function is displayed as a fraction: the numerator is `num(s)` and the denominator is `den(s)`.

Data Type Support

The Transfer Fcn block accepts and outputs signals of type `double`.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Numerator coefficients

Define the row vector of numerator coefficients.

Default: [1]

- For a single-output system, enter a vector for the numerator coefficients of the transfer function.
- For a multiple-output system, enter a matrix. Each row of this matrix contains the numerator coefficients of a transfer function that determines one of the block outputs.

Parameter: Numerator

Type: vector or matrix

Value: ' [1] '

Default: ' [1] '

See the Transfer Fcn block reference page for more information.

Denominator coefficients

Define the row vector of denominator coefficients.

Default: [1 1]

- For a single-output system, enter a vector for the denominator coefficients of the transfer function.
- For a multiple-output system, enter a vector containing the denominator coefficients common to all transfer functions of the system.

Parameter: Denominator

Type: vector

Value: ' [1 1] '

Default: '[1 1]'

Absolute tolerance

Specify the absolute tolerance for computing block states.

Default: `auto`

- You can enter `auto`, `-1`, a positive real scalar or vector.
- If you enter `auto` or `-1`, then Simulink uses the absolute tolerance value in the Configuration Parameters dialog box (see “Solver Pane”) to compute block states.
- If you enter a real scalar, then that value overrides the absolute tolerance in the Configuration Parameters dialog box for computing all block states.
- If you enter a real vector, then the dimension of that vector must match the dimension of the continuous states in the block. These values override the absolute tolerance in the Configuration Parameters dialog box.

Parameter: `AbsoluteTolerance`

Type: character vector, scalar, or vector

Value: `'auto'` | `'-1'` | any positive real scalar or vector

Default: `'auto'`

State Name (e.g., 'position')

Assign a unique name to each state.

Default: ' '

If this field is blank, no name assignment occurs.

- To assign a name to a single state, enter the name between quotes, for example, `'velocity'`.
- To assign names to multiple states, enter a comma-delimited list surrounded by braces, for example, `{'a', 'b', 'c'}`. Each name must be unique.
- The state names apply only to the selected block.

- The number of states must divide evenly among the number of state names.
- You can specify fewer names than states, but you cannot specify more names than states.

For example, you can specify two names in a system with four states. The first name applies to the first two states and the second name to the last two states.

- To assign state names with a variable in the MATLAB workspace, enter the variable without quotes. A variable can be a character vector, cell array, or structure.

Parameter: ContinuousStateAttributes

Type: character vector

Value: ' ' | user-defined

Default: ' '

Examples

The following Simulink examples show how to use the Transfer Fcn block:

- `slexAircraftExample`
- `sldemo_absbrake`
- `penddemo`

Characteristics

Data Types	Double
Sample Time	Continuous
Direct Feedthrough	Only if the lengths of the Numerator coefficients and Denominator coefficients parameters are equal

Transfer Fcn Direct Form II

Implement Direct Form II realization of transfer function

$$\frac{0.2 + 0.3z^{-1} + 0.2z^{-2}}{1 - 0.9z^{-1} + 0.6z^{-2}}$$

Library

Additional Math & Discrete / Additional Discrete

Description

The Transfer Fcn Direct Form II block implements a Direct Form II realization of the transfer function that the **Numerator coefficients** and **Denominator coefficients** **excluding lead** parameters specify. The block supports only single input-single output (SISO) transfer functions.

The block automatically selects the data types and scalings of the output, the coefficients, and any temporary variables.

Data Type Support

The Transfer Fcn Direct Form II block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Numerator coefficients

Specify the numerator coefficients.

Denominator coefficients excluding lead

Specify the denominator coefficients, excluding the leading coefficient, which must be 1.0.

Initial condition

Set the initial condition.

Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

Saturate to max or min when overflows occur

Select to have overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Characteristics

Data Types	Double Single Base Integer Fixed-Point
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No

Code Generation	Yes

See Also

Transfer Fcn Direct Form II Time Varying

Introduced before R2006a

Transfer Fcn Direct Form II Time Varying

Implement time varying Direct Form II realization of transfer function

Library

Additional Math & Discrete / Additional Discrete

Description

The Transfer Fcn Direct Form II Time Varying block implements a Direct Form II realization of the specified transfer function. The block supports only single input-single output (SISO) transfer functions.

The input signal labeled `Den No Lead` contains the denominator coefficients of the transfer function. The full denominator has a leading coefficient of one, but it is excluded from the input signal. For example, a denominator of $[1 \ -1.7 \ 0.72]$ is represented by a signal with the value $[-1.7 \ 0.72]$. The input signal labeled `Num` contains the numerator coefficients. The data types of the numerator and denominator coefficients can be different, but the length of the numerator vector and the full denominator vector must be the same. Pad the numerator vector with zeros, if needed.

The block automatically selects the data types and scalings of the output, the coefficients, and any temporary variables.

Data Type Support

The Transfer Fcn Direct Form II Time Varying block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Initial condition

Set the initial condition.

Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

Saturate to max or min when overflows occur

Select to have overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point
Direct Feedthrough	Yes

Introduced before R2006a

Transfer Fcn First Order

Implement discrete-time first order transfer function

Library

Discrete

Description

The Transfer Fcn First Order block implements a discrete-time first order transfer function of the input. The transfer function has a unity DC gain.

Data Type Support

The Transfer Fcn First Order block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Pole (in Z plane)

Set the pole.

Initial condition for previous output

Set the initial condition for the previous output.

Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer). in the Fixed-Point Designer documentation.

Saturate to max or min when overflows occur

Select to have overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Characteristics

Data Types	Double Single Base Integer Fixed-Point
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Transfer Fcn Lead or Lag

Implement discrete-time lead or lag compensator

Library

Discrete

Description

The Transfer Fcn Lead or Lag block implements a discrete-time lead or lag compensator of the input. The instantaneous gain of the compensator is one, and the DC gain is equal to $(1-z)/(1-p)$, where z is the zero and p is the pole of the compensator.

The block implements a lead compensator when $0 < z < p < 1$, and implements a lag compensator when $0 < p < z < 1$.

Data Type Support

The Transfer Fcn Lead or Lag block accepts signals of any numeric data type that Simulink supports, including fixed-point data types.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Pole of compensator (in Z plane)

Set the pole.

Zero of compensator (in Z plane)

Set the zero.

Initial condition for previous output

Set the initial condition for the previous output.

Initial condition for previous input

Set the initial condition for the previous input.

Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

Saturate to max or min when overflows occur

Select to have overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Transfer Fcn Real Zero

Implement discrete-time transfer function that has real zero and no pole

Library

Discrete

Description

The Transfer Fcn Real Zero block implements a discrete-time transfer function that has a real zero and effectively no pole.

Data Type Support

The Transfer Fcn Real Zero block accepts signals of any numeric data type that Simulink supports, including fixed-point data types.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Zero (in Z plane)

Set the zero.

Initial condition for previous input

Set the initial condition for the previous input.

Input processing

Specify whether the block performs sample- or frame-based processing. You can select one of the following options:

- `Elements as channels (sample based)` — Treat each element of the input as a separate channel (sample-based processing).
- `Columns as channels (frame based)` — Treat each column of the input as a separate channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

- `Inherited` — Inherit the processing mode from the input signal and delay the input accordingly. You can identify whether the input signal is sample or frame based by looking at the signal line. Simulink represents sample-based signals with a single line and frame-based signals with a double line.

Note When you choose the `Inherited` option for the **Input processing** parameter, and the input signal is frame-based, Simulink will generate a warning or error in future releases.

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input `u`. All other input signals must be sample based.

Input Signal <code>u</code>	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

Saturate to max or min when overflows occur

Select to have overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point
Direct Feedthrough	Yes

Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Transport Delay

Delay input by given amount of time

Library

Continuous

Description

The Transport Delay block delays the input by a specified amount of time. You can use this block to simulate a time delay. The input to this block should be a continuous signal.

At the start of simulation, the block outputs the **Initial output** parameter until the simulation time exceeds the **Time delay** parameter. Then, the block begins generating the delayed input. During simulation, the block stores input points and simulation times in a buffer. You specify this size with the **Initial buffer size** parameter.

When you want output at a time that does not correspond to times of the stored input values, the block interpolates linearly between points. When the delay is smaller than the step size, the block extrapolates from the last output point, which can produce inaccurate results. Because the block does not have direct feedthrough, it cannot use the current input to calculate an output value. For example, consider a fixed-step simulation with a step size of 1 and the current time at $t = 5$. If the delay is 0.5, the block must generate a point at $t = 4.5$. Because the most recent stored time value is at $t = 4$, the block performs forward extrapolation.

The Transport Delay block does not interpolate discrete signals. Instead, the block returns the discrete value at the required time.

This block differs from the Unit Delay block, which delays and holds the output on sample hits only.

Tip Avoid using `linmod` to linearize a model that contains a Transport Delay block. For more information, see “Linearizing Models” in the Simulink documentation.

Data Type Support

The Transport Delay block accepts and outputs real signals of type `double`.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Time delay

Specify the amount of simulation time to delay the input signal before propagation to the output.

Default: 1

This value must be nonnegative.

Parameter: `DelayTime`

Type: scalar or vector

Value: '1'

Default: '1'

Initial output

Specify the output that the block generates until the simulation time first exceeds the time delay input.

Default: Run-to-run tunable parameter

A Run-to-run tunable parameter cannot be changed during a simulation’s run time. However, changing it before a simulation begins will not cause Accelerator or Rapid Accelerator to regenerate code.

Also, the initial output of this block cannot be `inf` or `NaN`.

Parameter: `InitialOutput`

Type: scalar or vector

Value: '0'

Default: '0'

Initial buffer size

Define the initial memory allocation for the number of input points to store.

Default: 1024

- If the number of input points exceeds the initial buffer size, the block allocates additional memory.
- After simulation ends, a message shows the total buffer size needed.
- Because allocating memory slows down simulation, choose this value carefully if simulation speed is an issue.
- For long time delays, this block can use a large amount of memory, particularly for dimensionalized input.

Parameter: `BufferSize`

Type: scalar

Value: '1024'

Default: '1024'

Use fixed buffer size

Specify use of a fixed-size buffer to save input data from previous time steps.

Default: Off

On

The block uses a fixed-size buffer.

Off

The block does not use a fixed-size buffer.

The **Initial buffer size** parameter specifies the size of the buffer. If the buffer is full, new data replaces data already in the buffer. Simulink software uses linear extrapolation to estimate output values that are not in the buffer.

Note If you have a Simulink Coder license, ERT or GRT code generation uses a fixed-size buffer even if you do not select this check box.

- If the input data is linear, selecting this check box can save memory.
- If the input data is nonlinear, do not select this check box. Doing so can yield inaccurate results.

Parameter: FixedBuffer

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Direct feedthrough of input during linearization

Cause the block to output its input during linearization and trim, which sets the block mode to direct feedthrough.

Default: Off

On

Enables direct feedthrough of input.

Off

Disables direct feedthrough of input.

- Selecting this check box can cause a change in the ordering of states in the model when you use the functions `linmod`, `dlinmod`, or `trim`. To extract this new state ordering:

- 1 Compile the model using the following command, where `model` is the name of the Simulink model.

```
[sizes, x0, x_str] = model([], [], [], 'lincompile');
```

- 2 Terminate the compilation with the following command.

```
model([], [], [], 'term');
```

- The output argument `x_str`, which is a cell array of the states in the Simulink model, contains the new state ordering. When you pass a vector of states as input to the `linmod`, `dlinmod`, or `trim` functions, the state vector must use this new state ordering.

Parameter: `TransDelayFeedthrough`

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Pade order (for linearization)

Set the order of the Pade approximation for linearization routines.

Default: 0

- The default value is 0, which results in a unity gain with no dynamic states.
- Setting the order to a positive integer `n` adds `n` states to your model, but results in a more accurate linear model of the transport delay.

Parameter: `PadeOrder`

Type: character vector

Value: '0'

Default: '0'

Characteristics

Data Types	Double
Sample Time	Continuous
Direct Feedthrough	No

Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Variable Time Delay

Introduced before R2006a

Trigger

Add trigger port to subsystem or model

Library: Ports & Subsystems

Description

The Trigger block allows an external signal to control the execution of a subsystem or a model. To enable this functionality, add this block to a Subsystem block or at the root level of a model that is referenced in a Model block.

Then, configure the Trigger block to execute a subsystem or model:

- Once at each time step, when the value of the trigger signal changes in a way that you specify.
- Multiple times during a time step, when the trigger signal is a function-call from a Stateflow chart, Function-Call Generator block or S-function block.

Ports

Output

Trigger signal — External trigger signal for a subsystem or model

scalar

Trigger signal attached externally to the outside of an Subsystem block or a Model block that is passed to the inside of the block. To enable this port, select **Show output port**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `expression`

Parameters

Main

Trigger type — Select the type of event

`rising` (default) | `falling` | `either` | `function-call`

Select the type of event that triggers execution of the subsystem or model.

`rising`

Trigger execution of subsystem or model when the trigger signal rises from a negative or zero value to a positive value. If the initial value is negative, a rising signal to zero triggers execution.

`falling`

Trigger execution of subsystem or model when the trigger signal falls from a positive or a zero value to a negative value. If the initial value is positive, a falling signal to zero triggers execution.

`either`

Trigger execution of subsystem or model when the trigger signal is either rising or falling.

`function-call`

Trigger execution of subsystem or model when the trigger signal is a function-call event from a Stateflow chart, Function-Call Generator block, or an S-function block.

Programmatic Use

Block parameter: `TriggerType`

Type: character vector

Value: `'rising'` | `'falling'` | `'either'` | `'function-call'`

Default: `'rising'`

Treat as Simulink function — Create Simulink Function block

`off` (default) | `on`

Create a Simulink Function block by configuring a Subsystem block that is callable with arguments from a function caller.

`off`

Remove configuration.

on

Configure a Subsystem block as a Simulink Function block. The Trigger block must reside within the subsystem.

You can edit the function prototype that displays on the block face to specify input and output arguments for the block.

Dependency

To display and enable this parameter, select `function-call` from the **Trigger type** list.

Programmatic Use

Block parameter: `IsSimulinkFunction`

Type: character vector

Value: `'off' | 'on'`

Default: `'off'`

Function name — Specify function name for Simulink Function block

`f` (default) | function name

Specify the function name for a Simulink Function block. Alternatively, you can specify the name by editing the function prototype on the face of the block.

`f`

Default name for a Simulink Function block.

function name

Function name that displays on the face of a Simulink Function block.

Dependency

To display and enable this parameter, select `function-call` from the **Trigger type** list and select the **Treat as a Simulink Function** check box.

Programmatic Use

Block parameter: `FunctionName`

Type: character vector

Value: `'f' | '<function name>'`

Default: `'f'`

Enable variant condition — Controls activating the variant control (condition)

on (default) | off

Control activating the variant control (condition) defined with the **Variant Control** parameter.

off

Deactivate variant control of subsystem.

on

Activate variant control of subsystem. Selecting this parameter:

- Enables the **Variant control** parameter.
- Displays a variant badge on the face of the block indicating variant conditions are enabled.

Dependency

To display and enable this parameter, select `function-call` from the **Trigger type** list and select the **Treat as a Simulink Function** check box..

Programmatic Use

Block parameter: Variant

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Variant control — Specify variant control (condition) expression

(inherit) (default) | <logical expression>

Specify variant control (condition) expression that executes a variant Simulink Function block when the expression evaluates to true.

(inherit)

Default value for variant control. Inherits the variant condition from the corresponding Function Caller blocks in the model. When **Variant Control** is set as (inherit) the value for **Generate preprocessor conditionals** is inherited automatically from the Function Caller block in the model.

logical expression

A logical (Boolean) expression or a `Simulink.Variant` object representing a logical expression.

The function is activated when the expression evaluates to `true`.

If you want to generate code for your model, define the variables in the expression as `Simulink.Parameter` objects.

Dependency

To display and enable this parameter, select `function-call` from the **Trigger type** list, select the **Treat as a Simulink Function** check box and then select the **Enable variant condition** check box.

Programmatic Use

Block parameter: `VariantControl`

Type: character vector

Value: `'(inherit)'` | `<logical expression>` | `Simulink.Variant` object

Default: `'(inherit)'`

Generate preprocessor conditionals — Control enclosing variant choices

`off` (default) | `on`

Control enclosing variant choices within C preprocessor conditional statements.

`off`

Do not enclose variant choices within C preprocessor conditional statements.

`on`

When generating code for an ERT target, enclose variant choices within C preprocessor conditional statements (`#if`).

Dependency

To display and enable this parameter, select the **Enable variant condition** check box.

Programmatic Use

Block parameter: `GeneratePreprocessorConditionals`

Type: character vector

Value: `'off'` | `'on'`

Default: 'off'

Function visibility — Select scope visibility of function

scoped (default) | global

Select scope of Simulink Function block within subsystem or model.

scoped

Limit accessability of function to:

- Hierarchic level containing the Simulink Function block and levels below.
- One hierarchical level above with qualification.

global

Function accessible from any part of the model hierarchy.

Dependency

To display and enable this parameter, select `function-call` from the **Trigger type** list and then select the **Treat as a Simulink Function** check box..

Programmatic Use

Block parameter: FunctionVisibility

Type: character vector

Value: 'scoped' | 'global'

Default: 'scoped'

States when enabling — Select how to set block state values

held (default) | reset | inherit

Select how to set block state values when the subsystem or model is disabled.

held

Leave the block states at their current values.

reset

Reset the block state values.

inherit

Use the `held` or `reset` setting from the parent subsystem initiating the function-call. If the parent of the initiator is the model root, the inherited setting is `held`. If

the trigger has multiple initiators, set the parents of all initiators to either held or reset.

Dependencies

To enable this parameter, select `function-call` from the **Trigger Type** list.

This parameter setting applies only if the model explicitly enables and disables the function-call subsystem. For example:

- The function-call subsystem resides in an enabled subsystem. In this case, the model enables and disables the function-call subsystem along with the parent subsystem.
- The function-call initiator that controls the function-call subsystem resides in an enabled subsystem. In this case, the model enables and disables the function-call subsystem along with the enabled subsystem containing the function-call initiator.
- The function-call initiator is a Stateflow event bound to a particular state. See “Control Function-Call Subsystems Using Bind Actions” (Stateflow) in the Stateflow documentation.
- The function-call initiator is an S-function that explicitly enables and disables the function-call subsystem. See `ssEnableSystemWithTid` for an example.

Programmatic Use

Block parameter: `StatesWhenEnabling`

Type: character vector

Value: `'held' | 'reset' | 'inherit'`

Default: `'held'`

Propagate sizes of variable-size signals — Select when to propagate variable-size signals

`During execution (default) | Only when enabling`

Select when to propagate variable-size signals.

During execution

Propagate variable-size signals at each time step.

Only when enabling

Propagate variable-size signals when executing a Subsystem block or Model block containing an Enable port, Trigger port with **Trigger type** set to `function-call`, or Action Port block. When you select this option, sample time must be periodic.

Dependencies

To display and enable this parameter for a Trigger port block, select `Function-call` from the **Trigger type** list.

Programmatic Use

Block parameter: `PropagateVarSize`

Type: character vector

Value: `'During execution' | 'Only when enabling'`

Default: `'During execution'`

Show output port — Control display of output port

`off` (default) | `on`

Control display of an output port for a signal that identifies the trigger signal.

`off`

Remove the output port.

`on`

Display the output port and determine which signal caused the trigger. The width of the output port signal is the width of the triggering signal. The signal value is:

- 1 for a signal that causes a rising trigger
- -1 for a signal that causes a falling trigger
- 2 for a function-call trigger
- 0 in all other cases

Programmatic Use

Block parameter: `ShowOutputPort`

Type: character vector

Value: `'off' | 'on'`

Default: `'off'`

Output data type — Select output port data type

`auto` (default) | `double` | `int8`

Select output port data type for the signal that identifies the trigger signal.

auto

Data type is the same as the port connected to the output.

double

Double value.

int8

Integer value

Dependency

To enable this parameter, select the **Show output port** check box.

The Trigger block ignores the **Data type override** setting for the Fixed-Point Tool.

Programmatic Use

Block parameter: OutputDataType

Type: character vector

Value: 'auto' | 'double' | 'int8'

Default: 'auto'

Sample time type — Select calling rate

triggered (default) | periodic

Select the calling rate for a subsystem or model.

triggered

Apply to applications that do not have a periodic calling frequency.

periodic

Apply if the caller of the parent function-call subsystem calls the subsystem once per time step when the subsystem is active (enabled). A Stateflow chart is an example of a caller.

Dependency

To enable this parameter, select Function-call from the **Trigger type** list.

Programmatic Use

Block parameter: SampleTimeType

Type: character vector

Value: 'triggered' | 'periodic'

Default: 'triggered'

Sample time — Specify time interval

-1 (default) | Ts | [Ts, To]

Specify the time interval between function calls to a subsystem or model containing this Trigger port block. If the actual calling rate for the subsystem or model differs from the time interval this parameter specifies, Simulink displays an error.

-1

Inherit time interval from the trigger signal.

Ts

Scalar where Ts is the time interval.

[Ts, To]

Vector where Ts is the time interval and To is the initial time offset.

Dependencies

To enable this parameter, select `function-call` from the **Trigger type** list and `periodic` from the **Sample time type** list.

Programmatic Use

Block parameter: SampleTime

Type: character vector

Value: '-1' | 'Ts' | '[Ts, To]'

Default: '-1'

Enable zero-crossing detection — Control zero-crossing detection

on (default) | off

Control .

on

Detect zero crossings.

off

Do not detect zero crossings.

Dependencies

To enable this parameter, select rising, falling, or either from the **Trigger type** list.

Programmatic Use

Block parameter: ZeroCross

Type: character vector

Value: 'on' | 'off'

Default: 'on'

Initial trigger signal state — Select the initial state of the trigger signal

compatibility (no trigger on first evaluation) (default) | zero | positive
| negative

Select the initial state of the trigger signal.

compatibility (no trigger on first evaluation)

No trigger at the first evaluation of trigger signal. If you choose this option and the Trigger block is in a subsystem where the states are reset, the block does not reset.

zero

Zero. Helps to evaluate a rising or falling trigger signal at the first time step.

positive

Positive value. Helps to evaluate a falling trigger signal at the first time step.

negative

Negative value. Helps to evaluate a rising trigger signal at the first time step.

Dependency

To display and activate this parameter, select rising, falling, or either from the **Trigger type** list.

Programmatic Use

Block parameter: InitialTriggerSignalState

Type: character vector

Value: 'compatibility (no trigger on first evaluation)' | 'zero' | 'positive' | 'negative'

Default: 'compatibility (no trigger on first evaluation)'

Signal Attribute

Port dimensions — Specify dimensions for the trigger signal

1 (default) | [n] | [m n]

Specify dimensions for the trigger signal attached externally to the Model block and passed to the inside of the block.

1

Scalar signal.

[n]

Vector signal of width n.

[m n]

Matrix signal having m rows and n columns.

Dependency

To display and enable this parameter for a Trigger port block at the root-level of a model, select *rising*, *falling*, or either from the **Trigger type** list.

Programmatic Use

Block parameter: PortDimensions

Type: character vector

Value: '1' | '[n]' | '[m n]'

Default: '1'

Trigger signal sample time — Specify time interval

-1 (default) | Ts | [Ts, To]

Specify time interval between block method executions for the block driving the trigger signal.

-1

Inherit time interval.

Ts

Scalar where Ts is the time interval.

[Ts, To]

Vector where Ts is the time interval and To is the initial time offset.

Dependency

To display and enable this parameter for a Trigger port block at the root-level of a model, select `rising`, `falling`, or `either` from the **Trigger type** list.

Programmatic Use

Block parameter: `TriggerSignalSampleTime`

Type: character vector

Value: `'-1'` | `'Ts'` | `'[Ts, To]'`

Default: `'-1'`

Minimum — Specify minimum output value for the trigger signal

`[]` (default) | real scalar

Specify minimum value for the trigger signal attached externally to a Model block and passed to the inside of the block.

Simulink uses this value to perform:

- Simulation range checking. See “Signal Ranges”.
- Automatic scaling of fixed-point data types.
- Optimization of generated code. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. See “Optimize using the specified minimum and maximum values”.

`[]`

Unspecified minimum value.

real scalar

Real scalar value.

Dependency

To display and enable this parameter for a Trigger port block at the root-level of a model, select `rising`, `falling`, or `either` from the **Trigger type** list.

Programmatic Use

Block parameter: `OutMin`

Type: character vector

Value: `'[]'` | `'<real scalar>'`

Default: `'[]'`

Maximum — Specify maximum output value for the trigger signal

`[]` (default) | real scalar

Specify maximum value for the trigger signal attached externally to a Model block and passed to the inside of the block.

Simulink uses this value to perform:

- Simulation range checking. See “Signal Ranges”.
- Automatic scaling of fixed-point data types.
- Optimization of generated code. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. See “Optimize using the specified minimum and maximum values”.

`[]`

Unspecified maximum value.

real scalar

Real scalar value.

Dependency

To display and enable this parameter for a Trigger port block at the root-level of a model, select `rising`, `falling`, or `either` from the **Trigger type** list.

Programmatic Use

Block parameter: `OutMax`

Type: character vector

Value: `'[]'` | `'<real scalar>'`

Default: `'[]'`

Data type — Select output data type for the trigger signal

`double` (default) | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `boolean` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^,0)` | `<data type expression>`

Select data type for the trigger signal attached externally to a Model block and passed to the inside of the block.

`double`

Double-precision floating point.

single

Single-precision floating point.

int8

Signed 8-bit integer.

uint8

Unsigned 8-bit integer.

int16

Signed 16-bit integer.

uint16

Unsigned 16-bit integer.

int32

Signed 32-bit integer.

uint32

Unsigned 32-bit integer.

boolean

Boolean with a value of `true` or `false`.

`fixdt(1,16)`

Signed 16-bit fixed point number with binary point undefined.

`fixdt(1,16,0)`

Signed 16-bit fixed point number with binary point set to zero.

`fixdt(1,16,2^0,0)`

Signed 16-bit fixed point number with slope set to 2^0 and bias set to 0.

`<data type expression>`

Data type object, for example `Simulink.NumericType`. Do not specify a bus object as the expression.

Dependency

To display and enable this parameter for a Trigger port block at the root-level of a model, select `rising`, `falling`, or either from the **Trigger type** list.

Programmatic Use

Block parameter: `OutDataTypeStr`

Type: character vector

Value: 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'boolean' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'

Default: 'double'

Mode — Select data type category

Build in (default) | Fixed point | Expression

Select data type category and display drop-down lists to help you define the data type.

Build in

Display drop-down lists for data type and **Data type override**.

Fixed point

Display drop-down lists for **Signedness**, **Scaling**, and **Data type override**.

Expression

Display text box for entering an expression.

Dependency

To enable this parameter, select the Show data type assistant button .

Programmatic Use

No equivalent command-line parameter.

Interpolate data — Control how missing workspace data is estimated

on (default) | off

Control how missing workspace data is estimated when loading data from the MATLAB workspace.

on

Linearly interpolate output at time steps for which no corresponding workspace data exists.

off

Do not interpolate output at time steps. The current output equals the output at the most recent time step for which data exists.

Dependency

To display and enable this parameter for a Trigger port block at the root-level of a model, select `rising`, `falling`, or either from the **Trigger type** list.

Programmatic Use

Block parameter: `Interpolate`

Type: character vector

Value: `'on'` | `'off'`

Default: `'on'`

Trigger-Based Linearization

Generate linear models in base workspace when triggered

Library

Model-Wide Utilities

Description

When triggered, this block calls `linmod` or `dlinmod` to create a linear model for the system at the current operating point. No trimming is performed. The linear model is stored in the base workspace as a structure, along with information about the operating point at which the snapshot was taken. Multiple snapshots are appended to form an array of structures.

The block sets the following model parameters to the indicated values:

- `BufferReuse` = 'off'
- `RTWInlineParameters` = 'on'
- `BlockReductionOpt` = 'off'

The name of the structure used to save the snapshots is the name of the model appended by `_Trigger_Based_Linearization`, for example, `vdp_Trigger_Based_Linearization`. The structure has the following fields:

Field	Description
a	The A matrix of the linearization
b	The B matrix of the linearization

Field	Description
c	The C matrix of the linearization
d	The D matrix of the linearization
StateName	Names of the model's states
OutputName	Names of the model's output ports
InputName	Names of the model's input ports
OperPoint	A structure that specifies the operating point of the linearization. The structure specifies the value of the model's states (<code>OperPoint.x</code>) and inputs (<code>OperPoint.u</code>) at the operating point time (<code>OperPoint.t</code>).
Ts	The sample time of the linearization for a discrete linearization

Use the Timed-Based Linearization block to generate linear models at predetermined times.

You can use state and simulation time logging to extract the model states at operating points. For example, suppose that you want to get the states of the vdp example model when the signal `x1` triggers the Trigger-Based Linearization block on a rising edge.

- 1 Open the model and drag an instance of this block from the Model-Wide Utilities library and drop the instance into the model.
- 2 Connect the block's trigger port to the signal labeled `x1`.
- 3 Open the model's **Model Configuration Parameters** dialog box.
- 4 Select the **Data Import/Export** pane.
- 5 Check **States** and **Time** on the **Save to Workspace** control panel
- 6 Select OK to confirm the selections and close the dialog box.
- 7 Simulate the model.

At the end of the simulation, the following variables appear in the MATLAB workspace: `vdp_Trigger_Based_Linearization`, `tout`, and `xout`.

- 8 Get the index to the first operating point time by entering the following at the MATLAB command line:

```
ind1 = find(vdp_Trigger_Based_Linearization(1).OperPoint.t==tout);
```

- 9 Get the state vector at this operating point.

```
x1 = xout(ind1, :);
```

Data Type Support

The trigger port accepts signals of any numeric data type that Simulink supports.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Trigger type

Type of event on the trigger input signal that triggers generation of a linear model. See the **Trigger type** parameter of the Trigger block for an explanation of the various trigger types that you can select.

Sample time (of linearized model)

Specify a sample time to create a discrete-time linearization of the model (see “Discrete-Time System Linearization” on page 2-47).

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point
Sample Time	Specified in the Sample time parameter
Multidimensional Signals	No
Variable-Size Signals	No
Code Generation	No

Triggered Subsystem

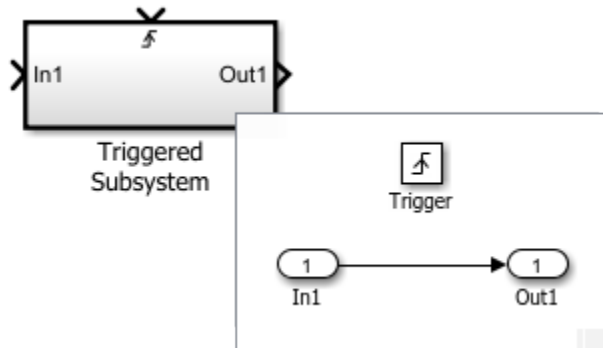

Subsystem whose execution is triggered by external input

Library: Ports & Subsystems

Description

The Triggered Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem that executes each time the control signal has a trigger event.

Use Trigger Subsystem blocks to model:

- A task that runs with the detection of an event.
- An interrupt from I/O hardware.
- A processor request to handle an exception or error.

Ports

Input

In — Signal input to a subsystem block

scalar | vector | matrix

Placing an Inport block in a subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated | bus

Trigger — Control signal input to a subsystem block

scalar

Placing a Trigger block in a subsystem block adds an external input port to the block.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

Output

Out — Signal output from a subsystem

scalar | vector | matrix

Placing an Outport block in a subsystem block adds an output port from the block. The port label on the subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated | bus

Trigonometric Function

Specified trigonometric function on input

Library

Math Operations

Description

Supported Functions

The Trigonometric Function block performs common trigonometric functions. You can select one of the following functions from the **Function** parameter list.

Function	Description	Mathematical Expression	MATLAB Equivalent
sin	Sine of the input	$\sin(u)$	sin
cos	Cosine of the input	$\cos(u)$	cos
tan	Tangent of the input	$\tan(u)$	tan
asin	Inverse sine of the input	$\text{asin}(u)$	asin
acos	Inverse cosine of the input	$\text{acos}(u)$	acos
atan	Inverse tangent of the input	$\text{atan}(u)$	atan

Function	Description	Mathematical Expression	MATLAB Equivalent
atan2	Four-quadrant inverse tangent of the input	$\text{atan2}(u)$	atan2
sinh	Hyperbolic sine of the input	$\text{sinh}(u)$	sinh
cosh	Hyperbolic cosine of the input	$\text{cosh}(u)$	cosh
tanh	Hyperbolic tangent of the input	$\text{tanh}(u)$	tanh
asinh	Inverse hyperbolic sine of the input	$\text{asinh}(u)$	asinh
acosh	Inverse hyperbolic cosine of the input	$\text{acosh}(u)$	acosh
atanh	Inverse hyperbolic tangent of the input	$\text{atanh}(u)$	atanh
sincos	Sine of the input; cosine of the input	—	—
cos + jsin	Complex exponential of the input	—	—

The block output is the result of applying the function to one or more inputs in radians. Each function supports:

- Scalar operations
- Element-wise vector and matrix operations

Note Not all compilers support the `asinh`, `acosh`, and `atanh` functions. If you use a compiler that does not support those functions, a warning appears and the generated code fails to link.

Block Appearance for the atan2 Function

If you select the `atan2` function, the block shows two inputs. The first input is the y -axis or imaginary part of the function argument. The second input is the x -axis or real part of the function argument. (See “Port Location After Rotating or Flipping” in the Simulink documentation for a description of the port order for various block orientations.)

Block Appearance for the sincos Function

If you select the `sincos` function, the block shows two outputs. The first output is the sine of the function argument, and the second output is the cosine of the function argument.

Definitions

CORDIC

CORDIC is an acronym for COordinate Rotation DIgital Computer. The Givens rotation-based CORDIC algorithm is one of the most hardware-efficient algorithms available because it requires only iterative shift-add operations (see References). The CORDIC algorithm eliminates the need for explicit multipliers. Using CORDIC, you can calculate various functions, such as sine, cosine, arc sine, arc cosine, arc tangent, and vector magnitude. You can also use this algorithm for divide, square root, hyperbolic, and logarithmic functions.

Increasing the number of CORDIC iterations can produce more accurate results, but doing so also increases the expense of the computation and adds latency.

Data Type Support

The block accepts input signals of the following data types:

Functions	Input Data Types
<ul style="list-style-type: none"> • sin • cos • sincos • cos + jsin • atan2 	<ul style="list-style-type: none"> • Floating point • Fixed point (only when Approximation method is CORDIC)
<ul style="list-style-type: none"> • tan • asin • acos • atan • sinh • cosh • tanh • asinh • acosh • atanh 	<ul style="list-style-type: none"> • Floating point

Complex input signals are supported for all functions in this block, except atan2.

You can use floating-point input signals when you set **Approximation method** to None or CORDIC. However, the block output data type depends on which of these approximation method options you choose.

Input Data Type	Approximation Method	Output Data Type
Floating point	None	Depends on your selection for Output signal type . Options are auto (same data type as input), real, or complex.
Floating point	CORDIC	Same as input. Output signal type is not available when you use the CORDIC approximation method to compute the block output.

You can use fixed-point input signals only when **Approximation method** is set to CORDIC. The CORDIC approximation is available for the sin, cos, sincos, cos +

$j\sin$, and atan2 functions. For the atan2 function, the relationship between input and output data types depends also on whether the fixed-point input is signed or unsigned.

Input Data Type	Function	Output Data Type
Fixed point, signed or unsigned	\sin , \cos , sincos , and $\cos + j\sin$	$\text{fixdt}(1, WL, WL - 2)$ where WL is the input word length This fixed-point type provides the best precision for the CORDIC algorithm.
Fixed point, signed	atan2	$\text{fixdt}(1, WL, WL - 3)$
Fixed point, unsigned	atan2	$\text{fixdt}(1, WL, WL - 2)$

For CORDIC approximations:

- Input must be real for the \sin , \cos , sincos , $\cos + j\sin$, and atan2 functions.
- Output is real for the \sin , \cos , sincos , and atan2 functions.
- Output is complex for the $\cos + j\sin$ function.

Invalid Inputs for CORDIC Approximations

If you use the CORDIC approximation method (see “Definitions” on page 1-1701), the block input has some further requirements.

For the \sin , \cos , sincos , and $\cos + j\sin$ functions:

- When you use signed fixed-point types, the input angle must fall within the range $[-2\pi, 2\pi)$ radians.
- When you use unsigned fixed-point types, the input angle must fall within the range $[0, 2\pi)$ radians.

For the atan2 function:

- Inputs must be the same size, or at least one value must be a scalar value.
- Both inputs must have the same data type.
- When you use signed fixed-point types, the word length must be **126** or less.
- When you use unsigned fixed-point types, the word length must be **125** or less.

This table summarizes what happens for an invalid input.

Block Usage	Effect of Invalid Input
Simulation	An error appears.
Generated code	Undefined behavior occurs. Avoid relying on undefined behavior for generated code or Accelerator modes.
Accelerator modes	

Parameters

Function

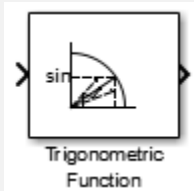

Specify the trigonometric function. The name of the function on the block icon changes to match your selection.

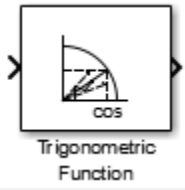

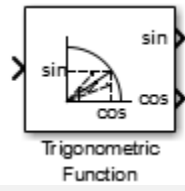

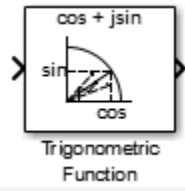

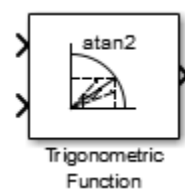

Approximation method

Specify the type of approximation for computing output. This parameter appears only when you set **Function** to `sin`, `cos`, `sincos`, `cos + jsin`, or `atan2`.

Approximation Method	Data Types Supported	When to Use This Method
None (default)	Floating point	You want to use the default Taylor series algorithm.
CORDIC	Floating point and fixed point	You want a fast, approximate calculation.

If you select `CORDIC` and enlarge the block from the default size, the block icon changes:

Function	Block Icon
<code>sin</code>	

Function	Block Icon
cos	
sincos	
cos + jsin	
atan2	

Number of iterations

Specify the number of iterations to perform the CORDIC algorithm. The default value is 11.

- When the block input uses a floating-point data type, the number of iterations can be a positive integer.
- When the block input is a fixed-point data type, the number of iterations cannot exceed the word length.

For example, if the block input is `fixdt(1, 16, 15)`, the word length is 16. In this case, the number of iterations cannot exceed 16.

This parameter appears when both of the following conditions hold:

- You set **Function** to `sin`, `cos`, `sincos`, `cos + jsin`, or `atan2`.
- You set **Approximation method** to `CORDIC`.

Output signal type

Specify the output signal type of the Trigonometric Function block as `auto`, `real`, or `complex`.

Function	Input Signal Type	Output Signal Type		
		Auto	Real	Complex
Any selection for the Function parameter	real	real	real	complex
	complex	complex	error	complex

Note When **Function** is `atan2`, complex input signals are not supported for simulation or code generation.

Setting **Approximation method** to `CORDIC` disables this parameter.

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Examples

sin Function with Floating-Point Input

Suppose that you have the following model:

The key block parameters for the Constant block are:

Parameter	Setting
Constant value	1
Output data type	Inherit: Inherit from 'Constant value'

The block parameters for the Trigonometric Function block are:

Parameter	Setting
Function	sin
Approximation method	None
Output signal type	auto

The output type of the Trigonometric Function block is the same as the input because the input type is floating point and **Approximation method** is None.

sincos Function with Fixed-Point Input

Suppose that you have the following model:

The key block parameters for the Constant block are:

Parameter	Setting
Constant value	1 This value must fall within the range $[-2\pi, 2\pi)$ because the Trigonometric Function block uses the CORDIC algorithm and the block input uses a signed fixed-point type.
Output data type	fixdt(1, 13, 5)

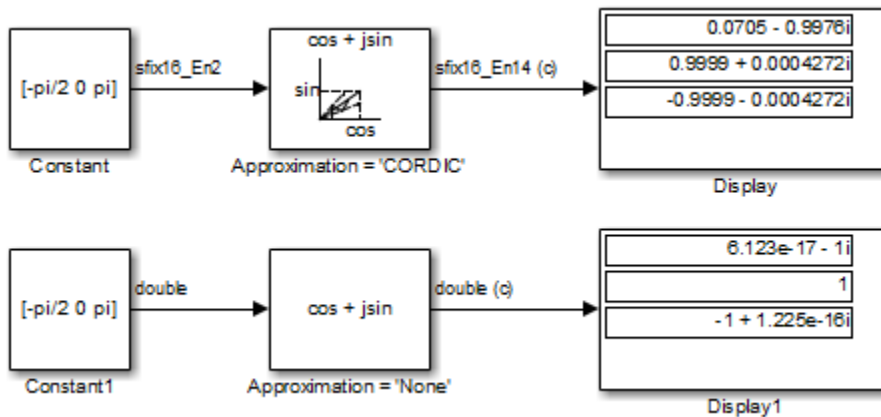

The block parameters for the Trigonometric Function block are:

Parameter	Setting
Function	sincos
Approximation method	CORDIC
Number of iterations	11

The output type of the Trigonometric Function block is `fixdt(1,13,11)` because the input type is fixed point and **Approximation method** is CORDIC. The output fraction length equals the input word length – 2.

Block Behavior for Complex Exponential Output

The following model compares the complex exponential output for the two different approximation methods:

The key block parameters for the Constant blocks are:

Block	Parameter	Setting
Constant	Constant value	$[-\pi/2 \ 0 \ \pi]$
	Output data type	<code>fixdt(1,16,2)</code>
Constant1	Constant value	$[-\pi/2 \ 0 \ \pi]$
	Output data type	<code>double</code>

The block parameters for the Trigonometric Function blocks are:

Block	Parameter	Setting
Approximation = 'CORDIC'	Function	cos + jsin
	Approximation method	CORDIC
	Number of iterations	11
Approximation = 'None'	Function	cos + jsin
	Approximation method	None

When the **Approximation method** is CORDIC, the input data type can be fixed point, in this case: `fixdt(1,16,2)`. The output data type is `fixdt(1,16,14)` because the output fraction length equals the input word length – 2.

When the **Approximation method** is None, the input data type must be floating point. The output data type is the same as the input.

Characteristics

Data Types	Double Single
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Unary Minus

Negate input

Library

Math Operations

Description

The Unary Minus block negates the input.

For signed-integer data types, the unary minus of the most negative value is not representable by the data type. In this case, the **Saturate on integer overflow** check box controls the behavior of the block:

If you...	The block...	And...
Select this check box	Saturates to the most positive value of the integer data type	<ul style="list-style-type: none"> For 8-bit signed integers, -128 maps to 127. For 16-bit signed integers, -32768 maps to 32767. For 32-bit signed integers, -2147483648 maps to 2147483647.
Do not select this check box	Wraps to the most negative value of the integer data type	<ul style="list-style-type: none"> For 8-bit signed integers, -128 remains -128. For 16-bit signed integers, -32768 remains -32768. For 32-bit signed integers, -2147483648 remains -2147483648.

Data Type Support

The Unary Minus block accepts and outputs signals of the following data types:

- Floating point
- Signed integer
- Fixed point

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Sample time

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than -1 . To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Saturate on integer overflow

Select to have integer overflows saturate. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Characteristics

Data Types	Double Single Base Integer Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	No

Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Uniform Random Number

Generate uniformly distributed random numbers

Library

Sources

Description

The Uniform Random Number block generates uniformly distributed random numbers over an interval that you specify. To generate normally distributed random numbers, use the Random Number block.

You can generate a repeatable sequence using any Uniform Random Number block with the same nonnegative seed and parameters. The seed resets to the specified value each time a simulation starts.

Avoid integrating a random signal, because solvers must integrate relatively smooth signals. Instead, use the Band-Limited White Noise block.

The numeric parameters of this block must have the same dimensions after scalar expansion. If you select the **Interpret vector parameters as 1-D** check box and the numeric parameters are row or column vectors after scalar expansion, the block outputs a 1-D signal. If you clear the **Interpret vector parameters as 1-D** check box, the block outputs a signal of the same dimensionality as the parameters.

Data Type Support

The Uniform Random Number block accepts and outputs a real signal of type `double`.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Minimum

Specify the minimum of the interval. The default is -1 .

Maximum

Specify the maximum of the interval. The default is 1 .

Seed

Specify the starting seed for the random number generator. The default is 0 .

The seed must be 0 or a positive integer. Output is repeatable for a given seed.

Sample time

Specify the time interval between samples. The default is 0.1 . See “Specify Sample Time” in the Simulink documentation for more information.

Interpret vector parameters as 1-D

If you select this check box and the other parameters are row or column vectors after scalar expansion, the block outputs a 1-D signal. Otherwise, the block outputs a signal of the same dimensionality as the other parameters. For more information, see “Determining the Output Dimensions of Source Blocks” in the Simulink documentation.

Characteristics

Data Types	Double
Sample Time	Specified in the Sample time parameter
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

The generator algorithm is identical to the one used in MATLAB Version 4.0 by the `rand` and `randn` functions. For details on the `mcg16807` algorithm, see “Choosing a Random Number Generator” (MATLAB) in the MATLAB documentation.

To use other algorithms supported by MATLAB in a Simulink model, generate a set of random numbers in MATLAB, and store the output as a `.mat` file. Use this `.mat` file as the random number input for your simulation. For more information, see “Creating and Controlling a Random Number Stream” (MATLAB). To create multiple independent streams using MATLAB, see “Multiple Streams” (MATLAB)

Note Using multiple seeds to generate multiple parallel independent streams for a generator algorithm is not recommended for the `mcg16807` algorithm. Instead, use the method described above.

Unit System Configuration

Configure units

Library

Ports & Subsystems

Description

The Unit System Configuration block specifies allowed and disallowed unit systems for the component. It restricts units systems for a subsystem or top model and all its children, unless you override it with another Unit System Configuration block in a child.

This block supports normal, accelerator, and rapid accelerator modes and fast restart.

Parameters

Disallowed unit systems

Displays disallowed unit system.

To designate a unit system as disallowed, select it in the **Allowed unit systems** column and click <<**Disallow**.

Default: None

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Allowed unit systems

Displays allowed unit system.

To designate a unit system as allowed, select it in the **Disallowed unit systems** column and click **Allow>>**.

Default: SI, English, SI (extended), CGS

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Allow all unit systems

Allow or restrict unit systems.

Default: On

On

Allow all unit systems.

Off

Restrict unit systems to those in **Allowed unit systems**.

Selecting the **Allow all unit systems** check box disables the **Disallowed unit systems** and **Allowed unit systems** parameters.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Unit Conversion

Convert units

Library

Signal Attributes

Description

The Unit Conversion block converts the unit of the input signal to the output signal. The block can convert if the units are separated by a scaling factor or offset, or are inverse units, for example:

- $y=a*U$
- $y=a*U+b$, where a is the scale and b is the offset
- $y=a/U$

This block supports normal, accelerator, and rapid accelerator modes and fast restart.

Data Type Support

The Unit Conversion block accepts and outputs real or complex values of the following data types:

- Floating point
- Built-in integer
- Fixed point

For more information, see “Data Types Supported by Simulink”.

Parameters

Output data type

Specify the output data type.

Default: `Inherit`: `Inherit via internal rule`

`Inherit`: `Inherit via internal rule`

Simulink chooses intermediate and output data types to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change.

`Inherit`: `Inherit via back propagation`

Output data type is inherited via back propagation. Internal rules determine the intermediate data types and Simulink casts the final results to the output data type.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Converting Units” for more information.

Characteristics

Data Types	Double Single Base Integer Fixed-Point
Sample Time	Inherited from driving block
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Unit Delay

Delay signal one sample period

Library

Discrete

Description

The Unit Delay block holds and delays its input by the sample period you specify. When placed in an iterator subsystem, it holds and delays its input by one iteration. This block is equivalent to the z^{-1} discrete-time operator. The block accepts one input and generates one output. Each signal can be scalar or vector. If the input is a vector, the block holds and delays all elements of the vector by the same sample period.

You specify the block output for the first sampling period with the **Initial conditions** parameter. Careful selection of this parameter can minimize unwanted output behavior. You specify the time between samples with the **Sample time** parameter. A setting of -1 means the block inherits the **Sample time**.

Note The Unit Delay block errors out if you use it to create a transition between blocks operating at different sample rates. Use the Rate Transition block instead.

Comparison with Similar Blocks

Blocks with Similar Functionality

The Unit Delay, Memory, and Zero-Order Hold blocks provide similar functionality but have different capabilities. Also, the purpose of each block is different. The sections that follow highlight some of these differences.

Recommended Usage for Each Block

Block	Purpose of the Block	Reference Examples
Unit Delay	Implement a delay using a discrete sample time that you specify. The block accepts and outputs signals with a discrete sample time.	<ul style="list-style-type: none"> sldemo_enginewc (Compression subsystem)
Memory on page 1-915	Implement a delay by one major integration time step. Ideally, the block accepts continuous (or fixed in minor time step) signals and outputs a signal that is fixed in minor time step.	<ul style="list-style-type: none"> sldemo_bounce sldemo_clutch (Friction Mode Logic/Lockup FSM subsystem)
Zero-Order Hold	Convert an input signal with a continuous sample time to an output signal with a discrete sample time.	<ul style="list-style-type: none"> sldemo_radar_eml aero_dap3dof

Overview of Block Capabilities

Capability	Block		
	Unit Delay	Memory	Zero-Order Hold
Specification of initial condition	Yes	Yes	No, because the block output at time $t = 0$ must match the input value.

Capability	Block		
	Unit Delay	Memory	Zero-Order Hold
Specification of sample time	Yes	No, because the block can only inherit sample time (from the driving block or the solver used for the entire model).	Yes
Support for frame-based signals	Yes	No	Yes
Support for state logging	Yes	No	No

Data Type Support

The Unit Delay block accepts real or complex signals of any data type that Simulink supports, including fixed-point and enumerated data types. If the data type of the input signal is user-defined, the initial condition must be zero.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

During simulation, the block uses the following values:

- The initial value of the signal object to which the state name is resolved
- Min and Max values of the signal object

For more information, see “Discrete Block State Naming in Generated Code” (Simulink Coder) in the Simulink Coder documentation.

Initial conditions

Specify the output of the simulation for the first sampling period, during which the output of the Unit Delay block is otherwise undefined.

Default: 0

The **Initial conditions** parameter is converted from a double to the input data type offline using round-to-nearest and saturation.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Input processing

Specify whether the Unit Delay block performs sample- or frame-based processing.

Default: Elements as channels (sample based)

Elements as channels (sample based)

Treat each element of the input as a separate channel (sample-based processing).

Columns as channels (frame based)

Treat each column of the input as a separate channel (frame-based processing).

Inherited

Sets the block to inherit the processing mode from the input signal and delay the input accordingly. You can identify whether the input signal is sample or frame based by looking at the signal line. Simulink represents sample-based signals with a single line and frame-based signals with a double line.

Note When you choose the `Inherited` option for the **Input processing** parameter, and the input signal is frame-based, Simulink® will generate a warning or error in future releases.

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input `u`. All other input signals must be sample based.

Input Signal <code>u</code>	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error

Input Signal u	Input Processing Mode	Block Works?
Sample based	Frame based	Yes
Frame based		Yes
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox) in the DSP System Toolbox documentation.

Frame-based processing requires a DSP System Toolbox license.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Sample time (-1 for inherited)

Enter the discrete interval between sample time hits or specify -1 to inherit the sample time.

Default: -1

By default, the block inherits its sample time based upon the context of the block within the model. To set a different sample time, enter a valid sample time based upon the table in “Types of Sample Time”.

See also “Specify Sample Time” in the online documentation for more information.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

State name

Use this parameter to assign a unique name to each state.

Default: ' '

- If left blank, no name is assigned.
- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

This parameter enables **State name must resolve to Simulink signal object** when you click the **Apply** button.

For more information, see “Discrete Block State Naming in Generated Code” (Simulink Coder).

Parameter: StateName

Type: character vector

Value: ' '

Default: ' '

State name must resolve to Simulink signal object

Require that state name resolve to Simulink signal object.

Default: Off

On

Require that state name resolve to Simulink signal object.

Off

Do not require that state name resolve to Simulink signal object.

State name enables this parameter. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than `None`.

Selecting this check box disables **Code generation storage class**.

Parameter: StateMustResolveToSignalObject

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Signal object class

Choose a custom storage class package by selecting a signal object class that the target package defines. For example, to apply custom storage classes from the built-in package `mpt`, select `mpt.Signal`. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes do not affect the generated code.

To programmatically set this parameter, use `StateSignalObject`.

For examples and more information about storage classes, see “Control Signals and States in Code by Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

`Simulink.Signal`

Use custom storage classes from the built-in package `Simulink`.

Package.Class

Use custom storage classes from the package that defines the class that you select.

If the class that you want does not appear in the list, select `Customize class lists`. For instructions, see “Apply Custom Storage Classes Directly to Signal Lines, Block States, and Outport Blocks” (Embedded Coder).

Code generation storage class

Select state storage class for code generation.

Default: `Auto`

`Auto`

`Auto` is the appropriate storage class for states that you do not need to interface to external code.

StorageClass

Applies the storage class or custom storage class that you select from the list. For information about storage classes, see “Control Signals and States in Code by

Applying Storage Classes” (Simulink Coder). For information about custom storage classes, see “Control Data Representation by Applying Custom Storage Classes” (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than Simulink.

State name enables this parameter.

TypeQualifier

Note **TypeQualifier** will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

Specify a storage type qualifier such as `const` or `volatile`.

- **Default:** ' ' (empty character vector)
- `const`
- `volatile`

Setting **Code generation storage class** to `ExportedGlobal`, `ImportedExtern`, `ImportedExternPointer`, or `SimulinkGlobal` enables this parameter. This parameter is hidden unless you previously set its value.

Parameter Name: `RTWStateStorageTypeQualifier`
Value Type: character vector
Default: ' ' (empty character vector)

Bus Support

The Unit Delay block is a bus-capable block. The input can be a virtual or nonvirtual bus signal subject to the following restrictions:

- **Initial conditions** must be zero, a nonzero scalar, or a finite numeric structure.
- If **Initial conditions** is zero or a structure, and you specify a **State name**, the input cannot be a virtual bus.
- If **Initial conditions** is a nonzero scalar, no **State name** can be specified.

For information about specifying an initial condition structure, see “Specify Initial Conditions for Bus Signals”.

All signals in a nonvirtual bus input to a Unit Delay block must have the same sample time, even if the elements of the associated bus object specify inherited sample times. You can use a Rate Transition block to change the sample time of an individual signal, or of all signals in a bus. See “Specify Bus Signal Sample Times” and Bus-Capable Blocks for more information.

You can use an array of buses as an input signal to a Unit Delay block. You can specify the **Initial conditions** parameter with:

- The value 0. In this case, all of the individual signals in the array of buses use the initial value 0.
- An array of structures that specifies an initial condition for each of the individual signals in the array of buses.
- A single scalar structure that specifies an initial condition for each of the elements that the bus type defines. Use this technique to specify the same initial conditions for each of the buses in the array.

For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

Examples

For an example of how to use the Unit Delay block, see the `sldemo_enginewc` model. The Unit Delay block appears in the `Compression` subsystem.

Characteristics

Unit Delay Enabled Resettable Synchronous

Delay input signal by one sample period when external Enable signal is true and external Reset signal is false

Library: HDL Coder / Discrete / Unit Delay Enabled
Resettable Synchronous

Description

The Unit Delay Enabled Resettable Synchronous block combines the functionality of the Unit Delay Enabled Synchronous block and the Unit Delay Resettable Synchronous block.

The Unit Delay Enabled Resettable Synchronous block delays the input signal u by one sample period when the external Enable signal is true and when the external Reset signal is false. When the Enable signal is false, the state and output signal hold the previous value. When the Reset signal is true, the state and output signal take the value of the **Initial condition** parameter. The Enable and Reset signals are true when E and R are nonzero and false when E and R equal zero.

The Unit Delay Enabled Synchronous block implementation consists of a Synchronous Subsystem that contains an Enabled Delay block with a **Delay length** of one and a State Control block in *Synchronous* mode. When you use this block in your model and have HDL Coder installed, your model generates cleaner HDL code and uses fewer hardware resources due to the *Synchronous* behavior of the State Control block.

Limitations

- The block does not support vector inputs on the Reset and Enable ports.
- You cannot use the block inside Enabled Subsystem, Triggered Subsystem, or Resettable Subsystem blocks that use *Classic* semantics. The Subsystem must use *Synchronous* semantics.

Ports

Input

u — Input signal

Scalar | Vector | Matrix | Array | Bus

The Unit Delay Enabled Resettable Synchronous block accepts the input signal of the data types listed below. For more information, see “Data Types Supported by Simulink”.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Input

E — Enable signal

Scalar

The Unit Delay Enabled Synchronous block accepts the Enable signal of the data types listed below. For more information, see “Data Types Supported by Simulink”.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

R — Reset signal

Scalar

The Unit Delay Resettable Synchronous block accepts the Reset signal of the data types listed below. For more information, see “Data Types Supported by Simulink”.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Output

y — Output signal

Scalar | Vector | Matrix | Array | Bus

Output data type always matches input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Initial condition — Initial output of simulation

0.0 (default) | `Scalar` | `Vector` | `Matrix` | `Array` | `Bus`

The **Initial condition** can take a scalar input or use the same data type as the input signal. You cannot run the simulation with NaN or Inf as the **Initial condition**.

Programmatic Use

Block parameter: `InitialCondition`

Type: character vector

Value: `'0'` | `'[n]'` | `'[m n]'`

Default: `'0'`

Sample time — Time interval between samples

-1 (default) | `Scalar` | `Vector`

The **Sample time** must be a real double scalar that specifies the period or a real double vector of length two that specifies the period and offset. The period and offset must be finite and non-negative with offset less than the period.

Programmatic Use

Block parameter: `SampleTime`

Type: character vector

Value: `'-1'` | `'[n]'` | `'[m n]'`

Default: `'-1'`

Block Characteristics

Data Types	<code>double</code> <code>single</code> <code>base integer</code> <code>fixed point</code> <code>bus</code>
Sample Time	<code>Inherit</code>

Introduced in R2017b

Unit Delay Enabled Synchronous

Delay input signal by one sample period when external Enable signal is true

Library: HDL Coder / Discrete / Unit Delay Enabled
Synchronous

Description

The Unit Delay Enabled Synchronous block delays the input signal u by one sample period when the external Enable signal is true. When the Enable signal is false, the state and output signal hold the previous value. The Enable signal is true when E is not zero and false when E is zero.

The Unit Delay Enabled Synchronous block implementation consists of a Synchronous Subsystem that contains an Enabled Delay block with a **Delay length** of one and a State Control block in Synchronous mode. When you use this block in your model and have HDL Coder installed, your model generates cleaner HDL code and uses fewer hardware resources due to the Synchronous behavior of the State Control block.

Limitations

- The block does not support vector inputs on the Enable port.
- You cannot use the block inside Enabled Subsystem, Triggered Subsystem, or Resettable Subsystem blocks that use Classic semantics. The Subsystem must use Synchronous semantics.

Ports

Input

u — Input signal

Scalar | Vector | Matrix | Array | Bus

The Unit Delay Enabled Synchronous block accepts the input signal of the data types listed below. For more information, see “Data Types Supported by Simulink”.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Input

E — Enable signal

Scalar

The Unit Delay Enabled Synchronous block accepts the Enable signal of the data types listed below. For more information, see “Data Types Supported by Simulink”.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Output

y — Output signal

Scalar | Vector | Matrix | Array | Bus

Output data type always matches input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Initial condition — Initial output of simulation

0.0 (default) | Scalar | Vector | Matrix | Array | Bus

The **Initial condition** can take a scalar input or use the same data type as the input signal. You cannot run the simulation with NaN or Inf as the **Initial condition**.

Programmatic Use

Block parameter: InitialCondition

Type: character vector

Value: '0' | '[n]' | '[m n]'

Default: '0'

Sample time — Time interval between samples

-1 (default) | Scalar | Vector

The **Sample time** must be a real double scalar that specifies the period or a real double vector of length two that specifies the period and offset. The period and offset must be finite and non-negative with offset less than the period.

Programmatic Use

Block parameter: SampleTime

Type: character vector

Value: '-1' | '[n]' | '[m n]'

Default: '-1'

Block Characteristics

Data Types	double single base integer fixed point bus
Sample Time	Inherit
Direct Feedthrough	Yes
Multidimensional Signals	Scalar
Variable-Size Signals	Yes
Zero-Crossing Detection	No

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

Fixed-Point Conversion

Design and simulate fixed-point algorithms using Fixed-Point Designer™.

Resettable Synchronous

Introduced in R2017b

Unit Delay Resettable Synchronous

Delay input signal by one sample period when external Reset signal is false

Library: HDL Coder / Discrete / Unit Delay Resettable Synchronous

Description

The Unit Delay Resettable Synchronous block delays the input signal u by one sample period when the external Reset signal is false. When the Reset signal is true, the state and output signal take the value of the **Initial condition** parameter. The Reset signal is true when R is not zero and false when R is zero.

The Unit Delay Resettable Synchronous block implementation consists of a Synchronous Subsystem that contains a Resettable Delay block with a **Delay length** of one and a State Control block in Synchronous mode. When you use this block in your model and have HDL Coder installed, your model generates cleaner HDL code and uses fewer hardware resources due to the Synchronous behavior of the State Control block.

Limitations

- The block does not support vector inputs on the Reset port.
- You cannot use the block inside Enabled Subsystem, Triggered Subsystem, or Resettable Subsystem blocks that use Classic semantics. The Subsystem must use Synchronous semantics.

Ports

Input

u — Input signal

Scalar | Vector | Matrix | Array | Bus

The Unit Delay Resettable Synchronous block accepts the input signal of the data types listed below. For more information, see “Data Types Supported by Simulink”.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Input

R — Reset signal

Scalar

The Unit Delay Resettable Synchronous block accepts the Reset signal of the data types listed below. For more information, see “Data Types Supported by Simulink”.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Output

y — Output signal

Scalar | Vector | Matrix | Array | Bus

Output data type always matches input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Initial condition — Initial output of simulation

0.0 (default) | Scalar | Vector | Matrix | Array | Bus

The **Initial condition** can take a scalar input or use the same data type as the input signal. You cannot run the simulation with NaN or Inf as the **Initial condition**.

Programmatic Use

Block parameter: InitialCondition

Type: character vector

Value: '0' | '[n]' | '[m n]'

Default: '0'

Sample time — Time interval between samples

-1 (default) | Scalar | Vector

The **Sample time** must be a real double scalar that specifies the period or a real double vector of length two that specifies the period and offset. The period and offset must be finite and non-negative with offset less than the period.

Programmatic Use

Block parameter: SampleTime

Type: character vector

Introduced in R2012b

Variable Time Delay, Variable Transport Delay

Delay input by variable amount of time

Library

Continuous

Description

The Variable Transport Delay and Variable Time Delay appear as two blocks in the Simulink block library. However, they are the same Simulink block with different settings of a **Select delay type** parameter. Use this parameter to specify the mode in which the block operates.

Variable Time Delay

In this mode, the block has a data input, a time delay input, and a data output. (See “Port Location After Rotating or Flipping” in the Simulink documentation for a description of the port order for various block orientations.) The output at the current time step equals the value of its data input at a previous time step. This time step is the current simulation time minus a delay time specified by the time delay input.

$$y(t) = u(t - t_0) = u(t - \tau(t))$$

During the simulation, the block stores time and input value pairs in an internal buffer. At the start of simulation, the block outputs the value of the **Initial output** parameter until the simulation time exceeds the time delay input. Then, at each simulation step,

the block outputs the signal at the time that corresponds to the current simulation time minus the delay time.

If you want the output at a time between input storing times and the solver is a continuous solver, the block interpolates linearly between points. If the time delay is smaller than the step size, the block extrapolates an output point from a previous point. For example, consider a fixed-step simulation with a step size of 1 and the current time at $t = 5$. If the delay is 0.5, the block needs to generate a point at $t = 4.5$, but the most recent stored time value is at $t = 4$. Thus, the block extrapolates the input at 4.5 from the input at 4 and uses the extrapolated value as its output at $t = 5$.

Extrapolating forward from the previous time step can produce a less accurate result than extrapolating back from the current time step. However, the block cannot use the current input to calculate its output value because the input port does not have direct feedthrough.

If the model specifies a discrete solver, the block does not interpolate between time steps. Instead, it returns the nearest stored value that precedes the required value.

Variable Transport Delay

In this mode, the block output at the current time step is equal to the value of its data (top, or left) input at an earlier time step equal to the current time minus a transportation delay.

$$y(t) = u(t - t_d(t))$$

Simulink software finds the transportation delay, $t_d(t)$, by solving the following equation:

$$\int_{t-t_d(t)}^t \frac{1}{t_i(\tau)} d\tau = 1$$

This equation involves an instantaneous time delay, $t_i(t)$, given by the time delay (bottom, or right) input.

Suppose you want to use this block to model the fluid flow through a pipe where the fluid speed varies with time. In this case, the time delay input to the block is

$$t_i(t) = \frac{L}{v_i(t)}$$

where L is the length of the pipe and $v_i(t)$ is the speed of the fluid.

Data Type Support

The Variable Time Delay and Variable Transport Delay blocks accept and output real signals of type `double`.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Select delay type

Specify the mode in which the block operates.

Default: The Variable Time Delay block has a default value of `Variable time delay`. The Variable Transport Delay block has a default value of `Variable transport delay`.

`Variable time delay`

Specifies a Variable Time Delay block.

Variable transport delay

Specifies a Variable Transport Delay block.

Setting this parameter to `Variable time delay` enables the **Handle zero delay** parameter.

Setting this parameter to `Variable transport delay` enables the **Absolute tolerance** and **State Name** parameters.

Parameter: `VariableDelayType`

Type: character vector

Value: `'Variable transport delay' | 'Variable time delay'`

Default: `'Variable time delay'`

Maximum delay

Set the maximum value of the time delay input.

Default: 10

- This value defines the largest time delay input that this block allows. The block clips any delay that exceeds this value.
- This value cannot be negative. If the time delay becomes negative, the block clips it to zero and issues a warning message.

Parameter: `MaximumDelay`

Type: scalar or vector

Value: `'10'`

Default: `'10'`

Initial output

Specify the output that the block generates until the simulation time first exceeds the time delay input.

Default: Run-to-run tunable parameter

A Run-to-run tunable parameter cannot be changed during simulation run time. However, changing it before a simulation begins will not cause Accelerator or Rapid Accelerator to regenerate code. Also, the initial output of this block cannot be `inf` or `NaN`.

Parameter: `InitialOutput`

Type: scalar or vector

Value: '0'

Default: '0'

Initial buffer size

Define the initial memory allocation for the number of input points to store. The input points define the history of the input signal up to the current simulation time.

Default: 1024

- If the number of input points exceeds the initial buffer size, the block allocates additional memory.
- After simulation ends, a message displays if the buffer is not sufficient and more memory needs to be allocated.
- Because allocating memory slows down simulation, choose this value carefully if simulation speed is an issue.
- For long time delays, this block might use a large amount of memory, particularly for dimensionalized input.

Parameter: `MaximumPoints`

Type: scalar

Value: '1024'

Default: '1024'

Use fixed buffer size

Specify use of a fixed-size buffer to save input data from previous time steps.

Default: Off

On

The block uses a fixed-size buffer.

Off

The block does not use a fixed-size buffer.

The **Initial buffer size** parameter specifies the buffer size. If the buffer is full, new data replaces data already in the buffer. Simulink software uses linear extrapolation to estimate output values that are not in the buffer.

Note ERT or GRT code generation uses a fixed-size buffer even if you do not select this check box.

- If the input data is linear, selecting this check box can save memory.
- If the input data is nonlinear, do not select this check box. Doing so might yield inaccurate results.

Parameter: FixedBuffer

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Handle zero delay

Convert this block to a direct feedthrough block.

Default: Off

On

The block uses direct feedthrough.

Off

The block does not use direct feedthrough.

Setting **Select delay type** to `Variable time delay` enables this parameter.

Parameter: ZeroDelay

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Direct feedthrough of input during linearization

Cause the block to output its input during linearization and trim, which sets the block mode to direct feedthrough.

Default: Off

On

Enables direct feedthrough of input.

Off

Disables direct feedthrough of input.

- Selecting this check box can cause a change in the ordering of states in the model when you use the functions `linmod`, `dlinmod`, or `trim`. To extract this new state ordering:

- 1 Compile the model using the following command, where `model` is the name of the Simulink model.

```
[sizes, x0, x_str] = model([], [], [], 'lincompile');
```

- 2 Terminate the compilation with the following command.

```
model([], [], [], 'term');
```

- The output argument `x_str`, which is a cell array of the states in the Simulink model, contains the new state ordering. When you pass a vector of states as input to the `linmod`, `dlinmod`, or `trim` functions, the state vector must use this new state ordering.

Parameter: TransDelayFeedthrough

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Pade order (for linearization)

Set the order of the Pade approximation for linearization routines.

Default: 0

- The default value is 0, which results in a unity gain with no dynamic states.
- Setting the order to a positive integer n adds n states to your model, but results in a more accurate linear model of the transport delay.

Parameter: PadeOrder

Type: character vector

Value: '0'

Default: '0'

Absolute tolerance

Specify the absolute tolerance for computing the block state.

Default: auto

- You can enter `auto`, `-1`, or a positive real scalar or vector.
- If you enter `auto`, or `-1`, then Simulink uses the absolute tolerance value in the Configuration Parameters dialog box (see “Solver Pane”) to compute the block states.
- If you enter a real scalar, then that value overrides the absolute tolerance in the Configuration Parameters dialog box for computing all block states.
- If you enter a real vector, then the dimension of that vector must match the dimension of the continuous states in the block. These values override the absolute tolerance in the Configuration Parameters dialog box.

Setting **Select delay type** to `Variable transport delay` enables this parameter.

Parameter: AbsoluteTolerance

Type: character vector, scalar, or vector

Value: 'auto' | '-1' | any positive real scalar or vector

Default: 'auto'

State Name (e.g., 'position')

Assign a unique name to each state.

Default: ' '

If this field is blank, no name assignment occurs.

- To assign a name to a single state, enter the name between quotes, for example, 'velocity'.
- To assign names to multiple states, enter a comma-delimited list surrounded by braces, for example, {'a', 'b', 'c'}. Each name must be unique.
- The state names apply only to the selected block.
- The number of states must divide evenly among the number of state names.
- You can specify fewer names than states, but you cannot specify more names than states.

For example, you can specify two names in a system with four states. The first name applies to the first two states and the second name to the last two states.

- To assign state names with a variable in the MATLAB workspace, enter the variable without quotes. A variable can be a character vector, cell array, or structure.

Setting **Select delay type** to Variable transport delay enables this parameter.

Parameter: ContinuousStateAttributes

Type: character vector

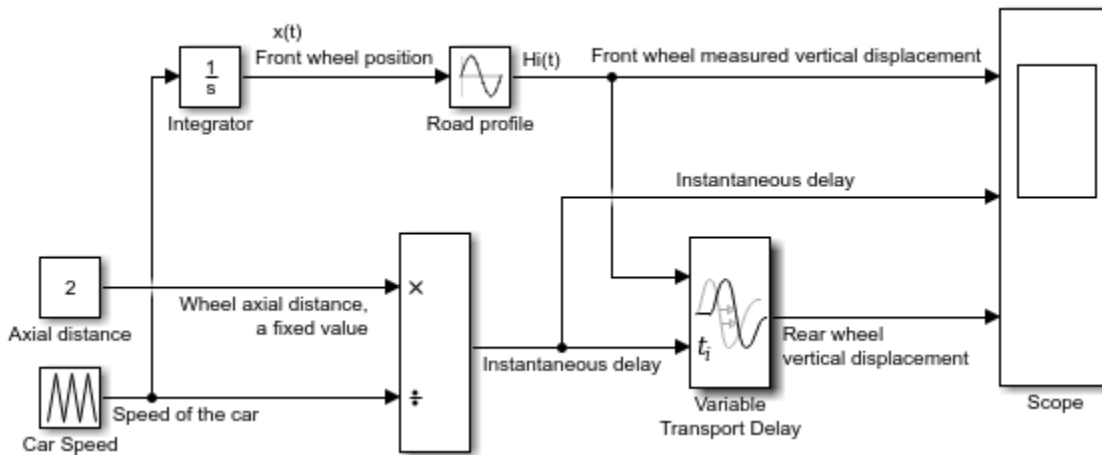

Value: ' ' | user-defined

Default: ' '

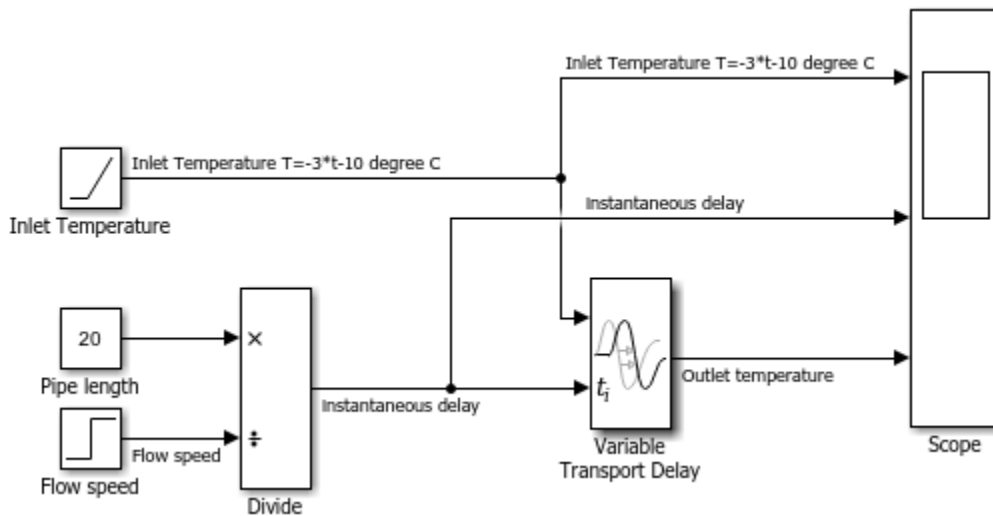

Examples

The `sldemo_VariableTransportDelay` and `sldemo_VariableTransportDelay_pipe` models show how you can use the Variable Transport Delay block.

The `sldemo_VariableTransportDelay` model shows how to model vertical wheel displacement on a one-dimensional car. The Variable Transport Delay block models the delay in vertical displacement of the rear wheel when the road profile changes:

The `sldemo_VariableTransportDelay_pipe` model shows how to model incompressible flow through a fixed-length pipe. The Variable Transport Delay block models the delay in temperature change at the outlet when fluid flow occurs:

Characteristics

Data Types	Double

Variant Sink

Route amongst multiple outputs using variants

Library

Signal Routing

Description

The Variant Sink block has one input port and one or more output ports. You can define variant choices as blocks that are connected to the output port so that, at most, one choice is active.

Each output port is associated with a variant control. The variant control that evaluates to `true`, determines which output port is active.

During simulation, Simulink connects the active choice directly to the input port of the Variant Sink block and ignores the inactive choices.

Parameters

Ports and associated conditions

A table of port choices, variant controls, and conditions. The **Variant control** that evaluates to `true` determines which input port must be active.

Default: The table has a row for each variant choice exiting in the Variant Sink block. See each column parameter for its default value:

- “Port” on page 1-1759
- “Variant Control” on page 1-1759
- “Condition (read-only)” on page 1-1760
- “Define, Configure, and Activate Variants”
- “Introduction to Variant Controls”

Port

Number of the input port that is connected to one variant choice upstream of the Variant Sink block

A read-only field, based on the input port that is connected to one variant choice upstream of the Variant Sink block.

Click  to add a port or  to delete an existing one.

Variant Control

Displays the variant controls available in the base workspace. The variant control can be a Boolean condition expression or a `Simulink.Variant` object representing a Boolean condition expression. If you want to generate code for your model, you must define the control variables as `Simulink.Parameter` objects.

Default: `Variant`

To enter a variant name, double-click a **Variant control** cell in a new row and type in the variant control expression. Click **Apply** after you edit a variant control name. If you add or delete a variant control without applying the changes, the previous edits on the variant control name are lost.

Parameter: `VariantControls`

Type: cell array of character vectors

Value: Variant control that is associated with the variant choice.

Default: ''

Condition (read-only)

Displays the **Condition** for the variant controls that are `Simulink.Variant` objects.

A read-only field, based on the condition for the associated variant control in the base workspace. Create or change a variant condition in the `Simulink.Variant` parameter dialog box or in the base workspace.

- “Create Variant Controls Programmatically”
- `Simulink.Variant`

Override variant conditions and use the following variant

Ignores the variant control value while determining the active variant and uses the overridden variant control as the active variant. The overriding variant control must be defined in the variant block dialog box.

If you do not select this option, Simulink determines the active variant choice based on the variant control that evaluates to `true` in the global workspace.

When you select this option, the variant badge indicates the change.

Default: Off

On

Use the specified variant instead of selecting the active variant from the variant control.

Off

Determine the active variant choice based on the variant control that evaluates to true.

This parameter enables **Variant**.

Parameter: OverrideUsingVariant

Type: character vector

Value: ' ' if no overriding variant is specified.

Default: ' '

- “Working with Variant Choices”

Variant

Select the variant control that Simulink uses if you select **Override variant conditions and use the following variant**.

Default: ' '

The **Variant** drop-down list displays all variant controls that are currently defined in the base workspace or a data dictionary. Use valid MATLAB identifiers to specify variant controls.

Override variant conditions and use the following variant enables this parameter.

Parameter: OverrideUsingVariant

Type: character vector

Value: Specified by the variant control expression.

- Simulink.Variant

Allow zero active variant controls

To simulate a model (containing a variant block) without an active variant choice, select the **Allow zero active variant controls** option. When this option is selected and there

is no active variant choice, Simulink disables all the blocks connected to the input and output stream of Variant Sink block. The removed blocks are ignored from update diagram or simulation.

If you do not select this option, Simulink generates an error when there is no active variant choice.

When you select this option, the variant badge indicates the change.

Default: Disabled

Parameter: AllowZeroVariantControls

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Show variant condition on block

When you select this option, Simulink annotates each variant control (condition expression) on the Variant Sink block ports.

Default: Disabled

Parameter: ShowConditionOnBlock

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Analyze all choices during update diagram and generate preprocessor conditionals

When you select this option, Simulink analyzes all variant choices during an update diagram or simulation. This analysis helps Simulink to maintain consistency of all

variant branches during simulation and code generation. Simulink routes the output of the active and inactive regions to an internal `VariantMerge` block.

When this option is selected, the preprocessor conditionals (`#if`) are generated in the code with ERT-based targets.

When you select this option, the variant badge indicates the change.

Default: Disabled

- The check box is available for generating ERT targets only.
- **Override variant conditions and use following variant** is cleared ('off')

Parameter: `GeneratePreprocessorConditionals`

Type: character vector

Value: 'off' | 'on'

Default: 'off'

- “Represent Variant Source and Sink Blocks in Generated Code” (Embedded Coder)

Variant Source

Route amongst multiple inputs using variants

Library

Signal Routing

Description

The Variant Source block has one or more input ports and one output port. You can define variant choices as blocks that are connected to the input port so that, at most, one choice is active.

Each input port is associated with a variant control. The variant control that evaluates to `true`, determines which input port is active.

During simulation, Simulink connects the active choice directly to the output port of the Variant Source block and ignores the inactive choices.

Parameters

Ports and associated conditions

A table of port choices, variant controls, and conditions. The **Variant control** that evaluates to `true` determines which input port must be active.

Default: The table has a row for each variant choice feeding into the Variant Source block. See each column parameter for its default value:

- “Port” on page 1-1766
- “Variant Control” on page 1-1766
- “Condition (read-only)” on page 1-1767

- “Define, Configure, and Activate Variants”
- “Introduction to Variant Controls”

Port

Number of the input port that is connected to one variant choice upstream of the Variant Source block

A read-only field, based on the input port that is connected to one variant choice upstream of the Variant Source block.

Click  to add a port or  to delete an existing one.

Variant Control

Displays the variant controls available in the base workspace. The variant control can be a Boolean condition expression or a `Simulink.Variant` object representing a Boolean condition expression. If you want to generate code for your model, you must define the control variables as `Simulink.Parameter` objects.

Default: `Variant`

To enter a variant name, double-click a **Variant control** cell in a new row and type in the variant control expression. Click **Apply** after you edit a variant control name. If you add or delete a variant control without applying the changes, the previous edits on the variant control name are lost.

Parameter: `VariantControls`

Type: cell array of character vectors

Value: Variant control that is associated with the variant choice.

Default: ''

Condition (read-only)

Displays the **Condition** for the variant controls that are `Simulink.Variant` objects.

A read-only field, based on the condition for the associated variant control in the base workspace. Create or change a variant condition in the `Simulink.Variant` parameter dialog box or in the base workspace.

- “Create Variant Controls Programmatically”
- `Simulink.Variant`

Override variant conditions and use the following variant

Ignores the variant control value while determining the active variant and uses the overridden variant control as the active variant. The overriding variant control must be defined in the variant block dialog box.

If you do not select this option, Simulink determines the active variant choice based on the variant control that evaluates to `true` in the global workspace.

When you select this option, the variant badge indicates the change.

Default: Off

On

Use the specified variant instead of selecting the active variant from the variant control.

Off

Determine the active variant choice based on the variant control that evaluates to true.

This parameter enables **Variant**.

Parameter: OverrideUsingVariant

Type: character vector

Value: ' ' if no overriding variant is specified.

Default: ' '

- “Working with Variant Choices”

Variant

Select the variant control that Simulink uses if you select **Override variant conditions and use the following variant**.

Default: ' '

The **Variant** drop-down list displays all variant controls that are currently defined in the base workspace or a data dictionary. Use valid MATLAB identifiers to specify variant controls.

Override variant conditions and use the following variant enables this parameter.

Parameter: OverrideUsingVariant

Type: character vector

Value: Specified by the variant control expression.

- Simulink.Variant

Allow zero active variant controls

To simulate a model (containing a variant block) without an active variant choice, select the **Allow zero active variant controls** option. When this option is selected and there

is no active variant choice, Simulink disables all the blocks connected to the input and output stream of Variant Source block. The removed blocks are ignored from update diagram or simulation.

If you do not select this option, Simulink generates an error when there is no active variant choice.

When you select this option, the variant badge indicates the change.

Default: Disabled

Parameter: AllowZeroVariantControls

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Show variant condition on block

When you select this option, Simulink annotates each variant control (condition expression) on the Variant Source block ports.

Default: Disabled

Parameter: ShowConditionOnBlock

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Analyze all choices during update diagram and generate preprocessor conditionals

When you select this option, Simulink analyzes all variant choices during an update diagram or simulation. This analysis helps Simulink to maintain consistency of all variant branches during simulation and code generation. Simulink routes the output of the active and inactive regions to an internal `VariantMerge` block.

When this option is selected, the preprocessor conditionals (`#if`) are generated in the code with ERT-based targets.

If this option is selected during code generation, the data type and the semantics at all input ports of the Variant Source block must be same to avoid failure.

When you select this option, the variant badge indicates the change.

Default: Disabled

- The check box is available for generating ERT targets only.
- **Override variant conditions and use following variant** is cleared ('off')

Parameter: `GeneratePreprocessorConditionals`

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Variant Subsystem Variant Model

Template subsystem containing Subsystem blocks as variant choices

Library: Simulink / Ports & Subsystems

Description

The Variant Subsystem and Variant Subsystem blocks each can have one active choice for simulation. The Variant Subsystem block is a template preconfigured to contain two Subsystem blocks to use as variant systems. The Variant Model block is a template preconfigured to contain two Model blocks to use as variant systems. The Variant Subsystem and Variant Model blocks (variant system container blocks) can contain a mixture of Subsystem and Model blocks as variant systems. The variant system container blocks can also include Inport, Outport, and Connection Port blocks. There are no drawn connections inside the variant system container blocks.

Each variant system is associated with a variant control that is created in the base workspace. The variant control determines which variant system is active. The variant control can be a condition expression, a `Simulink.Variant` object specifying a condition expression, or a default variant. The variant control that evaluates to `true` determines the active variant.

When you select the **Specify output when source is unconnected** option in the Outport block that is in a variant subsystem container block, you can specify a nonground value as its output. Specify the data type in the **Signal Attributes** section of the Outport block dialog box.

Note If you need to use variant systems that are conditionally executed models (models with control ports), then use a Model block as a container for variant models. Otherwise, use a Subsystem Variant or Model Variant block to contain variant systems. Support for using a Model block to contain model variants will be removed in a future release.

For new models, use a Model block for model variants only if you need to use variants that are conditionally executed models (referenced models with control ports). Using a

Model block for variant models is supported for backward compatibility. However, support for using a Model block to contain model variants will be removed in a future release. For an example of a model that uses a Variant Subsystem block as a container for variant models, see “Model Reference Variants”.

Ports

During simulation, Simulink disables the inactive ports in a variant subsystem container block.

Input

Input_Port_1 — Input port corresponding to root-level Inport blocks contained in variant subsystem

same data types accepted by Inport blocks

Each Subsystem or Model block contained within a variant subsystem represents one variant system. If the inport names on a variant system are a subset of the inport names used by the variant subsystem container block, then variant system blocks can have different numbers of inports than the variant subsystem container block has.

Output

Output_Port_1 — Output port corresponding to root-level Outport blocks contained in variant subsystem

same data types accepted by Outport blocks

Each Subsystem or Model block contained within a variant subsystem represents one variant system. If the outport names on a variant system are a subset of the outport names used by the variant subsystem container block, then variant system blocks can have different numbers of outports than the variant subsystem container block has.

Parameters

Variant choices (table of variant systems) — Table of variant choices, variant controls, and conditions

empty table (default)

The table has a row for each variant system contained in the variant subsystem. If there are no variant systems, the table is empty.

You can use buttons to the left of the **Variant choices** table to modify the elements in the table.

To...	Click...
Create and add a new subsystem choice: Place a new subsystem variant choice in the table and create a Subsystem block in the variant subsystem container block diagram.	
Create and add a new model variant choice: Place a new model variant choice in the table and create a Model block in the variant subsystem container block.	
Create/Edit selected variant object: Create a Simulink.Variant object in the base workspace and open the Simulink.Variant object parameter dialog box to specify the variant Condition .	
Open selected variant choice block: Open the subsystem block diagram for the selected row in the Variant choices table.	
Refresh dialog information from Variant Subsystem contents: Update the Variant choices table according to the variant system and values of the variant control in the base workspace.	

Name (read-only) — Variant system name

' ' (default) | name of Subsystem or Model block contained in the variant subsystem

This read-only field is based on the variant system name. To add a subsystem variant choice, click . To add a model variant choice, click .

Variant Control — Variant control in base workspace

Variant (default) | boolean condition expression | a Simulink.Variant object representing a boolean condition expression | a Simulink.Parameter object (required for code generation)

To enter a variant name, double-click a **Variant control** cell in a new row and type in the variant control expression.

Programmatic Use

Structure field: Represented by the read-only `variant.Name` field in the `Variant` parameter structure

Type: character vector

Value: Variant control that is associated with the variant choice

Default: ''

Condition (read-only) — Condition for variant controls

'' (default)

This read-only field is based on the condition for the associated variant control in the base workspace. Create or change a variant condition in the `Simulink.Variant` parameter dialog box or in the base workspace.

Override variant conditions and use the following variant — Override variant conditions and use specified variant

`off` (default) | `on`

To choose the active variant based on the evaluation of the variant conditions, use the default (`off`). To choose the active variant based on the value specified in the **Variant** parameter, select the **Override variant conditions and use following variant** parameter.

For **Override variant conditions and use following variant** option, the variant control need not be a Boolean condition expression or a `Simulink.Variant` object. Variant controls that start with a % symbol are ignored.

When you select this option, the variant badge indicates the change.

**Dependencies**

This parameter enables the **Variant** parameter.

Programmatic Use

Parameter: `OverrideUsingVariant`

Type: character vector

Value: '' if no overriding variant is specified

Default: ''

variant — Name of variant to use if overriding variant conditions

'' (default) | character vector

If you select **Override variant conditions and use following variant**, specify the name of the variant to use. The variant name must be valid MATLAB identifier.

For **Override variant conditions and use following variant** option, the variant control need not be a boolean condition expression, or a `Simulink.Variant` object. Variant controls that start with a % symbol are ignored.

Tip You can use the **Variant** drop-down list to see a list of variant controls that are specified in the variant choice section.

Dependencies

To enable this parameter, select the **Override variant conditions and use the following variant** parameter.

Programmatic Use

Parameter: `OverrideUsingVariant`

Type: character vector

Value: character vector specifying the variant control expression

Default: ''

Allow zero active variant controls — Simulate model without using active variant

off (default) | on

To simulate a model (containing a variant system) without an active variant choice, select the **Allow zero active variant controls** option. When you select this option and there is no active variant choice, Simulink disables all the blocks connected to the input and output stream of variant subsystem container block. The disabled blocks are ignored from update diagram or simulation.

If you do not select this option, Simulink generates an error when there is no active variant choice.

Dependencies

- No (default) option of variant is selected
- **Override variant conditions and use following variant** is cleared ('off')

Programmatic Use**Parameter:** AllowZeroVariantControls**Type:** character vector**Value:** 'off' 'on'**Default:** 'off'**Analyze all choices during update diagram and generate preprocessor conditionals — Generate preprocessor conditionals**

off (default) | on

When generating code for an ERT target, this parameter determines whether variant choices are enclosed within C preprocessor conditional statements (`#if`).

When you select this option, Simulink analyzes all variant choices during an update diagram or simulation. This analysis provides early validation of the code generation readiness of all variant choices.

When you select this option, the variant badge indicates the change.

**Dependencies**

- The check box is available for generating only ERT targets.
- **Override variant conditions and use following variant** is cleared ('off').

Programmatic Use**Parameter:** GeneratePreprocessorConditionals**Type:** character vector**Value:** 'off' 'on'**Default:** 'off'**Propagate conditions outside of Variant Subsystem — Propagate variant conditions outside of variant subsystem container block**

off (default) | on

When you select this option, Simulink propagates the variant conditions outside of the variant subsystem container block to determine which components of the model are active during simulation.

When you select this option, the variant badge indicates the change.

Programmatic Use

Parameter: PropagateVariantConditions

Type: character vector

Value: 'off' 'on'

Default: 'off'

Vector Concatenate, Matrix Concatenate

Concatenate input signals of same data type to create contiguous output signal

Library

Math Operations, Signal Routing

Description

The Concatenate block concatenates the signals at its inputs to create an output signal whose elements reside in contiguous locations in memory.

Tip The Concatenate block is useful for creating an output signal that is nonvirtual. However, to create a vector of function calls, use a Mux block instead.

You use a Concatenate block to define an array of buses. For details about defining an array of buses, see “Combine Buses into an Array of Buses”.

The Concatenate block operates in either vector or multidimensional array concatenation mode, depending on the setting of its **Mode** parameter. In either case, the block concatenates the inputs from the top to bottom, or left to right, input ports.

Vector Mode

In vector mode, all input signals must be either vectors or row vectors [1xM matrices] or column vectors [Mx1 matrices] or a combination of vectors and either row or column vectors. The output is a vector if all inputs are vectors.

The output is a row or column vector if any of the inputs are row or column vectors, respectively.

Multidimensional Array Mode

Multidimensional array mode accepts vectors and arrays of any size. It assumes that the trailing dimensions are all ones for input signals with lower dimensionality. For example, if the output is 4-D and the input is $[2 \times 3]$ (2-D) this block treats the input as $[2 \times 3 \times 1 \times 1]$. The output is always an array. The block's **Concatenate dimension** parameter allows you to specify the output dimension along which the block concatenates its input arrays.

If you set the **Concatenate dimension** parameter to 2 and inputs are 2-D matrices, the block performs horizontal matrix concatenation and places the input matrices side-by-side to create the output matrix, for example:

If you set the **Concatenate dimension** parameter to 1 and inputs are 2-D matrices, the block performs vertical matrix concatenation and stacks the input matrices on top of each other to create the output matrix, for example:

For horizontal concatenation, the input matrices must have the same column dimension. For vertical concatenation, the input matrices must have the same row dimension. All

input signals must have the same dimension for all dimensions other than the concatenation dimensions.

If you set the **Mode** parameter to Multidimensional array, the **Concatenate dimension** parameter to 3, and the inputs are 2-D matrices, the block performs multidimensional matrix concatenation, for example:

Data Type Support

Accepts signals of any data type that Simulink supports, including fixed-point, enumerated, and nonvirtual bus data types. All inputs must be of the same data type. Outputs have the same data type as the input.

For more information, see “Data Types Supported by Simulink”.

Parameters

Number of inputs

Specifies the number of inputs for the block.

Default: 2

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Mode

Select the type of concatenation that this block performs.

Default: `Vector` (for the Vector Concatenate block), `Multidimensional array` (for the Matrix Concatenate block)

`Vector`

Perform vector concatenation (see “Vector Mode” on page 1-1780 for details).

`Multidimensional array`

Perform matrix concatenation (see “Multidimensional Array Mode” on page 1-1781 for details).

This parameter enables **Concatenate dimension**.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Concatenate dimension

Specifies the output dimension along which to concatenate the input arrays.

Default: 2

- Enter 1 to concatenate input arrays vertically.
- Enter 2 to concatenate input arrays horizontally.
- Enter a higher dimension to perform multidimensional concatenation on the inputs.

Selecting `Multidimensional array` for **Mode** enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated
Sample Time	Inherited from driving block

Weighted Sample Time

Support calculations involving sample time

Library

Signal Attributes

Description

The Weighted Sample Time block is an implementation of the Weighted Sample Time Math block. See [Weighted Sample Time Math](#) for more information.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point
Multidimensional Signals	No
Variable-Size Signals	No
Code Generation	Yes

Introduced before R2006a

Waveform Generator

Output waveforms using signal notations

Library

Sources

Description

The Waveform Generator block outputs waveforms based on signal notations that you enter in the **Waveform Definition** table.

This block supports these syntaxes for the signal notations:

- Function syntax — Specify all arguments in the specific order for the signal syntax (see “Supported Waveforms” on page 1-1787).
- Name-value syntax — Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`. For more information, see “Supported Waveforms” on page 1-1787.

This block supports normal, accelerator, and rapid accelerator modes and fast restart.

Supported Operators

Operation	Operator
Absolute value	<code>abs()</code>
Addition	<code>+</code>
Division	<code>/</code>

Operation	Operator
Multiplication	*
Parentheses	()
Subtraction	-
Unary minus	-

The Waveform block observes the following rules of operator precedence:

- 1 ()
- 2 + - (unary)
- 3 * /
- 4 + -

Supported Waveforms

Enter signal notations in the **Waveform Definition** table, one waveform definition per line. To add a waveform definition, click **Add**. The new waveform appears as an empty character vector. The block interprets empty character vectors or white space character vectors as ground.

To remove a waveform definition, click **Remove**. You can select multiple waveforms using **Ctrl+click** or **Shift+click**.

- “Constant” on page 1-1787
- “Gaussian Noise” on page 1-1788
- “Pulse” on page 1-1789
- “Sawtooth” on page 1-1790
- “Sine Wave” on page 1-1791
- “Square” on page 1-1793
- “Step” on page 1-1794

Constant

Constant values can be:

- Numbers
- Workspace variables
 - Scalar, real variables only
- Built-in MATLAB constant, pi

- 1
- 1.1
- x
- pi

Gaussian Noise

```
gaussian(mean,variance,seed)
```

```
gaussian('Mean',mean,'Variance',variance,'Seed',seed)
```

- mean — Mean value of the random variable output.
 - Default: 0
- variance — Standard deviation squared of the random variable output.
 - Default: 1
 - Value: Positive constant or positive real scalar variable
- seed — Initial seed value for the random number generator.
 - Default: 0
 - Value: Constant or real scalar variable

```
gaussian('Mean',0,'Variance',10,'Seed',1)
```

Pulse

```
pulse(amplitude,trigger_time,duration)
```

```
pulse('Amplitude',amplitude,'TriggerTime',trigger_time,'Duration',duration)
```

- `amplitude` — Value of signal when pulse is high.
 - Default: 1
- `trigger_time` — Elapsed simulation time when signal changes to amplitude, in seconds.
 - Default: 1
 - Value: Constant or real scalar variable
- `duration` — How long the signal remains at the given amplitude before returning to ground, in seconds.
 - Default: 1
 - Value: Positive constant or positive real scalar variable

```
pulse('Amplitude',1,'TriggerTime',1,'Duration',1)
```

Sawtooth

```
sawtooth(amplitude,frequency,phase_offset)
```

```
sawtooth('Amplitude',amplitude,'Frequency',frequency,'Phase',phase_offset)
```

- `amplitude` — Sawtooth peak value.
 - Default: 1
- `frequency` — Waveform frequency, in rad/s.
 - Default: 1
- `phase_offset` — Horizontal signal shift, based on elapsed simulation time, in seconds.
 - Default: 0

```
sawtooth('Amplitude',1,'Frequency',1,'Phase',0)
```

Sine Wave

```
sin(amplitude,frequency,phase_offset)
```

```
sin('Amplitude',amplitude,'Frequency',frequency,'Phase',phase_offset)
```

- `amplitude` — Amplitude of sine wave.
 - Default: 1
- `frequency` — Waveform frequency, in rad/s.
 - Default: 1

- `phase_offset` — Phase offset, in rads.
 - Default: 0

```
sin('Amplitude',1,'Frequency',1,'Phase',0)
```

To get the cosine waveform:

```
sin('Amplitude',1,'Frequency',1,'Phase',pi/2)
```

Square

```
square(amplitude,frequency,phase_delay,duty_cycle)
```

```
square('Amplitude',amplitude,'Frequency',frequency,'Phase',phase_delay,...  
'DutyCycle',duty_cycle)
```

- `amplitude` — Amplitude of signal.
 - Default: 1
- `frequency` — Waveform frequency in rad/s.
 - Default: 1
- `phase_delay` — Horizontal signal shift based on elapsed simulation time, in seconds.
 - Default: 0
- `duty_cycle` — Percentage of high signal per period (0–100%). The block clips the minimum signal to 0% and the maximum signal to 100%.
 - Default: 50

```
square('Amplitude',1,'Frequency',1,'Phase',0,'DutyCycle',50)
```

Step

```
step(step_time,initial_value,final_value)
```

```
step('StepTime',step_time,'InitialValue',initial_value,'FinalValue',final_value)
```

- `step_time` — Elapsed simulation time when signal changes from `initial_value` to `final_value`, in seconds.
 - Default: 1
 - Value: Constant or positive real scalar variable.
- `initial_value` — Value of signal when elapsed simulation time is less than `step_time`, in seconds.
 - Default: 0
- `final_value` — Value of signal when elapsed simulation time is greater than or equal to `step_time`, in seconds.

- Default: 1

```
step('StepTime',1,'InitialValue',0,'FinalValue',1)
```

Supported Operations

The Waveform Generator block outputs one signal at a time. You can change this output signal. Express frequency and phase offset parameters in radians. You can also:

- Nest signal notations, for example:

```
sin('Amplitude',sin('Amplitude',1,'Frequency',1,'Phase',0),'Frequency',1,'Phase',1)
```

- Reference real scalar variables in the base or model workspace, for example:

```
sin('Amplitude',x,'Frequency',y,'Phase',z)
```

x , y , and z exist in the base workspace.

For more information on waveforms, see “Supported Waveforms” on page 1-1787.

To quickly determine the response of a system to different types of inputs, you can vary the output signal of the Waveform Generator block while a simulation is in progress.

Data Type Support

The Waveform Generator block outputs scalar values. The default data type is double. However, the block also supports a large subset of Simulink data types, including fixed point (see “Output data type” on page 1-695).

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Output Signal

Select the signal. The number corresponds to the line item in the **Waveform Definition** table. You can change this parameter while a simulation is running.

Default: 1

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Waveform Definition

Enter signal notations in the **Waveform Definition** table, one waveform definition per line. For more information on waveform definitions and how to enter them, see “Supported Waveforms” on page 1-1787.

Default: none

Output minimum

Lower value of the output range that Simulink checks.

Default: [] (unspecified)

Specify this number as a finite, real, double, scalar value.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Parameter: OutMin

Type: character vector

Value: ' [] '

Default: ' [] '

Output maximum

Upper value of the output range that Simulink checks.

Default: [] (unspecified)

Specify this number as a finite, real, double, scalar value.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Parameter: OutMax

Type: character vector

Value: ' [] '

Default: ' [] '

Output data type

Specify the output data type.

Default: Inherit: Inherit via back propagation

Inherit: Inherit via back propagation

Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. For example, if the block multiplies an input of type `int8` by a gain of `int16` and ASIC/FPGA is specified as the targeted hardware type, the output data type is `sfix24`. If `Unspecified` (assume 32-bit Generic), i.e., a generic 32-bit microprocessor, is specified as the target hardware, the output data type is `int32`. If none of the word lengths provided by the target microprocessor can accommodate the output range, Simulink software displays an error in the Diagnostic Viewer.

It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

- Specify the output data type explicitly.
- Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
- To specify your own inheritance rule, use `Inherit: Inherit via back propagation` and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.

Inherit: Inherit via back propagation

Use data type of the driving block.

double

Output data type is double.

single

Output data type is single.

int8

Output data type is int8.

uint8

Output data type is uint8.

int16

Output data type is int16.

uint16

Output data type is uint16.

int32

Output data type is int32.

uint32

Output data type is uint32.

boolean

Output data type is boolean.

fixdt(1,16)

Output data type is fixed point fixdt(1,16).

fixdt(1,16,0)

Output data type is fixed point fixdt(1,16,0).

fixdt(1,16,2^0,0)

Output data type is fixed point fixdt(1,16,2^0,0).

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Control Signal Data Types” for more information.

Data type override

Specify data type override mode for this signal.

Default: `double`

`Inherit`

Inherits the data type override setting from its context, that is, from the block, `Simulink.Signal` object or Stateflow chart in Simulink that is using the signal.

`Off`

Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

This parameter appears only when the **Mode** is `Built in` or `Fixed point`.

Signedness

Specify whether you want the fixed-point data as signed or unsigned.

Default: `Signed`

`Signed`

Specify the fixed-point data as signed.

`Unsigned`

Specify the fixed-point data as unsigned.

Selecting **Mode** > `Fixed point` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Word length

Specify the bit size of the word that holds the quantized integer.

Default: 16

Minimum: 0

Maximum: 32

Selecting **Mode** > Fixed point enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors.

Default: Binary point

Binary point

Specify binary point location.

Slope and bias

Enter slope and bias.

Selecting **Mode** > Fixed point enables this parameter.

Selecting Binary point enables:

- **Fraction length**

Selecting Slope and bias enables:

- **Slope**

- **Bias**

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specifying a Fixed-Point Data Type”.

Fraction length

Specify fraction length for fixed-point data type.

Default: 0

Binary points can be positive or negative integers.

Selecting **Scaling** > `Binary point` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Slope

Specify slope for the fixed-point data type.

Default: 2^0

Specify any positive real number.

Selecting **Scaling** > `Slope and bias` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Bias

Specify bias for the fixed-point data type.

Default: 0

Specify any real number.

Selecting **Scaling** > `Slope` and `bias` enables this parameter.

For more information, see “Specifying a Fixed-Point Data Type”.

Lock output data type setting against changes by the fixed-point tools

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor.

Default: Off

On

Locks the output data type setting for this block.

Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change the output data type setting for this block.

Parameter: `LockScale`

Type: character vector

Value: 'off' | 'on'

Default: 'off'

For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Integer rounding mode

Specify the rounding mode for fixed-point operations.

Default: `Floor`

Ceiling

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

Floor

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

Simplest

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

Zero

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

Parameter: `RndMeth`

Type: character vector

Value: `'Ceiling'` | `'Convergent'` | `'Floor'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Default: `'Floor'`

For more information, see “Rounding” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

Saturate on integer overflow

Specify whether overflows saturate.

Default: Off

On

Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Off

Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.

- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Parameter: SaturateOnIntegerOverflow

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Sample time

Enter the time interval between sample time hits or specify -1 to inherit the sample time.

Default: 0.1

This value cannot be 0 (continuous) or inf (constant). For more information, see “Sample Time”.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Mode

Select the category of data to specify.

Default: `Inherit`

`Inherit`

Inheritance rules for data types. Selecting `Inherit` enables `Inherit` via back propagation.

`Built in`

Built-in data types. Selecting `Built in` enables a second menu/text box to the right. Select one of the following choices:

- `double (default)`
- `single`
- `int8`
- `uint8`
- `int16`
- `uint16`
- `int32`
- `uint32`
- `boolean`

`Fixed point`

Fixed-point data types.

`Enumerated`

Enumerated data types. Selecting `Enumerated` enables a second menu/text box to the right, where you can enter the class name.

Expression

Expressions that evaluate to data types. Selecting `Expression` enables a second menu/text box to the right, where you can enter the expression.

Clicking the **Show data type assistant** button enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

See “Specify Data Types Using Data Type Assistant”.

>> (Show data type assistant)

Displays the **Data Type Assistant**, to help you to set the **Output data type** parameter.

Characteristics

Data Types	See “Data Type Support” on page 1-1797
Sample Time	Specified in the Sample time parameter

Introduced in R2015b

Weighted Sample Time Math

Support calculations involving sample time

Library

Math Operations

Description

The Weighted Sample Time Math block adds, subtracts, multiplies, or divides its input signal, u , by a weighted sample time, T_s . If the input signal is continuous, T_s is the sample time of the Simulink model. Otherwise, T_s is the sample time of the discrete input signal. If the input signal is constant, Simulink assigns a finite sample time to the block based on its connectivity and context.

You specify the math operation with the **Operation** parameter. Additionally, you can specify to use only the weight with either the sample time or its inverse.

Enter the weighting factor in the **Weight value** parameter. If the weight, w , is 1, that value does not appear in the equation on the block icon.

The block computes its output using the precedence rules for MATLAB operators (see “Operator Precedence” (MATLAB) in the MATLAB documentation). For example, if the **Operation** parameter specifies $+$, the block calculates output using this equation:

$$u + (T_s * w)$$

However, if the **Operation** parameter specifies $/$, the block calculates output using this equation:

$$(u / T_s) / w$$

Data Type Support

The Weighted Sample Time Math block accepts signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Operation

Specify operation to use: +, -, *, /, Ts Only, or 1/Ts Only.

Weight value

Enter the weight of sample time.

Implement using

Select one of two modes: online calculations or offline scaling adjustment. This parameter is visible only when you set **Operation** to * or /.

Result of (Ts * w)	Output Data Type of Two Modes	Block Execution
A power of 2, or an integer value	The same, when Output data type is Inherit: Inherit via internal rule	Equally efficient in both modes
Not power of 2 and not an integer value	Different	More efficient for the offline scaling mode

Note When the **Implement using** parameter is not visible, operations default to online calculations.

Tip The **Saturate on integer overflow** parameter is visible only if:

- The **Operation** parameter specifies + or -.
- The **Operation** parameter specifies * or / and the **Implement using** parameter specifies Online Calculations.

Output data type

Specify whether the block inherits the output data type by an internal rule or back propagation.

Tip If you enter an expression in the edit field, the expression must evaluate to one of the two inherit rules.

Integer rounding mode

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

Saturate on integer overflow

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Do not select this check box.	<p>You want to optimize efficiency of your generated code.</p> <p>You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.</p>	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the <code>int8</code> (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as <code>int8</code> , which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as <code>int8</code> , is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point
Direct Feedthrough	For all math operations except T_s and $1/T_s$

While Iterator

Repeat execution of a subsystem while a logical condition signal is true

Library: Ports & Subsystems

```

> cond while {
> IC     ...
>       }

```

Description

When placed in a subsystem block, a While Iterator block controls execution of the subsystem. During a simulation time step, this block repeats execution of the subsystem while an input logical (Boolean) condition signal to the block is true (1).

Placing a While Iterator block in a Subsystem block makes it an atomic subsystem.

Ports

Input

cond — Logical condition signal

scalar

Signal with the result from evaluating a logical condition. Because the subsystem is not externally triggered during a time step, evaluating a condition as true (1) or false (0) must reside within the subsystem.

The data type and values of the signal can be:

- Logical (Boolean) — true (1) or false (0) .
- Numerical — true (any positive or negative number) or false (0).

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

ic — Initial logical condition

scalar

Signal with the initial logical condition. At the beginning of each time step:

- If IC is false (0), the subsystem does not execute during the time step.
- If IC is true (value not equal to 0), the subsystem starts executing and continues to repeat execution as long as the `cond` signal is true.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Output Arguments

Iteration number — Signal with the number of iterations

scalar

Signal with the number of While Iterator Subsystem block executions during each time step.

Data Types: `double` | `int8` | `int16` | `int32`

Parameters

Maximum number of iterations — Specify maximum number of iterations

-1 (default) | integer

Specify maximum number of iterations allowed during a time step.

-1

Any number of iterations as long as the `cond` signal is true (value not equal to 0) . If you specify -1 and the `cond` signal never becomes false (0), the simulation runs in an infinite loop. In this case, the only way to stop the simulation is to terminate MATLAB.

integer

Maximum number of iterations during a time step.

Programmatic Use**Block parameter:** MaxIters**Type:** character vector**Value:** '5' | '-1' | '<integer>'**Default:** '5'**while loop type — Select type of block**`while (default) | do-while`

Select type of block.

`while`

The While Iterator block has two inputs, a `cond` (logical condition) input and an `IC` (initial logical condition) input. The source of the `IC` signal must be external to the While Iterator Subsystem block.

At the beginning of each time step:

- If the `IC` input is true (value not equal to 0), the blocks in the subsystem repeat execution while the `cond` input is true. This process continues during a time step as long as the `cond` input is true and the number of iterations is less than or equal to the **Maximum number of iterations**.
- If the `IC` input is false, the While Iterator block does not execute the contents of the subsystem.

`do-while`The While Iterator block has one input, the `cond` (while condition) input.

At each time step, the blocks in the subsystem repeat execution while the `cond` input is true (value not equal to 0). This process continues as long as the `cond` input is true and the number of iterations is less than or equal to the **Maximum number of iterations**.

Programmatic Use**Block parameter:** WhileBlockType**Type:** character vector**Value:** 'while' | 'do-while'**Default:** 'while'**States when starting — Select block states between time steps**`held (default) | reset`

Select how to handle block states between time steps.

held

Hold block states between time steps. Block state values persist across time steps.

reset

Reset block states to their initial values at the beginning of each time step (in other words, before executing the first iteration loop in the current time step).

Programmatic Use

Block parameter: ResetStates

Type: character vector

Value: 'held' | 'reset'

Default: 'held'

Show iteration number port — Control display of output port

clear | select

Control display of output port for signal with number of block executions. The value of the signal from this port starts at 1 and is incremented by 1 for each succeeding iteration.

off

Remove output port.

on

Display output port for signal with iteration number.

Dependency

Selecting this parameter enables the **Output data type** parameter.

Programmatic Use

Block parameter: ShowIterationPort

Type: character vector

Value: 'off' | 'on'

Default: 'off'

Output data type — Select output data type for current iteration number

int32 (default) | int16 | int8 | double

Select output data type for iteration number signal. The value of this signal is the number of iterations during a time step and the total number of iterations at the end of a time step.

- int32
Signed 32-bit integer.
- int16
Signed 16-bit integer.
- int8
Signed 8-bit integer.
- double
Double-precision floating point.

Dependency

Select the **Show iteration number port** check box to enable this parameter.

Programmatic Use

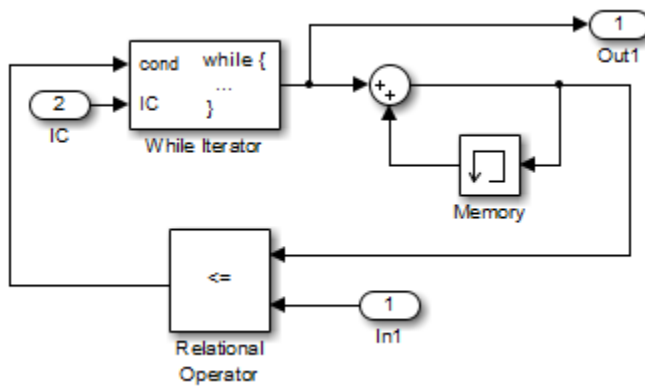

Block parameter: OutputDataType
Type: character vector
Value: 'int32' | 'int16' | 'int8' | 'double'
Default: 'int32'

Examples

The While Iterator block can output the current iteration number, starting at 1. This model computes N, where N is the first N integers whose sum is less than 100.

The While Iterator subsystem includes these blocks.

The While Iterator block uses these parameter settings:

- **Maximum number of iterations** set to 20
- **States when starting** set to reset

The model is the diagrammatic equivalent of this pseudocode.

```

max_sum = 100;
sum = 0;
iteration_number = 0;
cond = (max_sum > 0);
while (cond != 0) {
    iteration_number = iteration_number + 1;
    sum = sum + iteration_number;
    if (sum > max_sum OR iteration_number > max_iterations)
        cond = 0;
}

```

Topics

“Use Control Flow Logic”

Introduced before R2006a

While Iterator Subsystem

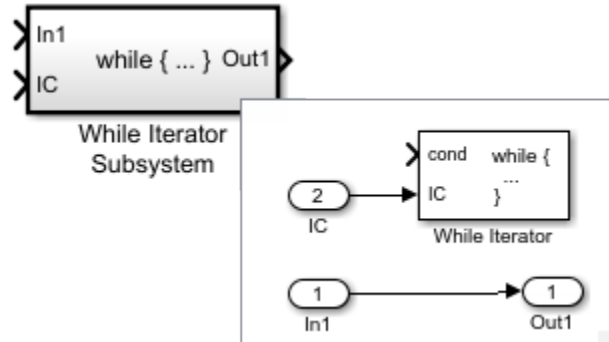

Subsystem that repeats execution during a simulation time step

Library: Ports & Subsystems

Description

The While Iterator Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem that repeats execution during a simulation time step while a logical (Boolean) condition is true.

Use While Iterator Subsystem blocks to model:

- Block diagram equivalent of a program while or do-while loop.
- An iterative algorithm that converges on a more accurate solution after multiple iterations.

When using simplified initialization mode, if you place a block that needs elapsed time (such as a Discrete-Time Integrator block) in a While Iterator Subsystem block, Simulink displays an error.

If the output signal from a While Iterator Subsystem block is a function-call signal, Simulink displays an error when you simulate the model or update the diagram.

Ports

Input

In — Signal input to a subsystem block

scalar | vector | matrix

Placing an Inport block in a subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

IC (initial logical condition) — Control initial execution of a subsystem block

scalar

Placing a While Iterator block connected to an Input block in a Subsystem block adds this external input port to the block.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Output

Out — Signal output from a subsystem

scalar | vector | matrix

Placing an Outport block in a subsystem block adds an output port from the block. The port label on the subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Width

Output width of input vector

Library

Signal Attributes

Description

The Width block generates as output the width of its input vector.

You can use an array of buses as an input signal to a Width block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

Data Type Support

The Width block accepts real or complex signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean
- Enumerated

The Width block also supports mixed-type signal vectors.

When the **Output data type mode** is not `Choose intrinsic data type`, the block supports only built-in numeric types. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Note The Width block ignores the **Data type override** setting of the Fixed-Point Tool.

Output data type mode

Specify the output data type to be the same as the input, or inherit the data type by back propagation. You can also choose to specify a built-in data type from the drop-down list in the **Output data type** parameter.

Output data type

This parameter is visible when you select `Choose intrinsic data type` for **Output data type mode**. Select a built-in data type from the drop-down list.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated Bus
Sample Time	Constant
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

Wrap To Zero

Set output to zero if input is above threshold

Library

Discontinuities

Description

The Wrap To Zero block sets the output to zero when the input is above the **Threshold** value. However, the block outputs the input when the input is less than or equal to the **Threshold**.

Data Type Support

The Wrap To Zero block accepts inputs of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean

The block output has the same data type as the input. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Tip If the input data type cannot represent zero, parameter overflow occurs. To detect this overflow, go to the **Diagnostics > Data Validity** pane of the Configuration Parameters dialog box and set **Parameters > Detect overflow** to warning or error.

Parameters

Threshold

When the input exceeds the threshold, the block sets the output to zero.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point
Direct Feedthrough	Yes
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Introduced before R2006a

XY Graph

Display X-Y plot of signals using MATLAB figure window

Library

Sinks

Description

The XY Graph block displays an X-Y plot of its inputs in a MATLAB figure window.

The block has two scalar inputs. The block plots data in the first input (the x direction) against data in the second input (the y direction). (See “Port Location After Rotating or Flipping” for a description of the port order for various block orientations.) This block is useful for examining limit cycles and other two-state data. Data outside the specified range does not appear.

A figure window appears for each XY Graph block in the model at the start of simulation.

Data Type Support

The XY Graph block accepts real signals of the following data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Note The XY Graph block does not support stepping back in a simulation.

Parameters

x-min

Specify the minimum x -axis value. The default is -1 .

x-max

Specify the maximum x -axis value. The default is 1 .

y-min

Specify the minimum y -axis value. The default is -1 .

y-max

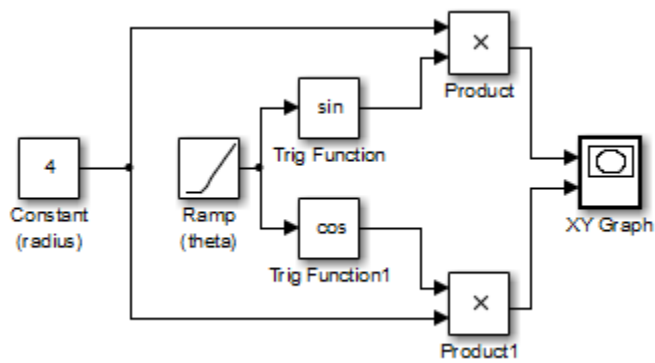

Specify the maximum y -axis value. The default is 1 .

Sample time

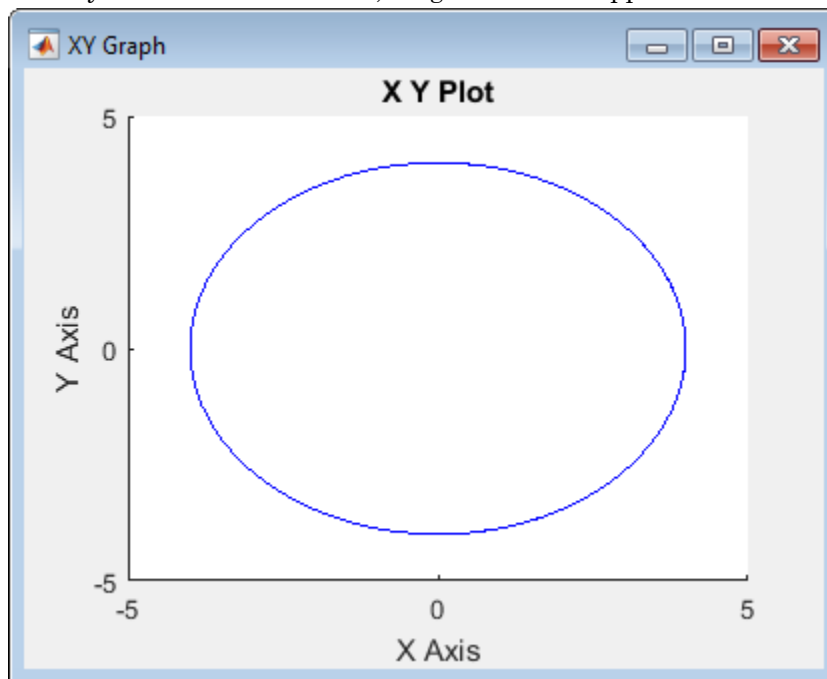

Specify the time interval between samples. To inherit the sample time, set this parameter to -1 . See “Specify Sample Time” in the Simulink documentation for more information.

Examples

The following model computes the points that define a circle of radius 4, centered at the origin of the x - y plane.

When you simulate the model, a figure window appears.

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point
Sample Time	Specified in the Sample time parameter
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	No

Introduced before R2006a

Zero-Order Hold

Implement zero-order hold of one sample period

Library

Discrete

Description

The Zero-Order Hold block holds its input for the sample period you specify. The block accepts one input and generates one output. Each signal can be scalar or vector. If the input is a vector, the block holds all elements of the vector for the same sample period.

You specify the time between samples with the **Sample time** parameter. A setting of -1 means the block inherits the **Sample time**.

Tip Do not use the Zero-Order Hold block to create a fast-to-slow transition between blocks operating at different sample rates. Instead, use the Rate Transition block.

Comparison with Similar Blocks

Blocks with Similar Functionality

The Unit Delay, Memory, and Zero-Order Hold blocks provide similar functionality but have different capabilities. Also, the purpose of each block is different. The sections that follow highlight some of these differences.

Recommended Usage for Each Block

Block	Purpose of the Block	Reference Examples
Unit Delay	Implement a delay using a discrete sample time that you specify. The block accepts and outputs signals with a discrete sample time.	<ul style="list-style-type: none"> sldemo_enginew (Compression subsystem)
Memory on page 1-915	Implement a delay by one major integration time step. Ideally, the block accepts continuous (or fixed in minor time step) signals and outputs a signal that is fixed in minor time step.	<ul style="list-style-type: none"> sldemo_bounce sldemo_clutch (Friction Mode Logic/Lockup FSM subsystem)
Zero-Order Hold	Convert an input signal with a continuous sample time to an output signal with a discrete sample time.	<ul style="list-style-type: none"> sldemo_radar_em1 aero_dap3dof

Overview of Block Capabilities

Capability	Block		
	Unit Delay	Memory	Zero-Order Hold
Specification of initial condition	Yes	Yes	No, because the block output at time $t = 0$ must match the input value.
Specification of sample time	Yes	No, because the block can only inherit sample time (from the driving block or the solver used for the entire model).	Yes
Support for frame-based signals	Yes	No	Yes
Support for state logging	Yes	No	No

Data Type Support

The Zero-Order Hold block accepts real or complex signals of any data type that Simulink supports, including fixed-point and enumerated data types.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Sample time (-1 for inherited)

Specify the time interval between samples. To inherit the sample time, set this parameter to -1 . See “Specify Sample Time” in the online documentation for more information.

Do not specify a continuous sample time, either 0 or $[0, 0]$. This block supports only discrete sample times. When this parameter is -1 , the inherited sample time must be discrete and not continuous.

Bus Support

The Zero-Order Hold block is a bus-capable block. The input can be a virtual or nonvirtual bus signal. No block-specific restrictions exist. All signals in a nonvirtual bus input to a Zero-Order Hold block must have the same sample time, even if the elements of the associated bus object specify inherited sample times. You can use a Rate Transition block to change the sample time of an individual signal, or of all signals in a bus. See “Specify Bus Signal Sample Times” and “Bus-Capable Blocks” for more information.

You can use an array of buses as an input signal to a Zero-Order Hold block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

Examples

The following models show how to use the Zero-Order Hold block:

- `sldemo_radar_eml`
- `aero_dap3dof`

Characteristics

Data Types	Double Single Boolean Base Integer Fixed-Point Enumerated Bus
Sample Time	Specified in the Sample time parameter
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Memory, Unit Delay

Introduced before R2006a

Zero-Pole

Model system by zero-pole-gain transfer function

Library

Continuous

Description

The Zero-Pole block models a system that you define with the zeros, poles, and gain of a Laplace-domain transfer function. This block can model single-input single output (SISO) and single-input multiple-output (SIMO) systems.

Conditions for Using This Block

The Zero-Pole block assumes the following conditions:

- The transfer function has the form

$$H(s) = K \frac{Z(s)}{P(s)} = K \frac{(s - Z(1))(s - Z(2)) \dots (s - Z(m))}{(s - P(1))(s - P(2)) \dots (s - P(n))},$$

where Z represents the zeros, P the poles, and K the gain of the transfer function.

- The number of poles must be greater than or equal to the number of zeros.
- If the poles and zeros are complex, they must be complex-conjugate pairs.
- For a multiple-output system, all transfer functions must have the same poles. The zeros can differ in value, but the number of zeros for each transfer function must be the same.

Note You cannot use a Zero-Pole block to model a multiple-output system when the transfer functions have a differing number of zeros or a single zero each. Use multiple Zero-Pole blocks to model such systems.

Modeling a Single-Output System

For a single-output system, the input and the output of the block are scalar time-domain signals. To model this system:

- 1 Enter a vector for the zeros of the transfer function in the **Zeros** field.
- 2 Enter a vector for the poles of the transfer function in the **Poles** field.
- 3 Enter a 1-by-1 vector for the gain of the transfer function in the **Gain** field.

Modeling a Multiple-Output System

For a multiple-output system, the block input is a scalar and the output is a vector, where each element is an output of the system. To model this system:

- 1 Enter a matrix of zeros in the **Zeros** field.

Each *column* of this matrix contains the zeros of a transfer function that relates the system input to one of the outputs.

- 2 Enter a vector for the poles common to all transfer functions of the system in the **Poles** field.
- 3 Enter a vector of gains in the **Gain** field.

Each element is the gain of the corresponding transfer function in **Zeros**.

Each element of the output vector corresponds to a column in **Zeros**.

Transfer Function Display on the Block

The Zero-Pole block displays the transfer function depending on how you specify the zero, pole, and gain parameters.

- If you specify each parameter as an expression or a vector, the block shows the transfer function with the specified zeros, poles, and gain. If you specify a variable in parentheses, the block evaluates the variable.

For example, if you specify **Zeros** as $[3, 2, 1]$, **Poles** as $(poles)$, where $poles$ is $[7, 5, 3, 1]$, and **Gain** as $gain$, the block looks like this:

$$\frac{gain(s-3)(s-2)(s-1)}{(s-7)(s-5)(s-3)(s-1)}$$

- If you specify each parameter as a variable, the block shows the variable name followed by (s) if appropriate.

For example, if you specify **Zeros** as $zeros$, **Poles** as $poles$, and **Gain** as $gain$, the block looks like this:

$$\frac{gain \cdot zeros(s)}{poles(s)}$$

Data Type Support

The Zero-Pole block accepts real signals of type `double`. For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Zeros

Define the matrix of zeros.

Default: $[1]$

- For a single-output system, enter a vector for the zeros of the transfer function.
- For a multiple-output system, enter a matrix. Each *column* of this matrix contains the zeros of a transfer function that relates the system input to one of the outputs.

Parameter: `Zeros`

Type: vector

Value: '[1]'

Default: '[1]'

Poles

Define the vector of poles.

Default: [0 -1]

- For a single-output system, enter a vector for the poles of the transfer function.
- For a multiple-output system, enter a vector for the poles common to all transfer functions of the system.

Parameter: Poles

Type: vector

Value: '[0 -1]'

Default: '[0 -1]'

Gain

Define the vector of gains.

Default: [1]

- For a single-output system, enter a 1-by-1 vector for the gain of the transfer function.
- For a multiple-output system, enter a vector of gains. Each element is the gain of the corresponding transfer function in **Zeros**.

Parameter: Gain

Type: vector

Value: '[1]'

Default: '[1]'

Absolute tolerance

Specify the absolute tolerance for computing block states.

Default: `auto`

- You can enter `auto`, `-1`, a positive real scalar or vector.
- If you enter `auto` or `-1`, then Simulink uses the absolute tolerance value in the Configuration Parameters dialog box (see “Solver Pane”) to compute block states.
- If you enter a real scalar, then that value overrides the absolute tolerance in the Configuration Parameters dialog box for computing all block states.
- If you enter a real vector, then the dimension of that vector must match the dimension of the continuous states in the block. These values override the absolute tolerance in the Configuration Parameters dialog box.

Parameter: `AbsoluteTolerance`

Type: character vector, scalar, or vector

Value: `'auto'` | `'-1'` | any positive real scalar or vector

Default: `'auto'`

State Name (e.g., 'position')

Assign a unique name to each state.

Default: `' '`

If this field is blank, no name assignment occurs.

- To assign a name to a single state, enter the name between quotes, for example, `'velocity'`.
- To assign names to multiple states, enter a comma-delimited list surrounded by braces, for example, `{'a', 'b', 'c'}`. Each name must be unique.
- The state names apply only to the selected block.
- The number of states must divide evenly among the number of state names.
- You can specify fewer names than states, but you cannot specify more names than states.

For example, you can specify two names in a system with four states. The first name applies to the first two states and the second name to the last two states.

- To assign state names with a variable in the MATLAB workspace, enter the variable without quotes. A variable can be a character vector, cell array, or structure.

Parameter: ContinuousStateAttributes

Type: character vector

Value: ' ' | user-defined

Default: ' '

Characteristics

Data Types	Double
Sample Time	Continuous
Direct Feedthrough	Only if the lengths of the Poles and Zeros parameters are equal
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

Functions — Alphabetical List

add_block

Add block to model

Syntax

```
h = add_block(source, dest)
h = add_block(source, dest, 'MakeNameUnique', 'on')
h = add_block(sourceIn, destIn, 'CopyOption', 'duplicate')
h = ( ____, Name, Value)
```

Description

`h = add_block(source, dest)` adds a copy of the block `source` from a library or model to the specified destination model and block name. This syntax creates the block at the same location as it appears in the model or the library model.

If you are copying between models or from a library, load the destination model first.

`h = add_block(source, dest, 'MakeNameUnique', 'on')` ensures that the destination block name is unique in the model. This syntax adds a number to the destination block name if a block with that name exists, incrementing to ensure a unique name.

`h = add_block(sourceIn, destIn, 'CopyOption', 'duplicate')` duplicates an inport block in a subsystem, giving the destination block the same port number as the source block. Duplicate an inport to branch a signal from an input port without creating a port or adding lines. For more information, see “Creating Duplicate Inports” on page 1-767.

`h = (____, Name, Value)` uses optional `Name, Value` arguments.

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

With the `add_block` function, you can use block parameter and value pairs. For a list of all the block parameters, see “Common Block Properties” on page 6-109 and “Block-Specific Parameters” on page 6-128.

Examples

Add Block to Model from a Library

Add the block from the Simulink library to the model `f14`.

Load or open the destination model.

```
open_system('f14');
```

Add the Scope block from the Simulink Sinks library to `f14`, naming the new block `MyScope`.

```
add_block('simulink/Sinks/Scope','f14/MyScope');
```

Add a Block from Another Model

Add a copy of a block from the model `f14` to `vdp`.

Load or open the destination model.

```
open_system('vdp');
```

Add the Actuator Model block from `f14` to `vdp`.

```
add_block('f14/Actuator Model','vdp/Actuator Model');
```

Add a Block Using a Unique Name

Add the block from the Simulink library to the model `vdp`. Because there is already a block named `Scope` in `vdp`, use the `MakeNameUnique` option to ensure that the new block name is unique.

Load or open the destination model.

```
open_system('vdp');
```

Add the Scope block from the Simulink Sinks library to vdp, ensuring that the name is unique.

```
add_block('simulink/Sinks/Scope','vdp/Scope','MakeNameUnique','on')
```

Duplicate an Inport Block in a Subsystem

Add an inport block in the f14/Controller subsystem that uses the same port number as another inport in that subsystem.

Duplicate the Stick Input (in) block in the Controller subsystem, naming the copy Stick Input (in)2. The resulting block uses the same port number as Stick Input (in) but does not add an inport on the parent subsystem. The signal that enters that port branches to both inports.

```
add_block('f14/Controller/Stick Input (in)',...  
'f14/Controller/Stick Input (in)2','CopyOption','duplicate')
```

Add a Block and Set Parameters

Add a block from a library to a model and set parameters using a Name, Value pair.

Load or open the destination model.

```
open_system('vdp');
```

Add a Gain block from the library to vdp, and set the Gain value to 5.

```
add_block('simulink/Math Operations/Gain','vdp/Five','Gain','5')
```

Input Arguments

source — Block to copy to model

block path name | library block path name

Block to copy to model, specified as:

- The full block path name if you are copying the block from another model, for example, 'vdp/Mu'. This usage copies the block and its settings.
- The library block path name if you want to add a block from a library, for example, 'simulink/Math Operations/Gain'.

To get the library block path name, you can hover over the block in the Library Browser. Alternatively, you can open the library model, select the block, and enter `gcb` at the command line. To open the library model, in the Library Browser, right-click the library name in the library list and select **Open *library_name* library**.

You can also use the syntax '`built-in/blocktype`' as the source block path name, where *blocktype* is the programmatic block name—the value of the `BlockType` parameter (see “Common Block Properties” on page 6-109). However, blocks added using '`built-in/blocktype`' sometimes have different default parameter values from library blocks.

For subsystems and masked blocks, use the library block path name. Using the `BlockType` value (`SubSystem`) creates an empty subsystem.

Example: 'vdp/Mu', 'simulink/Sinks/Scope'

dest — Name and location of new block

block path name

Name and location of the new block in the model, specified as the block path name.

Example: 'f14/Controller/MyNewBlock'

sourceIn — Inport block whose port number to copy

block path name

Inport block whose port number to copy, specified as the block path name.

Example: 'f14/Controller/Stick Input (in)', 'myModel/mySubsystem/In1'

destIn — Inport block to create

block path name

Inport block with duplicate port number to create, specified as the block path name. Create the destination block in the same system as the source block.

Example: `'myModel/mySubsystem/DupPortIn'`

Output Arguments

h — New block

handle

New block, returned as a handle.

“Create Annotations Programmatically”

Introduced before R2006a

add_exec_event_listener

Register listener for block method execution event

Syntax

```
h = add_exec_event_listener(blk,event,listener);
```

Description

`h = add_exec_event_listener(blk,event,listener)` registers a listener for a block method execution event where the listener is a MATLAB program that performs some task, such as logging runtime data for a block, when the event occurs (see “Listen for Method Execution Events”). Simulink software invokes the registered listener whenever the specified event occurs during simulation of the model. You cannot register a listener for virtual blocks.

Note Simulink software can register a listener only while a simulation is running. Invoking this function when no simulation is running results in an error message. To ensure that a listener catches all relevant events triggered by a model's simulation, you should register the listener in the model's `StartFcn` callback function (see “Callbacks for Customized Model Behavior”).

Input Arguments

`blk`

Specifies the block whose method execution event the listener is intended to handle. May be one of the following:

- Full pathname of a block
- A block handle
- A block runtime object (see “Access Block Data During Simulation”).

event

Specifies the type of event for which the listener listens. It may be any of the following:

Event	Occurs...
'PreDerivatives'	Before a block's Derivatives method executes
'PostDerivatives'	After a block's Derivatives method executes
'PreOutputs'	Before a block's Outputs method executes.
'PostOutputs'	After a block's Outputs method executes
'PreUpdate'	Before a block's Update method executes
'PostUpdate'	After a block's Update method executes

listener

Specifies the listener to be registered. It may be either a character vector specifying a MATLAB expression, e.g., `'disp(''here'')` or a handle to a MATLAB function that accepts two arguments. The first argument is the block runtime object of the block that triggered the event. The second argument is an instance of `EventData` class that specifies the runtime object and the name of the event that just occurred.

Output Arguments

`add_exec_event_listener` returns a handle to the listener that it registered. To stop listening for an event, use the MATLAB `clear` command to clear the listener handle from the workspace in which the listener was registered.

Introduced before R2006a

add_line

Add line to Simulink model

Syntax

```
h = add_line(sys,out,in)
h = add_line(sys,out,in,'autorouting',autoOption)
h = add_line(sys,points)
```

Description

`h = add_line(sys,out,in)` adds a line in the model or subsystem `sys` that connects one block's output port `out` to another block's input port `in`. This syntax draws the most direct route from port to port, for example, diagonal lines or lines that go through other blocks.

You can connect ports when:

- The input port does not already have a connection.
- The blocks are compatible for connecting.

`h = add_line(sys,out,in,'autorouting',autoOption)` connects blocks, specifying whether to route the lines around other blocks.

`h = add_line(sys,points)` adds a line drawn by (x,y) coordinate `points` relative to the upper-left corner of the Simulink Editor canvas before any canvas resizing. If either end of the line is within five pixels of a corresponding port, the function connects the line to it. The line can have multiple segments.

Examples

Connect Blocks Using Port Numbers

Use the block port numbers to add a line to connect blocks.

Create a model and open it.

```
open_system(new_system('connect_model'));
```

Add and position a Constant block and a Gain block.

```
add_block('simulink/Commonly Used Blocks/Constant','connect_model/Constant');  
set_param('connect_model/Constant','position',[140,80,180,120]);  
add_block('simulink/Commonly Used Blocks/Gain','connect_model/Gain');  
set_param('connect_model/Gain','position',[220,80,260,120]);
```

Connect the blocks. Each block has one port, so specify port 1.

```
add_line('connect_model','Constant/1','Gain/1');
```

Connect Blocks Using Port Handles

Get the port handles and connect the ports using `add_line`.

Open the model `vdp`.

```
open_system('vdp');
```

Delete the line that connects the Mu gain block to the Sum block.

```
delete_line('vdp','Mu/1','Sum/2');
```

Get the port handles from the Mu block and the Sum block.

```
h = get_param('vdp/Mu','PortHandles');  
h1 = get_param('vdp/Sum','PortHandles');
```

Look at the `h1` structure. Notice the two handles for the `Inport` property.

```
h1
```

```
h1 =
```

```
struct with fields:  
  
    Inport: [47.0002 54.0002]  
    Outport: 39.0002  
    Enable: []  
    Trigger: []
```

```

    State: []
    LConn: []
    RConn: []
    Ifaction: []
    Reset: []

```

Index into the Outport and Inport properties on the port handles to get the handles you want and connect them. Connect to the second inport.

```
add_line('vdp',h.Outport(1),h1.Inport(2));
```

Add a Branched Line

You can branch a line by adding a connection programmatically. You can use the `points` syntax to draw the segment, or you can draw the line by specifying the ports to connect. When using the port, use automatic routing to improve the look of the branched line.

Add a scope to the vdp model above the outport.

```
vdp
add_block('simulink/Commonly Used Blocks/Scope','vdp/Scope1');
set_param('vdp/Scope1','position',[470,70,500,110]);
```

Connect the Integrator block x1 to Scope1. This code branches the existing line from the x1 output and connects it to the scope. With autorouting on, the resulting line is segmented.

```
add_line('vdp','x1/1','Scope1/1','autorouting','on')
```

Connect Blocks Using Points

You can use points on the canvas as the start and end of each segment. Get the port locations using `get_param` with the 'PortConnectivity' option.

Open the model vdp and delete the line that connects the Mu and Sum blocks.

```
vdp
delete_line('vdp','Mu/1','Sum/2')
```

Get the port locations for Mu. Mu has two ports. The first is the input port, and the second is the output port.

```
mu = get_param('vdp/Mu', 'PortConnectivity');  
mu.Position
```

```
ans =  
  
    190    150
```

```
ans =  
  
    225    150
```

Get the port locations for Sum, which has three ports. The second position is the lower input port.

```
s = get_param('vdp/Sum', 'PortConnectivity');  
s.Position
```

```
ans =  
  
    250    135
```

```
ans =  
  
    250    150
```

```
ans =  
  
    285    145
```

Connect the ports using the output and input points.

```
add_line('vdp', [225 150; 250 150])
```

Connect Blocks Using Autorouting Options

This example shows the effect of adding lines with and without autorouting options.

Create a model route. Display default block names.

```
open_system(new_system('route'));  
set_param('route', 'HideAutomaticNames', 'off')
```

Add blocks as shown. Add an inport and output to each subsystem.

Add lines to connect the outputs from Subsystem to the inputs of Subsystem1.

```
add_line('route', {'Subsystem/1', 'Subsystem/2'}, ...
        {'Subsystem1/1', 'Subsystem1/2'})
```

Because you did not use the autorouting options, the function draws straight lines, which pass through the Gain block.

Delete the lines. Add lines again, this time using the autorouting option set to 'on'.

```
add_line('route', {'Subsystem/1', 'Subsystem/2'}, ...
        {'Subsystem1/1', 'Subsystem1/2'}, 'autorouting', 'on')
```

The lines route around the Gain block.

Delete the lines. Add lines again, using the smart autorouting option. When you use an array to connect two sets of inports and outports, 'smart' autorouting routes them together if doing so makes better use of the space.

```
add_line('route',{'Subsystem/1','Subsystem/2'},...
        {'Subsystem1/1','Subsystem1/2'},'autorouting','smart')
```

Input Arguments

sys — Model or subsystem to add line to
 character vector

Model or subsystem to add the line to, specified as character vector.

Example: 'vdp', 'f14/Controller'

out — Block output port to connect line from
 block/port name or number character vector | port handle | array of port designators

Block output port to connect line from, specified as:

- The block name, a slash, and the port name or number. Most block ports are numbered from top to bottom or from left to right. For a state port, use the port name State instead of a port number.
- The port handle that you want to connect from.
- An array of either of these port designators.

Use 'PortHandles' with `get_param` to get the handles.

Example: 'Mu/1', 'Subsystem/2', h.Outport(1) {'Subsystem/1', 'Subsystem/2'}

in — Block input port to connect line to
 block/port name or number character vector | port handle | array of port designators

Block input port to connect line to, specified as:

- The block name, a slash, and the port name or number. The port name on:
 - An enabled subsystem is Enable.
 - A triggered subsystem is Trigger.
 - If Action and Switch Case Action subsystems is Action.
- The port handle that you want to add the line to.
- An array of either of these port designators.

Use the 'PortHandles' option with `get_param` to get handles.

```
Example: 'Mu/1', 'Subsystem/2', h.Inport(1), {'Subsystem/1', 'Subsystem/2'}
```

autoOption — Type of automatic line routing

'off' (default) | 'on' | 'smart'

Type of automatic line routing around other blocks, specified as:

- 'off' for no automatic line routing
- 'on' for automatic line routing
- 'smart' for automatic line routing that takes the best advantage of the blank spaces on the canvas and avoids overlapping other lines and labels

points — Points of the line to draw

matrix

Points of the line to draw, specified as at least a 2-by-2 matrix. Add a row for every segment you want to draw. Specify points as (x,y) coordinates from the upper-left corner of the Editor before any canvas resizing.

```
Example: [100 300; 200 300; 200 300; 200 500]
```

Output Arguments

h — Line

handle

Line created by `add_line`, returned as a handle.

add_param

Add parameter to Simulink system

Syntax

```
add_param('sys','parameter1',value1,'parameter2',value2,...)
```

Description

The `add_param` command adds the specified parameters to the specified system and initializes the parameters to the specified values. Case is ignored for parameter names. Value character vectors are case sensitive. The value of the parameter must be a character vector. Once the parameter is added to a system, `set_param` and `get_param` can be used on the new parameters as if they were standard Simulink parameters. Simulink software saves these new parameters with the model file.

Note If you attempt to add a parameter that has the same name as an existing parameter of the system, Simulink software displays an error.

Examples

This command

```
add_param('vdp','DemoName','VanDerPolEquation','EquationOrder','2')
```

adds the parameters `DemoName` and `EquationOrder` with `'VanDerPolEquation'` and `'2'` to the `vdp` system. Afterward, you can use the following command to retrieve the value of the `DemoName` parameter.

```
get_param('vdp','DemoName')
```

See Also

`delete_param` | `get_param` | `set_param`

Introduced before R2006a

addFile

Add file to Simulink Project

Syntax

```
addFile(proj, file)
```

Description

`addFile(proj, file)` adds a file to the project `proj`.

Examples

Add Files to a Project

Open the airframe project and create a project object.

```
sldemo_slproject_airframe  
proj = simulinkproject;
```

Remove a file.

```
removeFile(proj, 'models/AnalogControl.mdl')
```

Add the file back to the project.

```
addFile(proj, 'models/AnalogControl.mdl');
```

Create and save a new model.

```
new_system('mymodel');  
save_system('mymodel');
```

Add the new file to the project and return a project file object.

```
newPrjFile = addFile(proj, 'mymodel.slx');
```

Use the project file object to manipulate the file, for example, adding a label.

```
addLabel(newPrjFile, 'Classification', 'Design')
```

Input Arguments

proj — Project

project object

Project, specified as a project object. Use `simulinkproject` to create a project object to manipulate a Simulink Project at the command line.

file — Path of file

character vector

Path of the file to add relative to the project root folder, including the file extension, specified as a character vector. The file must be within the root folder.

Example: `'models/myModelName.slx'`

Introduced in R2013a

addFolderIncludingChildFiles

Add folder and child files to Simulink Project

Syntax

```
addFolderIncludingChildFiles(proj, folder)
```

Description

`addFolderIncludingChildFiles(proj, folder)` adds a folder and all child files to the project `proj`.

Examples

Add Folders to a Project

Open the airframe project and create a project object.

```
sldemo_slproject_airframe  
proj = simulinkproject;
```

Create a new folder in the project folder.

```
new_folder_path = fullfile(proj.RootFolder, 'new_folder')  
mkdir(new_folder_path);
```

Create a new folder in the previous folder.

```
new_sub_folder_path = fullfile(new_folder_path, 'new_sub_folder')  
mkdir(new_sub_folder_path);
```

Create a new file in the folder.

```
filepath = fullfile(new_sub_folder_path, 'new_model_in_subfolder.slx')  
new_system('new_model_in_subfolder');  
save_system('new_model_in_subfolder', filepath)
```

Add this new folder and child files to the project.

```
projectFile = addFolderIncludingChildFiles(proj, new_folder_path)
```

Input Arguments

proj — Project

project object

Project, specified as a project object. Use `simulinkproject` to create a project object to manipulate a Simulink Project at the command line.

folder — Path of folder

character vector

Path of the folder to add relative to the project root folder, specified as a character vector. The folder must be within the root folder.

Example: 'models'

`slupdate`

Introduced before R2006a

attachComponent

Attach a component to a configuration set

Syntax

```
attachComponent(cs, component)
```

Description

`attachComponent(cs, component)` attaches a component to a `Simulink.ConfigSet` object.

Examples

Replace Solver Component for Active Configuration Set

Replace the solver component of the active configuration set of one model with the solver component of another model.

Get the active configuration set for `modelB`.

```
hCs = getActiveConfigSet('modelB');
```

Get the 'Solver' component for this configuration set.

```
hSolverConfig = getComponent(hCs, 'Solver');
```

Create a copy of the component.

```
hSolverConfig = copy(hSolverConfig);
```

Get the active configuration set for `modelA`.

```
hCs = getActiveConfigSet('modelA');
```

Attach the copy of the 'Solver' component from modelB to modelA.

```
attachComponent(hCs, hSolverConfig);
```

Input Arguments

cs — Configuration set object

ConfigSet object

A configuration set object that you can attach a component to.

component — Component object

SimulinkConfigComponent object

A component that you can attach to configuration set.

See Also

Simulink.ConfigSet

Topics

“About Configuration Sets”

“Manage a Configuration Set”

Introduced before R2006a

attachConfigSet

Associate configuration set or configuration reference with model

Syntax

```
attachConfigSet(model, configObj)
```

```
attachConfigSet(model, configObj, allowRename)
```

Arguments

`model`

The name of an open model, or `gcs` to specify the current model

`configObj`

A configuration set (`Simulink.ConfigSet`) or configuration reference (`Simulink.ConfigSetRef`)

`allowRename`

Boolean that determines how Simulink software handles a name conflict

Description

`attachConfigSet` associates the configuration set or configuration reference (configuration object) specified by `configObj` with `model`.

You cannot attach a configuration object to a model if the configuration object is already attached to another model, or has the same name as another configuration object attached to the same model. The optional Boolean argument `allowRename` determines how Simulink software handles a name conflict between configuration objects. If `allowRename` is `false` and the configuration object specified by `configObj` has the same name as a configuration object already attached to `model`, Simulink software generates an error. If `allowRename` is `true` and a name conflict occurs, Simulink software provides a unique name for `configObj` before associating `configObj` with `model`.

Examples

The following example creates a copy of the current model's active configuration object and attaches it to the model, changing its name if necessary to be unique. The code is the same whether the object is a configuration set or configuration reference.

```
myConfigObj = getActiveConfigSet(gcs);  
copiedConfig = myConfigObj.copy;  
copiedConfig.Name = 'DevConfig';  
attachConfigSet(gcs, copiedConfig, true);
```

See Also

| [getConfigSet](#) | [getConfigSets](#) | [openDialog](#) | [setActiveConfigSet](#)

Topics

“Manage a Configuration Set”

“Manage a Configuration Reference”

Introduced before R2006a

attachConfigSetCopy

Copy configuration set or configuration reference and associate it with model

Syntax

```
myConfigObj = attachConfigSetCopy(model, configObj)
```

```
myConfigObj = attachConfigSetCopy(model, configObj, allowRename)
```

Arguments

model

The name of an open model, or `gcs` to specify the current model

configObj

A configuration set (`Simulink.ConfigSet`) or configuration reference (`Simulink.ConfigSetRef`)

allowRename

Boolean that specifies how Simulink software handles a name conflict

Description

`attachConfigSetCopy` copies the configuration set or configuration reference (configuration object) specified by `configObj` and associates the copy with `model`. Simulink software returns the copied configuration object as `newConfigObj`.

You cannot attach a configuration object to a model if the configuration object has the same name as another configuration object attached to the same model. The optional Boolean argument `allowRename` determines how Simulink software handles a name conflict between configuration objects. If `allowRename` is `false` and the configuration object specified by `configObj` has the same name as a configuration object already attached to `model`, Simulink software generates an error. If `allowRename` is `true` and a name conflict occurs, Simulink software provides a unique name for the copy of `configObj` before associating it with `model`.

Examples

The following example creates a copy of ModelA's active configuration object and attaches it to ModelB, changing the name if necessary to be unique. The code is the same whether the object is a configuration set or configuration reference.

```
myConfigObj = getActiveConfigSet('ModelA');  
newConfigObj = attachConfigSetCopy('ModelB', myConfigObj, true);
```

Introduced in R2006b

addLabel

Attach label to Simulink Project file

Syntax

```
addLabel(file, categoryName, labelName)
addLabel(file, categoryName, labelName, labelData)
```

Description

`addLabel(file, categoryName, labelName)` attaches the specified label `labelName` in the category `categoryName` to the file.

`addLabel(file, categoryName, labelName, labelData)` attaches the label with data `labelData`.

Examples

Attach a Label to a Project File

Open the airframe project and create a project object.

```
sldemo_slproject_airframe;
proj = simulinkproject;
```

Get a particular file by name.

```
myfile = findFile(proj, 'models/AnalogControl.mdl')
```

```
myfile =
```

```
ProjectFile with properties:
```

```
Path: 'C:\Work\temp\slexamples\airframe\models\AnalogControl.mdl'
Labels: [1x1 slproject.Label]
```

```
Revision: '2'  
SourceControlStatus: Unmodified
```

Get the Labels property of the file.

```
myfile.Labels  
  
ans =  
  
Label with properties:  
  
File: 'C:\Work\temp\slexamples\airframe\models\AnalogControl.mdl'  
Data: []  
DataType: 'none'  
Name: 'Design'  
CategoryName: 'Classification'
```

Attach the label 'Artifact' to the file.

```
addLabel(myfile, 'Classification', 'Artifact')  
  
ans =  
  
Label with properties:  
  
File: 'C:\Work\temp\slexamples\airframe\models\AnalogControl.mdl'  
Data: []  
DataType: 'none'  
Name: 'Artifact'  
CategoryName: 'Classification'
```

Index into the Labels property to get the label attached to this file.

```
reviewlabel = myfile.Labels(1)  
  
reviewlabel =  
  
Label with properties:  
  
File: 'C:\Work\temp\slexamples\airframe\models\AnalogControl.mdl'  
Data: []  
DataType: 'none'  
Name: 'Artifact'  
CategoryName: 'Classification'
```

Detach the new label from the file.

```
removeLabel(myfile,reviewlabel)
```

Attach a Label to a Subset of Files

Attach the 'Classification' category label 'Utility' to all files in the project that have the .m file extension.

Open the airframe project and create a project object.

```
sldemo_slproject_airframe;  
proj = simulinkproject;
```

Get the list of files.

```
files = proj.Files;
```

Loop through each file. If a file has the extension .m, attach the label 'Utility'.

```
for fileIndex = 1:numel(files)  
    file = files(fileIndex);  
    [~, ~, fileExtension] = fileparts(file.Path);  
    if strcmp(fileExtension, '.m')  
        addLabel(file, 'Classification', 'Utility');  
    end  
end
```

In the Simulink Project **Files** view, the **Classification** column displays the label Utility for each .m file in the utilities folder.

Attach a Label and Label Data to a File

Open the airframe project and create a project object.

```
sldemo_slproject_airframe;  
proj = simulinkproject;
```

Create a new category 'Review'.

```
createCategory(proj, 'Review', 'char');
```

For the new category, create a label 'To Review'.

```
reviewCategory = findCategory(proj, 'Review');
createLabel(reviewCategory, 'To Review');
```

Get a particular file by name.

```
myfile = findFile(proj, 'models/AnalogControl.mdl')
```

```
myfile =
```

```
ProjectFile with properties:
```

```
Path: 'C:\Work\temp\slexamples\airframe\models\AnalogControl.mdl'
Labels: [1x1 slproject.Label]
Revision: '2'
SourceControlStatus: Unmodified
```

Attach the label 'To Review' and a character vector of label data to the file.

```
addLabel(myfile, 'Review', 'To Review', 'Whole team design review')
```

Index into the Labels property to get the second label attached to this particular file, and see the label data.

```
myfile.Labels(2)
```

```
ans =
```

```
Label with properties:
```

```
File: 'C:\Work\temp\slexamples\airframe\models\AnalogControl.mdl'
Data: 'Whole team design review'
DataType: 'char'
Name: 'To Review'
CategoryName: 'Review'
```

In the Simulink Project **Files** view, for the AnalogControl.mdl file, the **Review** column displays the To Review label with label data.

Alternatively, you can set or change label data using the data property.

```
mylabel = myfile.Labels(2);  
mylabel.Data = 'Final review';
```

Input Arguments

file — File to attach label to

file object

File to attach the label to, specified as a file object. You can get the file object by examining the project's `Files` property (`proj.Files`), or use `findFile` to find a file by name. The file must be in the project.

categoryName — Name of category for label

character vector

Name of the category for the label, specified as a character vector.

labelName — Name of label

character vector | label definition object

Name of the label to attach, specified as a character vector or a label definition object returned by the `file.Label` property or `findLabel`. You can specify a new label name that does not already exist in the project.

labelData — Data to attach to label

character vector | numeric

Data to attach to the label, specified as a character vector or numeric. Data type depends on the label definition. Get a label to examine its `Data` property using `file.Label` or `findLabel`.

Functions

`createLabel` | `findFile` | `findLabel` | `removeLabel` | `simulinkproject`

Introduced in R2013a

bdclose

Close any or all Simulink system windows unconditionally

Syntax

```
bdclose  
bdclose('sys')  
  
bdclose('all')
```

Description

`bdclose` with no arguments closes the current system window unconditionally and without confirmation. Any changes made to the system since it was last saved are lost.

`bdclose('sys')` closes the specified system window.

`bdclose('all')` closes all system windows.

Examples

This command closes the `vdp` system.

```
bdclose('vdp')
```

See Also

`close_system` | `new_system` | `open_system` | `save_system`

Introduced before R2006a

bdIsDirty

Whether block diagram has unsaved changes

Syntax

```
isDirty = bdIsDirty(bdname)
```

Description

`isDirty = bdIsDirty(bdname)` returns whether or not the loaded block diagram `bdname` has unsaved changes.

Examples

Check Models for Unsaved Changes

Check if models contain unsaved changes using `bdIsDirty`.

Check if a single model is dirty.

```
vdp  
bdIsDirty('vdp')
```

```
ans =
```

```
    logical
```

```
    0
```

Check if a cell array of models are dirty.

```
vdp  
sf_car  
bdIsDirty({'sf_car', 'vdp'})
```

```
ans =
    1×2 logical array
    0     0
```

- “Manage Shadowed and Dirty Model Files”

Input Arguments

bdname — Loaded block diagram name

character vector | cell array of character vectors | double array

Loaded block diagram name, specified as a character vector, a cell array of character vectors, or a double array. All character vectors must be the names of loaded block diagrams. All doubles must be the handles of loaded block diagrams. It is an error to supply an invalid handle, a handle to anything other than a block diagram, a path to a block or subsystem, or a block diagram that is not loaded.

Data Types: `double` | `char` | `cell`

Output Arguments

isDirty — Whether block diagram has unsaved changes

logical scalar | logical array

Whether block diagram has unsaved changes, returned as a logical array with one entry for each block diagram. The logical value is true if the block diagram has been modified in memory since it was loaded or last saved, and false if there are no unsaved changes.

Topics

“Manage Shadowed and Dirty Model Files”

Introduced in R2017a

bdIsLibrary

Whether block diagram is a library

Syntax

```
isLibrary = bdIsLibrary(bdnames)
```

Description

`isLibrary = bdIsLibrary(bdnames)` returns whether the loaded block diagrams specified by `bdnames` are libraries.

Examples

Check Whether Block Diagrams Are Libraries

Load some block diagrams and get a handle to one of them.

```
load_system({'sf_car', 'hydlib', 'vdp'})  
h = get_param('hydlib', 'Handle');
```

Check whether `sf_car` is a library. The returned value 0 indicates that it is not.

```
bdIsLibrary('sf_car')
```

```
ans =  
    0
```

Check whether `hydlib` and `vdp` are libraries. The returned value shows that `hydlib` is a library and `vdp` is not.

```
bdIsLibrary({'hydlib', 'vdp'})
```

```
ans =  
1     0
```

Using the handle to `hdlib`, check whether `hdlib` is a library. The value returned shows that it is.

```
bdIsLibrary(h)
```

```
ans =  
1
```

Input Arguments

bdnames — Names or handles of loaded block diagrams

character vector | cell array of character vectors | double | array of doubles

Names or handles of loaded block diagrams, specified as a character vector, a cell array of character vectors, a double, or a double array. All character vectors are names of loaded block diagrams. All doubles are handles of loaded block diagrams.

Data Types: `char` | `cell` | `double`

Output Arguments

isLibrary — Logical array showing whether block diagrams are libraries

logical scalar | logical array

Logical array showing whether block diagrams are libraries, returned as a logical scalar or array (1 for a library, 0 otherwise).

`bdIsLoaded` | `bdroot` | `find_system`

Introduced in R2015a

bdIsLoaded

Whether block diagram is in memory

Syntax

```
isLoaded = bdIsLoaded(bdnames)
```

Description

`isLoaded = bdIsLoaded(bdnames)` returns whether or not a block diagram is in memory. `bdnames` can be a character vector or a cell array of character vectors. All character vectors must be valid block diagram names. It is an error to supply a path to a block or subsystem.

`isLoaded` is a logical array with one entry for each block diagram name.

Examples

```
bdIsLoaded('sf_car')
```

returns a logical scalar.

```
bdIsLoaded({'sf_car','vdp'})
```

returns a 1-by-2 logical array.

Introduced in R2008a

bdroot

Return name of top-level Simulink system

Syntax

```
bdroot  
bdroot(obj)  
bdroot(handle)  
bdroot(sys)
```

Description

`bdroot` with no arguments returns the name of the current top-level system.

`bdroot(obj)`, where *obj* is a character vector specifying a system or block path name, returns the name of the top-level system containing the specified object name. The `bdroot` of an empty character vector generates an error. Prior to issuing `bdroot`, make sure that the top-level system is loaded.

`bdroot(handle)`, where *handle* is the numeric handle for a system or block, returns the numeric handle of the top-level system containing the specified object. Prior to issuing `bdroot`, make sure that the top-level system for each element in the cell array is loaded. If you specify a vector of handles, Simulink returns a list of handles of the top-level systems.

`bdroot(sys)`, where *sys* is a cell array of system names or a vector of system handles. Prior to issuing `bdroot`, make sure that the top-level system for each element in the cell array is loaded. If you specify a vector of handles, Simulink returns a list of handles of the top-level systems.

Examples

This command returns the name of the top-level system that contains the current block.

```
bdroot (gcb)
```

This command returns the name of the top-level system that contains the current system.

```
bdroot (gcs)
```

This command returns the numeric handle of the top-level system that contains the current block.

```
bdroot (gcbh)
```

If `gcbh` is a cell array of system names or handles, it returns a cell array containing the corresponding top-level system names or handles.

If `gcbh` is a numeric array of system handles, it returns a numeric array containing the corresponding top-level system handles.

Introduced before R2006a

dlinmod

Extract discrete-time linear state-space model around operating point

Syntax

```
argout = dlinmod('sys', Ts)
```

```
argout = dlinmod('sys', Ts, x, u)
```

```
argout = dlinmod('sys', Ts, x, u, para, 'v5')
```

```
argout = dlinmod('sys', Ts, x, u, para, xpert, upert, 'v5')
```

Arguments

<i>sys</i>	Name of the Simulink system from which the linear model is extracted.
<i>x</i> , <i>u</i>	State (<i>x</i>) and the input (<i>u</i>) vectors. If specified, they set the operating point at which the linear model is extracted. When a model has model references using the Model block, you must use the Simulink structure format to specify <i>x</i> . To extract the <i>x</i> structure from the model, use the following command:

```
x = Simulink.BlockDiagram.getInitialState('sys');
```

You can then change the operating point values within this structure by editing `x.signals.values`.

If the state contains different data types (for example, 'double' and 'uint8'), then you cannot use a vector to specify this state. You must use a structure instead. In addition, you can only specify the state as a vector if the state data type is 'double'.

<i>Ts</i>	Sample time of the discrete-time linearized model
'v5'	An optional argument that invokes the perturbation algorithm created prior to MATLAB 5.3. Invoking this optional argument is equivalent to calling <code>linmodv5</code> .

para

A three-element vector of optional arguments:

- *para*(1) — Perturbation value of delta, the value used to perform the perturbation of the states and the inputs of the model. This is valid for linearizations using the 'v5' flag. The default value is 1e-05.
